Task interpretation is a key theoretical component in students understanding, academic performance, and appropriate and effective task engagement [6]. Task interpretation theorizes that there are three layers of information construction: explicit, implicit, and socio-contextual information about tasks [5]. Explicit features of a task are overtly presented descriptions and are often described in assignments and are the aspects of the task that give it structure and some type of cohesiveness across students [13]. Implicit features of a task include information that students might be expected to extrapolate beyond assignment descriptions such as connection to learning concepts or resources to completing the task [13]. Finally, socio-contextual features include information about the broader course, such as beliefs about knowledge and expertise or beliefs about ability [13]. The importance of task interpretation, or task understanding, when working with a manipulative is that understanding problems is influenced by implicit and explicit aspects that may or may not be accurate. Task understanding is also affected by a social or cultural context that may help the student base a strategy to understand and solve the task. Therefore, it is important to investigate how these three layers of information construction are incorporated when using the manipulative during truss analysis in order to determine if the manipulative can be used in meaningful pedagogical ways.

III. Research Goals

The use of manipulatives can help the learning outcomes of engineering students, particularly in the context of ill-structured problems while relating concepts to their own background and prior knowledge. However, not enough studies have been done related to the use of manipulatives and their relationship to task interpretation and students' problem solving approaches. Therefore, it is important to consider the inclusion of manipulatives in the engineering statics courses and evaluate their relationship to academic achievement in engineering students. The intent of the project is to improve conceptual understanding of the forces involved in truss design and to assess students' task interpretation (explicit, implicit and socio-contextual) of a truss analysis engineering problem. The fundamental research questions are: (1) Would a physical manipulative help students improve task understanding in an engineering statics course? and (2) How do these students reconcile their initial understanding and interpretation about internal forces in a truss after the use of the physical manipulative?

IV. The Study

The study involves a mixed methods approach comprised of different intervention sessions with selected students. Participants include six engineering students randomly selected from a statics course at a public university. The students are presented with a problem involving a truss analysis. The objective of the task is to predict what is happening on the system followed by a specific explanation or reasoning behind such prediction. The task given to the students involves answering different questions related to the analysis of forces in a truss, such as identifying two force members, zero force members, etc. This problem has posed different challenges for students in the current course due to the students' unfamiliarity with engineering concepts in statics. Students are asked to solve the problem during a think-aloud process where students identify the information necessary to solve the problem. The think-aloud process helps identify the explicit, implicit and socio-contextual aspects of the task as they work toward understanding the design that solves or explains the engineering problem [13]. Knowledge may be in the form of social context (beliefs about understanding and expertise from their relationships and discourse practices), explicit resources (terminology and specific instructions), or implicit resources (different concept connections or extrapolations). Data collection involves think-aloud tasks that elicit students' task interpretations and perceptions [13]. Broadly speaking, the collection of a protocol involves the recording of a research participant's verbalization while working to solve a problem, usually one specified by the researcher. This verbal thought process, as well as follow-up interviews and observations, are recorded and transcribed. The purpose is to generate a verbal text that a researcher can analyze to provide an account of cognitive processes [14]. Implicit and explicit layers of information from the students' verbalizations may or may not be correct, and this allows the researcher to identify how many of their implicit and explicit layers of information are accurate in order to create a coding system for analysis.

Once the prediction, solution, and subsequent explanation have been made, the students have the opportunity to work with the manipulative. Two types of data are collected during the process: *concurrent*, in which a participant thinks aloud during the process of completing the task, and *retrospective*, in which a participant completes components of the task or the whole task and then is prompted to reconstruct the process from memory [14]. Once they have worked with the manipulative, a final interview is conducted to determine if the students concur with the predictions made and determine any assimilation problems and possible elimination of misconceptions. The prediction and final interview may consist of descriptions of design load calculations, reactions and free body diagrams, presentation of engineering calculations, and determination of zero force members. All questions are open-ended questions and help describe the kind of thinking and kind of knowledge the students emphasize during the task assignment. In this process, student may connect different stories that they can relate to the type of assignment being investigated.

Constant comparative analysis is used to critically draw important information about the participants. The constant comparative method consists of identifying a phenomenon, object, or event, then comparing incidents applicable to each category, and finally integrating such categories and their properties [15]. Thus, this method combines category coding with simultaneous comparison of all incidents observed as well as simultaneous comparison across categories. The constant comparative analysis would create a coding system used to compare, contrast and determine frequencies of different sets of beliefs, ideas or perceptions.

V. IMPLICATIONS

This project is intended to promote an instructional technique that is relevant to students in engineering. Providing engineering students with opportunities to communicate science and engineering through physical manipulatives, drawings, charts, tables, graphs, and computer-developed simulations increases participation and promotes more focus on communication for understanding. It provides the students with the time to build context, common experiences, thinking skills, cooperative learning, comfort level and a positive attitude toward learning. The results obtained from this study will be used to modify and expand further research regarding engineering physical and virtual manipulatives, curriculum materials, and practices to help the linguistically and culturally diverse classrooms. At the time of the FIE 2013 Conference, results from this research will be presented.

***Abstract*— The area of mobile city guides has grown really fast in the last years based on new mobile capabilities. This growth has been fostered by the evolution of ubiquitous systems and the great penetration of smartphones in the society. In this paper we propose a generic model to support a new way of visiting the city: instead of as a place for tourism, we see it as a place for learning in which located educational resources are available for end users. The model has been conceived as a way to encourage them to create their own educational tours, in which Learning Points Of Interest are set up to be discovered. Two main use cases are supported by the model: formal (conducted by a teacher) and informal (no educator is related to the learning experience) outdoor mobile learning. Details about the impact of the conjunction of tourism, learning and gamification dimensions in the model design, as well as about the model itself are provided. Finally, a mobile application prototype developed in the context of the FI-CONTENT European project is presented as a proof of concept of the model.**

Keywords—Mobile Learning; Gamification; Educational Tours; Learning Object

I. INTRODUCTION

The area of mobile city guides has grown really fast in the last years based on new mobile capabilities such as connectivity or location context. This growth has been fostered by the evolution of ubiquitous systems and the great penetration of smartphones in the society. Mobile city guides are changing the way people experience tourism, plan their travels and share these experiences. Many mobile city guides exist nowadays such as Stay [1], Tourist Eye [2], or Lonely Planet [3] providing guides for travelling worldwide. Moreover, a lot of cities offer also their own mobile city guide. The main aim of these guides is to provide basic information about locations that are useful or interesting. These locations are formally known as Points Of Interest (POIs). Other common features are personalized recommendations, customized travel guides, sharing travelling information, offline access and augmented reality functionalities. In addition, new features can be added to these mobile tourist applications in order to provide new services. For instance, [4] proposed a mobile tourist service built by integrating mobile guide services with other services such as notifications and payments. In the same way, these mobile applications can be expanded further to include mobile learning. So, they can be repurposed in the education domain. Bearing in mind this idea, we propose a new way of visiting the city: instead of a place for tourism we see it as a place for learning in which located educational resources are available for end users interested in discovering history, legends or curiosities about the cities they live in or visit. Furthermore, in order to provide engaging and motivating learning experiences a gamified dimension is also considered together with the tourism and learning dimensions.

The idea of enriching and gamifying traditional tourist tours is not new. For instance, the “Matera Tales of a City” project [5] provides a web platform and a gamified mobile application to allow tourists to access to cultural contents (e.g. 3D reconstructions or audio guides) while attending places.

Using a real city (or the world) as a gamified scenario is not new either. The stage used to play MEECO [6] is a real city, where citizens can virtually register their real ecological actions such as recycle or biking using their mobile devices.

Nevertheless, no learning approaches have been defined to take advantage of mobile city guides benefits in the educational field. Bearing this in mind, we present in this paper a generic model that defines a new learning approach based on the use of the city as a learning gamified platform considering three dimensions: tourism, learning and gamification. This new learning approach arises from the combination of the areas of mobile city guides, mobile learning and gamification according to Fig. 1.

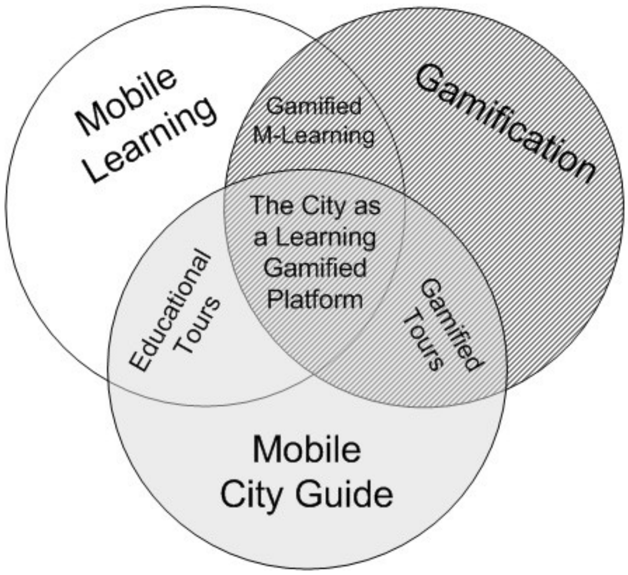

Fig. 1. The City as a Learning Gamified Platform research field.

The model has been defined based on a scenario designed in the context of the FI-CONTENT (http://www.fi-content.eu) European project. One of the aims of this project is to validate and evaluate the service infrastructure provided by the FI-WARE (http://www.fi-ware.eu) European project. For this reason, a scenario based on the city as a gamified platform was proposed and selected to test specific components and technologies developed as part of the FI-WARE project. The main use cases and requirements of this scenario were identified and used as a basis for the model definition. Lastly, as a proof of concept, an application prototype has been developed using FI-WARE elements.

The rest of the paper is organized as follows. The next section reviews related work of mobile learning, adventure in education and gamification. Section 3 introduces the FI-CONTENT and FI-WARE projects and illustrates the main use cases. Section 4 explains the model in detail. Section 5 presents the application prototype. Then, section 6 provides some discussion. The last section finishes with some concluding remarks together with an outlook on future work.

II. Related Work

As technology evolves, faster wireless and mobile networks and more powerful handheld devices are available at lower cost. These technological advancements are creating the ideal conditions for Mobile Learning (M-Learning). There are several definitions of the term M-Learning. A commonly accepted one can be found in [7] which defines M-Learning as "any sort of learning that happens when the learner is not at a fixed, predetermined location, or learning that happens when the learner takes advantage of the learning opportunities offered by mobile technologies". This definition can be completed by adding that M-Learning also aims to allow learners to assimilate learning anywhere and at any time [7], [8]. Another common goal of M-Learning applications is to allow learners to accomplish learning activities by taking all contextual elements into consideration [9]. This brings the concept of context. According to [10] context is "any information that can be used to characterize the situation of an entity", where an entity is defined as "a person, place or object that is considered relevant to the interaction between a user and an application, including the user and applications themselves". Some studies have already showed that learning can be effectively extended to handheld devices and that M-Learning applications can be used to complement classroom or distance learning [11]. This type of learning opens up new opportunities for educators because the learning activity is not limited to the classroom; it can also be completed anywhere and anytime, without requiring strict supervision by the teacher [12]. Novel learning opportunities can also arise by introducing collaboration [13]. These new chances are especially relevant for informal learning, where the learning activities usually take place outside educational establishments and formal curricula of schools.

On the other hand, new opportunities in formal and informal learning can also be achieved by incorporating adventure into education. Some approaches aim to achieve this goal in a pedagogically meaningful way. The first one was Adventure Education (AE), which is a form of experiential learning typically associated with cooperative games, problem-solving tasks and high adventure activities [14]. Despite AE not necessarily occurs out of the classroom, it is sometimes used wrongly as synonymous of outdoor learning, which is precisely characterized by experiencing learning activities in the outdoors. Another approach called Adventure Learning (AL) was defined by Doering in 2006 [15]. It can be defined as a hybrid distance education approach that provides students with opportunities to explore real-world issues through authentic, field-based narratives within an online learning environment. Lastly, one more approach exists based on the novel concept of User-Drive Adventure Learning Environments (UDALE) allowing learners to create and share self-initiated AL projects. UDALE merges components of AE and AL. It aims to engage learners in their own physical adventure while concurrently teaching others about a real-world issue, sharing authentic data and employing technology for data collection and collaboration [16]. Due to UDALE tools, mobile learning is being explored as a mean to introduce adventure into education and engage learners in AL.

Finally, educators can also provide new learning experiences by applying gamification in education. Although gamification lacks a universal definition an appropriate one can be found in [17], which defines gamification as "the use of game design elements in non-game contexts". In education, gamification can be used to promote learning because many of the elements of gamification are based on educational psychology and are techniques that designers of instruction, teachers, and professors have been using for years [18]. Examples of common elements used in gamified applications are, among others, badges, leaderboards and scoring systems. A typical example of a gamified application is Foursquare (http://www.foursquare.com), in which users can collect badges for accomplishing activities such as check-in a certain number of times to specific POIs (e.g. 20 different pizza places). Hence, gamification can be applied to M-Learning to provide more engaging learning experiences, especially beyond the classroom walls.

III. Scenario

A. FI-CONTENT and FI-WARE projects

FI-WARE is a European project which main goal is to advance the global competitiveness of the European Union economy by introducing an innovative infrastructure for cost-effective creation and delivery of versatile digital services, providing high QoS (Quality of Service) and security guarantees. The project also intends to demonstrate how this infrastructure can support novel Future Internet (FI) services in multiple sectors such as healthcare, telecommunications or education in a more productive, reliable and efficient way. The service infrastructure is built upon building blocks called Generic Enablers (GEs). A GE can be defined as a component that offers at least one reusable and commonly shared functionality and can serve a multiplicity of usage areas. The identification and specification of GEs are key goals of the FI-WARE project together with the development of reference implementations of them.

The FI-CONTENT European project aims to shape the next generation Internet providing a framework to allow transformations of novel and inventive scenarios into technical outputs and demonstrating usage beyond current state of the art. FI-CONTENT is focused on several content areas such as virtual environments, games, educational entertainment and culture and user created content. The scenarios are proposed by a consortium formed mostly by major content providers, game companies, broadcasters, research institutes and academic institutions. One of the foremost aims of FI-CONTENT is to validate and evaluate the existing GEs provided by FI-WARE in different scenarios for their future implementation by using working prototypes.

B. Use cases

A scenario grounded on the city as a gamified platform can provide several novel learning experiences. These experiences are very diverse but all of them share the mobility component. Learners are moving across the city visiting different places, i.e. the learning activities are undertaken outdoors. All of these activities will interact in some respects with different elements of the city such as citizens or locations. On the one hand, learning can be produced by visiting POIs and gamification can be used to encourage participants to do that. On the other hand, people can interact in different ways collaborating, competing, teaching or leading. Taken into account that the presence of an instructor influences significantly the learning experiences in this scenario, two main use cases were identified related to formal and informal outdoor learning, respectively.

1) Formal Outdoor Learning

This use case describes a scenario in which a teacher creates an educational tour targeted for his/her students related to the current subject that is being studied in class. First off, the teacher creates the educational tour selecting the different POIs and learning materials. Besides adding existing materials, the teacher can create new specific contents or adapt the existing ones. Then, the teacher has to explain the rules of the learning experience in the classroom. Students can use their own smartphones to access to the educational tour and perform all the activities available. The tour starts leaving the classroom and adopting the entire city as the learning environment. Since this moment, students are involved in an adventure in which they have to achieve a set of goals. The achievement of the goals is based on the discovery of selected city locations and the realization of learning activities related to these places. These activities will be triggered when the students arrive to the associated location. A learning activity can be, for instance, watching a video about the place, a quiz that asks questions that require the student to explore physically the place to answer or a puzzle game that challenges the student´s intelligence. Moreover, several elements may be involved in an activity. For instance, a learning activity may consist of a video and a quiz that ask a question about it. This way, students have to overcome diverse challenges based on the realization of learning activities through their mobile devices. As a consequence of performing successfully a learning activity, new goals or missions can be offered to the student and new elements can come into play. Finally, other actions can be carried out by the students during the tour such as take geo-located photos about specific topics and share them through an online environment.

2) Informal Outdoor Learning

This use case describes a learning scenario which lacks the presence of an instructor and where anyone can create his/her own educational tour and offer it to the community. The learning experience is based on the same principles than the previous use case. Each participant has to achieve a set of goals, whose achievement depends on the discovery of POIs and the realization of specific activities. However, this use case is focused on providing more joyful and engaging learning experiences in the process of discovering POIs. First off, each participant or player assumes the role of a character like in a role playing game. Optionally, the adventure can be set in a fictional or historical setting, explaining the backstory and the motivation. Each character has its own mission composed by a set of goals. In this scenario, Virtual Objects (VOs) are scattered around the city. Players can find VOs in some POIs, and they can watch and collect them via their mobile devices using augmented reality. Players can also trade with VOs. New goals are defined around VOs. For instance, the mission of a player may be to collect all of the pieces of the Philosopher's Stone and bring them to a specific spot. Some goals may also require collaboration to be achieved. This way, players are involved in an adventure which tests their ingenuity and their problem-solving and teamwork skills. Finally, two game elements are included in the scenario to encourage competition: leaderboards and badges. The leaderboard is built based on scores that can be earned by achieving goals or finding VOs, while badges can be collected undertaking different actions.

C. Requirements

Based on these use cases, several requirements were identified and numbered from *Requirement 1* to *Requirement 7*.

1. The learning experiences must be provided by educational tours, which should be available for mobile devices since the learning occurs outdoors. Furthermore, they should be able to be created and designed by anyone.
2. Learning activities (e.g. videos, quizzes, mini games) are very diverse and can be combined to build more complex ones. Therefore a logical choice is to build them as Learning Objects (LOs) [19], [20].
3. The learning activities are tied to locations and hence the LOs must be associated with POIs.
4. Virtual Objects (VOs) are tied to POIs and participants can obtain them using their mobile phones.
5. Each participant may have a character associated with a specific mission and/or goals to achieve. Some goals may require teamwork to be achieved.
6. Several actions performed by participants or triggered by the occurrence of certain events have to be considered (e.g. reveal new POIs or goals, take a picture, etc.).

7. Certain events (e.g. activity completion or POI discovery) should allow participants to achieve badges or earn a certain amount of score points. A leaderboard based on these scores ought to be provided.

IV. Model

Based on the requirements derived from the use cases analysis, we define a model for the educational tour entity considering three dimensions: tourism, learning and gamification. This means that any educational tour can be represented by three components or vectors, each of them related to one dimension. The magnitude of these components relies on diverse factors of the educational tour such as LOs, POIs or VOs quantity, academic load or the role played by game mechanics in the learning experience. Therefore, educational tours tailored for different use cases will lead to different representations. To illustrate this idea, Fig. 2 shows the representation of the educational tours corresponding to the above mentioned use cases.

In the first case the learning component is the strongest one, since the educational tour has been created by a teacher with a strict educational purpose. Gamification is limited to provide a set of goals and maybe by including puzzle-like LOs. On the other hand, the second case has a very strong gamification component due to the preparation of the tour as a role playing game. In this case the LOs will be in most cases riddles, mini games, jigsaws and ability tests, which sometimes can offer less educational contents for the sake of entertainment and thus the learning component can be weaker. The tourism component mainly relies on the quantity of POIs. However, the more time participants spent consuming LOs, less time they will have to visit new locations.

A. Educational Tour Structure

In order to allow people to easily create educational tours regardless of their technical knowledge, they should use an e-Learning authoring tool. For this reason, the educational tours must follow a standardized structure that can be easily represented. This way, they can be implemented as web contents accessible through mobile devices and exported to standard e-Learning formats like SCORM (Sharable Content Object Reference Model) [21]. As a consequence we achieve the *Requirement 1*.

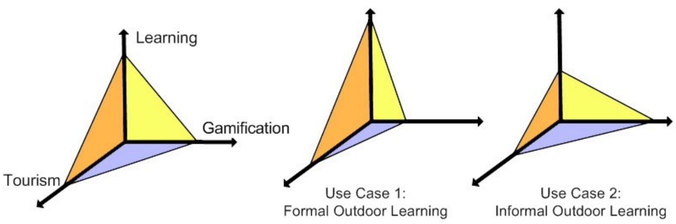

Fig. 2. Educational Tour Representation.

This model defines the structure of the educational tours including the description of the different components, their properties and how they relate among themselves. Fig. 3 summarizes this structure.

The learning activities are the building blocks of the tour. Providing them as LOs allows people to easily create and customize them conforming to e-Learning standards by using e-Learning authoring tools. Furthermore, it allows the reuse of a big amount of existing learning materials. *Requirement 2* is met thanks to this strategy.

To associate the LOs with POIs (i.e. *Requirement 3*), we have created the concept of Learning Point of Interest (LPOI). A LPOI can be defined as a POI that has a LO associated, or in other words, a LO that is tied to a location. Since a LPOI is nothing more than a particular LO, it can be formed by aggregating other LOs. The set of all LPOIs is called scenario.

In an educational tour, a LPOI can also be associated with Virtual Objects (VOs). *Requirement 4* is fulfilled as consequence of this linkage. In addition, VOs can be used by participants to touch off specific events in the tour (e.g. by bringing one to a specific POI).

An educational tour has a set of characters or roles. Each role has one mission with a uniquely associated goal and optionally a set of initial VOs. Goals are always related to LPOIs, VOs or both. The model considers three types of goals: go to a LPOI and accomplish the learning activities (i.e. consuming the LOs), bring a VO to a LPOI, and a combination of any of them. For instance, a collaborative goal can be defined by linking two simple goals: bring a VO to one location and bring another VO to a different location. Since a participant cannot be in two locations at the same time he/she will have to look for a partner. Since all of the goals are defined objectively based on existing entities, it is easy for a mobile application to manage them. Moreover, missions can also be split into activities. An activity is like a mission, but its associated goal is a "partial goal". This structure allows the achievement of the *Requirement 5*.

The accomplishment of an activity may result in the execution of an action. Actions cause effects over different entities of the tour. The main actions are: "Reveal a hidden LPOI", "Show a new activity" and "Give one VO to a certain participant". Actions can be performed as a response to a particular event (hence defined by the author of the tour), or because of a participant decision. For example, a VO can be given to a participant for discovering a LPOI or because of a barter deal between players. This modeling of the action entity covers the *Requirement 6*.

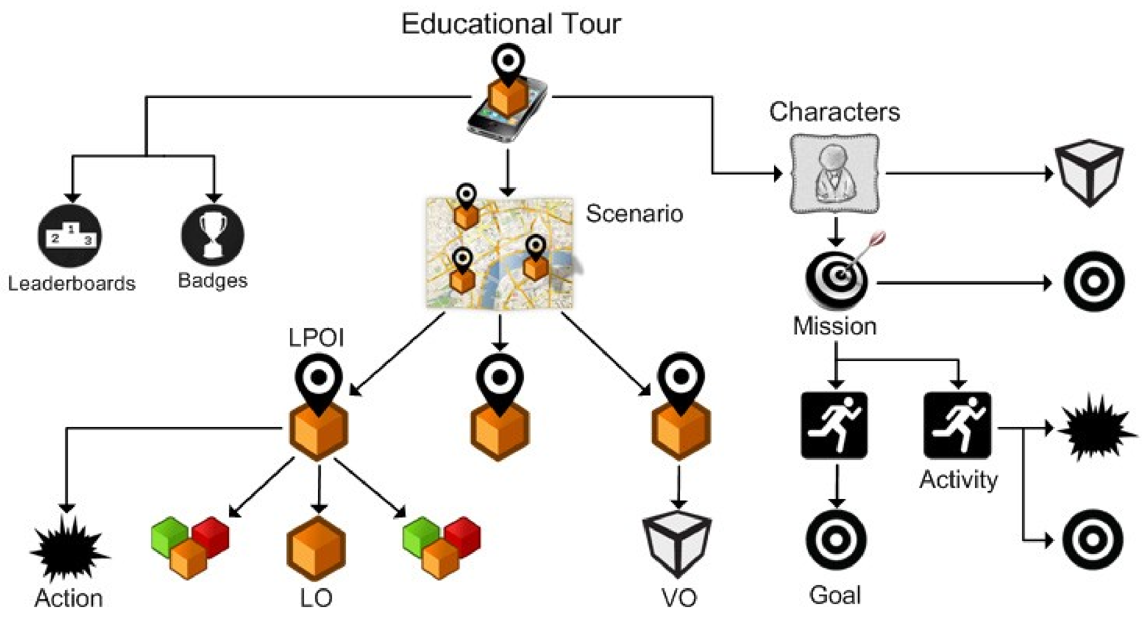

Fig. 3. Educational Tour Structure.

Lastly, in order to satisfy the *Requirement 7*, two more elements are considered in an educational tour: a leaderboard and a set of badges. There are two actions related to this: "Give a badge to a specific participant" and "Add score to a specific participant". Thereby, a participant can earn score points or achieving a badge by discovering and/or realizing the learning activities of a LPOI or by accomplishing a goal.

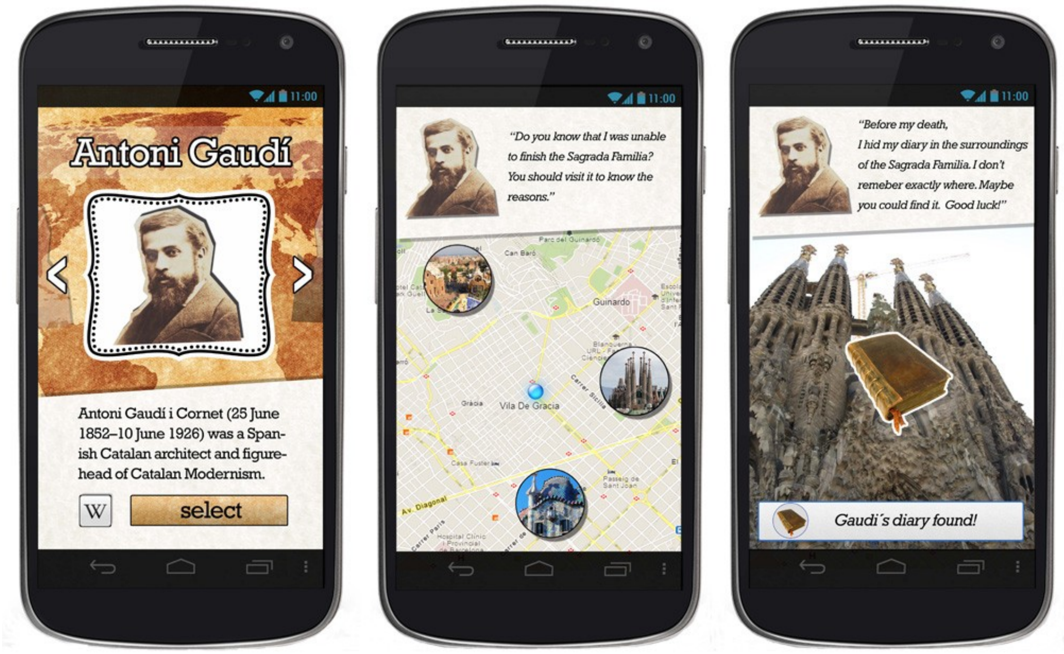
V. PROTOTYPE

As a proof of concept, an application prototype (Fig. 4) has been developed on top of the cloud services provided by the following GEs of the FI-WARE platform.

- *Location* to retrieve the users' location and notify the system when a user arrives to a LPOI.
- *Publish/Subscribe Context Broker* to notify users about certain news or events.
- *Identity Management* to provide authentication and authorization.

The application provides a set of educational tours of the city of Barcelona. Each tour is grounded on an historical character who will guide the user around the city. These characters explain different stories and curiosities related to their experiences throughout the tour. Characters can also propose different activities to accomplish. Fig. 4a shows the initial screen where a historical character from Barcelona can be chosen between Antoni Gaudi, Joan Miró or Pablo Picasso among others. After the selection of a character (in the Fig. 4 Antoni Gaudi) the educational tour starts. Then several LPOIs are revealed in a map as well as the current user's location. Fig. 4b represents this situation, where three LPOIs are showed: one in the Güell Park, other in the Sagrada Familia and another one in the Casa Batlló. Moreover, the user receives an initial advice from the virtual fellow traveller, recommending him/her to visit one LPOI. As we can see in Fig. 4b Antoni Gaudi is recommending the user to visit the Sagrada Familia. If the user follows this advice, a clue to perform activities related to the LPOI will be given upon his/her arrival. In the case illustrated, Gaudi confesses that he lost his diary in somewhere in the surroundings of the Sagrada Familia, encouraging the user to look for it. Fig. 4c shows the result of finding the VO representing the diary using augmented reality capabilities.

This application meets the two above mentioned use cases. This was achieved by providing several educational tours, each of them tailored for a different use case. On the one hand, it provides educational tours that could have been created by teachers with strong learning objectives related to the current subject studied in their classroom (e.g. an art history class). On the other hand, it also provides educational tours with weaker educational purposes, focusing more in the tourism and gamified dimensions. This kind of tours could have been created, for instance, by the tourism office of Barcelona or by a group of friends.



a) b) c)

Fig. 4. Prototype screenshots.

VI. Discussion

The model presented in this paper satisfies several use cases of outdoor M-Learning. Learning approaches focused on incorporating adventure into education such as AE and AL usually involves the realization of learning activities outdoors. Hence, in these cases, the model can be very useful providing more engaging learning experiences. Furthermore, the learning experiences can be tailored to be adapted to the desired use case by strengthening the correspondent component (tourism, learning or gamification). Another application of this model can be found in the emerging UDALE environments, since one of the challenges in its implementation is to provide an optimal structure and scaffolding for teachers and learners to allow them to create their own learning experiences [16].

However, some limitations exist when the model is put into practice. Learning experiences rely on mobile devices and hence they are limited by the technology capabilities of these devices. For example, if the mobile device is unable to determine the current location of the user for a prolonged time, they would not detect if the user arrives to a new LPOI. This fact can ruin the whole learning experience. Therefore, this technological issue limits the scope where the model can be applied. We designed the model for a city scenario, but it can fail or being unable to be applied to rural areas, where the connectivity is worse, or even to indoor scenarios where the geo-location is really complicated.

Finally, bearing in mind the tourism, learning and gamification components in which an educational tour can be decomposed, it is worth questioning if educational tours with a strongest learning component are the most effective or if it is better to include game elements to increase motivation at the expense of a weaker learning component.

VII. Conclusions and Future Work

We have presented a generic model which allows creating educational tours covering the main use cases of a scenario grounded on the city as a learning gamified platform. This model was created with the main aim of taking advantage of the benefits of linking the areas of Mobile City Guide, M-Learning and Gamification. As a consequence, the created educational tours can be represented by three dimensions: tourism, learning and gamification. Lastly, as a proof of concept, a mobile application prototype has been developed in the context of the FI-CONTENT European project to guarantee the achievement of the use cases and to ensure that the model is ready to be applied in real scenarios.

We have showed that the city can be effectively used as a place for learning. Several novel learning opportunities can be achieved in formal and informal outdoor M-Learning by using the city as a learning platform in combination with gamification. Also, this approach can enhance the experiences in existing learning approaches such as Adventure Education or Adventure Learning. Although these learning experiences can be limited by technological constraints, these limitations will be overcome since the technological advancements are creating the ideal conditions to use the city as a gamified learning platform.

Open challenges after this research consists of refining the mobile application prototype into a final product ready to be delivered to the public as well as the different components used in the service. Also, we plan to develop an authoring tool capable of creating the educational tours according to our model. This will allow us to test completely this new learning approach in the real world with teachers, learners and citizens as end users.

Since this is a novel research field, it opens several new research lines towards the exploitation of the city as a learning environment. In the considered scenario, places are passive elements. Learners can interact with the Learning Objects associated with them but not with the places themselves. Thereby, an interesting research line to investigate would be to consider in the model that different places and urban elements may be intelligent entities that interact with the participants. For example, an intelligent recycle container could give a badge or score points to a participant (or citizen) for recycling appropriately a certain amount of trash. Bearing all this in mind, we believe that Smart Educational Cities can become a next frontier in education.

ACKNOWLEDGMENT

We wish to acknowledge our gratitude and appreciation to all the FI-WARE and FI-CONTENT project partners, and each one of the project team members, for their contribution during the development of various ideas and concepts presented in this paper. We also would like to thank the SAAN project (TIN2010-19138) for funding this work.

***Abstract* – In recent years, issues related to teaching and learning have been more and more discussed and investigated by the scientific community. Mobile learning (m-learning) environments, despite the benefits provided, are still considered as new and incipient products. Among the limitations observed in the construction and adoption of such environments, we highlight the lack of specific quality guidelines to allow an adequate evaluation of them. In short, the planning and execution of a systematic evaluation among m-learning environments can ease their selection and adoption by apprentices, tutors and educational organizations. Motivated by this scenario, in this paper we propose a process for the quality evaluation of mobile learning environments. To validate our ideas, we have applied the proposed process in the quality evaluation of a set of m-learning environments. The promising results achieved suggest the feasibility of adopting the process for quality evaluation purposes in the m-learning domain.**

Keywords – quality evaluation process, mobile learning environments, quality model

I. INTRODUCTION

In recent years, learning environments have shown an increasing importance, playing a fundamental role in teaching and training activities, both in academic and industrial settings [1,2]. Together with the advent of ubiquitous computing, learning environments have also provided a new modality of education – the mobile learning (m-learning) [3, 4, 5, 6].

Mobile learning is characterized by the ability to promote a strong interaction among apprentices and tutors, enabling them to contribute, participate and access the learning materials through mobile devices (e.g., mobile phones, tablets, laptops, among others) at anytime and anywhere. So, the main goal is to provide greater motivation, convenience and flexibility to the learning processes in general.

Despite the benefits of m-learning, it is still considered a new and incipient concept, having some limitations in its construction and use [5, 6]: (1) reduced processing power; (2) variable screen size; (3) limited energy (battery dependent); (4) transmission rates generally smaller than those of the fixed network; (5) adequacy to usability aspects; (6) lack of architectural patterns; and (7) lack of requirements and quality guidelines for the educational practices.

Quality aspects, in particular, represent an important issue to be addressed, mainly because of the growing popularity of mobile applications in different sectors of the society. In this emerging scenario, quality is not only related to technical aspects. There is also a need for dealing with intrinsic issues (e.g., educational, socio-cultural and economic) related to the daily activities of apprentices and tutors [7].

Few studies regarding quality guidelines for mobile applications have been found in the literature. As a consequence, there is no well-defined and widely used mechanism to support the quality evaluation of mobile educational environments. In this paper we propose a process for quality evaluation of mobile learning environments. In short, the process establishes a set of quality metrics as well as the levels of punctuation and the judgment criteria. A quality model for mobile learning environments, defined in a previous work [18], is also used as part of the process. To validate our ideas, the process is applied in the quality evaluation of three mobile learning environments.

This paper is organized as follows. In Section II, we provide an overview of the main topics on which this paper relies: m-learning and quality evaluation processes. In Section III, we briefly describe a quality model for m-learning environments. In Section IV, we present the quality evaluation process we have worked on. In Section V, we illustrate the application of the proposed process for evaluating three different m-learning environments. Finally, in Section VI, we summarize our conclusions and perspectives for further work.

II. BACKGROUND

A. *Mobile Learning*

The rapid growth of information technologies along with the increasing flexibility in communications among users have provided new modalities of learning as well as innovative ways to deal with the limitations of traditional learning. For instance, due to the advent and evolution of technology, allied to the ubiquitous computing, a new modality of education based in mobile computing, referred to as mobile learning (m-learning), has emerged [8].

Several attempts to define m-learning can be found in the literature. Rachid and Ishitani [9] define m-learning as any type of teaching/learning that occurs when the apprentice is not in some fixed place, or when the individual is taking advantage of learning opportunities offered by mobile technologies. Ozdamli and Cavus [10] consider m-learning as an activity that enables individuals to be more productive when they consume/create or interact with the information, mediated by mobile devices.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Whatever the definition adopted, the use of learning environments through mobile devices brings benefits that go beyond affordability, convenience and communication [11, 12]. For example, with mobile devices apprentices can use the most different types of applications (e.g., text processors, photos, games), specific environments for learning, Web access, collaboration tools, social networks, among others.

Despite the benefits provided, and even with the increasingly demand for flexible, reliable and high-quality mobile learning applications, there are few studies dealing with quality aspects in the particular context of m-learning development. Furthermore, the existing studies generally focus on some quality characteristics in separate (e.g., accessibility) [8, 12, 13]. On the other hand, considering mobile applications in general, some proposals on how the quality should be assessed can be found. For instance, Spriestersbach and Springer [21] identified the major challenges in the development of mobile applications, relating such challenges into the quality characteristics described by the ISO/IEC 9126 standard. Mantoro [22], in turn, suggests some adjustments to this quality model in order to assure the quality of context-aware applications.

The identification and understanding of quality criteria, requirements and metrics for m-learning environments is a complex task [7, 12]. Different factors are involved in the development and adoption of such environments. Additionally to technical aspects, educational components, attributes of ubiquitous computing, criteria of mobile usability, among others, should also be taken into consideration. Besides that, there is a need for the establishment of specific processes for quality evaluation in the context of mobile learning. The idea is to ensure that evaluations can be effective and capable of being replicated in different organizations, for a wide range of m-learning environments.

B. *Evaluation Process for Software Quality*

Several processes for the evaluation of software quality can be identified in the literature. Most of them, however, are specific for a particular type of software products, hindering their application to different domains.

In order to define an adequate quality evaluation process for m-learning environments, we were based on ISO/IEC 14598 standard [14]. Shortly, ISO/IEC 14598 is a guide for quality evaluation in software products, which allows the definition of evaluation requirements in terms of quality characteristics as stated in ISO 9126 standard [15]. The defined process can be used to evaluate products in development as well as products already finished. It comprises five stages [14]:

- A*nalysis of Evaluation Requirements*: the objectives of the evaluation are described, and the requirements to be evaluated are established. Different points of view can be considered, depending on the users of the product;
- *Specification of the Evaluation*: the goal is to define the scope of the evaluation, and the measurements to be performed in the product. Constraints, methods to be used and responsibilities of all people involved in the evaluation process are defined as well;
- *Design of the Evaluation*: the procedures to be followed to perform the measurements previously specified are documented. The evaluator must produce a plan that describes the resources required to conduct the evaluation (e.g., deadlines, evaluation team, associated risks and all the activities involved);
- *Execution of the Evaluation*: the evaluation is performed and the results achieved are summarized in a report;
- C*onclusion of the Evaluation*: the evaluation report is reviewed and delivered.

The adoption of an evaluation process based on ISO/IEC 14598 standard is relevant in order to establish a process that is repeatable, reproducible, impartial and objective. Actually, the aim is to have a practical and non-bureaucratic process, easy to be adopted by companies and organizations [16, 17].

III. A QUALITY MODEL FOR M-LEARNING ENVIRONMENTS

According to Guerra [17], to effectively perform a quality evaluation, it is necessary the use of a quality model specifically defined for the domain of the software under evaluation. In this work, we have adopted a requirements catalog for mobile learning environments, defined by Duarte Filho and Barbosa [18], as the basis for our quality model.

The catalog comprises three levels of hierarchy [18]: (i) *Criteria for Evaluation (Level 1):* responsible for determining the specific criteria that must be considered during the evaluation of the m-learning environment; (ii) *Requirements (Level 2):* composed of development and quality requirements, this level provides relevant guidelines regarding both the development and the quality evaluation of m-learning environments; and (iii) *Descriptions:* corresponds to the textual descriptions of the requirements defined in the previous level.

Figure 1 illustrates the general structure of the catalog. A brief description of the proposed criteria and requirements is presented next. In total, 44 requirements, organized into nine criteria, were defined.

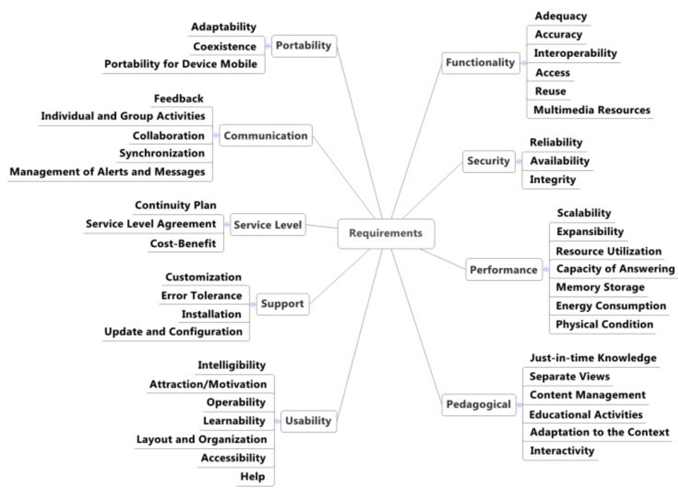

Fig. 1. Catalog of requirements for mobile learning environments [18].

The *technical criteria* deal with assumptions and constraints regarding functionality, security and performance.

- *Functionality:* Mobile learning environments, as any other software product, have to provide functions that meet the explicit and implicit users' needs. Regarding *functionality*, six requirements were defined: *adequacy*; *accuracy*; *interoperability*; *access*; *reuse*; and *multimedia resources*.
- *Security:* Since m-learning environments are mostly used via remote access (web), security is an important issue to be addressed in the development of such systems. Regarding *security*, three basic requirements were identified: *reliability*; *availability*; and *integrity*.
- *Performance:* In the scope of m-learning environments, performance is mainly related to the response time, expansibility and scalability, processing power, memory storage capacity and battery consumption. Thus, seven requirements were defined: *scalability*; *expansibility*; *resource utilization*; *capacity of answering*; *memory storage*; *energy consumption*; and *physical conditions*.

The *educational criteria* aim at providing greater competence and adaptation to the educational practices, taking into account pedagogical and usability aspects.

- *Pedagogical:* Additionally to the basic functional requirements, m-learning environments must address educational and pedagogical requirements in order to ease and support teaching and learning activities. Six requirements were defined regarding *pedagogical* issues: *just-in-time knowledge*; *separate views*; *content management*; *educational activities*; *adaptation to the context*; and *interactivity*.
- *Usability:* Interface is one of the strong points for software acceptance by the users. In the context of learning environments, especially for mobile devices, the interface should be easy to learn and to be recognized and remembered. Seven basic requirements on *usability* were defined: *intelligibility*; *attraction/motivation*; *operability*; *learnability*; *layout/organization*; *accessibility*; and *help*.

Regarding *economic criteria*, it is necessary to have a balance between the costs and the benefits involved in the m-learning environment application, taking in consideration aspects such as support and service level.

- *Support:* Support can be considered as a quality differential for m-learning environments. Every service provided must have an efficient support to its users in order to enable questions. Regarding *support*, four main requirements were identified: *customization*; *error tolerance*; *installation*; and *update/configuration*.
- *Service Level:* The establishment of service levels in the context of m-learning environments aims at improving the security in the use of such applications while guaranteeing the continuity of the services. Three main requirements were defined regarding *service level*: *continuity plan*; *service level agreement* (SLA); and *cost-benefit*.

Finally, the *socio-cultural criteria* assure the adequacy to issues relate to a particular social group and to the cultural level of the user of the mobile learning environment, taking into account communication and portability aspects.

- *Communication:* Communication is an essential characteristic for e-learning and m-learning environments. Regarding *communication*, five requirements were identified: *feedback*; *individual and group activities*; *collaboration*; *synchronization*; and *management of alerts and messages*.
- *Portability:* The apprentice must be able to interact with the objects of m-learning anytime and anywhere, ensuring convenience and flexibility during the learning process. Three man requirements were defined: *adaptability*; *coexistence*; and *portability for mobile devices*.

IV. Proposal of a Quality Evaluation Process for M-Learning Environments

To effectively evaluate and compare a mobile learning environment, it is important to follow a systematic and well-defined evaluation process. Besides that, the process should be capable of being followed by different organizations. Our proposal of a process to evaluate the quality of m-learning environments is described next.

Initially, it is necessary to define the actors and their roles with respect to the activities of the evaluation process. In the case of m-learning environments, there are three main actors that can participate in the evaluation process: (i) *Requester*: person/entity who asks for an evaluation, specifying what are the main purpose and objectives; (ii) *Evaluator*: person who knows the quality guidelines and knows how to apply the evaluation process, serving as a guide and primary contact between the process and its participants; and (iii) *Specialist*: person who has full knowledge regarding the application context of the mobile learning environment.

The evaluation process is illustrated in Figure 2. It is based on the best practices and knowledge prescribed in the ISO/IEC 14598 standard [14], being composed of six main steps. It is important to notice, however, that such steps were simplified and specifically adapted to the context of m-learning.

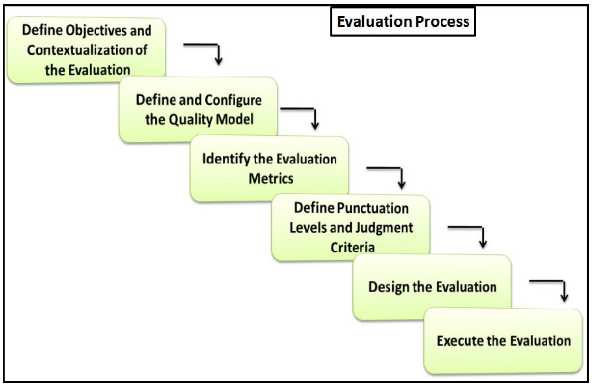

Fig. 2. Steps of the quality evaluation process for m-learning environments.

Define Objectives and Contextualization of the Evaluation: The objective of the evaluation is to analyze and compare mobile learning environments in relation to technical, educational, economic and socio-cultural aspects, identifying strengths and weaknesses of each environment considered. The idea is to perform the evaluations through quality guidelines specifically defined for this kind of software product, thereby ensuring the effectiveness in the assessments.

Define and Configure the Quality Model: The quality model adopted in the evaluation process is based on the Duarte Filho and Barbosa's model [18]. This model was chosen since it establishes a well-defined set of quality criteria and requirements for mobile learning environments, which has been prioritized and evaluated by specialists in the area.

Identify the Evaluation Metrics: In this step, the quality requirements should be mapped into attributes that can be measured and scored. In short, the measurable attributes are set up based on the knowledge of specialists, by creating simple and straight questions that are evaluated and scored by means of a checklist. In total, 90 questions were created and classified into nine distinct groups, according to the criteria defined in the quality model. Table I summarizes the main objectives of the questions that compose the checklist.

TABLE I. *MAIN OBJECTIVES OF THE QUESTIONS IN THE CHECKLIST.*

Quality Criterion	Objective of the Questions
Functionality	Questions in this group aim at evaluating aspects of functionality, such as cohesion and accuracy in performing the tasks. They allow checking if the m-learning environment works correctly according to the apprentices' and tutors' needs.
Usability	Questions in this group aim at evaluating if the users are able to easily employ the system options, and verify their level of satisfaction in relation to ergonomics, interface, among other characteristics of usability.
Security	Questions in this group aim at evaluating items regarding the access of users, reliability, integrity and availability of the mobile learning environment.
Performance	Questions in this group are concerned with the operation of the m-learning environment during the access of several users, in different organizations. The type of data transmitted is also considered in the evaluation.
Pedagogical	Questions in this group aim at evaluating educational and learning requirements. Issues of interactivity, motivation, and adjustments to the context of the apprentices are considered as well.
Support	Questions in this group aim at assessing the system behavior after occurring changes in their functions. Treatments of incidents and problems as well as corrections of bugs and defects are also considered.
Service Level	Questions in this group aim at evaluating the process of planning, control and definition of service level agreements (SLA), ensuring transparency in legal issues.
Portability	Questions in this group aim at verifying the system behavior with respect to different mobile devices, browsers and even with different operating systems.
Communication	Questions in this group aim at evaluating the effectiveness of the communication among users. Communication can be done in several ways (asynchronous or synchronous) through mobile devices.

For the sake of space, the proposed checklist for m-learning environments is not presented herein. The complete list of questions is available in Duarte Filho and Barbosa's work [19]. It is important to highlight that the checklist was elaborated as a template in order to facilitate its application by the evaluator.

Define Punctuation Levels and Judgment Criteria: To define the punctuation levels for the questions in the checklist, firstly we have to specify the type of nominal answers that can be applied in these questions.

For each one of the 90 questions created, the punctuation level is defined as follows: (i) maximum value: "1" (highest score); (ii) minimum value: "0" (lowest score); and (iii) intermediate values with the interval of "0.25". The score for each quality criterion is obtained by the sum of the scores achieved by its respective questions. This process is applied for the nine criteria established in the quality model. In the end, a final score for the m-learning environment under evaluation is obtained. Notice that by knowing each score separately, the requestor of the evaluation is able to prioritize adjustments and improvements on the criteria that did not achieve the required level of quality.

The judgment criteria are defined from the Martinez's work [20], in which three levels for judgment are established: *Superior*, *Medium* and *Lower*. To achieve the *Superior Level*, the m-learning environment must be in accordance with at least 80% of the quality requirements specified, i.e., the final score can vary from 80 to 100, on a scale of 0-100. To get the *Medium Level*, the system must be in accordance with at least 50% of the requirements, i.e., the final score can vary from 50 to 80. In the *Lower Level*, less than 50% of the requirements are achieved, i.e., the final score varies from 0 to 50.

Design the Evaluation: The evaluation must be designed according to specific guidelines for the system domain. In the case of mobile learning environments, for instance, the evaluation must be based on educational activities (e.g., exchange of information among tutors and apprentices, use of forums/wikis, application of tests, among others). Manuals of the environment should also be considered.

Execute the Evaluation: At the final stage, the evaluator has to execute three main tasks: (i) collect the quality measures; (2) compare the measures with respect to the quality criteria predefined; and (iii) judge the data obtained during the evaluation.

V. APPLYING THE QUALITY EVALUATION PROCESS: A CASE STUDY IN THE M-LEARNING ENVIRONMENTS DOMAIN

In order to conduct a preliminary validation of the proposed evaluation process, it was applied in the analysis of three mobile learning environments (Figure 3): *Blackboard Mobile*[1], *Desire2Learn Mobile* [2] and *Mobl21* [3]. Due to space limitations, we have detailed focus on the quality evaluation of *Desire2Learn*, and then we provide an overview of the obtained results to the other environments.

A. *Quality Evaluation of Desire2Learn*

Initially, the questions of the checklist were answered by the evaluator through the use of *Desire2Learn*. Consider, for instance, the quality criterion of "Usability". The first column

[1] www.blackboard.com/platforms/mobile/overview.aspx
[2] www.desire2learn.com/products/mobile/
[3] www.mobl21.com

of Table II corresponds to the number of each question in the checklist related to this criterion; the second column shows the scores given by the evaluator for each question. The sum of these scores represents the level of quality achieved by *Desire2Learn* with respect to “Usability”. This process was repeated for each criterion of the quality model. The scores achieved for all criteria are summarized in Figure 4.

According to Figure 4, “Functionality” and “Security” obtained the highest scores, being the only criteria in the *Superior Level* of quality. All the other criteria were at the *Medium Level*. It is important to notice that these criteria deal with general aspects of a traditional learning environment, i.e., they do not address specific characteristics of a mobile system.

a-) Blackboard Mobile b-) Desire2Learn c-) Mobl21

Fig. 3. Mobile learning environments

TABLE II. SCORE OF EACH QUESTION RELATED TO “USABILITY”

Question	Score
1	1
2	0
3	1
4	0
5	1
6	0.5
7	1
8	0.5
9	1
10	1
Total	**7.0**

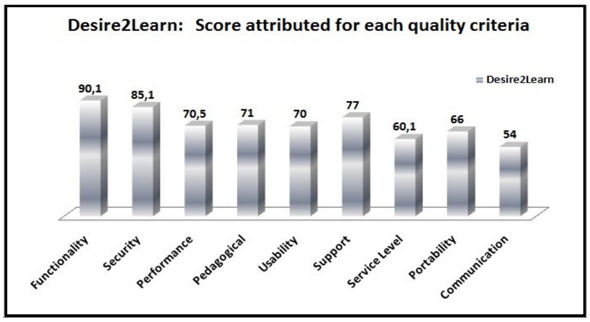

Fig. 4. *Desire2Learn*: Scores achieved for each quality criterion.

On the other hand, “Communication” and “Level of Service” obtained the worst scores among the quality criteria evaluated. Considering that these criteria deal with issues directly related to mobile systems, this result suggests a weak aspect regarding the quality of the environment under evaluation. Therefore, planning the evolution of *Desire2Learn*, specific improvements with respect to communication and level of service should be prioritized.

Then, the scores of each criterion were added and the arithmetic average was calculated. The final score for *Desire2Learn* was 71.5. According to the judgment criteria previously defined, the m-learning environment shows a *Medium Level* of quality.

B. Summary of Evaluation Results

Next we discuss the overall results obtained to the three mobile learning environments evaluated. Figure 5 summarizes the scores for each quality criterion in relation to the environments evaluated.

From Figure 5 we can notice that, in general, the m-learning environments have shown good scores in relation to the criteria of “Functionality”, “Security”, “Performance” and “Pedagogical”. These criteria correspond to the technical and educational/pedagogical areas, as defined by Duarte Filho and Barbosa [18] and by Economides [7]. On the other hand, we also may notice a decrease in the scores related to “Usability”, “Level of Service”, “Portability” and “Communication”, which are closely related to economic and socio-cultural aspects.

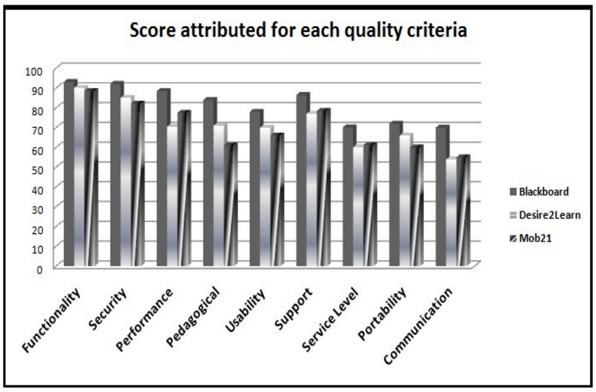

Fig. 5. Overall scores achieved for each quality criterion.

Adding all the scores achieved for each criterion and then computing the arithmetical average, it is possible to verify the final score for each one of the evaluated environments. Figure 6 shows the comparison among the final scores obtained.

From the evaluation performed, it was also possible to identify some strengths and weaknesses that the m-learning environments had in common (Table III). Such analysis is helpful in providing additional information to the requestor, suggesting potential aspects for future adjustments and changes in the products evaluated.

TABLE III. MOBILE LEARNING ENVIRONMENTS: SUMMARY OF COMMON POSITIVE AND NEGATIVE ASPECTS IDENTIFIED.

Criteria	Positive Points	Negative Points
Functionality	Most of the functions presented in the environments were capable of satisfying in an accurate and efficient manner both the users' needs and the educational practices.	During the evaluation, limitations related to the reuse of learning objects were identified, mainly due to the lack of using a standard reuse technique.
Security	The environments showed several technical mechanisms to ensure a greater security, assuring reliability and integrity to the users' information.	No mechanism to verify the number of times the users try to login using a wrong password was identified in the evaluated environments.
Performance	The environments showed to be effective in relation to the scalability of new users, using multi-tenant (use of the system by different users at the same time). Its use can also be performed by different organizations, ensuring confidentiality to the data.	The environments presented limitations regarding the inclusion of new services (scalability). In general, they do not provide a well-defined interface contract, hindering the inclusion of new services and components.
Pedagogical	The environments were well-evaluated in terms of content and educational activities management, allowing the use of information and knowledge transfer by means of texts, images, graphics, multimedia, games, audio, among others elements.	The environments do not provide an adequate separation of visions among tutors and apprentices, having problems in relation to the management of permissions and specific features.
Usability	The environments showed a variety of well-defined buttons and menus, organized together with adequate tabs of services and functions.	A weakness observed was the lack of help systems, demonstrations and tutorials, hindering the use of the environment, mainly by inexperienced users.
Support	The environments provided an efficient process for installation, update and configuration, ensuring that these tasks be treated in an easy, fast and automatic way, thus avoiding errors by the users.	Customizations, personal changes and actions in the environment were not well-adapted for the end user.
Service Level	The environments showed a good cost-benefit relation regarding purchase and maintenance, being economically viable to reach a specific group of apprentices, enabling the use and distribution of the system.	The environments provided an SLA. However, it was not well-defined, presenting ambiguities and not clarifying the legal implications with respect to non-compliance of essential clauses to the system operation.
Portability	The environments showed an adequate behavior while in use in different mobile devices, preserving all the functions and educational characteristics.	Some problems in relation to the hardware configuration were observed.
Communication	The environments presented a set of efficient tools for collaboration, such as wikis, games, micro-blogs and discussion groups.	Problems with respect to the management of warnings and messages were identified, hindering the correct receiving of SMS/MMS by users.

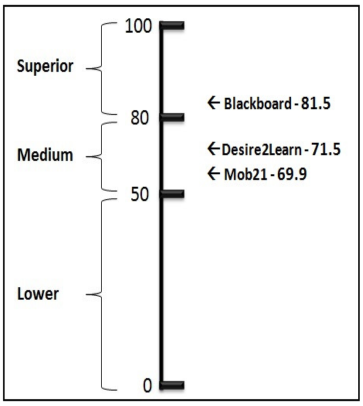

Fig. 6. Final scores achieved by each mobile learning environment

As a complement to the results already discussed, each environment was analyzed in separate. In general, the advantages and disadvantages identified are more related with functional and educational aspects.

<u>*Blackboard Mobile*</u>

The analysis performed in *Blackboard Mobile* pointed out the following advantages: (1) compatibility between different operating systems; (2) good interaction with users; (3) content grouped according to tasks and interactive forms; and (4) configuration facilities in the mobile device hardware.

As the main disadvantages we highlight: (1) proprietary software; (2) synchronization defective; (3) lack of support to previous versions of operating systems; and (4) versions conflict, requiring product verification and update.

<u>*Desire2Learn Mobile*</u>

Desire2Learn has characteristics that point out advantages, such as: (1) optimized access to content for apprentices/tutors; (2) communication and direct connection of interactive resources; (3) compatibility with several different operational systems; and (4) product customization.

On the other hand, some aspects can be considered as disadvantages: (1) low security; (2) inefficient control access; (3) it does not have content filter and optimization of broadband connection; (4) proprietary software; and (5) limitations on customization due to versions conflict.

<u>*Mobl21*</u>

During the evaluation of *Mobl21* the following advantages were identified: (1) free software via GNU-GPL; (2) portability among operating systems and databases; (3) interaction with the learner in real time, via SMS; (4) levels of perception of the m-learning environment in different colors (depending of context); (5) simultaneous access of users; and (6) information content arranged in several groups.

The main disadvantages are: (1) no control of bandwidth network; (2) latency in relation to web services; (3) it requires high computational power of the mobile device; and (4) difficulties to adapt the interface to different mobile devices.

As a final remark, it is also worth to notice that only minor problems were found during the execution of the case study. Furthermore, the evaluation process demonstrated to be effective and feasible to be applied together with the quality model previously established [18]. As a good practice, all results must be summarized and recorded in a final report.

VI. Conclusions and Further Work

In this work we proposed a systematic process for the quality evaluation of mobile learning environments. The aim is to help users (apprentices/tutors/administrators) in evaluating, comparing and selecting mobile learning environments. These environments should be compatible with pedagogical, socio-cultural, functional and economic criteria, ensuring higher quality and standardization to the educational practices.

The proposed process was based on a quality model [18], specifically defined to the m-learning domain. The ISO/IEC 14598 standard [14] was considered as well. The practical evaluation is performed by means of a checklist that, through a set of evaluation metrics, addresses all the criteria established by the quality model.

Furthermore, the process comprises a set of well-defined stages, enabling the evaluation be applied and reused by different evaluators, in various organizations and for different m-learning environments.

In order to validate our ideas, the process was applied in the quality evaluation of three mobile learning environments. The obtained results suggest the process is effective and feasible to be adopted in the quality evaluation of mobile learning environments.

Despite of the promising results achieved, we highlight the need for a more formal validation. Thus, systematic and controlled experiments, considering a wider set of mobile learning environments, have been planned and should be performed in short term.

***Abstract*— Reusing Learning Objects saves time and reduces development costs. Hence, achieving their interoperability in multiple contexts is essential when creating a Learning Object Repository. On the other hand, novel web videoconference services are available due to technological advancements. Several benefits can be gained by integrating Learning Objects into these services. For instance, they can allow sharing, co-viewing and synchronized co-browsing of these resources at the same time that provide real time communication. However, several efforts need to be undertaken to achieve the interoperability with these systems. In this paper, we propose a model to integrate the resources of the Learning Object Repositories into web videoconference services. The experience of applying this model in a real e-Learning scenario achieving interoperability with a web videoconference service is also described.**

Keywords— online learning; videoconference; learning objects; interoperability; repository

I. INTRODUCTION

Digital Learning Objects are the building blocks of e-Learning activities. A Digital Learning Object (hereafter just LO) may be as simple as a paragraph of text or an image, or can be a more complex object like a quiz or an educational game. Due to the immensity of learning resources on the Internet, Learning Object Repositories (LORs) play a key role by facilitating their discovery and reuse. The repurposing of LOs in multiple contexts is essential to enable cost-effective development and foster collaboration between organizations. Hence, achieving their interoperability is one of the main challenges when creating a LOR.

On the other hand, the adoption of novel HTML5 [1] technologies and the growth of cloud computing services are enabling the development of innovative web videoconference services. These new technology solutions provide high quality services at low cost as well as unprecedented easy access since users just need a web browser to establish a real time communication.

These new services can offer huge benefits for distance and blended learning. They allow the sharing, co-viewing and synchronized co-browsing of educational resources at the same time that provide real time communication. However, to take advantage of these benefits, the LOs have to be integrated with the videoconference services.

Basic LOs like a simple image are very easy to integrate, but more complex ones, which can have a high degree of interactivity, need more sophisticated solutions. There are several interoperability standards for LORs, but they are usually more focused on achieving interoperability among them than on increasing the ability of their resources to be reused. On the other hand, some standards have been defined to integrate LOs in external environments such as Learning Management Systems (LMSs), but they were not designed with web videoconference services in mind. Therefore it is not possible to take full advantage of the power of these tools using existing standard solutions.

In this paper we propose a novel model to integrate the LOs of a LOR into web videoconference services. We also present the experience of implementing this model in a real e-Learning scenario, in which we achieve the interoperability with a web videoconference service called MashMeTV (http://mashme.tv).

The rest of the paper is organized as follows. The next section reviews related work of LORs focused on interoperability. Section 3 explains the model. Section 4 presents the scenario in which it has been applied as well as the use case. The last section finishes with some concluding remarks together with an outlook on future work.

II. RELATED WORK

The Learning Object Metadata (LOM) standard [2] defines a Learning Object as "any entity, digital or non digital that may be used for learning, education or training". However, in e-Learning this term usually covers only digital entities. The main aim of providing educational resources as LOs is to facilitate reuse [3]. Reusing LOs instead of repeatedly authoring them can lead to several benefits such as savings in time, reducing development cost and even enhancing the quality [4]. A key factor in improving reusability and interoperability of LOs is metadata, where their information is specified including their structure, properties and educational characteristics.

Usually, LOs are created using e-Learning authoring tools and stored, searched and accessed using LORs. A LOR stores both LOs and their metadata, either by storing them physically together or by presenting a combined repository to the outside world [5]. LORs also allow users to search and retrieve LOs. To provide the most possible resources, they take LOs from other LORs using different methods such as federated searches or harvesting. Metadata plays an important role in facilitating the retrieval process since LORs typically support advanced searches based on LOM properties (e.g. subject, target age). The most widespread standard to define the metadata scheme is LOM, although some LORs have implemented their own scheme. LORs also provide several services to users beyond searching and storing such as favorites, recommendations of LOs based on user's history and private repositories.

Some different interpretations exist for the term interoperability. It is often considered as the capability of one system to communicate and interact with others. But in this context, interoperability can be also defined as the ability of "enabling information that originates in one context to be used in another in ways that are as highly automated as possible" [6]. In this paper we always refer to interoperability according to this second definition. Then, a crucial factor of a LOR is to provide interoperable LOs. Or in other words, to provide LOs that can be integrated automatically with LMSs and third party websites. Several approaches exist to achieve interoperability with different systems. First off, most e-Learning authoring tools build LOs conforming to some e-Learning standard such as SCORM (Sharable Content Object Reference Model) [7] or AICC (Aviation Industry Computer-Based Training Committee) allowing their reuse in LMSs. Furthermore, many LORs offer the possibility of exporting their resources to some of these standards.

Lastly, we must take into account that not all integrations are equally strong. Some approaches (e.g. SCORM) allow communication between the LOs and the context in which they are running while others do not. In the context of videoconference services, regarding the achieved degree of interoperability, the LOs can be *shared* (i.e. each participant sees his/her own isolated instance of the LO), *co-viewed* (i.e. all participants see the same LO) or *co-browsed* (i.e. all participants can also realize actions over the co-viewed LO synchronously). For instance, the Bridgit videoconferencing tool [8] achieves LO interoperability by using computer desktop sharing. Therefore the LO can be co-viewed since all participants can see the same LO at the same time, but co-browsing is not possible since the only participant who can interact with the LO is the one who is sharing the computer desktop. Some other videoconference services offer computer desktop sharing (e.g. Google Hangouts) but all of them have this limitation.

III. MODEL

This model has been designed with Web Videoconference Services (hereafter WVSs) in mind. Its main aim is to satisfy the main use cases of a scenario where a WVS is used for distance and blended learning: sharing, co-viewing and synchronized co-browsing of LOs.

The designed solution is based on the idea that if a LOR can export its resources to e-Learning standards to integrate them in LMSs, then it also would be possible to export these resources using certain conventions to allow their integration into WVSs.

According to this model, all LOs are delivered as web resources including a lightweight component that provides an API (Application Programming Interface), which enables the communication between the context in which LOs will be used and themselves. Fig. 1 illustrates this idea that will be explained in detail along the next sections.

A. Delivering interoperable Learning Objects

The LOR provides a main function: Request/Deliver LO. This function is in charge of attending the requests of LOs and delivering them enabling their reuse in the way that the interoperability can be achieved as highly automated as possible. Several steps are carried out to attend a LO request:

1. If the LO is not in a web-ready format it should be adapted. This adaption can be done when the LO is stored in the LOR or on the fly in a less efficient way. Hence, if an image is requested, the LOR will deliver a simple HTML page with the image embedded in it.

2. Besides the LO, a lightweight JavaScript API (hereafter LO API) will be attached to the HTML page in order to detect the events triggered as a response of the user's actions. This API also provides functions to replicate these actions. This step makes no sense for non-interactive resources (e.g. an image) and then in those cases can be skipped. However, if an interactive LO is requested like an HTML5 video, the API allows to detect when a user plays or stops the video as well as to replicate any of these actions.

3. Finally, the HTML page will be delivered to the application or website that requested the LO. This application will integrate the LO using an HTML element called *iframe*.

B. Introducing the iframe element

Before continuing with the explanation of the model, we present in this section a brief summary of the iframe element. An iframe is an HTML element that is used to insert or integrate other HTML documents or resources inside a website. For instance, a YouTube video can be embedded in a website using an iframe. The iframe element was standardized by the W3C (World Wide Web Consortium) and is supported in all modern browsers. Other kind of HTML elements can be used to embed web content in a website (e.g. embed or object), but the iframe is the only one that allows bidirectional communication between the website and the embedded object in a standardized way. Following with the previous example, using the YouTube API it is possible to detect when the user clicks on the play button or to play the video automatically without the user intervention.

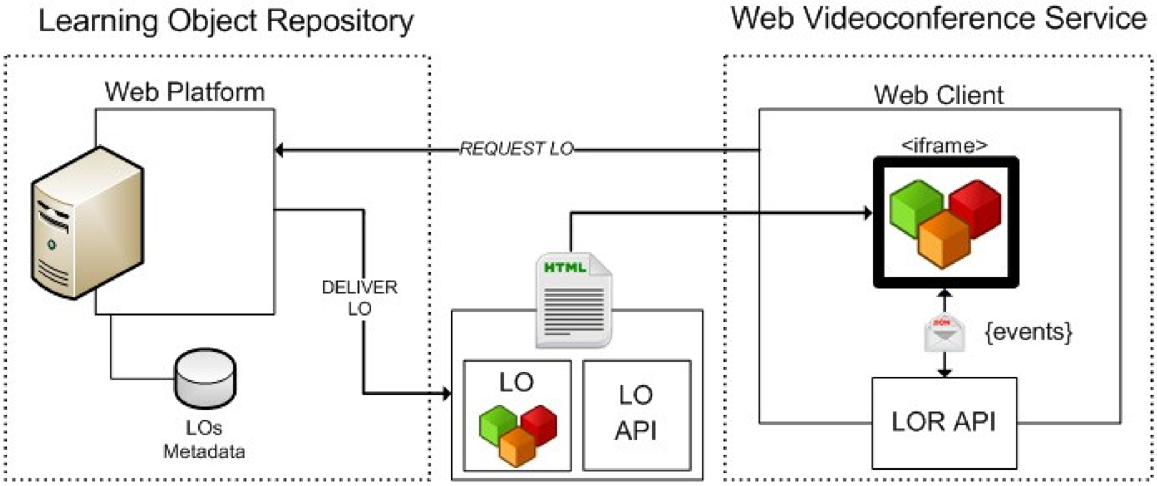

Fig. 1. LOR model to achieve interoperability with web videoconference services

C. Delivering particular LOs

In section 3A we saw that using a common API it is possible to automatically detect and replicate the events of standardized web elements such as an HTML5 video. However, this approach is not valid for particular LOs since they have their own specific actions. For example, the actions that users can perform in a slideshow (e.g. advance slides) are quite different that the actions they can do in an educational game (e.g. jump or shoot). Then, each kind of particular LO needs to provide its own LO API. As an example, Slideshare (http://www.slideshare.net) provides an API to interact with its presentations that specifies six actions: *jumpTo*, *next*, *previous*, *first*, *last* and *getCurrentSlide*.

Taken into account that these resources are usually created through authoring tools, the model specifies a convention that can be followed by these tools in order to create LOs that can be automatically integrated into WVSs. This way, teachers can create their own LOs (or adapt their existing ones) and share and co-browse them in a videoconference session.

Our solution requires the authoring tool to define each action that can be performed in the LO together with its corresponding triggered event. It needs to be able to replicate the different actions and detect their corresponding events. Therefore, in this case authoring tools will be in charge of providing the LO API. Furthermore, it is advisable that they include the possible events in the LO metadata or at least use the "Interactivity Level" parameter specified by LOM which describes the degree of interactivity of the LO.

For example, if a slideshow authoring tool wants to integrate their presentations into WVSs following this model, it may provide a LO API considering one action *jumpTo* to go to a specific slide, and its corresponding event *onSlideEnter* triggered when the user enters in a new slide. This way, if a user goes to slide 5, the *onSlideEnter* event will be triggered with the parameter 5. On the other hand, if the *jumpTo* method is invoked with the parameter 5 the slideshow will advance to slide 5. The key idea relies on the fact that in both cases, the final state of the slideshow is the same.

D. Delivering Learning Object events

In the previous sections we have explained how to detect the user actions for standard web resources and particular LOs as well as how to replicate these actions based on the events triggered. In this section, we are going to explain how these actions are delivered in a WVS environment. First off, the WVS should include the API of the LOR (hereafter LOR API) the same way as it includes third party APIs from external services like YouTube or Slideshare to integrate their resources (i.e. videos and slideshows). Fig. 1 also illustrates this fact. This API includes two functions: *onMessage* to receive the messages from the LO API and *sendMessage* to send them. These methods enable communication between the LOR API and the iframe in which the LO is inserted. This way, a bidirectional communication channel is built between the LO and the web videoconference client (hereafter just client) through the LOR API.

Fig. 2 represents through an example the different actions that are carried out to deliver the LO events. In this example, Alice and Bob are participating in a videoconference session talking and co-browsing a slideshow presentation. They are commenting the sixth slide. In a certain moment, Alice clicks on a button to go to the seventh slide.

1. The Alice's slideshow (i.e. the slideshow that Alice is seeing) advances to slide 7. As a consequence an event is triggered and handled by the LO API. Then, it composes a message including all relevant information about the event, in other words, all the information needed to replicate the event. Finally, the LO API notifies the LOR API.

2. The LOR API receives the message and delivers it to the client, which will send it to the Messaging Server of the WVS.

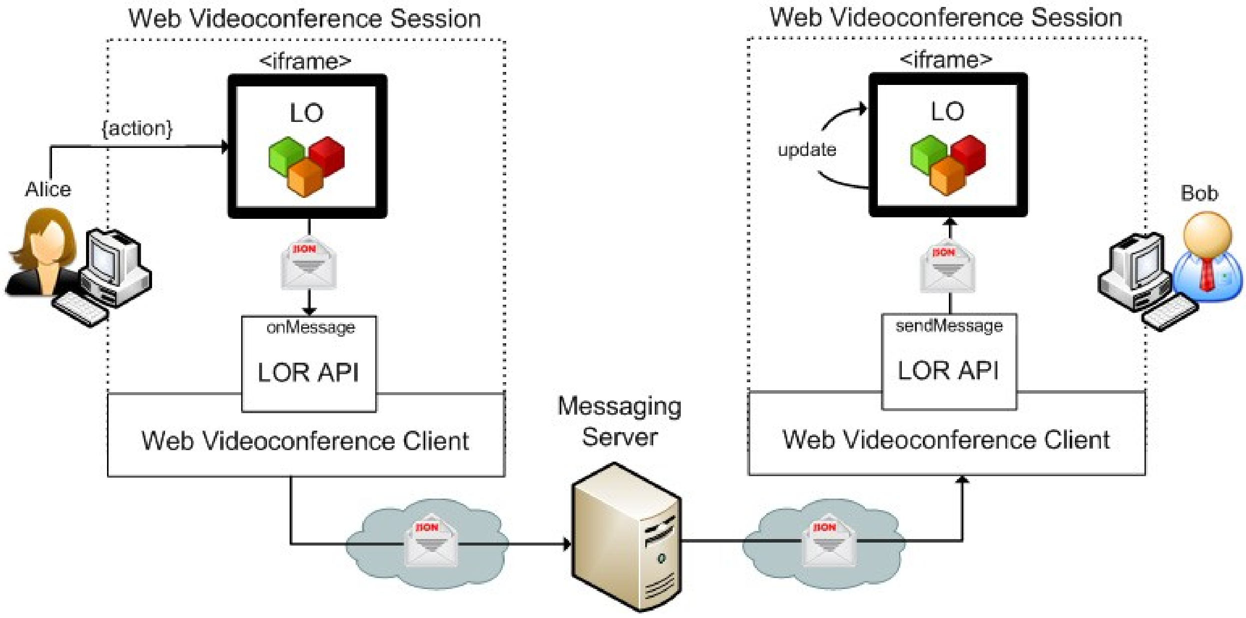

Fig. 2. Delivering Learning Object events

3. The Messaging Server do not have to read or understand the message generated by the LO, it just have to broadcast the message to the rest of the participants (in this case just Bob) through the network using its usual data channel.

4. After the broadcasting, Bob's client receives the message and sends it to the LO API.

5. When Bob's LO receives the message, it composes the original event and replicates the action. Therefore, Bob's slideshow also advances to slide 7. Hence, the final state of Alice's and Bob's slideshows is the same.

This is an example of co-viewing, but considering that Bob can also perform actions in the slideshow in the same way Alice does, co-browsing is also provided.

E. Achieving synchronized co-browsing

Previous section shows an example of co-browsing, but it is not synchronous. Considering again the initial situation of the previous example where the slideshow is in the sixth slide. If Alice clicks on the next button and at the same time Bob clicks on the previous button, Alice notifies that she advances to slide 7 while Bob notifies the he advances to slide 5. As a consequence, the final state will be different: Alice will be in the slide 5 since she receives Bob's notification, while Bob will be in the slide 7 due to Alice's notification. This problem is called "state synchronization" and is one of the biggest concerns in the development of distributed real time applications that requires synchronization (such as online multiplayer games). In the field of games, it has been defined as "the problem of maintaining the same game state information on each of the players' instance of the game and generating the actions of each player belonging to the same game instance" [9]. This definition is perfectly valid in our context, replacing game for LO and players for participants. After all, a LO can be an educational game.

Due to this problem, achieving synchronized co-browsing requires to use some distributed synchronization mechanism to order the events produced by the different LO instances. Several synchronization mechanisms and algorithms can be used to deal with this problem such as the logical clocks mechanism, which can be provided by different algorithms like the Lamport timestamps [10] or the vector clock [11]. Any synchronization mechanism that guarantees the ordering of the events is valid to apply the proposed model. However, some mechanisms do not operate completely in the client and need to implement logic in the Messaging Server, and therefore they may be unviable in common scenarios where access to the Messaging Server is not possible.

Another concern that should be taken into account is latency (i.e. time delay experienced), since it is the most critical network aspect related to the user experience of online distributed real time applications (e.g. multiplayer games) [12]. Fortunately, several latency avoidance mechanisms exist to alleviate the latency problem such as dead reckoning [12] and lockstep synchronization [13] that can be useful in this context.

Finally, to illustrate all these concepts, we give below a straightforward example of a solution to achieve synchronized co-browsing. In this solution a new operation mode is provided by the LO API. In this mode each time a user tries to perform an action, instead of allowing him/her to do the action and then notify it to the rest of the participants, the action will be prevented but the notification will be sent. Then, the WVS has to broadcast the event not only to the rest of the participants, but also to the user who originates the broadcasted event. This way, all participants will receive the event approximately at the same time depending on their latencies.

After that, a simple implementation of a lockstep event-locking mechanism is used to achieve synchronized co-browsing. In this mechanism the server distributes the events periodically. During each period or time slot, the clients can send their events to the server to be broadcasted, but the messages that arrive too late will be considered lost. Hence the state is updated every period. Consequently, the server just has to deal with the "event collisions": when two incompatible events are received in the same time slot. In this example we use a straightforward approach that consists of allowing just one event per time slot and in case of collision choosing one randomly and discard the rest.

This implementation has some limitations. For example, new participants (i.e. those that enter in the videoconference session when several actions have been performed over the LO) will not be able to compose the full LO state. So, a last improvement can also be made. The server can store all actions performed over the LO, and deliver them to the new participants that join later.

Finally, back again to the example where Alice and Bob click a button at the same time but considering now the solution described above, the process will occur in the following way:

1. After the clicks, Alice's and Bob's slideshows remain static but one notification per event is sent.
2. The two messages are delivered to their corresponding clients and sent to the Messaging Server.
3. As the two messages will arrive in the same time slot, the Messaging Server choose one randomly, for example, the Alice's message, and broadcast it to all participants (Alice and Bob).
4. When the message arrives, each client sends it to its corresponding LO.
5. The Alice's action is performed in both slideshows. As a consequence, the final state of Alice´s and Bob's slideshows is the same again.

F. The Iframe Gateway Method

In previous sections we have seen how to integrate LOs into WVSs. However, in those examples, a little effort from the WVS was always required to achieve interoperability. It needs to include the LOR API and provides message broadcasting. In some occasions, a WVS may be interested in performing other actions like encrypting messages, but these actions are not mandatory.

In some cases a WVS (e.g. Google Hangouts) may have its own API to provide third party web applications with functionalities like messaging (allowing communication between application instances) or access to users' information. This model takes advantage of this fact to make possible to achieve interoperability with a WVS without requiring its cooperation when it provides its own API (WVS API). This way it is not necessary for the WVS to include the LOR API and the integration process can be completely done by the LOR.

To add this improvement, an extra step is introduced in the Request/Deliver LO function described in Section 3A. Instead of directly delivering the web page with the embedded LO, the LOR inserts it in an iframe and delivers a new HTML page that includes this iframe and that will act as a gateway between the WVS and the LO. We call this method the "Iframe Gateway". Its operation is represented in Fig. 3. The LO still communicates with the LOR API. But in this occasion, the LOR API will deliver the messages to the *iframeGateway*, which will communicate with the web videoconference client through the public API of the WVS. This is a good strategy since it keeps intact both WVS and LOR APIs and can be implemented with little effort.

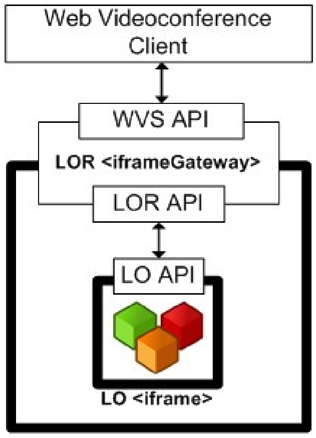

Fig. 3. Iframe Gateway Method

IV. VISH: A CASE STUDY

The GLOBAL excursion (Extended Curriculum for Science Infrastructure Online) project [14] is a European project which main aim is to enrich science teaching in European schools. Via a central web portal, called the Virtual Science Hub (ViSH), GLOBAL excursion provides scientists, teachers and their pupils a package of activities, materials and tools for enabling the integration of e-Infrastructures into school curricula. The ViSH platform includes a social network, an e-Learning authoring tool and a LOR that stores all the LOs created or uploaded by users and institutions.

The authoring tool allows ViSH users to create a novel LO called Virtual Excursion [15], [16]. Virtual Excursions are presented as rich interactive slideshows. They can contain diverse resources: multimedia files, e-Infrastructure resources (e.g. a webcam or a remote pendulum), web games and flashcards among others. Flashcards are resources presented as a background image with several "hot zones" identified by arrows where the user can touch and see additional contents that the teacher has previously tagged [17]. The e-Infrastructure resources are provided by scientific institutions and allow students to virtually visit different infrastructures such as research laboratories or natural parks. However, sometimes the guidance of an expert is required to enjoy these resources. For example, a scientist may be required to control a microscope and explain the concepts to the students.

The selected solution in the GLOBAL excursion project to connect scientist and classrooms in real time was to share the Virtual Excursions in a WVS. This was achieved by applying the presented model both to the ViSH LOR as well as to the authoring tool used to create the Virtual Excursions.

A. MashMeTV

In this web platform people can share many resources such as pictures, Slideshare or PDF presentations, blackboards, maps and YouTube videos. All elements are synchronized with the room (i.e. conference session) ensuring that all participants see the same at the same time. For this reason, MashMeTV was selected as the most appropriate WVS to co-browse synchronously the ViSH LOR resources. A new button was added in all excursions of the ViSH platform in order to init a MashMeTV videoconference session sharing the desired resource. This way, all participants can explore synchronously the Virtual Excursions and at the same time communicate in real time among them. As an example, Fig. 4 shows a flashcard shared in a MashMeTV session.

The first step to achieve integration was applying the model to the existing e-Learning authoring tool. As a result, the authoring tool provides a LO API which is capable of detecting all actions performed over a Virtual Excursion and replicating these actions based on their corresponding events. Since MashMeTV provides its own API, the integration with the ViSH LOR was performed successfully using the Iframe Gateway method. In this case the ViSH LOR acted as *iframeGateway* to connect the LO API with the official API of MashMeTV.

Since this integration, MashMeTV has been used regularly to hold meetings with scientists, students and teachers, sharing and co-browsing a lot of Virtual Excursions. Moreover, teachers of the ViSH Platform were fascinated with the possibility of creating their own learning resources and sharing them easily through a videoconference service. They were delighted because this feature allows them to guide their pupils in the exploration of different Virtual Excursions while they have real time expert guidance.

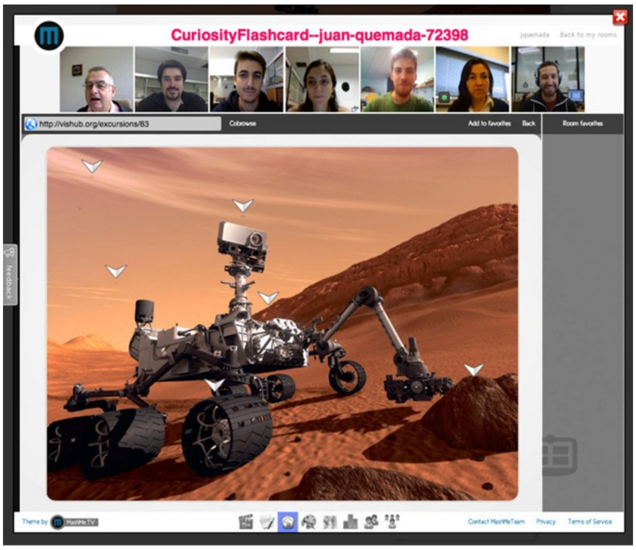

Fig. 4. Flashcard shared through MashMeTV

V. Conclusions and Future Work

We have presented a model to integrate LOs into WVSs. Achieving interoperability with WVSs can lead to several benefits such as co-viewing and synchronized co-browsing of the LOs. However, some efforts need to be undertaken to make this integration possible: LORs should provide LOs in web-ready format, e-Learning authoring tools should provide a suitable API for their LOs, and WVSs should provide an own API or include the LOR API and take charge of messaging. In case of using the WVS API, the LOR should act as a gateway between the LO and WVS APIs. Synchronized co-browsing also requires implementing some synchronization mechanism. Finally, the experience of applying the model in a real e-Learning scenario achieving interoperability with a WVS has been also presented.

New learning opportunities to increase students' readiness and engagement arise when integrating LOs into videoconference systems as a consequence of the combination of real time communication and synchronized co-browsing. A good example of this is the GLOBAL excursion project, in which the integration of e-Infrastructures resources (e.g. a microscope) with a videoconference service is used to connect scientists and classrooms.

Creating interoperable LOs that can be shared and co-browsed in videoconference services may be very easy for educators if e-Learning authoring tools follow a specific model and automate the process.

The immediate next step of this work consists of validate the model in more WVSs such as Google Hangouts.

In addition, this research opens new lines of investigation as a result of the integration of LOs into videoconference systems. We plan to use this model in the development of educational online multiplayer games that take advantage of videoconference features, where players can communicate and play in real time collaborating or competing among them.

Finally, based on the lessons learned from developing the Iframe Gateway method, we plan to adapt this model to build a LO Gateway with the main aim of achieving the interoperability of standardized e-Learning resources (e.g. SCORM packages) with web videoconference services.

VI. Acknowledgment

We wish to acknowledge our gratitude and appreciation to all the GLOBAL excursion project partners, and each one of the project team members, for their contribution during the development of various ideas and concepts presented in this paper. We also would like to thank the SAAN project (TIN2010-19138) for funding this work.

***Abstract*—The present paper discusses the use of text mining to support the design of a pedagogical agent that mediates synchronous online discussions of academic texts by undergraduate students of English as a foreign language. The pedagogical agent proposed here has the instructional role of a tutor collaborator that participates in the chat discussion following mediation strategies grounded on sociocultural theory to assist the collective writing. Furthermore, we propose a pedagogical agent model that uses text mining techniques to identify when students deviate from the main topics that should be addressed in their discussions in a real time chat. Another important function enabled by the use of the text mining tool involves the assessment of the discussion relevance in relation to the base text, which supports the pedagogical agent decision towards a more adequate intervention. The conception of using text mining to guide the pedagogical agent in the mediation of the students' discussions has been based on previous research that has already shown how this particular mining tool could support educators' work in the evaluation of essays and of students' contributions in discussion forums. Preliminary results of this study are also presented showing the agent's potential to foster students' online conversations.**

Keywords—text mining tool; pedagogical agent; online learning.

I. INTRODUCTION

In recent years, text mining have become more popular in the field of Education, being used mostly to help students in learning tasks and to assist educators in monitoring students' activities and evaluating their work. This paper aims to present a pedagogical agent which makes use of a text mining tool to assist collective writing in computer-mediated reading discussion. In order to establish the pedagogical agent's mediation strategies, the points of contact between Vygotsky's sociocultural theory and research on second and foreign language acquisition have been exploited. Moreover, the relevance of using the text mining tool as a base of knowledge for the pedagogical agent to deal with reading discussions chats is thoroughly discussed.

II. THEORETHICAL FRAMEWORK

A. Pedagogical Agent and Language Education

Intelligent tutoring systems (ITS) have been defined as computer systems whose goal is to provide customized instruction or feedback to learners [1], usually without intervention from a human teacher. ITS differ from traditional content-delivery computerized learning systems by adding intelligence to improve the effectiveness of a learner's experience [2]. They use a variety of computational resources to properly interact with the learner. Intelligent tutoring systems are often adaptive mechanisms which are capable of personalizing learning according to individual student characteristics, such as knowledge of the subject, mood and emotion [3] and learning style [4]. Such systems can use virtual characters as a way to interact with users. In this study, a virtual character has been designed in the form of a pedagogical agent whose goal is to mediate reading chat discussions between undergraduate students of English as a foreign language.

The use of Pedagogical Agents (PAs) in Educational applications has demonstrated that, by simulating social interaction, these animated characters may improve student's engagement and learning experience [5].

Pedagogical agents are human-like virtual characters used in interactive learning systems that can operate continuously and autonomously, searching and interpreting information to support learners' activities through a more natural interaction. Based on students' behavior and writings, the PAs are capable of adapting their actions and interventions, providing feedback

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

and guiding problem solving, reflection, understanding and collaborative learning [6] [7] [8].

PAs are designed by the arrangement of image, sound and gesture to consistently represent by their behavior a human-like entity generating the feeling in the students that they have their own identity and life, what was called by Lester et al. [9] "the persona effect". This life-like behavior is considered to be an important motivational factor for students in interactive learning environments resulting in a positive effect on their perception (through affective dimensions such as clarity, credibility and encouragement) over the PAs' importance and their learning. The "persona effect" can, therefore, motivate students to engage in activities as they feel they may get help whenever they need[9]. Thus, the use of PAs intends to make learning a fun experience, keeping the student's engaged in a more extended interaction with the environment and minimizing the feeling of isolation in the context of distance education [9];[10]; [11]. Besides, the use of natural language mechanisms (e.g. AIML-Artificial Intelligence Markup Language) enables PAs to establish social bonds with the students, facilitating learning through a more compelling interaction with the learning environment and contents [12].

According to Gulz [13], the PAs' benefits for learning involve: the increase of motivation; perception of ease and comfort in the learning environment; the promotion of fundamental behaviors of learning; the ease of information and communication processes; the realization of a need for personal relationships in learning; and gains in terms of memory, understanding and problem solving.

Moreover, PAs can present contents to the students; they may guide task and problem solving through helpful statements and task resolution models. They can also highlight important issues, and recommend new exercises and reference materials according to students' progress [14].

Furthermore, according to Kim et al. [10], PAs can be designed to act based on human instructional roles, following pedagogical mediation metaphors, such as the expert, the motivator, the mentor [15], the pair [10], and the tutor [16].

Baylor and Kim [14] present the development and validation of three PAs' based on three instructional roles, i.e. the expert, the motivator and the mentor, functioning in an agent-based research environment (MIMIC - Multiple Intelligent Mentors Instructing Collaboratively). These roles were operationalized through image, animation, affect, voice, and dialogue composition. The design of the expert agent was based on studies that indicated that experts have a better performance and show emotional stability. Thus, the expert agent was designed as a middle-aged person with a more formal speech, having the role of providing information succinctly and accurately to students. The motivator agent was based on the idea that the support from a social model with a similar level of knowledge can promote both learning as motivation. In addition, verbal encouragement to students' performance facilitates their perception of self-efficacy in the task. Based on this, the motivator was personified as a younger person with an informal speech. It did not participate as an authority on the subject, but as an enthusiastic partner that suggested its own ideas, encouraging the student to continue in the tasks, and asking questions to promote reflection. Moreover, this agent would express the typical emotions of the learning process, such as frustration, confusion and pleasure, seeking empathy and connection with the students. The third agent role investigated by Baylor and Kim [15] was the mentor, designed to incorporate the features of both the motivator and the expert by acting as a collaborative guide that provided accurate information, but who would also show different emotions. The mentor agent was less formal than the expert agent and offered ideas and emotions with a more professional and confident tone in relation to the motivator. According to this categorization, the agent developed in this work has the role of a mentor, as detailed in the next section.

A similar metaphor for PAs design has been called the Learning Companion, in which the PA plays the role of a learning partner that simulates peer interaction in computer-based learning. The construction learning companions is based on the principle that interacting with a pair of similar degree of competence may increase the students' belief on their self-efficacy [10]. Based on the definition of Learning Companions, one might think that this type of agent resembles the role of the motivator agent, as defined by Baylor and Kim [15]. However, the performance of the Learning Companion agent also has features related to the role of expert, as it provides accurate information to support the completion of a given task.

In addition to these agent models, Graesser et al. [16] proposed a pedagogical agent to understand the contributions of students and simulate discursive patterns and pedagogical strategies typical of a human tutor, called AutoTutor. It was used to serve undergraduate students in introductory courses to computer use, by supporting students in knowledge building through a dialogic tutorial. The AutoTutor had several different features, such as the ability to question the student as to cover all the topics on the subject under study, to guide the student's thinking in solving the task and keeping his/her focus on the main issue. The agent could also motivate the student to continue the activity by offering positive feedback and making a summary at the end of the task.

It is worth mentioning here that the mediation metaphors that are the basis for the development of the expert, the motivator, the mentor and the tutor agents stem from a computer-based teaching and learning conception in which the focus is on the individual's production and on the interaction with the system. Furthermore, these PAs do not work with collaborative production in synchronous communication tools, using collective interaction data to make their interventions. Besides, these studies do not have a clear theoretical background from a teaching and learning perspective.

Conventional Learning Systems, as Kim et al. [10] claim, tend to support individualized learning of contents, leaving aside social interactions as a means for learning and for motivation. However, social interaction, according to the sociocultural perspective, is essential for the promotion of learning and development [17], [18], [19]. According to Heidig and Clarebout [20], more research is needed to identify conditions under which pedagogical agents can contribute to student learning. The authors highlight the fact that the exploration of appropriate roles for pedagogical agents as well as relevant characteristics of learners has been largely neglected in current research.

Within this scenario, the present study proposes a pedagogical agent that is capable of mediating students' discussions in a chat room, using the sociocultural theory as a basis for the interventions the agent makes in order to promote second and foreign language learning.

The pedagogical agent proposed here bears some similarities with the mentor agent described in Baylor and Kim [15], for it uses its expertise to give accurate information and encourage students, and tutor agent [16], by seeking not only to engage students to the topic of discussion, but to promote students' reflection for the improvement of their reading. Another important aspect to emphasize is the agent's proactive and reactive behavior towards students' actions, posing questions, giving positive feedback and answering to students' doubts regarding foreign language vocabulary.

B. The pedagogical agent according to sociocultural theory of learning

Sociocultural theory considers learning to be a regulatory process that is mediated by social interaction among individuals, cultural artifacts (computer, pedagogical agent) and speech [21]. Through interaction, knowledge constructed and shared (interpsychological activity), it is internalized by the individual (intrapsychological activity), and reused in future experiences [17], [18], [19], [22]. Thus, we understand a pedagogical agent as a tool capable of mediating learning, as it participates with students in a reading chat discussion, addressing their needs with an individualized intervention, fostering a higher regulation over language use and content information.

In [17] and [19], Vygotsky conceives a potential area for learning, called the Zone of Proximal Development (ZPD), which is measured by the distance between what the novice can accomplish alone (the current level of development), and what he can do under an expert supervision or in collaboration with more capable peers (the level of potential development). So learning is a process that must be analyzed through what the student can do while struggling to solve problems like linguistic and knowledge gaps to better communicate meaning.

Following the theoretical construct of the ZPD, the interaction with a pedagogical agent can promote language learning and the development of different skills [10]. For that reason, the present study proposes a PA that employs its language and content expertise to mediate students' discussion and whose mediation strategies are directed towards learners' current and potential actions as they struggle to negotiate, collaborate and to improve their foreign language production [23].

Furthermore, the assistance given by the pedagogical agent with the objective of helping students do the task of discussing properly a specific text can be related to the term scaffolding created by Wood, Bruner and Ross [24]. According to these authors, scaffolding happens when a teacher chooses the right intervention to help the student to actively develop his regulation over the task itself, promoting autonomy. During this mediation process, the continuous feedback on students' actions may motivate them to reflect upon language gaps to be solved. In relation to feedback according to the sociocultural theory, errors are seen as part of the natural process of learning and peers and experts can provide support as well as a counterpoint in the production of meaning. In this context, evaluative feedback is a social and interactive negotiation of meaning and form in which the teacher or a pedagogical agent, in the case of this study, responds to students' writings, transforming or asking the students to reformulate their sentences [25]. It is a pedagogical movement that promotes greater awareness and reflection of the students on their language and learning, motivating them to be more accurate in their writing, to write more and keep focus on the subject.

In this scenario, studies show that the collaborative nature of the interaction and the extensive use of language are essential conditions for the promotion of learning [26], [27], [28]. Within this perspective, group assignments are spaces that enable the co-construction of knowledge by sharing production goals, negotiation of meaning and form, mutual support and feedback. The design of the PA for this study aims to create a fertile environment for collaborative learning, in which its intervention simulates mediation movements observed in teacher-student and student-student interactions during collaborative tasks.

III. THE PEDAGOGICAL AGENT'S DESIGN

The sociocultural perspective towards foreign language learning and teaching reflect upon the design of the pedagogical agent's mediation strategies based on the use of a text mining tool in order to assess students' construction of meaning in a more accurate manner. The pedagogical agent developed for this research was called Pascall (Pedagogical Agent to Support Collaborative Language Learning) and is considered to be a proactive and reactive tutor collaborator [16] that seeks to mediate a discussion chat in a virtual learning environment. In the case of this particular implementation of the pedagogical agent, we have chosen the virtual learning environment Moodle, as it is the main virtual learning environment used in the university where this research has been carried out.

As an autonomous program, the pedagogical agent runs continuously, accessing Moodle's database to examine the registered chat dialogues and to trigger textual interventions inside the chat room. After an *n* number of initial messages exchange between the students, the pedagogical agent begins to store the conversation, in which the time of each message is recorded. Thus, these pieces of information can be used to investigate not only the chat content, but also the learner's participation.

Pascall's architecture consists of three knowledge bases according to Figure 1.

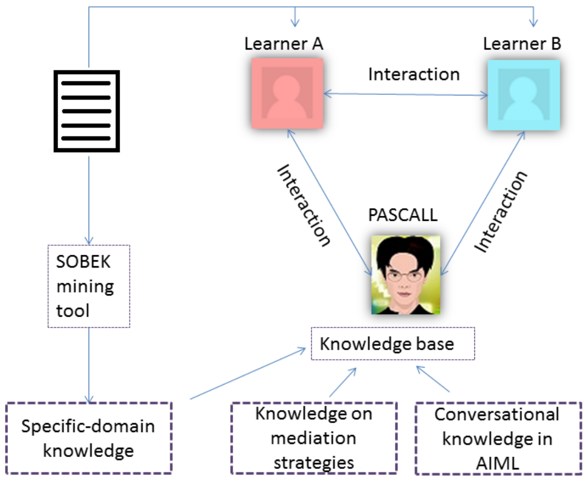

Figure1: The pedagogical agent model.

The first one is the knowledge on mediation strategies, with interventions directed towards identified language use programmed according to pedagogical goals and pedagogical constructs. Added to this, the second knowledge base consists of specific domain content elicited from texts by the mining tool called Sobek. This is one of the main information used by the pedagogical agent's language assessment and the corresponding mediation strategy.

The third knowledge base has been structured with AIML (Artificial Intelligence Markup Language) to store conversational knowledge in order to produce a more natural interaction with students. It assists the agent to recognize patterns in the user's interaction and provide an appropriated response. It is worth mentioning that, by using such mechanism, the pedagogical agent created here can be adapted for any course since it is possible to increment its AIML knowledge base with information about any theme.

Regarding the pedagogical agent's mediation strategies, it has been designed to support students' discussions through collaborative and negotiation movements, corrective and evaluative feedback, along with verbal encouragement. Relevant for this study, however, are the interventions the PA is programmed to do by assessing (1) the relevance of what is being said by the students, (2) theme deviation and (3) unexplored concepts, keeping them focused on the task of building a more complete and coherent reading.

Before the agents' mediation strategies are further discussed, the text mining tool Sobek and its main functions are presented in the next section.

A. The text mining tool Sobek

Text mining has been defined as a technique that has as a main goal to retrieve qualitative information from texts, which are considered to be non-structured sources of information [29]. The process of text mining consists in creating a model from the data retrieved, analyzing patterns and returning relevant information to the user. The use of text mining has grown exponentially in recent years due to the increasing amount of information found particularly in the Internet. A common use for text mining is to tag books, magazines, web searches, home pages or any other source of textual information. Through text mining it is possible to identify the key concepts of a text and relate them to one another.

In this work, we have used the text mining tool called Sobek [30], developed initially to be used by teachers in a distant learning courses as a way to summarize students' writings. The operation of Sobek is divided into three stages. The first stage is the identification of relevant concepts of a text; the second stage is the identification of relationships among concepts; the third stage is the graphical presentation of the results of the mining process in the form of a graph depicting the main concepts of the text and their relationships. Next we describe each stage and its main features.

The first stage of Sobek consists in separating the text into words. In this process, spaces and punctuation are considered as divisors. The separated words are then mapped into concepts that may consist of a single word (called a "simple concept") or many words or sentences (called "compound concept"). The mapping is a statistical process, which takes into consideration the frequency with which each word is found in the text. When a set of words frequently appear in sequence, the idea related to this set of words may not be described by a single word, hence a compound concept is formed (e.g. "Global Warming"). While Sobek is doing the process of identification of concepts, a set of words called "stop words" is used to remove those that do not add relevant information (e. g. articles; prepositions; pronouns). After identifying all different concepts, a method of stemming is activated to reduce possible redundancies such as concepts with the same meaning.

The second stage is the identification of relationships among concepts. A textual analysis is done comparing, for example, two concepts when they are distant not more than 'z' words of each other and when there is no end punctuation between them. Trying to reduce the number of connections among concepts to display only those that appear more constantly, Sobek establishes a maximum of 'r' links that could be allowed for each concept. This value is proportional to the frequency of that concept.

The third stage is the construction of a graph as a result of the extracted concepts from the text. In the graph built by Sobek, the concepts are presented as nodes, and these nodes display the relationships among them as links. To provide a more meaningful visualization of the graph, Sobek presents each node with a different size and color, differentiating them by bigger size and darker colors according to their frequency. This frequency will also implicitly increase the number of connections that a concept may have, thus, making the most frequent concepts even more important. The tool also has other functions to enable the editing of the graphs, such as functions for adding, removing and editing nodes.

B. Integrating SOBEK into the pedagogical agent model

The design of the pedagogical agent aims to create an environment for collaborative learning, in which the PA's intervention simulates mediation movements [31].

Before the chat session starts, learners must be presented with a text in order to establish the subject that will be discussed. This text is also used by the pedagogical agent to extract from it the main concepts and relationships, using Sobek in the background. This information serves as a comparison basis to evaluate whether the learners are discussing the given theme or not. During the chat session, the pedagogical agent collects the messages exchanged between the users. Those messages are mined using Sobek and the resultant concepts and relationships are compared with the ones extracted from the main text. When students log on Moodle's chat, the pedagogical agent is triggered, showing up visually just as another participant in the chat.

As mentioned in Section II-A, the pedagogical agent receives a text as an input, the same text students use to study before the chat session. This text has its concepts and the relationship between them extracted by the use of Sobek. In possession of this data, the PA constantly extract the concepts from the students chat and compares them to the concepts extracted from the original text. This comparison is made using the equation established by Azevedo et al. [32]. It compares the relative frequency of each concept and its relationships.

This comparison may have one of three possible outcomes:

1. The students did not mentioned any of the concepts found in the original text;
2. The students are mixing messages about the text with messages that deviate from it;
3. The students are discussing the text and a high number of concepts are similar.

For each situation, a series of predetermined messages are used to indicate the student about their progress and either motivates them to continue the good work or suggest them some topics they can talk about. In the first two scenarios, the PA indicates to the students that they are not properly discussing the text and indicates the most important concepts the students did not talk about. If all concepts were discussed by the students, than it simply indicates that they are deviating from the topic. In the last scenario, a positive reinforcement is given, as to incentive the students to continue the good work. These interventions intend to keep students focused on the task of developing a more complete and coherent discussion.

Interactions between the pedagogical agent and students are not limited to interpreting the chat content or standard messages. Students may request help from the PA at any moment. The PA is capable of providing help by translating words or sentences in English and Portuguese. Students may request this help by typing specific commands on the chat. The PA interprets those commands and uses internet resources to translate the required sentence.

Similar to this, students may also request the PA to give them synonyms or definitions about a concept. Using specific messages for each case, the PA acts according to the students request and provides them with the necessary help.

It is important to highlight that these mediation strategies follow a sociocultural perspective, as the PA role consists of raising students' awareness of their language production, and promotes the development of higher regulation over the task of discussing thoroughly a text. Besides, the PA as a tutor collaborator is proactive and reactive to students' actions, fostering an autonomous attitude towards their own learning process.

IV. THE STUDY

In our experiments we have used the open-source virtual learning environment Moodle. Among the many features available in the virtual learning environment, it has forums, quizzes, surveys, multimedia resources and chat rooms. All course materials can be created using Moodle, which makes it simple for teachers to use it and develop their own contents.

Moodle's data is stored in a relational database, which contains, among other information, all chat sessions. Therefore, it is possible to use these databases to retrieve the conversations from any chat room or user.

The Pedagogical agent described in this paper is capable of retrieving such information directly from Moodle's database. It collects, organizes and analyzes the messages exchanged by the users in order to identify specific contents or the main topics of the conversation. Whenever an intervention is required, the agent sends a command to Moodle's server specifying the type of intervention, message and intended chat room. Through this process the agent continually collects the messages from the database and sends intervention commands whenever necessary.

A. The experiment

The present study was conducted with undergraduate students of English language and literature in a university in southern Brazil. In an English class of 27 pre-intermediate students, a sequence of meetings was done in a computer lab where the main tasks involved the participants in discussing texts in Moodle's chat. The texts' theme was language teaching and technology and the discussions were based on comprehension questions. Immediately after each task, the students were asked to report their perceptions regarding the task, the performance of the pedagogical agent and their learning. The writings produced by each student and reports were, then, analyzed to investigate the effects of the pedagogical agent's mediation strategies on language learning.

The participants were divided into groups of three and entered in their own chat room. When students logged on Moodle's chat, the pedagogical agent was triggered, showing up visually just as another participant in the chat, but presenting itself as a tutor collaborator with a pedagogical intention to assist their discussion on the proposed text, as shown in Figure 2. The pedagogical agent worked mediating the collaborative writing task according to the students' actions.

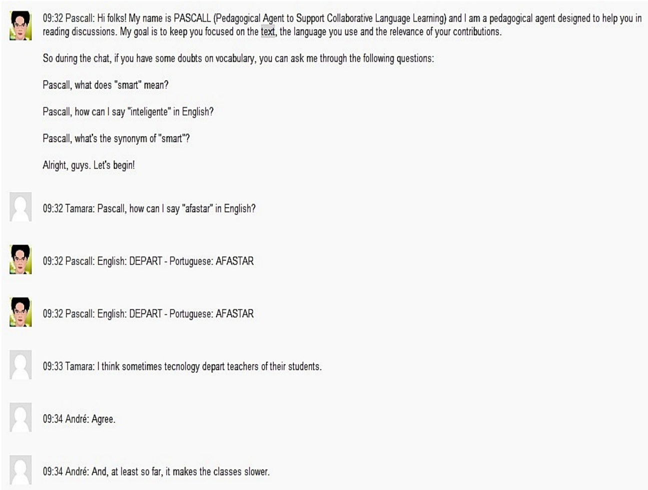

Figure 2: The PA introducing itself.

In order to promote a better use of the foreign language being studied, the PA made comments on the students' discussion in terms of its relevance, as previously stated. We can see in Figure 3 that the PA gave a positive feedback to the students' discussion.

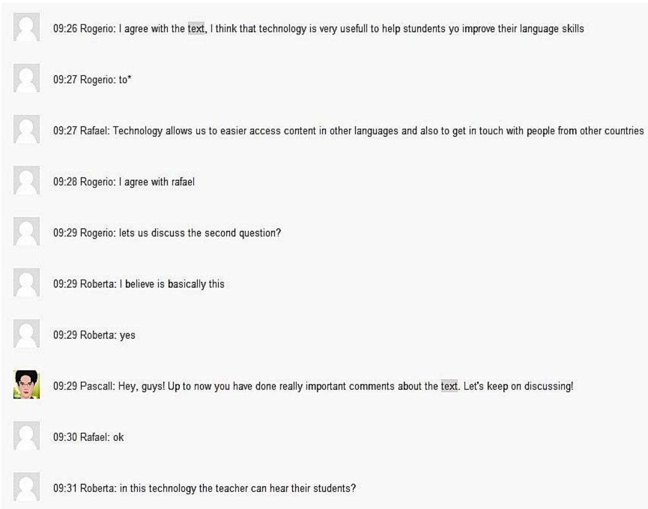

Figure 3: The PA's intervention on discussion relevance.

This intervention was created to address students that presented a highly relevant discussion compared with the text given to the students. The observation of the PA leads to the conclusion that that the intervention was appropriate, since students were bringing relevant contributions to the reading discussion. Besides, the students responded to the PA's request, showing that it was seen by the students in a positive way.

Besides assessing the relevance of students' contributions signaling the importance of meaning making, the pedagogical agent assisted learners in remembering important concepts that were unexplored, as Figure 4 indicates.

Figure 4: The PA's intervention on theme deviation.

It can be seen that the PA tried to bring the focus of the discussion back to the text through the indication of a topic that could be explored. It can be observed that the PA tried to bring the focus of the discussion back to the text through the indication of a topic that could be further exploited.

These are just a few examples of the interventions made by the PA in these initial experiments with a group of students of Languages.

After the task, students' individual reports suggest that they realized the interventions Pascall made during the chat, such as calling their attention to the relevance of their discussion, and suggesting a topic of text when they were talking about another subject. These interventions were considered useful for doing the task, since according to the participants, the pedagogical agent helped them remain focused on the discussion proposed, to be more active in group discussion and to explore the possibilities that a text offers to a more profitable discussion.

V. Concluding Remarks

The data suggest that the pedagogical agent Pascall, through the use of the text mining tool SOBEK, could make appropriate interventions in students' discussion by identifying both the relevance of what was being written and the theme deviation. These interventions were noticed by participants who responded positively to its mediation. Thus, this study indicates that the pedagogical agent developed can be a mediational tool in the development of reading comprehension and written expression in a foreign language. Also, this research contributes to the field of Computers in Education by applying theories of learning to the design of computational tools for educational purposes, bringing relevant contributions to computer-mediated communication. Finally, the study innovates by demonstrating the pedagogical application of a text mining tool regarding the construction of a pedagogical agent's mediational actions to help students bring relevant contributions to a reading discussion

Towards an Understanding of ECE Students' Use of Online Homework Help Forums

Abstract— **Online discussion forums have emerged as a popular Web application to build and support online communities for numerous engineering interest areas and practice. However, a review of engineering education literature reveals scant research on the use of online discussion forums for engineering learning beyond the classroom. This study addresses this gap in knowledge through a study of the "Homework Help" section on AllAboutCircuits.com to examine what students sought help for and for what purpose. We downloaded over 6,000 discussion messages spanning over 8 years and extracted the textual data with a Python program. Instead of analyzing the data through manual means, we utilized the Natural Language Toolkit (NLTK) to capture textual patterns and leverage a topic modeling approach, Latent Dirichlet Allocation, to identify connected clusters of words. Linguistic Inquiry and Word Count (LIWC) analysis was also used to determine how often students use words associated with cognitive processes. We found that the homework help section of informal online discussion forums cater to students seeking help on fundamental ECE topics. Our findings also suggest that online discussion forums are supportive learning environments, as students freely engage in meaningful inquiries and social interactions with other learners.**

Keywords— online discussion forums; text mining; hybrid instruction; electrical and computer engineering

I. BACKGROUND

The current cohorts of engineering college students are referred by many as the Millennials or Generation Net [1]. Many of them have grown up with computer technology, and they are highly proficient at using computer devices and leveraging the Internet to support their learning beyond the classroom [1]. Some of these technologies include Wikipedia, MOOCs, video tutorials, E-textbooks and online discussion forums. Amongst these technologies, text-based online learning platform such as online discussion forums have emerged as an effective tool to support teaching and learning in a variety of settings including learning management systems, MOOCs and online courses. With increasing computing power and internet speeds, online discussion forums have improved leaps and bounds in terms of usability, functionality and user-friendliness. It is therefore no surprise that online discussion forums are also used to support online communities for specific engineering areas or practices beyond the classroom.

In this study, we direct our focus on online microelectronics communities which have grown tremendously over the past few years. Relying on discussion forums (or message boards) platforms, these communities have attracted hundreds of thousands of students and enthusiasts from all over the world. Table 1 describes the basic participation information of 5 popular online discussion forums associated with electrical and computer engineering. The participation figures in Table 1 suggest that the discussion forums are of significant reach to a large number of engineering students who in turn have contributed millions of message posts to these forums. This phenomenon also raises a question for both engineering education researchers and practitioners: What are students learning on these forums? As there are massive archives of participant data and learning activities, we are not able to immediately make sense of the learning activities in these forums.

TABLE I. ELECTRICAL AND COMPUTER ENGINEERING ONLINE DISCUSSION FORUMS

Site	Message Count	Membership
AllAboutCircuits.com*	570,000**	202,000
Arduino.cc	1,176,000	128,000
EdaBoard.com	1,174,000	483,000
Electro-Tech-Online.com	796,000	191,000
ElectronicsPoint.com	83,000	23,000

***Descriptive data rounded off to nearest thousand and compiled in April 2013.*

II. RESEARCH QUESTIONS

While the online communities themselves are tied to a broad content area, they cater to a wide variety of discussion topics through the setup of distinct discussion sections or sub-forum. One specific section that will be of much interest to engineering educators is the homework help discussion section. Within this discussion section, engineering students seek help on homework problems directly tied to ECE curriculum coursework.

A review of education research literature reveals that there is limited research on online homework help discussion forums associated with engineering learning. Thus, the purpose of this research is to fill this gap in knowledge by exploring what online ECE students sought help for and for what purposes. The research setting for this study is a homework help section of AllAboutCircuits.com, which is a prominent online community associated with a diverse range of engineering topics from the ECE domain. We examine the students' written contributions in search for consistent patterns of conversational behaviors, major themes of discussion and students' use of words associated with cognitive processes. Our research questions are:

1) Which words are frequently used by students who seek homework help?
2) What are the major themes of discussion?
3) How often do students use words associated with cognitive processes?

To answer the research questions, we leverage three text analysis approaches: keyword analysis, topic modeling and Linguistic Inquiry and Word Count (LIWC) analysis. In the following sections, we will highlight both the merits of using each of them and our findings.

III. Methods

A. Keyword Analysis

Keyword analysis is an analytical technique that looks for repeats of words within a text collection and computes the frequencies of occurrences for each word. This analysis technique allows one to examine the words that consistently appear in a text collection. As many English words with the same root will have similar meanings, there is a need to reduce words in the data to their root or stem form (for instance, both words "engineers" and "engineering" will be reduced to engineer). In this research, the well-established Snowball word stemmer was used to perform the word stemming process [2].

Amongst a variety of computational approaches used in keyword analysis, this research draws on the Natural Language Toolkit (NLTK) which is an established open source Python toolkit with very proficient libraries for text processing [3]. NLTK has been well-utilized in educational research to further the understanding of learning and interaction amongst students. Haythornthwaite and Gruzd [4] utilized NLTK to explore noun phrases in an online bulletin board for a graduate class and based on the prevalence of words such as "thanks" and "agree", they suggest that the bulletin board was a supportive avenue for learning. On the other hand, Worsley and Blikstein [5] used NLTK to explore students' speech about electronics and mechanical devices and found that speech markers (such as adverbial modifiers) that are indicative of domain-specific expertise. While these research work are exploratory in nature, they highlight the potential of NLTK in deepening our understanding of students' conversational behaviors and supporting the assessment of learning in online environments.

B. Topic Modeling

Topic modeling refers to a statistical approach aimed at identifying semantic topics within text documents [6]. Amongst several topic modeling techniques, Latent Dirichlet Allocation (LDA) is a widely used model as it is an unsupervised model which does not require the construction of additional training data sets. LDA can be described as a generative probabilistic model aimed at discovering latent topics within text documents together with the words that are associated with the latent topics [6]. In this research, we leveraged LDA to analyze the first posts in each discussion thread with the goal of identifying connected topics (made up of sets of related words) and trends within the identified topics. An open source package, GibbsLDA++ [7], has been used for this research.

Based on a limited literature review, we did not find any use of LDA in educational research. However, LDA has been well-exploited in the social sciences where researchers explore large corpuses of text data originating from speeches, newspaper articles and journal publications [8]., Based on the extensive research conducted through LDA, it appears that LDA is an appropriate approach for seeking meaning in large corpuses of text [8]. It is with this notion that we utilized LDA to explore discussion themes within the massive corpus of text originating from online discussion data in our site of study.

C. Lingusitic Inquiry and Word Count Analysis

LIWC (Linguistic Inquiry and Word Count) is a text analysis program that was developed to examine psychological processes in textual data based on 80 language categories that range from affective to cognitive processes [9]. LIWC checks each word of a text against internal dictionaries and reports the percentage of total words in each category. By counting words in psychologically relevant categories, LIWC is appropriate for detecting meaning in the content of what people write or talk about.

In education research, LIWC has been utilized to examine students' textual utterances in a diverse variety of settings. Much research is aimed at analyzing students' spoken and written language to analyze theoretical constructs tied to cognition and emotions. For instance, LIWC has been used to examine students' expressed emotions in an online discussion forum about the grades they received on term projects [10]. Mehl and Pennebaker [11] have used LIWC to examine students' use of language in their natural conversations outside of the classroom. LIWC has also been used to analyze students' writing styles and their relationship to their creativity levels obtained from a test [12] and other researchers have used LIWC to extract conversational features from message board used for engineering design projects [13]. These research studies suggest that LIWC is appropriate for examining psychological processes in students' written messages in the online discussion forums.

IV. Data Collection

The data collection draws from web scraping techniques. A total 87,264 web pages from the years 2003 to 2011 (in HTML format) from AllAboutCircuits.com were downloaded using an automated web crawler. A Python scraping program was written to extract participant information and textual contribution into a MySQL database. The focus of this research was placed on the first posts of each discussion thread in one of the fifteen sub-forums titled "Homework Help". The 6,749 first posts were sampled for data analysis and represent students' seeking of help. Table II summarizes the basic descriptive statistics for this sampled data set.

TABLE II. Participation Information of Homework Help Section

Variables	Count
Posts	6,749
Words	726,137
Average Length of Each Post	107

V. FINDINGS

A. Keyword Analysis

Based on the use of NLTK toolkit, we conducted an evaluation of the keywords and obtained a cumulative graph representing the top 50 most frequently occurring word in the Homework Help forum (see Fig. 1). It is not surprising that the word "circuit" and "voltage" and "power" were amongst the top 5 most frequently occurring words. On the other hand, words that are indicative of social moves are also found in the list. The words "thanks" and "please" occurred frequently according to the cumulative word count graph. This suggests that students are seeking help for their homework-related tasks but at the same time, they are socializing with the community members who are providing help to them.

Words that provide contextual information of students' learning task such as "problem" and "project" occurred to a lesser extent. The occurrence of these words suggests that this is a practice of this online community – students are providing contextual information so that help-givers will find it easier to provide help. Resource artifacts also feature frequently in our analysis. For instance, words such as "code" and "www" suggest that both program codes and web links to external resources frequently featured in students' questions.

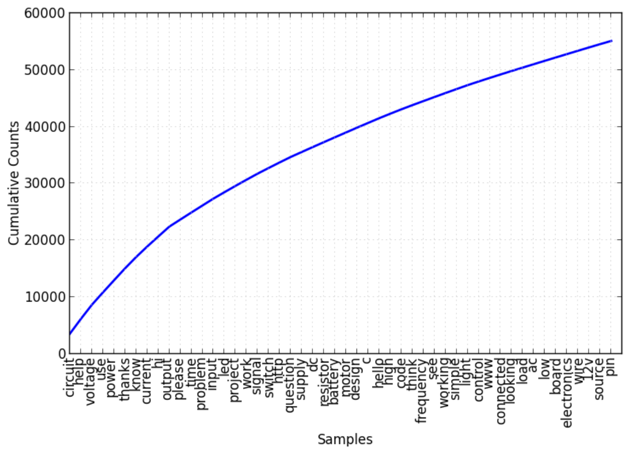

Fig. 1. Cumulative Word Count of Top 50 Frequently Occurring Words as determined by keyword analysis.

Based on the cumulative word counts, the top 20 most frequently occuring words that are closely associated with electrical and electronics engineering are also obtained (see Table III). This descriptive finding is compiled for the purpose of discussing words that occurred frequently in students' first post where they sought homework-related help. The majority of words, i.e. *circuit*, *voltage*, *power*, *current*, *output*, *input, LED*, *switch*, *DC*, *resistor*, *battery* and *electronics*, are intrduced to students in their initial circuits and electronics courses. These words are commonly associated with the contruction of simple DC circuits. Following these introductory courses, a more advanced electronic course would include AC analysis including the words *signal*, *motor*, *frequency, load* and *AC*, in addition to the words from the introductory courses. An introductory course in signals and systems would introduce *control* in conjunction with the previously used words *output*, *input*, *signal*, *frequency* and *load*. Although ECE students traditionally take introductory programming courses early in their curricula, only *C* and *code* made this list. Likewise, the words *digital* and *logic* from introductory digital design courses are not included. Additionally, words from more advanced courses, e.g. *electromagnetic*, *DSP* (digital signal processing), *FFT* (fast Fourier transform), *microwave* and *VHDL* (VHSIC hardware description language), are not contained among the most frequent words.

TABLE III. TOP 20 MOST FREQUENTLY OCCURRING WORDS ASSOCIATED WITH ELECTRICAL AND COMPUTER ENGINEERING

Rank	***Word***	***Rank***	***Word***
1	Circuit	11	Resistor
2	Voltage	12	Battery
3	Power	13	Motor
4	Current	14	C
5	Output	15	Code
6	Input	16	Frequency
7	LED	17	Control
8	Signal	18	Load
9	Switch	19	AC
10	DC	20	Electronics

B. Topic Modeling

In our research, LDA analysis return sets of connected words which allow us to make inferences from these sets of connected words to derive the topic or theme of discussion. In Table IV, we describe each topic and the words that are linked to each topic. Findings from LDA analysis (see Table IV) show that salient topics can be discovered by examining the sets of sample vocabulary.

Based on the sets of sample words, we can infer students are having discussions on various ECE topics such as microcontrollers, switches, transistors, circuits, motors, PCB design and PWM controllers. For instance, the interconnected set of words "switch, "relay", "button", "flip" and "trigger" is indicative of the topic of "electronic switches" while the connected words of "BJT", "capacitance" and "amplifiers" point to students' discussion on transistors. It appears that LDA is an appropriate approach to explore a relatively large corpus of text with the goal of understanding the overarching themes of discussions. Our findings add another dimension to our previous findings from keyword analysis by illuminating discussion topics that occurred but did not have words that appear frequently enough to feature in word count analysis. For instance, the word "motor" does not occur frequently to feature in top 50 frequently occurring words but turned up with other connected words such as “speed”, “control” and “drive” to suggest that students discussed about the broad topic of motors and servos.

TABLE IV. LDA TOPICS AND SAMPLE WORDS

LDA Topic	Sample Words
Switches	Switch, Relay, Button, Flip, Trigger
Transistors	BJT, Capacitance, Amplifiers
Engineering Project	Project, Build, Design
Circuits	DC, AC, Resistance
Motors	Motor, Speed, Control, Drive
PCB Design	Antenna, PCB, inductance
PWM Controllers	Sensor, PWM, Motion
Microcontrollers	12V, 6V, Calculations, PIC

C. Lingusitic Inquiry and Word Count Analysis

Through LIWC, we explore students’ written text by looking for pre-defined markers of cognitive mechanisms [9]. The “cognitive mechanism” linguistic category represents general cognition and provides important insights as to how students process and interpret information [9]. Within the cognitive mechanism category are the subcategories “insight”, “cause”, discrepancy”, “tentative” and “certainty” which each is represented by an predefined set of dictionary. Each subcategory of cognitive mechanism is represented by words in a predefined dictionary. For instance, the subcategory “insight” suggests that an individual may be able to grasp the solution to the problem at hand and comprises of 195 words including “realize”, “see” and “understand”.

Findings suggest that cognitive words that are indicative of insight, cause, discrepancy and tentativeness occur at a mean rate of approximately 3 (see Table V) while on the other hand words that is indicative of “certainty” occur at a substantially lower rate of less than 1 time per post. This finding reaffirms that students are indeed seeking homework help under the circumstance that they know little about a content area and are less certain about the question at hand.

TABLE V. LIWC FINDINGS

Cognitive Categories	Examples	# Words in Dictionary	Mean Word Count
Insight	Realize, see, understand	195	2.51
Cause	Because, infer, thus	108	2.83
Discrepancy	Should, would, could	76	2.34
Tentative	Maybe, perhaps, guess	155	3.25
Certainty	Always, never	83	0.99

VI. LIMITATIONS

Findings are limited to the “Homework Help” sub-forum in the site of study “All about Circuits” and may not be generalizable to other online help forums. As the title of the site of study “All about Circuits” suggests that discussion on the forums are limited to topics associated circuits or lower introductory ECE topics, it is possible that the site of study may have influenced the type of questions asked on “Homework Help” sub-forum. We however note that there are a number of other sub-forums dedicated to a diverse range of ECE topics including RF circuits, embedded systems and software programming.

VII. CONCLUSION

In this research, three text analysis methodologies were utilized to examine students’ first posts in a homework help sub-forum of a popular ECE online discussion forum to gain deeper insights into the help sought. Particularly, this research brings attention to the vast amount of learning taking place outside of the classroom in the form of asynchronous discussion. With the linguistic diversity prevalent in this educational setting, it appears that online informal discussion forums are a flexible and convenient tool for engineering students who want to quickly access the expertise of other engineering learners.

The first approach, keyword analysis, allows us to explore the most frequently occurring words and make inferences from the list of frequently occurring words. Through keyword analysis, we find that much of the vocabulary used in the students’ inquiries suggest that students sought help using fundamental electrical engineering words such as “power” and “circuits”. We then highlight both the lack of keywords from non-circuits based introductory level courses, e.g. digital design and introduction to programming, and the lack of keywords from advanced courses, e.g. electromagnetics and digital signal processing. Our findings suggest that students are also socializing, providing contextual information and sharing knowledge by making references to external resources. For instance, they were making social moves using “thanks” and provide the context of their problem at hand using words such as “project” and describing their “problem”. Furthermore, external web reference in form of “www” and code snippets featured frequently in the data. In sum, it appears from this preliminary work that students are engaging in a supportive learning environment. A subsequent analysis should incorporate keywords beyond the top fifty in order to determine how much less frequent missing keywords are.

In our second approach, we used LDA topic modeling and obtained sets of interrelated words. Based on our inferences on each set of connected words, we identified a handful of topics that are being discussed on the homework help sub-forum. We found that the themes of discussion are closely related with topics in the domain of ECE. For instance, the sets of connected words suggest that students are discussing about ECE topics such as microcontrollers, switches, transistors, circuits, motors, PCB design and PWM controllers. We conclude that online discussion forums feature significant amount of online discussion on topics that feature heavily in ECE curriculum.

In our third approach, we leveraged the LIWC program to examine markers of cognitive processes aimed at identifying the frequencies of use of words associated with five subcategories of cognitive mechanisms. The 5 dictionaries are termed "insight", "cause", "discrepancy", "tentative" and "certainty and each comprises of words we use to look matches in each discussion topic. As expected, our findings suggest that the cognitive process "certainty" was relatively less prevalent in the homework help-seeking discussion. This suggests that students approach online help forums with a degree of uncertainty and a lack of mastery on the content area of concern. In sum, LIWC shed light on the cognitive dimension of students' written text and deepened our understanding on their help-seeking approaches.

We believe that the findings can potentially inform practice, particularly giving engineering educators a quick snapshot of what types of help were sought online and which ECE topics were most likely to be challenging to the help-seeking students. In sum, we found that the homework help section of the studied informal online discussion forum cater to students learning about fundamental ECE topics and less on advanced topics. Our study also raises an important point – online help forums are supportive avenues for engineering students seeking to extend their knowledge and make connections to other students beyond the classroom.

***Abstract*—Many diverse domains—in the sciences, engineering, healthcare, and homeland security—have been grappling with the analysis of "Big Data," which has become shorthand to represent extremely large amounts of diverse types of data. A recent Gartner report predicts that around 4.4 million IT jobs globally will be created by 2015 to support Big Data, with 1.9 million of those jobs in the United States. Therefore, understanding approaches and techniques for handling and analyzing Big Data from diverse domains has become crucial for not only in computing but also engineering students. The mini-workshop will make use of active and collaborative learning exercises to introduce faculty in computer science, software engineering, and other disciplines to concepts and techniques involved in managing and analyzing Big Data. Approaches for incorporating Big Data into the engineering and computing curricula will also be presented.**

Keywords—big data, data analytics, data mining, data-intensive applications

I. Motivation

Big Data has become a catchphrase to describe data so large that it is not amenable to processing or analysis using traditional database and software techniques; such Big Data is noted for its volume, varieties of data types, and rapid accumulation. IBM estimates that 2.5 quintillion bytes of data are created daily, and that 90% of the data being used in the world today was generated in the past couple of years [1]. The advent of Big Data poses considerable enterprise challenges: what portion of this Big Data get stored; how is this storage managed; how quickly can this Big Data be analyzed to enable enterprises to take quick action on enhance productivity, meet or change directions, reduce risk, and more; how can this data be stored securely; what data privacy issues are involved; and so on.

A 2011 McKinsey Global Institute research report projected that the United States needs 140,000 to 190,000 more workers with "deep analytical" expertise and 1.5 million more data-literate managers, whether retrained or hired [2]. Since then, Gartner predicts that 4.4 million IT jobs globally will be created by 2015 to support big data with 1.9 million of those jobs in the United States [3]. Big Data, or "large-scale, diverse, and high-resolution data sets" [4] is found in business, science, engineering, healthcare, critical infrastructure management, and a variety of other domains. A partial list of directorates and agencies from the NSF program solicitation on Big Data contains engineering, mathematics, geosciences, computer science, biological sciences, education, National Cancer Institute, National Human Genome Research Institute, the Office of Polar Programs, and more [4]. Therefore, exposure to Big Data and its analysis would greatly benefit students in engineering and computing programs.

This session will provide an introduction to Big Data and how it can be brought into the classroom. The rest of this paper will present a description of the workshop including the planned workshop agenda; the proposed workshop learning outcomes; and the professional preparation and background of the presenters.

The goals of this mini-workshop on Big Data align with FIE 2013's third focus area: interdisciplinary programs. The workshop provides its attendees with "collaborative learning experiences at the frontiers."

II. Workshop Description

This mini-workshop will demonstrate methods to incorporate concepts, topics, and assignments in Big Data management and Big Data analytics in computing and engineering courses. Drawing on their experience with teaching large scale data management and mining, the presenters will highlight Big Data's characteristics, supporting technologies, and scope.

Table I outlines the tentative agenda for the mini-workshop.

TABLE I. Tentative Workshop Agenda

Event	Duration
Presenters and participants introductions	5 min
Introduction to Big Data using a relevant exercise	10 min
Big Data technologies (Hadoop, AWS, etc.), demo, and a relevant exercise	20 min
Big Data analytical techniques, demo, and a relevant exercise	25 min
Incroporating Big Data into the curriculum	15 min
Big Data: participant discussion moderated by the presenters	14 min
Conclusion	1 min

The presenters will introduce typical issues in collecting, preparing, storing, and analyzing Big Data for use in teaching applications. Next, participants will work with sample course modules and exercises covering technologies such as high-

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

performance file systems (e.g., Hadoop and Google File System); NoSQL database systems; cloud computing and storage; programming models (e.g., MapReduce) used in data-intensive applications; and data mining platforms such as Weka, Rattle, R, and Mahout.

Participants will then work through a short analytical exercise using a large data set. Finally, the workshop will conclude with a participant discussion on issues in embedding Big Data topics into existing classes and the influence of Big Data on careers for their graduates. The session will include demonstrations of software and data analysis techniques for Big Data as applied in inter-disciplinary settings, and discussions of sources for domain-specific data.

Attendees will be provided with sample lecture materials and exercises, which will consist of course modules that may be used in their own teaching practice.

III. Workshop Learning Outcomes

The learning outcomes for this mini-workshop are as follows.

- Attendees will explain the main issues and concepts in Big Data management and analytics.
- Attendees will discuss the influence of Big Data in different fields and identify career opportunities in Big Data Analytics for their students.
- Attendees will identify ways to incorporate Big Data management and analytics topics and assignments in relevant computing, engineering, and engineering technology courses.
- Attendees will apply skills needed to implement a Big Data management and analytics environment that can be used for pedagogical purposes.

IV. Qualifications of the Presenters

The two presenters are members of the PhD faculty in Computing and Information Sciences at Rochester Institute of Technology. The PhD program is an interdisciplinary *use-inspired* program that applies computing to solve specific problems across multiple domains.

Dr. Romanowski is an associate professor with RIT's Center for Multidisciplinary Studies, and conducts research in large-scale data mining, particularly in engineering design, product lifecycle management, and critical infrastructure. In addition to teaching undergraduate and graduate Computer Science courses in data mining and data cleaning, she teaches courses in quality management, design of experiments, statistics, history/manufacture of siege weapons, and new product design and development. She received her PhD in Industrial Engineering from the University at Buffalo (SUNY).

Dr. Raj is a professor in RIT's Computer Science department, and his current research interests currently include in large-scale data management, distributed/mobile computing, security, and critical infrastructure protection. He is also interested in computing education methodologies, and is involved in program assessment, evaluation and accreditation. Dr. Raj teaches courses in database systems, cloud and large-scale data management, distributed systems, and security. Prior to RIT, he was a software designer, developer, architect and manager in the Information Technology Division at Morgan Stanley, where he architected, built and managed globally distributed database infrastructures for financial applications handling Big Data. He received his PhD in Computer Science from the University of Washington, Seattle.

Both faculty members are experienced teachers who use active learning techniques extensively and teach in multiple settings: traditional classroom, online learning, and blended settings. They jointly taught a course on Big Data Analytics in the spring term at RIT. They also led a team of multidisciplinary faculty (including industrial engineering, computer science, software engineering, computing security, and information technology & sciences) who developed an advanced graduate certificate program in Big Data Analytics.

***Abstract*—There have always been critics of education and such criticism has led to a slow ebb and flow in the predominant beliefs that surround the purpose of education [1]. However in the last several years a perfect storm appears to be brewing driven by the rising costs of higher education, continuing maturation of information technologies, and a public dialog that often characterizes higher education as in need of reform [2, 3]. While there is no general consensus on the future of higher education generally, and engineering education specifically, some believe that the model of higher education familiar to most engineering faculty will undergo dramatic changes in the next decade [4]. What is the probability that the engineering education will look significantly different in ten years' time? How might our current model be disrupted; how can engineering educators not only prepare for possible disruptions, but take advantage of new opportunities? What new directions for engineering education research open up if the structure of higher education changes? This special session will elicit from the experiences of participants ways they have (or have not) seem disruptive changes on their campus. By comparing experienced change to those predicted in studies that have examined how disruptions might affect higher education [5], we hope to help the session participants develop a preliminary set of theories of change that may guide their decision making and opinions regarding disruptive forces in higher education.**

***Keywords—disruption; higher education; technology; economy** (key words)*

I. WHY DISRUPTION AND WHY NOW?

The fact that from their inception nearly a millennium ago universities were designed with the goal of preserving and transmitting knowledge, presents modern-day challenges for higher education. The university as a societal institution can trace its lineage back nearly one thousand years to localities that scholars travelled to for education. The word "university" itself is shortened from the Latin phrase "*universitas magistrorum et scholarium*" which translates as "community of masters and scholars" reflecting the guild structure common at that point in time. This location-centric model made sense given the historical context; at that time oral recitation of written texts, hand-copied by students, was an efficient and massively parallel means of information transmission. Before the advent of the printing press information was an extremely valuable commodity- a single book could cost as much as a small farm but had value disproportional to today's cost [6]. The knowledge-centric structure of universities made sense when information was scarce, localized, and expensive to obtain. Some argue, however that this structure now serves to undermine their function in the information age [7]. While reform of education is a perennial topic, generally all efforts at change retain the primacy of knowledge. From the emergence of courses and the curriculum in the 16th century [8] to modern efforts to integrate videos, on-line courses, games, and the current focus on Massively Open On-line Courses (MOOCs), efforts at change generally address ways to reorder, redefine, acquire, retain, and/or transfer knowledge.

Despite the pressures for reform, universities have generally been resistant to change. Such resistance likely stems from the university's historical role as a guardian of tradition and its success in enculturation. Given today's model of universal education, faculty members are products of similar educational systems and thus think about education within the bounds, ideas, and terminology of that system. Indeed, our own educations have so well defined us that it can be extremely challenging to think about the educational system from alternative perspectives. An inability to step outside of the status quo, however, can lead to eventual disruption. Many organizational change models (e.g. evolutionary, social cognition, cultural, institutional, punctuated equilibrium, and Panarchy) describe systems which become increasingly rigid until they are forced to adapt. Weick and Quinn [9], in placing much of the change literature on a spectrum from episodic to continuous change points out that "*Lewin's three stages of change—unfreeze, change, and refreeze—continue to be a generic recipe for organizational development*" and that "*to understand organizational change one must first understand organizational inertia, its content, its tenacity, its interdependencies*."

This special session will examine what disruption might mean to engineering education, what forms it might take, and what opportunities disruption engenders. While for many the word "disruption" can be used in the sense of creating chaos, it means an interruption in the normal course of events. Disruption thus has the equipotential to harm institutions, organizations and individuals, as well as to lead to growth and evolution. Disruption in higher education, no matter how unlikely past events make it seem, is important to consider since the "community of masters and scholars" has a great impact on society. Universities remain open repositories of specialized expertise which allows individuals, institutions, and societies to function in a complex world of interconnected systems. Research and technologies that originate in universities drive economic growth, and industries demand an increasingly educated workforce. It can therefore be concluded that the impact of disruption on our educational system will

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

directly impact our nation's competitiveness, vitality and prosperity.

II. Disruptions to be Considered

At the time this paper is being written the most talked about potential disruption to the historical model of engineering education is the Massively Open Online Course, or MOOC. While there have been MOOC-like online learning experiences for some time, the current focus was sharpened when over 160,000 students signed up for an online artificial intelligence course taught by Stanford professor Sebastian Thrun, that soon thereafter led to the founding of Udacity, one of the privately funded firms that offers MOOCs.

Fig. 1. Six inter-related and synergistic factors that the special session will initially utilize to characterize potential disruptions.

While MOOCs are currently the most visible and apparent of the forces that can potentially change the historical model of higher education, there are other disruptive forces that are also affecting universities. To frame the conversation the special session will preliminarily classify six potential dimensions of disruption, as shown in Figure 1. These six dimensions are, in no particular order:

- Technological: Advances in technology, typically related to transmission of information, which enable at least some of the traditional functions of a university education to be offered remotely.
- Organizational: How universities are structured and governed. This dimension includes changes in management and power structures within the university.
- Philosophical: Changes in beliefs and attitudes of these within the higher education system and society at large, which may include the value of higher education. The term philosophical denotes that beliefs are organized around some internally consistent schema, even when this schema is not easily articulated.
- Economic: All universities rely on sources of external funds for their operation--endowments, gifts, state and federal funds, and/or student tuition-- and thus changes to the revenue and operating costs of universities can be a catalyst for disruption.
- Regional: Disruptions can arise from local or regional trends such as population growth or decline, closing or off-shoring of major employers, or longer term population and demographic changes.
- Societal/Political: Universities, while historically insulated from larger social change, are affected by societal, as well as local and national, political factors. These may include regulatory policy or changes to how students fund college (e.g. government subsidization of student loans). Special interest groups can target universities, either to support or undermine their function.

Disruptions are rarely characterized by a single dimension. The previous example of MOOCs combines elements of technological innovations with economic dimensions given the relatively low cost (approximately $US 0.50 per student) to offer a large scale course. MOOCs also have elements of the philosophical dimension since their popularity reflects beliefs as to their efficacy, as well as the political dimension, since accepting credentials of MOOCs requires garnering support from multiple groups.

III. Goals of the Special Session

The goal of this special session will be to familiarize participants with current trends and literature around potentially disruptive events in engineering education, and to stimulate discussion amongst the community about these trends. At the end of the session participants will have been given the resources to independently explore several of the wide-ranging perspectives on potential future disruptive changes to higher education generally and engineering education specifically.

The special session is not designed to teach or communicate facts about disruption, but rather to evoke from participants their own beliefs and opinions about the likelihood and severity of disruptive events in their own university. The overarching goals of the workshop are to:

1. Create a forum in which a discussion of both likely and unlikely future scenarios of engineering education are discussed that build from the lived experiences of participants.
2. Change the conversation about disruption from one based on fear or scarcity to one that gives equal weight to opportunity and exploration.
3. Identify possible new opportunities that will arise for engineering education research and have participants self-identify possible new directions for their own research interests.
4. Develop a preliminary set of theories of change that can help guide participants' strategic decision making.

IV. Organization of Special Session

The organization of the special session will focus on eliciting experiences from participants that either support or refute the six hypothesized dimensions or modalities of disruption. The organization of the special session will help compare participant's beliefs and experiences with the larger national dialog. The session will tentatively be organized into six sequential activities

A. Introduction & Background Reading

A list of readings that cover various aspects of disruption in higher education will be compiled before the session and given to participants. Since this space is changing very rapidly, the list will be handed out at the start of the session, and also be made available after the session on a web site that will be provided to the participants. Participants will be informed of the goals of the session, organization, and time line. Some of the major works on disruption in higher education will be presented to ground later discussion.

B. Scenario Analysis

The jigsaw technique will be used to divide participants into small groups to analyze a potential scenario of disruption. Each participant will be handed a stack of cards at the door, and organized by groups given the letters on the cards. The first discussion will be for six different groups to discuss each of the dimensions that can characterize potential disruptions. This group will be disbanded, and new groups of six formed that contain at least one person who attended the discussion on each dimension. The groups will each be given a different scenario, and the groups will discuss the effect of the scenario on engineering education. An example scenario might be that "ABET announces it is closing its doors, and your program now has no requirement for accreditation." Following discussion, each group will report out on the results of the scenario analysis.

Following the first, hand-picked scenario, each group will be asked to develop their own scenario that combines one or more experiences of participants in the group, and analyze the disruptive effects on engineering education. For this second scenario the groups will be asked to identify three research topics or questions that would help them adapt to or profit from the disruption. Groups will again report out and outline their scenarios on large cards or poster boards.

C. Developing a Theory of Action

The groups will again be reorganized to the first groups in order to stimulate new conversations while avoiding the need for further introductions. The presenters will provide a brief background on theories of change/action to ground the next task for participants. Groups will be asked to develop several assumptions or hypotheses about possible disruptive changes that can be integrated into a theory of action. An example of such a hypothesis might be "New technologies for learning will continue to evolve, and increasingly support development of alternative pathways beyond traditional colleges and universities." Groups will be asked to write down their hypotheses on large cards or poster boards that can be displayed to other groups.

D. Final Report-Out and Conclusions

To conclude the session an open and free-ranging discussion of the session will be held to elicit if there is group or majority consensus for any of the hypotheses generated when theories of action/change were developed. Participants will be asked if any of the scenarios suggest research questions/directions that deserve further investigation or consideration by the engineering education community.

E. Post Session Actions

All written artifacts from the session will be collected, and a scribe will be assigned to record oral conversations. Each participant will sign a study release form to be able to use their written material. The outcomes of this session will be analyzed to identify possible disruptive scenarios. Results will be made available on a web site, and e-mailed to participants who were willing to provide their e-mail address on a list available during the session.

V. CONCLUSIONS

It is important that scholarship in Engineering Education not lose sight of the larger context and forces which affect higher education as a whole. The goal of this special session is to have the community identify possible disruptions to the current models of engineering education; recognize disruptions with their local context, and path(s) to achieve this goal. The outcomes of this session and feedback from the community will be analyzed to determine alignment with, as well as divergence from, the current dialogs around disruptions in higher education [2-5].

A Teaching Method for Using Metaphors in Interaction Design

Anderson Cavalcante Gonçalves and Deller James Ferreira
Informatics Institute
Federal University of Goiás
Goiânia, Brazil
andersongoncalves@inf.ufg.br, deller@inf.ufg.br

***Abstract*— the consistent use of metaphors in the context of Human Computer Iteration (HCI) helps to reduce the cognitive load necessary for understanding the functionality of a computational interface. Students´ understanding about a good usage of metaphors in HCI improves their ability to properly critique and design computer interfaces. However, is not simple to students to learn how to use metaphors in interaction design. To teach students to develop interactive experiences by means of metaphors is not an easy task. This work proposes a teaching method for using metaphors during the design of website, desktop, mobile or tablet interfaces and present results of a successful case study concerning the proposed teaching method. The teaching method developed is a model of collaborative learning based on King's questioning model and Ferreira's creative dimensions, that consists in creative tasks allied to questionnaires with structured questions and are designed to encourage interaction, group learning and to foment creativity in students.**

Keywords—metaphors; interaction; design; teaching; learning

I. Introduction

According to Lakoff and Johnson [1], our conceptual thinking is fundamentally metaphoric in nature. They see metaphor not as a mere figure of speech but as a fundamental cognitive mechanism, where experiential structure is projected from a source domain to a target domain. Intuitive interaction with technology is based on the unconscious application of prior knowledge by the user. Besides, design is about invention. Invention can be product of juxtaposition. Metaphor is about juxtaposition. So, the link between metaphors and user interfaces is inevitable. Metaphors are a powerful and usual tool for designing intuitive interaction.

The use of metaphors in computational interfaces makes the user experience more familiar and concrete. Metaphor is not a mere figure of speech; it is a fundamental cognitive mechanism for understanding. According to Lakoff and Johnson [1], the essence of metaphor is understanding and experiencing one kind of thing in terms of another. Considering interaction design, it is desirable an interface familiar to the user, enabling an easy learning and use. Metaphors application reduces the time spent on user training or, in specific cases, no training is required.

The use of metaphorical concepts is one of the resources available for creating intuitive user interfaces. Entertainment websites, online stores, social networks, and others require an interface easy to learn and use. The interaction design should be well organized, easy to be interpreted and used by the users. Metaphoric concepts can be used in an expressive way to achieve this goal.

Metaphorical concepts are pervasive in the culture of a society. Lakoff and Johnson [1], stated that the metaphorical concept is inherent to subconscious and govern our whole way of thinking. Thus, the good use of metaphors in interface design is a feature that will make the interaction much easier to understand. Nielsen and Molich [2] established that we should minimize the cognitive load of the user. In other words, they stated that the designer should facilitate the reasoning required to interpret an interface. Also, they state that in a user interface there must be a match between the system and the real world, the designer should use phrases and concepts familiar to the user, rather than system-oriented terms.

The use of metaphors is a powerful resource that can be applied to achieve these heuristics. The appropriate application of metaphorical concepts turns an interface into a better interface. The interface design consists in defining how content is organized and presented to the user [3].

The consistent use of metaphors in the context HCI helps to reduce the cognitive load necessary for understanding the functionality of a computational interface. Students´ understanding about a good usage of metaphors in HCI improves their ability to properly critique and design computer interfaces.

However, there are misleading uses of metaphors, it is not simple to students to learn how to use metaphors in interaction design. To teach students to develop interactive experiences by means of metaphors it is not an easy task. Students need to understand the user experiences, concerns, skills, interests and expectations and must develop the ability to create good designs based on user's knowledge.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Constructing effective metaphors is to some extent a complex skill because it depends on the creative ability of designers to see new analogies, in order to choose the right set of correspondences. These correspondences have to enhance some aspects and hide others, because metaphoric mediation carries elements of the concept that are consistent, but also inconsistent when using metaphors to comprehend one thing in terms of the other. For Schwartz and Fischer [4], metaphors have highlights levels of complexity as well as the need for sufficient support to build complex understandings, but it does not easy capture the diversity of contexts that students might experience that could lead to the same abstraction. Metaphors can be difficult to learn and teach, because they have a high level of complexity. Students may have different interpretations of each other, which makes teaching difficult.

According to Hodges [5], if we examine the metaphor closely, its connotations are often the darkest when applied to teaching. Having a problem in one's research is motivating; having a problem in one's teaching is, well, a problem. In order to overcome the difficulty to teach metaphors in HCI, we suggest the teacher must apply a teaching method that encourages creativity and also criticism in interaction design.

In this work, we aim to awaken and stimulate the use of metaphors in teaching and learning interaction design with the aim to stimulate students' abilities to discern what is a good or bad design, allowing students to differentiate an interaction design that it is aesthetically good but possesses a bad functional design, and to propose new ideas and solutions.

In this work, we propose a teaching method to teach metaphors in human computer interaction design that fosters student's creativity and criticism. This method is based on collaborative learning and creative dimensions proposed by Ferreira [6] and the discussion method proposed by King [7].

The creative dimensions, proposed by Ferreira [6], contain underlying dialogical processes that aligns dialogues with mental processes linked to both adaptive and innovative creativity. The creative dimensions constitute a pedagogical framework for design exercises for use in the teaching of human computer interaction, making possible to teachers create significant human computer interaction collaborative learning experiences to students, fostering them to activate mental processes underlying creativity.

On the other hand, in the discussion method group proposed by King [7], questions that trigger patterns of discourse in learning groups are designed to facilitate the construction of complex knowledge and problem solving.

Our teaching method proposes a combination Ferreira's framework [6] and Kings [7] types of questions to propose a repertory of interaction design exercises exploring the use of metaphors. In our teaching method, we also approach the most common metaphorical concepts as structural, visual, functional, and positional metaphors, and consider where, when, why and how they are applied in the field of HCI. This metaphorical knowledge is part of the teaching method and are used during the tasks and questions created.

In this work, we present a case study comparing the teaching method proposed in an undergraduate HCI class (treatment group) and a method involving students' discussions and informal teacher mediation in another undergraduate HCI class (control group). The case study conducted showed significant results.

In section II, we show the importance of the application of metaphoric concepts to human computer interaction and show systematic aspects of metaphors. In section III, we describe the teaching method proposed in this article. In sections IV and V, we present a case study of the application of the teaching method proposed and the results obtained.

II. METAPHORICAL CONCEPTS APPLIED IN HUMAN COMPUTER INTERATION

Metaphorical concepts are applied in the design of computational interfaces in order to facilitate the human-computer interaction. The interaction is facilitated by means of the user's prior knowledge, making the user experience rich and intuitive. In order to consistently apply metaphors we need to know and understand how they are structured, and know in which situations it is appropriate to apply them. Nielsen [8] advocates that a metaphor misused diverts the user understanding to something not desired. Hence, a contextualized interpretation is necessary to appropriately apply a metaphorical concept. A contextualized interpretation provides a subconscious understanding of a metaphor.

According to Lakoff and Johnson [1], a subconscious understanding of a metaphor is the cause of its systematic understanding. For example, the phrase "I will destroy it with my speech" is based on the metaphor "argument is war", after reading this phrase our subconscious systematically follows the practice of the society. The metaphorical concept does not lead to an association with the concept of a war, an individual with experience are able to know that someone will not shattered, but their arguments are deconstructed. The systematic aspect highlights some characteristics of confrontation and hidden the feature of physical trauma. The systematic aspect evokes structural, functional, visual, and positional aspects.

A. *Structural Metaphors*

Structural metaphors are formed from the structure of an object, entity, group, finally elements of everyday life. The idea is to use an organizational hierarchy, for example, a website of a library should contain the same organizational structure of a library, in which books are organized by class and type.

B. *Functional Metaphors*

Functional Metaphors contextualize actions that can be done on a website or in another environment. The functional metaphors evoke prior knowledge of the user in relation to something that has already been seen or used in their daily lives. In a text editor find examples of functional metaphors. Can metaphorically "cut", "paste", "copy" documents or fragments of a document into another, as if using paper, scissors and glue. So the tasks in the website become easy to understand and use.

C. *Visual Metaphors*

A visual metaphor can be defined as the representation of a person, place, thing, or idea by way of a visual image that suggests a particular association or point of similarity. Visual metaphors are linked to graphical elements common to a particular culture. According to Lakoff and Johnson [1], The concepts inherent subconscious govern our way of being, from speech, to the way we act and one of these concepts is the metaphorical concept. A usual visual metaphors example is the use of floppy disks images to represent "buttons" present in many different interfaces. It is used to save a document during text editing.

D. *Positional Metaphors*

According to Lakoff and Johnson [1] positional metaphors are those in which a system of concepts is organized by reason of another. The positional metaphors use the concept of spatial orientation. For example say that happy is up, sad is down. Then we have the understanding that good is up and bad is down. This name is given because in most cases there is a spatial orientation: upward, downward, outward, inward, and so on. An example is the metaphor "happy is up". Another example is that people usually places names or most important items at the top of a list, this is due to the metaphor "is more important up".

The use of metaphors in HCI is evident in many interaction patterns and interface designs. For example, the Apple´s desktop metaphor, wizard pattern, canvas plus pallet pattern, menus, buttons, dashboards, carousel pattern, breadcrumbs pattern, and so on.

Once described some metaphoric uses in human interaction computer, then we will address the teaching method proposed in this work.

III. Teaching Method for Using Metaphors in Interaction Design

The use of metaphors is essential to the user experience become simple and intuitive. It facilitates user understanding and interactivity. According to Baumer [9] metaphors can be powerful aids for understanding because they can help the understanding of novel concepts.

However, learn to apply metaphors in computing environments it is a difficult task. Although metaphors abound in human thinking, they can be surprisingly difficult to notice simply due to their ubiquity.

In this work, we developed a teaching method based on collaborative learning for teaching metaphors in interaction design. Collaborative learning is a successful method to awaken creativity. Creative solutions emerge from interactions that encourage students to express and evolve their ideas in specific problems.

According to Jonassen and Land [10], knowledge originates from productive discourse among individuals, the social relationships that bind them, and the physical artifacts, theories, models and methods that they use and produce. Productive discussions provide satisfactory results in collaborative learning, providing students the opportunity to share and co-construct knowledge.

Creative solutions are built during joint activities that trigger productive discussions. Creative and collaborative dimensions proposed by Ferreira [6] promote productive discussions, where students are encouraged to widen and deepen the design space. Students extend the design space when a new idea emerge and deepen the space of the project when an idea is developed.

Ferreira´s pedagogical framework allows the teacher to elaborate tasks that nourishes creative discussions during collaborative problem solving in interaction design [6]. The author considers that creative products occurs as stimulation of many different planes. The framework contains seven collaborative and creative dimensions to be applied by the teacher. According to Ferreira [6], the dimensions are: immersion, unpacking opportunities, exploring complementary ways, surpassing limits, expanding, discovering and developing unpredictable places. The dimensions contains dialogic processes that are dialogs aligned with mental creative processes associated to both adaptive and innovative creativity. Dialogic processes afford ideas build on other ideas, while people collaborate. The framework helps and challenges teachers to be aware of how complex students´ activities can be elaborated during collaborative learning. Considering students perspectives, during productive discussions they are able to detect relevant and irrelevant information, recognize the familiar, deal with new information, adapt and reapply techniques, among other creative important processes.

The use of provocative questions is another strategy that encourages students to interact productively. The students absorb and transcend knowledge when they engage themselves in profitable interactions.

King´s model approaches provocative questioning to induce relevant cognitive, meta-cognitive and socio-cognitive processes in participants [7]. Effective learning interactions induce complex cognitive processes including the analytical thinking necessary to create metaphors.

According to King [7], learning is constructed during interaction with others. During the interaction the students engage in the exchange of ideas, opinions and perspectives. The speech is composed of provocative questions, explanations, justifications, assumptions and conclusions. The construction of knowledge occurs when students explain concepts to each other. The questioning is a procedure that asks questions and answers. The interaction during the discussion results in a high level of learning. The model proposed by King consists of structured questions on issues of entry, for example: "How similar to?", "How does it relate?", "What do you remember and why?”. Comprehension questions, for example: "What does it mean?", "What's important." Connection issues, for example: "How are similar?", "What is different between?", "How can it be used for?", "What are the strengths and weaknesses?" [7]. Strategic issues, which can be planning, monitoring and evaluation.

The method proposed in this paper involves the development of group assignments focusing on the use of metaphors in HCI. Using our method, the teacher is able to elaborate group tasks and questions that encourage students engage themselves in productive discussions.

The teacher is invited to approach the dimensions proposed by Ferreira [6], questioning the model proposed by King [7] and knowledge about metaphors when designing exercises.

The teaching method involves structured questions as described in the model proposed by King. The questions are prepared according to the scenario presented to the student. The scenarios involve well and badly designed websites, when we focus on metaphoric concepts. The connection between the scenario and the questions is based on the dimensions proposed by Ferreira [6]. The tasks elaborated considering Ferreira´s framework and King´s model allow the students to expand the solution space, while discussing ideas jointly situated in a specific, smaller, bigger or different context.

Ferreira´s framework motivates the activation of mental processes relevant to creativity, while the questions from King´s model provoke them even more for reflection and to be creative. For example, students are encouraged to seek relationships among different ideas, think out of a particular context, find solutions and ideas out of context, interact with each other, expand the solution space, and think differently.

In this way, the students have the opportunity to scrutinize metaphors in different contexts and are urged to find solutions and improvements in the application of metaphoric concepts in interaction design. Besides, the combination of these techniques provides the student with the ability to generate creative solutions and alternatives during the group discussions. According to Preece [3], the generation of alternatives is a key aspect in the interaction design.

IV. THE CASE STUDY

The case study aims to examine the effectiveness of teaching the use of metaphors in interaction design by means the proposed teaching method.

In this preliminary case study, four tasks based on the proposed method were analyzed. The preliminary results indicated that the proposed teaching method has potential to help teachers to mediate students' creativity when using metaphors in interaction design.

The students investigated were engaged in two classes of undergraduate Software Engineering at Federal University of Goiás in 2011 and 2012. There were 44 students in the class of 2011 and 42 students in the class of 2012. Each class was divided into groups of 6 (six) students and each group was evaluated by means of discourse analysis of online discussions.

A. Students' Profile and Communication Tools Used

Students are studying Software Engineering at the Federal University of Goiás. Students have the profile of software developer. They are learning about the concepts related to interface design, as metaphors, usability guidelines and interaction patterns in the human computer interaction design course.

A communication tool used was the Moodle platform, which facilitates iterations among students. Each student post messages concerning their responses and opinions. The Moodle is a tool for course managing that also can be used for distance learning. Using the forums the student can post a message at any time and place.

B. Description of Tasks (Treatment Group)

The tasks required are described following.

1) Discuss having in mind the questions related to the website Taisho: www.taishoflorianopolis.com.br. During the discussions you must engage critically and constructively with the ideas of others. Express yours opinions, inferences, and propose appropriate solutions. Following we describe the questions regarding the Taisho website:

Why is it important to use a visual metaphor on the website? The elements observed on the website are similar to real objects? How the geisha and the shamisen relate to each other? The menu contained in the Website is an example of positional metaphor? Did the visual metaphors facilitate user interaction in the website? Are the metaphors used readily apparent to any user? Explain why the metaphors were used? Explain how each metaphor interferes with the user's perception? How the used metaphors are similar to elements of everyday life? Are the metaphors used inherent in the culture of the target audience? What are the strengths and weaknesses of the use of visual metaphors in the website? Is the user able to associate the elements present in the metaphorical interface actions and objects represented? The website has a stable context? The positioning of the metaphors in the interface facilitates the identification of the company name? The name has a reasonable size and its location is noticeable? The different metaphorical elements are in harmony? These elements contribute to the user understanding about the information contained in the website? The interface emphasizes the services offered by the company? The interface services are clear from the user perspective?

2) Discuss having in mind the questions related to the websites Sitotis: www.sitotis.hr and Thedeepestsite: www.thedeepestsite.com. During the discussions you must engage critically and constructively with the ideas of others. Express their opinions, inferences, and propose appropriate solutions. Following we describe the questions regarding the websites:

The metaphor in this company logo helps in understanding related to your industry? From the perspective of the user interface in relation to which it is possible to satisfactorily answer the purpose of the website? The website Interface is sufficiently self-explanatory? The metaphors present in the website immediately contribute to the understanding of its interface? The user interface is constrained by the reliance of the text contained in the description of the website to orient yourself? You understand so simple services offered by the website? The positioning of the website menu provides the user to find the desired options in a simple and immediate? The user can effortlessly navigate the website? It is able to distinguish the options? It has a precise notion of what is in each option? The graphics and animations present on website show the actual content? The metaphors used emphasize a content merely illustrative? Or are indispensable in navigating the website? The user is able to associate the elements present in the metaphorical interface actions and objects that represent? Scrolling the page is done vertically? The metaphor in this present action is clearly perceived? From the perspective of the user interface in relation to which it is possible to satisfactorily answer the purpose of the website? The website Interface is sufficiently self-explanatory? The metaphors present in the website immediately contribute to the understanding of its interface? The user can effortlessly navigate the website? It is able to distinguish the options? It has a precise notion of what is in each option?

3. Choose a Website to design your Mobile interface.

a) Take a look at the patterns shown in class 10 and 11 concerning mobile and navigation patterns. Also take a look at the supplementary bibliography

b) Use metaphors in the design of the website. Discuss having in mind the usability guidelines, particularly guidelines for mobile intrfaces. Think outside the box when designing the website. Consider the following questions about metaphors:

- What types of metaphors are more suited to the context of your mobile interface?
- Does the metaphor used help the user to concentrate on the main service offered by the website?
- How visual metaphors can be used to enhance the understanding and simplicity of the website in a mobile environment without sacrificing your design?
- Is it possible to use metaphors emphasize most relevant content to users?
- How can we subtly integrate metaphors and the graphic style of the website?
- Does the metaphor used provide users a logical path to follow, minimizing the effort required for understanding, making navigation easy and obvious?
- What functional metaphors can be used to facilitate the execution of some tasks?
- The use of structural metaphors can make navigation easier and more intuitive for the user?

4. *Each student must individually choose a context to adapt the wizard pattern using metaphors. Defend your choice in your group grounding yours arguments on the items "when" and "why" of the wizard pattern. Each student must design a wizard and defend your idea, based on item "as" the wizard should be implemented. Discuss, choose and refine the best idea considering the following questions:*

- The Wizard makes clear to the user what is the goal to be achieved?
- The user is notified if he tries to start a new job before completing the current?
- The user has the option to go back and change the data entered in the previous step?
- It is visible to the user in that step is missing and how to achieve the goal?
- The Wizard is simple and intuitive and does not require much effort on the user understand how to use it?
- Do the metaphors used help the wizard to became more simple and intuitive?
- Do the metaphors used help the user to concentrate on the goal to be achieved?
- Why metaphors were used? The metaphors contribute significantly to the user reach success in every step and fulfill the purpose of the wizard?

C. Description of Tasks (Control Group)

The tasks were in accordance with the following collaborative script:

Read a text about metaphors and evaluate the use of metaphors in the Websites Taisho and Sitotis. Based on the text and previous classes on this subject. Express your opinions regarding the use of metaphors in the Website.

D. Model Used in the Discourse Analysis

The model used in the discourse analysis was proposed by Newman, Webb's and Cochrane [11].

The Newman, Webb and Cochrane's Model is described by ten categories:

1. Relevance: Relevant states or diversions.

2. Importance: Important points and issues or unimportant points and trivial issues.

3. Novelty, new info, ideas, and solutions: New problem related information or repeating what has been said.

4. Bringing outside knowledge or experience to bear on problem: Drawing on personal experience or sticking to prejudice or assumptions.

5. Ambiguities; clarified or confused: Clear statements or confused statements.

6. Linking ideas, interpretation: Linking facts, ideas and notions or repeating information without making inferences or offering an interpretation.

7. Justification: Providing proof or examples or irrelevant or obscuring questions or examples.

8. Critical assessment: Critical assessment or evaluation of own or others' contribution or uncritical acceptance or unreasoned rejection.

9. Practical utility (grounding): Relate possible solutions to familiar situation or discuss in a vacuum.

10. Width of understanding (complete picture): Wide discussion or narrow discussion.

Categories 1 to 9 were explored in this case study.

E. Results

Each student was individually analyzed according to the model of Newman, Webb's and Cochtane [11]. The result obtained by all students in the group, produced the group average. The average of all groups produced the overall result of the class.

Statistics of the overall outcome of the class in 2011 is shown in table I.

TABLE I. STATISTICS OF INTERACIONS IN 2011

Category	Average
1.Relevance	19.5%
2.Importance	18.5%
3.Novely, new info, ideas, solutions	3.25%
4.Bringing outside knowledge or experience to bear or problem	8.25%
5.Ambiguities	24.37%
6.Linking ideas, interpretation	9.37%
7.Justification	2%
8.Critical assessment	35.62%
9.Practical utility (grounding)	10.87%
Overall average of the class in all categories	14.63%

Each category was examined individually in each group and the results were obtained by calculating the percentage from 0 to 100 per category group. The percentage was obtained by examining the student's posts. Each student post was analyzed according to each category. The result was obtained by analyzing the positive factors of each category.

During the course in 2011, it was not used the teaching method proposed in this article. The students were asked to evaluate and discuss the use of metaphors in websites considering no question.

Table II contains the general outcome of the interactions analysis in 2012.

TABLE II. STATISTICS OF INTERACTIONS IN 2012

Category	Average
1.Relevance	71.65%
2.Importance	58.73%
3.Novely, new info, ideas, solutions	32.86%
4.Bringing outside knowledge or experience to bear or problem	10.68%
5.Ambiguities	5.48%
6.Linking ideas, interpretation	10.27%
7.Justification	19.48%
8.Critical assessment	49.71%
9.Practical utility (grounding)	10.06%
Overall average of the class in all categories	29.82%

In category 1 we obtained 71.65% of relevant assertions. This result indicates that students had a significant improvement in the ability to make relevant statements. In category 2 it was obtained 58.73% of important issues. The result obtained in the category two indicates a significant improvement in addressing important issues. In the category 3 it was obtained 32.86% of new information, ideas and solutions. Students were able to propose new ideas, solutions and information. In category 4 we obtained 10.68%. Students were able to bring the information out of knowledge. In category 5 it was obtained 5.48% of ambiguities. In category 6 we obtained 10.27% of union ideas and new interpretations. In category 7 we obtained 19.48% of justification. Students were able to justify their ideas and affirmations. In category 8 we obtained 49.71% of critical assessment. The students' ability to make critical evaluations greatly improved. In category 9 we obtained 10.06% of practical utility. The average in all categories of the class of 2012 was 29.82%.

The results achieved were satisfactory. Compared with the class in 2011, class in 2012 achieved an overall gain of 15.19 percent. There was a clear improvement in all categories. In some categories there were a significant gain. Gains related to category 3 were 29.61 percent and earnings were related to category 8 of 14.09 percent. The category 1 and category 2 also greatly benefited. We note that the category 3 was the most favored. The students have acquired the ability to propose something new, new ideas and solutions, which is essential for a software engineer and interaction designer. Category 8 related to critical thinking also had a great improvement.

The statistics presented show that the use of our teaching method in teaching the use of metaphors interaction design instigates and encourages the student to infer criticism and find more effective and creative solutions for the design of computational interfaces.

In tasks two and three we analyzed the products designed and presented by each group of students. In the analysis we used the creativity checklist for website design of Zeng [12], analyzing important design factors, such as: aesthetically appealing design, interactive design, novel and flexible design, affective design, design important, common and simple design and personalized design.

Analysis of the products was successful. The results obtained in speech analysis have been confirmed in the analysis of the product. Students who possessed better performance in the categories of speech produced and presented the best products.

The critics and creativity promoted by collaboration and productive interactions among students, trigged by the application of the teaching method, contributed effectively in student learning. The students applied the concepts discussed adequately. The discussions resulted in products of high quality design.

V. CONCLUSIONS

In this paper, we highlight the use of metaphors in interaction design. The use of metaphors improves the interaction design, providing more respect and importance to computational interfaces. We addressed different types of metaphors, such as visual, functional, structural and positional metaphor. The proper use of metaphors produces a positive and significant impact on usability of user interfaces. Their use in user interfaces can improve its interface and provide substantial gains in user productivity.

Students find it difficult to learn and apply metaphorical concepts in interaction design. In order to overcome this problem, we addressed a teaching method to teach creativity and criticism in the context of interaction design using metaphors. A case study was designed and successfully applied. The preliminary results show that the teaching method based on collaborative learning through the development of questions that stimulate group discussion achieved good results. There was a significant improvement in the class where the method was applied compared to class where there was no application of the method.

The results show the relevance of the study and the teaching method applied. This work contributes to teachers to arouse students' creativity, directing and encouraging them to infer creative solutions and to proper criticize interaction design. This contributes greatly to their learning. In this way, the student aggregates the knowledge necessary to criticize and design a more intuitive interface that is simpler to learn and use.

To assure that the teaching method can indeed provide an effective approach to teaching metaphors in HCI, we intend to further investigate its application in future HCI undergraduate courses. We will compare students' performance considering tasks based on the teaching method to ill-structured and structured tasks not based on the teaching method.

Computer Science Education as Part of an Undergraduate Program in Community Information Systems

Dalit Levy
Dept. of community information systems, Zefat Academic College
Zefat, Israel
dalitl@zefat.ac.il

***Abstract*— Social information systems have recently emerged as an empowering force for communities, organizations, and businesses. Consequently, new academic programs have been proposed around the globe, aiming at establishing a framework within which students gain experience in the socio-technical process of designing information systems in business, libraries, health, government, education and beyond. These new interdisciplinary programs often regard computer science (CS) as one of their supporting pillars and therefore include some core CS courses, aiming at educating broad-minded practitioners rather than expert programmers in the field of information systems. This paper presents some thoughts on incorporating CS education in academic programs intended for non-CS majors and proposes an approach called 'Program by Design' for the first CS course in a new undergraduate program in community information systems.**

Keywords—Introductory Programming Course, Pedagogy, Design Recipes.

I. Introduction

In the last two decades we have witnessed an invasion of homes, workplaces, public spaces, and both local and global organizations by information technology tools and systems. The advents of the World Wide Web, wireless communications, and miniaturized computing technology have considerably expanded this invasion into mobile devices and remote communities. The widespread everyday use of computers and information systems reflects a shift in conceptualizing the technology as more social than it was perceived before: 'the computer started as a totalitarian tool, but has now also been embraced as a social tool' [1]. More recently, over the last several years, social information systems have gained significant popularity. Social networking sites, social sharing and tagging systems and social media attract several million users a day all over the globe. These kinds of information systems provide their individual users with increased social presence, much broader access to information and knowledge, and powerful means of communication. At the same time, social information systems emerge as an empowering force for both local and global communities, organizations, and businesses.

Following these radical changes [2], a new interdisciplinary area of study has evolved, arguing that the social and the technological mutually shape each other. Studies in this area touch several different fields, including CS, information systems, information science, and some social sciences [3]. By examining the social aspects of computing, the fields of Social Informatics and Community Informatics aim to ensure that technical research agendas and information systems designs are relevant to the lives of people and organizations. Community Informatics aims further at empowering communities through the use of technology, especially those groups who are excluded from the mainstream communication systems [4].

The increasing interest among different communities of practice in integrating human and social considerations into traditional information systems curricula has led to the development of new academic programs around the globe. These are aimed at establishing a framework within which students develop analytical skills to identify and evaluate the social consequences of systems based on information and communication technologies (ICT-based systems), and gain experience in the socio-technical process of designing information systems in business, libraries, health, government, education and beyond. The latest model curricula for undergraduate degrees in information systems recommended in 2009 by a joint task force of the Association for Computing Machinery (ACM) and the Association for Information Systems (AIS) also supports reaching beyond the schools of management and business. While information systems curricula have been traditionally targeted to business schools, the current task force believes that the discipline provides expertise that is critically important for an increasing number of domains [5].

Currently, many undergraduate programs in information systems (IS) around the globe operate either as part of the faculty of engineering or within the context of the business environment and related activities. This is also the case in our country, where the new community–oriented IS program here reported has only recently opened. Although other IS programs in the country might offer one or more courses dealing specifically with social aspects of IS and ICT, these courses are considered marginal.

The new undergraduate program in Community Information Systems has been developed in our College in light of the global trends discussed above and, in addition, as a response to the educational gap identified between various population sectors in our country. The program seeks to be sensitive to the increasing demand for higher education of the population in a rural part of the country, by considering the multi-cultural facets of businesses, organizations, and communities, and to empower these developing communities by using advanced technologies and information systems. The curriculum combines theory and practice while emphasizing subjects that are relevant to the workforce and the organizations surrounding the college, thus creating "Practice of Relevance" for its students [6]. Section II further describes the program and its curriculum as an intersection of disciplines.

The discipline of computer science (CS) is often perceived by IS programs as one of their supporting pillars. CS methods and ideas, which are at the root of ICT innovations and information systems design processes, are thought to have the potential to contribute to a greater understanding of those creations. Moreover, advancing students' understanding of computing has been thought of as critical to developing the needed workforce for the 21st century [7]. Therefore, students in IS programs in general, and in an interdisciplinary program such as Community IS in particular, should study fundamental CS courses in order to acquire the needed broad foundation in computing and consider its breadth of application. Section III therefore proposes a CS track tailored for non-CS majors in order to give them an understanding of the principles and practices of computing as well as its potential for transforming the world [8]. The 'Program by Design' approach [9] found especially appropriate for the first course in this CS track is detailed in Section IV. The last section of this paper offers early remarks on implementing 'Program by Design' at Zefat Academic College.

II. About the Community IS Program

The College's undergraduate program in Community IS has been approved by the national council for higher education at the end of 2010 and the first students have started their course of study in the fall term of 2011. The program's main assumption is that the revolutionary development of information technologies in general and of information systems in particular, changes organizational structure and organizational practices. Therefore, the workforce as a whole will benefit from acquiring basic academic knowledge in information systems, not only the engineers or those in managerial positions [7]. The notion of "community" in Community Information Systems is broad, including business communities as well as non-profit organizations, global or local organizations, public communities, cultural communities, and rural communities.

Imagining information system as a junction connecting (i) human users, (ii) supporting technologies, and (iii) organizational environment, the new curriculum includes (i) psychological and sociological aspects, (ii) information technologies and systems, and (iii) issues of organizational culture. This interdisciplinary approach can be seen also in Community Informatics (CI) undergraduate and graduate programs in Canada, USA, Australia, Italy, and many more [10] and in the emerging field of ICT and Development. The interdisciplinary nature of these fields calls for creating interdisciplinary academic programs that will support educating "more capable learners, more innovative teachers, more creative thinkers, more effective leaders and more engaged global citizens" [11]. Such programs enable students' specialization both in the technical and the social aspects of information systems. They also expose learners to the breadth of human arenas and communities supported by information systems like public health, economic development, education, and many more.

The three years curriculum is structured around "Information Technologies and Systems" as a core area of study. Required core courses provide half of the program credits - 60 out of 120 credits, where one credit typically equals fifteen class hours.

Additional ten credits are offered through elective courses in the core area of study. The rest of the credits are equally divided between two supporting areas of study: (a) "The Knowledge Society" and (b) "Information in Organizations". As can be seen in Table 1, students are exposed to the interdisciplinary nature of the program from Year 1. In the second and third years, students elect either area (a) or (b) as an area of specialization.

The core of the curriculum contains required foundation courses in three tracks: information and communication technologies (ICT), information systems (IS), and computer science (CS). The latter track is further described in Section III below. Area (a) "The Knowledge Society" includes required courses like digital culture, sociology of the internet, and evaluating digital communities. Area (b) "Information in Organizations" includes required courses like knowledge management and organizational behavior. As Table 1 demonstrates, while students elect only one area of specialization, they also take some required courses in the other area. That way the program provides the multidisciplinary knowledge required for entry-level positions in a wide spectrum of organizations.

TABLE I. DISTRIBUTION OF COURSES IN DIFFERENT AREAS OF STUDY

Area of study		***Year 1***	***Year 2***	***Year 3***	***Sum of Credits***
Core: Information Technologies and Systems	Required credits	21	22	17	60
	Elective credits		4	6	10
Sum of core credits		**21**	**26**	**23**	**70**
Areas of specialization:	Required credits in Area (a)	10	6	4	20
(a) The Knowledge Society	Required credits in Area (b)	10	6	4	20
(b) Information in Organizations	Elective (a) OR (b)		4	6	10
Sum of credits in areas of specialization		**20**	**16**	**14**	**50**

The structure of the Community Information Systems program separates the core of the curriculum from the electives with the intent of supporting the creation of a sound knowledge base of information systems, at a level appropriate for undergraduate students. At the same time, the courses in both areas of specializations mark the social, cultural, organizational, and human aspects as central to the knowledge base of information systems, thus can support the conceptual development of a multi-faceted body of knowledge by those who will study according to the new curriculum in Community Information Systems.

As a result of such integrated curriculum, we view graduates who are both information-technology-oriented and social-oriented, and thus can empower the communities where they live and work.

III. THE COMPUTER SCIENCE TRACK

As has been noted above, the new curriculum builds upon three parallel core tracks – 20 credits each, one of which focuses on computing principles and practices. This computer science track has been designed to suit the characteristics of the students in the program on the one hand, and to make computer science discourse and culture understandable by those students on the other hand. In other words, it is this track's goal to enable the graduates' participation in the professional discourse used among programmers, software designers, and software development teams. Towards this goal, four successive courses (4 credits each) are offered at the main computer science track, as is illustrated in Fig. 1. Java was selected for the second and the third object-oriented programming (OOP) courses because it is considered simpler than C++ for introducing OOP concepts for non-CS majors.

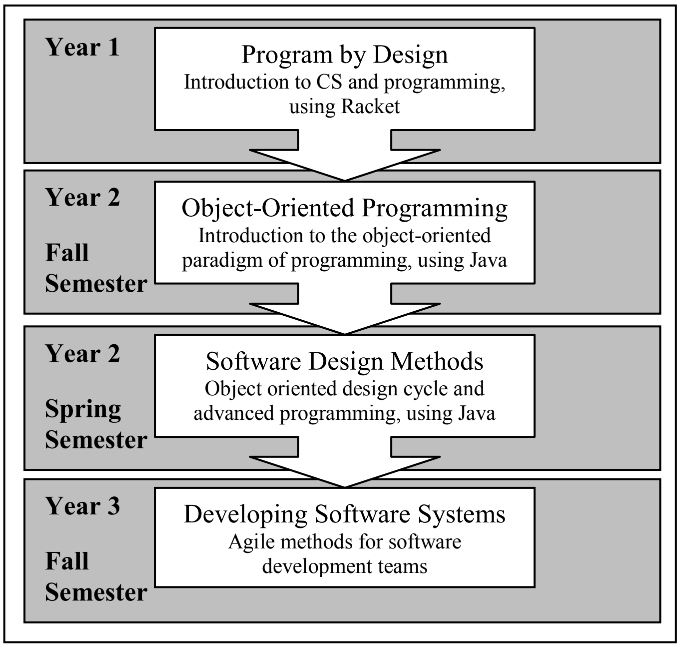

Fig. 1. The Flow of the Required Courses in the Computer Science Track

Together with few more CS courses (required courses such as data structures and electives such as applications programming), the 20 credits CS track integrates theory and practice while engaging students in the full cycle of software design. Since the students are not majoring in CS, and thus might not have an advanced mathematical and scientific background, the CS track starts with an educational approach called 'Program by Design' [9, 12] which is based on Racket programming [13]. As is detailed in the next section, this approach seems especially appropriate for a first programming course for non-CS majors, by focusing on developing design practices and desired programming habits from day one, by immersing learners into the profession's jargon, and by experiencing real coding with pictures instead of the conventional arithmetic jumpstart [14].

IV. THE FIRST COURSE IN THE COMPUTER SCIENCE TRACK

'Program by Design' is a longitudinal educational effort whose mission is 'to turn computing and programming into an indispensable part of the liberal arts curriculum'[1] both in high schools and undergraduate colleges. Led by Matthias Felleisen, the 2011 SIGCSE award winner for outstanding contribution to CS education, a group of CS professors and their students from several universities developed an innovative curricula and outreach program in order to address some of the most well-known issues in introductory programming courses [22], like the "blank page" syndrome, program diagnostics, visualizing programming and thinking processes [15], emphasizing testing [16], and tailoring IDEs for learners' needs and prior knowledge by offering a series of pedagogic language subsets, in which at every level the error messages never depend on knowledge that the student does not yet have.

Rooted in the paradigm of functional programing [16], 'Program by Design' is a functions-first approach to teaching introductory programming and problem-solving emphasizing good software engineering practices such as early testing from the beginning [17]. This is combined with the Racket IDE [13], featuring different language levels, simple syntax, customized error messages, and support for 'algebra of images' that enables students to write code for graphic- and animation-rich computing problems [14]. Most importantly, this educational approach offers design recipes to lead beginner students through a sequence of steps to obtain an understanding of the problem's nature and the solution program's behavior, hence the approach title. Testing is an integral part of the design recipe enabling test-first development [18]. Thus, the multi-step design recipe is useful not only to write programs but also to diagnose them. The design recipe scales naturally to the design of more and more complex systems of functions. This in turn empowers students to design programs for deep and interesting problems after just a minimum of introduction to the language, the environment, and the design recipes [9, 19].

The features of 'Program by Design' make the approach especially suitable as a starter for a computer science track of courses in the liberal-arts-oriented undergraduate curriculum in Community Information Systems. Since 'Program by Design' also includes support for transitioning to object-oriented

[1] http://www.programbydesign.org/overview

programming in Java and a method for using design recipes as part of an Object Oriented Programming IDE, the second course in the computer science track builds naturally on the first while further focusing on the systematic design of programs and classes as a preparation for the more advanced computer science courses (see the courses of Year 2 and Year 3 in Fig. 1).

An overview of the main computer science concepts in the first course is provided in Table 2. The course meets once a week for a four-hour lab session. The sessions are freely organized as a blend of short lecturer presentations, individual lab work, pair programming, and reflective class discussions. During the first weeks of the course, the students focus on fundamentals of programming by dealing with tasks involving pictures of their own choice, like overlaying one picture upon another, cropping certain parts of a picture, and drawing "the big picture" by combining picture parts [14]. Such focus is made available by the special library of functions that supports "algebra of images" included in the "beginner student" dialect of Racket IDE. Programming with pictures also enables students to creatively develop a small-scale programming project at an early stage of the course.

TABLE II. COURSE STRUCTURE

Week	Content
1-2	Built-in functions for manipulating pictures
3	Global variables as names for complex functional expressions
4	Contracts and error tracking
5	First mini-project: flags
6	Defining new functions
7	Parameters as local variables, scope
8	Design recipes and test cases
9	Second mini-project: simple animation
10-11	Conditionals
12	Structures
13	Final project

One recurring pedagogical pattern is weaved into many of the learning experiences and curriculum materials. In coordination with the test-first approach [18] and with Racket's unique function called check-expect[2] [12] that play an essential role in developing the culture of 'Program by Design', students are constantly asked to predict what they would expect to happen in a given situation before running the program, and write it down; to carefully observe and check the results of running the program; and finally to explain the results (which may or may not be what they predicted). This learning pattern follows the very well-known Predict-Observe-Explain structure [20] found successful in science education [21]. By using such pattern within the context of learning to program and by being able to embed it within the actual code, non-CS majors have the opportunity to experience one of the key components of the professional process of program design even at very early stages.

V. SUMMARY

A first course in computer science is in some sense an almost impossible task [14], in which students with various backgrounds need to learn (a) the grammar and the components of a programming language and (b) how to analyze a problem and design a program to solve it using that language. It is considered quite easy to get caught up in the details of (a) at the expense of (b), but the language itself might be obsolete by the time the students finish their course of study. The much more lasting knowledge is constructed through dealing with how to design a program that is both correct and easy to write, read, modify, and repair.

This might be true for any first computer science course, whether in middle school, high school, or college. It is certainly true for an introductory course for non-CS majors who are not intended to become professional programmers, as is the case described above. The focus on design patterns, which are step-by-step "recipes" for getting from a vague description of a problem to a working computer program, gives such students the "taste" of how professional programmers work in real-life contexts. The emphasis on test-first tools and pair programming helps the students experience a culture of programming and thus better understand the professional discourse among teams of programmers.

As the new program in Community Information Systems has only recently opened at our college, the implementation of 'Program by Design' with the first students has been in its early trial phase and the following conclusions are thus preliminary. However, even at this early stage, three central principles have proven viable for non-CS majors with variable background in programming. First, using pedagogically-grounded language tools and IDEs can indeed support novice learners' focus on the design process rather on the specifics of the language. Second, initiating the programming venture with tasks within the world of pictures, graphics, and animations, while building on an "algebra of images" rather than on arithmetic, opens up a whole new and unprejudiced context for both novices and those who have had some previous programming experience (or even a lot of experience). Within such a context, creativity often shows itself both at the level of the design process and at the level of the product. And third, applying test-first design and strict documentation requirements as early as possible (the third or four week) enforces disciplined programming while illustrating in a concrete way the program's desired behavior. Within the context of pictorial functional programming, students can combine small pieces of code into quite a complex program at an early stage. From the very beginning of the course they practice writing test cases before writing each function definition, and gain experience in phrasing each piece's contract [19], expected result, and test cases.

[2] Racket has a check-expect function which can be used inline with other Racket code to compare the result of two expressions.

In summary, although the students in the Community IS program are not expected to become professional programmers, their exposure to these basic features of software engineering makes them more able to talk to computer scientists, understand these professionals' concerns, collaborate with them in developing and maintaining organizational and communal IT projects, and at the same time to develop their own interdisciplinary career on a proper foundation. In the specific case here described, it is too early to tell how successful the CS introductory course will be in these regards. However, considering other cases, it is clear that one key to the success will be the distilling of well-known functional principles of programming into generally applicable design recipes that work also in other paradigms like that of object-oriented programming.

In light of current trends that call for programming for all[3] and regard coding as the literacy of the 21st century, the proposed CS track tailored for non-CS majors presents a valuable alternative to consider. Together with its 'Program by Design'-based introductory course, such a CS track has the potential to give students majoring in any field an understanding of the principles of computing and knowledge about the practices of computing professionals. That knowledge will undoubtedly support students' ability to make the choice so much needed "In the emergent, highly programmed landscape ahead… - Program or Be Programmed" [23].

Assessing the Effectiveness of Video Feedback in the Computing Field

Walter W. Schilling, Jr.
Department of Electrical Engineering and Computer Science
Milwaukee School of Engineering
Milwaukee, WI 53202
Email: schilling@msoe.edu

***Abstract*—Engineering students exhibit a wide array of learning styles across the perception, input, organization, processing, and understanding dimensions. To improve students performance in the classroom, many techniques have been developed to address these variances. The computing fields, however, tend to have a large percentage of students who are visual learners. These students learn best by seeing, and they can perform very well in the classroom with the appropriate usage of teaching styles.**

However, when it comes to providing feedback to students on submitted assignments, the main method employed is the written comment, which is not conducive to visual learners. This method is most prevalent in the academic community because overall, it is the simplest form of feedback that a faculty member can provide to students. However, written feedback is often highly ineffective at improving student performance, as many students simply do not read the comments because the students feel they are not relevant to their performance.

This paper presents an assessment of an alternative method for providing feedback to students: video feedback. In lieu of written feedback, students are provided feedback for software engineering exercises through the use of a short video made via video capture. The video captures in multimedia format the instructors perceptions and actions when grading a given assignment. The video includes both aural commentary as the assignment is assessed, as well as dynamic visuals of the grading process, demonstrating failures and improvements that can be made in the submitted assignment. The article describes the pedagogical foundation for the technique, specifics of the technique used, student perceptions of the technique, and an assessment of the learning gains from using such a method in a junior level class. In general, students are show to prefer the technique versus traditional grading, and an improvement in overall outcomes for the course is shown to exist as well.

I. Introduction

It is well known within the educational community that students exhibit different learning styles. Effective educators use different techniques to address these learning styles in the lecture and lab environment. Active learning, Co-Operative Learning, problem based learning, inquiry based learning, POGIL, and other techniques are all routinely applied in the classroom to improve student achievement.

Feedback has been shown to be the single most powerful influence on student success[1]. For feedback to be meaningful, it must meet many criteria, including being applicable to the student [2], delivered in a timely fashion, engaging to the students, and relevant to the topic at hand[3]. If students do not feel that this is true, they often ignore the feedback, either throwing away the assignment or simply looking at the final grade[4].

To facilitate better feedback, effective instructors use grading rubrics to assess student performance. Rubrics aid faculty members in being more efficient and consistent in grading. However, too much reliance on simply grading with rubrics has been attributed to causing "more superficial thinking, less interest in whatever one is doing, less perseverance in the face of failure, and a tendency to attribute the outcome to innate ability and other factors thought to be beyond ones control."[5].

Despite all of the changes to the classroom brought on by technology, the composition of student feedback has generally remained unchanged. Written comments make up 79% of feedback received by students, though 45% of students reported that they rarely received individual written feedback on assignments [6], and many students readily admit that they do not read written comments[7]. This is unfortunate, for as Hounsell states:

> *"It has long been recognized, by researchers and practitioners alike, that feedback plays a decisive role in learning and development, within and beyond formal educational settings. We learn faster, and much more effectively, when we have a clear sense of how well we are doing and what we might need to do in order to improve."*[8]

In certain environments, oral feedback has been used. Oral comments have long been used in the artistic areas, where an adjudicator records audio feedback to a musical ensemble overtop of a performance recording[9]. Oral comments have also been used informally in class and in team "coaching" situations where the instructor takes on a "mentoring" role.

Recent work, however, has shown that audio commentary has significant advantages in helping students to learn. In research studies, students have shown a preference for audio commentary over written comments [10]. Students believed that audio feedback was of higher quality than written feedback, easier to understand, and more personal than written feedback[11]. Audio feedback also has been linked to a feeling of increased personal involvement and increased retention of content[12]. These are clearly beneficial aspects of audio feedback.

However, while very beneficial to auditory learners, such an approach may not be as beneficial to visual learners. Visual learners tend to learn best through picture, charts, diagrams,

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

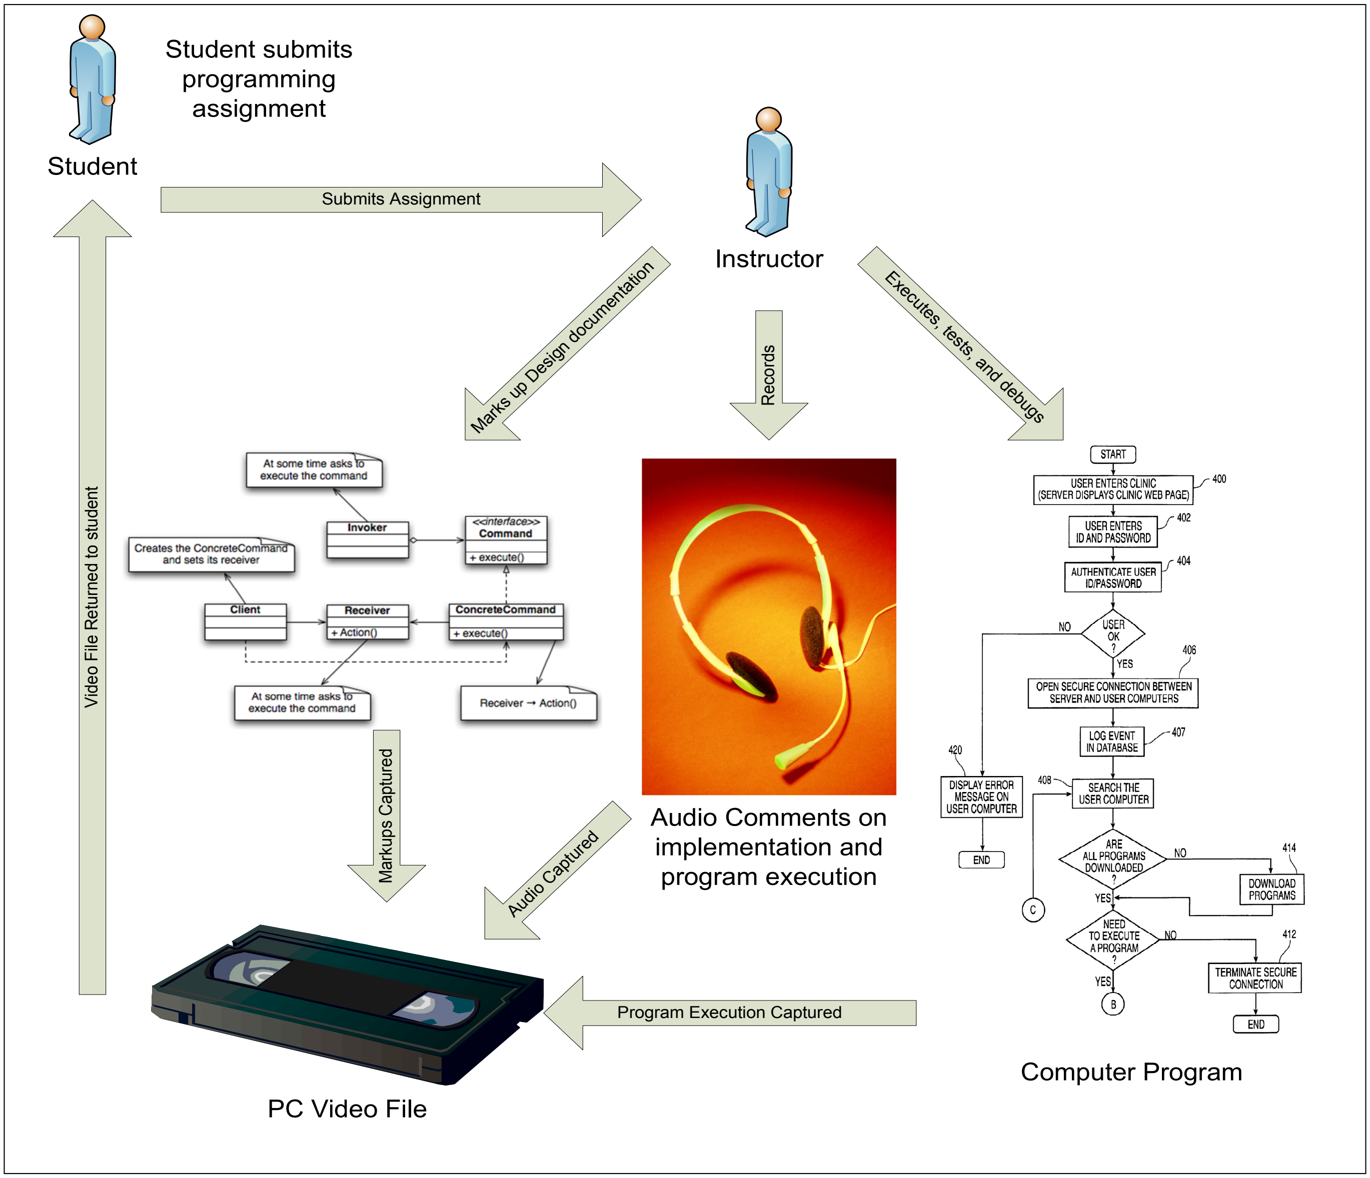

Fig. 1. Video Grading Process

flowcharts, visual similarities, and color coded markups. Visual learners also tend to be the majority of students in the engineering disciplines[13]. Certain engineering fields, software engineering, civil engineering, and architectural engineering, for example, are extremely visual in nature, and problems with design may better expressed visually through markups and sketches than oral commentary. Audio commentary in and of itself does not aid the visual learner over written comments. Thus, while audio commentary is an improvement over written feedback, it still is not optimal. To truly reach all student learning styles, feedback to the students must also incorporate visual feedback. This has led to the concept of multimedia feedback using customized videos. With this approach, it is now possible for students to receive both oral and visual feedback in a timely fashion.

II. Multimedia Grading using Videos

Video grading uses many of the same production techniques as the inverted classroom, in that the instructor creates a video during the grading session, except that the video is customized to each student or student team based on submitted work, and the focus of the video is to provide targeted meaningful feedback rather than to introduce a new concept. This is, in some manner, more difficult than the traditional usage of videos, as the traditional usage of videos requires the instructor to carefully design the video to maximize all students' learning whereas this approach generates a customized video for each student or team.

Video grading, shown in Figure 1, starts in much the same manner as any other form of electronic grading. A student submits to an instructor an assignment in electronic format. In the software engineering field, this includes a lab report with documentation and source code for a program implementation.

- “I thought the video was interesting. It was very nice to receive more feedback than a few red words within the code. Perhaps going through the report wasn’t necessary, unless it was to answer questions being asked in it. It just seemed you were reading to me what I had written to you. Going through the code was very helpful though.” CE2810, Spring 2012
- “As per your request I just wanted to let you know that I felt the video feedback was very nice. It was really helpful to see what you thought of my code and where/how it could be improved. In particular, I didn’t even think about putting attributes static where appropriate. The only problem I can see with the video feedback is that the video files are massive! 11 megabytes when MSOE only offers us a measly 95...” CE2810, Spring 2012

Fig. 2. Sample student comment on video grading from the first course.

Instead of simply marking up the assignment with annotations, the instructor captures the markups as they are created and adds additional oral explanations.

While video grading can aid students in any assignment, in the computing area it is especially relevant. In the software engineering field, many of the deliverables from students manifest themselves as executable code. The instructor can execute the programs and capture the output, clearly showing the behavior of the system. The student, in turn, can see exactly what the instructor was marking up and hear exactly why the markups were made.

One distinct advantage of this process is that in addition to aiding visual learners, it really helps the students to see the non-linear process of assessing a submission. For example, when an instructor grades an assignment, he may refer back to a previous page if something contradictory is found later on or if a duplicated point is found. With this approach, since the student is visualizing exactly what the instructor saw when the assignment was graded, the student sees the instructor returning to the previous location and clearly can follow the reference.

III. Student Assessment of Technique

Video grading has been used in multiple courses at the Milwaukee School of Engineering since the Spring of 2012.

The first course for which video feedback was used was an embedded systems course. In this course, students created simple embedded systems in the C programming language, and demonstrated their operation on an embedded board. Deliverables for assignments consisted of C source code, build files, and a simple lab report describing the design and implementation of the program. Video feedback was tried purely on an experimental basis, and comments mainly dealt with explaining the problems of implemented source code as well as explaining the meaning of associated compiler warnings which were generated during code compilation. A brief review of the submitted reports was also provided. Students provided informal feedback to the professor through freeform e-mail messages, and overall, the comments were found to be very favorable, as is shown in Figure 2.

This initial success led to the application of the process in a software requirements course. In this course, students elicited requirements from stakeholders for a medical project. Deliverables were principally in the document format and were completed in teams of 4 to 5. Feedback from the professor mainly focused on the critique of the requirements artifacts, as well as questions addressing ambiguities found in the artifact. Unlike the first experience, there were no executable programs delivered by the students. Students found this to be a very beneficial experience, and responded very positively to the experience[14].

Simultaneously with the requirements course, the technique was applied to a course in operating systems design. In this course, students learned about the design aspects for an operating system. Deliverables for this course consisted principally of C programs and design documentation for those programs. Feedback from the professor focused on several aspects, including source code commenting, source code structure and syntax usage, debugging of source code, and ad-hoc testing of the code in a Linux virtual machine.

At the end of the course, students were asked to complete a brief survey detailing their experiences. The survey was intended to answer multiple questions about the approach. First and foremost, there was a need to know if the students watched the videos. No matter how successful they might be, if the students did not watch the videos, then they would not receive the feedback on their assignment, negating the purpose for the video grading session. This then led into an assessment of the effectiveness of the video presentations and commentary. If the students did not feel the feedback was at least equivalent to traditional feedback mechanisms, then the technique would not be successful. The final area of assessment dealt with the technical issues of video feedback, such as making certain the videos were legible and could be seen clearly, as well as were the videos of the proper length.

Overall, based on the survey results shown in Figure 3, the technique was viewed extremely favorably by the students. 86% of students indicated they watched the majority of the videos, with only 14% indicating they watched only 2 videos. While it is impossible to determine if the students were attentive to the video, the fact that they watched the videos seems to indicate they were interested in the feedback that was provided.

While the quantitative assessment provided a strong endorsement for the technique, the written comments provided by the students indicated a few areas of concern. One area students exhibited concern over was the ability to re-review the comments. With traditional paper based comments, a student can easily re-read the comments from the instructor. This process was not as easy to do with video grading, as the only way to review the commentary was to watch and listen to the video again, taking more time. Furthermore, locating a specific comment was believed to be easier with traditional paper grading, as again, a student could skim all comments until the desired comment was found.

Another area of concern expressed by students was the relationship between coverage and time. While the students stated that full coverage of a large lab might be time prohibitive, they

Question	Strongly Agree	Agree	Neutral	Disagree	Strongly Disagree
I found the video format more helpful than traditional paper-based assignment feedback.	29%	57%	7%	0%	7%
I found the audio commentary more helpful than traditional written comments.	50%	29%	14%	0%	0%
I was able to read the text on the video.	57%	36%	0%	0%	7%
I was able to clearly see what was being described in the video.	31%	62%	0%	0%	8%
I prefer video feedback to traditional feedback in computer courses.	38%	54%	0%	0%	8%
I felt that the length of the videos were:	**Way Too Short** 0%	**Too Short** 0%	**About Right** 100%	**Too Long** 0%	**Way Too Long** 0%
How many of the videos did you watch?	4 or more 57%	3 29%	2 14%	1 0%	0 0%

Fig. 3. Student survey results.

- Excluding the audio, as I see that's in the following question, the video format helps most in being able to show a test run of the assignments.
- I thought it was very insightful to hear what you were thinking as you were thinking it. Sometimes a lot of that thought process is lost when written down, so a video record helps catch that info. Additionally, it helps that we see exactly what problems you're having with running the program, if there are any.
- Easier to reread paper than go back in video.
- While hearing the feedback vs reading the feedback makes no difference to me, handwriting at times can be very hard to read. This was eliminated using the videos.
- The audio commentary has much higher potential for actual reviewing of the code than of written comments. I think a large part is the ability to be nonlinear in how the code is analyzed, as opposed to written comments on a listing having to be in order of each file. More depth can also be gone into on specific points of the code than what can be fit in the margins of a listing. The downside came from the fact that for larger labs, only a small portion of the code was really covered in the videos; however the amount of time required to go more in-depth on larger labs could be prohibitive in itself. I feel that a combination of audio and written comments, maybe with the audio focusing on higher level structural/design with more targeted written comments where required, would provide more useful feedback with larger labs.
- Would have liked them to be slightly longer on labs which contained more code
- I think they were pretty solid. They provided just the right amount of information. It was nice.
- I think in a course like operating systems, where the labs are a little more technical and have a product where we need to demonstrate something, video grading is very helpful.
- You should look into some video editing tools to help with proper compression. This would help with the issues of distributing the videos.

Fig. 4. Sample student comment on video grading from CS3841 Design of Operating Systems.

expressed a concern that in trying to fit the grading session into a short video, problems in the assignment might be missed.

IV. Comparison of Student Outcome Performance

The Design of Operating course had been taught multiple times previously by the same instructor. The lab sequence was identical in learning outcomes and the same grading rubrics were used in previous offerings of the course. Thus, it was possible to compare students' performance across the different offerings to determine the impact of video grading.

For each lab assignment, students were assessed in a number of areas using a 5 point grading rubric. While the specifics of the rubric varied between assignments, a score of "5" was defined to represent work which was fully compliant with the assessment criteria and no major or minor errors were noted. A score of "4" indicated the assessment item was mostly complete, though some minor error was detected in the work. A score of "3" indicated the work was slightly flawed, with multiple minor errors being detected during assessment. A score of "2" indicated the work had a significant flaw present which was uncovered during assessment. A score of "1" indicated the work was significantly flawed, with multiple major errors being detected during assessment. "0" indicated the item was absent and therefore could not be assessed.

Figure 5 provides a plot of student achievement on each of the laboratory assignments conducted in the Design of Operating Systems course. The chart includes the average assessments on programming and design related rubric assessments. Any assessments of writing skills or other "non-technical" aspects of the assignments were removed from the assessment to allow a focus on the core technical material of the course. It includes two control groups representing last two offerings of the course using "traditional" grading techniques as well the "experimental" course using video grading. The chart indicates that the video grading cohort tended to score lower on the first lab than the two control groups. However, the final three labs show scores higher than the two experimental groups. Furthermore, with the exception of lab 3 which was one of the two most technically challenging labs to the students in the course, the video grading class tended to improve their performance with each submitted lab.

The differences between student performance are more striking if the results are normalized to the first lab score, as is shown in Figure 5. In essence, with the exception of one of the control groups, students always scored better on the

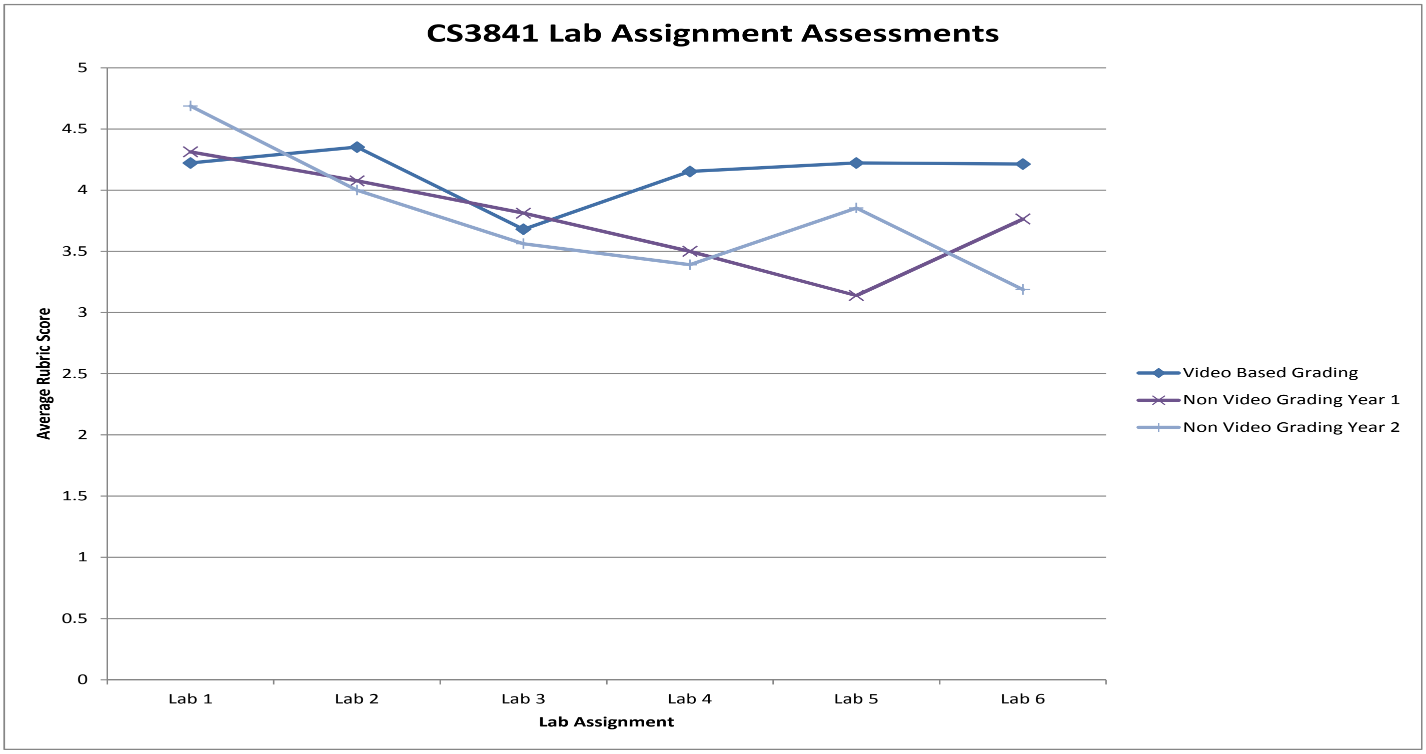

Fig. 5. Average student achievement on selected rubric assessments for operating systems labs.

lab assignments which were graded using video grading. And, whereas in the control groups, the overall student achievement on the last labs was less[1] than what was obtained on the first lab, the students in the course using video grading achieved approximately the same across all labs. This indicates that the students in the video grading course effectively performed better on the same assignments than those in the non-video grading course.

V. Impact upon the Faculty Member

A shift in technology can have significant impacts upon the faculty member. When considering a technique such as video grading, it is important to weigh the change in effort in order to apply the technology.

The first question which must be answered is does video grading require additional faculty time or does it offer a reduction in the time spent grading. Overall, it was found that video grading did not increase the time spent grading by a significant amount. Given that the operating systems design course had been taught previously and used the same sets of labs, a direct comparison could be made, normalized for the number of students. Overall, the net amount of time spent grading per student was within 5% when using video grading and traditional grading using a rubric and tablet PC to markup report submissions.

[1] While diminishing assessments like this can be disconcerting, the latter labs were significantly harder than the first lab, and thus, it is not surprising that student achievement on later labs is lower than the first lab, as there simply are more areas in which a student can make a mistake due to increased complexity.

The time spent assessing the submission was about the same as would be spent with traditional feedback mechanisms. There was an added processing component that would not be present in traditional grading dealing with generating the videos from the video capture. For an video of approximately 5 minutes, this post-processing added 3 minutes to the amount of time spent grading each assignment. However, this processing was batched and performed off-line when the professor was not present, making the recording time the limiting factor for grading.

From an anecdotal level, there did seem to be more students coming in during office hours to discuss problems with lab assignments versus previous offerings. This have been a small sign of increased student engagement in the course. However, detailed quantifiable data is not available to further quantify this impact.

VI. Conclusions and Future Work

From the data available, it is very difficult to assess causality for the performance improvement seen in the data. Based on the lab 1 assignment, which is primarily a pre-requisite assessment, it would have been assumed that the video grading group should have performed lower than previous sections, as at the start, they lacked fundamental skills. However, this trend did not occur, and the video grading course outperformed students in the other two offerings.

Part of the performance improvement may have come from students being more engaged in the course because of the video grading. As a student, it is very easy to disregard a comment from an instructor when the student is unable to

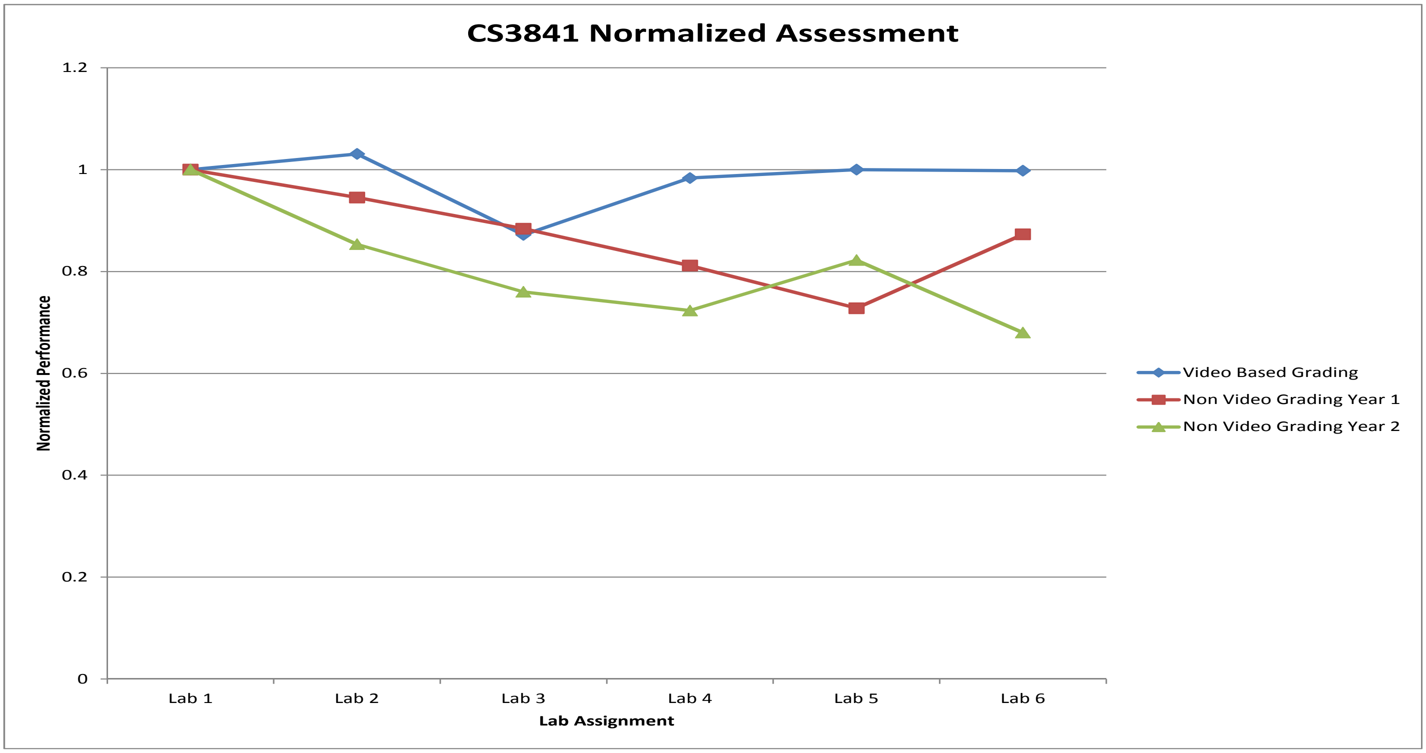

Fig. 6. Normalized student achievement on selected rubric assessments for operating systems labs.

reproduce the problem on his or her own computer. However, it is harder to disregard the problem if specific video evidence is provided showing exactly the manner in which the software behaved when provided with a set of input stimuli. This extra engagement certainly may have forced students to understand their mistakes from one lab assignment so as not to repeat them on the next assignment. This may have also contributed to the increase in office hour visits.

Students may also have had a more personal attachment to the feedback provided since it came in a video format. In traditional grading, the student only sees the final, impersonal marks on the page. With video grading, the student can hear the instructor speaking as well as see the thought process going into the assessment, improving information transfer. This in-depth understanding of thought process applied by the professor may help to elevate the student's own thought processes as the next lab is completed, again improving their performance.

There is obviously much more research to be done to assess the effectiveness of video grading. To make video grading successful, it is imperative that the results are duplicated in other larger studies. The scope of this evaluation was small (one class at one institution) and the sample size was also very limited. However, it is believed that this is an acceptable way for assessing student work that offers advantages in the digital age, especially in the computing field where assignments involve complex dynamic systems.

Once it can be determined if this technique is effective, it is important to further understand the cognitive aspects which contribute to the success of the technique. Does the student perform better because they are more engaged in the course, or do they perform better because the multi-sense feedback is more effective than traditional feedback forms? This aspect requires collaboration outside of the engineering discipline to completely explain.

One of the most important questions to answer is what type of assignment benefits the most from this form of assessment. This course focused on using the technique with simple programming exercises, but the approach could be applied to UML designs, user interface designs, and other aspects of software engineering.

It is also important to try and understand the learning styles of the students who benefit the most from video grading. It is possible that some types of students might receive a greater benefit from this approach versus traditional techniques, whereas other students might be placed at a disadvantage by using such a technique.

This technique also has vast applications to non-traditional learning. Distance education courses often are viewed as impersonal by students. A technique such as this might increase students interest in the course through asynchronous personalization of feedback. Another area of potential application is the Massive Open Online Course movement (MOOC). Due to their size, assessment in MOOCs is typically limited to automated assessments or peer assessments by fellow students. A video grading technique might increase student engagement and improve the very poor completion rates (less than 3%) for the courses[15].

VII. SUMMARY

This article has described an innovative grading technique for engineering assignments. Using this technique, assessments are returned to the students using a video capture system. In addition to seeing the assignment marked up in a dynamic fashion, students are provided with audio comments which further describe the thoughts of the instructor when grading the assignment.

Overall, the process is found to be time effective, varying by less than 5% versus traditional grading techniques. More importantly, however, students tended to achieve higher scores on assignments when video grading was employed than they did with traditional grading.

Portable Lab Modules on Cloud Computing

Peng Li
Department of Technology Systems
East Carolina University
Greenville, NC 27858
lipeng@ecu.edu

***Abstract*— Cloud computing is a highly scalable model for delivering information technology resources and applications, on demand, as a service, to end users through the network. In recent years, cloud computing has been adopted rapidly and extensively in industry. Notable public cloud services include Amazon Elastic Compute Cloud (EC2) and Google App Engine, among others. There is a fast growing demand for professionals with cloud computing skills. However, the demand is not being fulfilled, partially due to the inability of educational institutions to keep up with technological advancements, as well as a lack of hands-on educational material.**

We have been developing portable virtual lab modules which can be used to teach basic cloud computing concepts and skills early and often. The labs run on virtual machines and can be ported between different courses and between different platforms. The virtual labs can be deployed in centralized or decentralized ways. To meet the learning outcomes, the students are expected to: 1) comprehend the fundamental concepts of cloud computing; 2) identify the building blocks of cloud computing systems; 3) understand the basic operation of open source cloud infrastructures; and 4) recognize commonly used, commercial cloud computing services and applications.

Keywords—cloud computing; virtualization; virtual laboratory; online education

I. Introduction

Cloud computing has made transformative changes in Information Technology (IT) services in industry, government and education. Cloud computing is a highly scalable model for delivering IT resources and applications, on demand, as a service, to end users through the network [1]. Notable public cloud services include Amazon Elastic Compute Cloud (EC2) and Google App Engine, among others. Meanwhile, many companies and institutions have been deploying private cloud infrastructures, hosted on platforms such as Xen, KVM, OpenVZ, VMware vSphere and Microsoft Hyper-V. Cloud computing can be implemented in different ways. Therefore, there are many different cloud solutions provided by different vendors such as VMware, Citrix, Red Hat and Microsoft. The existing education material is usually designed by a particular vendor and focuses on vendor-specific technology.

There is a fast growing demand for professionals with cloud computing skills. A quick search at online job sites such as monster.com, or dice.com, will demonstrate that there are a great number of open positions for information technology professionals with cloud computing skills. It is likely that today's professionals will work in a more and more virtualized environment that requires basic cloud computing skills. Not only information technology specialists, but also professionals in science and engineering, will need some basic understanding of cloud concepts. However, there are few educational resources which cover cloud computing in a vendor-neutral way [2].

We are working on developing hands-on instructional material on cloud computing, covering the general concepts and various open source and commercial solutions. Instead of making major curriculum revisions or inserting new courses into the already crowded curriculum, we plan to develop portable lab modules which can be reused in multiple courses as supplemental projects.

II. Project Description

A. Purpose

The purpose of this project is to introduce basic cloud computing concepts to a large group of students early and often. Many virtual labs can be performed in centralized or decentralized ways [3]. In the centralized approach, the virtual lab environments are hosted on the central servers on campus, remotely accessible by students using a client program. In the decentralized approach, the students can download and run the virtual lab environments on their personal computers using a hosted hypervisor such as VMware Workstation or Oracle VirtualBox. As a result, the students will be able to conduct the labs at any place and at any time. Due to the availability of free hosted hypervisor programs such as Oracle VirtualBox, the costs of the decentralized approach are relatively low.

The tentative titles of lab modules are as follows: 1) Open Source Cloud I: Container-based Cloud; 2) Open Source Cloud II: Xen Cloud Platform; 3) Open Source Cloud III: Virtual Computing Lab; 4) Cloud Management using Red Hat Enterprise Virtualization (RHEV); 5) Exploring Amazon Elastic Compute Cloud; 6) Google Cloud Connect; 7) Microsoft Windows Azure and Hyper-V; and 8) Distributed Cloud Storage.

The lab modules are portable in that they are independent and can be used in different courses, moved between different platforms and deployed in different institutions. Since the lab modules do not depend on each other, the instructor can adopt the ones which can fit into her/his schedule.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

B. Method

The labs are to be performed on different virtual cloud environments. As shown in Fig.1, a virtual cloud environment typically contains one or more custom virtual machines and virtual networks, supported by bare-metal (native) hypervisor or hosted hypervisor. The hosted hypervisor runs on top of a conventional operating system such as Windows or Linux and supports guest virtual machines. Examples of hosted hypervisor include Oracle VirtualBox and VMware Workstation, among others. The bare-metal hypervisor is installed directly on the host physical server, controls the physical server and supports guest virtual machines. Examples of bare-metal (native) hypervisor include Xen, KVM, VMware ESXi, and Microsoft Hyper-V, among others. In Fig. 1, on the first layer of virtual machines, another layer of bare-metal (native) hypervisor or hosted hypervisor or container-capable operating system is installed to support more virtual machines, forming the building blocks of private clouds. This type of VM-inside-VM or Cloud-inside-Cloud solutions may not be efficient for real-world enterprise applications but are useful in academic teaching and research owing to its portability [4]. By setting up the hypervisor on a virtual machine, it is possible to create an image of the whole system which contains a virtual cloud environment. This image can be moved (ported) around and deployed easily on different platforms.

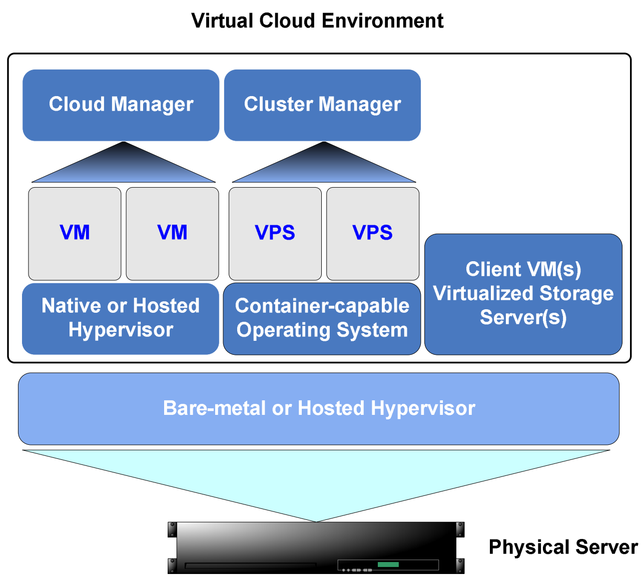

Fig. 1. A typical virtual cloud environment

The project development will follow a four-step procedure. In the first step, the outcomes and tasks of each lab are identified. For example, an outcome can be defined as so: "After this lab is completed, the students will understand the process for setting up a private cloud system using Microsoft Hyper-V." In the second step, the lab manual, the answer sheet, the virtual cloud environment, and supporting material (e.g. demonstration videos) will be developed. In the third step, the newly created lab modules will be tested and deployed. In the fourth step, the lab modules will be evaluated and adapted.

In the past few years, we have created multiple custom virtual environments and deploy them in centralized and decentralized settings. We have accumulated extensive experiences in designing virtual labs. Most of the newly created labs in this project will be hosted by a centralized cloud infrastructure including fifteen high-performance servers that were received through an equipment grant from Hewlett-Packard. Some labs can also be deployed in a decentralized manner, in which students run the virtual labs on their personal computers.

C. Assessment

To meet the learning outcomes, the students are expected to: 1) comprehend the fundamental concepts of cloud computing; 2) identify the building blocks of cloud computing systems; 3) understand the basic operation of open source cloud infrastructures; and 4) recognize commonly used, commercial cloud computing services and applications.

This project is still work in progress. To measure whether the learning outcomes are met at the end of the project, the lab reports submitted by students will be evaluated. In addition, a pre-class survey and a post-class survey will be conducted anonymously and voluntarily to assess the outcomes, the degree of interest, the degree of satisfaction with the project, the usability and the availability of the virtual cloud environments. The surveys will contain true/false, multiple choice, multiple answer and opinion scale questions.

III. Summary

The goal of this project is to design portable lab modules which can be used to introduce basic cloud computing concepts to students with various background early and often. The project is currently in the phase of developing custom virtual cloud environments. The lab modules, once completed, can be deployed independently, in decentralized and centralized manners. The students will be able to perform the labs using the virtual environments.

We believe this approach will serve the students well because 1) it provides students with multiple opportunities to learn cloud computing; 2) it does not require major changes to the curriculum and 3) it can be deployed and adjusted quickly.

Acknowledgment

This project is partially sponsored by the HP Catalyst Initiative, award number 4585086.

Functional Approaches to Teaching Concurrency

Michael J. Lutz
Rochester Institute of Technology
Rochester, NY, USA
mjl@se.rit.edu

***Abstract*—Traditional approaches to addressing issues of concurrency rely on mechanisms added to standard imperative languages such as Java, such as "synchronized" methods and blocks, combined with a "wait/notify" mechanism used to block and awaken processes when a shared resource is not in an acceptable state. The problem with this approach, however, is that mutable state is potentially accessible via many paths, and each such path must be analyzed for possible race conditions, deadlocks, and safety violations.**

The root cause of many concurrency problems is attributable to shared, mutable state. In light of this, two approaches to mitigating concurrency problems are immutable variables and state isolation within distinct concurrent actors. Erlang, a language developed at Ericsson for distributed, fault-tolerant switches, is a language supporting both approaches.

This paper reports on an experiment to include Erlang as part of an existing course on concurrent systems design. This version of the course is currently underway, and the Erlang material is being introduced as this is written. Results from the approach will be ready well before the conference, and should serve as an inspiration (or warning) to others considering such a change.

Keywords—software engineering; concurrent and distributed systems; functional languages; computing education.

I. INTRODUCTION

In simpler times, relatively few software engineers were concerned with concurrency. For the most part such concerns were restricted to those developing operating systems, networking protocols, and database transaction processing systems. The vast majority of engineers worked in the stable world of sequential processes, where program statements were executed in the order written, and where reproducibility could be assumed when diagnosing and repairing faults. While graduates of computing programs were usually exposed to concurrency issues in an operating systems or database management course, the material could be safely ignored once the final exam was over.

This is no longer the case - today's software environment is one of large-scale distributed processing, with local concurrency on multi-core computers. To increase performance in the future, developers will have to rely on explicitly concurrent and distributed computation. All of the problems that hounded the select few in the past - race conditions, deadlocks, liveness concerns, safety issues, irreproducible execution - must now be faced by the majority of software engineers.

II. THE BANE OF CONCURRENCY - SHARED, MUTABLE STATE

It is not at all obvious that traditional imperative languages, such as Java and C, are up to the challenge presented by pervasive concurrency. These languages are prone to race conditions, where a variable's value depends on the execution order of instructions in independent concurrent entities (threads, processes, tasks). For example, it is a trivial (and enlightening) exercise to create race conditions in Java on a multicore system - simply have two or more independent threads increment a public shared variable one million times. Even if the variable is declared **volatile** - as a hedge against memory caching inconsistencies - interleaved instructions almost always results in a final value much less than expected.

Imperative languages typically address this problem by providing a locking mechanism to ensure mutually exclusive access to shared, mutable state. Sometimes this is built into the language: Java supports **synchronized** methods and blocks to lock an object, as well as **wait** and **notify** to synchronize on the object's state [1]. C provides similar functionality in the POSIX Pthreads library [2] via semaphores and condition variables. These mechanisms, based on classic work of Dijkstra [3] and Hoare [4], are sufficient to address concurrency issues. Unfortunately, they are also prone to erroneous use.

Thus, even with this support, it is difficult to design and implement thread-safe components and systems. This is especially true when the increased performance is the primary motivation for concurrency. For safety, exclusive access is required when manipulating mutable state. For performance, the locking to ensure exclusion must not be too conservative. What is more, reasoning about the paths through which unexpected state conflicts may arise is especially difficult under concurrency. It is part of the Java concurrency community's lore that most Java programs are only accidentally thread safe - to date. Catastrophic synchronization errors can remain hidden for months or years until triggered by just the right combination of concurrent activity [5].

III. FUNCTIONAL LANGUAGES - A WAY OUT?

If concurrency problems are exacerbated by simultaneous attempts to alter shared, mutable state, two alternatives become apparent: eliminate mutable state and/or eliminate sharing.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Emphasizing immutability has been the province of functional languages, beginning with LISP [6] and continuing up to modern successors such as Clojure [7] and Haskell [8]. While unfamiliar to many software developers, after decades of development these languages appear poised to challenge conventional wisdom that only imperative languages provide the flexibility and performance required by modern applications. Not only do compilers for these languages generate code competitive with those for C, Java, etc., they also model a world of pure values, along with functions to transform them. Without mutable variables, function side-effects are impossible and common sources of race conditions eliminated.

Actor languages [9] address sharing by encapsulating any mutable state in an active actor process (or thread). Actors receive serialized requests for service; since requests themselves are normally immutable, and only the actor can change its internal state, data races among requestors are eliminated.

Some emerging languages, such as Scala [10] and Erlang [11], provide linguistic support for both immutable state and actor based concurrency. Advocates for these languages argue that by eliminating shared, mutable state, these systems enable simpler designs and more easily verified construction of concurrent and distributed systems. It is not that deadlock, livelock, etc. magically disappear, but they become less likely and easier to discover, diagnose and repair.

What is more, proponents argue, functional languages scale better in an age of multicore processors and pervasive hardware caching. Ericsson used Erlang, for instance, to create highly reliable, distributed telephony switches based on Erlang's "inexpensive process" model. The YAWS web server, written in Erlang, continues to provide service well beyond a load that causes a traditional Apache server to die [12]. In large measure this is due to the pervasive (not to say profligate) use of Erlang processes, whose low overhead is largely attributable to immutable state.

Over the past several years, I have become convinced that there is at least a grain of truth to the claims of functional language supporters. In any event, given the rise commercial systems using this technology, such as GitHub [12] and Twitter [13], as well as open-source databases like CouchDB [14], it is time software engineering programs acknowledge these developments in their courses.

IV. THE EXPERIMENT

This spring, I am using both Java and Erlang in the department's course on *Principles of Concurrent System Design*. As it turns out, this spring quarter has proven ideal for this experiment:

1. I am teaching the one and only section of the course (thus there is no need to coordinate with other course sections).
2. This is the final course offering, as in the fall of 2013 RIT is moving from quarters to semesters. This last offering serves as a "stalking horse" for the organization of a new semester course covering concurrent and distributed systems.
3. Only eight students are enrolled, making it easier to address issues that inevitably arise when undertaking such experiments.

What could possibly go wrong? Well, two significant risks come to mind.

First, students may spend so much time mastering Erlang as a technology that they have no time left to learn how to apply it functional approaches effectively. Second, unless we are careful, students may fail to understand how Erlang's approach differs from that of Java (with which they are most familiar). The first problem may be alleviated by intelligent use of on-line materials and in-class exercises; for the second, I plan to assign problems where the solutions in Java and Erlang are significantly different.

It could be argued that Scala, with its surface similarity to Java, would be a better vehicle for the experiment. So why was Erlang selected?

First, the similarities between Java and Scala, once one gets past the curly braces, are deceiving. Scala is a large, flexible language that embodies the concepts of "class" and "object" in novel ways. The sheer size of Scala and its libraries threatened to overwhelm presentation of concepts.

Second, Erlang has a radically different concrete syntax, and uses a Prolog-like matching mechanism to disambiguate different invocations of a given function. There is little chance that students will "write Java code in Erlang."

Third, Erlang's processes are orthogonal to any operating system thread support. As mentioned above, this makes the use of processes (and attendant concurrency) the natural way to partition Erlang computations; there is no way to avoid processes when using Erlang.

Finally, processes can only interact by sending and receiving asynchronous messages. Message passing nicely complements shared memory access in Java.

V. COURSE OUTLINE

The course comprises two modules. The first four weeks are devoted to traditional, state-based concurrency with Java - to do otherwise would be an injustice to those students who will work with imperative languages after graduation. In addition to small in-class activities, teams of four each develop a concurrent game in Java.

The remaining six weeks are devoted to concurrency and basic distributed processing using Erlang. The initial plan is to devote a week and a half to the sequential, functional subset of Erlang, followed by two and a half weeks on Erlang for concurrent and distributed systems. The final two weeks will use Erlang as a vehicle to discuss both classic problems in concurrent and distributed systems (e.g., Dining Philosophers) as well as pragmatic issues of performance, load balancing, etc. In addition, the teams will design and construct a concurrent application with Erlang.

As of the date this paper was submitted, the Java module is over and students are completing the sequential Erlang component. So far, concerns about student ability to come up to speed with a functional language have proven largely unfounded. The next few weeks will determine whether or not the class is able to work effectively in the Erlang environment and create interesting concurrent (or distributed) applications.

VI. Initial Submission Conclusions

My expectation is that students will, on the whole, come to grips with the concepts of functional concurrent development, and amaze me with their projects. I certainly hope so - otherwise the department will have to reconsider the use of Erlang (or any other functional, actor-based system) in the new semester course.

The theory (or hope) is that both state-based and immutable, function-oriented concurrency can be covered in the new course. Come FIE in the fall, we'll know.

VII. Post-Course Conclusions

My expectations were, if anything, exceeded. Indeed, the final class of seven students was enthusiastic about learning both the functional approach Erlang promotes as well as using Erlang to build concurrent and distributed systems.

After a series of in-class activities and homework problems, the class asked to work on a final project (of about two weeks duration) as a single group. While our software engineering program emphasizes teamwork and team-based projects, usually the team size is restricted to three or four students. However, after I told them I'd expect a project at least twice as ambitious as I would for two smaller teams, I allowed the class to proceed as a single team.

In the end, they created a distributed, extensible, multi-user game based on the old *Adventure* game from the 70s and 80s. I was more than happy with the text command approach, as it kept the focus on design incorporating both concurrency and distribution, as well as on the intelligent use of Erlang's data types and process structuring mechanisms. The demonstration on the final day was awe-inspiring, as was the final product. What's more, while individual contributions varied, it was clear from the documentation and version control logs that every team member made a significant contribution.

As to acceptance of Erlang, I asked the class for their opinion as to whether Erlang (or a similar functional language) should be incorporated into the semester version of the concurrent and distributed systems course. The vote was unanimous in favor of retaining Erlang. As one student put it:

> We've been using Java for years, so the concurrency constructs in the end were just a simple increment. Erlang forces you to think about both problem solving and concurrency in a radically different way, and made it valuable.

In summary, the combination of Java's traditional concurrency control via locks and conditions with the functional approach of Erlang and its preference for message based interaction seems to have given student's a deeper understanding of the issues raised by concurrency. Based on this experiment, we are comfortable with the decision to continue teaching both approaches as an integral part of the new semester course.

Using an Embroidery Machine to Achieve a Deeper Understanding of Electromechanical Applications

Irene Rothe, Andrea Schwandt
Dept. of Electrical Engineering, Mechanical Engineering and Technical Journalism
Bonn-Rhine-Sieg University of Applied Sciences
Sankt Augustin, Germany
irene.rothe@h-brs.de, andrea.schwandt@h-brs.de

***Abstract*—Understanding the functionality of real-world machines and thinking about their improvements is a method to deepen the acquired knowledge of electrical and mechanical engineering students. The Department of Electrical Engineering, Mechanical Engineering and Technical Journalism of the Bonn-Rhine-Sieg University of Applied Sciences in Germany provides a project-based learning environment in the so-called "project weeks". Three weeks of a term are available to do some real-world projects besides the regular courses [1]. This provides a "project-based" learning environment that enables the students to connect theory and practice and to apply knowledge and skills to solve practical problems. In the winter term 2012/13 an unusual open-defined project was offered for the first time to third-semester students showing high potentials. The students were presented with an unknown embroidery machine and their task was to improve it, depending on their knowledge and abilities.**

This article describes a project in which an embroidery machine was used as a basis for developing better understanding of many aspects of electrical and mechanical engineering.

Keywords—embroidery machine, microcontroller, programming, project management

I. Introduction

Undergraduate students of electrical and mechanical engineering have to learn lots of different subjects like mathematics, computer sciences, microcontrollers, principles of electrical engineering, measurement engineering and others. To achieve a deep understanding and to see the connection between all of these different areas, students need to apply and improve their knowledge (obtained so far by theoretical lectures) on electrical and mechanical applications of the real world.

The department of Electrical Engineering, Mechanical Engineering and Technical Journalism provides a project-based learning environment in the so-called "project weeks". Three weeks of a term are available for projects besides the regular courses [1]. This provides a "project-based" or "problem-based" learning **Error! Reference source not found.** which enables students to connect theory and practice and apply knowledge and skills to solve problems. Creativity and soft skills can be trained. The projects from which the students can choose are artificial ones and real ones.

This article describes a very open-defined project of the winter term 2012/13 which was offered to third semester students. They were confronted with an embroidery machine and the task to improve it in whatever ideas they had depending on their knowledge and abilities. Section II describes the motivation for using an embroidery machine and how the three weeks were prepared and organized in front. Section III describes the realization of the project. Section IV will give an outlook and Section V discusses the evaluation of the project.

II. Motivation for Using an Embroidery Machine as a Tool in a Problem-Based Project

The project weeks at the Bonn-Rhine-Sieg University in Germany (BRSU) are a good possibility for students to apply their knowledge already obtained in lectures and hands-on labs of previous terms. Some of the offered projects have very specific goals, others are more open because the subject is very new and/or it runs the first time and no experiences exist for the teachers. These are some kind of little research projects.

How did the idea of using an embroidery machine come up? The two authors (one professor and one research associate) are big fans of sewing, stitching and other kinds of crafts. So, it seemed kind of naturally that one day the idea would come up to use a programmable embroidery machine as a topic for a project. It also would make a contrast to most of the other projects dealing with automobiles or robots. As described in [2], an embroidery machine includes many aspects electrical and mechanical engineering students get taught during their study and it fits perfectly the requirements of the project weeks at the BRSU. Additionally, a very happy event occurred, the IVC (Institute of Visual Computing) at our university offered to support our idea by offering the money for the machine.

A. Preparation

The preparation started by searching for an embroidery machine which would meet the requirements and would have a reasonable price. The decision for a Brother machine of type Innov-is 950 was made.

This machine is a sophisticated embedded system with high precision, automated stitching control and a touch-screen interface.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The main goal was set up by the authors: The students should improve the unknown embroidery machine in different pre-defined ways (defined by the authors, like stitching arbitrary pictures obtained by photos). The authors have to make clear to the students that it is mandatory to have some promising beginnings or even results within the team at the end of the three weeks in order to obtain a project success. The students have to discuss carefully all together possible ways to go.

The following project tasks were defined by the authors:

- Apply known methods from software/project engineering
- Understand the mechanism of the embroidery machine
- Document all newly obtained technical expertise
- Do a detailed investigation in the literature and on the internet to find out if similar things were done before by others.

B. Skills to be Taught in the Project Weeks

During the project weeks the students should reach the following learning goals with respect to the curriculum of the university for the project weeks. They should:

- Organize themselves as a team including choosing a team leader,
- Develop a project plan,
- Experience self-directed learning,
- Establish team meetings and define milestones,
- Apply knowledge obtained in lectures of previous terms, and
- Write a project documentation and prepare a presentation.

The last day of the last project week is saved for the presentation. The students summarize their results and evaluate their work.

The supervisors (the two authors) give feedback during the whole project, help with problems, make sure the team is able to work and check the documentation regularly.

III. First Results of the Project

Projects are organized in small groups at BRSU, normally including 15 students. They are supervised by one professor and a resaearch associate of the faculty. Because of the innovation of the project the authors decided to keep the team a little bit smaller then usually, so only 8 students could assign to this project.

Figure 2: Promotion and logo for the project

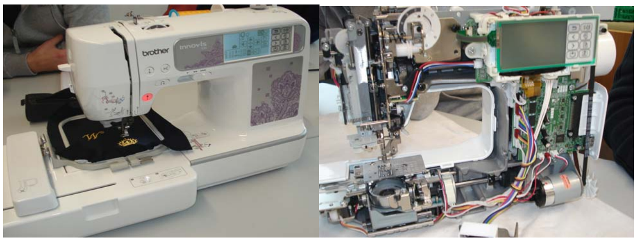

Figure 3: Brother embroidery machine, disassembled (right)

A. First Week

A lecture was held on the first day of the first project week. The authors gave information about team work (project organization methods like SCRUM and tools), goals and tasks for each of the three project weeks.

On the second day, the team was left alone. Only after half a day, the team made the request to be allowed to disassemble the machine in order to understand its mechanism. Of course, this was allowed by the supervisors.

The team started to prioritize possible ideas for improvement of the machine (given by the authors) and put them into two categories nice to have and realistic to do. They divided their group into sub teams, selected a team leader and assigned tasks to each of the sub-teams.

During the first week the students understood and documented the mechanism of the stitching process. At the end of this week they came up with the idea to build and program their own motor control systems: motor control for moving the stitching frame and for the needle itself. In this way they could bypass the software embedded in the machine which seemed to be in no way accessible to them. The authors discussed this direction and decided to give up the idea of going into the software and follow the path proposed by the students instead. Because of the open-defined project this was alright and not such a big surprise. So, the authors put together a list of needed technical things to be ordered for use in the second week.

B. Second Week

The authors used the time in-between the first two project weeks to check the documentation, and gave their feedback at the first day of the second project week. Mostly, this included comments about better understanding or missing descriptions.

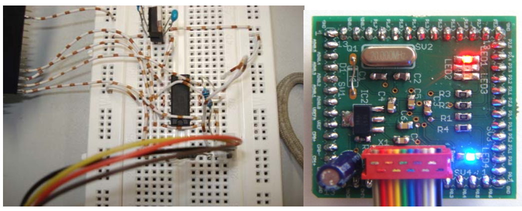

Figure 4: Development board of motor control for moving the stitching frame (left), "BRSU plug-in board" (right)

To build their own motor control systems, the students started with the installation of a microcontroller on a development board and connected it to the stepper for moving the stitching frame of the embroidery machine.

From previous lectures (by the authors and other members of the faculty) they knew the microcontroller C8051F021 from Silicon Labs used on a BRSU-developed board, the so-called "BRSU-evaluation system" including the "BRSU plug-in board" **Error! Reference source not found.**. The students implemented a program in the programming language C to control the motor of the embroidery machine responsible for moving in x- and y-direction for creating a stitching pattern/image. In this phase the teaching assistant worked close with the students to help and support them.

C. Third Week

The last week was used to improve and to eliminate bugs of the motor control for moving the stitching frame. Additionally, the students started to build a development board to control the motor responsible for the needle movements, which is an analog controlled one. The students decided to work with a PWM (pulse width modulation) circuit.

They also finalized their documentation and worked on the presentation to be presented by their team leader at the last day of the third week in front of the authors and the whole group.

I. POSSIBLE FURTHER ENHANCEMENTS

Using the project documentation future student teams in upcoming project weeks can go on understanding the machine even better and work on improving the machine, like:

- Improve the motor control responsible for moving the stitching frame.
- Understand the embedded software.

It seems that a wide range of further projects is possible using the first steps made in this initial project.

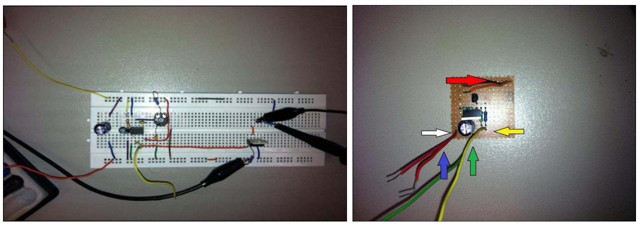

Figure 5: Development board of the student's motor control for the needle (left), final board (right)

IV. EVALUATION

The student's feedback was collected by the authors at the end of the third week by asking questions like:

- Did you obtain new technical understanding?
- Was the project too difficult or too easy for you?
- Did you obtain experiences in project organization, management and team work?
- How did you feel about the very open-defined project goals?

The students reported that they learned new technical knowledge as well as team working skills. Further, they reported that they were able to make good use of the theoretical lectures of the two previous terms. However, all students complained having only one machine to do testing and understanding the mechanism was not enough. They further reported that they would have liked more specified engineering tasks to investigate at the beginning of the project but, on the other hand, claimed that the openly designed project had also its advantages like fitting the tasks better to the real existing abilities of the group. They all summarized that only three weeks are not enough to really follow up all the ideas they had.

V. SUMMARY

A major concern of the Department of Electrical Engineering, Mechanical Engineering and Technical Journalism of the Bonn-Rhine-Sieg University is to provide its students the opportunity to work on real-world problems. Therefore, our department has introduced three project weeks per semester.

In the winter term 2012/13, an open-defined project was offered for third-term students for the first time by a professor and a research associate. The students were confronted with an embroidery machine. Their task was to understand the machine and to improve it depending on their abilities with support from the supervisors.

The embroidery machine as a small and compact device turned out to provide many different electromechanical aspects and was a good tool to be used as a main focus for students during practically project weeks.

ACKNOWLEDGMENT

The authors would like to thank their students who made the project so successful, the whole engineering department who helped to install the project and the IVC (Institute of Visual Computing at BRSU) for supporting it.

Pedagogical Analysis and Multifaceted Evaluation of an Engineering Co-op Program

Suleyman Uludag*†, M. Fatih Demirci*, Erdogan Dogdu* and Fahri Aydos*

***Abstract*—The ever-increasing complexity and challenges of the higher education coupled with more public scrutiny for its efficacy necessitate more in depth analysis and evaluation of the educational best practices. One such practice is the cooperative (co-op) education. While co-op education has been around for more than a century, its implementation is still barely more than nominal in higher education. Even though there are studies published to demonstrate its effectiveness, more in depth studies, both spatial and temporal, seem to be warranted to narrow the widening gap between students' jobs-first and institutions' intellectual-experience-first expectations. In this paper, we summarize the first and highly successful co-op program in Turkey at TOBB University of Economics and Technology (TOBB ETU). Our analysis include a taxonomy of different co-op programs to contextualize TOBB ETU's. Further, we touch upon the theoretical underpinnings from a variety of generally accepted foundational work. As part of the evaluation of the program, we provide a preliminary assessment of a longitudinal study as the first from Turkey and one of a very few from the non-US, international institutions. We believe that ours is the first to report an evaluation of co-op programs in terms of pre-co-op, post-co-op and graduated students *separately*.**

I. INTRODUCTION

As part of the increased focus on the efforts to assess student learning outcomes in higher education, different forms of learning are also gaining attention. Figure 1 shows a high-

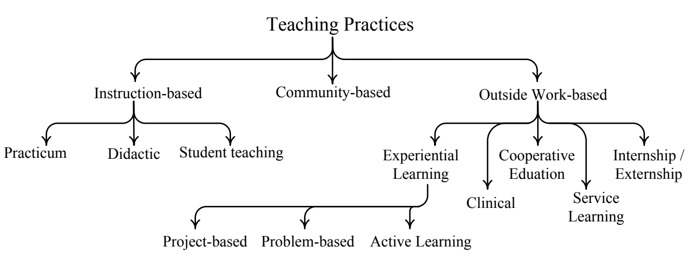

Fig. 1: A high-level taxonomy of teaching strategies in higher education for improved learning.

level taxonomy for various different teaching strategies and techniques that may be employed by instructors to increase student learning and retention[1]. The focus of this paper is on reporting the results of a preliminary assessment of the first cooperative education program in Turkey adopted by the TOBB University of Economics and Technology (TOBB ETU) for the past ten years. We note that this is the first of a set of longitudinal studies to assess the TOBB ETU co-op program from multiple perspectives. Even though there are some studies published to demonstrate the effectiveness of co-op education, as detailed in Section III-A, more in depth studies, both spatial and temporal, seem to be warranted to narrow the widening gap between students' (jobs first then intellectual development) and institutions' (intellectual and social experience first then jobs) expectations, as recently reported in 2012 Freshman Survey by the Cooperative Institutional Research Program [1] of UCLA. Similar divide between student expectation and university offering in terms of intellectual and social experience has also been highlighted by Salman Khan of the Khan Academy [2]. He states that students with co-op program experience graduate with a more expansive world view and more maturity. However, there is still resistance, as self-evident from the very low percentage of universities offering co-op education[2], to co-op education as a legitimate component of academic learning techniques and more validation efforts, as reported in this paper, are needed.

While we included co-op education separate from experiential learning in Figure 1, some experts consider the former as a form of the latter. The term experiential learning is usually attributed to David A. Kolb [5], who has formulated it in terms of the Kurt Lewin's model of action research [6], John Dewey's model of learning [7], Piaget's model of learning and cognitive development [8]. Kolb defines learning in [5] as "*the process whereby knowledge is created through the transformation of experience. Knowledge results from the combination of grasping and transforming experience*". His Experiential Learning Theory (ELT) models the learning process as a closed loop consisting of four, interconnected stages; active experimentation, concrete experience, reflective observation, and abstract conceptualization, as shown in Figure 2 [9].

It is not surprising then, from the emphasis Kolb's ELT puts on experience for learning, that some consider co-op education as a form of experiential learning. Yet, there is no conclusive evidence to show that all four stages of the ELT is manifest in a typical co-op education. A goal of this study is to seek some preliminary answers to this open question as well.

[1]While it is outside of the scope of this paper to get into the details of each item in Figure 1, we use it to contextualize our study.

[2]It is not easy to find the exact percentage of the universities offering a co-op program. If one were to look at the only co-op international professional organization WACE's (The World Council and Assembly on Cooperative Education) list [3] of universities with co-op education, there are only 50 for the US out of 4,495 Title IV-eligible institutions [4] of higher education, the low ratio, and, hence resistance for wider practice can be clearly seen.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

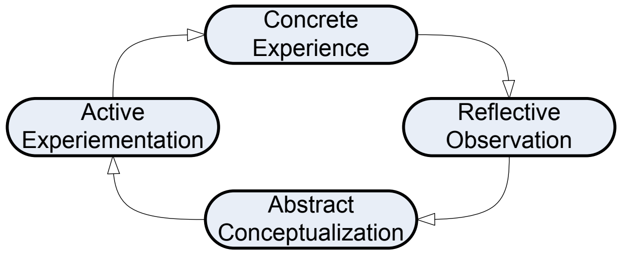

Fig. 2: Kolb's closed loop of Experiential Learning Theory model.

Cooperative education may be defined as the application of the classroom theoretical knowledge in a real-world workplace setting during the program of a college degree. While co-op education has been around for more than a century, its implementation is still barely more than nominal in higher education both in the US and worldwide. In this paper, we summarize the first and highly successful co-op program in Turkey at TOBB ETU. As part of the evaluation of the program, we provide survey results from pre-co-op, post co-op and graduated students[3]. A through statistical analysis of the survey data is presented to assess the co-op program from different perspectives. Such a longitudinal study seems to be missing in the literature both for the US institutions, where co-op programs originated, and for the international universities. We note that this paper presents what we term as a prelude to a longer-term longitudinal study to assess the overall success of the first co-op program in Turkey that can provide important clues and insight to the universities worldwide.

The rest of this paper is organized as follows: Section II delves into the pedagogical and theoretical underpinnings of co-op education. A taxonomy of co-op education programs as implemented by universities across the globe is presented in Section III together with the related work. Section IV summarizes TOBB ETU's co-op program details. Survey results, their analyses and a discussion are provided in Section V. Concluding remarks and synopsis of future work are given in Section VI.

II. Pedagogical Framework for Co-op

First, we provide a brief summary of the recent developments and trends of college students and the employers who are hiring college graduates. Priority of incoming college students is dominated by job-related reasons and financial concerns after graduation with unprecedented percentages (close to 90%) according to the UCLA's 2012 Freshman Survey [1]. Further, students are increasingly more dissatisfied with the didactic style of teaching and would like to be actively involved, self-directed, and responsible for their own learning [10]. The industry is reporting with more frequency that the recent college graduates are deficient in communication skills, ability to work in teams, flexibility, ability to accept ambiguity comfortably, ability to work with people with diverse backgrounds, understanding globalization, and ethics [11]. Employers are demanding skills not developed in schools [10].

In light of these observations, co-op education seems to be well poised to address most of these student and industry concerns. Even though there are studies published to demonstrate its effectiveness, more in depth studies, both spatial and temporal, seem to be warranted to better align the concerns of the higher education institutions, students and the employers with respect to the co-op programs. At the same time, there has been a significant resistance and skepticism against co-op education, as evident with very low percentage of institutions offering one[2], even by the faculty of the institutions adopting the co-op education. More validation and assessment efforts are thus needed.

In the following subsections, we briefly summarize the pertinent pedagogical theory behind the co-op education to delineate its academic rationale. A synopsis of the benefits of different stakeholders is also provided.

A. Theoretical Background

As we have discussed in Section I, Jean Piaget's landmark work on cognitive theory (humans as active processors of information around them) [8] has been the basis of the most of the theoretical work on co-op education. Another foundational work that is cited by all the theoretical models to explain co-op education is the philosophy of John Dewey's [7] that education and learning are social and interactive processes. Dewey's work is considered to be central to any discussion of experiential learning and co-op education.

Kolb [5], as noted in Section I, is the developer of the experiential learning concept. With his emphasis on experience, the connection to co-op education is clear.

Sternberg and Wagner's theory [12] about *Practical Intelligence* (PI) is another building block of the co-op education's pedagogical framework. They postulate that PI is what enables us to acquire practical skills. Thereby, they provide a broader conceptualization of intelligence than traditional intelligence and standardized tests. Thus, they draw attention to the importance of intelligence not only in schools but in everyday life, including both job-related and domestic settings. In Jean Lave's Situated Learning Theory, it is the human social activity that yields learning [13]. Learners participate as newcomers in communities of practitioners in acquisition of knowledge. Finally it is also noteworthy to mention the organizational framework developed in [11] that categorizes educational impact of work-related experience on student learning into three nested domains: Single-work experience, entire college experience and schooling in general contexts.

B. Benefits of Co-op Education

The benefits accrued as a result of co-op education may be analyzed in terms of the four major stakeholders of the process:

[3]As part of our ongoing work, we are in the process of surveying other university students without co-op programs, employers of our co-op program, university administration and engineering faculty members.

1) Student Benefits [14]-[19]: Practical real-world and career-related experience, enhancing and reinforcing academic learning, exposure to specialized facilities, test driving career goals, increasing self-confidence, effective networking opportunities, employability, documented work experience, interdisciplinary experience from the workplace, starting salary, more responsible jobs, reducing the college education price tag, increased disciplined thinking, improved learning, taking responsibility for learning, learning how to learn, improved problem solving and analytical thinking, improved performance in the classroom, increased GPA, and increased commitment to educational goals.
2) Employer Benefits [20], [14] : Hiring more motivated new employees, improving the corporate image, saving on the cost of operation, forming a more dynamic work environment, coming up with a pool for career recruitment, establishing university connections, low cost recruiting with less steeper learning curve for the hires, research link, and fresh ideas from the universities.
3) Institution (university) Benefits [14]: Easier job placement of students after graduation, enhanced relationships with industry, curriculum development, staff development, fresh ideas from industry via co-op students, and potential for research and other collaborations.
4) Faculty Benefits [14] [16]: Research collaboration opportunities, funding possibilities, potential to update teaching style and repertoire to stay relevant and current, enriching the classroom from the fresh ideas brought from the workplace, and opportunity for program assessment, such as for ABET.

It is quite likely that there are direct and indirect benefits to the economy and society. However, these are difficult to quantify and have not been reported in the literature.

III. Related Work and Taxonomy

A. Related Work

The first study published about co-op education [21] states that there is strong evidence that the co-op program is an educational strategy of considerable merit. National Research Council's (NRC) Panel on Technology Education [22] concludes that co-op contributes significantly to the career preparation of students and recommends expansion of co-op education. Positive impact of co-op programs on self-esteem, autonomy, sense of purpose and interpersonal relationships of participating students is presented in [10]. An assessment of a co-op program in Computer Science is reported in [23]. The positive impact of co-op programs on GPA, length at school, starting salary, reduced job search time and development of soft skills is provided in [24]. A satisfactory implementation of an unstructured but inexpensive program in Finland is detailed in [25]. The assessment of co-op program benefits to employers is conducted in [26] with the conclusion that cooperative education is beneficial to companies that support it. Rationale for co-op education in Computer Science without an assessment is given in [16].

Distinguishing characteristics and areas of our contributions are as follows: There are limited number of survey-based assessment reports published in the literature. Ours adds a valuable and recent contribution to the assessment of co-op programs. To the best of our knowledge, the majority of the co-op program assessments are from the US institutions with some Canadian universities. We report a preliminary assessment of a longitudinal study as the first from Turkey and one of a very few from the non-US, international institutions. To the best of our knowledge, ours is the first to report an assessment of co-op programs from students' perspective who have not started any co-op yet, who have done at least one and who have graduated ***separately***.

B. Co-op Education Taxonomy

Since the first co-op program was initiated at the University of Cincinnati in 1906 by Herman Schneider, a number of operational options has emerged for its implementation [27]. Figure 3 shows a simple classification of the co-op program options in terms of operational decision parameters.

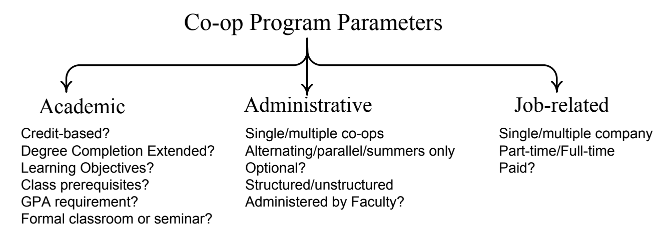

Fig. 3: A simple taxonomy of co-op program implementations.

IV. Co-op at TOBB ETU

TOBB ETU is established in 2003 in the capital city of Ankara, Turkey and started to take its first students in the 2004-2005 academic year. The university has grown in the last ten years to six colleges (Engineering, Medicine, Economics and Administrative Sciences, Science and Letters, Fine Arts, and Law) and about 30 departments. The total undergraduate student body is a little over 3500 students, and there are about 430 graduate students in M.Sc. and Ph.D. programs. Full time faculty members are about 250 and the school has around 120 staff members.

Engineering school is founded with Computer Engineering Department, Electrical and Electronics Engineering Department, Industrial Engineering Department, Mechanical Engineering Department and recently added Biomedical Engineering Department and Material Science and Nanotechnology Engineering Department to its body. Established engineering departments accept a strict 80 undergraduate students each year and the new departments take 20 to 40 students via a nationwide national university entrance examination. All engineering departments attract very successful high school graduates in the top 1% as full-scholarship students (no tuition, monthly stipend). About half of the students have some form of scholarship like no tuition, reduced tuition, etc.

TABLE I: Co-op terms in a typical curriculum for TOBB ETU students.

Year	Fall Semester	Spring Semester	Summer Semester	August
1st	1/1	1/2	2/1	Off
2nd	2/2	3/1	Co-Op	Off
3rd	3/2	Co-Op	4/1	Off
4th	Co-Op	4/2	-	-

TOBB ETU is a foundation university, and is established and supported by the Union of Chambers and Commodity Exchanges of Turkey (TOBB)[4], the largest non-governmental business organization in Turkey with branches all over the country and with a total membership of more than 1.3 million enterprises. Due to the strong relationship with the business world in Turkey, the founding organization TOBB established the university with the aim of building a strong university-industry relationship. For this purpose, the university chose the co-op model from its start as a mandatory part of the education. All programs are required to participate and all students are required to participate in order to graduate. The current 4-year programs follow the schedule in Table I with 8 in-school education semesters and 3 in-industry full-time internship, therefore a total 11 semesters in 4 years. Each semester is 3.5 months long. Due to the time-compressed schedule, in-school education semesters are tight with more lecture hours. For example, 3-credit courses have 4 hour lectures a week for 6 weeks and 3 hour lectures for the remaining 6 week, a total of 42 hour lectures in a semester. Due to the programming difficulties some lectures are done on Saturdays and some out of class exams are scheduled for evening and weekend hours. There are also less holiday time in between semesters and during the summer. This is the only school-wide co-op program among Turkish universities with such a heavy schedule.

The co-op program is executed by an administrative office at the university in co-operation with the schools and faculty. The office maintains a large list of co-op enterprises, currently more than 1200. Students who are scheduled to go to the co-op term enter their company preferences in a web-based information system. Companies can view students' CVs, can schedule an interview with them and select the students who requested a co-op with them based on their qualifications. A faculty member visits the location where the student is working at least once during the co-op term. At the end of the co-op term students are required to write a detailed report about the company and the institution where they worked, the work they have done, and their experiences. The company evaluates the student using a standard evaluation form. The student report and the company evaluation form are returned to the student's department and the student advisors evaluate the reports and the company evaluation forms of the students. All returning students are required to present their work in 20 minutes in front of other co-op students and the faculty in one of the presentation sessions. All other students can also attend the presentations. The faculty advisors at the end of this evaluation process enter a Pass/Fail grade for the students. Student who did not do satisfactory work and received low evaluation points from the company are required to repeat the co-op term. Students who did not submit satisfactory reports are required to re-write their reports upon the request of the faculty advisors.

[4]http://tobb.org.tr.

V. Methodology and Evaluation

In order to evaluate the co-op program at TOBB ETU, we grouped students into three different categories and asked them different survey questions. These categories are formed by students who have not yet attended to any co-op (Group 1), students who have participated in at least one co-op and still continue their education (Group 2), and alumni (Group 3). Since co-op is mandatory at TOBB ETU, Group 3 students have completed all three co-ops successfully before graduating.

Since the co-op terms start from the third year, students in Group 1 consists of freshman and sophomore. Table II presents the survey questions of this group.

TABLE II: Survey questions for Group 1 students, who have not done any co-op yet

Q1. I was familiar with the co-op program at TOBB ETU before coming here.
Q2. The co-op program played a significant role in choosing TOBB ETU
Q3. The co-op experience will increase my chance of finding a better job after graduation
Q4. I believe that I will benefit from Coop Education
Q5. I have to study harder in order to show what I know during my co-op.
Q6. I would still participate in all three co-ops even if they were optional
Q7. Reduced holiday time did not have an effect on my decision to study at TOBB ETU.

After students complete at least one co-op term, we wanted to see how the co-op experience meets their expectations and if they still think they will benefit from this program. Table III shows all survey questions for Group 2.

After students graduate, we wanted to record if they $really$ benefited from the co-op program. TOBB ETU had its first graduates at the end of 2007-08 academic year and we contacted them through the alumni office, which keeps the contact information for most students graduated so far. While some of these graduated students are currently enrolled in M.Sc. and Ph.D. programs at TOBB ETU for graduate studies, most of them work outside (in academia or industry). Our questions for this group are presented in Table IV.

The number of participants in groups 1, 2, and 3 is recorded as 187, 64, and 314, respectively. Surveys are done anonymously, the respondents are not asked about their identity. They are asked about their gender though, and the male and female distributions are 53% and 47% for Group 1, 89% and 11% for Group 2, and 61% and 39% for Group 3 respectively.

Q1. I have been exposed to real-world problems through the co-op program in my field of study that would have been impossible with only in-class college experience
Q2. The co-op experience has broadened my professional perspective and practical problem solving skills.
Q3. My co-op experience helped me see some of my academic deficiency areas
Q4. I started taking my studies more seriously and studying harder as a result of the co-op experience
Q5. My contribution to classes in terms of questions, comments, or interactions with professors increased after the co-op experience
Q6. I felt that I need to take better advantage of the educational opportunities at school after the co-op experience
Q7. My co-op experience helped me deal with class term projects more effectively in terms of ideas and producing better quality work
Q8. Based on my co-op experience so far, the co-op is likely to increase my overall academic success
Q9. The co-op experience increased my self-confidence
Q10. As a result of your co-op program, I am able to relate class material to the real world problems and developments better
Q11. I feel academically more mature after the co-op experience
Q12. 14. I expect that my co-op experience will reduce my job search time after graduation
Q13. My soft skills (communication, presentation, group work, interpersonal relationships) improved after the co-op experience
Q14. I started taking more proactive role in deciding what elective courses, independent studies and/or research (seminar) courses I should take after the co-op program
Q15. Overall, my co-op program enhanced and reinforced my learning as part of the college experience
Q16. My co-op experience was helpful in discovering my areas of academic and/or professional interests
Q17. Overall, I believe that I will benefit from Coop Education

TABLE III: Survey questions for Group 2 students, who have participated in at least one co-op and still continue their education.

Q1. I have matured professionally as a result of co-op experience.
Q2. Co-op delayed my graduation
Q3. Co-op program contributed to my professional development?
Q4. There should be a co-op program for grad students, too?

TABLE IV: Survey questions for alumni (Group 3)

A. Analysis and results

Survey responses for most questions are in the form of Likert scale [28] with 5 response types: strongly disagree (SD), disagree (D), neutral (N), agreed (A), strongly agreed (SA).

23.0% female respondents and 21.9% male respondents agree (A) and 12.8% female respondents and 11.8% male respondents strongly agree (SA) with Q2 in II (Figure 4a). A total of 69.5% of all respondents in Group 1 agree or strongly agree that they chose TOBB-ETU because of the co-op program. And we should note again that Group 1 consists of students who entered TOBB ETU but did not experience co-op yet.

Figure 4b and Figure 4c present Group 1 responses for Q3 and Q4 in Table II, respectively.

Here, we obtain similar responses; while total 79% of the students agree or strongly agree with Q3, 75% of the participants agree or strongly agree with Q4. These results clearly show the importance of the co-op program among prospective college students and the positive expectations about the program. The male and female answers are very close to each other. In Figure 4d we see the responses for whether students still participate in all three co-ops in case they were optional (Q6, Table II). 67% of the students agree or strongly agree with attending all co-ops even if they were optional. This number coincides with responses in Figure 4a for Q2.

Since Q3, Q4, and Q5 in Table III are similar, we show the student responses to these questions in Figure 4e. The total percentages of the students who agree or strongly agree with these questions are 52%, 58%, and 45%, respectively. These results suggest that an effective co-op program helps students see their academic deficiency areas and take classes more seriously.

Figure 4f presents the responses for Q13 of Table III and Q1 of Table IV combined. The percentage of alumni who agrees or strongly agrees that they matured professionally as a result of co-op experience is 57% as shown in Figure 4f. Although this number is less than the percentage of the participants in Group 2 who agree or strongly agree that their soft skills improved after co-op, these numbers still present an important role of co-op for improving student skills in professional development.

In Figure 4g, we show Group 2 responses for Q15 in Table III. 60% of the students agree or strongly agree that co-op enhanced and reinforced their learning. Based on this percentage, we can conclude that co-op meets student expectations in general. Since Q1 and Q2 in Table III are similar, we show Group 2 responses to these questions in the same figure (Figure 4h). After students attend at least one co-op, 56% of them agree or strongly agree with facing the real-world problems that would have been impossible without co-op and 63% of them agree or strongly agree with improving their professional perspective and practical problem solving skills.

Figure 4i, Figure 4j, and Figure 4k depict all student responses to all questions in Groups 1, 2, and 3. Overall, at least 50% of participants have positive responses to the co-op program. Finally, in Figure 4l we show Group 2's error plot, which shows the variability of responses. We note that the error plots of both Groups 1 and 2 have similar patterns and thus they are omitted for brevity.

B. Discussion

Since TOBB ETU was established 10 years ago, the co-op program is still new to the university, students, and the companies. Thus, there are some operational issues regarding the program. Reduced holiday time, companies assigning tasks to students which are not related to or in line with their educational goals, insufficient open positions for co-op students in top companies, and companies not involving students in important projects because of confidentiality or security are are the main reasons for negative feedbacks from students. However, as indicated by the responses, almost all students and alumni see the benefits of this program. These problems are likely to settle down with more operational experience as we go through this unique educational program.

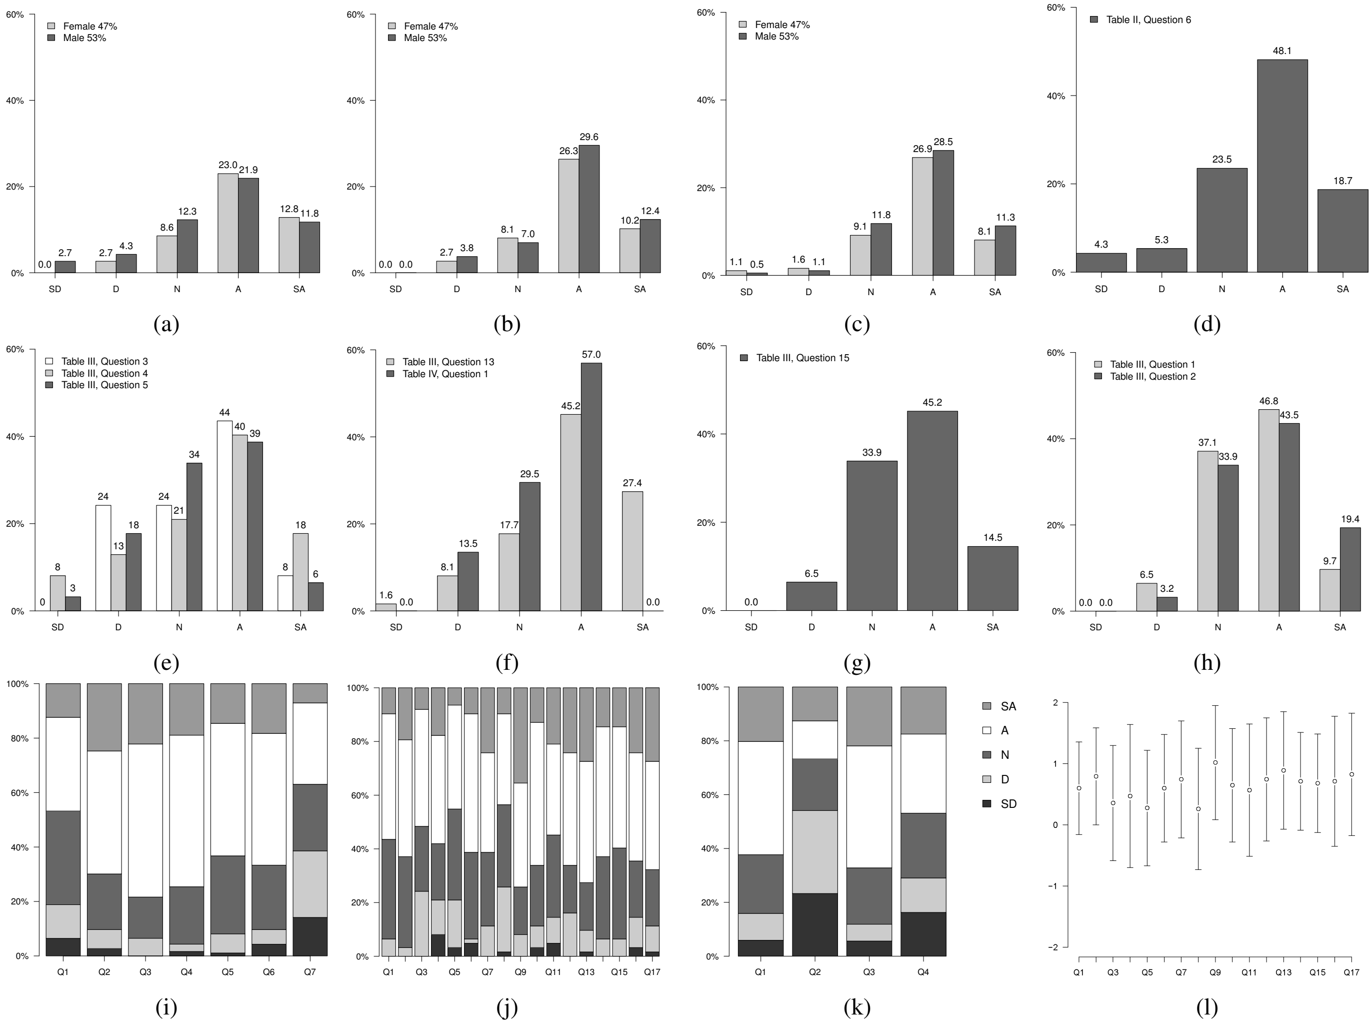

Fig. 4: Assessment plots. All y-axes are percentages and x-axes are survey responses. (a) Question 2 of Table II, (b) Question 3 of Table II, (c) Question 4 of Table II, (d) Question 6 of Table II, (e) Questions 3, 4, and 5 of Table III, (f) Question 13 of Table III and Question 1 of Table IV, (g) Question 15 of Table III, (h) Questions 1 and 2 of Table III, (i) All questions of Table II, (j) All questions of Table III, (k) All questions of Table IV, (l) Error plot of all questions from Table III. SD: Strongly Disagree, D: Disagree, N: Neutral, A: Agree, SA: Strongly Agree.

VI. Conclusion and Future Work

The playing field of the higher education has been changing rapidly. Educators and the institutions are urged to come with new, and of course effective, methodologies for producing longer lasting learning under the pressure of changing student profiles and attitudes. In this paper, we have provided an assessment of a century-old practice of co-op education which is still met with resistance and skepticism in terms of its place in higher education. We report the first co-op education program implemented in Turkey at TOBB University of Economics and Technology. Distinguishing characteristics and areas of our contributions are as follows: There are limited number of survey-based assessment reports published in the literature about co-op programs. To the best of our knowledge, the majority of the co-op program assessments are from the US institutions with some Canadian universities. We report a preliminary assessment of a longitudinal study as the first from Turkey and one of a very few from the non-US, international institutions. We believe that ours is the first to report assessment of co-op program from students perspective who have not started any co-op yet, who have done at least one co-op term and who have graduated from college ***separately***. Based on the survey results, we conclude that the TOBB ETU co-op program is highly valued and prominent determinant for the incoming students. Specifically, 69.5% of all respondents in the incoming students agree or strongly agree that they chose TOBB ETU because of the co-op program. In addition, majority of the students who have done at least one co-op agree or strongly agree that co-op enhanced and reinforced their learning. Finally, the value of the TOBB ETU co-op program is still appreciated by graduated students several years after the college.

We note that this paper presents results of what we term as a prelude to a longitudinal study to assess the overall success of the first co-op program in Turkey. As part of the future work, we will be expanding the current survey to include employers, faculty, university administration and students from other universities without co-op program to assess many different dimensions of the co-op experience.

***Abstract*—Two trends in the developed world – the marked growth in the percentage of the population identified as "elderly", and an increased reliance on computing technology – make it imperative that the high technology designers of tomorrow understand the challenges, capabilities and context of elderly users. Our graduate course on "software for senior citizens" provides a broad background of material from human-computer interaction, gerontology, literacy studies and cognitive and learning sciences. Students also gain first-hand experience through weekly tutoring sessions with local elderly residents. These sessions yield observations and generate contacts from which students generate research projects. This paper discusses our goals and motivations for the course, our experiences to date, and our plans for future iterations and opportunities for expansion.**

Keywords—Human-Computer Interaction, Gerontology, Digital Literacy, Service Learning

I. Introduction

As society in the United States and elsewhere in the developed world adapts to new uses and forms of computing, many of our elderly citizens are being left out. The movement toward digital technology has much to offer the elderly: a wealth of news and health information and the ability to stay in touch with distant friends and family, to name a few. But with digital literacy moving from an attractive option to a necessity, many seniors – especially those on fixed incomes and with limited access to current technology – are experiencing frustration and helplessness. It is not only a valuable opportunity but a moral imperative for students in computing disciplines to be aware of the challenges facing this important but overlooked constituency.

We have piloted a course that combines research in usability and digital literacy for the elderly with a community outreach program at the local public library. Our multidisciplinary graduate-level course investigates aspects of software design for an aging population. In their new role as tutors for the elderly, our students are placed in a position to question their implicit assumptions about use of technology.

The design and execution of this course could be characterized as a pilot or pre-study that aims to understand how the seemingly disparate activities of teaching, learning, research, and community outreach can be effectively combined. Results from this course could be used to evaluate the feasibility of partnering with community organizations to assist the elderly, assessment procedures in the classroom, new research methods developed by the students, and the development of future courses. This paper discusses our goals and motivations for the course, our experiences to date, and our plans for future iterations and opportunities for expansion.

II. Motivation

Senior citizens comprise the largest and fastest growing demographic in the digital divide. By the year 2050, the population of older Americans is projected to be 88.5 million, 20.2% of the total population [1]. At the same time, the pace of new technology adoption is accelerating. Seniors are suddenly forced to use computers to perform routine tasks that were previously paper-based, such as filing tax returns, using coupons, or changing their address. Most seniors do not have computers, have never used computers, or have only used computers at work. Even those with computer skills are often frustrated when they find that standards and norms have shifted since their last experience with computers, rendering their hard-earned skills worthless.

Our desire to create this course derives in part from the particular character of our local area and our university. Michigan Tech, located in the far northwest corner of the U.S. State of Michigan, near the shore of Lake Superior, is a research intensive university focused on technology, engineering, and scientific degree programs. Its international, high-technology atmosphere is in stark contrast to the experience of residents outside the university. County residents over age 65 constitute 15.2% of the 2011 population. Many of their relatives live far away, and those who stay struggle to get by in an economically depressed area with few jobs outside the university. Because of the larger than average number of elders without family support, many of whom are below the poverty limit, there is a strong need for help with digital literacy in this community.

As a pilot offering, the designers of this course seek to combine research and meaningful study of usability and digital literacy with a service learning component that supports the needs of the elderly. The service learning component of our course precipitates some unlikely pairings: on one hand, local residents with long family ties to the area and varying levels of technological literacy; on the other hand, graduate student tutors from around the globe, with extensive interest and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

experience in technology. These encounters are designed to help tomorrow's technologists understand the situation of the elderly and to foster consciousness as they create software for an aging population. Furthermore, through our community service activities we aim to ease elders' transition to a computer-based society.

III. Course Creation and structure

Software for Senior Citizens is a multidisciplinary course investigating aspects of software design for and use by an aging population. The course combines graduate-level readings and discussions with hands-on projects involving seniors from weekly help sessions at the public library. Students learn about the context that older users operate in (e.g. their attitudes, skills physical barriers) and engage in some design activity aimed at providing a better experience.

Our course leverages a successful outreach effort that we have continued since 2011 [2]. Students at our university have been meeting weekly at the local public library with community members, most of them 60 years of age or older. This series of meetings, called "Online at the Library", provides one-on-one tutoring for people with questions about digital technology. Some participants are ordinary people who may have never used a computer but suddenly find themselves required to conduct online banking transactions or update electronic retirement information. Others may have used computers but have fallen out of practice. Still others need help transferring skills from PCs to new mobile devices. Most of them struggle with things that those among the techno-literati find simple.

In creating the course, we follow a long tradition of service learning in university courses, and two efforts in particular to introduce students in computing disciplines to the context of elderly computer use. Pace University's undergraduate Intergenerational Computing course offers instruction in technology and gerontology theory and service learning involving personal tutoring at elderly residence facilities [3]. In a software design course at Iowa State University, students meet with real elderly users and design products based on their interactions [4]. The reports on these efforts have inspired us to combine the threads of theory, training, service learning and research into a single course.

IV. In the classroom

Two of the three weekly contact hours for the course take place at the university. Classroom activities include discussion of readings and activities to increase awareness and train students in research techniques.

Understanding the problem. Our initial readings delve into the demographics of an aging population and the physical, cognitive and social barriers faced by the elderly [5][6]. Of particular interest is the concept of lag: the lack of congruence between individual and environment that lies at the heart of many challenges for the elderly [7]. This theoretical construction has helped us to frame the particular concerns we have witnessed at our help sessions. Readings from literacy studies also helped to frame elderly computing skills as a literacy problem [8][9]. Identifying different levels of literacy, beyond the mechanical notion of functional literacy to higher levels of critical and rhetorical literacy, has allowed us to think of teaching digital literacy as something broader and more exciting than training of rote procedures [10]. Finally, readings on design for elderly use have provoked discussion of personal experiences with effective and flawed interface design [11][12].

Building empathy. Getting students to envision themselves as elders themselves is an important component of the course. Through a generous loan from the Ford Motor Company, students have taken turns wearing a "Third Age Suit", designed to constrain movement and obscure senses to simulate the effects of aging [13]. Experiences during the service learning sessions also bring to life the realities of aging; student experiences are shared during classroom sessions and on the course blog.

Figure 1: Wearing the Third Age Suit

Practicing methods. One course is not enough to cover the wide variety of analysis techniques available to designers. Students have discussed and practiced the "think aloud" approach to activity analysis [14] and ethnographic observation [15]. Students have also practiced user task analysis on common computer tasks, in an effort to understand their own approaches to accomplishing tasks online [16]. In their summary statements posted on the blog, students reflected on the difference between their own "digital native" behavior and that of the elders they had encountered at the library:

"I observed ____ using Amazon... I really liked how she scanned the screen in a circle around the streaming content, looking for affordances that would help her with her task. This was an obvious contrast to the way seniors try to read the screen; left to right, top to bottom. It seems seniors either try to read everything in a linear fashion, or freeze up and read nothing because of information overload."

"On Facebook, I was the user and ____ observed. I found Facebook difficult to setup. It was hard to find settings, especially privacy settings, to setup the account in the way I wanted. Facebook is completely open by default and I wanted to lock it down and then open up features I wanted as I discovered I need them. It was a very frustrating and time consuming experience (it took over an hour to create an account) I can't imagine a senior attempting to setup an account."

V. ONLINE AT THE LIBRARY

In the experiential component of the course, students help community members with real computing needs. In conjunction with the public library, we offer weekly computer help sessions open to anyone in the community (Fig. 2). Students in our class act as individual tutors, teaching elders how to use the Internet to keep in touch with people, share pictures and letters, find information, and much more. Participants are welcome to bring their laptop computers if they choose, or they may use the library's computers. People may attend as many of the sessions as they wish. Our students reflect on each week's tutoring session through a class blog and in-class discussions.

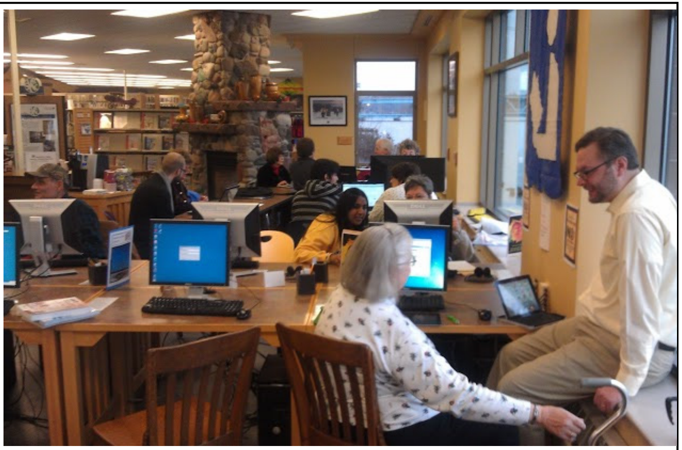

Figure 2: Online at the Library

While helping community members, students began to catalog common tasks that require assistance: sending pictures in email, bookmarking web pages, browsing the web, searching for people or information, paying bills online, using antivirus software, removing viruses or malware. Our course blog has been an effective repository of stories illustrating some of the problems seniors encounter while using computers:

Connecting to the Network. "I helped a gentleman get on the library network. Generally, when someone is unable to connect to the internet on a laptop, the first thing I look for is a switch or button on the sides of the laptop that can switch-off the wireless. These buttons are put there so you can turn-off wireless on a plane, or in a hospital, or just to conserve battery. In this case, there was a button on his keyboard, above the function keys, that toggled wireless."

Cursor Related Difficulties. "The woman I was working with [couldn't figure out] how to get the video started. I know that in many cases, there is a 'play' icon that appears superimposed on the video image - that is an affordance that draws the user toward mousing over the video. But in this case, there was nothing! It made me think about how mouse-over has quietly become a new standard behavior: if you can see something on the screen that you want to interact with, but you're not exactly sure what it is or what you can do with it, mouse over it."

Double Scrollbars are Confusing. "One elder spent 3 minutes looking for the Gmail send-button because it had scrolled out of view due to the size of the email he was sending, and Gmail uses a double vertical scroll bar, an inner one on the message, an outer one on the work page that includes 'send' buttons. This is ridiculously confusing, even to people who use it all the time." Classroom time is an opportunity to explore interface issues like this in depth (Figure 3).

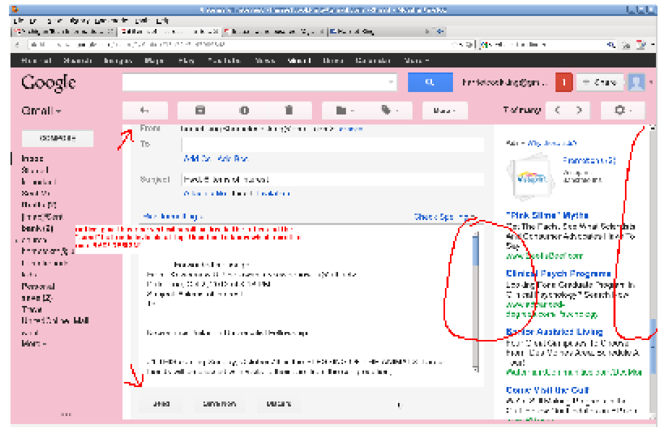

Figure 3: Discussing the double scrollbar problem in class

Students were reflective in their observations and often frank and even critical of themselves:

"What did you notice today at tutoring? Is it more about teaching or about what design we see that is annoying? I was bossy and made ___ practice attaching photos to her email. I told another that google maps directions are not helpful if she already knows a good local route, but at least I showed her how it would be helpful if she had no idea how to get somewhere."

"I helped ____ change his desktop picture and I bit my tongue when he picked something 'ugly'. So that was a small small small success on my personal growth."

"I'm afraid I was not in a great place this morning, having had to get up and into work very early to handle a problem with a live system. So I was tired, stressed, and irritable when I arrived at the library."

Students had fun working with the elders:

"Today I helped ____ learn about using Google products. That is to say we played the whole time."

"Today I helped a few different people and had a great time. One wanted to start learning excel, not sure I helped her that much. Another was very high frustration but seemed happy when she realized that things were not broken and it was not going to be hard to use her new system. Another wanted me to help her husband and I hope I did. Then I helped someone at the end and we learned together. A good tutoring day! Yay!"

Elders often come with focused, sophisticated questions:

"Then she asked about a more advanced topic. How does one insert a picture into a document. So I showed her how to do that from the insert tab. Then she wanted to know how to resize the image without distorting it. So we talked about selecting the image and using the handles to change its shape or to rotate it."

"____ had arranged his spreadsheet like you would arrange a set of papers on your desk. There were multiple tables laid side-by-side, but the rows of the tables didn't match up with one another. So when it came time to sort the entries in one of the tables, it was a nightmare. I carefully put each table into a separate worksheet (I'll admit, I did some steering on his laptop), then showed him how he could get to the various tables by clicking on the tabs. He's going to need some practice getting used to that – unless he understands tab navigation, he's going to wonder where those other tables went."

VI. RESEARCH PROJECTS

The tutoring experience at the library forms the basis for student-conducted research addressing technical, and social issues connected to the digital divide. These projects offer students the opportunity to pursue their interest in this area beyond the bounds of our course. We received IRB approval for including our library attendees as subjects in research projects. In their projects, students have investigated a range of topics: receptiveness to Twitter; effect of visual clutter on elders' ability to navigate unfamiliar websites; patterns of communication between tutor and student in the help sessions; use of user interface gestures by the elderly between different device platforms.

Are tablets the answer? One undergraduate student enrolled in the course wanted to find out why modern interfaces are difficult for elders to learn and use. Based on observations at the library of seniors using desktop computers, he concluded that there are three main aspects of user interfaces that posed the largest barriers: *mouse* (finding and manipulating the cursor, distinguishing between cursor and caret, distinguishing between click and double click, distinguishing between left and right click, selecting data), *windows* (finding the active window, moving between windows), and *files* (understanding the file hierarchy, locating files).

The student was interested in exploring the new paradigm of tablet computing as a potential solution for these problems. He led a group of library attendees through a series of tasks on an iPad. He concluded that the tablet paradigm eliminated the problems that seniors had using windows because only one application is active at a time. Likewise, because the iPad hides the file system, seniors did not experience any problems finding files. Although the touch-screen interface solves many of the mouse-related problems, it introduces some new problems: double tap and tap-hold confused seniors, and none of the seniors were able to copy-and-paste.

Communication patterns. A Ph.D. student in the course studied the patterns of communication exhibited between the seniors and tutors during help sessions at the library [17]. Her work consisted of data gathering at the help sessions and rhetorical analysis of the interactions between tutors and elders (Fig. 4).

Her observations revealed a range of strategies that tutors use in explaining and training. While the elderly attendees generally had few planned questions, running through activities together, with the "prop" of the computer artifact, elicited questions. Direction was more commonly used than demonstration, but when the latter is necessary, tutors tend to use "think aloud" to expose their mental model. Tutoring is tactical in nature, and often the methods of instruction must change in the moment – for instance, when tutors did not know a solution immediately, they frequently switched to an "explore together" pattern.

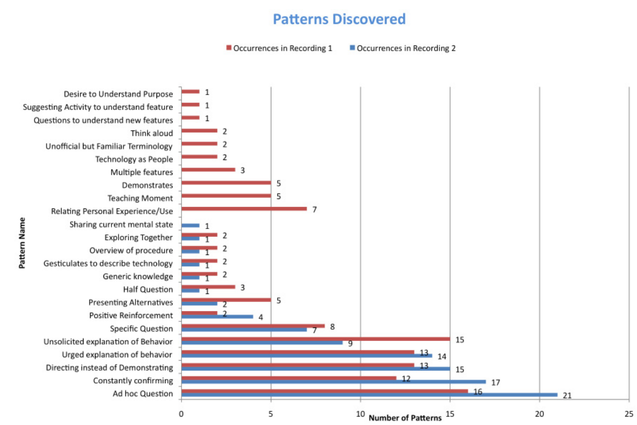

Figure 4: Communication pattern analysis

Lessons from our elders. After the end of the course, a number of the students collaborated on a conference paper detailing our findings, in the context of "lessons learned" for technology designers [18]. The main findings are summarized below:

- *Anxiety stifles exploration*. Stories from mass media provide unrealistic models of threats. Fears of losing data or compromising secret information reduce the kind of free-form exploration that students in the course use to learn about new interfaces.
- *Details obscure abstraction*. With the advent of multiple types of computing platform – tablets and smartphones, in addition to traditional personal computers – elders can get lost in the details of a particular device and fail to see the commonality between them. This is particularly problematic when addressing cloud-based services.
- *Lag complicates adoption*. Slow changes to infrastructure in our rural area puts elders at a disadvantage. Arcane and ever-changing vocabulary keeps elders in the dark, and their hard-earned computer knowledge depreciates rapidly with today's rate of technological change.

VII. WORLD USABILITY DAY

Students in the class participated in World Usability Day (November 8, 2012) by hosting an event on campus. The goal of the event was to raise awareness of the usability issues faced by the elderly.

We began the day by meeting with interested seniors to make signs for a march across campus (Figure 5). Seniors made signs indicating how they felt about technology, the questions they had about computers, or what they had learned from the students. Their slogans echo the concerns and frustrations we encounter at our help sessions: "I need computer – Computer no need me"; "How do you turn it on?"; "Device not Recognized"; "Files everywhere and yet I cannot find it!" Students and elders marched onto campus where we were stopped by the police! After we explained that we were non-violent and that this was an official, scheduled event, we were allowed to continue. This excited some of the senior citizens and we heard stories of their participation in protest marches while in college.

Figure 5: Seniors marching for World Usability Day

After the march, there was a poster session for students' research projects and a discussion forum. Seniors and students participated in an open forum, discussing their experiences working with each other to learn how to use computers.

VIII. FUTURE WORK

Our pilot of this course produced a rich discourse, both in class and online, a broad array of creative research projects, and assistance to the outreach program at the library. It should be noted that the class size was small - only five students - and that only Computer Science was represented. The structure of the course is well suited for interdisciplinary study, and we hope to bring a broader group of students together for the next offering of the course. Students in our Technical Communication and Cognitive Science programs would be particularly well suited for the course. We also plan to explore the option of scaling the course up to serve a larger body of students. Furthermore, we hope that by reporting on this course, we can help others develop similar programs in their communities.

ACKNOWLEDGMENTS

We wish to thank Professor Lauren Bowen for attending the course and providing expertise on digital literacy. Chris Alquist and the rest of the staff of the Portage Lake District Library have kindly shared their facility and time for our tutoring efforts. Cynthia Drake and other employees and volunteers at Little Brothers Friends of the Elderly have connected us with elders in need of our assistance. Chad Esselink and Ford Motor Company kindly provided the Third Age Suit. Finally, we wish to thank the students in our course and all the volunteers and attendees at "Online at the Library".

Internal Combustion Engine's Throttle Control as a Motivational Theme for Teaching Microprocessors Systems Lab Classes

Samuel E. de Lucena
Unesp – Sao Paulo State University
Guaratingueta, SP, Brazil
sdelucena@gmail.com

***Abstract*—The increased fuel economy and driveability of modern internal combustion engine vehicles (ICEVs) are the result of the application of advanced digital electronics to control the operation of the internal combustion engine (ICE). Microprocessors (and microcontrollers) play a key role in the engine control, by precisely controlling the amount of both air and fuel admitted into the cylinders. Air intake is controlled by utilizing a throttle valve equipped with a motor and gear mechanism as actuator, and a sensor enabling the measurement of the angular position of the blades. This paperwork presents a lab setup that allows students to control the throttle position using a microcontroller that runs a program developed by them. A commercial throttle body has been employed, whereas a power amplifier and a microcontroller board have been hand assembled to complete the experimental setup. This setup, while based in a high-tech, microprocessor-based solution for a real-world, engine operation optimization problem, has the potential to engage students around a hands-on multidisciplinary lab activity and ignite their interest in learning fundamental and advanced topics of microprocessors systems.**

Keywords—electronic throttle control; ICE control; chopper power amplifiers; hands-on education; laboratory experiences

I. Introduction

Contemporary society has been to a considerable extent shaped by transportation means and, in special, by individual transportation vehicles. The role played by internal combustion engine vehicles, and accordingly by carmakers, along with road and fuel infrastructure creation and operation is of paramount importance to modern industrial society. The whole car business encompasses a huge amount of employees and creates considerable wealth.

ICEVs have been experiencing a steady technological improvement since the beginning more than a century ago. Microprocessors along with sensors and actuators play a key role in permitting the fuel efficiency and driveability achieved by modern automobiles. Though tens and tens of microprocessors can be found in contemporary cars to carry out a myriad of different functions, hereafter our focus is on the microprocessor system used to control the vehicle's engine, the so-called engine control unit (ECU).

This work was supported in part by PROPe/UNESP and PROAP/Capes – Coordination for the Improvement of Higher Level Education (Brazil).

As we will see in the rest of this paper, microprocessors lab classes can be created that explore the microprocessor use in the control loops of ICEs. In particular, we will present and discuss an experiment using a microprocessor to control the position of a throttle valve according to an input signal representing the driver's desire for power. Given the ubiquity of cars and their fetish ("I drive, therefore I am."), we postulate that this type of lab activity can be motivational for engineering students and help to ignite their enthusiasm to learn basic and advanced topics on microprocessors systems. Relying strongly on hands-on approach to teach microprocessors systems is widely recognized as an effective pedagogy [1]-[6].

II. Electronic Fuel Injection (EFI)

A. Cylinder and Basic Elements

A great step towards the increase in fuel efficiency and engine performance, which also led to the generation of lower amount of pollutants escaping the gas pipe, was the replacement of carburetors by electronic-controlled fuel injection [7]. The latter control technology builds on technologies such as microprocessors, accurate air intake mass measurement and control, exhaust gases' oxygen sensor, and precise control of fuel injection using solenoid-operated nozzles (Fig. 1).

As a general rule, EFI control aims at maintaining the

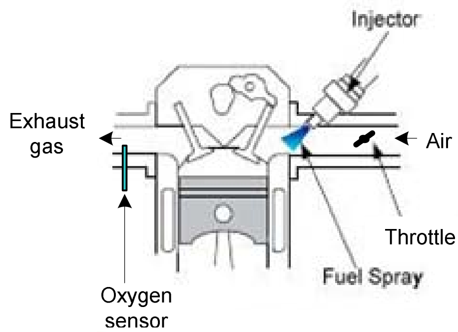

Fig. 1. Sketch of a cylinder of an internal combustion engine.

stoichiometric air/fuel ratio, the so-called lambda parameter, equal to unity. This could be achieved thanks to the microprocessor technology. The ECU receives information with the driver's need for power, which is conveyed by a gas pedal sensor (Fig. 2), and calculates (and controls) the amount of air and fuel to be burnt inside the cylinders, all in real-time.

B. *Throttle Body*

The ECU controls the amount of air entering the cylinders by controlling the position of the throttle's blade [8]. Therefore, the air control throttle is de facto a fundamental block of EFI. The throttle body is composed of a dc-motor which turns the valve's axis position by means of two cascade rack and pinion gears, against the forces of a planar, spiral, high-stiffness restoring spring and the air pressure on the throttle's blades (Fig. 3). A potentiometer whose sliding lead is connected to the valve's axis enables measurement of the valve's axis position.

III. MICROCONTROLLER-BASED THROTTLE CONTROLLER

A. *Overview*

Fig. 6 shows the block diagram for the microcontroller-based throttle controller. The control block itself is fully embedded in the 8-bit microcontroller (PIC18F4550-I/P from Microchip Inc.). Two channels of the 10-bit analog-to-digital converter (ADC) are used to read the gas pedal sensor (GPS) and the throttle position sensor (TPS). Indeed, the GPS establishes the set point for the controller and in this project was substituted by joystick potentiometer. The error ε is obtained by a simple subtraction between the two last values of GPS and TPS. The control algorithm's job is to null the error as fast as possible, with minimum overshoot, which are somewhat conflicting requirements.

The control algorithm main task consists in appropriately updating the duty cycle δ for the pulse width modulator (PWM), this also an internal microcontroller peripheral.

The throttle body is the plant to be controlled. Assuming the time constant of the mechanical unit (spring and inertia of valve, motor and gears) is much higher than that of the dc motor electrical circuit (dictated ultimately by coil inductance and resistance), the plant can be suitably regarded as a typical second-order system.

To convert the duty cycle signal δ into power, the 12-V voltage-output chopper amplifier sketched in Fig. 4 is deployed. Notice the simple interface connecting the microcontroller's PWM output to the chopper amplifier. Recall that the dc motor torque is proportional to the motor current. In turn, the motor current is proportional to the input voltage integral. In other words, the motor torque is in direct relation with the duty cycle δ. Therefore, as illustrated in Fig. 5, different duty cycles lead to different motor currents (mean value of motor voltage) and hence to different torques.

Throttle equilibrium position θ is dictated by motor toque T_m, amplified by the gears' radii ratios, and spring stiffness and perturbation torque due principally to the air pressure exerted on the blades. Coulomb friction has also an impact on the dynamic response of the entire system. The throttle position θ

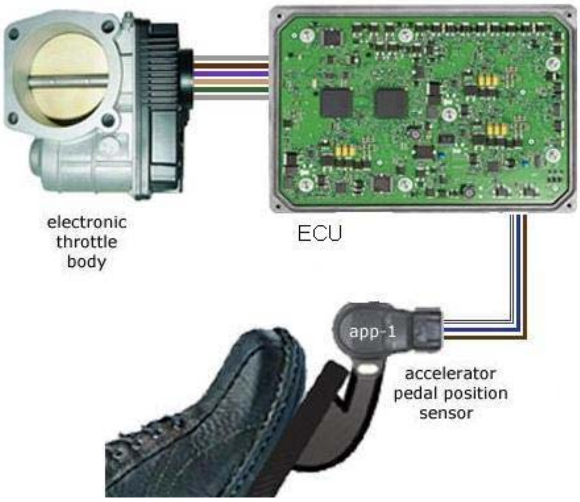

Fig. 2. ECU, gas pedal, and throttle body.

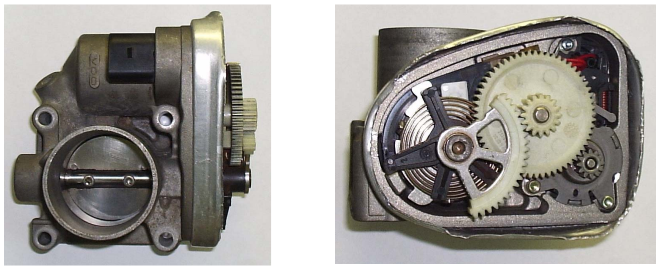

Fig. 3. Pictures of an open commercial throttle body.

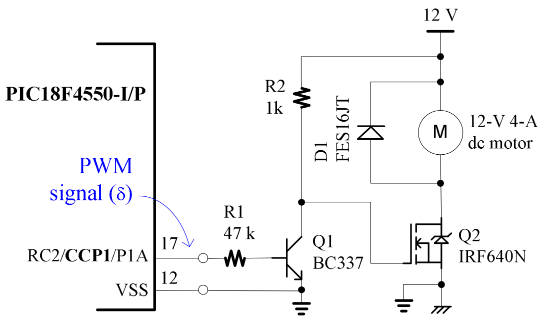

Fig. 4. Chopper-type power amplifier and interface to microcontroller.

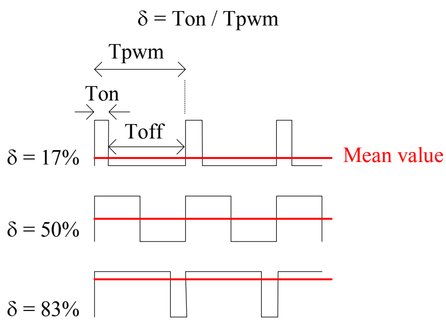

Fig. 5. PWM duty cycle δ is software controlled.

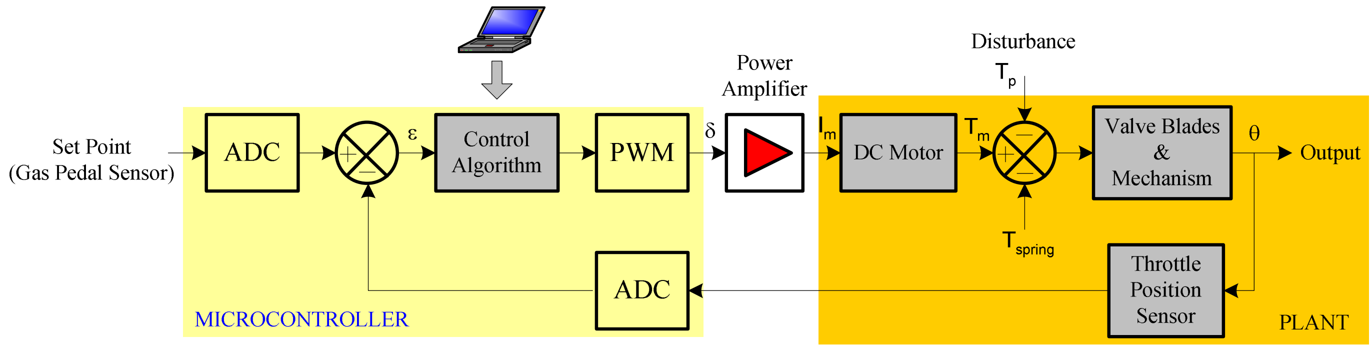

Fig. 6. Block diagram for the throttle position controller.

is sensed by a linear rotary potentiometer embedded into the throttle body. Circuit is omitted here for simplicity.

B. Control Strategy

Once the hardware is ready, several different control strategies might be put into action. Due to the fact that our students have had a mandatory course on classical control theory the year before they engaged in the microprocessors systems course, it was quite direct the adoption of classical proportional, integral and derivative (PID) control strategy in this lab design. Fig. 7 presents the flowchart for the implemented control strategy. Before beginning the control loop, values for the proportional, integral and derivative gains have to be chosen. Also, one must define the PWM frequency and initial values for the duty cycle δ and the error ε. Despite the existence of practical methods to establish the values for the aforementioned gains, e.g. Ziegler-Nichols' method, it seems interesting that students can play with these parameters in order to develop a feeling about their impact on the controller's performance and stability.

The error derivative is taken as the difference between the current value for ε and that calculated during the preceding iteration. Obtaining the error integral is a bit more laborious, since one needs to store several samples for the error ε, each of which corresponds to the error value gathered during an earlier sampling interval. In this lab design, we adopted six consecutive error values and calculated the error integral as a simple summation of these values. This could be easily done by creating a vector with six elements and replacing the oldest element (i.e. the oldest error value) as a new error was calculated. At program start, this vector had all elements zeroed. All programs were written in C language.

IV. Experimental Results and Discussion

Fig. 8 shows a picture of the final experimental assembly. For the sake of simplicity, the microcontroller programmer and the personal computer containing the integrated development environment (IDE) were not included.

Many experiments were realized with the working throttle body under control of programs downloaded to the microcontroller board. Gains for the proportional (K_p), integral (K_i) and derivative (K_d) terms were chosen at will and subsequently the system's step response was recorded and analyzed. Fig. 9 presents the result of such an experiment. One can easily observe that the throttle angular position follows

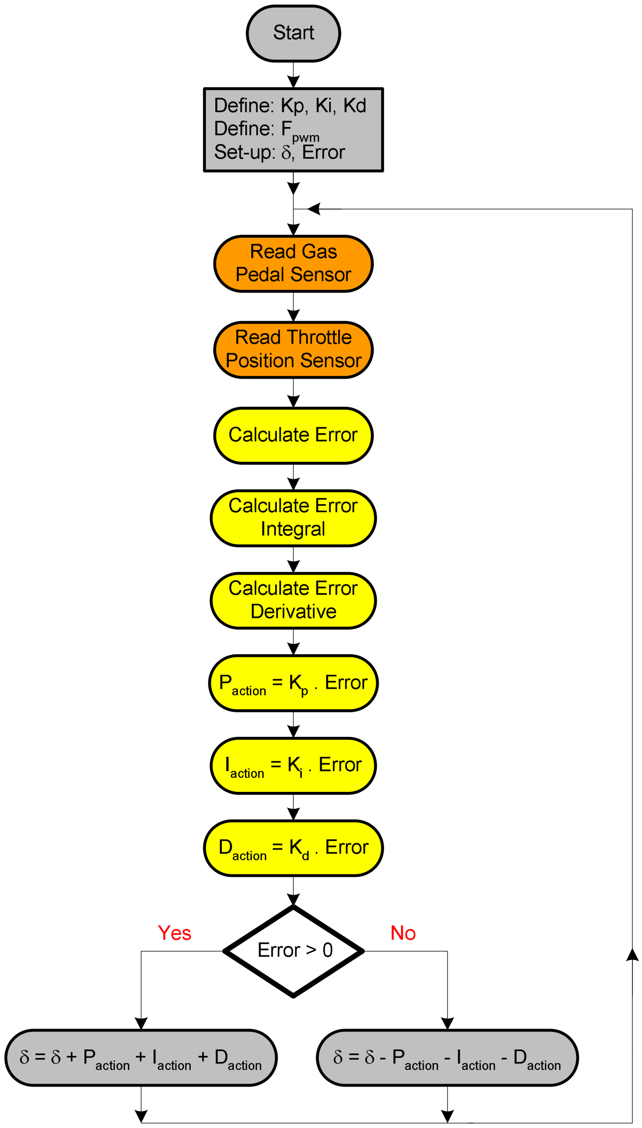

Fig. 7. Flowchart for the implemented PID control strategy.

pretty well the gas pedal signal. Recall that a joystick plays the role of the GPS in this setup. The step response's waveform makes it clear that the system exhibits a considerable overshoot. Students must be aware of this system behavior and discuss about the dominating factors, when it comes to overshoot control. Debating about possible improvements and tradeoffs are of utmost importance for students to develop critical thinking skills.

To better illustrate the system ability to follow the input signal, an experiment was carried out wherein the control system's input and output signals were overlapped on the oscilloscope screen. As clearly depicted in Fig. 10, the plant's output follows the input signal quite well. Perhaps, one should make it clear at this point that in ICEVs the throttle valve position is not to follow the gas pedal signal. Instead, its position is determined by the ECU in a manner that leads to stoichiometric fuel/air ratio. On the other hand, students must acknowledge the fundamental tests to be carried out with the throttle position control system that ultimately guarantees the valve angular position will suitably obey the commands issued by the ECU.

The signals shown in Fig. 11 are to highlight the real-time updating of the PWM's duty cycle as changes in the throttle position occur. Here students can observe the real-time correction action of the closed-loop control system. They are stimulated to use their fingers to force the blades out of its equilibrium position, i.e. artificially introducing a perturbation into the system, just to observe the fast change in duty cycle values provided by the control program in its struggle to keep the error as small as possible.

Microprocessors systems course (MPS) is a mandatory subject at our university. It lasts two terms and consists of 3 hours of theory and two of lab weekly. Electrical engineering students are allowed to get enrolled in this course after they have successfully attended digital electronics course (DE). By far, besides having attended the DE course, the students enrolled in MPS have already succeeded in linear control systems course and analog electronics course. These students are in their fourth academic year, in an undergraduation course that extends for five years. Regarding classes, the last year's workload is relatively light, for the students have to fully dedicate three days a week to their internships at industry.

Lab classes of MPS are run typically with groups of 10 students. The year this lab design happened, a team of four students was assigned the task of designing part of the hardware and software for the microcontroller-based throttle controller. We have used project-based learning (PBL) as instructional pedagogy, concerning the laboratory classes during the second semester of the aforementioned course. The students faced tough problems regarding time management and sharing the tasks among them. Also, the team found quite difficult to decipher on its own the innards of the microcontroller's PWM, a fundamental structure for the implementation of the control strategy. Yet another peripheral that took so much time for students to tame was the ADC. Unfortunately, the industrial-grade C-language compiler utilized was plagued with a terrible error in the built-in library function to read the ADC: the compiler documentation states

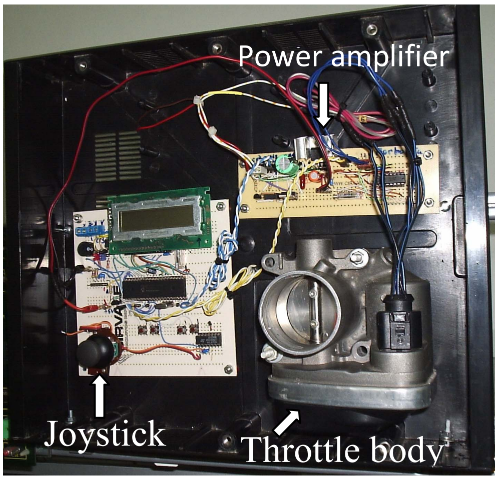

Fig. 8. Microcontroller board, chopper amplifier and throttle body.

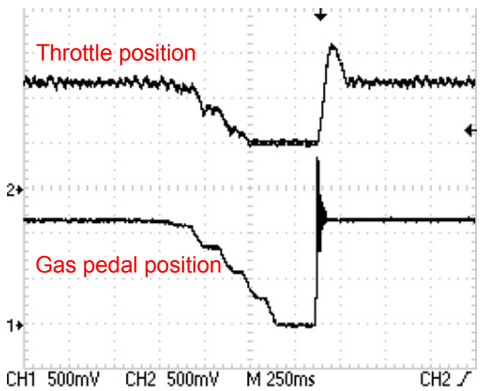

Fig. 9. Gas pedal sensor signal and throttle position sensor signal.

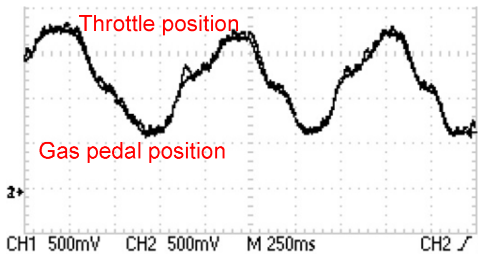

Fig. 10. Overlapped pedal sensor signal and throttle position signal.

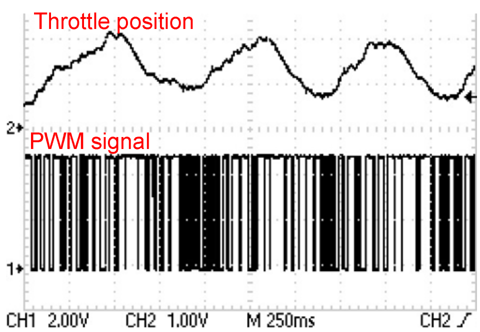

Fig. 11. Throttle position sensor signal and corresponding microcontroller-generated PWM signal.

that this function returns an integer number. Nonetheless, the ADC returned wrong data as revealed by tests deploying known input voltage values. Correct values might only be read when using float type variable. This type of problem is quite difficult to be tackled by students, since they are fully confident about the tools (e.g. IDE, measuring instruments, power supplies and so on) they are using. As a result, it took a long time for students to get suspicious about the compiler and look for help.

V. Conclusion

Modern ICEVs are equipped with state-of-the-art digital technology to control the amount of fuel and air to be mixed and burnt inside the cylinders. Also, the spark ignition is under ECU control. The overall goal is fuel economy, driveability, and emission of smaller quantities of pollutants. In a nutshell, what is sought is the optimization of engine operation under rough and varying environmental conditions. To do that, the ECU counts on sensors and actuators, such as the sensor for oxygen concentration in the exhaust gas and the sensor for the angular position of the throttle valve. Key actuators are the throttle valve, to control the amount of air intake into the cylinder, and the solenoid-operated nozzles, to inject known amounts of fuel into the cylinders. This paper dealt with the development of a microcontroller-based throttle controller by a team of students of the fourth year of the electrical engineering undergraduation course at our university. The project was assigned to students so that they could work on it during their weekly hours of microprocessor systems lab classes.

Initially planned to run under pure project-based learning (PBL) instructional pedagogy, it turned out that difficulties faced by students were so intense that they were poised to fail in fulfilling project goals. Students faced huge difficulty in translating their knowledge of linear control theory into the practical application they were assigned with. In particular, though they had had a year-long course on linear control, they could not manage to apply their skills on analyzing control system using their transfer functions and Matlab-like environments to the development of the throttle position controller. For instance, they were unable to discuss about the appropriate sampling frequency for the controller. This fact reminds us that bridging the gap between theory and practice will always be highly challenging for both students and faculty. Lab classes of modern control systems rely heavily on such computer programs as Matlab®/Simulink® and Labview®. These are powerful tools that accelerate product development and scientific research. Today these tools are a must in scientific and high-tech industries. However, for they hide hardware and software details, a glory for scientists and engineers who can now concentration on the problem solution architecture and algorithms, they go precisely in the opposite direction, when it comes to teaching solutions using microprocessors/microcontrollers. Here, details are of paramount importance and can only be grasped by directly struggling with them, as advocated by active learning pedagogies.

Furthermore, students encountered tough difficulties in understanding the innards of microcontroller peripherals such as the ADC and PWM. Seemingly a more effective approach would be the adoption of these fundamental microcontroller peripherals in the lectures on microprocessors systems. Nowadays, these topics are treated in a very general purpose way, i.e. students are taught general principles about ADC and so on, which does not help them when they have a specific microcontroller at hand.

With a much frequent helping hand of instructor, the team could see the throttle controller operating nicely. However, given the high degree of instructor interference during the project development, it is more correct to think of the instructional pedagogy as a blend of PBL and traditional one.

The ubiquity of ICEVs in modern societies along with the lure of youth for these machines underpinned our decision to introduce car technology as a motivating theme to teach microprocessors lab classes. Despite the difficulties cited above, we strongly support the idea that a blend of PBL and traditional instructional pedagogies, along with ICEV-inspired applications, can be much effective in igniting students' interest in learning microprocessors systems more profoundly. And this, beyond doubt, can ease their future migration to industry.

Using Scrum to Teach Software Engineering:

a case study

***Abstract*— The diffusion of agile methodologies in software development makes them more mature for corporative environment. However, teaching agile methodologies on the academic environment poses many difficulties and limitations. This paper describes a case study where an innovative approach for teaching software development technologies was adopted. In this approach, the entire course was designed to fit Scrum's principles, so that the students could apply them as they were learning it. Also, the course's main project was to be developed in sprints, as proposed in Scrum. After almost two years using this approach, in this paper we describe our experience and perform a critical analysis. We observed some positive points, such as the practical nature of learning by example, and a better preparation of the students regarding agile methodologies. As negative points, we highlight the impossibility of delivering complete products in earlier sprints, and some interaction and collaboration difficulties. The main conclusion of this study is that, for the approach to work in our academic scenario, a modified version of the Scrum methodology was necessary.**

Keywords—agile methodologies, software engineering, academic teaching, SCRUM

I. Introduction

The software market demands readiness for unexpected and quick changes, and the earlier software engineering methodologies did not seem to be appropriate for many practitioners. Agile methodologies, such as Scrum [1], are a response to this demand. As a direct consequence of this evolution, there is an increasing need to place more emphasis on teaching Scrum in order to prepare students for their professional careers [2].

It is a known fact that teaching software engineering cannot be restricted to presenting concepts and methodologies as abstract ideas. It requires the integration of applied methodology and theory into the practice of software development, otherwise students may fail to develop a deep understanding or appreciation of the most important ideas [3]. For this reason, most software engineering courses have a large project, meant to be its final piece, also known as capstone project. Mahnic presents a discussion about the use of agile methods in capstone projects, based on different literature reviews [2]. While there are many successful stories that favor agile methodologies in these scenarios, Mahnic argues that there are some reports indicating that a more traditional, disciplined process paradigm would be more suitable for the still inexperienced students.

We were facing the same dilemma in our university. We have a two-year lato sensu (specialization) graduate course in software development, which has been offered since 2003. As the final part of this course, students must develop a large project to put into practice the concepts they learn. Until recently, they followed a traditional process, moving from requirements to the finished software product in a single iteration. However, this model was causing problems, mainly because of the lack of proper time management. Due to different factors, such as limited availability of the students and a long wait until they reached enough maturity to start developing the project, the delivery of unfinished and/or poor quality projects was very frequent.

An agile methodology seemed to be a perfect solution, as it is a structured process, but that supports both creativity and productivity in a team project. It also allows for flexible, self-controlled time and task management that enables students to react on the varying workload in their jobs [4]. So, as pointed out by Schneider and Johnston [5], we asked ourselves: should we try to change the scenario, and introduce the practices of agile methodologies in software development education?

We decided to follow this path, by adopting a Scrum-based approach to teach software development technologies and software engineering concepts. In the approach, some Scrum practices, such as iterative and incremental development based on sprints, were integrated into the academic environment, so that the learning itself could happen in an iterative and incremental way. To fit this format, the entire course had to be reorganized so that the disciplines could deliver the necessary contents for the sprints to succeed.

In this paper we present the approach in details, and also perform a critical analysis after two years of experience with it. We highlight the main positive and negative points, and try to make suggestions to improve it in the future.

The remainder of this paper is organized as follows. Section II presents the background and scenario of the study. Section III presents the sprint planning for this course. In Section IV we present our critical analysis and suggestions for the second version of the course. Finally, in section V we present some concluding remarks and future work.

II. BACKGROUND

The initiative described in this paper was conceived in the context of a lato sensu (specialization) graduate course, in the area of software development for the Web, offered at UFSCar – Federal University of São Carlos – SP – Brazil, since 2003. In this course, students learn different software development techniques and concepts, such as programming, modeling, database design, human-computer interaction, web development and project management. The course has also a practical component, in the form of a mid-size software project, where the students can put most of the theory in practice. The course project was supposed to be developed in parallel with the theoretical activities, in groups of six or less students.

But since the beginning of the offering, we observed that many projects reached the end of the course as incomplete, or with fundamental flaws that could not be corrected in time. We identified two main possible causes for this problem. The **first** one is the fact that most students have a limited availability because they have jobs and/or work in different areas. They typically have 6-8 hours per week to work on practical assignments, and this was causing many delays.

A **second** possible cause is the fact that many students seeking this degree have little or no knowledge in computer sciences, while others have practical knowledge, but never got a bachelor or engineer's degree. We typically have 20% of the students without knowledge in software engineering and 30% of the students working in other areas. As a result, the classes normally start with a very heterogeneous distribution in terms of academic formation and practical background. Many students do not reach a degree of knowledge that is sufficient for the project to start until much later in the course. So the project normally started only after one year or more.

After many discussions, the course organizers came to the conclusion that the solution to this problem was not to change the course duration – 444 hours distributed over two years – but to better distribute theoretical and practical effort.

Together with this observation, there was the fact that agile methodologies were already included in the course program, as a subject related to project management. But it was being taught in an abstract way, leading some students to wrong conclusions or even boredom.

As a response to these two problems, the course was reorganized to employ the concepts and principles of agile methodologies. Because it follows the agile ideology [1], even though it is not specifically tailored for teaching, Scrum was adopted as the model for the iterative approach to be followed during the course.

First, it was established that the project was to be developed iteratively and incrementally. At short periods of time, or sprints, students should deliver parts of the system, until it is complete. In parallel, the theoretical disciplines of the course were reorganized to deliver the necessary content for each one of these sprints to succeed.

The expectation behind this proposal was that students could start development earlier, and have less risk of delivering an incomplete project in the end. It would also make them practice agile development in a mid-size project, reducing the gap between theoretical software engineering teaching and practical agile concepts.

Next section presents the detailed course setup and description of the course project, according to the agile approach.

III. COURSE PROJECT

Initially, it was established that the course disciplines would be divided according to their applicability in the project. For this reason, the course started with an overview of Scrum, basic programming, requirements and analysis. More advanced contents, such as database design and programming frameworks, were to be introduced later, and so on. This was done for the theoretical part of the course, which resulted in four phases, described next.

The **first phase** had an estimated duration of 3 months, and consisted in an introductory phase. It was also called "pre-Scrum" phase, and was dedicated to the activities that are not related to actual development. In this period, there were teaching activities about the development process, environment preparation and basic programming. The disciplines that were part of this phase were:

- Agile software development: studies about the software development methodology that would be used in the projects. In this course, Scrum was adopted;
- Free software development platforms: preparation of the environment to be used in the project. In this case, the students would have to work with CentOS [6], PostgreSQL [7] database and Java IDEs NetBeans [8]; and
- Java certification: a basic java discipline, intended to help students get acquainted with the language that should be used to develop the projects.

The **second phase,** which had duration of 4-5 months, involved the actual usage of the agile methodology. In this phase, the disciplines focused on requirements, analysis and design. The goal was to enable the analysis and design of the project to be developed. But since the students should already be developing part of their projects, some software development techniques were explored, such as web development, mobile computing, and database activities. This would allow them to deliver a few parts of the software that involved only basic programming. Other parts of the project, that required advanced knowledge on database persistence or a more complex framework, would be introduced later.

In the **third phase**, with duration of 5-6 months, there were the disciplines that would provide most of the content of the course. Here the focus was on giving a complete coverage of most recent web development topics, such as human-computer interaction, object-relational persistence frameworks, service-oriented architecture, reuse-driven development, test-driven development, among others. The content of this phase was intended to be used by the students during most of the part when developing their projects.

In the **fourth and final phase**, which was supposed to last 2 months, the disciplines involved advanced topics, to close the theoretical part of the course. Project management, advanced development topics, such as data warehouse and optimization, and even scientific methodology, helped to give students a better understanding of which topics could be further explored later in their career.

These four phases characterize the theoretical part of the course; however they were not applied in a sequential way. Since we were following an iterative process based on Scrum, the actual division of activities was different. The course was organized around the project, and thus it was divided into eight sprints of three months each. At the end of each sprint, students were supposed to deliver part of their projects, as working software.

To support these deliveries, the disciplines had to be arranged to provide students with the necessary knowledge in each sprint, in order to allow a logical evolution from sprint 1 to 8. So, early sprints have more focus on disciplines from the phase one of the theoretical part of the course. And late sprints have more focus on the disciplines from phase four.

There had to be some repetitions, as some disciplines had too much content. In these cases where the same discipline appears in more than one sprint, only part of the content was given at each time. For example, the "agile software development" discipline appears in six sprints, each time introducing new concepts, starting with basic concepts and ending with practical examples and guidelines. "Object-relational patterns and frameworks" is another example, appearing in three sprints, basic concepts in the first and

TABLE I. BASIC COURSE SCHEDULE

Sprint	Disciplines	Sample deliverables of one of the groups
Pre-Scrum	- Agile software development - Free software development platforms - Java certification	None
1	- Web programming - Pattern-based software modeling - User interface design and evaluation for the web - Object-relational patterns and frameworks - Agile software development - Database design	- Class models - Database models - Basic CRUD operations for users - System authentication
2	- Pattern-based software modeling - User interface design and evaluation for the web - Object-relational patterns and frameworks - Database design - Mobile computing - Agile software development	- Advanced CRUD (different user types) - Community creation - Update in the system layout - Update in the documentation
3	- Mobile computing - Web development frameworks - Object-relational patterns and frameworks - Agile software development	- Profile visualization - Profile data update - Sharing of public messages - Timeline visualization - Pending issues in authentication
4	- Service-oriented architecture and web services - Reuse-driven software development - Scientific methodology - Agile software development	- Design for mobile devices - Login/logout for Mobile - Information visualization - Multiple timeline visualization - Basic CRUD for other information - Message posting - Project mockup
5	- Test-driven development - Service-oriented architecture and web services - Reuse-driven software development - Scientific methodology	- Technical issues - Visual adjustments in the interface
6	- Reuse-driven software development - Performance optimization of Relational DBMS - Images and visual effects in web applications - Software development topics - Agile software development	- Image posting - Contact acceptance - Search for contacts and communities - Inclusion of contacts and communities - Community visualization and adding
7	- Data warehouse - Scientific methodology - Reuse-driven software development	- Video posting - Invitation/inclusion of people in communities - Administrative interface - Access privilege control - Community reports
8	- Project management in agile software development - Scientific methodology	- Technical issues

practical knowledge in the end.

Although it may seem that these sprints take longer than most sprints in industrial projects, which typically last between 2-3 weeks, in terms of work hours the duration is approximately the same, because students were supposed to work 8-10 hours per week on the course project.

Table I shows the basic course schedule, together with an example of the deliverables that one of the groups should provide at the end of each sprint. The deliverables refer to a system to help in the organization of scientific events, which was the domain of their project. In the next section more details about the project and the deliverables are presented.

The students must complete a mid-size software project as part of their course. In our approach, this should be done iteratively, to reduce the risk of incomplete projects in the end. So, the students had to plan what should be delivered, in term of user stories [9,10], at the end of each sprint. Due to the limitations of the academic environment, in comparison with an industrial project, in our approach students were allowed to deliver incomplete products in some sprints. In other cases, students could plan to deliver only enhancements or adjustments, instead of a product, in a sprint. Table I shows some examples of these cases in sprints 5 and 8. But every sprint should include some form of deliverable.

There was a product owner (PO) [9,10] assigned to each team of six students. The PO would be responsible for the definition of the stories and for following the results of the development. As this was also an exercise of Scrum itself, students had to practice the role of Scrum Master [9,10]. So, in each sprint, a different member of the team should act as Scrum Master, to put in practice the different concepts of the method and also learn his/her responsibilities.

Another important point of the project setup was the definition of the domain. We have observed that, in this course, the groups almost always follow a pattern: normally, students are professionals working on the software market, with little time to develop the activities. They also normally live in a distance from each other – only a few groups are composed of people living in the same city. The different areas in which they work also caused a great degree of heterogeneity and a knowledge gap between the members of a group.

To minimize the negative impact of these factors, we defined that all groups, without exception, should work on one out of two possible projects. Half of the groups would develop project A, and the other half would develop project B. With a regular class size of 35 students, this results in six teams with 5-6 students.

Two teachers would play the role of PO, one for each project. They were supposed to help during the planning meetings and give technical support regarding the development technologies and/or correct application of Scrum principles.

Control during the process would be performed with the help of an on-line sheet. In this sheet, students and teachers should include and maintain all the necessary information to allow a proper management of the development in each sprint.

Basically, when planning a sprint, the students would insert the stories in the sheet, together with the activities to be performed. With all activities available on-line, each member perform it. The Scrum Master (of that particular sprint) was responsible for maintaining the sheet, and also making sure the others keep it updated, so that he/she could follow the burndown chart [9,10]. In this sheet, the chart was automatically updated each time an activity was marked as completed. The following information was part of the sheet:

- **Product backlog**: list of stories of the system, with a detailed description and the acceptance criteria;
- **Sprint**: stories of the current sprint and the tasks needed to finish them;
- **Kanban**: repeats the tasks from the "sprint" part, and includes a status column ("to do", "blocked", "doing" and "done") and a task finish date column. Fig. 1 shows an example of this part of the sheet;
- **Burndown data**: based on the tasks table of the kanban sheet, this part keeps a comparison between the planned dates and the actual dates; and
- **Burndown chart**: graphical visualization of the burndown

fx Create the service to list the friendship requests

data. Fig. 2 shows an example of this part of the sheet .

Fig. 2. Example of a Burndown Chart

IV. CRITICAL ANALYSIS

In general, the approach was successful, as both of its goals were achieved:

1. All groups were able to deliver the complete project in the end of the course; and

2. Students managed to put some of the agile principles in practice, using them as they were learning them. This resulted in a better learning of agile concepts.

There were also some additional positive observations. In our case, both teachers acting as POs had previous experience with Scrum in practical scenarios, which has proven to be essential to provide a good alignment between the course content and the principles of agile development. The presence of these teachers as POs, and their constant availability, was also a positive result, since it allowed students to clear their doubts without taking too much time. The fact that the POs were teachers, specialized in Scrum and technical development concepts, and not business experts, did not result in a negative influence. This happened because the projects involved a domain which they were actually very familiar with – scientific events. The rotation of the Scrum Master role was also benefitial, allowing each student to play this part at least one time.

However, we observed many problems with the approach, and we believe these could be addressed to provide even better results in the future.

A first problem relates to the gradual evolution of the learning process in a normal course, and its contrast with the incremental and iterative approach proposed by most agile methods. There is a natural incompatibility between these two approaches, because each sprint represents a small, but complete, development iteration. This means that, in each sprint, the development team must perform activities that are related to almost all software engineering disciplines, even if only a little part of them at a time. Although we attempted to introduce these disciplines at the same time, much content was only really assimilated by students after two or three sprints, after the discipline was finished.

This explains why most groups were unable to deliver complete software in earlier sprints, because they simply did not have enough knowledge to implement a complete piece of software. For example, service-oriented architecture is only introduced in sprint 4, so it was impossible for some groups to implement a distributed part of the software in sprints 1, 2 and 3. More basic concepts, such as object-relational frameworks, were introduced only in the final stage of sprint 1. Some framework concepts were left to sprints 2 and 3, so many stories could not be completely implemented in these sprints.

When interviewed by us, some of the students reported this exact problem. Many complained about the mandatory deliveries in the early sprints, arguing that they still had not learnt the necessary concepts to implement what was being planned. Those ended up delivering incomplete software or software with conceptual errors. Of course, there were those students that already had the necessary knowledge, because they already work with development, but this is far from ideal.

A second problem we observed relates to inspection and self-management, two central aspects of Scrum [9,10]. Students reported that, because they are not physically close to each other, and because many of them had other time-consuming activities, some of the interaction tasks required for control in Scrum were not properly executed, or not executed at all. One example is the interaction between the Scrum Master and the rest of the team, which turned out to be very difficult under these conditions. The physical distance and the lack of responsibility and discipline of the other members of the team made it nearly impossible for the Scrum Master to control task execution in a continuous fashion. This is a serious flaw, because personal interactions is a strong principle of Scrum and agile methods in general.

Another issue is that, because there were only two possible projects, shared by all groups, there was always some kind of comparison happening between the students. Some felt pressured to keep up with the most experienced students, while others, less experienced students, felt intimidated by the top groups, becoming even frustrated in some cases.

We do not see any ideal solution for the first two issues, as we consider them to be innate to this particular academic environment. It is not possible, for example, to obligate students to be physically present at the university all the time, since this is a postgraduate course, and most students have their regular jobs. However, we did identify some improvement possibilities, that we intend to test in a future version of the course. These are described next.

A. Changes in the second version of the course

A first change relates to the definition of the POs. In the first version, two teachers acted as POs for all groups. This was not seen as a negative point in the first version, but only because the projects involved a domain the teachers were familiar with. As we wanted to change the domains, we decided to use actual business experts as POs. We also defined that they should not be familiar with technical details. The idea is to make the students experience what it feels like to deal with potentially real customers, having to work harder to establish the communication and capture the PO's knowledge.

A second change is that, differently from the first version, where there were only two projects from which students could choose, in this second version there were more options, allowing each group to work in a different project. This should reduce the comparison effect we observed earlier.

Another change in this second version is related to corrections and improvements made in the software, from one sprint to another. In the first version of the course, we observed that many groups were spending time in one sprint to correct mistakes made in the previous one. This happened because of the irregular learning curve discussed in previous section. In this version, we made it possible for students to include these corrections and improvements as valid deliverables. So, instead of delivering one complete piece of software in each sprint, a group was allowed to deliver an incomplete, or erroneous part of software, in one sprint, and plan its correction in a future sprint.

The changes described here are being currently tested, in a second offering of the Scrum-based version of the course. We expect to observe improvements related to some of the issues described in the previous section.

V. CONCLUDING REMARKS AND FUTURE WORK

Although we observed many problems and issues, the merging between teaching and an agile process has proven to benefitial to students. It leveraged the overall experience, from simpler theoretical classes, to a richer practical activity revolving around actual development, simulating the real challenges of this dynamic environment. Students were forced to not only understand the concepts and principles of agile development, but put them in practice and feel the difficulties faced by practitioners. In particular, they had to deal with technical challenges, process enactment challenges, personal interaction and inter-team relationship.

We perceived that some aspects of the methodology, such as scoping and delivery restrictions, had to be adapted to make the experience viable in an academic environment. Some of these adaptations were aldeady made during this first experience, while others are being tested in a second version. In either case, the adaptative nature of the course made this experiment possible.

Regarding the difficulties and problems that were observed, we conclude that some can not be easily solved, such as those related to the physical distance between the students and their lack of time and dedication. For others, we are currently experimenting some changes, as described in previous section, and we expect good results. Feedback from the teachers and the students will enlighten our path, and possibly raise new issues.

Besides these changes we already described, future work should deal with:

- Better distribution of the disciplines alongside the sprints, to provide a closer alignment with the deliverables. Perhaps there should also be some kind of guidance during the initial planning, in order to help students to start with simpler stories;
- Better choice of projects, to only include those that are amenable to a more logical division from simpler functionality to a more complex one; and
- Self-management formalization, to help Scrum Masters to deal with their teams. Currently, it is up to the team to define how they should be managed. However, this has proven to be problematic, because of the distance between its members. A more formal process, requiring more rigid control, would force students to have discipline and an active participation, specially in process control. Even if it goes against the agile principles, we believe this could be benefitial in this particular environment.

The experience, although in its first version and with glitches and corrections to be made, forcing students to not only understand the concepts wrapped up the process, but also to apply them and feel the difficulties faced by professionals who choose to use the method, as both procedural and planning relationship with the team.

It is felt that some aspects of the methodology, such as the closing of scope and delivery restrictions, sometimes must be adapted so that it becomes feasible to use the method in practice academic environment. The vision of the labor market and experience in agile methodologies presented by those involved was importance to design and optimized coordination of the course. Some strategies may not be considered agile, as the time between sprints and little interaction between the team members. The time between sprints is necessary because the teams need learn how to do and do it. The increase of interaction between the team members can be made and we have recommendations how to solve it in the next experience.

In the next experience some points will be analyzed to reduce the difficulty required to develop the full functionality in the sprints with only part of knowledge, requiring only the scope that has already been taught. The process for the development of Sprint requires weekly meetings replacing the daily meetings of the original conception of Scrum. The meetings will relate the status of the worksheets and they will show the progress of activities in parallel. These points will be not abandoned and they are essential for the correct handling of the use case, where someone can perform a checkpoint of these activities during the sprints, assessing whether the performance is occurring in the team. However, attention must be given up lest they undermine the progress of activities and the motivation of participants with a big load evaluation.

***Abstract*— A retrospective study was conducted on analyzing student performances on the personal energy audit assignment in the renewable energy sources course. We analyzed student scores from 2006, 2009, and 2012 years respectively and categorized them by declared major. In this assignment, we asked our students to calculate the amount of energy that they consumed in one week of their life in college and identify the activities that consumed the largest amount of energy. We also asked them if they would consider any habit changes after completing this assignment. The goal of this assignment was to introduce non-science and engineering students to the concepts of energy, power, electricity, heat, temperature, first and second laws of thermodynamics, embedded energy and world energy consumption. The most common categories included; energy consumed in heating up water, transportation, and electricity. Additionally, on calculating energy used by electricity, we asked the students to confirm their calculations by reading labels and using Kill-a-Watt reading devices. In total, the scores of more than 500 students were evaluated. We found that the average of the scores increased by 19% between 2006 and 2012, and by 14% between 2009 and 2012. Since we used a similar rubric for grading, this shows that the students were able to perform better as we provided more step-by-step instructions, and streamlined the lectures on basic physics and energy concepts in the first three weeks of the course. Moreover, we grouped the student's scores by their declared major. The four categories were engineering, social sciences, natural sciences, and undecided/other majors. We found that in 2006 the students with social science majors on average received the highest scores and in 2009 the students with natural science majors received the highest scores. Interestingly, the students with engineering majors showed the highest improvement in their scores between 2006 and 2012. The paper provides analysis of the student performances on this assignment and the overall effectiveness of this assignment.**

Keywords— personal energy audit

I. INTRODUCTION

While our nation faces the challenge of meeting the demand of growing energy consumption, personal energy audits are coming more and more common in residential and commercial sectors. In 2010, together, these two sectors consumed 41.2% of energy in the United States[1]. Currently, the important concepts of saving energy at home and at school are taught as early starting the third grade through the 12th grade and in college[2]. Concepts of energy management, solid waste and recycling are part of the curriculum starting in kindergarden through the 12th grade in high school[3]. Popular teaching methods include classroom activities and hands-on experiments. Home energy efficiency kits have been developed for students to take home, to facilitate discussions between students and their parents on various ways of saving energy. Typically such kits consist of incandescent light bulb, compact fluorescent light bulb, kill-a-watt meter, light meter, Teflon tape, low flow showerhead, kitchen sink aerator, thermometers, night light, radiation cans, humidity pens, and other related materials[4].

The use of SmartMeter technology is expanding dramatically in California. Pacific Gas and Electric Company (PG&E), provides energy services to 15 million people across 70,000 square miles in California, deployed 9 million advanced meters across the state. SmartMeters provide meter reads that include hourly intervals for electricity consumption and daily intervals for gas consumption. The energy use information is available online. Additionally, customers can also compare their home energy usage to other homes in the area as well as to weather patterns[5]. Last year, the National Energy Education Development Project in collaboration with PG&E launched a new SmartMeter curriculum module for students in grades six through eight that reinforces the need to conserve natural resources[6]. Information provided by Smart Meters can be used directly in student's personal energy audit assignments.

While conservation of energy is becoming more popular in K-12 curriculum, energy audits assignments are becoming a standard at college or four year institution courses on renewable energies and energy efficiencies.

At the University of California at Santa Cruz, the Renewable Energy Sources course is a theory based course with 19 lectures and eight hands-on laboratory experiments[7-9]. It is a 10 week course that meets general education requirements. The course has been offered every spring quarter since 2006. The course is designed for engineering and non-engineering undergraduate students and does not require any advanced mathematics or physics background. A sample list of lecture topics by instructors and guest lecturers include but are not limited to;

- World energy overview
- Energy basics, temperature and heat
- First and second laws of thermodynamics
- Solar energy
- Bioenergy
- Wind energy
- Ocean power
- Geothermal energy
- Social aspects of renewable energy (guest lecture)
- Nuclear energy (guest lecture)
- Local efforts on harvesting renewable energy (guest lecture)

This year, the eight hands-on laboratory experiments demonstrate the principals of the following; solar pathfinder, flywheel, wind turbine, hydroelectric, thermoelectric, hydrogen fuel cell car, greenhouse and solar power concentrators.

Additionally, the course involves required reading assignments, four written homework assignments, a midterm, a personal energy audit, a final exam and a final project proposal. Additional information and details about this course can be found at www.soe.ucsc.edu/courses/ee80j/.

II. Personal ENergy Audit Assignment

Around the third week of lectures, students receive a 20 minute lecture which outlines the requirements of the personal energy assignment. In this assignment, students are asked to conduct a personal energy audit to calculate the amount of consumed energy in one week of their life in college and to deliver their findings in the form of a report. The lecture also provides brief step-by-step instructions on how to calculate energy consumption of the most popular activities [10].

We ask the students to write their reports while following the report format shown below,

- Abstract
- Introduction (should include information about the student)
- Methods
    - List of energy services and sources
    - Transportation
    - Hot water consumption
    - Electricity usage (Watt-hours/week)
        - Calculated from labels
        - Measured with "Kill a Watt" meter
            - When appliances are on
            - When appliances are off
        - Verified through PG&E smart metering
        - Other
- Results
- Discussion (list of questions to answer)
    - Look for peaks of energy consumption, what do they consist of? What appliances were on during those particular hours?
    - How did your energy consumption change with the weather?
    - How did your home energy consumption compare to other homes in that area?
    - Which energy services are the biggest energy users?
    - How would you expect energy use for each service to change throughout the year?
    - Any surprises or noteworthy points?
    - From working on this project, would you now consider alternative energy sources for particular services?
    - From the calculations above, suggest a replacement for one of the high energy appliances? How much would it offset your energy consumption by?
    - Would you now consider a habit or lifestyle change?
    - Compare your results to the average American and European citizens.
- Conclusions

III. Results

At the end of the 2012 quarter, we asked every student in our class to complete a questionnaire which we asked a series of questions about the course. One of the questions asked was if the course had made the students more aware of energy use and its impacts. Another question was more specific to the energy audit assignment, which asked if the students had changed some of their personal energy use habits as a result of this course. We asked the students to rate their responses using the Likert scale. The results of our findings are presented in Table I. Seventy six percent of the students strongly agreed or agreed that this course made the students be more aware of energy use and its impacts. Almost sixty percent of the students have changed some of their personal energy habits as a result of taking this course.

TABLE I. Eng of Quarter Questionnaire, Spring 2012

Questions	***Strongly Agree***	***Agree***	***Neutral***	***Disagree***	***Strongly Disagree***
This course has made me more aware of energy use and its impacts.	30%	46%	18%	4%	0%
I have changed some of my personal energy use habits as a result of taking this course.	20%	39%	29%	7%	3%

Over the last six years, we improved our lecture instructions and the details of the assignment in order to show improvement in our instruction over the last 6 years. We conducted a retrospective study where we looked at the student's scores for the energy audit assignment when the course was taught in 2006, 2009 and 2012 (every 3 years). In total, the scores of more than 500 students were evaluated. We found that the average of the scores increased by 19% between 2006 and 2012 and by 14% between 2009 and 2012. Since we used a similar rubric for grading, this shows that the students were able to perform better as we provided more step-by-step instructions and streamlined the lectures on basic physics and energy concepts in the first three weeks of the class.

Additionally, we grouped the student's scores by their declared major. The four categories were engineering, social sciences, natural sciences and undeclared/undecided/other majors. We found that in 2006 the students with social science majors on average received the highest scores and in 2009 the students with natural science majors received the highest scores. Interestingly, the students with engineering majors showed the highest improvement in their scores between 2006 and 2012. Fig.1 contains the results of our findings.

Moreover, we looked at the performance of the students based on their grade level; freshmen, sophomores, juniors and seniors (students in their fourth year or higher). We found that sophomores received the highest scores in 2006 and 2012 while seniors received the highest scores in 2009. The highest improvement in scores between 2006 and 2012 was among juniors and the highest improvement between 2009 and 2012 was among freshmen. Lastly, we sorted the student's scores based on the student's gender. It was found that the male student population had the highest improvement from 2006 to 2012 and 2009 to 2012, while the female students received on average higher scores in 2006 and 2009. Fig. 2 and 3 contain the results of our findings respectively.

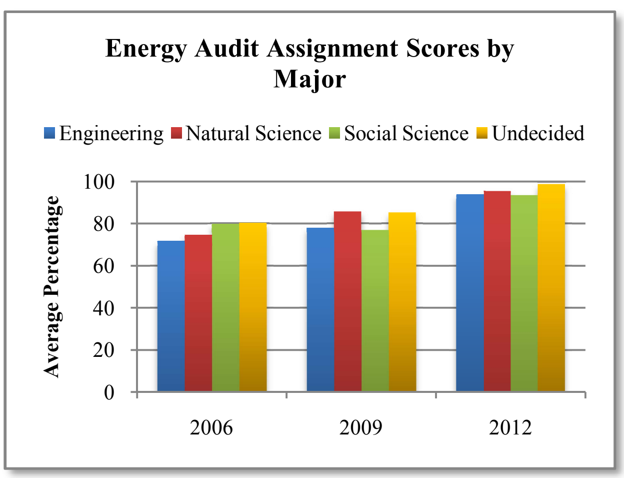

Fig. 1. Average Energy Audit Assignment Scores by Student's Major

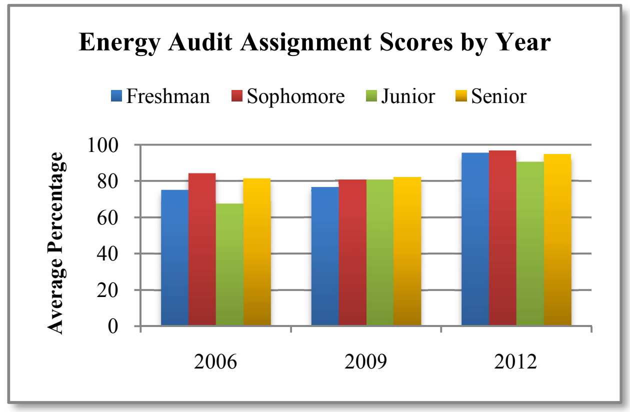

Fig. 2. Average Energy Audit Assignment Scores by Student's Year at the University. Note: Seniors are fourth year or higher.

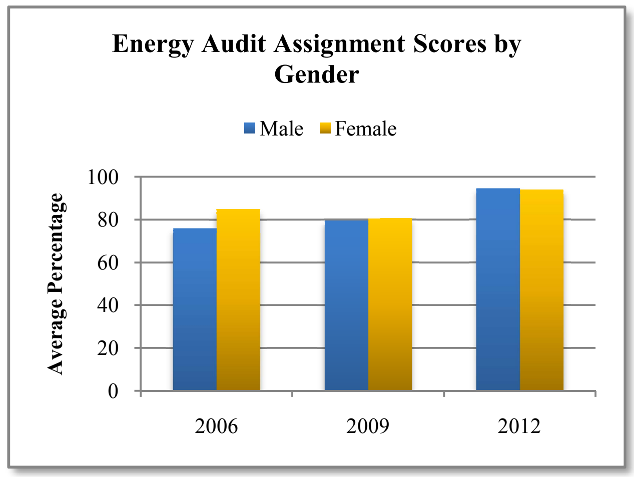

Fig. 3. Average Energy Audit Assignment Scores by Student's Gender.

IV. Long Term Follow Up

For long term follow up, we contacted our alumni students who took our renewable energy sources course exactly five years ago. At that time, our class enrollment was 139 students. Using social media, we were able to locate 75 of those students to whom we sent invitations to participate in an online survey in December 2012. We received responses from 27 students. Below is the summary of our findings;

- 93% of our students agreed or strongly agreed that our course significantly broadened their knowledge of renewable energies, energy conversion, energy storage, or clean energy technologies.
- 93% of our students recommend for other universities and colleges around the country to implement such a course into their institutions.
- 89% of our students agreed or strongly agreed that our course was a valuable course of their curriculum at UCSC.
- 89% of our students agreed or strongly agreed that our course sparked their interest in learning more about topics related to renewable energies.
- 74% of our students indicated that they have experienced a few habit changes since completing the personal energy audit assignment as part of this course.

- 93% of our students indicated that if they were to pass by a newspaper stand and to catch a glance of a title on the front page of a newspaper, “San Francisco voted to be powered by 100% renewable energy” they would read at least part of the article.

The outcome of this survey shows a great interest among our students in the environment in which they live in and the energies that power it.

ACKNOWLEDGMENT

Authors would like thank past and present students of our Renewable Energy Sources course. Additionally, the authors would like to acknowledge the financial support from NSF/DUE 1023054 Engaged Interdisciplinary Leaning in Sustainability grant.

Abstract*— At Hartnell Community College in Salinas, California, a renewable energy and energy efficiency course is a theory based course with several hands-on laboratory experiments. The course is designed for engineering and non-engineering students who are looking to transfer to a 4 year institution. Similar courses at 4 year universities, usually meet general education requirements. This course does not require any advanced mathematics or physics background. In order to enhance student learning in this course, we offered an additional hands-on laboratory experiment on concentrating solar power. The laboratory kit consisted of affordable and widely available materials that included 24 telescoping mirrors, stands, steel cup, thermometer, timer, and a cup of water. We asked the students to design, assemble, and test a central receiver concentrator with the goal to boil water contained in a steel cup. Upon achieving this goal, students were then asked to calculate the efficiency, define losses, and recommend ways of increasing efficiencies and therefore improving their systems through. The design challenge for the students is to determine the optimum position for the mirrors. Additionally, we asked the students to comment on the following; the effects of the time of the day and weather conditions, direct commercial applications, the process of generating electricity from solar concentrators. In order to record the level of improvement, each student was given the same questionnaire before and after completing the laboratory experiment. Upon grading the questionnaires, our assessment showed a 30% average on pre questionnaires scores and a 73% average on post questionnaire scores, suggesting a 43% improvement. This paper presents the results of our findings on performance improvements in further detail.

***Keywords*— concentrating solar power, laboratory experiment, solar concentrators, questionnaires.**

I. INTRODUCTION

A solar concentrator is considered one of the cleanest technologies for harvesting renewable power. There are several ways of concentrating solar power. The most popular methods are through using one or the combination of one of the following:

- A parabolic trough concentrator is a solar thermal energy collector. It is constructed as a long parabolic mirror with a tube running its length at the focal point. The sunlight is reflected by the mirror and concentrated on the tube. It usually rotates to track the sun that moves across the sky.
- A central receiver concentrator also known as central tower concentrator is also a solar thermal energy collector. In such design, a tower is used to receive the focused sunlight from an array of flat, movable heliostats (or mirrors).
- A parabolic dish concentrator is also a solar thermal energy collector. In this design, one or more parabolic dishes are used to concentrate solar energy on a single focal point. It is considered one of the most powerful types of collectors. [1]

For the purpose of this laboratory experiment, the authors chose to focus their attention on a central tower concentrator system. Recently, these types of systems have received more interest on a large scale. Typically, large scale systems of this kind cover several square kilometers, consisting of thousands of heliostats, and one central tower.

In the United States, several power plants of this kind are in production in the Mojave Desert, California. The first prototype was completed during the 1980s, it is capable of generating 10 MW of power. Fig. 1 demonstrates a photograph of this power plant on the left [2]. At the same time, internationally, PS10 and PS20 solar power towers were completed in 2006 and 2009, generating 11 and 20 MW of power respectively, providing energy for over 10,000 homes in the city of Seville, Spain[3]. Fig. 1 shows a photograph of the PS20 power tower on the right.

Fig. 1. Barstow central receiver system (left). SP20 central power tower in Seville, Spain (right).

II. METHODS

The goals of this laboratory experiment were to illustrate the principles of concentrating solar energy, to familiarize students with relevant technologies, and for students to gain knowledge and skills in calculating efficiencies.

To achieve these goals, we introduced a miniature version of a central power concentrator system that mimics the insights of a large scale system. Next, we asked the students to design, assemble, and test a central receiver concentrator with the goal to boil water contained in a steel cup. Upon achieving this goal, students were then asked to calculate the efficiency, define losses, and recommend ways of improving their systems.

The students were encouraged to work in groups of no more than three students. The laboratory was approximately 90 minutes. Each individual student was provided with a paper based laboratory write-up and each group was given a laboratory kit consisting of discrete components. Each laboratory kit consisted of 24 telescoping mirrors, a stand, a steel cup, 6 oz. of water, a thermometer, and a stop watch. The telescoping mirrors, steel cup, thermometer, and stop watch are affordable and commercially available instruments. The steel cup was previously welded to the extendable arm of one of the original telescoping mirrors. The stand was custom made to provide support for the 24 mirrors and the steel cup with support.

Next, the students were asked to read the laboratory instructions, follow directions, conduct the laboratory experiment, and fill in the required information while showing their calculations. The students were then asked to follow the instructor outside to collect the needed data. Below is the list of 13 steps summarizing the laboratory instructions. Additionally, the students were provided with formulas needed for the calculation of efficiency.

Laboratory Instructions

Due to the large diversity of student backgrounds, we provided more detailed instructions than if it was all engineering students.

1 Using the data published by the National Renewable Energy Laboratory in Colorado, determine the amount of solar energy available at your location today. Calculate the solar power density available to this location per day.

2 With your group partners, discuss possible configurations of harvesting solar power using the 24 telescoping mirrors. Your goal is to build an energy harvesting device that brings a cup of water to boil in the least amount of time and therefore achieving the highest efficiency possible.

3 Choose one mirror configuration that you and your partners agree would achieve the highest efficiency and discuss it with your instructor.

4 Proceed to the outside location with your instructor.

5 Place the stand in the desired location. Next, position your lab components in the following order; cup holder with a mounted cup, water, thermometer, telescoping mirrors. DO NOT TOUCH THE CUP AND THERMOMETER ONCE THE FIRST TELESCOPING MIRROR IS IN PLACE. SERIOUS BURNS MAY OCCUR.

6 Record the temperature of water and time periodically (every 30 seconds or 1 min).

7 Once the desired temperature of the water is achieved, disassemble your device by first removing the mirrors, letting the steel cup cool off for several minutes. Next, remove the cup holder with a cup and finally pour out the water in a safe location.

8 Please return to your classroom.

9 Calculate the amount of energy needed to raise the given amount of water by certain number of degrees Celsius.

10 Calculate the amount of power that was put into the system to raise the temperature of water.

11 Estimate the circular area (in meters2) of the solar concentrator that you built. You can do so by estimating the radius and calculating the area.

12 Calculate the power density of your device.

13 Lastly, calculate the efficiency of your system.

Discussion Questions

- Why do you think the efficiency of your system is so low? Define at least three losses in your system.
- Taking the losses into consideration, identify at least three ways of improving the efficiency of your system.
- If you and your partners had another chance at conducting the same experiment, what would you have done differently from the beginning?
- What effects do the time of day and weather have on this experiment?
- Brainstorm several direct commercial applications of the solar concentrator.
- Develop a scheme to generate electricity from a solar concentrator.

III. RESULTS

A total of 14 students participated conducting this experiment. The class consisted of eleven males and three females, nine 1st year, three 2nd year, two 3rd year students, ten declared engineering majors, two social science majors, and two undecided majors.

All students were able to complete this laboratory experiment successfully in a given period of time. Several groups modified their design and techniques during mirror configuration and assembly processes. Fig. 2 shows photographs of students assembling their set-ups.

Fig. 2. The students are gathering data from their central tower concentrating laboratory set-ups.

IV. STUDENT ASSESSMENT

In order to test the acquired knowledge, each student was required to complete a questionnaire before and after the experiment. The questionnaires were called, pre and post questionnaires respectively. The pre and post questionnaires consisted of ten identical questions with five multiple choice answers with the last question being “I don’t know” on the pre questionnaire and “I still don’t know” on the post questionnaire. The list below contains questions from the pre questionnaire. Each questionnaire was graded on a scale of one to ten, where each score represented a number of correct answers.

Pre Questionnaire

Due to diverse academic backgrounds, the questions were chosen to access the base line knowledge of the subject area prior to the experiment as well as test knowledge gained after the experiment.

1 In the last decade, what was the fastest growing renewable power technology worldwide?

a Wind Turbines
b Photovoltaics
c Fuel-Cells
d Electric Vehicles
e I don't know

2 How long have solar concentrating devices been around?

a a few years
b a few decades
c a few hundreds of years
d a few thousands of years
e I don't know

3 How much power (over one year) are we capable of harvesting in California using photovoltaic systems alone?

a a kilowatt
b a MegaWatt
c a GigaWatt
d a TeraWatt
e I don't know

4 What is a heliostat?

a photovoltaic cell
b a photovoltaic array
c a solar dish
d a mirror
e I don't know

5 In the winter time, how many hours during the day do we receive 70% of sunlight?

a 8 hours
b 7 hours
c 6 hours
d 5 hours
e I don't know

6 If a solar concentrating device has a circular area with radius of 10 cm. What is the area of such device?

a 20 cm
b 60 cm^2
c 100 cm^2
d 300 cm^2
e I don't know

7 In Arizona, on average, 7 kWh/m^2 of solar energy density is available a day. If a solar concentrating device has an area of 2 m^2, how much energy is acquired by such device.

a 3.5 kWh
b 7 kWh
c 14 kWh
d 28 kWh
e I don't know

8 If you have a device that consumes 100 Joules of energy in 10 seconds. How much power does it consume?

a 10 Watts
b 100 Watts
c 1000 Watts
d 10000 Watts
e I don't know

9 If a kitchen kettle raises the temperature of 300 gr of water from 20°C to 60°C? How much energy does it consume in doing so? (please neglect all losses) (specific heat constant is 4.186 Joules/gr °C).

a 1.2 kJ
b 2.5 kJ
c 25 kJ
d 50 kJ
e I don't know

10 If a solar concentrating device is exposed to 1000 Watts of power per day and it harvests 200 Watts of power on daily basis, what is the efficiency of this device?

a 10%
b 20%
c 50%
d 100%
e I don't know

Upon grading the questionnaires, our assessment showed a 30% average on pre questionnaires scores and a 73% average on post questionnaire scores, suggesting a 43% improvement. Additionally, the students answered on average 2.5 questions as "I don't know". After completing the laboratory experiment, the students answered on average 0.8 questions as "I still don't know" suggesting 17% improvement.

V. Conclusion and Future Work

Overall, the students in the class showed improvement in learning and understanding concepts about concentrating solar energy. Our future plans include transferring paper based laboratory write-ups and assessment to computer based interactive applications. Additionally, one way of expanding this laboratory experiment is by adding a Sterling engine kit that would convert heat into rotational energy as part of this experiment. Fig.3 demonstrates potential addition. Other potential additions could include a variety of thermoelectric devices.

Fig. 3. Sterling engine powered by solar energy. The design challenge for the students is to determine the optimum position for the mirrors.

Acknowledgment

The authors would like to thank the students for their participation and interest in conducting this laboratory experiment. Additionally, the authors would like to acknowledge financial support from the NSF-ATE program 1104311.

Design, Construction, and Testing of an Electric Machine Test-bed for Use in Laboratory and Research Education

Trever J. Hassell, Aurenice M. Oliveira, and Wayne W. Weaver
Michigan Technological University - tjhassel@mtu.edu, oliveira@mtu.edu, and wwweaver@mtu.edu

***Abstract*—Research and education into various methods of improving energy efficiency for electrical devices has become increasingly important to meet future energy needs. Because of this need, an electrical machine test-bed was designed and built in collaboration with a senior design team for the purpose of furthering research and education in the area of power electronics and motor drives. Both the engineering education and research capabilities aspects of this test-bed have an important role in educating engineers with skills to quickly contribute to the power and energy related industry. This paper will discuss the design, construction, and testing of a research quality electric machine dynamometer and test-bed for use in undergraduate and graduate (UG/Grad) education, as well as for research into power electronics and motor control .**

Keywords—electrical machine; dynamometer; test-bed; engineering education; power electronics

I. Introduction

Dynamometer systems are used extensively in testing and verification procedures in various applications relating to automotive, industrial, and manufacturing fields. The advantages of using a dynamometer are to simulate a wide range of loads a system may experience, precise controllability, and unit testing prior to the unit under test reaching the customer. Electrical machine drive systems are used invarying degrees of dynamometer systems for both research and design, and for product validation. In order to investigate some of the latest technology and control techniques for electric machine drives applications, an electrical machine test-bed was designed and built with the purpose for both research into these topics and to compliment undergraduate laboratory course in power electronics and motor drives.

Fig. 1. Testbed Infrastructure Control Cabinet

II. Architecture and Design

The electric machine test-bed is a collection of various commercially available and custom made components. It is designed to enable a wide variety of electric machine configurations and applications, as it provides a platform for testing of innumerous projects. The current configuration of the test-bed features two identical 20 HP ABB induction machines in a back-to-back testing configuration. The “dynamometer” is controlled via an ABB (full 4-quadrant) variable frequency drive. The “prime mover” machine is driven from a custom IGBT inverter and is controlled via a dSPACE embedded controller. A Himmelstein compact a compact digital torque meter measures both shaft speed and shaft torque. The power wiring of the test-bed is controlled by a Motor Controller and Safety System Enclosure (MCSSE), shown in Fig. 1. The MCSSE includes a standalone PLC system that controls the power flow throughout the system. The test-bed machine mounting tables were built in modular fashion to accommodate various machine types and size.

While designing the dynamometer test-bed, safety was a top concern. The test cell safety layout is shown in Fig. 2 and shows two zones of safety; the green zone and red zone. These zones are a mental construct used to indicate to the test cell user where the areas of concerns are located. There are no physical barriers, or markings, in the test cell to differentiate the zones. The green zone has virtually no added risk or safety concerns, whereas the red zone requires greater caution. The “green zone” is the intended area for the operator to be during any testing or computer use and has no greater risk due to the test cell components. The “red zone” has significantly greater risk of injury because of the test-bed table, cables and cable trays, and the exposed test cell electrical components; such as the inverter, dc power supply, transformer, dynamometer, and enclosure. These devices have adequate guarding to protect from injury, however the risk is greater around these components. To protect the torque sensor cables, a cable tray was placed on the floor below the workbench. The users should observe caution when working around the workbench. The workbench also has several electrical components that could cause risk of injury and the user should be cautious when working around this. For the mentioned reasons the “red zone” is determined to have an increased risk and increased user caution.

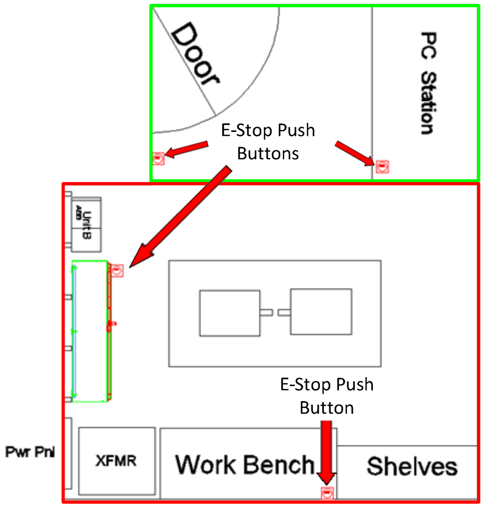

Fig. 3. Testbed Floor Layout

Throughout the entire test cell system there are several varying power supplies with the majority of power supplies powering the inverter controls and control devices including 5 VDC and 15 VDC powers supplies to power the signal isolation and interface board. The MCSSE has only two external power sources, the "Main Power" source (MPS) (208 VAC 3ph) and the "Control Power" source (CPS) (120 VAC 1ph). Table I lists all of the electrical energy levels present in the system and the rated maximum current carrying (fused limited) ability of the circuit.

TABLE II. TEST CELL ELECTRICAL POWER OPERATION LEVELS

Name	Voltage	Max Current	Description
Main Power[a]	208 V_{AC} 3ph	50 A_{rms}	Line feeds to Motors
Motor 1	208 V_{AC} 3ph	50 A_{rms}	Load feeds for Motor1 (Prime Mover)
Motor 2	480 V_{AC} 3ph	30 A_{rms}	Load feeds for Motor2 (Absorber)
Control Power[a]	120 V_{AC} 1ph	10 A_{rms}	Micrologix, Aux Fans, DC Power Supply
Control System	24 V_{DC}	10 A_{dc}	Test cell I/O, Stop PB, safety relay

[a.] denotes external power source

A. Electrical Power Stage Design

The test-bed architecture was design for two electric machines "back to back" testing. A one-line schematic is shown in Fig. 4 for the current system configuration. This system configuration allows a lower amount of energy supplied from the building infrastructure. At full load, the energy flow is in a clockwise direction and only the losses in the system are needed from the building power system. The "back to back" testing configuration consists of two identical induction machines that are mechanically coupled together via flexible motor couplings and torque sensor. There is only one source of electrical energy for the electrical machines, a 208 VAC 50 Amp 3 phase receptacle, which is supplied from a power panel from the building infrastructure. This source would supply two "loads"; the magna dc power supply/inverter and an ABB frequency drive. The Magma dc power supply powers the APS inverter which supplies power, decoupled frequency, to the "Prime Mover" electrical machine, M1. Because the frequency drive operates at a different voltage than the main source power a transformer is needed. The frequency drive would then supply the "Absorber" electrical machine, M2.

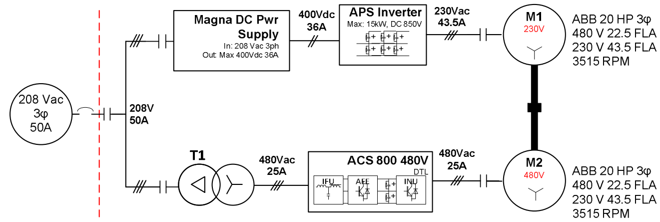

Fig. 4. One Line Testbed Circuit

B. Control Stage Design

The control state consist primarily of a custom design MCSSE that houses all of the test cell infrastructure controller hardware. The MCSSE includes five 60 A contactors that can control the flow of electrical energy in the test cell. The contactors are controlled via a Allen-Bradley Micrologix controller and a Allen-Bradley safety relay. The safety relay monitors the emergency stop push-buttons using two different electrical circuits for redundancy. If one of the contacts on the ESPB happens to malfunction, the safety relay will detect this and remove the electrical power to the outputs of the Micrologix, therefore opening the contactors, and removing the main power source to the electrical machines. If the safety relay does not detect an issue, the Micrologix controller has control on turning the contactors on and off, based on its user defined program. The advantages of having both devices controlling the contactor operation, is the reliability of the safety relay and functionality of the being able to program using the Micrologix.

The control stage power is derived from a separate power source than that of the electrical power stage. This allows the control stage to operate independent of the power stage being energized. This was a specific design choice to allow for commissioning and troubleshooting purposes. This design choice minimizes the exposure to high voltage and power wiring, when working with solely a control system issue. The power and control stage system level electrical schematics were developed and the MCSSE layout was design specifically to keep the high voltage ac power separate from the low voltage dc safety system power. Fig. 5 shows the MCSSE with the enclosure doors open. The green box indicates the low voltage dc wiring. This is done to minimize any induced voltage on the dc Safety System control circuits which may cause undesired behavior. The presence of the low voltage ac (120 VAC single phase) is necessary to power the dc power supply, Micrologix controller, enclosure ventilation fan, and the inverter heat sink fan, it is located inside the green box (upper right hand corner). This location was chosen to minimize any induced voltage on the low voltage dc circuits.

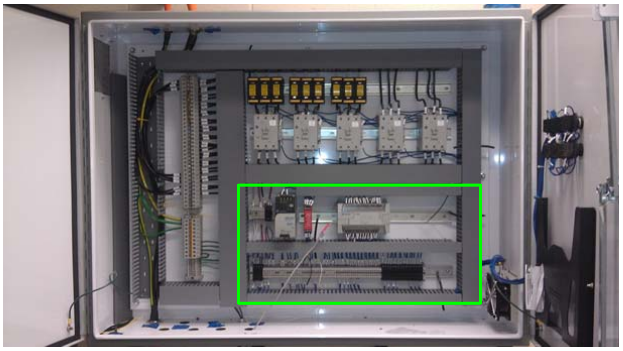

Fig. 5. Testbed Infrastructure Control Panel Layout

C. Test-bed Modularity

The test-bed system was design and built to be able to incorporate various application and configurations. It's designed is only constrained by the voltage and current levels off 600 V and 60 A respectively. The test-bed electrical machine table, shown in Fig. 6, was design with industry standard "T-slots" for mounting that are spaced with several mounting widths for various electrical machine sizes. The tabletop is also made considerably wider that the current induction machines, to allow for future expansions. The Micrologix controller was also purchase to allow for future expansion of I/O channels and possible future implementation of a Human-Machine interface touch panel.

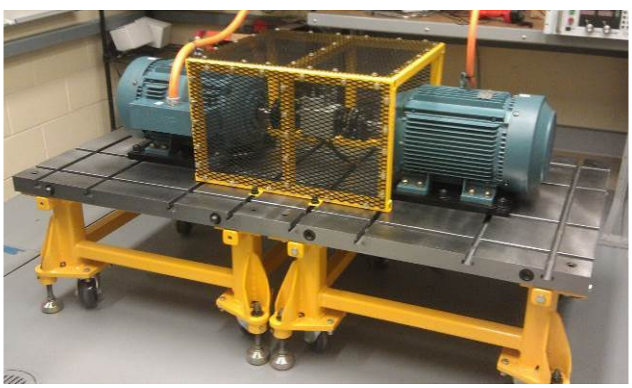

Fig. 6. Dynamometer Test Bed Table

III. Component Discussion

The test-bed is primarily comprised of off-the-shelf commercial products. The components are integrated together to form a functional electric machine dynamometer test-bed. The one-line system is classified into two distinct portions; the "prime mover" and dynamometer. TABLE III lists the different subsystems within the testbed as seen in Fig. 7. The top branch of the circuit, or prime mover, consists of the subsystems A and B. The lower branch of the one-line diagram is classified as the dynamometer and consists of subsystems E through F.

TABLE III. Test cell Major Components

Abbr. Letter	Component Name
A	Dc Power Supply
B	Dc-AC Inverter
C	Induction Machines
D	Motor Coupling Assembly
E	Isolation Transformer
F	Variable Frequency Drive
G	Controller Station
H	Control Signal Isolation and Interface

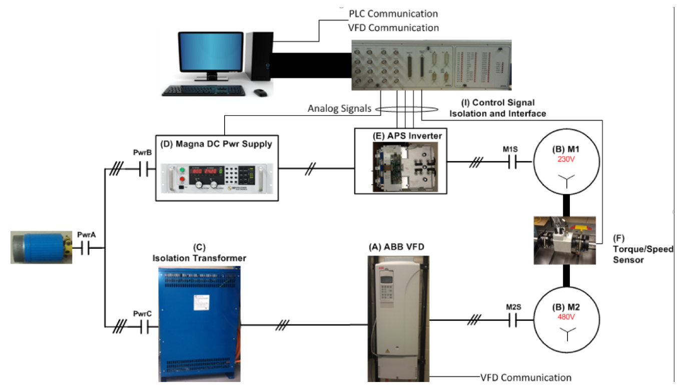

Fig. 7. Test-bed System and Component Integration Overview

A. Prime Mover Components

The "prime mover" components consist of the dc power supply and inverter. These two components allow for control over Motor 1 via the dSPACE embedded controller. The dc power supply converts the three phase voltage supplied by the building infrastructure into a dc potential, which then feeds the 3 level inverter. The inverter uses common control switching techniques such as volts per hertz, field oriented control, and direct torque control to send the appropriate voltage and current waveforms to Motor 1.

The dc power supply is manufactured by Magna-Power Electronics and is available in a variety of input and output configurations. The model used in test-bed is a TSA400-36 and has a 240 volt, 3 phase input. Its nominal output power is 15 kW with a max dc output of 400 V and 36 A. It has three modes of operation; Normal, constant voltage, or constant current. For the "Normal" mode the TS series power supplies can be configure for control by rotary mode input, local sensing, internal control, and external control. With this configuration, the operator can select either a constant voltage or a constant current output using the front panel controls. The mode is determined by the limits of the voltage or current settings. During operation whichever limit is lower for that particular operating point it will determine the operation mode, either constant voltage or constant current, that will be governing the control. For the test-bed application the dc power supply is configured to be constant voltage control by setting the current limit to the maximum value. The embedded controller then sends an analog signal to the power supply governing the dc output voltage. However one major drawback is the dc power supplies inability to sink current and absorb power from the electric machine.

The inverter can be configured as either dc to dc power converter or a dc to ac single/three phase inverter. It main function is to power and control the "prime mover" machine. The unit is manufactured by Applied Power Systems, Inc. The inverter, part number IAP75T120, is a standard IGBT sixpack configuration consisting of 6 IGBT arranged in 3 phases, each containing two IGBTs. The inverter can accept up to a 850 Vdc input, operates at switching frequencies up to 20 kHz, and has a maximum phase current of 75 A. It features built protection systems for output over-current, input over-voltage, heatsink over-temperature, control under-voltage, and short circuit protection. It also features opto-isolated (fiber-optic) gate drive and fault signal output for electrical isolation and noise immunity.

B. Dynomometer Components

The dynamometer components consist of the isolation transformer, variable frequency drive, and the second induction machine, Motor 2. The variable frequency drive (VFD), was donated from ABB Automation and Power based out of New Berlin, Wisconsin. It is intended to provide the load torque in the dynamometer system. It is an ultra-low harmonic (ULH) VFD, which minimizes the amount of harmonics injected from the grid or power supply. The VFD features insulated gate bipolar transistor (IGBT) controlling the supply side of the drive line connections to the dc link, known as an active front end (AFE). This is in contrast to the conventional diode bridge used in other VFD systems [1]. The AFE permits the ABB VFD to control the line current to sinusoidal waveform and the built in harmonic mitigation eliminates the need for additional, expensive equipment like transformers or line reactors. The AFE also ensures that the drives meet the harmonic distortion standards set by the IEEE 519 1992 standard. The ABB VFD also features Direct Torque Control, and open-loop dynamic speed-control with accuracy matching ac drives using closed loop flux vector control, Start-up Assistant estimates motor parameters by the user entering nameplate info, and Adaptive Programming.

The isolation transformer is needed because of the different potentials between the building supplied voltage level (208 Vac) and the required input voltage of the VFD (380-500 Vac). The transformer was purchase to be configured as a 30 kVA step-up, step-down, or isolation transformer. The ability to use the transformer in any one of these three configurations allows for future flexibility and varying electric machine voltage potentials while added only approximately 25 % more in purchase costs.

C. Electric Machine and Coupling Components

The electric machines used in the current configuration are 20 HP dual winding induction machines; wired for 230 VAC or 480 VAC. They have a rated frequency of 60 Hz, rated speed of 3515 RPM, and a full load current of 22.5 A/45.0 A depending on their wiring configuration. Unfortunately there was no documentation for this donated equipment, so only nameplate information is available. Further machine values and parameters are discussed in section IV.

The motor coupling assembly is comprised of a torque sensor and two flexible coupling units as shown in Fig. 8. The assembly is a "mechanically floating" system. This means there is no support to the sensor holding off the test bed. Excluding the shafts, the only means of mechanical connection is strap (cable) used to mechanically "ground" and keep the sensor from spinning with motion of the shafts. The only force the mechanical "grounding" strap would need to provide is the frictional bearing force of the sensor.

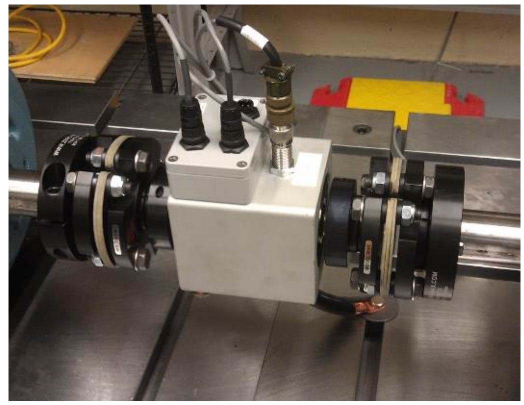

Fig. 8. Torque Sensor and Flexible Coupling

The torque sensor is commercially available unit purchased from S. Himmelstein and Company, which specializes in torque sensors of all type. It has a max continuous torque rating of 113 Nm and 226 Nm overload rating. It provides both shaft torque and speed information to the embedded controller from an external signal condition unit purchased with the sensor.

The torque sensor used is in conjunction with flexible couplings manufactured by Zero-Max. Theses couplings are intend to minimize any misalignment in the horizontal direction which would translate to axially torque that could possible damage the torque sensor. The flexibility comes from the composite discs that are a "clover" shape and are made of laminated, flexible sheets. The same flexible coupling units can be order with a variety of input and output shaft sizes, lending it to be appropriate with future configuration flexibility.

D. Test-bed Operational Controls

The current test-bed operation control is comprised of three independent interfaces. The inverter embedded controller, which sends the control signals to the inverter unit, is an ACE 1104 unit supplied from dSPACE. This system was chosen for its known behavior in laboratory classes and its relative ease of use. This controller features two digital signal processors (DSP). The "primary" DSP performs the control algorithm execution therefore performing the majority of the calculations, and executes at a rate of about 100 µs. The other DSP, or "Slave" DSP, controls the switching action sent to the inverter via pulse width modulation (PWM). The slave DSP can operate at switching frequencies in excess of 100 kHz. The DS1104 and breakout box features 8 ADC analog inputs (4 multiplexed, 4 parallel), 20 digital input/output (I/O), 8 channel DAC analog outputs, two DSP, serial communication port, and digital incremental encoder interface.

The VFD has several options for user control input such as front panel keypad, and using a fieldbus adaptor that can communicate on various industry communication protocols. For the test-bed configuration, the VFD communicates via Modbus RTU receiving its commands using LabVIEW from the test-bed computer. This configuration allows the VFD to be controlled through the common test-bed computer. From the user station, the VFD can be turned on/off, reference torque, and reference speed can be commanded.

The test cell infrastructure controls was designed to be a standalone system, independent of the VFD and inverter control systems. The test-bed infrastructure controls what power stage components are supplied the primary 3 phase power from the main power source. The test cell infrastructure controls consist of the power wiring, fuses, contactors, and a programmable logic controller (PLC). Based upon the user provided control inputs, the PLC decides the states of the outputs. Example of these control inputs are contactors, the safety relay, start/stop pushbuttons, fans, and indicator lights. The outputs of the system are the 3 phase power contactors as well as a few indicating lights. The high level control scheme of the test cell safety system puts the system in one of five states; "Ready", "Enabled", "Powered", "ON" and "Fault". These states dictate what, if any, combination of contactors and indicating lights are on.

IV. System Parameterization and Performance

To utilize this system as an educational platform, its behavior must be observed and quantified. There are several unknown areas, component efficiency, system response, and electric machine parameters that needed to be understood and characterized. These areas include induction machine parameter estimation, component operation efficiency, and system response data.

To employ any type of modern electric machine control techniques such as FOC or DTC [2]-[3], the induction machine parameters needed to be determined. Precisely knowing these parameters allows for accurately modeling and designing the control algorithms is used to command the system. The method used to derive the equivalent electrical machine parameters listed in TABLE V. Several tests were performed to estimate the parameters of the ABB 20 HP induction machines; No-load and blocked rotor tests. These tests were conducted according to [4]. The no-load test obtains the number of pole pairs by comparing ratio of the electrical frequency over the mechanical frequency are various values, up to rated speed. In addition the machine was operated at rated voltage and rated speed, and the data in TABLE IV was obtained.

TABLE IV. No-Load Test Data

L-L Voltage (Vrms)	Line Current (Irms)	Freq. (Hz)	Speed (RPM)	Real Power (W)	Apparent Power (VA)
220.04	7.463	60.044	3590	723	2808

TABLE V. Machine Parameter Estimation Symbols

Symbol	Name	Value	Unit
R_s	Stator Resistance	150	mΩ
R_r	Rotor Resistance	2.977	mΩ
L_{ls}	Stator Leakage Inductance	303.57	μH
L_{lr}	Rotor Leakage Inductance	202.38	μH
L_m	Magnetizing Inductance	42.7712	mH
N_p	Number of Pole Pairs	1	--
J	Moment of Inertia	0.0526	Kg-m^2

The block rotor test involves a rotor blocking device that prohibits the rotor to spin. Since no commercially available device was available for the induction machines used, a custom rotor blocking fixture was designed and built. The blocked rotor test applies 25% rated frequency and rated line current. For this particular system the current test was about 90% of rated current due the lack of current source ability of the dc power supply. The blocked rotor data was collected as shown in TABLE VI.

TABLE VI. Blocked Rotor Test Data Values

L-L Voltage (Vrms)	Line Current (Irms)	Freq. (Hz)	Speed (RPM)	Real Power (W)	Apparent Power (VA)
16.68	40.301	15	0	719	1148

V. Benefits

The test-bed was built to meet the demand for an easily configurable platform to further research in the areas of power electronics, motor drives, and electric vehicle propulsion systems. Hence, it was built to be flexible in order to adapt to a variety of areas and be easily transformed to any future research or educational need.

A. Direct Project Interaction

The test-bed was built with a relatively low cost which was accomplished by incorporating the design and construction tasks into graduate and undergraduate students' project work. By integrating senior design, faculty funded project and industrial partnership, the overall project cost was reduced, while increasing the direct student exposure to concepts they usually have no hands-on. Our industry partner ABB Inc. Medium Voltage Drives, Research and Development group donated several key components used in the test-bed.

The project team consisted of a graduate student and three undergraduate students. The team was led by the graduate student doing research in the areas of motor drives and electric machines. The undergraduate students received Capstone Senior Design credits for this project. The team members received numerous benefits from involvement with this type of capstone project that they would not get in a traditional senior design project. The first major benefit was working on a real collaborative multi-disciplinary project among faculty, undergraduate and graduate students. They also learned how to work with real system design requirements. Students were also exposed to industry tool such as CAD design and layout, dSPACE embedded controller, National Instruments LabVIEW VFD control, PLC programming, Allen-Bradley Micrologix Program, communication (ModBus) integration, sensor integration, fault detection, OSHA safety standards. The senior design students will be able to apply in their career the technical knowledge from the use of the development tools they were exposed to during all phases of the project as well as some experience with complex system level problem solving.

B. *Research Potential*

There are many research topics that the test-bed is intended to be utilized. These topics include electric drive systems, electric or hybrid-electric vehicles propulsion, power electronic converter principals and topologies, and ac micro-grids components. Investigation into high performance machine control algorithms is a clear example of research opportunity. The initial test-bed system was characterized using a lower performance control algorithm, slip control. A higher performance induction machine control algorithms allow for a starting point in the machines controls research. This research topic is applicable to industrial companies in Variable Frequency Control of electric machines. Some applications are for Pump stations for both mining properties and municipals, fan control systems for HVAC.

The test-bed would also serve to investigate areas in an electric vehicle propulsion system. The prime mover described in Section III.A would be used to emulate an electric vehicle propulsion system. The current AC machine topology (asynchronous 3 phase induction machine) is the propulsion system for the Tesla Roadster [5]. Another electric propulsion topology utilizes an AC synchronous machine, specifically AC permanent magnet, is currently used in the Chevrolet Volt [6] and Nissan Leaf [7] propulsion systems. Given the modularity design of the testbed system, it could easy be modified to replace the prime mover machine with an AC permanent machine and emulate this propulsion topology.

The current system configuration has some limitations, specifically two quadrant machine operation. For full vehicle simulation the dc power supply would need to be replaced by a battery pack, because the current dc power supplies inability to sink current. If propulsion only drive cycle scenario, no regenerative braking conditions, a simulated battery voltage/current profile from the output of the dc power supply could be emulated. The current inductions machines could be used as common electric machine types for automotive propulsion systems or they would either be replaced with differing machines, as needed by the EV propulsion system architecture.

To utilize the test cell for a three phase ac MicroGrid, it would need to be modified according to the combination source and load desired. Minimal testbed hardware configuration would need to be changed, however the test cell infrastructure controller scheme would require substantial development, most notably if the test cell was not used as a machine type load. This changed relates to the order and timing of the contactors that control the power flow in Fig. 4.

The test-bed can be configured for an typical industrial motor drive type application by replace the dc power supply with a 3 phase hex-bridge converter to converter the 3 phase line voltage to a dc bus voltage. This approach is known as an Active Front End (AFE) and is common in most modern motor drive systems. The AFE configuration allows for increase input power quality [8]. This would require a slight hardware configuration change however the control scheme and system signal would need to be altered significantly. Using an AFE over the current DC power supply would also have the added benefit of allow for current sinking ability and regenerative braking applications.

C. *Undergraduate Laboratory Experiences*

The incorporation of this test-bed into the curriculum of the power electronics and motor drives laboratory was one of the main objectives of the test-bed. The motor drives lecture and lab introduces engineering students to various types of electric machines and their control algorithms. Fig. 9 illustrates the actual academic bench top system. This bench top system has the same flexibility of changing to various machines types, both AC and DC. The advantage to this bench top system is the safety in size and reduced complexity. With this bench top system students study the major machine topologies such as DC machines, AC synchronous machines (permanent magnet), and AC asynchronous machines (induction).

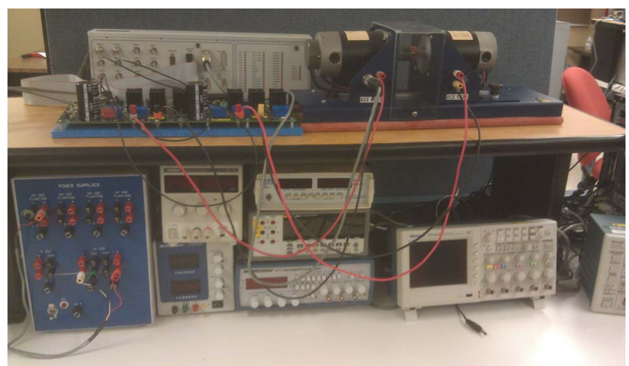

Fig. 9. Academic Motor Drive System

One common topology used throughout industry is the induction machine. The motor drives lab focuses several weeks on this particular machine, where students characterize its behavior. However, the system which students perform their experiments is significantly different in power level and setup compared to an actual test electric machine testbed seen in industry. This is done to reduce the risk and complexity the students would experience and allow them to place focus to fundamental concepts.

The different level of complexity can be easily observed by comparing the electric machine test-bed (shown in Fig. 1, Fig. 5, and Fig. 6) to the academic bench top system (shown in Fig. 9). Even though the reduced complexity is beneficial for the students start learning these topics, many students commented that they do not know how the academic systems correlates to system they will see in an industrial setting. Exposure to the test-bed gives students an example of an industrial type setup. To reduce the complexity and safety the bench top system is at a very low power level and uses measurement data from the power electronic converter board. Using these on board sensor circuits is not as accurate or consistent as separate measurement equipment. While this simplified method of data collection works for the educational objectives, it leaves a gap between how similar tasks are executed in industry. The test-bed also exposes students to industry quality data acquisition and measurement devices. The test-bed equipment consists of Yokogawa power analyzer, LEM current sensors, Himmelstein torque/speed sensor, APS power converters, ABB variable frequency drive, and Tektronix Mixed Domain Oscilloscope with smart voltage and current probes. This equipment exposes engineering students to the types of power and data acquisition device they will encounter in their engineering career.

This test-bed serves as an excellent platform to introduce students to industrial grade dynamometer systems and measurements devices. It relates the concepts the students are learning in the classroom to an actual industrial system. It also introduces students to think about subsystems within a more complex test-bed and how these subsystems interrelate to each other, which is crucial for systems engineers [9]. During the last lab experiment for the motor drive class, students solely focused on the electric machine test-bed system. Basics of energy flow and conversion principals are discussed in relation to their newly gain knowledge of motor drive concepts, obtained during the semester recitations and lab. Students also performed the same system performance test outlined in Section IV. This allowed them to see and interact with typical industrial type equipment.

The power electronics lecture and lab introduces engineering students to different types of electric energy conversion principals and topologies, and their control systems. Starting in Fall 2013 to the test-bed will be used to demonstrate some of the difficult topics including dc to ac conversion, Pulse Width Modulation, and power filtering. The test-bed will be used to discuss on how these topics interrelate within a system. Similarly to the topics discussed in a previous motor drives course, the test-bed will be used to focus an entire lab session to discuss the energy conversion process. These concepts are demonstrated and discussed using the inverter feeding electric energy to prime mover electric machine. In addition, students can see a direct use of the topics taught in lecture in a typical industrial application. In addition, the various electrical energy voltage and domains (discussed in Section II) will be presented demonstrating how these individual topics interrelated within the test-bed.

VI. CONCLUSIONS

A research quality test-bed was designed and constructed with emphasis placed on flexibility and integrated modular systems. This allows to easy adaption to future projects and research topics. The test-bed was also tested to demonstrate its functionality and to define a baseline for its operation. Its dynamic and steady state characteristics where also defined along with the characterization of the current induction machines. We discussed the use of the test-bed in various research areas that could be utilized based on current configuration or with some modifications. In addition to serve for research purposes, the test-bed is a very useful platform for engineering education in power electronics and motor drives, exposing students to industry typical applications and configurations.

ACKNOWLEDGEMENTS

The author would like to express their gratitude to ABB Inc., Medium Voltage Drives, Research and Development group located in New Berlin WI for donating several key components used in the testbed.

Using Matlab's Simscape Modeling Environment as a Simulation Tool in Power Electronics and Electrical Machines Courses

Trever J. Hassell, Wayne W. Weaver, and Aurenice M. Oliveira
Michigan Technological University - tjhassel@mtu.edu, wwweaver@mtu.edu, and oliveira@mtu.edu

***Abstract*— In this paper the use of MATLAB, and in particular Simscape, will be discussed as a simulation tool to model multi-domain physical systems in power electronics and electrical machines courses. The overall system response (both static and dynamic) of power electronics and electrical machine circuits are demonstrated and emphasized using Simscape language. Including Simscape in the curriculum reinforces conceptual ideas presented in lectures, as it increases students' focus on conceptual material, and their familiarity to modeling systems using MATLAB/Simulink.**

Keywords—power electronics; motor drive systems; engineering education; MATLAB/Simulink/Simscape environment.

I. Introduction

Electrical energy conversion has become ubiquitous in modern electronic devices, and in turn, creates a need to educate electrical engineering students in the fields of power electronics and motor drives. These fields are complex and involve other electrical engineering areas such as basic electronics, power systems, signal processing, and control systems. In addition to this wide breath of knowledge, students must also grasp the concepts of static versus dynamic nature of these systems. In the traditional lecture format, concepts are presented for both power electronics and electrical machines in a static nature, where the dynamics of the mathematical relations are ignored to reduce the complexity of the problems. This traditional approach works for student to learn the basic concepts. However, with the current computation and technological progress, simulation of these systems has become easily obtainable in a classroom environment with minimal computation requirements. The use of simulation in a classroom environment greatly improves the understanding behavior of more complex systems that cannot be simplified. Formulating control algorithms for these systems is also desired, in addition to observing their impact in the system behavior, which can be very difficult for undergraduate students to understand in a mathematical state space modeling approach. The use of simulation packages, such as MATLAB/Simulink/Simscape, reduces the complexity of the control algorithm implementation and observation of the system behavior.

In addition to help students to better understand complex systems, scientific computing and simulation are valuable skills for engineering students entering the workforce[1]. Both skills have several benefits to students. The first major benefit is the visualization and reinforcement of basic concepts and system behavior. The second major benefit is the exposure to a modeling and simulation environment that may be useful in future engineering tasks. The use of simulation in complex systems, such as power electronics classes have proven as a beneficial educating tool as discussed in [2] and [3]. By incorporating an easily understandable simulation environment into the traditional lecture material, students can visualize the dynamics and static response without the need to understand the complicated underlying mathematical relationships.

The assessment methodologies for this course uses indirect and direct measurements to assess the applicable ABET a-k criteria [4]. The assessment results indicate that the use of the Simscape simulation package increased students' focus on conceptual material and their familiarity to modeling systems using MATLAB/Simulink. The results also indicate improvements in the student comprehension of key concepts, and increased students' confidence to start their careers in the industry.

II. Matlab and Simscape Background

MATLAB has long been a tool both engineers and scientist used for numerical computations. Its native environment is based on the C programming language, however, it has a graphic editor, Simulink, which allows for multi-domain simulation environments. An additional toolbox for Simulink known as Simscape provides the fundamental building blocks to create simulation in common physical domains such as electrical hydraulic, pneumatic, among others. In addition to providing base building blocks, Simscape allows users to create their own custom defined blocks. These custom defined blocks are programmed similarly to MATLAB language.

Simscape is a physical modeling language that is designed to emulate physical systems appearance. It is similar in form to electrical circuits simulation in SPICE simulation package. Its main advantage is the integration of a common engineering tool, MATLAB/Simulink. It also has the ability to be used in conjunction with multi-domain environments. The ability to model various domains (electrical, mechanical, thermal, etc.) is an incredible power for teaching material involving several different domains. One example is a course taught in the Electrical Engineering department in the area of Electrical Machinery and Drives. The topics covered in the course combines both electrical and mechanical domains in one simulation environment, Simulink, as demonstrated in Fig. 1. This figure illustrates the multi-domain capability of Simulink and Simscape by using basic blocks available in the Simscape

basic library to construct a Class E Chopper drive coupled to a permanent magnet dc machine (PMDC). The mechanical load simulated is a fixed torque application. The components shown in the blue and red box, respectively, denote the defined electrical and mechanical domains. This multi-domain simulation is executed in one single environment allowing undergraduate students to have easy visualization of the system level response.

version. The foundational library includes basic elements that cover multi-domain simulation listed in TABLE II. The foundational library contains all the necessary components for basic demonstration of the fundamental concepts to undergraduate students. Simulations can easily be constructed without the need for additional toolboxes to be purchased and therefore lowering the additional cost if students choose to purchase the student version of MATLAB/Simulink. This was

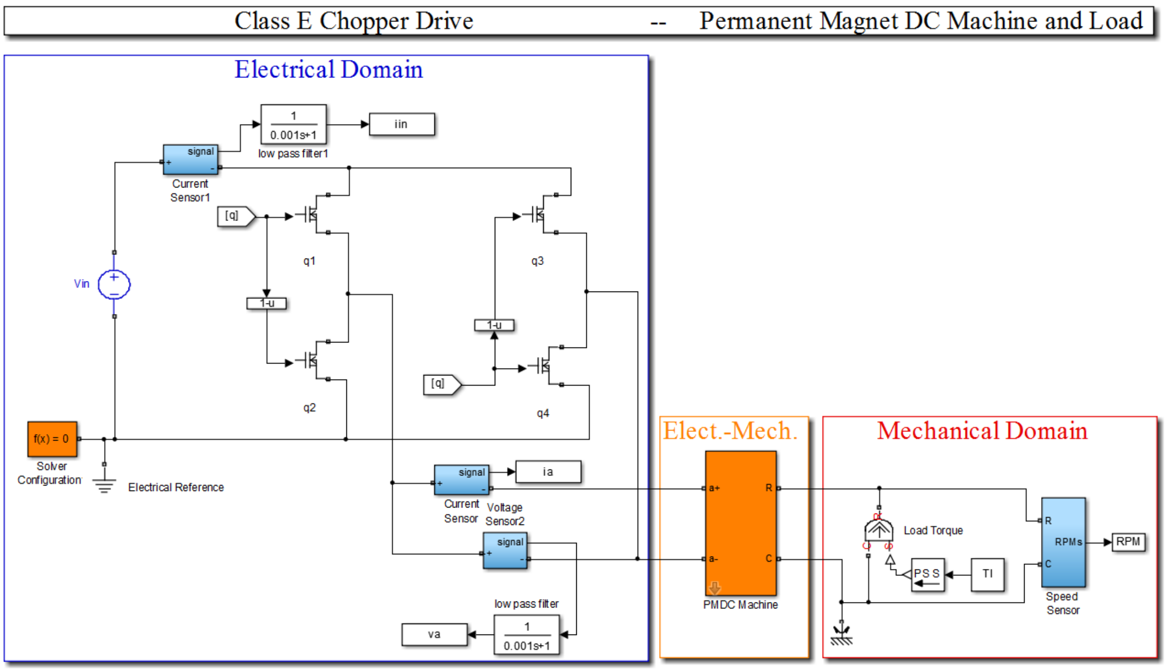

Fig. 1. Multi-Domain Simulation Environment

The simulation shown in Fig. 1 was developed using the Simscape foundation library set. Simscape consist of several additional toolboxes, as shown in TABLE I, which can be purchase with Simulink. The additional block sets are populated with common components for a specific engineering field. An example is the SimPower Systems toolbox which contains component ranging for various ideal electrical sources, electric machine models, power electronics elements, and passive elements. The major drawback, and reason for not incorporating the additional Simscape Library toolbox, was the additional cost to students. Each one of the additional block sets can be purchased separately as required by the simulation application.

TABLE I. ADDITIONAL SIMSCAPE LIBRARY BLOCKSETS

Name	Modeling Domain
Foundation	Basic Blockset (multi-domain)
SimDriveLine	Mechainical Driveline Simulation
SimElectroncis	Electrical Circuit Simulation
SimHydraulics	Hyrdaulic Systems Simulation
SimPowerSystems	Electrical Power Sytems Simulation
Utilities	--

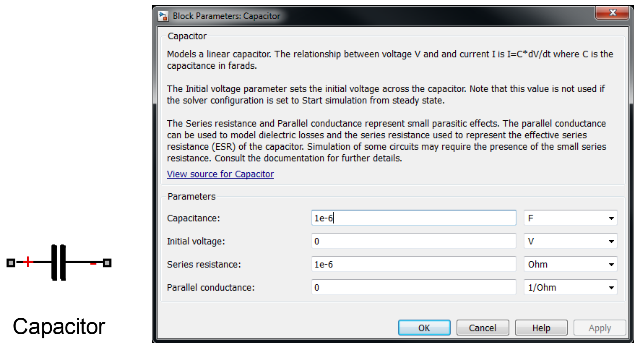
The foundational library block set was used exclusively in lecture material, to minimize the cost for students and institutions, with the purchase price of $39.00 for the student

an important point in our decision to use this simulation package since both power electronics and motor drives courses have distant learning students which may not be able to take advantage of the university site license.

TABLE II. SIMSCAPE FOUNDATIONAL LIBRARY BLOCKSET

Name	Modeling Domain Units
Hydraulic	Pressure, Flow
Magnetic	Flux, Magneto-Motive Force
Mechincal	Force, Torque (Linear, Rotational)
Physical Signals	Dicrete, Delays, Linear, Non-Linear
Pneumatic	Mass/Heat Flow, Pressure and Temperature
Thermal	Heat Flow, Temperature

The Simscape foundation library is based on an open model structure that allows the user to view and edit the model code behind the block. In other available Simulink block libraries the model may be described in the documentation, but is not accessible to the user which often leads to a “black box” impression for students. With Simscape, an instructor or student can dig underneath every box to revel the model code. The Simscape block code is not typical MATLAB code. In fact, it is a separate language based on a causal differential-algebraic relationships. For example, the graphical model of a capacitor is shown in Fig. 2.(a) and the parameters are shown in Fig. 2.(b). There is a hyperlink in the parameter dialog for each foundation library model that opens the Simscape language editor. A simplified version of the code for a capacitor is shown in Fig. 3. This electrical model block has single port with a defined voltage across the terminals and the currents through the device. The model equations in Fig. 3 define the voltage and current relationship. This code can then be copied, modified and re-compiled to create user defined models and libraries.



(a) (b)

Fig. 2. Simscape Block Parameter Example

```
component capacitor < foundation.electrical.branch
% Capacitor

  parameters
    c  = { 1e-6, 'F' };    % Capacitance
    v0 = { 0, 'V' };       % Initial voltage
    r  = { 1e-6, 'Ohm' }; % Series resistance
    g  = { 0, '1/Ohm' };   % Parallel conductance
  end

  variables
    vc = { 0, 'V' }; % Internal variable for
voltage across capacitor term
  end

  equations
    v == i*r + vc;
    i == c*vc.der + g*vc;
  end

end
```

Fig. 3. Simscape Programming Language

It is important to note that only blocks from the Simscape Blockset library can be connected to Simcape blocks. Special converter utility blocks are required to convert Simcape variables and states from Simscape sensor blocks to what are called “Physical Signal” data types with associated units. To convert from this physical signal to a normal unit less Simulink data type, a second conversion block is required.

Some of the benefits of MATLAB, in addition to the multi-domain capability, are the strong engineering industry presence, and extensive help and example files available to students on-line. Simscape also has the flexibility of user component and subsystem development and customization. An example of this is demonstrated in Fig. 1. The PMDC is a custom made subsystem that models the physical behavior of PMDC machine. The subsystem is masked, meaning that only the parameters of the model are display when opening the subsystem, as shown in Fig. 4. This is helpful to make the simulation code modular and easier for students to absorb. The actual model component can be viewed by “looking under the mask” via the right-click menu in Simulink, as seen in Fig. 5. Custom Simscape blocks can also be defined by the user in the native Simscape language.

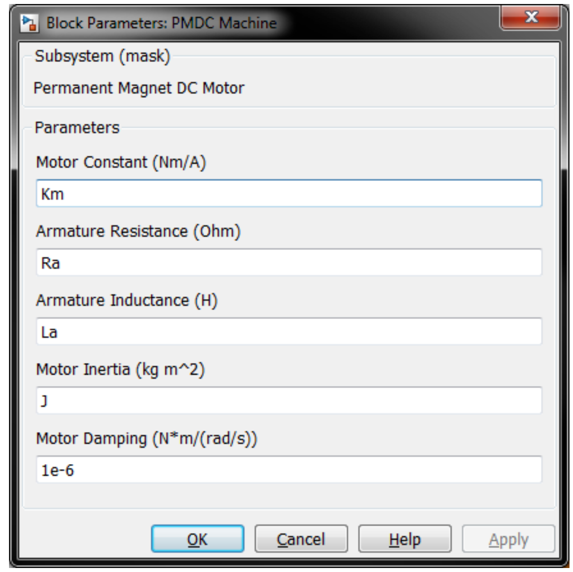


Fig. 4. PMDC Blocked Parameters

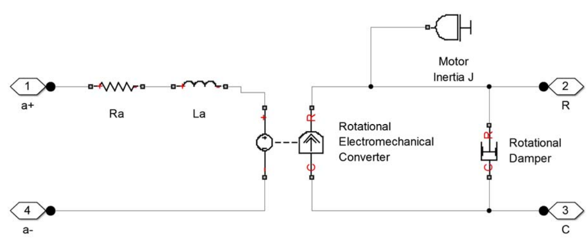

Fig. 5. PMDC Simscape Component Model

III. SIMULATION INTERGRATED INTO LECTURE

The approach used in both Power Electronics and Electric Machines lecture courses, with optional lab, was to create dynamic simulation examples using the Simscape basic building blocks. The examples compliment the previously developed material, which generally were static, steady state, response. The same static, steady state, relationship were presented and discussed; in addition, we use simulation to demonstrate both the static steady-state response and dynamic response.

A. Simulation Implemenation

A typically lecture would contain one or two simulation examples. These examples would first be discussed in a static sense with the general mathematical relationship presented. One of the early examples presented in the power electronics lecture was a boost converter. The boost converter is a DC-DC converter where the output is greater than or equal to the input as shown in Fig. 6. The static steady-steady average value mathematical relationship is shown in (1). This relationship is ideal, meaning no losses are modeled, and predicts the output voltage based on the input voltage and duty cycle, D_1; where the duty cycle has a value rang of 0 to 1 and is typically represented in the percent form. The relationship in (1) predicts that the output voltage will be that input voltage, given a duty cycle value of zero. With a duty cycle of 1 the output voltage is predicted to be infinite, however, this response is not practical. In a real circuit, each circuit component (inductor, capacitance, switching devices, and wires) has parasitic components that limit the range of predictable output to approximately 80 %. Above 80 %, the model is significantly different than the actual response and is no longer valid. Fig. 7 demonstrates the normalized steady state response. Both the ideal and non-ideal behavior are discussed in the lecture with emphasis placed on students' understanding the appropriate application of each.

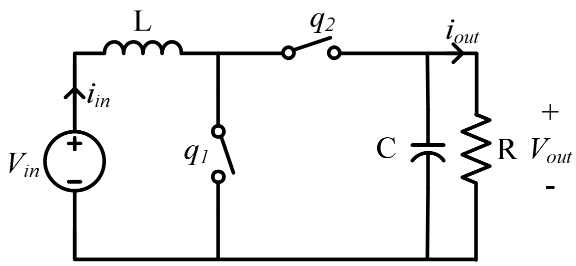

Fig. 6. Boost Converter Circuit Diagram

$$V_{\text{out}} = \frac{1}{1-D_1} V_{\text{in}} \tag{1}$$

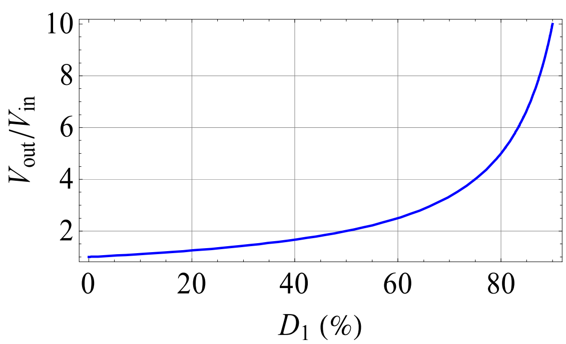

Fig. 7. Boost Converter Normalized Output

After understanding this basic relationship and behavior, the students are then presented with a functional simulation comprised of both the dynamic systems response from the initial conditions and steady-state (static) response. The first connection presented in lecture is the "hand worked" steady state solution and the steady state simulation response comparing similarities and differences. For a brief example consider(1) with D_1 of 50 %. The normalized output is twice the input. The circuit is then simulated using Simscape as shown in Fig. 8, and confirmed by the state-state solution, shown in Fig. 9. This response shows the approximate steady-state solution to be 20 V, or twice the input voltage of 10 V. The slight difference in the simulated output voltage is due the component models having very low, but not zero, parasitic values. The dynamic response shown in Fig. 9 demonstrates a startup condition where the initial value of the inductor current and capacitor voltage is zero. These initial conditions can be easily changed through the Simscape block parameters dialog box.

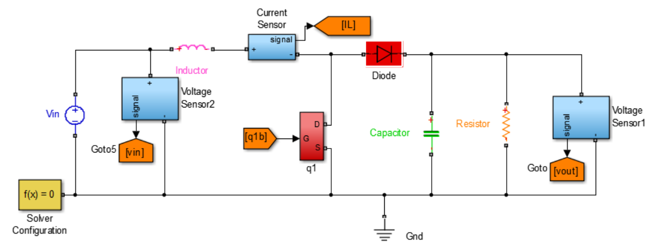

Fig. 8. Boost Converter Simulation Circuit

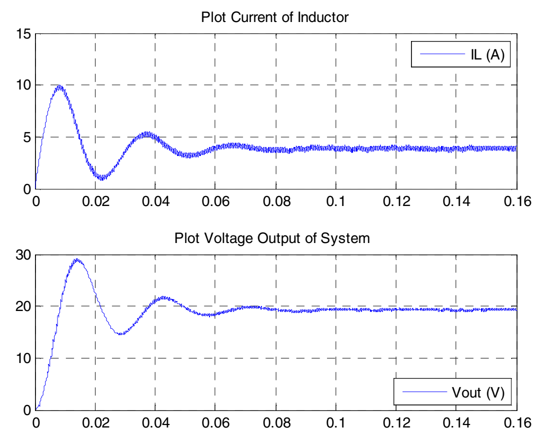

Fig. 9. Boost Converter Response with 10 V Input and 50 % DC

When comparing Fig. 6 and Fig. 8, the actual circuit and simulation look similar. This approach of using a simulation environment that emulates the physical system is a crucial concept that allows the minimal amount of student modeling ability while retaining the feature of visualized system response. This shifts the focus away from the simulation topics and emphasis is placed on obtaining system response. This approach was widely found in literature, including [5] and [6]. One relevant note is that the refereed authors' had different opinions on the MATLAB/Simulink effectiveness as research tool. For instance, in [5] the authors stated MATLAB to "lack some the basic modern object oriented and high-level programming language features".

Given continuity to the objective of having students focusing their attention on the -main concepts and not on the simulation environment, operational Simscape simulations were presented in the lectures. Basic circuit analysis was presented, where the static response values where calculated and confirmed with the simulation results. The dynamic response was also discussed, specifically with relation to the initial conditions (assumptions). These initial conditions were changed to demonstrating the effect on the transient response.

An example can be seen when comparing Fig. 9 and Fig. 10. The boost converter system response shown in Fig. 9 demonstrated the "start-up response" if the two energy storage elements (inductor and capacitor) in the converter are uncharged. Fig. 10 shows the "start-up response" when these two element have some initial energy stored when the input is applied. The initial conditions used for this example were 20 V on the capacitor and 5 A in the inductor. Both Fig. 9 and Fig. 10 show the same type of behavior. The simulation starts at the initial condition and eventually settle to the approximately the same steady-state average values of 19.5 V measured across the output and 4 A through the inductor.

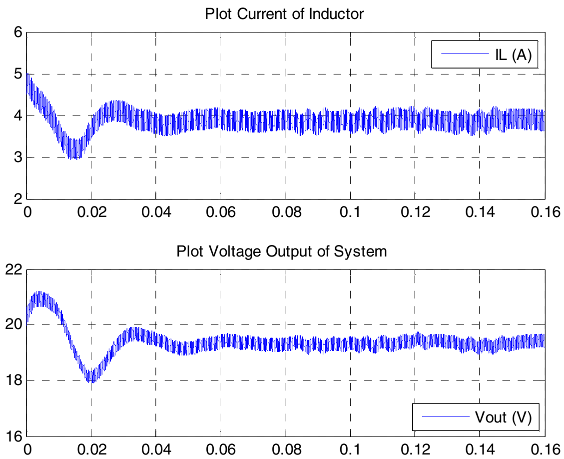

Fig. 10. Boost Converter Response with non-zero Initial Conditions

Some of the key concepts essential for students to understand power electronic converters are differences and similarities of the average mode model and the switching mode model. Many modern power supplies use a switch mode topology for energy conversion and therefore have a specified ripple in their output voltage and current. A switch mode power supply (SMPS) is an electric device that efficiency converts electrical energy from one form or potential to another, through switching between different energy storage elements. This switch action causes an inherent ripple in the output waveforms however the ripple is a very small percentage of the average value of the output. The difference can be seen when viewing Fig. 11, which demonstrates the steady state average mode model and switching model in the same graph. Both model responses are presented together in the same response graph. Typically, students are first presented with the average mode model where the switching action and behavior is then super imposed onto the average mode response. However, with demonstration utilizing Simscape both model can be discussed and understood together. The "live" nature of easily integrated simulated models allows students to make observations and predictions about changing circuit parameters and how the changes may affect circuit behavior. This "predict and see approach" is reinforced in lecture where the students are asked to predict a given changed to the circuit. An example of this would be to predict how the output waveform would differ if the capacitor was doubled. A brief discussion would then take place in lecture, the simulation would quickly be executed, and the output observed. The relatively easy nature of Simscape allows the focus of the discussion to be placed on the lecture topic and not on the simulation environment.

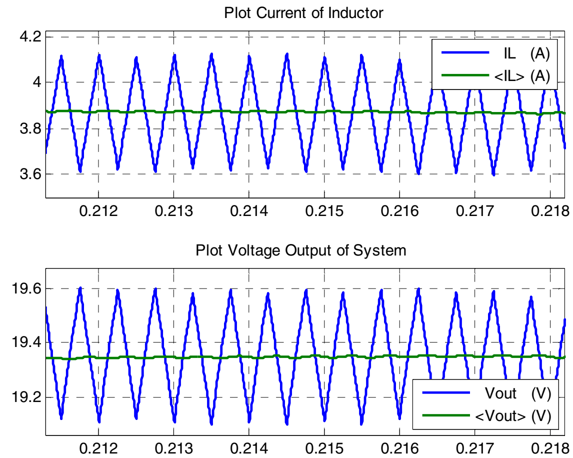

Fig. 11. Boost Converter Steady-State Switching Response

After the lecture, students were asked to answer homework questions comprising of both basic concepts topics (handwork problems) and a simulation component. The simulation components were a slight variation of the simulation example presented in lecture, again, to allow students to focus their attention on the conceptual ideas and less focus on the simulation environment.

B. *Typical Examples*

In each class over 25 examples were presented and available for students to experiment with. General topic areas for Power Electronics and Motor Drives are listed in TABLE III and TABLE IV respectively.

TABLE III. GENERAL LISTING OF CONVERTER EXAMPLES PROVIDED IN POWER ELECTRONICS

Topic Area	Name	Topic Area	Name
Basic	Resistor and Inductor Load	DC/DC	Push-Pull
DC/DC	Buck Converter	AC/DC	Rectifier (Full & Half)
DC/DC	Boost Converter	AC/DC	Charge Pumper
DC/DC	Buck-Boost Converter	DC/AC	Voltage Source Inverter
DC/DC	Flyback	DC/AC	PWM Inverter

These examples are provided to the students to experiment and learn. It is also strongly encourage for students to adapt the simulation model to a different application. All examples include an initialization and plotting script. This gives the students exposure to model parameterization and numerous post processing functions in MATLAB.

TABLE IV. SIMULATION EXAMPLES PROVIDED IN MOTOR DRIVES

Topic Area	Name	Topic Area	Name
Basic	Passive Load Modeling	Machines	PMDC Machine
Pwr Elec.	DC-DC Converter	Machines	PMAC Machine
Pwr Elec.	DC-AC Inverter	Machines	Induction Machine
Load	Hoist Load Modeling	Application	HEV Model

IV. BENEFITS

Historically, power electronics and electric machines undergraduate courses have had laboratory components where the student had exposure to hardware and dynamic responses of the systems. However, in recent years there has been a movement for more on-line courses, including power electronics and motor drives. To compensate for the lack of a laboratory experience for distance learning students, the use of MATLAB/Simulink/Simscape have been added to these courses. With the modeling and simulation assignments students are able to visualize the dynamic response of the system without the need for advanced material in dynamic modeling that is not appropriate for an undergraduate course. This simulation approach first reinforces the basic concepts and give another perspective to allow for great student retention. It has also been a proven methodology for greater student learning as discussed [2] and[7].

The use of MATLAB/Simulink/Simscape exposes, or reinforces undergraduate students with a very common industry tool, enhancing their skill set and employability as an engineer. It has the added benefit of relatively low curve for students, and for instructor development, when compared to various other methods of simulation incorporated into power electronics courses such as Java [8]. Simscape allows for user defined component development, however, the majority of power electronics and motor drives topics are easily simulated with the pre-defined components included in the foundational library.

V. OUTCOMES AND ASSESSMENT

Assessment of student outcomes is important for any engineering programs as a feedback element for course improvement and as a requirement for ABET accreditation of these programs. The ABET-EAC defines outcomes as “what students are expected to know and be able to do by the time of graduation. These relate to the knowledge, skills, and behaviors that students acquire as they progress through the program.” The ABET Criteria 3 – Program Outcomes [4] requires that engineering programs must demonstrate outcomes (a-k), and includes: (a) an ability to apply knowledge of mathematics, science and engineering; (e) an ability to identify, formulate, and solve engineering problems; (k) an ability to use the techniques, skills, and modern engineering tools necessary for engineering practice. The new methodologies that we used in the two courses discussed in this paper successfully satisfy the applicable ABET a-k criteria 3. The use of MATLAB 's Simscape modeling environment as a simulation tool in power electronics and electrical machines courses particularly satisfy criteria 3-k. The criteria 3-k has been interpreted as an ability to use and to learn appropriate software programs and computer simulation tools, as well as capability to collect engineering data using modern instruments..The assessment methodologies to document the achievement of this outcome for the courses discussed in this paper used indirect and direct measurements. The direct measurements included graded assignments and class exams. The indirect measurements included surveys and end of semester instructor evaluation. The performance indicator that we used here are in line with performance indicators for criteria 3-k as in [9]. The surveys results are discussed below. The assessment results indicate that the use of the Simscape simulation package increased students’ focus on conceptual material and their familiarity to modeling systems using MATLAB/Simulink. The results also indicate improvements in the student comprehension of key concepts, and increased students’ confidence to start their careers in the industry.

Surveys were given to the students of the power electronics and motor drives courses to assess their experience and perception of the modeling and simulation tools used in the courses. The results are summarized in TABLE V and TABLE VI in the percent of the students that responded. The column headings indicate Strongly Agree, Agree, Disagree, and Strongly Disagree from left to right respectively.

TABLE V. POWER ELECTRONIC STUDENT SURVEY DATA RESULTS

Question	SA	A	D	SD
“Prior simulation abilites are proficient”	6	44	13	13
“Believe added simulation skills will be benefical”	41	48	9	0
“Enhance employability”	55	34	6	0
“Simulation significantly helped understanding of core concepts”	58	41	0	0

TABLE VI. MOTOR DRIVES STUDENT SURVEY DATA RESULTS

Question	SA	A	D	SD
“Prior simulation abilites are proficient”	4	35	52	9
“Believe added simulation skills will be benefical”	39	54	7	2
“Enhance employability”	48	46	4	2

In the motor drives course, 54 students responded to the survey and 43 students responded to the survey in the power electronics course. To the question “Prior to entering this class, would you rate your modeling and simulation abilities proficient?” the responses from the motor drives course demonstrated that they students believe they were below the curve in ability. The responses to this question was also comparable in the power electronics class. While most students (92%) have used MATLAB in a previous course, 79% had never used Simulink or Simscape. However, 96% of the students agreed or strongly agreed that MATLAB/Simulink/Simscape is an important engineering tool. In addition, 94% of respondents agreed that their experience in MATLAB/Simulink/Simscape has enhanced their employability. Over 90% of the students also mentioned that Simscape toolbox had a relatively low learning curve, and all the students agreed that the modeling and simulation portion of the course helped them to understand the course concepts. In the surveys the students were also asked to "describe if the use simulation has helped or hindered their comprehension of the course material". The majority of students (57%) indicated that the simulation has helped them. Some of these students commented on the learning curve and simulation issues they experienced but ultimately believed the simulation help with the course concepts comprehension. Those who explicitly stated that the simulation content hindered (30%), felt the extra time and effort to learn this new language was not worth the benefit to see the system dynamics and behavior.

A common point of contention with the students was when experiencing issues with the simulation files, which required a significant amount of time to investigate the issue. This was unexpected - because of two facts: first, the students were senior level with "prior" knowledge and experience with MATLAB in several classes. Second, students were provided with working simulations during lecture. They only had to slightly modify the parameters values and re-run. The intent behind this approach was not to have student focusing their time on model development. However, this caused the un-intended consequence of students' inability to recognize the appropriate steps that were needed to understand and modify the simulation file for proper execution. Increasing student competency in the basic course concepts with minimal impact to the students' time was the main objective. Closing the assessment loop and finding ways to improve future teaching offerings of these courses based on prior student feedback is one easy methodology to achieve our main objective [10]. Based on the students' feedback, the following actions will be taken to lower the simulation workload on students in future course offerings:

1. Supplemental MATLAB/Simulink lectures will be prepared. This will help students who do not have the basic MATLAB language skills when entering the course.
2. Require initial basic simulations files to be developed solely by the students. This will increase the students understanding of the simulation process and avoid the basic simulation issues encountered previously.
3. Reduce the number of occurrences of simulations in each homework assignment. Typical homework examples consist of 2-3 simulation questions. By reducing to 1-2 questions student continue to get the exposure of simulation while lower the overall workload on simulation.

VI. Conclusions

A new simulation approach was used to further reinforce concepts in power electronics and motor drives courses. By utilizing a widely used engineering tool MATLAB/Simulink/Simscape, students obtained simulation and modeling exposure that will enhance their employability as future engineers. Simscape allowed for relatively low learning and development curves for students and instructor, respectively.

As an extension of MATLAB Simscape can utilize a large user examples and help info database making the adaption of simulation environment to various engineering domains. This multi-domain capability allows for simulation of the power electronic and motor drives systems with realistic loads, while minimizing the difficulty of model multi-domain systems. The students were provided with simulation examples coupled with a minimal amount of simulation information to learn, which allowed them to focus on the core lecture material, rather than the simulation environment itself. Assessment results indicated improvements in the students' comprehension of key concepts, and increased students' confidence to start their careers in the industry.

***Abstract*— Increased energy demand in IT is growing rapidly as the world becomes more industrialized. Projections show that IT growth will continue to increase, with annual network growth at 45%. Increasing worldwide energy demands results in an increase in both costs and climate change.**

Using the energy efficiency topic, we address 5+ ABET learning outcomes, including ethics and local/global impact. One learning goal of this section is for students to learn what constitutes sound ethical reasoning and what does not (e.g. egoism). Another goal is to categorize the social implications of the technology into spheres of concern (local/national/global) and basic ethical theories (virtue/deontology/consequentialism). One of the best ways to teach ethics is to engage the students in identifying the ethical perspectives in use. We have created a table of justifications for energy efficiency and categorized them by ethical theory. Our main source for these reasons is *Hot, Flat, and Crowded*, by Thomas L. Friedman. For homework, students write a paper that includes both a technical and societal/ethical component to it.

Keywords—Education; Energy efficiency; Ethics; Sustainability; Green computing.

I. INTRODUCTION

Data centers require 40 times the energy requirements of a regular office [3]. Projections show that IT growth will continue to increase, with annual network growth at 45%. With improved technology this growth can be reduced, with estimations for savings ranging to 55% overall energy and 80% in infrastructure [1]

Green computing is in its infancy, but there are three good reasons to start teaching it now. The two obvious reasons are energy efficiency (cost containment) and the environment. However a third benefit is that this topic helps to achieve ABET program learning outcomes, including the difficult ones of analyzing ethical/social issues and local/global impact of computing, and continuing professional development.

Research on energy efficiency is not yet mature, but there are many papers on engineering energy efficiency (e.g., [4-8]). However, papers on teaching energy efficiency in a computer science or computer engineering curriculum are rarer. One CS text, *A Gift of Fire* [10], does include a case study: "Modeling Climate", which briefly discusses climate simulations, but does not delve into energy efficiency.

Mann et al. [19] develop a framework for Computing Education for Sustainability, and evaluate resources for teaching. They define two philosophical goals: "Does the resource reinforce computing as a pathway or tool for achieving sustainable practices? Does the resource implicitly or explicitly define sustainability in a way the student can understand?" We agree and try to meet both requirements. In addition, we meet their required areas of "Curriculum integration" and "Linking and Connecting" (i.e. to world issues).

Talebi and Way [20] discuss technologies that can be taught in the classroom. They suggest: turn off equipment, power saving modes, eliminating phantom loads, extending computer lifecycle by upgrading with efficient components, purchasing energy efficient equipment (Energy Star), and using alternative power sources. They also suggest the use of Kill-a-Watt and 'Watts Up?' energy measurement devices, and provide sample results for desktop versus laptop. They do not discuss ethics as part of their learning goals.

Cai [21] points out ABET has called for a shift towards sustainability education in engineering disciplines, and sustainability is attracting the attention of students around the world. (Approx. 2/3 of CS faculty agree [12].) Cai has developed a course that is half about Green Computing and half about Network Services, at Michigan Technological University. It includes topics of: general concepts, virtualization technology, data centers, power-aware computing, smart power management, electronic waste, and regulatory compliance. The course was well received by mostly IT majors, with a high rating of 4.7 out of 5.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

We propose combining the teaching of energy efficiency and ethics. The paper "Computing for the Social Good" [11] reminds us that ACM CS-2008 computer science curriculum recommends a single course on professional, ethical, and societal issues, plus complementary modules that integrate these topics into technical courses. After surveying computing departments, they summarize that "the survey shows that there is still much uncertainty in what social issues include, how they relate to computing, what pedagogies to use, and where and when they can best be presented." We believe that integrating ethics and energy efficiency serves as an excellent 'complementary module' that can serve as an introduction or development of ethical thought and an intriguing research area within technology.

The CS ethics text, *Ethics for the Information Age* [13], presents a number of ethical classifications, including 'ethical egoism', Kantism (i.e., Deontological), and Utility. We present a simplified version of Egoism, Deontological, Consequentialism (or specifically Utility), and Virtue, and apply it toward Energy Efficiency in this paper.

This paper first introduces how we teach and have taught this module, as well as related accreditation issues. Next, we review ethic theory, and apply it toward societal reasons for energy efficiency. Technical vocabulary is introduced in lecture to help students to understand technical papers. Finally, we discuss our results in the classroom as lessons learned and a conclusion.

II. MODULE OVERVIEW

The energy efficiency module is introduced as a later module in a 3-credit hour CS 355 Computer Architecture course, offered once yearly to Computer Science undergraduates who have completed CS 245 Assembly Language. CS 355 covers processor and memory design, but also applied topics: hardware security and energy efficiency.

Energy Efficiency is a 3-hour module towards the end of the semester. It includes a lecture, an active-learning exercise with Kill-a-Watt [23], and a homework writing and presentation assignment. The two-hour lecture reviews ethical theory, societal reasons for energy efficiency, and technical aspects of energy efficiency. The technology aspect of energy efficiency topic is lightly-covered because students will get into technical depth in their papers/presentations. The lecture materials are discussed later in the paper.

During the homework assignment, students write a paper that includes a social/ethical/business and technical component. Students also do presentations on their papers (with time allocated according to class size).

Student assessment includes evaluation of the student paper, and questions related to ethical and social impacts on an exam.

The first semester this was taught, students were enthusiastic about the topic, and most papers and presentations were very good and interesting. However, it was observed that the non-technical ethical and social aspects of the papers were weak, particularly in comparison to the technical aspects. Thus, the ethical aspect of the course was strengthened with help from a Philosophy professor (author 2), who teaches ethics. This paper presents results from a more mature ethics component related to energy efficiency.

III. ACCREDITATION

Whether or not the department is ABET-accredited, any accreditation agency is interested in program and course learning outcomes, preferably taught at multiple levels in the curriculum. ABET has proposed student outcomes, which are demonstrated by mapping the outcomes to courses. This topic meets many student outcomes, including some of the difficult ones for computer science: local-global issues, ethics, and continuing professional development. The full text for each addressed ABET student outcome is provided first, in bold.

(a) An ability to apply knowledge of computing and mathematics appropriate to the discipline

This lecture and written assignment emphasize knowledge of computing hardware, affecting processors or computing equipment, network equipment, and data centers. The emphasis is on computer or data center architectural design, power consumption and computer life cycles.

(e) An understanding of professional, ethical, *legal, security and* social issues and responsibilities

An introduction to ethics and social issues is provided in the lecture. Students are expected to categorize potential justifications within one or more ethical theories. In addition they must discuss ethical and social issues within a written paper (and possibly presentation).

(f) An ability to communicate effectively with a range of audiences

Students write a research paper on a selected topic, and then present on it. Required components of the research paper and presentation include: a literature review and brief description of proposed technologies, an analysis of the usefulness of the proposed technologies, and an analysis of the ethical and local-global impact of implementing the technology. These aspects require students to research, analyze, write, and present.

If teams present a summary of their work, then teamwork (another ABET outcome) is also part of the assignment.

(g) An ability to analyze the local and global impact of computing on individuals, organizations, and society

Energy efficiency mainly impacts economics and the environment, but both can have an effect locally, nationally, and globally. Students must analyze the societal impact of their topic in their paper and presentation.

(h) Recognition of the need for and an ability to engage in continuing professional development

Energy efficiency and green computing is a new technology. As such, it is rapidly evolving and unstable. It would be difficult for an instructor, who does not do research in this area, to become or stay current in the technology. Therefore, having students write and present a literature review in a selected topic introduces students to learning about technologies on their own. The instructor learns as well from reading the reports and seeing the presentations. The instructor can point out that since this research is rapidly evolving, this is an example of a need for continual professional development in the field.

(i) An ability to use current techniques, skills, and tools necessary for computing practice.

This is a minor learning outcome, compared to the others. Students learn to use Kill-a-Watt to learn about electricity, and use Excel to learn to produce graphs and work with equations.

While not all ABET student outcomes are addressed as part of this assignment (or should be), we have shown that six are addressed. However, these goals should not be addressed in only one place in the curriculum. Whether for ABET or HLC (Higher Learning Commission) accreditation, another recommendation is that learning goals are not pooled in one course, but reinforced at three levels: introduction, development or reinforcement, and mastery. For us, these learning goals serve at the introduction, development, or reinforcement levels.

IV. ETHICS AND SOCIETAL IMPACT

The first part of the lecture is on ethics and the societal impact of climate change. One learning goal of this section is for students to learn what constitutes sound ethical reasoning and what does not (e.g. egoism). Another goal is to categorize the social implications of the technology into spheres of concern (local/national/global) and basic ethical theories (virtue/deontology/consequentialism). After a theoretical introduction to ethics, the lecture discusses ethical theories in relation to green computing.

A. Ethics and Social Impact Classifications

By the definition of ethics, one must be careful that the conversation not become about self-interested impacts. For instance, we might note that using lead to create circuit boards introduces a deadly toxin to our water supply; I drink from that water supply; therefore, I don't want to use lead to create circuit boards. This is both reasonable and practical but not clearly ethical. Kant points out that people do not need an incentive to act in their own interest, since they do so naturally [16]. Therefore, we can never be certain of the motivation of a person who acts in a way that benefits herself; she might be acting ethically but she might also be acting just to save her own skin.

We classify ethical ways of thinking three ways: Virtue Ethics, Deontology, and Consequentialism. For contrast, we also present Egoism. Thus, the four categories are identified as follows:

1) Egoism

Right action is determined by what is in the individual's self-interest. An egoist would justify energy efficiency by saying, "an efficient design will allow me to make buckets of money." This justification sits on Lawrence Kohlberg's lowest stage of ethical development [14]. Because self-interest thinking can actually lead people to break society's rules and norms we wish to move students away from this way of thinking.

2) Virtue Ethics – Aristotle [15]

Right action is that which promotes human flourishing. A Virtue Ethicist would justify efficiency by saying "that is what a good engineer does." To flourish we must strive for excellence at our telos (end). One might challenge the student towards this way of thinking by asking "In the best world, what would your design look like?" Further telos-oriented questions might include: Would your role model approve of this design? Or, very specifically: would the person of good character exploit workers in a foreign country in order to make products affordable in the US? Would a good engineer design a product that uses as much power as it can draw or would he strive for efficiency?

3) Deontology – Immanuel Kant [16]

Right action is that which is done from duty. A Deontologist would justify efficiency by saying, "it is my duty to be efficient." To determine duty one must ask "can my rule of action be universalized without contradiction?" Often this is recognized as "do unto others as you would have them do unto you." One might encourage the student to ponder the Deontological view by asking "would everyone be able to employ a design like this one?"

To explain further, Kant prohibits actions if they produce a contradiction when implemented in a universalized way. For example, lying is self-contradictory: the point of a lie is to pass off untruth as truth; if we universalize lying so that everyone lies then no one will accept our untruths as truth; so, lying, when universalized, contradicts itself. Friedman's point about limited world resources is useful here: can every nation on the planet use as much power as the United States?

4) Consequentialism – John Stuart Mill [17]

Right action is that which creates the greatest happiness. A Utilitarian would justify energy efficiency by saying, "it will allow the most number of people to have access to and to utilize our products." Being careful to not confuse happiness with momentary pleasure, one might stimulate thinking in the student towards the Utilitarian view by asking "Will this produce more happiness than the alternatives?"

Although Consequentialism is easy to grasp and agree with, it is hard to live by. From experience, students balk at the idea that they might be required to sacrifice some of their own happiness in order to increase the happiness of others. There is no tenable argument that can show that my happiness is worth more than your happiness. Thus, a Utilitarian must accept that her happiness is not more important than anyone else's. So, even though iPhones have made hundreds of thousands of Americans happy, we might still be morally prohibited from buying them, if tens of thousands of Chinese that are employed to make them are more unhappy than the happiness we Americans receive.

5) Local/National/Global Impact

The learning objective is the identification and discussion of issues at each sphere of influence. The spheres are defined below:

Local: Has an impact within a participating local organization or within the region.

National: Has an impact at the national level, e.g., through increased economic (or other) measures: GNP, increased competitiveness, cleaner environment.

Global: Has an impact outside the nation: impacts one or more external nations or world conditions (e.g., energy, poverty, environment, world peace.)

B. Applying Ethical Theory to Energy Efficiency

One of the best ways to teach ethics is not only to provide the theory, but to engage the students in identifying the ethical perspectives in use. One excellent source for ethics related to climate change is *Hot, Flat, and Crowded* [2], by Thomas L. Friedman (best-selling author of *The World is Flat*). This book covers the expected growth of energy consumption, the problem of climate change, and potential technological directions and political issues. We have taken Friedman's justifications for energy efficiency, and created a table categorizing the reasons by ethical theory and geographical impact. Because of its length, this table: Table 1: Ethical Reasons for Energy Efficiency, is currently located as an appendix to the paper.

In lecture, the instructor discusses the justifications for energy efficiency before categorizing into ethical theories. The lecture also provides students with ideas for social/ethical topics that they could write on. One of the most impressive issues Friedman discusses is that until recently there were two energy hogs: America and Europe. Now with India and China emerging, there are four. As other heavily-populated regions further develop, there will be the equivalent of 9 'Americomes' consuming fossil fuel power. Friedman shows how this growth affects five major issues: energy and natural resources, petrodictatorship, climate change, energy poverty, and biodiversity loss [2]. These social issues related to energy use include traditional conservative issues: oil production helps to fund Muslim extremists, and desert war conditions requires massive air conditioning, leading to trucking of petrol across unfriendly terrain. However, the book has a very holistic view that also describes how petrol has led to less freedom in the middle-east.

V. TEACHING ENERGY EFFICIENCY

The technical part of the lecture introduces some concepts of energy efficiency in processors and data centers. The goal is to discuss vocabulary and core concepts to help students in understanding their readings. The first aspect is to show that IT can benefit from energy efficiency, through recent and projected energy usage statistics [4, 6]. To sum up projections, computers have become more energy efficient, but demand is increasing. For example, network traffic volume is expected to increase 190 times between 2006 and 2026 [6]. Recent estimates indicate that up to 40% of data center costs are for air conditioning [7].

The lecture then demonstrates the power usage of a number of recent processors [22], and describes how the factors affecting power consumption relate:

$$\text{Power} = \text{CapacitiveLoad} \;\; x \;\; V^2 \; x \;\; \text{Freq} \qquad (1)$$

Computers and networking devices can be made more efficient, through dynamic power scaling, including adaptive rates, and low power idle [4,5]. Important vocabulary includes:

- Sustainability: Minimizes environmental impact, including greenhouse gas emissions, use of raw materials, and hazardous waste. [19].
- ICT (Information & Communication Technology)
- DVFS (Dynamic Voltage and Frequency Scaling)
- Leakage: Power loss within a chip, often thermally-induced.
- PUE (Power Usage Effectiveness): Total_Power/Computer_Power
- ECRvL (Energy Consumption in Relation to Variable Load)

Some discussion of novel but maybe controversial techniques may also be discussed. Energy can be reduced using alternative techniques such as an air economizer, which uses colder outside air to assist in air conditioning. Chillers are tubes which carry colder water to where they are needed. Also, running the room temperature higher but within computer specifications may be useful if leakage does not result in greater energy loss [8]. Alternatively, turning some computers off during slow periods and improving airflow can reduce electrical costs. Green actions also include using computers longer, recycling, and reselling the computers.

To prepare computer science students for the active learning lab, the lecture reviews Ohm's law, and definitions for voltage, current, and resistance. Then the instructor shows how to calculate kilowatt hours, greenhouse gas emissions, and electrical costs, producing annual statistics, using a downloadable Excel spreadsheet. A one-hour active learning Kill-a-Watt exercise has students measuring the volts, amps, watts, frequency (etc.) to contrast a desktop with a laptop computer. They enter the results into an Excel spreadsheet, and produce a graph. The spreadsheet includes automatic equations to calculate expected annual electrical costs and greenhouse gas emissions. The following two equations show how to calculate kilowatt hours, and pounds of carbon dioxide, as a function of kilowatt hours [9]:

$$\text{KWH}=[\text{Watt} * 24 \text{ (hrs/day)} * 365 \text{ (days/year)}]/1\text{K} \quad (1)$$

$$\text{Pound}_{CO2} = 1.75 * \text{KWhour} \quad (2)$$

Thus, the active learning activity gives them experience with electricity measurement and Microsoft Excel. Following this brief introduction, students choose their own topics to look up and research.

After the ethics and energy efficiency lecture, students write a paper by researching an aspect of energy efficiency, related to computers. Students were allowed to pick any topic they wanted from the five categories: 1) data center efficiency; 2-3) Computer and network efficiency; 4) Smart grid/Smart home; 5) Green IT lifecycle (procurement, disposal). The instructor discouraged students from selecting computer efficiency, since a first view of these papers indicated that they involved advanced electrical engineering. However, upon further analysis, it was determined that some papers are readable by undergraduate computer scientists.

The student paper was required to include the following sections, with the following findings:

Motivation (Society/Ethics): Students were to define their goal or preferred impact of lower energy consumption and the societal and/or ethical implications. Students were then to discuss the business, political, or societal effects of the technology. This could relate to local versus international issues, or barriers to implementation. This 20-point topic asks students to perform a literature review using 2-3 non-technical sources on the societal effects of their chosen topic.

Technology: This section is divided into *Technology Vocabulary* (10 points) and *Technology Description* (30 points). The Vocabulary section encourages students to look up words as part of continuing professional development. The hope was that students would not be afraid of papers they did not at first understand.

For Technology Description, students were to describe three to four methods of energy efficiency using professional technology and other references. Most students did well. However, some student papers defined, but did not describe the technology. Thus, lower ratings were given when there was no demonstration of good technical understanding.

Evaluation: In this 10-point section, students were to describe the tradeoff of one versus the other technology technique, possibly in relation to societal or business impacts. Mature answers gave thoughtful and creative answers or considerations, beyond the obvious.

Conclusion: Students were to summarize the contribution of their paper, describing the 'take-home message'.

References: Students were to list each reference used in the paper, properly reference material in their text, and provide the diverse reference material. References needed to be from professional (IEEE/ACM), non-technical (environmental, business), and web sources. Non-technical references ensure that a holistic/multiple perspectives are considered. Reference material is requested to verify information and ensure no cheating. Proper referencing is worth 10 points.

Writing: Students were also evaluated on their writing. Good grammar and spelling, and adherence to the paper outline provided full points for this 20-point section.

VI. LESSONS LEARNED

Lecture. During Year 2 lecture, social arguments were presented and discussion ensued over the proper ethical category. In a short time, students could accurately discern the proper ethical categories. Table 1 was provided to students for study purposes.

Papers/Presentations. In Year 1 (before the ethics/social emphasis) students covered the technology aspect reasonably well in papers and presentations, but it was clear that there was no systematized evaluation of ethics or local/global issues. Also, students used only technical references.

In Year 2, papers were required to include 2+ non-technical references that considered social aspects of energy efficiency, and 68% of students complied. Students' Motivation section often included social aspects that included government statistics or a story/example of the issue in society. This made their Motivation more powerful and believable. However, only 14% of students discussed any ethical categories in their paper, and of those, most only mentioned Egoism (!) In Year 3 the paper outline will clearly state that students must discuss the ethical category of their arguments.

Each student did a 5-10 minute presentation on their paper. (In Year 2 they could present on either hardware security or energy efficiency.) In spite of the redundancy for certain topics, there was rarely overlap, and all talks were interesting. Presentation grades tended to mirror paper grades. It was useful for students to learn from the other students' presentations.

Exams. In Year 1, the exam study sheet and exam required ethical discussion about energy efficiency. Students appeared to do well with that question. In Year 2, students needed to describe two techniques to achieve energy efficiency in processors, and define and apply ethical categories. The specific exam question was to apply the four ethical categories to hardware security. Here, the percentage of students correctly defining two or all four ethical categories was 42% each. For the processor efficiency questions, the percentage of students getting a 0, 1, or 2+ points was 25%, 25% and 50%, respectively.

Teacher evaluations for this course for both years were at or higher than average for the department and the instructor. Lecture and spreadsheet materials are available by contacting the author.

VII. CONCLUSION

Energy efficiency is an advanced, interesting, and practical topic in computer architecture. The topic can be used to achieve some difficult ABET learning outcomes.

This paper focused on an integrated method that introduces ethics, local/global issues, communication, technology, and continuing professional development. We provide a table of reasons for energy efficiency categorized by ethical theory. The teaching of ethics and local/global aspects and the paper writing assignment helps students to observe, contemplate, and categorize ethics related to technology.

TABLE I. ETHICAL REASONS FOR ENERGY EFFICIENCY

	Reasons for Energy Efficiency	Local/ National /Global	Examples for Ethical Categories
1	*Americans live beyond our means*. Americans buy goods from China, and China buys U.S. treasury bills. This enables Americans to buy more Chinese goods. These goods require energy to produce and ship. (Ch. 1[2])	N,G	Egoism: As an American, it is bad for me that China owns most of our debt. Virtue: This is bad because the person of good character wouldn't be in debt. Utilitarianism: This may lower worldwide happiness, due to the unsustainability of environmental destruction and (possibly) the exploitation of low-wage Chinese workers.
2	*Provide Sustainability*: "If we want to maintain our technological, economic, and moral leadership, and a habitable planet, rich with flora and fauna, leopards and lions, and human communities that can grow in a sustainable way – things will have to change around here, and fast." (Ch. 2-3 [2])	L,N,G	Egoism: "If WE want to maintain OUR leadership… and a habitable planet…" This focuses on our benefit only. Virtue: "…rich with flora and fauna, leopards and lions,.." The person of good character respects other species and would not destroy the environment. Utilitarianism: "…and human communities that can grow in a sustainable way…" Sustainability assumes long-term happiness (survivability) for all. Deontology: "… things will have to change around here, and fast." It is our duty to be stewards of the environment. This statement could argue at different levels simultaneously.

3	*World Growth in Wealth*: Previously there were two continents with high energy consumption: U.S. and Europe. China and India are emerging to double the Earth's energy consumption. Since their populations are so large, eventually their consumption will itself double. Add the rest of far-east Asia, Russia, and Brazil-Middle East, and the energy consumption can equal nine times the U.S. – or more. (Ch. 5 [2])	L,N,G	Egoism: Higher energy costs impacts my profit. Utilitarianism: Current energy use, implemented worldwide, is not sustainable and leads to unhappiness (assumes limited resources or that consumption has a negative effect: pollution). Deontology: Our way of living does not work on a larger, worldwide scale.
4	*Oil Revenues fuel Muslim Extremists*: Saudi Arabia constitutes only 1% of the world Muslim population, but funds 90% of the expenses of the entire faith, through Wahhabi fundamentalism. Although Wahhabis are not the base religion of the terrorists, our oil purchases indirectly encourage terrorist activities, through fanaticism and donations by the wealthy. (Ch. 6 [2])	N,G	Egoist: Terrorism may harm the speaker. Utilitarian: Terrorist activities are seen as detrimental to aggregate happiness. Virtue: A good person would not help to fund terrorists, even indirectly.
5	*Global Wierding:* Scientific reasons to assume climate change is occurring ([18], Ch. 7 [2]) E.g.: Measurement of average CO2 in atmosphere has increased from 280 in 1750 to 390 ppm in 2007. E.g.: CO2 and water vapor are greenhouse gases. They hold more heat than oxygen or nitrogen. E.g.: Warmer air holds more water and thus causes more intense storms and dryer terrain.	L,N,G	Scientific reason is going to be, in almost all cases, Utilitarian reasoning. Utilitarian: More CO2 increases global temperatures and makes human life more difficult. Therefore we should avoid increasing CO2. The happiness of the species is at stake. Virtue: Even if these scientific facts do not prove that CO2 causes climate change, a good person would minimize impact to the environment.
6	*Biodiversity:* "It gives me goose bumps" says Career, who founded a non-profit to promote sustainable ranching on the Amazon frontier. "It's like witnessing a rape. You can't protect it. There's too much money to be made tearing it down. Out here on the frontier, you really see the market at work." (Ch. 8 [2])	L, N, G	Egoist: Raping nature will kill tourism. Virtue: Protecting the environment is a good thing to do. Deontological: It is my duty to reject the rape of nature because it leads to a (universal) extinction of species, and loss of human enjoyment of the natural environment.
7	*Energy Poverty:* As other regions become wealthier, competition will cause the price of energy to increase. This will make it more difficult for the remaining underdeveloped nations to compete. (Ch. 9 [2])	L,N,G	Utilitarian: We must strive for equality of wealth (or happiness) for all nations. Deontology: Our energy use will result in haves and have-nots. Therefore, it cannot be universalized, and is bad.
8	*Increased Competitiveness:* Energy efficiency can reduce costs and provide new technologies for sale worldwide. (Ch. 10, 14 [2])	L,N,G	Egoism: The new costs and technologies benefit me. Utilitarian: the new costs and technologies will make people happy, since there will be lower prices and more jobs for all.
9	*Losing the Battle:* Despite efforts to green America, the greenhouse gas problem is measured at increasingly higher rates annually. The problem must be taken much more seriously. (Ch. 11 [2])	L,N,G	Egoism: Will the additional costs outweigh the benefits to me? Utilitarian: Will the additional costs outweigh the benefits to humanity? Virtue: What is the right thing to do?
10	*Inefficient Power Utilities:* Power utilities have little incentive to be efficient, since they grow with higher consumer demand. Thus, utilities build for peak demand, instead of encouraging consumers to use power during low energy consumption times. IT will help to make utilities more efficient. (Ch. 12 [2])	L,N,G	Egoism: This could also be a solution. Commonly, we provide an incentive for companies to change behavior (here, save energy). We focus on their egoism in order to improve the well-being of all. Deontology: A universal solution goes to the source (the power plant) instead of assuming all individuals will adhere to fixes.

The Use of a Classroom Response System to More Effectively *Flip* the Classroom

Terry Lucke*, Ulrike Keyssner and Peter Dunn

***Abstract*—Classroom Response Systems (CRS) have been shown to improve student learning outcomes by encouraging student engagement with the course content, instructors and student peers. The system's ability to provide immediate and quality feedback to both students and instructors, particularly in large classes, is highly desirable. While CRS has been used for well over a decade and been shown to successfully improve student engagement and participation, a number of studies have also identified that its use could potentially mean that less material is able to be covered in lectures. Clearly, the approach of cramming CRS into already content-heavy class time does not embrace the potential for CRS to improve student engagement and student learning. The use of CRS should be planned as an integral component of the course which enhances and reinforces the learning outcomes. The effectiveness of CRS depends strongly on the quality and variety of the questions, and the design of the activities to encourage students to engage with the questions.**

This case study explores the use of a new, low-cost, state-of-the-art CRS (Top Hat Monocle) which allows students to use their mobile devices (phones, tablets, laptops) to respond to a variety of numerical, multiple-choice, short-answer and open-ended discussion questions posed during face-to-face workshops. In order to allow sufficient time to fully engage with the workshop activities traditional lectures were revised and the classroom lecture was flipped. Students worked through narrated lecture material (hand-e-lectures) online, prior to attending the workshops. CRS was included as part of the e-lecture content and feedback from this was incorporated into the workshops. Workshops extended the e-lecture content by including a variety of carefully designed, engaging activities (many were group activities) that used CRS questions to facilitate discussions, problem solving and case study analysis to enhance student cognition. Overall, the new flipped lecture and CRS teaching format demonstrated a substantial increase in the level of student engagement, motivation and attendance compared to previous cohorts.

Keywords— Classroom response systems (CRS); engagement; Top Hat Monocle; flipped classroom; hand-e-lecture

I. INTRODUCTION

Traditional Classroom Response Systems (CRS) are instructional technologies that allow instructors to rapidly collect and analyse student responses to questions posed during class [1]. Typically, students are presented with a question and a small number of multiple-choice answer options, and students vote for one of the options using the electronic hardware (clickers). The instructor can then display the students' responses, provide feedback and facilitate class discussion regarding the responses. This type of rapid feedback is an ideal form of assessment [2] as it is positioned close to the leaning, and students' responses are anonymous to other students, unlike other forms of response like raising hands. The use of CRS allows instructors to provide immediate formative (and, in some cases, summative) feedback, particularly in large classes [3]. Feedback is the 'most powerful single influence' on student achievement, and providing timely feedback is one of the main support conditions for student learning to take place [4]. For this reason, the use of CRS has great potential for student learning outcomes.

CRS have been shown to improve student learning outcomes by encouraging student engagement with the course content, instructors and student peers [5, 6]. Research has indicated that CRS make classrooms more engaging for students, improve student participation and interaction, improve cognition and retention, and can even improve grades [7]. Including effective active learning strategies is fundamental to providing a successful engineering education [8].

The ability of a CRS to provide immediate and quality feedback to both students and instructors, particularly in large classes, is highly desirable. It is vital that the device used to deliver student responses is user-friendly, reliable and inexpensive; the sustainability of the system for instructors and staff will determine its long term use. Many traditional CRS only allow students to answer simple multiple-choice type questions. Unless these types of questions are well designed, they may not allow students to demonstrate their depth of knowledge or understanding, or to develop higher-order thinking skills such as analysis, synthesis, and evaluation [9]. This study explores the use of a new, low-cost, state-of-the-art CRS (Top Hat Monocle) which allows students to use their mobile devices (phones, tablets, laptops) to respond to a variety of numerical, multiple-choice, short-answer and open-ended discussion questions posed during face-to-face workshops.

While CRS has been used for well over a decade and been shown to successfully improve student engagement and participation, a number of studies have also identified that its use could potentially mean that less material is able to be covered in lectures [6]. Toto and Nguyen [8] recognised that it is very difficult to continue to cover the amount of material needed while also opening up class time to include the active learning strategies so necessary in engineering. Demetry [10] reinforced this view by maintaining that content-crammed courses have been a perennial barrier to more widespread adoption of pedagogies of engagement in engineering education.

Clearly, the approach of cramming CRS into already content-heavy class time does not embrace the potential for CRS to improve student engagement and student learning. The use of CRS should be planned as an integral component of the course [9] which enhances and reinforces the learning outcomes. The effectiveness of CRS depends strongly on the quality and variety of the questions, the design of the activities to encourage students to engage with the questions, and most importantly, allowing sufficient time for students to read, comprehend, discuss and work through the questions at their own pace, as well as allowing enough time for them to submit their answers in a stress-free environment. Trying to add the use of a CRS alongside traditional lecture class material, rather than augment the use of the CRS, will not demonstrate the true benefits of using CRS to students and will generally also not improve student learning.

This study trialled the introduction of a new, state-of-the-art CRS in a third year engineering Fluid Mechanics course to improve student engagement, motivation and cognition. The course was completely redesigned and restructured to address and alleviate content-cramming issues [6, 8, 10]. It was recognised that for the potential benefits of CRS to be fully realised, more time must be allocated for student engagement and the active learning components of the course. In order to allow sufficient time to fully engage with the CRS and other classroom activities, traditional lectures were revised and the classroom lecture was flipped [10, 11]. This paper presents the initial case study results.

II. Flipping for Learning

Flipping allows for an instructor to provide traditional, low cognitive level, lecture materials in an alternative format outside the classroom, freeing up class time normally used to 'convey' information to students [8]. Instruction that used to occur in class was then accessed in advance of class (generally at home), so that students were well prepared and could derive the most benefit from time spent in the face-to-face learning environment [12]. Students worked through specially developed narrated lecture material online each week using our learning management system (LMS), prior to attending the face-to-face class sessions. Face-to-face sessions were then used to foster student engagement by working through typical problems, providing feedback, introducing advanced concepts, and facilitating student discussions and other collaborative learning activities [8, 12]. Toto and Nguyen [8] maintain that flipping lectures retains the best qualities of the traditional teacher-centred lecture model while also including the best qualities of the active learning or student-centred teaching model.

In order to avoid confusion, the weekly narrated flipped lectures were renamed hand-e-lectures to reflect the convenience and flexibility these online lectures offered students. The time slot allocated for the original lecture was renamed the workshop. The students could work through and study the hand-e-lectures when and where they wanted, and for as long as they wanted. Different students learn at different rates and this arrangement allowed them to spend as much time on the material as the needed. All students need time to be able to absorb and process the information needed before it can be applied [8]. In order to encourage students to utilise and engage with the hand-e-lectures, a number of graded CRS questions were included as part of the online hand-e-lecture content. In order to answer the weekly online hand-e-lecture questions, students were first required to register as students on the Top Hat Monocle (THM) website (https://www.tophatmonocle.com/).

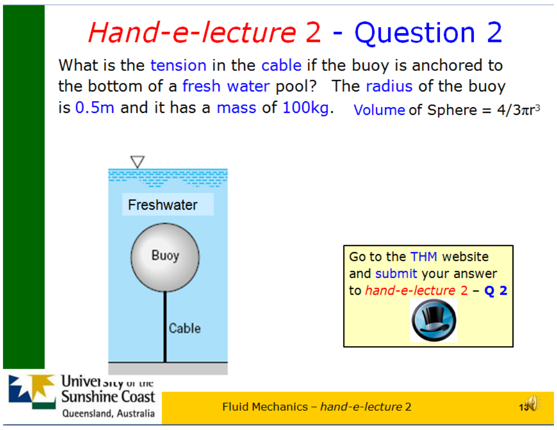

Fig. 1. Typical *hand-e-lecture* CRS Question

Typically, each hand-e-lecture would contain between four and six CRS questions based on the weekly lecture material (Fig. 1). Students were required to solve and submit answers to the CRS questions before attending the workshop session. Students could submit their answers to the CRS questions online, using a PC, laptop or Smartphone, or by SMS if these were not available. Reports showing the range of student responses to the hand-e-lecture questions were generated before each workshop and these were used to provide feedback and to identify any problem areas. Fig. 2 shows a typical report from a numerical answer-type question. The numbers listed down the left hand side of Fig. 2 show the various student responses to that particular question. The percentages listed down the right hand side of Fig. 2 represent the percentage of students that submitted that response. The numbers in the horizontal report bars show the actual number of students. The correct answer (200) is highlighted yellow in Fig. 2.

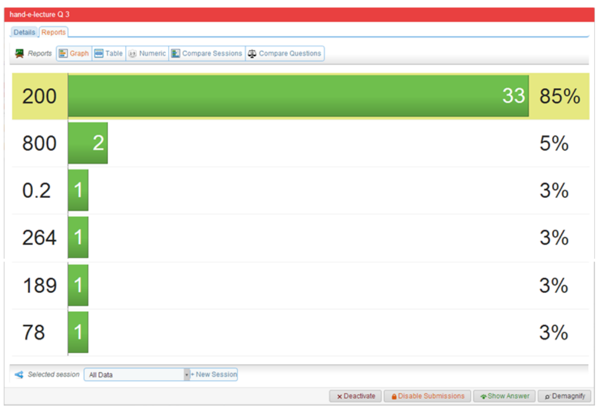

Fig. 2. Typical *hand-e-lecture* CRS Question Report

Workshops extended the hand-e-lecture content by including a variety of carefully designed, engaging activities (many were group activities) that used CRS questions to facilitate discussions, problem solving and case study analysis to enhance student cognition. Students used their mobile devices (phones, tablets, laptops) to respond to the CRS questions posed during the workshops. This arrangement also provided opportunities to identify potential problem areas, and to enable on-going assessment and evaluation of learning outcomes. To encourage participation in the workshops, students were also graded on their participation in the CRS process and on the correctness of their responses to the questions. A maximum of 15% of the total student grade was allocated for participation in the hand-e-lecture and workshops using the CRS.

One of the many pedagogical benefits of the instant feedback provided by the CRS in the workshops was that it allowed students to evaluate their own performance and to monitor their own understanding of the workshop content [6]. This has been shown to result in a significant increase in students' long-term retention of knowledge [13, 14]. A further pedagogical benefit of receiving instant feedback on the students' responses was that the instructor could immediately identify areas that students were having difficulties with, or conversely, areas where the students were having no problems understanding. This allowed the instructor to adjust their instruction to provide further explanation on any problem areas, or to move on to the next topic with confidence that the students have understood. The flexibility that the instant CRS feedback gave the instructor in the workshops was particularly valuable. Traditional lectures are usually 'passive' in nature and it is very difficult to tell whether students are actually learning [8].

A further benefit of using the new CRS to ask students to answer summative questions posed in the hand-e-lectures and workshops was that the instructor could tell at a glance how students were doing overall. The new CRS trialled in this study provided instant EXCEL score sheets for all questions at the click of a button. This was very valuable information as it allowed the instructor to identify any individual students that were struggling. The instructor could then intervene and spend more time one-on-one with the students to provide extra instruction before the students became frustrated or gave up [15]. The instant score sheets also allowed the instructor to identify areas of general misunderstanding within the class and provide extra explanation where required. An added benefit of this was that the students quickly realised that the instructor was very aware of how much effort the students were, or were not, putting into their learning.

III. Evaluation

A range of evaluation methods were used to gauge the effectiveness of the new teaching format in achieving increased student engagement, including classroom observation, student surveys using THM, feedback from student emails, and analysis of attendance and assessment results.

A significant increase in the levels of student engagement was observed during the new workshops. Students actively participated in the workshops using their mobile devices. There was always much interaction and discussion among the students whenever a new THM question was posed. This was generally accompanied by a significant change in noise level within the classroom. It was interesting to observe how the noise level changed after each new question was posed as it generally followed a similar, cyclic trend, namely:

- The noise level would rise substantially as soon as the question was posed as students discussed the question amongst themselves;
- The noise level would gradually reduce over the next minute or so, as the students started working on their questions individually;
- The noise level would then reduce to nearly zero when the students were deeply engaged with their solutions;
- The noise level would then slowly start to rise again as more students submitted their answers on THM and discussed their answers with others.

From the instructor's point of view, this cyclic trend in noise levels was a very useful gauge of the appropriate time to move on to the next topic or question.

The CRS was also used to survey students on their perceptions of using the new technology and to gain a deeper understanding of how its use could be improved. At various times during the course, a number of evaluation questions were posed for evaluation purposes. The CRS was also used to obtain information on technical issues, such as which internet browser or phone provider the students were using or how they found the registration process and similar logistical queries. Fig. 3 shows the results of the survey question: *"Do you like or do you not like being able to participate in the Workshops using THM?"* This question was asked in the second week of the new course at the end of the second workshop.

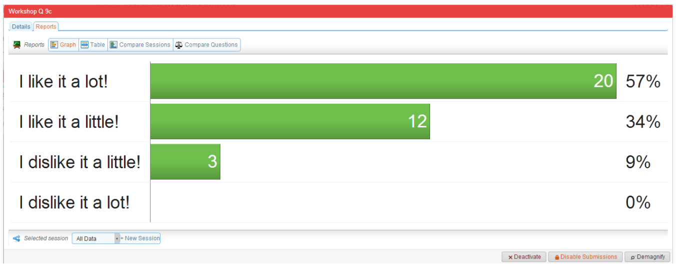

Fig. 3. Report of One of the THM Evaluation Questions

As shown in Fig. 3, 91% of students surveyed (n=35) liked that they were able to participate in the workshops using the new CRS (THM). This was very encouraging, particularly as most of the students had never used a CRS before and this was only two weeks after they had first been introduced to THM. However, three of the students said they didn't like it much. Another benefit of the reporting system is that it is very easy for the instructor to see which students are responding to the questions. As it turned out, the three students that said they disliked it a little answered in the negative for all of the CRS evaluation questions posed that day. They also got most of their answers to the workshop questions wrong. Perhaps they were just having a bad day?

Fig. 4 shows the results of the survey question: *"Do you think that the new hand-e-lecture and Workshop format will or will not help you to better understand the course material?"* This question was also asked in the second week of the new course at the end of the second workshop.

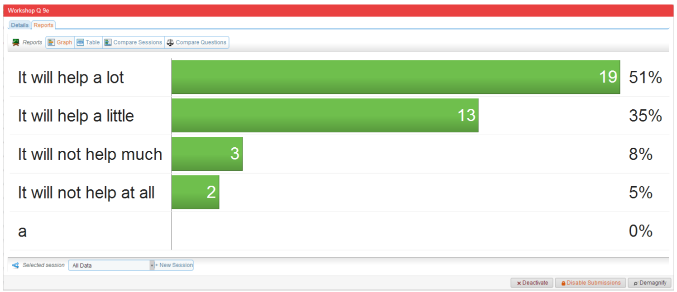

Fig. 4. Second THM Evaluation Question Report

As shown in Fig. 4, 86% of students surveyed (*n*=37) thought that the new hand-e-lecture and Workshop format would help them to better understand the course material. Fig. 5 shows the results of the survey question: *"Do you like or do you not like being able to work through the material whenever it suits you?"*

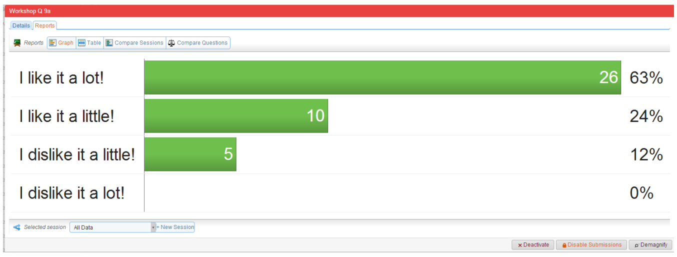

Fig. 5. Third THM Evaluation Question Report

As shown in Fig. 5, 87% of students surveyed (*n*=41) liked being able to work through the material whenever it suited them. Student feedback on the other evaluation questions posed produced similar positive results which reinforces previous research findings that CRS promotes greater student engagement and higher levels of motivation [5, 7, 8, 10, 12, 16].

The CRS was also used to collect feedback on technical and logistical issues associated with the use of the system. As this was the first time that this system had been trialled anywhere in Australia, another of the study aims was to investigate different students' experiences of interacting with THM using different Australian internet and mobile telephone service providers. In addition, the students' views on, and experiences with the registration process was of interest in this study. One of the first week's hand-e-lecture questions asked: "How did you find the registration process through the Top Hat Monocle website?" The results are shown in Fig. 6.

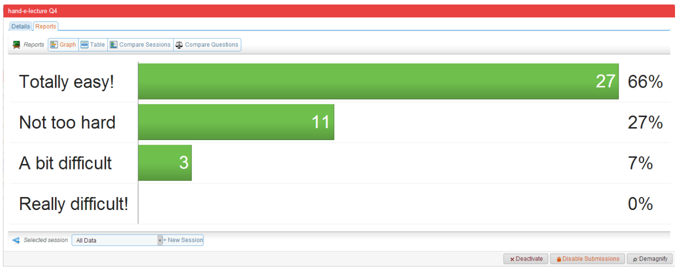

Fig. 6. Report of Evaluation Question on Registration Experience

As shown in Fig. 6, 93% of students (*n*=41) found the registration process easy. This is a very good result considering that this question was asked in the very first week of semester and most students had never used any type of CRS beforehand.

In addition to the formal evaluation that was conducted on the new teaching format, students were also asked to provide informal feedback by way of email on their perceptions of the new teaching format. While this invitation did not generate a large number of responses, the feedback that it did generate was generally very positive and supportive of the new teaching format. Two examples of this student feedback on the new teaching format are shown below:

- *"One of my favourite things is that we are exposed to, and tested on our understanding of new material at our own pace. This enables me (us) to bang our heads against something we find a bit curly until we have at least some understanding of it (or failing that narrows it down to 1 or 2 points that are easily cleared up in the 'workshop'). So when we are exposed to it in the workshop it's nothing new and we can focus on its applications and broader implications."*
- *"Between the hand-e-lectures, the THM questions and the TuT questions I am engaged, and importantly not swamped, by material to keep it on my mind and to 'hold', if you will, the learning. That way the workshops are more like a spit and polish of the rough knowledge from the HeL and the TuT questions are the double check."*

The new flipped lecture and CRS teaching format demonstrated a substantial increase in the level of student engagement, motivation and attendance compared to previous cohorts [7, 8, 10]. However, the increased levels of engagement did not appear to reflect on any large increase in students' individual grades in comparison to previous cohorts, although at the time of writing, the final grades were not yet complied. There are also many variables that could influence the results from one student cohort to the next and these would have to be taken into account to enable a realistic comparison. This was the first time that this new teaching method has been trialled and the inconclusive nature of the results could be attributed to the preliminary nature of this case study. The study is ongoing and it is expected that as more data becomes available, this will allow a comprehensive analysis to be undertaken on the pedagogical benefits of this new teaching format.

IV. CONCLUSION

This case study explores the use of a new, low-cost, state-of-the-art CRS which allows students to use their mobile devices (phones, tablets, laptops) to respond to a variety of numerical, multiple-choice, short-answer and open-ended discussion questions. In order to allow sufficient time to fully engage with the CRS and other classroom activities, traditional lectures were revised and the classroom lecture was *flipped*. Students worked through specially developed lecture material online each week prior to attending the face-to-face class sessions. Face-to-face sessions were then used to foster student engagement by working through typical problems using the CRS, providing feedback, introducing advanced concepts, and facilitating student discussions and other collaborative learning activities.

A number of inter-related issues are contained in this paper that were difficult to tease apart. Separating the advantages of using a CRS in general, using THM in particular, the way in which the instructor used THM, and the overall teaching quality of the instructor is very difficult. The data gathered and discussed in this paper regarding THM are inextricably linked to the manner in which THM was used.

Overall, the new flipped lecture and CRS teaching format demonstrated a substantial increase in the level of student engagement, motivation and attendance compared to previous cohorts. Generally, students' perception of the effectiveness of using the new teaching format was overwhelmingly positive. The study is ongoing and it is expected that as more data becomes available, this will allow a comprehensive analysis to be undertaken on the pedagogical benefits of this new teaching format.

Development of an Automated Manufacturing Course with Lab for Undergraduates

Deborah Munro, Ph.D.
Donald P. Shiley School of Engineering
University of Portland
Portland, United States
munro@up.edu

Abstract*— Many engineering programs at universities across the country have dropped machine shop and manufacturing courses from their curriculum due to budget constraints, accreditation requirements, and concerns about student safety. At the University of Portland, we have resurrected and enhanced a hands-on advanced CAD and automated manufacturing course that introduces students to advanced solid modeling techniques in CAD, such as sweeps, lofts, and surfacing methods. In addition, students learn manual machining and vacuum forming in our machine shop, along with learning how to create tool paths for CNC machining their designed CAD parts out of wax on various three axis end mills, a 3D printer, and a 3D laser scanner. The end mills were all refurbished and/or repaired over a period of four years to get this course up and running. A commercial software package, MasterCAM, was used in conjunction with SolidWorks as the platform from which to learn about automated manufacturing. In addition, a MakerBot 3D printer was built from a kit to give students experience with future manufacturing techniques. The 3D laser scanner was student designed and built and creates CAD surface models of parts, useful for learning about reverse engineering. The machinable wax used for machining is recycled, melted down, and formed into blocks again for reuse. This saves considerable money. Our goal has been to enhance design quality in our curriculum through experiential learning. Prior to taking this course, all mechanical engineering students are required to take a solid modeling CAD course to learn the basics. However, our experience has been that students do not conceptually understand the importance of designing for manufacture. Although emphasized in all courses, without the hands-on experience, it is difficult for students to remember to apply fillet radii to the bottom of pockets, for example. When faced with having to fit a block with sharp corners into a machined pocket with its default small corner radii, however, learning is instantaneous. The early outcomes of this course show students have learned a great deal about design for manufacturing and manufacturing techniques from taking this course.

Keywords- experiential learing, manufacturing, CNC machining, hands-on laboratory experiments, undergraduate engineering, 3D printing, rapid prototyping, MasterCAM, SolidWorks

I. INTRODUCTION

This article covers the reintroduction last year of an automated manufacturing course in the mechanical engineering department at the University of Portland. This course existed for many years, but faded away in 2000 after the instructor retired and the small end mill used for the course stopped functioning. Over the past four years, it has been my goal to revitalize this course and begin offering it again. The new and improved version of this course will now be offered every year.

Why offer an advanced CAD and automated manufacturing course? It has safety risks, equipment purchase, maintenance, and refurbishment costs, and requires a large investment of time and faculty resources to provide a lab-based course to a couple dozen students. The reasons are numerous, but mainly hinge around the fact that the demographic of our engineering student body has changed, and the vast majority of our students have had no exposure to or use of manufacturing equipment of any kind. Since the early 1980s, two-thirds or more of high schools nationwide have eliminated their technical education classes [1], mechanical and electronic devices have become too complex for the average teenager to work on [1], and many colleges have had to eliminate lab courses due to budget constraints. Engineering students frequently graduate with little hands-on, experiential learning, and there is a "disconnect [and] engineering students are not adequately prepared, in [industry's] view, to enter today's workforce" [2]. Also, the world of manufacturing is changing, and engineers of the future will need to be able to work with new equipment, technologies, and manufacturing techniques. Awareness of these techniques will be key to their professional development and success as engineers [3].

The need to shift from scientific inquiry to engineering design has been addressed by the Next Generation Science Standards, as being critical for our students [4]. The core concepts they want students to acquire are achieved through the experiential learning we have implemented:

1. Analyze a major global challenge to specify qualitative and quantitative criteria and constraints for solutions that account for societal needs and wants.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

2. Design a solution to a complex real-world problem by breaking it down into smaller, more manageable problems that can be solved through engineering.

3. Evaluate a solution to a complex real-world problem based on prioritized criteria and trade-offs that account for a range of constraints, including cost, safety, reliability, and aesthetics as well as possible social, cultural, and environmental impacts.

4. Use a computer simulation to model the impact of proposed solutions to a complex real-world problem with numerous criteria and constraints on interactions within and between systems relevant to the problem.

The National Research Council of the National Academies has also been involved in revising our K-12 science education, and they are also focusing on integrating scientific inquiry with the skills of engineering practice [5]. They have stressed that a narrow focus on conceptually teaching science has led to the unfortunate consequence of students believing science is a body of isolated facts. By integrating the knowledge of a science with skills simultaneously, students' minds are cultivated to be able to engage in scientific and engineering inquiry.

This type of experiential learning needs to be carried forth into the college level. In another National Research Council publication, "Promising Practices in Undergraduate Science, Technology, Engineering, and Mathematics Education: Summary of Two Workshops", the authors found that some of the strongest predictors of success were in-class activities that actively engaged students in the learning [6]. They found notable success when students were involved in problem-based learning, beginning with a problem to be solved, followed by some content delivery of theory, skills, or case studies, followed by small group activities, and completed by designing a solution.

At our university, we have noticed that students often make "manufacturing errors" in their CAD solid models, such as neglecting to put fillets in the bottoms of holes. This is due to their ignorance of manufacturing tools and how they are used. "The disappearance of tools from our common education is the first step toward a wider ignorance of the world of artifacts we inhabit" [1]. It is difficult, if not impossible, for us to explain why such things as fillets are required on their designs, since they have no context to understand what we are saying. We feel this points to an underlying weakness in problem solving among our students, as the vast majority of our curriculum uses textbooks with "answers" in the back of the text. This problem persists all the way into our senior design capstone sequence, where students produce beautiful CAD models and assemblies that cannot be manufactured or assembled. Thus, we have embarked on a strategic plan to increase the amount of design and experiential learning in our mechanical engineering curriculum.

The redesigned advanced CAD and automated manufacturing course is intended to provide hands-on experiential learning through a variety of equipment and software tools. The lab now contains four end mills, all three axis, a 3D laser scanner for reverse engineering, and a small 3D printer. Additionally, student teams have lab rotations through the machine shop to learn manual machining, vacuum forming, and molding techniques. The remainder of this paper discusses all of the course curricula in detail, the equipment and how it was refurbished, the costs of establishing this course, and the outcomes achieved.

II. Lab Equipment Details

All our mechanical engineering students are required to take an introductory course in engineering graphics, which includes the use of SolidWorks®. This knowledge is used in follow-on classes, such as finite element analysis (also required), a balsawood bridge design competition, and in senior design. Students coming into the advanced CAD and automated manufacturing course have this background in CAD, which is used as a basis to begin the instruction with the introduction of new software, MasterCAM for SolidWorks®. This new product offering by MasterCAM is an add-in module embedded within the graphical user interface of SolidWorks®. Thus, it is easy for students to adapt to the increased functionality, and they are comfortable switching between modes to edit or adjust dimensions on their CAD models, and then return to their tool path model. MasterCAM® allows the students to embed their CAD model in a block of material and then machine away the excess until the CAD model is again revealed. For 2012, we used SolidWorks 2012 (Educational edition) and MasterCAM X6. We upgrade to the latest revision of all software every year.

The CAD and CAM modeling was taught in a computer classroom that contained 35 Windows 7 workstations with enhanced graphics cards and 21 inch LCD monitors. The textbook used for the MasterCAM was "MasterCAM for SolidWorks X6" by In-House Solutions. The text came with all the CAD models to do the exercises in all 13 chapters, but to improve the students' CAD skills, I had them make all their own models and only provided the models for classroom exercises. The chapters were very thorough, perhaps too complete, as the students could follow step-by-step to create their tool paths. However, all the lab rotations were open-ended designs that the students developed themselves, and they had to then create their own tool paths from scratch.

Lectures in the computer classroom were one day per week, and labs were the other day each week. The first five lecture periods were devoted to learning MasterCAM and refreshing CAD skills by building the models for the exercises. The next eight lecture periods were devoted to learning advanced techniques in SolidWorks. As there are no good textbooks on SolidWorks, I worked with my local software distributor (MCAD in Beaverton, Oregon) to obtain a couple of their instructional course books. These were outdated by one revision, 2011, but they allowed me to copy, paste, and combine them in any way I wished to make an instructional course pack. I pulled mainly from their

"SolidWorks Advanced Part Modeling" and "Surface Modeling" books. As I did not have any of the referenced models, and the books were meant to be used with instructor guidance, there were many challenges with the course pack I created. However, we were able to cover many advanced topics, including sweeps, lofts, and surfaces.

On lab days, the students had two weeks at each of six stations. During the first lab period, students would read the various equipment tutorials I had prepared and dry run through the entire set up procedure. Then, they would build their own model and machine it the following week. As the semester progressed and the students got more enthused about what they could do, the time to machine their models increased, so the students often came back on their own time (in pairs) and finished their machining.

For the lab, I utilized machinable wax. There were a number of wax blocks available from the prior course in 2000, and a crock pot and aluminum mold that had been made into a wax recycling system. The machinable wax blocks were 3 inches by 6 inches by 1.5 inches thick, and new ones cost about six dollars each to purchase. So, we utilized the wax recycling system to melt down all the stored shavings and discarded projects into new blocks. The color was muddied from blue or purple to a brownish purple at first, as the stored shavings had bits of plastic and other debris. When collecting the shavings from the new blocks, we purchased a clean shop vacuum that attached to a five gallon bucket. We used only that bucket for the new blocks, and they molded into serviceable and nicely colored new blocks.

The lab contains four end mills, a 3D laser scanner, and a 3D printer. In addition, the machine shop contains a manual end mill and a vacuum forming machine. Each of these pieces of equipment will be discussed below, including when it was purchased, how it was refurbished, and its capabilities.

A. EMCO PC-50 Mill by Maier Industries

This small, tabletop three-axis mill was purchased in the 1990s for the original automated manufacturing class. It was purchased without the onboard controller and instead used a Windows 98 and DOS-based software interface. My predecessor had determined that a couple of the cards in the EMCO were faulty and had purchased replacement cards. I had those installed, but could not get the computer to run. It turns out that someone had inadvertently disposed of the Windows 98 computer that served as the controller. Fortunately, they had removed the ISA card first. According to Maier, the Windows 98 environment cannot be emulated, so I had to locate another Windows 98 computer that had an ISA slot. Most Windows 98 computers used PCI slots, so it was challenging, but I finally managed to locate one that met my needs. The MasterCAM software would not run on this computer, however, so a Windows 7 computer was also needed. To transfer files, we use the CD Read/Write drive, as the Windows 98 computer cannot read a USB drive. All of this could be overcome by refurbishing the EMCO with a new controller, but that would cost $6000. It is slated for refurbishment sometime in the next three years, depending on other lab needs. The EMCO itself machines beautifully and produces high quality parts in wax, plastic, and aluminum. It is a very safe machine that will only operate when the door is closed, and it will stop itself rather than exceed a safe travel limit. There are many of these EMCO PC-50 mills around, and they are a low cost way to start an automated manufacturing course.

B. Techno Da Vinci Mill by Techno, Inc. Education Division

The lab contains two Techno Da Vinci three-axis tabletop mills that were purchased in 2005 to support a mechanical systems and controls lab course. Although they were outfitted with Dremel®-style rotary cutting tools, they were used exclusively as pen plotters. The encoders were outdated technology, and the software interface was extremely challenging for the students to learn how to use. These were refurbished with all new encoders in the spring of 2012. The refurbishment took one day, and each mill cost $7500. These two mills now interface through Techno CNC Interface software directly to MasterCAM and have been the most popular ones to use in the course. They are capable of machining up to three feet square, but that requires additional fixturing. They are each outfitted with a vise that holds the wax blocks.

The Techno mills are still available for purchase and are widely supported by local distributors. They are straight forward to operate and provide a great learning environment; however, the rotary tools provide inferior cutting and the collets make tool change difficult. The collet must be removed from the rotary tool in order to put in a new tool bit. Collets of one-quarter and one-eighth inch are available, so end mill tool bits are limited to smaller sizes. Also, the gantry-style movement of the rotary bit is jerky and does not provide as nice a surface finish as the other mills we have. For safety, I had both mills outfitted with Plexiglas shields and hinged doors. I also had an air blowing system attached to each tool head to help clear wax shavings.

C. Bridgeport Explorer I CNC Mill by Bridgeport

I purchased this three-axis knee mill in 2009 off of Craigslist for $3000 and then moved it up to the university in a pickup truck using a forklift and chains to get it in and out of the truck. The mill was transported to near the door of the building and then lowered onto a rolling platform to bring into the classroom through the double doorway. It was then lifted with the forklift again and placed in its final position. It required three-phase power, which was previously installed for it during the building renovation. The Bridgeport mill was in good working condition, but very outdated. I had the computer, keyboard, and software updated for $4000. The mill was also cleaned up and painted and got a new adhesive panel backdrop for the controls. The software is a standard Fanuc controller, suitable for our machine, and I downloaded the post for it for free from MasterCAM. To place files on the machine, we purchased a special USB drive that plugs into the back. This USB drive provides access codes and also serves as extended machine memory. For safety, I had three six-foot high Plexiglas rolling walls made to surround the three sides of the machine. The machine has oil coolant, but I opted to use the mill only for wax during the course. It is capable of machining aluminum as well as steel and can support the use of large tool bits.

D. 3D Laser Scanner (Student built)

Manufacturing techniques are changing rapidly, and one trend is biomimicry and reverse engineering, where designs are organic and inspired by nature. Traditional CAD software is notoriously ill-equipped to model organic forms, so engineers are searching for new ways to input CAD geometry and surfaces into their designs. One way to input such surface data is with the use of a laser. Our device is a green line laser that is hand-swept over the object of interest. A student developed this for me in 2010. Behind the object is a grid of calibration dots that allow the software, we use David®, to capture the surface contours. The object can be rotated multiple times, and the finished scans can be aligned in the software to recreate the entire object. The surfaces are then fused together, and the finished object can be viewed in SolidWorks and printed on a 3D printer. Our 3D laser scanner is of very low quality, but it illustrates the concepts well, and students gain a lot from the awareness of such techniques.

E. Cupcake 3D Printer by MakerBot

I won this 3D printer from MakerBot in 2010 by entering an essay contest, explaining how I would use it in my courses. The printer came as a kit with hundreds upon hundreds of pieces, but if I were to have purchased it, the cost would have been only $1500. Now, they are even cheaper. Building the printer (and then optimizing it) provided several of my students with interesting focus and independent study projects that gave them valuable hands-on experience with hardware and electronics. The software is open source and is called Replicator G. The Cupcake is an ABS extruder (fused layer deposition). It works like a hot glue gun, melting the ABS plastic at 250 degrees Celsius and building layer-by-layer on the heated build platform. The build platform is less than three inches on a side, but the resolution is actually not bad for hobbyists. Like the 3D scanner, its purpose was to expose students to this new manufacturing technique, as industry is beginning to manufacture car parts and other exciting designs that could never be machined using conventional methods.

3D printing is truly the future of manufacturing. Many of our senior projects desire 3D printed prototypes, and we have had to send these requests out to local industry, as our capabilities are limited. However, a donor has given us $25,000, which we supplemented with departmental funds, and we have purchased a Stratasys Dimension 1200es SST. This new 3D printer has a 10 x 10 x 12 inch build volume and can print in nine different colors of ABS plastic. We chose this printer because it provided robust, functional parts that could be used directly as prototypes, and had relatively high resolution of .010 inches. The speed is moderate compared to other technologies, but we were pleased that the scaffolding material was environmentally safe and water soluble. Parts are placed in a water-based solvent part washer for several hours and are then rinsed in the sink. The solvent can be poured down the drain and replaced as needed. Since the water-based solvent is heated to 70 degrees Celsius, we are requiring students to wear insulated dish gloves, safety glasses, and masks, just to make sure they are not exposed to any chemicals unnecessarily.

F. Manual Machining and Vacuum Forming

In the machine shop, we have a three-axis Bridgeport mill. Students are asked to machine a paperweight out of aluminum. The purpose of this training is to help them gain a realistic sense of what feeds and speeds mean in the MasterCAM software. It also lets them feel the resistance of the machine if they make too deep of cuts or try to travel at too fast of a speed.

Also in the machine shop, we have a vacuum forming machine. The plastic material, such as polystyrene, is held in a sheet and heated from above the object to be captured. When it reaches the right temperature, the sheet is lowered quickly, and air ports in the lower table seal the plastic around the object. Finished molds are then trimmed out of the cooled sheet and can be filled with a hardening foam or plastic material to make replicates of the original object.

G. Safety

To minimize the risk to our students, we conduct two full class periods of training, one for the automated manufacturing lab and each piece of equipment it contains, and one for the machine shop. Students are not allowed into either location without safety glasses, pants, and closed toe shoes. They must use leather gloves to change tool bits and must have all shields engaged before turning on the machines. Other safety is also covered, such as tying back long hair, not wearing loose clothing, and applying appropriate force to vises and collet nuts. Both the instructor or technician and a lab assistant are present at all times. Once students are fully trained, they are permitted to use the machines outside of class time, whenever the building is open. They are required to work in pairs, and they have to carry written permission with them, in case anyone asks if they are allowed in the lab. Any injuries are reported to the university. So far, one student cut his hand on a tool bit when checking to see if the wax block was secure in the vise (it came loose). A second student used his personal pocket knife to open a cardboard box and cut his hand.

III. RESULTS

This past academic year, 25 students took this new course in advanced CAD and automated manufacturing. The students each completed over ten MasterCAM tool path codes, and about a dozen SolidWorks models. As teams of four, the students also fabricated six of their own designs, one on each piece of equipment, as well as a final project on a machine of their choice. Many students incorporated surface modeling in their designs and many others built mechanisms of several wax-cut pieces, such as the Geneva mechanism in the photo. Since then, many of these students have continued to use what they learned to make projects on their own or as part of their senior design prototypes. One team machined an entire foam RC airplane wing on one of the Techno mills for their senior project. Another used the MakeBot to make a buckle for a medical device, also for their senior project.

There have been numerous glitches throughout this first year course offering. The Bridgeport mill developed some mechanical problems and had to be repaired. It was also limited to 256 kilobyte files, and some of the feature-based milling techniques in MasterCAM exceeded this limit. I did not learn until after the semester ended that the USB drive could allow us to machine larger files. The Techno mills do not adequate grip the tool bits in the collets unless the collets are first removed from the rotary tool and assembled with the tool bit. Also, the collets were old and had some looseness. Thus, some of our early attempts failed to machine properly, because the tool bit loosened and starting falling out of the collet during machining. New collets were purchased, and the students were trained on the proper technique for changing tool bits. Hopefully, some replacement rotary tools with a chuck key system can be found in the future. The MakerBot printer was having trouble with the ABS plastic not adhering to the heated build platform. This was resolved by adding a raft under the parts. The larger, looser surface area of the raft was better at adhering. The raft then had to be peeled off the part after fabrication. Finally, the 3D laser scanner software, David® 2.0, could only produce .STL files. This is not an editable format in SolidWorks®. There are other software options out there at free or low cost, so those will be investigated.

IV. DISCUSSION

This course was very well-received by the students and received a lot of positive feedback. The overall assessment of the course by the students was 4.78 out of 5.00, with 78% giving a rating of "strongly agree" on the course being a valuable learning experience. The remaining 22% answered "agree" to this question. Below are some of the comments students made about the course:

"I really enjoyed learning the advanced CAD and automated manufacturing techniques learned during this course. I think all of these skills will be very beneficial to my career."

"It is a fantastic introduction to Advanced CAD and Automated Manufacturing. It has been the most hands-on of any class I have had so far, and thus has been the most enjoyable. I certainly like that several different types of automated manufacturing are introduced in the lab."

"The course teaches an engineer how to bring their designs to reality and the problems that arise in manufacturing a product from a drawing. The instructor was prepared for problems when they arose and was able to keep the course moving forward even when problems resisted."

The students also gave me some beneficial feedback to help improve the course this next year. One of their main criticisms was the time slot. Because we needed both a computer classroom and a heavily-used lab, the course was offered at night. This interfered with student jobs, placed the course back-to-back with an optional review course many of the students were enrolled in, and limited how late we could stay, since the machine shop technician needed to go home. Thus, next year, we are switching semesters the course will be offered. In the spring semester, we can offer the course in the late afternoon with no conflicts.

Another complaint was the poor quality of the course pack I created for SolidWorks and the amount of advanced techniques we were able to cover. The students were not as skilled at SolidWorks from their introductory class as I had anticipated, so a lot of time was needed to go over more remedial skills. Most of them did not know how to create a dimensioned engineering drawing, either, so that will need to be added to the instruction next year. Because of these challenges, we did not get an in depth coverage of surface modeling. I am working with an exceptional student to develop my own advanced CAD book for SolidWorks for next year's course.

V. CONCLUSIONS

As our knowledge of science and engineering increases in complexity, we feel it is important to maintain the hands-on skills portion of scientific inquiry, as well as to develop student ability to formulate a problem and design an engineering solution that addresses all of the many faceted issues that may be involved. As the integration of design into the engineering curriculum is now an ASME and ABET criteria, we are addressing this issue across multiple courses.

Overall, this new course offering in advanced CAD and automated manufacturing has been a successful addition to our curriculum. There is a lot of room for improvement, but the main objectives of the course, which were to give students experiential learning and thus improved design skills through hands-on manufacturing of their own designs, has been achieved. It is a future goal to assess the impact this has on our student outcomes.

ABSTRACT—*This paper discusses an innovative approach to teach engineering concepts using Virtual Reality based Learning Environments (VLEs). New learning modules have been created using Virtual Reality technology and introduced in interdisciplinary senior level and graduate level courses targeting mechanical, industrial and electrical engineering students. These Virtual Reality based learning environments have been used to teach micro systems related topics as part of overall efforts to enhance the learning experiences of students. The learning outcomes including student performance are discussed. The process undertaken to design and develop these VLEs are elaborated along with the technologies used to develop such environments. A brief discussion of next generation Internet technologies which hold the potential to impact engineering and K-12 education is also provided.*

I. INTRODUCTION

This paper discusses the potential of Virtual Environments which use Virtual Reality (VR) technology for education and learning activities. In general, such Virtual Environments (VE) are widely used in various engineering domains from robotics assembly to more complex space systems design. Virtual Learning Environments (VLEs) are a subset of virtual environments which are created and used for educational and learning contexts at university and K-12 levels. In this paper, we discuss the design and introduction of these VLEs to teach engineering concepts at Oklahoma State University to both undergraduate and graduate students.

Virtual Reality [1-22] and Cyber computing techniques [23] are among the more recent technologies adopted for educational purposes. The potential of using such technology to teach simple and complex Science, Math and Engineering (STEM) concepts is significant [22, 23, 24]. Our students live in a cyber enhanced digital world where use of digital technologies is commonplace. Educational trends need to explore adoption of such technologies. As noted in [23], computer or software based learning tools refer to a larger set of tools and environments which enable students to learn using some type of a computer technology (which may be web based or running on a PC). Virtual Learning Environments (VLE) are a smaller subset of such computer based learning environments [23, 24].

II. VIRTUAL LEARNING ENVIRONMENTS (VLE)

VLEs involve the creation of 3D based graphics rich environments that can also interface with Virtual Reality technology (such capabilities are crucial to supporting both immersive and non-immersive interactions by users or students. With recent advances in Internet technology (such as Internet2 and the more advanced GENI type frameworks, see [23]), the impact of such VLEs is expected to rapidly transform the way our students learn.

Virtual Reality, in general, can be described as a technology that enables the creation of a 3 dimensional (3D) simulation environments; users can interact with such environments using 3D eyewear and trackers (figure 2). The 3 levels of immersion are non, semi and full immersion [22].

Non immersive environments [22, 23] do not provide active stereo views of the target simulation; here the environment looks similar to a typical 2D computer screen (figure 1); this is the most basic of VLEs. At the next level are Semi immersive environments; these can provide active 3D stereo views of target environments and users can interact using trackers, sensors and 3D eyewear (or stereo eyewear, see figure 2). The screen of interaction can be a computer screen or a much larger wall sized screen. These environments are referred to as 'semi immersive' [23, 24] as the user can interact with the 3D environment when they want to but also can look

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

away at the real world around him or her (meaning they are partially immersed).

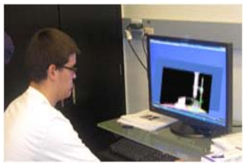

Fig 1: A non immersive VLE

Fig 2: A semi immersive VLE

Fully immersive environments are environments where your reference to the real world is completed eliminated (or the immersion is 360 degrees). Users can wear Helmet Mounted Displays (HMDs) on which the target environments are projected. Other types of such environments are also called CAVEs (CAVE Automated Virtual Environments) where multiple projectors are mounted in various configurations.

The term 'Virtual Prototype' [7, 20-21] has many descriptions; in this paper, we use the description as in [7], where it is described as a three Dimensional (3D) computer model which seeks to 'mimic' a target (or 'real world') object, system or environment using Virtual Reality technology. This model can be a representation of a target environment, a simple object or a system of 'objects' at various levels of abstraction.

Several reports highlight the potential of computer simulations in engaging and motivating students especially in Science Technology Engineering and Mathematics [STEM]. However, as noted in [11], there is a need for additional research to study the impact of such simulations oriented learning to improve science achievement.

Other researchers such as Sourin [16] report a 14% improvement when students utilized a virtual world during their learning of computer science concepts. Other less extensive studies involving student surveys report that students indicated that virtual reality environments helped them learn [17, 18].

Research papers have also attempted to address what the students experience when interacting with such VLEs. In [12, 13], the authors outline a phenomenon referred to as *flow* where individuals enter a state of completely focused motivation which facilitates learning**;** when students experience such a state of 'flow'**,** they report that they became focused only on the task and become less aware of extraneous factors [14, 15].

In the context of *engineering education*, it is important to note that other than our own pilot project (discussed in section 4) involving use of Virtual Reality to support learning, there have been very few reports on the impact of using VLEs and related technologies in engineering at the university level [11]. In the context of technology, it should be noted a majority of the literature reviewed deal with *non-immersive simulation* environments [1-10]. While there is a growing literature of studies utilizing virtual reality and simulations for student learning [19], very few studies have attempted to demonstrate objectively that learning can be enhanced when students have access to virtual reality learning environments.

As indicated earlier, the main emphasis in this paper is on how VLEs are used in teaching engineering concepts at the college level and the impact on student learning. Results from a pilot study involving use of VLEs in teaching engineering students will be discussed

III. Developing the VIRTUAL Learning Environments

Since 2004, VLEs have been used by J. Cecil's group (while he was at New Mexico State) to introduce students to complex engineering concepts in various manufacturing domains including computer aided manufacturing, electronics assembly as well as emerging domains such as micro and nano assembly. In recent years, the process of creating virtual prototypes in general has also been studied for various engineering domains including micro assembly [25].

The main phases in creating such VLEs include:

1) Identify the Learning Objectives and Target Student body
2) Understanding of the engineering process of interest
3) Design the Virtual Learning Environment (VLE)
4) Build the VLE

In the first phase, the instructor identifies the learning objectives specific to the students in the course. Subsequently, a collaborative team of experts, VLE designers, and education assessment specialists design and develop the VLE under the supervision of the instructor in phases 2, 3 and 4. In the second phase, the understanding of the target engineering process takes place. As such, the experts bring in their content and skills to engage in understanding the process that goes on in the development of the VLE. The third phase is the software design of VLE.

Designing the VLE is one of the most important phases in the creation of a Virtual Learning Environment (VLE). This complex phase involves developing a detailed architecture of the VLE (including identifying and specifying the various modules in the software environment); formal techniques such as creating collaboration, sequence and class diagrams are useful as they provide a structured way to design the VLE. The fourth phase is the building of the VLE using software tools and VR technology. A key part of this activity include developing (or 'coding') the various components or modules of the VLE.

IV. IMPLEMENTATION OF VLE IN CLASSROOM

Several VLEs have been created and used as part of engineering courses targeting senior and graduate students from industrial, mechanical and aerospace engineering programs. These VLEs have been used in a course titled Introduction to Micro Devices Assembly course at Oklahoma State University (OSU). These VLEs were developed as part of a pilot initiative funded as part of an NSF DUE project. Two of the VLE based modules introduced students to the design of micro assembly work cells as well as assembly planning techniques using Genetic Algorithm (GA) based concepts.

In the Micro Assembly course (IEM 4353/5343), one of the topics where the students did not perform well related to Genetic Operators including cross over, mutation and inversion. Specifically, one of the identified issues was problems involving forming new child sequences when various GA operators (such as cross over, mutation, etc.) were used; subsequently, these operators were adopted as part of a more complex assembly planning approach. The creation of the VLEs focused on improving student understanding of these operators as well as helping students develop robust work cell designs involving assembly of micron sized parts using a given set of physical design elements (such as micro positioners, grippers, cameras, etc).

A semi-immersive VLE was created where students were able to run a number of simulations using various sets of parent links for assembly sequence generation tasks. When a user wanted to continue their learning for different problems or questions, the VLE randomly changed the sequences of the parents to provide a diverse variety of examples (there was no limit to this number of examples); students could pause during the simulation as well as navigate or zoom in to get a better view of the problem question as well as the answers in the examples. Students could learn at their own pace and could learn interactively by selecting different candidate links. For example, in figure 3, the use of the cross over operator is shown (within the VLE).

One of the benefits of using such a VLE based approach is that it allowed students to learn by exploring various options and by executing a limitless supply of examples. Students could pause the simulation when a certain step in the sequence was not clear and repeat a step if necessary.

The design of micro assembly work cells was also taught using the VLEs (see figure 4). In this activity, the students were introduced to the major design components involved in automating robotic micro assembly tasks which included using cameras, micro positioners, advanced grippers and control components. They were then evaluated on their understanding of the functionality of these devices; subsequently, they had to develop their own design of their work cell based on these design elements.

The results showed that after introducing semi immersive based VLE based teaching techniques, there was an improvement in the overall performance of the students in understanding concepts in the 2 topics in which they were introduced. Assessment data was collected based on performance in homework and exam questions.

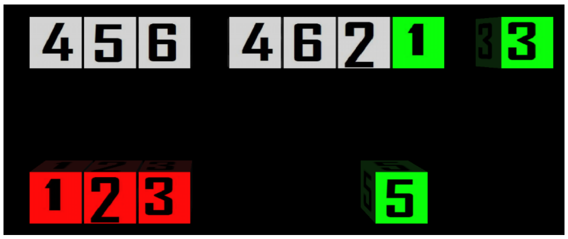

Figure 3: Closeup view of a VLE for teaching GA operators

The most significant outcome was in the improvement in the student performance in understanding concepts in the modules in which the VLEs were introduced. Assessment data was collected for 60 students based on performance in quizzes, homework and exam questions. The performance of the students with and without the VLEs was studied. Thirty students were taught these concepts using the traditional lecture and discussion approach. Another thirty students were taught the same concepts using the VLEs. The initial assessment results indicated the following:

(i) Student performance in quizzes increased by 22%;

(ii) Student performance in homework and exams increased by 30% (for the modules in the 2 topics: work cell design and genetic algorithms (GA) operators).

The experiences of the group of students were also studied through surveys. A majority of these students (86%) preferred VLE based learning over traditional classroom lectures and discussions. There were ten undergraduates and twenty graduate students who learnt the micro assembly concepts using VLEs.

A more detailed discussion of the outcomes can be found in [4]. Our assessment and analysis work is continuing in this and other engineering courses. This study is one of the first that has focused on the design and impact of such VLEs in engineering education. As discussed in [7], the use of VLEs holds significant potential in impacting learning in engineering education.

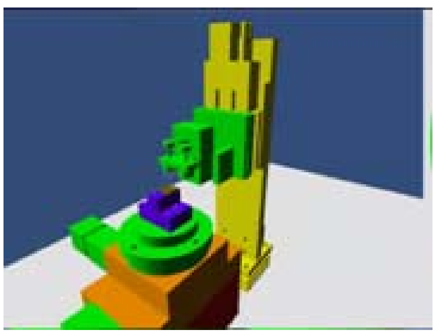

Figure 4: Closeup view of one of the virtual micro assembly work cells (developed as part of the VLE based learning approach to teach work cell design)

Other assessment and evaluation activities are continuing on studying the impact of using VLEs to teach engineering concepts. It is important to note that this is a pilot study and is the first of its kind targeting engineering students. In this pilot study, there was no assessment of the learning patterns of the students or their backgrounds. Data was not collected about the performance of students based on gender, race and economic background. Additional comprehensive studies are needed to throw more light on the learning patterns of a diverse body of students. Future studies also need to address the impact of team based learning when using VLEs.

V. OTHER EMERGING CYBER TECHNOLOGIES

One of the more recent developments is the adoption of cyber technologies and tools to support educational activities. The adoption of cloud technologies as well as other next generation Internet tools is expected to revolutionize the way students access, share and learn using distributed resources from different locations.

As part of a pilot initiative, one of the VLEs modules related to teaching micro assembly work cell design was made accessible through a cloud. Students were able to access this learning module through their ‘smart’ phones.

Two other important initiatives in Next Generation Internet and Computing are underway which hold significant potential in impacting engineering and STEM education in a significant manner. The GENI (www.geni.net) initiative involves the design and deployment of the next generation of Internets (which is being funded by the US National Science Foundation NSF). These advanced networks and approaches (being explored in these initiatives) have several innovative aspects including software defined networking and adoption of cloud technologies; these networks will enable students and teachers in distributed locations to access and share resources especially involving high bandwidth data; using such networking approaches and technologies will enable sharing of VLE based environments (involving rich 3D virtual reality data), as well as enable students to interact with distributed manufacturing equipment in educational labs (where camera monitoring of remote manufacturing and engineering activities enables better learning).

The US Ignite initiative (http://us-ignite.org/) is another initiative whose outcomes will profoundly impact engineering and education (among other areas). It seeks to foster next-generation Internet applications that provide transformative public benefit using ultrafast high gigabit networks. The six national priority areas are Education & Workforce, Advanced Manufacturing, Health, Public Safety, Energy, and Transportation. Both the GENI and US Ignite initiatives underscore the impact of next generation computing frameworks on engineering and educational practices.

In a pilot demonstration of the potential of next generation Internet frameworks, educational activities involving sharing of resources and learning modules among K-12 and engineering students was conducted in spring 2013 involving Oklahoma State University and University of Wisconsin Madison.

Apart from demonstrating the use of such technology for school students, an important objective was to demonstrate the feasibility of this next generation technology on helping children with autism learn using VLEs that were equipped with haptic interfaces (figure 5). One of these demonstrations involved children with autism interacting with their teacher at another location using haptic device (which enabled them to "feel" the objects they touched virtually inside a computer); the next generation collaborative framework was used to teach science and math concepts to autistic students in grades 1 and 1 from a local school (Sangre Ridge Elementary) in Stillwater; this pilot demonstration was part of a project aimed at supporting learning activities for children with autism; some of these activities have been recorded and posted on youtube.com at https://www.youtube.com/watch?v=BAfd2ax6tk4. Another recording of interactions among middle school students (from Stillwater Middle School) can be found at http://youtu.be/EIlNqpCAIu4 [25]. In these demonstrations, students at different locations could interact with each other and explore a micro robotics simulation environment using next generation Internet networks.

These collective pilot demonstrations highlight the potential of the next generation Internet frameworks for supporting educational activities; while the current Internet has had a phenomenal impact on education, the next generation of Internets holds the potential to further revolutionize educational activities especially for engineering and STEM learning contexts. It will enable (a) teachers and students to interact with each other from different locations, (b) facilitate special education students to learn using immersive and haptic interfaces as well as (c) enable accessing resources from geographically distributed location using cloud and other related technologies.

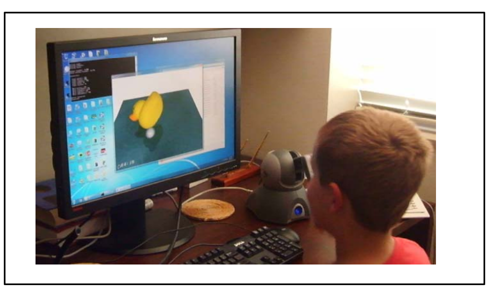

Figure 5: Using next generation Internet technologies for supporting learning among children with autism

.

Figure 6: View of a virtual solar system

VLEs (with or without networking capabilities) can also be used to supporting teaching Science Technology Engineering and Mathematics (STEM) concepts for K-12 students including children with autism. One of the VLEs created was a virtual solar system for elementary school students (figure 6). Other VLEs developed for middle school students introduce them to physics concepts including properties of matter including mass-volume-density relationships.

VI. CONCLUSION

In this paper, we have provided an overview of Virtual Learning Environments (VLEs) and their use in engineering education. A brief discussion of the process of creating such VLEs was also provided. The impact on student learning as part of an engineering course at Oklahoma State University (OSU) was also discussed.

One of the main challenges in the development of VLEs is that it is a time consuming process; the creation of a VLE can range from six months to more than a year (depending on the scope and level of complexity of the targeted engineering concepts). The faculty and engineers involved need to also be familiar with Virtual Reality technology and design of VLEs [22-24]. As the outcomes of this study for engineering students (reported in this paper) indicate, (once the VLE is developed), the impact on student learning and performance can become the basis to justify the investment in cost and time.

The paper also briefly discussed the emergence of next generation computer networking technologies and related initiatives including GENI and US Ignite. Pilot demonstrations conducted highlight the potential of these emerging technologies to support engineering and STEM education.

ACKNOWLEDGEMENT

This material is based upon work supported by the National Science Foundation (under grant numbers 1032359, 0965153, 1256431, 1257803), Sandia National Laboratories, Los Alamos National

Laboratory and the Mozilla Foundation. Other funds were obtained through two grants from Oklahoma State University's (OSU) Interdisciplinary Creative Grant program (Office of the Provost, OSU) in 2011 and 2012 respectively. Their assistance is gratefully acknowledged.

***Abstract* — Recent developments in computer programming environments have been introduced to the academic community. Scratch is one of such environments which seek to offer innovation features as a support to teaching computer programming. This study reports on the results from a case study conducted with young students for teaching algorithms and programming.**

Keywords — programming teaching; algorithms teaching; Scratch.

I. Introduction

Much has been argued, both for and against the use of computers in Education. Those who argue for their use have claimed that computers may cut down school drop-out rates and improve low performance indexes in several subjects. On the other hand, critics have emphasized that both educators and students still lack capacity for the massive insertion of technology in the classroom.

In the 80's, during a discussion about the role that computing would have on education in the future, some researchers stood for the idea that by the end of the 20th century, students would get their education from computers and no longer from teachers. This forecast did not come true [1]. However, in the 21st century, the contributions to society and, especially, to education, made by information and communication technologies cannot be ignored.

Reference [2] emphasizes the major advantages of the use of computers in education: it arouses curiosity; increases creativity; helps in the learning process; raises productivity in relation to the required time for studying; and emphasizes the need for continuous training to keep up with technological development.

Training students to face several everyday situations and also those in the job market means a challenge to modern schools that intend to offer conditions so that a student is inserted in a society which entails ever more information and communication technologies.

This article addresses a common issue in the computer courses area: the difficulty in learning the contents of algorithm and programming subjects. These subjects deal with key contents for the background of computer professionals. Students face serious learning difficulties with them; likewise, teachers experience severe problems on how to teach them.

In Brazil, in particular, Basic Education curriculum does not include algorithms and computer programming subjects. Perhaps this fact adds to the great degree of difficulty faced by students at the beginning of the graduation course. The purpose of this study is to report the qualitative and quantitative results from teaching algorithm and programming subjects in a research conducted with students in the city of Assis.

The guideline of the study was based on the principle that the adoption of a computational tool for teaching algorithms and computer programming may improve logical-mathematical thinking and problem-solving skills of young students.

Computational resources used by teachers as pedagogic tools can be classified as: educational or applicational. In this study, the former will be approached. The purpose of educational software is to make teaching-learning processes easy, and this study is based on this point of view.

This study has been divided into 5 sections: this Introduction, which shows the goals and reasons for the performance of the study; the next section explains the related works to this paper; the third section addresses the educational support, Scratch; the fourth section reports the case study conducted with young students and, finally, the last section shows the author conclusions and guidelines for future studies.

II. Related Works

The use of Scratch, the educational tool adopted in this study, as shown by other researchers, increases student engagement in the initial aspects of programming [3, 4, 5]. Positive reports were also found on the use of activities such as the creation and development of games in introductory subjects to the Computer Science course [6, 7, 8].

An important research related to this study explored the use of the contents of conditional structure with young students from 12 to 13 years of age [4]. Students received training on the Scratch programming environment and then were carried out to build an application that controls the functionalities of an elevator, as requested by the user. The results, from the pedagogical point of view, were very interesting, because the Scratch environment was able to encourage students to understand the use of conditional sentences. Moreover, Scratch has the potential to provide students to view themselves as technology makes and not simply as consumers of technological products.

In their studies [7] have reported their experiences using Scratch with young students at Harvard University and The College of New Jersey. The authors note that after a short time using Scratch, students said they would prefer to develop programming activities to play video games.

Concerned about the number of dropouts and failures in introductory courses in Computer Science, [5] worked with blockC, an extension of Scratch, for teaching the C language. The experiment was conducted with 40 students at the University of Cagliari. Preliminary results were very interesting because the blockC helped students avoid syntax errors and remember the command syntax C.

III. SCRATCH

Scratch is a new programming language which was designed in order to facilitate the learning process of beginners who are starting to learn algorithms; it was developed by the Lifelong Kindergarten Group located within the MIT Media Lab, with the Squeak programming language, (http://scratch.mit.edu) [9].

It has graphic interface resources and commands in the form of building blocks that users easily understand. It also offers sound, music, charts and animation resources, which lead to more significant results and better development of systematic thinking for beginners.

Even though it is a form of introduction to programming, Scratch allows students to have a solid base on programming logics and mathematics, which are its main features.

The expected result of a Scratch-developed project is the user's improvement in creativity and intuitive learning capacity. The learn-as-you-play method spares the users of the boring static environment and the effects of the more common programming environments, in which the lack of a specific character causes several problems [10].

One of Scratch's major features is making the creation of applications by children and beginners with no programming language background whatsoever easier; it is recommended for people who are curious about programming, and its motivational features' sole limit is creativity.

IV. CASE STUDY

A. Participants

With the purpose of getting to know the research's target public, the social and economic level of students selected randomly was determined. The result was a group of ten students from public schools in the city of Assis, in the age range from 11 to 13 years old. All students had internet-access computers at home and said they used the computer to play, and, in some cases, to use social networks. It is important to point out that the students had no experience with computer programming. This group of students was made up of nine boys and one girl; the students' social status, according to current standards, is middle class.

B. Procedures and Results

The study was divided into three stages: pre-test, Scratch course and after-test.

The first stage involved giving a pre-test with the purpose of checking the students' reliability and knowledge level about the content to be studied. The pre-test was made up of essay questions in which students had to assess the expression versus variable relation, as well as the use of parentheses in the general precedence of arithmetic operators and the construction of variables which accumulate values.

The students' performance in the pre-test is shown in Table I:

TABLE I. STUDENT'S PERFORMANCE

Scale of right answers	**% of students**
0.0 – 3.0	50
3.1 – 6.0	10
6.1 – 10.0	40

The overall average of correct answers was 4.4 and the standard deviation was 4.402.

As seen in Table I, 50% of the students showed little or no knowledge of the content required in the pre-test. Afterwards, the activities in connection with the 2nd stage of the case study began.

In the second stage, students took a 30-hour weekly course on Scratch for three months. The course had activities for students to learn the main initial features of the programming logics and develop skills to deal with any programming language. Note that the study is essentially focused on solving problems and on the development of logical-mathematical thinking.

During the course period, students worked with basic principles of information processing, logics, data storing and retrieving, comparisons, conditional and repetition commands, sprites motion and sensors, change in behavior and appearance of sprites and sound commands. These activities were a background for the development of ludic projects.

Finally, in the 3rd stage, students answered a test about the covered contents.

The assessment was made up of essay and multiple choice questions. There were questions to identify types of data, description on what a certain script would execute, coming up with a solution for problems which would be solved by block-grouping and identification of basic concepts of computer programming.

The achieved performance, after the conduction of the after-test is shown in Table II.

TABLE II. RIGHT ANSWERS OF THE AFTER TEST

Scale of right answers	% of students
0.0 – 3.0	50
3.1 – 6.0	30
6.1 – 10.0	20

Students had a global average of 4.0 points and the standard deviation was 2.614.

Even though the global average did not achieve a significantly positive value, note that 63.5% of students successfully answered the question in which they had to describe the operation of scripts which addressed conditional and repetition structures, and the use of memory variables.

This was an important after-test result, since it helped us understand which concepts and skills were well taught in the 2nd stage and which require additional time to be taught.

V. CONCLUSIONS

The guideline of this study was based on the principle that the adoption of a computational tool for teaching logic and computer programming may help improve the capacity to solve problems and also the mathematical logical thinking of students. During three months, teenage students attended classes about Scratch programming language with the purpose of achieving the goal established for this study.

After the conduction of the case study, the initially formulated hypothesis was partially confirmed, for the reasons explained herein. The results of students' assessment clearly show that important skills were acquired after this study was conducted: identification of the problem and use of conditional and repetition structures.

During the conduction of this research, it was noted that students were motivated at all times to learn the content, which contributed to the good progress of the offered activities. The projects designed by the students as well as the positive answers given in the after-test are reasons for the future use of this approach with students enrolled in the 1st grade of Computer Science courses.

Models of Adoption and Best Practices for Mobile Hands-On Learning in Electrical Engineering

Yacob Astatke[a], Mohamed F. Chouikha[b], Kenneth A. Connor[c], Aldo A. Ferri[d], Bonnie H. Ferri[d], Kathleen Meehan[e], Dianna L. Newman[f], Meghan M. Deyoe[f], and Deborah J. Walter[g]

Abstract - **Pedagogical practices in electrical engineering education have been shifting away from teacher-centered learning during the past decade. An innovation that has enabled the adoption of inquiry-based and problem-based learning into the curriculum using experimentation coupled with simulation and analysis has been the development of portable oscilloscopes and other instruments that rely on tablet or laptop computers to perform some of the data processing and to act as the display. Faculty members at six institutions of higher learning have incorporated hands-on experimental activities into existing courses and/or developed new courses that take advantage of these new tools. Assessment data collected by these faculty members have demonstrated that the change towards student-centered learning facilitated by portable electronics increased student interest in electrical engineering, built student confidence in their ability to design circuits and systems, and supported the development of a deeper understanding of the theories that the students investigate or apply in the hands-on activities. A summary of the challenges that are faced in the different implementation models and a discussion of best practices are presented.**

Index Terms – **Electrical and Computer Engineering Pedagogy, Hands-On Learning, Portable Laboratory Kit.**

I. Introduction

Education in electrical engineering (EE) has long had an experimental component. However, recent innovations in inexpensive, portable instruments that measure time-varying signals as well as generate arbitrary waveforms have enabled new pedagogical approaches in the teaching of theoretical concepts and design practices, and have allowed students to be actively involved in the demonstration of the application of these concepts and practices in either (or both) formal and informal learning environments. Hence, inquiry-based and problem-based learning can be integrated into the curriculum with a focus on student-centered learning rather than instructor-centered lectures.

Background on Pedagogical Approach

Engineering education research that has provided clear evidence of enhanced learning has driven much of the shift to student-centered learning. As noted in the recent National Academy Press report [1], one area where discipline-based education research has had less impact is in learning experiences traditionally limited to laboratory courses. Most institutions continue to hold lab courses in specialized classrooms where students construct prescribed circuits that demonstrate some subset of the theories presented in a companion lecture course, make measurements as required in the experimental procedures, and document the results in formal lab reports. Few experiments are designed to encourage students to freely investigate concepts. In addition, students typically cannot access equipment outside of their scheduled lab, presenting a barrier to those students who may wish to explore ideas on their own time. Direct classroom exploration also is hindered; transporting rack-mounted or bench-top instruments to the classroom to demonstrate concepts to students during lecture can be very challenging. Thus, instruction on abstract concepts and practical application of those concepts are segregated by time, learning environment, and, sometimes, by instructor.

In the early-2000s, several groups independently began to develop a pedagogical approach, hands-on learning, to test the hypothesis that the lack of connection between theory and practice has led to the decrease in student interest in the field and to determine if a more student-centered learning environment can stimulate a deeper understanding of the principles in EE and increase student engagement [2-4]. Faculty members at other institutions have partnered with these pioneers [5,6], contributing to the number of hands-on activities. The concepts demonstrated in the hands-on experiments have expanded beyond circuits and, the number of courses in which hands-on learning is incorporated has increased. Several methodologies have been adopted to integrate hands-on learning to address the needs and constraints at each institution, within different undergraduate degree programs at the same institution, and in various teaching modalities of the same course at one institution. A collaborative effort began in 2012 to review the activities at six institutions that have been engaged in the development of hands-on learning in EE and to identify the best practices for each model of implementation [7].

II. Portable Electronic Instruments

Although the set of equipment that each institution has chosen for the hands-on activities differs, the common denominator in each experimental platform is a portable

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

electronic instrument that can measure time-varying voltage signals (i.e., an oscilloscope). Several of the portable instruments have options that include one or more arbitrary function generators, dc voltage supplies, spectrum analyzer, and the ability to display a Bode plot. And, surprisingly, some of these scopes have a measurement frequency range that extends into the MHz range, well beyond the maximum frequency that the typical breadboard can support. These oscilloscopes leverage the USB ports on students' laptop or tablet computers for power and the computers' capabilities to analyze and display the measured signals. As the instruments range in size from a pack of cards to a paperback book and are light-weight, they can be carried to a classroom for use by students (assuming that the seats in the room do not have small writing areas) or may be used at home in practical homework assignments and projects.

The portable oscilloscopes are inexpensive, ranging from $99-$199 per unit. Other expenses include the breadboards, components, and, occasionally, a digital multimeter. Generally, the cost is born by the institution, where the equipment may be distributed to students for each hands-on activity or loaned to the students for part or all of their academic careers. In some settings, partial or total cost may be borne by students who are expected to have the equipment available for hands-on activities at any time during their academic careers. The components used in the hands-on activities are typically provided by the institution.

III. Models Of Implementations

The predominate instructional goal at each of the six universities was to support problem-based learning, where one of three general models of instruction has been employed to meet this goal. The first model of instruction represents a blended approach, where the classroom experience is a combination of lectures and hands-on activities used to reinforce the concepts. The second mode of instruction is the inverted, or flipped, classroom, where students are expected to read material outside the classroom prior to their investigation of the concepts via hands-on activities in the classroom. Within this approach, students read about the theories that they have seen applied in the hands-on activity in class and about which they have been asked to develop their own conjectures. The third model uses outside-of-the-classroom hands-on activities that are part of homework problems, design projects, and/or a nontraditional laboratory component. The last model of implementation has been also used in the development of online laboratory courses [8,9].

In each model, hands-on activities are developed to provide students with a different perspective on concepts, particularly the ones that students have found difficult to understand when they are presented only as an abstract theory. Typically, students work in small groups when the hands-on activities are conducted in a classroom environment. Students may work individually or in teams when activities are performed outside of the classroom.

In blended instruction, the number of hands-on activities introduced into each course is limited to target the most challenging concepts. This approach reduces the barriers to adoption for course instructors as there is limited training required of the new instructor in each course on the hands-on activities; there is minimal disruption of the traditional instructional mode, which minimizes the perception about loss of class time that is being devoted to hands-on learning. Additionally, the effort required to develop hands-on learning activities is smaller when compared to the other two models. A challenge to this approach is logistical. The length of the class places constraints on the type of hands-on activities that can be introduced. To address this, portions or all of the circuits used in the hands-on activity can be pre-built, allowing students to focus on making measurements and analyzing experimental results. Desk space must be available to conduct the hands-on activities, which places constraints on the classrooms available to hold these courses.

The inverted classroom can alleviate some of the logistical issues associated with the blended instructional model as the entire class period can be dedicated to the hands-on activity. This approach requires a new approach to teaching and learning; both the instructor and students must be willing to adapt to this model. There is a greater effort required for this approach as learning materials must be developed for the hands-on activities as well as the instructional materials that students study outside of the classroom. It is relatively easy, however, to adopt the inverted classroom model after implementing the blended instructional model.

The nontraditional laboratory model places a greater responsibility for independent learning on students when compared to the traditional lab model where an instructor or teaching assistant is usually present or to the other two models. Supplemental materials that address common issues confronted by students, hardware-related or conceptual, have to be available to students as they conduct the hands-on activity. The instructor of the companion lecture course may not be responsible for the nontraditional lab, minimizing the number of faculty members who must learn how to teach the lab course; however, this separation may increase the chance of disconnect between the lecture and experiment.

IV. Assessment Results

Assessment of students learning at each of the institutions has shown that students' response to the hands-on learning activities, regardless of the model of implementation, has been extremely positive. Hands-on application, exploration, and practices improve student understanding in the class as a whole. Results indicate that the greatest impact of hands-on learning is the conceptual understanding by students who had the weakest grasp of the material after lecture-based instruction. Students also express a higher degree of confidence in their ability to be engineers because the hands-on activities have helped develop their abilities to design solutions to meet specifications in the projects. The hands-on activities also increase student engagement in the discipline.

Development of a common assessment tool to evaluate student learning across the six institutions has begun to compare the various models of implementation. The assessment results will help identify differences in learning that tied to the implementation method and to highlight areas for improvements in a particular method of implementation can be made to equalize student understanding of concepts. Also under construction is the development of an assessment tool to evaluate the stages of concern by the faculty when adopting hands-on learning and adapting the pedagogical approach to meet the needs of their students and the constraints within their institution to determine the supports required to insure a successful implementation. A discussion on these two assessments will be presented.

CONCLUSION

Researchers at six institutions have joined together to assess the value of the pedagogical methods and to determine the supports needed for students, as they progress towards their bachelors' degree, and for faculty members, as they change their teaching styles. Several issues must now be addressed at these institutions as they move to create the infrastructure to sustain and maintain the hands-on pedagogical practices and to foster adoption of the approach by others. Challenges include the identification of the best practices in design and implementation of student-centered learning that takes into account variations in institutions' culture, organizational structure, and available resources, optional paths to sustain change at institutions that have developed or adopted hands-on learning, and efficient and effective models that promote adoption of the pedagogical approach by addressing the concerns of students, faculty, staff, and administration.

ACKNOWLEDGEMENTS

Financial support was received from the Electrical and Computer Engineering Departments at Morgan State U., Howard U., Georgia Tech, Virginia Tech, and Rose-Hulman Institute of Technology, and The Electrical, Computer, and Systems Engineering Department at RPI, Hewlett-Packard, Analog Devices, and the National Science Foundation (awards 0817102, 0717832, and 0618645, 1226114, 1226087, 1226065 and 1226011). One author (KM) acknowledges technical assistance received from MathWorks and Digilent, Inc. Other faculty members, staff, and students, too numerous to name, have supported the development of hands-on activities at each institution.

Playing Online Games on Facebook: The Conscious and Unconscious Learning in Database Design

Hwee-Joo Kam Greg Gogolin Doug Blakemore Gerald Emerick
Information Security & Intelligence
Ferris State University
Big Rapids, MI

Abstract — This study intends to examine how conscious and unconscious learning in game-based learning (GBL) enhance student's understanding in database design. Conscious learning refers to intentional learning whereas unconscious learning indicates unintentional learning. Using Facebook's online games, this study evaluates the effectiveness of GBL in enabling students to grasp the normalization concept and Entity-Relationship Diagram (ERD). Additionally, this study adopts content analysis of the semiotics approach for data analysis. The preliminary findings reveal that unconscious learning encompasses student's realization in that a purportedly simple online game is built on a complex, highly functional database. The preliminary results also uncover that conscious learning constitutes (1) student's cognitive reflection on normalization concepts during database design and (2) a better understanding of ERD resulted from the collaborative effort of database design. Drawing on these findings, this study infers that the aforementioned outcomes of unconscious learning lead to student's appreciation of conscious learning.

Keywords—database design; game-based learning; entity-relationship diagram

I. Introduction

The abstract and complex domain of database design [4] poses challenges for educators to impart knowledge while making it difficult for learners to comprehend the intricate modeling concepts. Essentially, the core studies of database design are conceptual data modeling and relational database design [5]. This learning scope demands high level abstraction that brings about ambiguity and vagueness to learners [5] and imposes a heavy cognitive load that degrades learner's understanding of the subject matter [11].

To improve student learning in database design, previous studies [5] suggested using Game-Based Learning (GBL). In essence, GBL theory posits that learning is often experience based or exploratory, relying on experiential, problem-based, or exploratory learning approaches [8]. Accordingly, this study adopts online games on Facebook to examine how GBL fosters the understanding of core concepts of database design through conscious and unconscious learning.

This study collected data from 25 students who worked in different groups. Using the semiotics approach for data analysis, the preliminary findings uncover that unconscious learning mainly constitutes student's recognition of a complex, highly functional database structure in the online game platform. On the other hand, the conscious learning incorporates student's cognitive reflection on Entity-Relationship Diagram (ERD) and normalization concept related to database design.

II. Motivation and Research Objectives

There are a few studies focusing on using GBL to fulfill the pedagogical objectives. These studies usually highlighted the interactive visualization in support of learning, the motivation factor that engaged students in the learning process, the challenges of incorporating GBL into curriculum, and how GBL supported problem solving and collaborative learning [6-9]. However, there are not many studies discussing the conscious and unconscious learning of an abstract subject matter, such as database design.

Therefore, this study intends to examine the conscious and unconscious learning of database design in the context of GBL. In this respect, this study intends to uncover how learners explicitly produce relational data model by applying the complex, abstract knowledge that is held tacit. The research findings will then shed lights on how to promote the overall understanding of database design.

III. Literature Review and Theoretical Framework

A. *Game-Based Learning (GBL) and a Dichotomy between Conscious and Unconscious Learning*

The theoretical framework embodies GBL model and theory postulated by the previous studies. Drawing on the GBL theory, GBL entails problem-based learning (PBL) [8] encompassing active and collaborative learning [14]. Additionally, experiential gaming model posits that GBL supports reflective learning [9] wherein learners consciously think, analyze, and learn through the reflection of their experience [1]. We argue that both problem-based and reflective learning represent conscious learning. In essence, conscious learning involves learners who intend to learn, pay attention to learning, hold high awareness for learning, and control their learning processes [15]. Accordingly, problem-based and reflective learning requires learner's active participation, awareness, and initiative, thus exemplifying conscious learning.

On the other hand, unconscious learning refers to incidental learning characterized by "*discovering something while in the process of doing something else*" [15]. That is, learning is unintentional and a by-product of learner's activities. Previous studies suggested that GBL engendered unconscious learning [6]. While playing games, learners experimented, explored and brainstormed for problem solving so as to achieve their learning goals but somehow they inadvertently encounter a new discovery unrelated to their original learning objectives.

B. Core Concepts of Database Design

Essentially, the concepts of database design encompass Entity-Relationship Diagram (ERD) and normalization. ERD is a logical representation of the physical database system to be constructed [3]. In particular, ERD consists of entities (person, thing, place etc.) and the relationships among the entities. On the other hand, normalization is a technique to create successful database design by eliminating data redundancy to avoid data anomalies [3].

IV. RESEARCH METHODOLOGY

A. Research Design

In the context of conscious and unconscious learning, this study measures how GBL promotes the learning of database design in relation to conceptual and relational data modeling. The core concepts incorporate Entity Relationship Diagraming (ERD) and Normalization. At the beginning of the database class, students were taught the core concepts of database design. Then, by the end of the semester, students were required to play an online game (e.g. Treasure Madness, Farmville) on Facebook to know all the items (e.g. coins earned, treasure collected etc.) involved in the games. After comprehending the online game's structure, student had to apply what they learned earlier to design ERD for the online game. Each entity in the ERD must reach third normal form.

B. Content Analysis of the Semiotics Approach

This study employs content analysis under the semiotics approach for data analysis. Semiotics is mainly pertained to the meaning of signs and symbols in language wherein words/signs can be classified into main conceptual categories attributing to theory testing [13]. Content analysis, a form of semiotics, discovers structures and patterned regularities in the text and draws inferences hinged on these regularities [13].

Content analysis of the semiotics approach is appropriate to analyze written text made of student's feedback. Using this approach, this study found regular patterns in text to uncover the preliminary research findings.

C. Data Collection

This study was conducted in a regional Midwestern University. We spent two semesters to collect qualitative data with student's written feedback. There were a total of 8 groups consisting of 25 students. We had 6 traditional students and 19 non-traditional students. These students were sophomore and they had no prior knowledge of database design. The student's age ranged from 19 to 55. The average age was 31.There was only one female student involved in this study. Upon completing the group projects, each student was required to provide written feedback regarding their learning experience. Overall, this study had collected 60 pages of written feedback.

D. Data Analysis

The important notion that frequently appeared in text was student's realization of the complexity involved in developing a purportedly simple online game. About 60% of students came to this realization.

"When I first looked at the game Treasure Madness I thought that it was very simple, and easily made. Since I've been designing a database for this game I quickly realize that it's nowhere near easy to make such a simple game as this…."

"Even the simplest games and computer applications can have a very complex database structure holding them up. The Facebook application Treasure Madness drove that point home with me as my group and I analyzed and designed a database from its structure."

Next, we discovered that about 40% of the students gained understanding of database functionalities in the real world.

"*I've seen how involved a real-world database project can be and how important a well-designed can be for storing and fetching information.*"

"*…A database can work with a flash game…and what type of data is in those tables and how it all comes together make a popular game. The game has multiple objects and even objects can store other objects"*

"I realized that ERD was an essential part of being able to understand how a database works. ERD is also an essential part of being able to run accurate queries….."

Additionally, 32% of the students used ERD as a visualization tool for team communication.

"I created a basic model of the ERD which allowed us to visualize what we had talked about and to demonstrate ideas and concepts."

"The most useful tool, in my view is the ERD. It really helps to have a visual representation of what the database looks like to work from."

Another emerging key point was reflection on the previous lessons taught in class as well as learning reinforcement through collaborative effort. Approximately 68% students claimed that they experienced learning reflection and reinforcement.

"Doing the group project, I gained a better understanding of how to develop an ERD….One of the relationships within our diagram that I had the most trouble understanding was the unary relationship….however through examination with my group, I was better able to understand this concept and apply it… "

"After a period of observation and interaction with the popular online game, our team developed an understanding of how the data was stored [and] this helped with normalization."

V. DISCUSSION

Analysis results reveal that there are four emerging core categories consisting of (1) student's recognition of the complex database structure in the Facebook's online game; (2) student's realization of database functionalities in the real world; (3) student's discovery of Entity Relationship Diagram (ERD) as a visualization tool for team communication; and (4) cognitive reflection on learning.

As mentioned, this study intends to examine the effectiveness of GBL in enhancing student learning related to the core database design concept (ERD and normalization). Building on the analysis results, we argue that conscious learning subsumes cognitive reflection on learning. That is, students were well aware of their learning objectives concerning ERD and normalization. Hence, students actively constructed an ERD and ensured that each entity attained third normal form. In doing so, students participated in problem-solving under a group collaborative environment. During the process of problem-solving, students reflected the knowledge [4] gained from the lectures and applied their knowledge within their groups. Alternatively, students engaged in metacognitive activity in that students involved in the cognitive mode of conscious thinking, analyzing, and learning through the reflection of the knowledge and experience earned in the past [7].

The rest of the core categories represent unconscious learning. In other words, we contend that unconscious learning incorporates student's recognition of database complexities in the Facebook's online games, student's realization of database functionalities in the real world, and student's discovery of ERD as a visualization tool for team communication.

We assert that the learning outcomes of unconscious learning enable students to perceive the usability of Entity-Relationship Diagram (ERD) coupled with the complexity and functionalities of database in real life. Accordingly, students may appreciate their initial learning objectives (conscious learning) once they discover the importance and sophistication of database (unconscious learning). That is, the outcomes of unconscious learning demonstrate that the initial learning objectives (conscious learning) are worthwhile, thereby leading to student's appreciation and justification of their conscious learning efforts. This draws parallel with the previous studies suggesting that students will appreciate learning when they perceive the pedagogical objectives as worthwhile [2].

VI. CONCLUSION AND FUTURE RESEARCH

Since this is a research-in-progress, this study only uncovers the preliminary finding. That is, in the Facebook's online gaming platform, a combination of intentional/conscious and unintentional/unconscious learning of database design promotes student learning. Conscious learning fosters the cognitive reflection of database design knowledge. Not only the unconscious learning sheds light on the critical role of database in online games but also helps learners to appreciate the learning objectives and justify their efforts invested in conscious learning.

At the preliminary stage, the research implication suggests that Game-Based Learning (GBL) can motivate learners by facilitating authentic experience that leads learners to discover the elements in support of their original learning goals. In the future study, we plan to run pre-test and post-test studies and compare the student learning outcomes between the students who have experienced GBL and those who have not. Overall, this is a research-in-progress so more in-depth study is required to yield meaningful findings for improving student learning.

***Abstract*— The game industry has suffered an impressive explosion of popularity, becoming the largest entertainment industry in the world. Games have become a sophisticated extension of the reality and an interesting way for complementing human mind utopias. Training software allows the trainee to immerse in quasi-real controlled situations that could be measured by trainers. In this work we discuss the duality existing between the training based on a serious game and a simple game, based on state of the art technologies. Then we show a training system for telecommunications technicians based on a combination between serious games and "traditional" e-learning platform. We show results for a trial made with a group of students from different disciplines (not only engineering) in order to evaluate learning outcomes using serious games versus other learning approaches. In this paper we discuss such results and make a descriptive statistical analysis of the results.** *(Abstract)*

Keywords-component; games, serious games, e-learnning, training software.

I. Introduction

The term Serious Game sound like a contradiction; play is about simulation, a game is fun, pleasant and free. Then the question is: How can a game be serious? To take something seriously means that you are talking honestly and it is well known that in a game you have to lie, knowing that you are lying. It differs from a "true lie" because all the people involved in the game know that you are lying, because it has been arranged from the beginning [4]. However, if the game is used with a specific finality, beyond the game itself, then we can say that is a Serious Game [8].

Generally speaking, the game searches for the satisfaction of the player [5]. Any additional consequence is far beyond the game finality. It means that the use of this recreational experience with a learning goal, then we are talking about serious games [8]. This special kind of game has shown an especial interest in the consequences of the game, conceiving those experiences as training processes or development guides [3]. Playing is a quite fun way of training, is the way as a lion learns hunting. Without training games, perhaps a young lion will not survive, or die while learning. Another example of this kind of "Serious Games" is combat pilots, because you cannot train a pilot in a real combat without a high risk of losing human lives or pay a high cost. A previous simulated training process is quite important, before passing to the real life. Simulation conditions are quite real, but simulated. If the plain crashes, nobody gets hurt. One of the characteristics of a serious game is that the goal is a serious one; they are not designed for leisure or entertainment but for learning.

Otherwise, conventional training software does not consider the user preferences or interest. They presume that if a user is using the software, then he needs to learn about such issue. For this reason, there is no interest for developing an "emotional" interface. Perhaps boring is one of the premises of this kind of software, converting these developments in a digital version of a traditional lecture imparted in a classroom. Finally the result is a new format for teaching, not a change in the learning process where the human contact is lost and the potential of new virtual media is not exploited. That's why in recent years, the concept of serious games and the use on 3D technologies has been taking relevance, and especially with the use of open technologies [7], [9].

In this paper we mention a serious game for learning telecommunications and an evolution of such game that was developed as a training tool used for training technicians in Radio Frequency related activities and for learning in undergraduate courses. With this software, we conduct a trial with undergraduate students in order to compare learning outcomes between "traditional" learning activities like reading notes, learning activities using multimedia content and the game.

The main contribution of this paper are the results of our trial, using descriptive statistics, to show the relationship between learning activities like reading, multimedia (video) watching and playing and the learning outcomes derived from each activity. For this purpose we apply a test to 66 undergraduate students from different disciplines after they have done some of the mentioned learning activities with different combinations: one activity and two (i.e. read and play). In this initial study, we have found some evidence of a bigger dispersion of results. Also, we found that the scores associated with the game activity are more disperse than those associated with traditional activities. A similar result is obtained for those students that play the game and read.

The paper is organized as follows: Section II, discuss aspects of training software and serious games; in section III, we describe a training tool based on serious games; in section IV we describe the evaluation process; in section V we show statistical results and finally the conclusions and further work.

II. FROM TRAINING SOFTWARE TO SERIOUS GAME

A training program or conventional education, like used in lectures, typically use a behaviorist approach; i.e. the system guides the student through a series of pre-defined steps which goal is to take the student in a "A" grade of knowledge or competence and lead him to a competence "B", guiding the student through a series of steps or data that lead to the same final point, using almost always the same predetermined way. Behaviorist approach knows the learning goal and the shortest way to guide the apprentice to reach the goal.

On the opposite side, the constructivist approach gives more relevance to the learning experience than the way from A to B. The learning experience is more important than the knowledge itself. The learning goal is important but not the most relevant. The ways to reach the goal have the same importance than the goal. The apprentice experience during the learning process is quite important as the learning itself.

Then, the serious game is proposed as a tool with a constructivist approach, where the immersion grade is high enough as in real training process. Besides, the player (apprentice) is influenced with an emotive load and surprising situations, exploiting the advantages of virtual media and gaming technology, with it sensorial richness.

The basic idea is that serious games act in similar way as entertaining games. A good example of this kind of games are Flight Simulators, originally designed for pilot training but later used also for entertainment to add other aspects such challenging missions. The difference is only the goal of the game: Training or leisure. We developed a serious game with the idea of training engineers in specialized activities related to radio communication systems and, at the same time, use it in undergraduate courses.

The game called "TESt" absorbs the complexity of some concepts like antenna type, radiation pattern, etc, (Figure 1), related with the mathematical behavior of such models. Besides, it is supported in real maps, obtained from Digital Terrain Models from real cities that usually represents a challenge for radio planning. All these features are linked with several missions, oriented to improve the abilities of the player.

Moreover, the game is supported by a real planning tool [1], the results are similar to those obtained from a commercial planning tool (Figure 2), like those used by mobile operators. Towers, antennas (Figure 1) and other elements are modeled with high realism. In this way the concept of a serious game is fully applied to this tool.

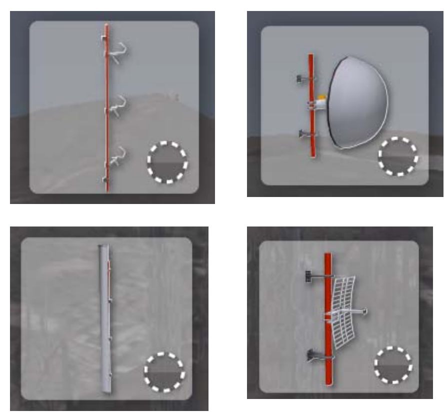

Figure 1 An example of 3D models of antennas

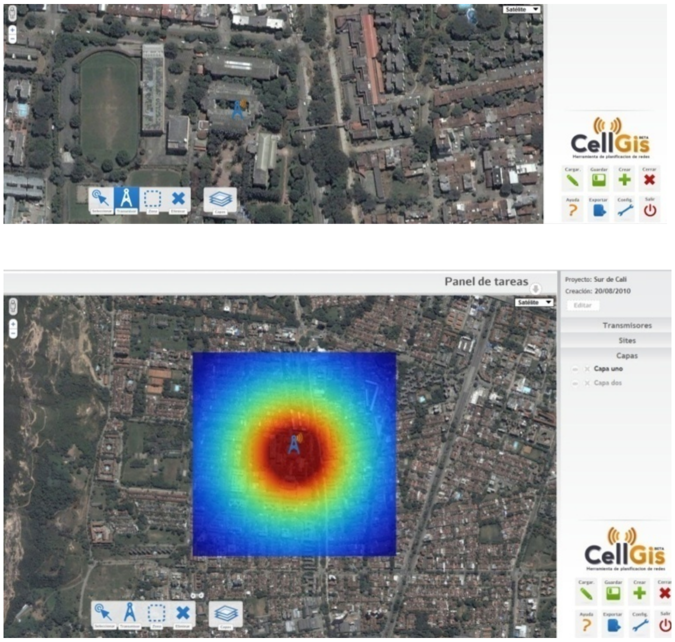

Figure 2 Results from CellGIS Planning Tool

III. SERIOUS GAMES AS TRAINING SUPPORT: TEST

From the experience obtained with the development of COMCITY [6], we begin the development of a training system for radio technicians that develop activities in the outside, as installations or technical surveys on radio stations. This work requires some specific skills, and then the system has some specific requirements. This system was called TEST (TESAmerica Software Training), from the name of the company that will use it initially.

TEST is a series of “virtual learning objects” (a total of 6 “missions”) running on a learning platform (Moodle), which combines serious games with training software. The goal of the system is to train people for a specific job and evaluating the most qualified people for the outside job. TEST is in part an application of COMCITY for specialized training.

In order to complain with TEST requirements, we modify some aspects in COMCITY, specifically some missions and scenarios with problems oriented to some typical task that the trainees will perform in their jobs. In these missions, the trainee must solve problems related with radio technologies (Wimax, UMTS, etc), antenna type (panel, monopole, dipole, etc) and frequency bands.

For example, in the antenna identification mission, shown in Figure 3 and Figure 4, the player must solve eight cases, including: telecommunications support to the army, coverage of a transmission of bicycling tour and restore communication for the public transport service. The player navigates between cases and by selecting the most suitable antenna for each case, taking into account: environmental conditions, radio technology needed and available frequency band.

Figure 3 Cases for antenna identification mission

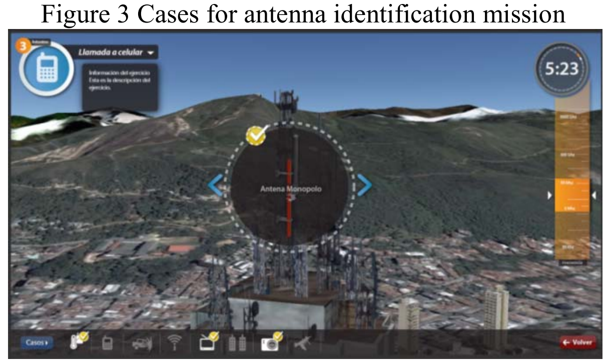

Figure 4 Capture of a mission for antenna identification

In this serious game, we try to reproduce real situations that the student will face in their real activities, preparing them to recognize potentially dangerous situations. Each activity that the player executes is associated with typical activities performed in real situations in remote areas where the trainee will work in a future, if the training process is successful.

In this way, the player (student, trainee) makes associations between real objects that will find in a real situation, but through simulated situations in a 3D environment.

In total, we developed six different missions with different objectives. Besides the Antenna mission, we also develop a Fresnel Mission (to verify pathloss in a microwave link), a Hunting mission, to locate interferers, a Site Survey Mission, oriented to identify objects in a real telecommunications building, and a Site Search Mission, oriented to identify potential candidates for radio transmitters location.

IV. EVALUATION PROCESS

With the antenna mission, we took a set of 66 students from different levels and disciplines, and give them the material for read, view the multimedia application and play the game, in order to evaluate the learning process. After each process (e.g. reading, multimedia viewing and playing) we evaluate some basic competences about identification of antenna type. For this purpose we use a basic test.

After the initial process, we select the groups and assign a different activity. People who have read written material then view the multimedia and other group plays the game, people that have played the game then read the written material and other group views the multimedia and so on. After this process we made another test that evaluates the same competences. Evaluation results are shown in the next section.

V. RESULTS

A. Statistical distribution for students results.

In Figure 5 we show the distribution of the obtained score in the evaluation made by the students after doing some of the learning activities described, or a combination of them. The ideal scenario for any teacher or educator is this where the score or learning outcome is concentrated in high grading results than low ones, i.e. the grades follow an asymmetric left shifted distribution.

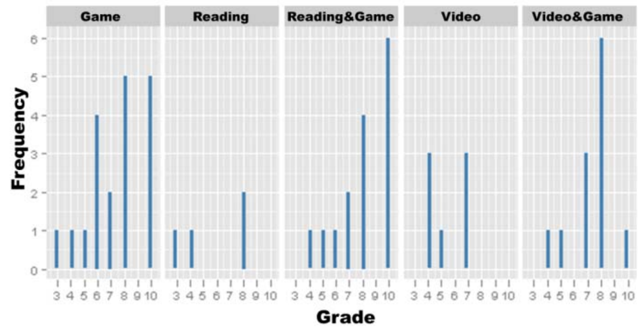

Figure 5 Statistical distribution of the obtained scores

So far, for our five different learning activities, it can be observed that the results obtained for students which read and play (Reading&Game in the figure) is the most desirable distribution. In a similar manner, the least desirable result is the one obtained from the students that only see the multimedia application (video).

B. Results' descriptive statistics.

Another way to analyze the results obtained from the different learning activities performed by the students is to analyze the descriptive statistics results associated to the grades obtained (shown in Table I). The highest mean grade correspond to the students that have read and played; meanwhile, the lowest mean grade corresponds to those who only saw the multimedia. Therefore, those students that read and play have a more desirable distribution in their results, but also a higher mean grade.

On the other hand, the median of the results for those students that saw the multimedia was the lowest (median 5), and for the remainder of the activities the median is 8. Regarding the minimum grade obtained by the students, this corresponds to the scenarios where the student only read or only played and its value is 3; whereas the higher grade obtained was 10 and corresponds to the students that perform the following activities: Play, Read-Play and Video-Play.

Table I Descriptive Statistics

		Play	Read	Read and Play	Video	Video and Play
Descriptive Statistics	Observations	21	5	15	7	13
	Mean	7,38	6,2	8,07	5,43	7,54
	Standard Deviation	2,01	2,49	1,98	1,51	1,66
	Median	8	8	8	5	8
	Min	3	3	4	4	4
	Max	10	8	10	7	10
	Asymetry Coefficient	-0,33	-0,34	-0,55	0,12	-0,51
	Kurtosis Excess	-0,29	-2,8	-0,44	-2,65	0,97
	Variation Coefficient	0,27	0,40	0,25	0,28	0,22

Asymmetry coefficient means a long tail on the left side meanwhile the value is more negative and vice-versa when the value is bigger than zero. Considering the results shown in Table I, it is possible to confirm what we intuited initially respect to the ideal scenarios. A lower quantity of people with low grades is found when the asymmetry coefficient is lower than zero; in this case the shifted to left distribution is that related with Read and Play, meanwhile the least desirable scenario is the Multimedia (Video) seeing activity.

Kurtosis excess means how normal (adjusted to Gaussian distribution) is the grades distribution depending on the activity. When the students just read or just saw the Multimedia before the test, the grades obtained are distributed in a less normal way than for the other learning activities.

C. Variance Analysis

After describing our experiment, the evident question that rises is: ¿is the expected score different depending on the learning activity assigned to the student? In Figure 6 we graph the estimated average score and its corresponding 95% confidence interval. Intuitively, the Figure let us thing that the average score for the learning activities that imply the game are higher than those that do not include a game.

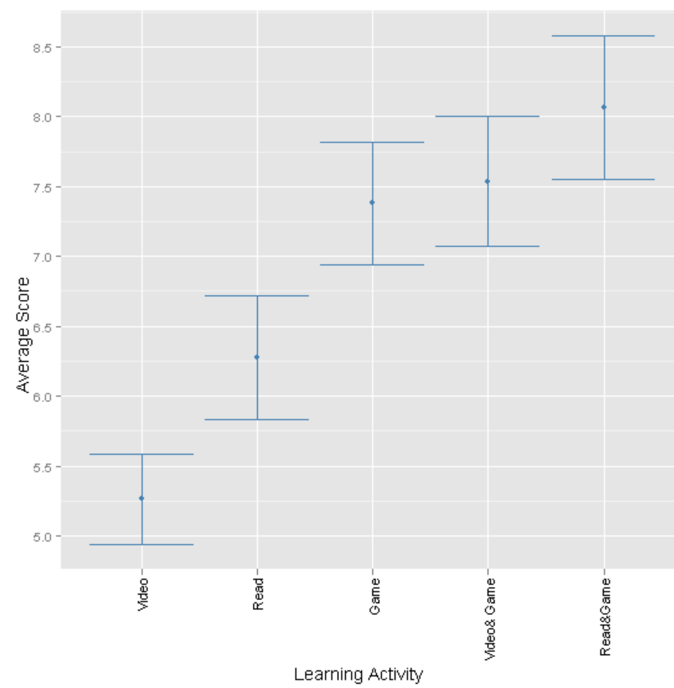

Figure 6. Confidence Intervals for the average score for the different learning activities

Due to differences shown in Figure 1 we estimate a one-way ANOVA model that let us test the null hypothesis that:

$$H_0: \mu_{playing} = \mu_{reading} = \mu_{watching\ a\ video} = \mu_{read\&watching\ video} = \mu_{watching\ video\ \&\ playing}$$

versus the alternate hypothesis that at least one mean is different. In this case the blocks correspond to the five different groups of activities assigned to each student. The dependent variable is defined as the score received by the student after taking the same evaluation. The results are reported in Table **I**Table **II**.

Table II. ANOVA

	GL	SSE	MSS	F	Sig.
Blocks	4	87.972	21.993	6.7373	***
Residuals	81	264.412	3.2643		

(***) Nivel de significancia de 1%

D.

E. Some comments about Learning Styles

In our University, we use the Felder and Silverman test in order to obtain the learning style of each student at the freshman semester. Having the learning styles of the students involved in this test, we made a quick analysis of the correlation between the learning style and the grades obtained in the different learning activities. Our initial hypothesis was that we will found a close correlation between learning activity and learning styles with results.

Our big surprise was that we do not found correlation that can relate the student learning style with the grade obtained in the performed activity. This result is a bit confusing for us, and then we expect to make more tests in order to have conclusive results about this result.

VI. CONCLUSIONS

We have shown statistical results for a serious game applied to a learning environment, with quite interesting results about the importance of combine learning strategies in order to improve learning outcomes.

Our results show that traditional learning activity like reading results on low grading and a big dispersion. On the other hand, the highest mean was found when the students combine reading with playing. This mean was accomplished with the lowest dispersion and a good shape of the distribution (left shaped).

Thereby, these results suggest some hypothesis that can be explored in future work. These hypotheses are:

1) The average grading of those students to which a game is assigned with a traditonal activity like reading obtained better results than those whom only a traditional activity was assigned.
2) Results' dispersion that use games in their learning process are better than those who use traditional learning activities.

Serious games are an excellent tool to acquire new knowledge and an approach to real skills, applicable directly in job environment.

TEST has become in an excellent experience for the creation of mechanisms for training and evaluation of candidates and for support of learning process in undergraduate courses.

The maturity of development tools influence the use of 3D games and allows designers, developers and educators to find a common place to obtain important results in knowledge generation.

The simulation of real situations gives us an efficient and inexpensive way to training and learning by experience.

The experience in the creation of serious games in COMCITY and TEST, allowed us to transform the complex concepts of a specialized area of knowledge and make them available to students in ways simple and striking, in a multimedia environment that involves different learning styles.

***Abstract* - This paper presents adaptable materials that teach programming fundamentals via game programming with Greenfoot, a free Java based game development platform. The materials consist of five independent modules, each of which focuses on a group of related computing fundamentals. Each module includes the shell of a game, lessons that teach programming fundamentals, hands-on exercises that apply the fundamentals to add functionality to the game, and questionnaires and content-based quizzes that can be used to assess the effectiveness of the lessons. An instructor's guide is also included. These materials were used to teach computing concepts to high school students in two different venues in summer 2011 and 2012. Formal assessments found that the students experienced a significant increase in knowledge in computing and an increased interest in computing and likelihood of taking computing courses in the future. The paper describes the motivation for this work, how it relates to other works, the teaching and assessment materials, the key concepts covered in each module, the venues in which the materials were tested, and the results. It also discusses how the instructional materials can be used in other venues and provides a link to the materials so that others may use them.**

Keywords –programming concepts; game programming; introductory computing

I. Introduction

This paper presents instructional materials designed by a team of undergraduates to teach computing concepts using game programming. They have been used successfully in two summer academies for high school students. The materials are modular and can be used in a variety of settings with a variety of target audiences. They are freely available for download. This goal of this paper is to describe and share these resources with others who may want to use them to teach introductory computing concepts and/or to stimulate interest in computing.

Section II describes the motivation for this work. Section III describes related works and what sets this work apart from others. Section IV describes the instructional materials. Section V describes each of the instructional modules in detail and includes sample excerpts from the instructional materials and assessment instruments. Section VI describes the venues in which the materials were tested and the results and describes other venues in which they can be used. It also includes conclusions and a link to a site from which the materials can be downloaded.

II. Motivation

According to the United States Bureau of Labor Statistics, the demand for software and application developers is expected to grow 30% from 2010 – 2020, and the demand for network and computer systems administrators is expected to grow 28% within the same period [1, 2]. Given this projected demand for positions that are necessary to our increasingly technology-based society, we need to encourage more students to consider Computer Science as a career. Unfortunately, the current supply of Computer Science graduates will not meet this projected demand. The number of students majoring in Computer Science plummeted between 2001 and 2007. Enrollments have risen since 2008, but are still much lower than the 2001 levels [3]. Similarly, Computer Science Bachelor's degrees awarded declined sharply between 2004 and 2009, have risen over the last three years, but are still not near the 2004 level [3]. Computer Science degrees awarded to women continues to decline, with only 11.7% of degrees awarded to women in 2010-2011 [3]. While the recent increases in overall enrollments and degrees awarded are encouraging, we still must produce more Computer Science graduates to meet the growing demand for skilled professionals. Educators are seeking ways to make computing more attractive to students. One such approach is to engage them in funs hands-on applications like game programming.

Games are not only fun; they also make important pedagogical contributions. Numerous studies have shown that video games can facilitate learning in math, science, engineering, geography, health, and other areas, including programming. Egenfeldt-Nielsen provides an overview of these studies and describes the contribution of video games from the perspective of different learning theories, including constructionism and the socio-cultural approach [4]. Both of these theories stress the importance of active learning as opposed to passive transfer of knowledge. Constructionism, which builds upon Piaget's Constructivism [5], stresses the

This research was possible through funding by the Collaborative Research Experience for Undergraduates (CREU) program. CREU is funded by the CRA-W and the CDC. The 2011 INSPIRED High School Computing Academy was supported in part by a National Science Foundation Broadening Participation in Computing Grant under Grant Number 0634288.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

importance of active learning using artifacts to facilitate learning. The video game provides a micro-world in which students can actively create and manipulate virtual artifacts. The socio-cultural approach that embodies the theory of Vygotsky [6] and others stresses the importance of having a teacher or peer guide the student. The video game provides a springboard for discussion with the teacher or peers.

Ke [7] synthesized findings from studies between 1985 and 2007 on computer-based instructional games. Only one out of 65 studies addressing effectiveness of instructional gaming found conventional teaching to be more effective than gaming. Studies on game-based cognitive or motivational processes found that games foster high-order reasoning and provide motivation across different learner groups and different learning situations. Studies on instructional game design found that instructional support must be included to have students learn the domain information rather than simply learn to play the game.

Using video game creation as an educational tool for programming has many practical advantages. Game programming allows the student to get visual feedback that illustrates the working of programming constructs and reinforces the theoretical concepts. Once the game is finished, students have a tangible product with which they can interact. Students can share their game with friends and family through sharing mechanisms that many educational game programming platforms provide. Game programming is an easily accessible medium. It requires only software and a computer on which to install that software. Groups and individuals that already have computers only need to install the game programming software. Using game development instructional materials, students can learn computer science concepts in a fun and engaging way. Having students complete the hands on activities with a partner can also help develop pair-programming habits and teamwork skills.

III. Background, Related Works, Contribution

Several game-based platforms have been used to teach introductory computing concepts. For a review of the most popular ones see [8]. Two of the most frequently used are Scratch [9] and Alice [10]. Scratch uses a purely drag-and-drop method of programming with blocks that generate scripts. It is often used for middle school students. Alice uses a drag-and-drop interface that generates Java-like code. It can be used to teach object oriented programming concepts. It has been used for middle school through introductory college students. In a special session at the 2010 ACM SIGCSE Symposium on Computer Science Education, Scratch, Alice and Greenfoot developers agreed that a progression from Scratch or Alice to Greenfoot is good in learning to program [11].

Greenfoot was developed at the University of Kent and Deakin University with support from Sun Microsystems. Greenfoot is a free IDE and is designed for high school and undergraduate level students [12]. It won the Premier Award for Excellence in Engineering Education Courseware in 2010. There is a textbook for teaching introductory computing using Greenfoot [13]. Greenfoot uses the Java programming

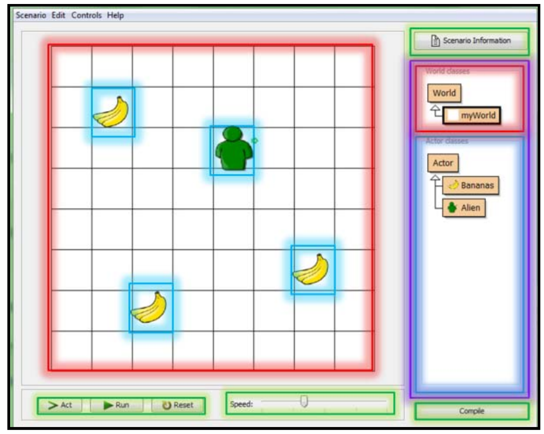

Figure 1. A sample slide of the Gathering Biofuel presentation illustrating the components of Greenfoot's interface.

language to create simulations and games. It utilizes both graphical and textual elements in its interface to teach students programming. A recent nationwide survey of undergraduate computer science departments found that Java was the language used by the largest percentage of surveyed schools to teach CS1 (48 percent) and CS2 (58 percent) [14]. Because Java is used in many Advanced Placement CS courses in high schools and is used as the entry level programming class in many universities, Java-based Greenfoot is a great tool for beginning programmers who want to learn a common programming language. Greenfoot also provides a mechanism for developers to share their creations. Allowing a budding programmer to share her creation with her family and friends can help keep her engaged when she receives positive feedback for her accomplishments, and it can help spark the interests of those who view her creation and encourage them to try programming as well.

Figure 1 illustrates Greenfoot's interface and points out its key components. One component is the world window. The world is made up of a 2-dimensional grid whose size is determined by the World's class constructor. Actors can populate this world. Actors are objects instantiated from classes created by the programmer. These created classes must extend the Actor class, which is provided by Greenfoot. Greenfoot illustrates inheritance in the Java programs in the right-most panes of its graphical interface. This is represented by the arrow coming from each subclass that points to the superclass. In the example in Figure 1, myWorld inherits from World, and Bananas and Alien inherit from Actor. This visual depiction of the relationship between superclass and subclass can be used to teach the concept of inheritance. Each created Actor subclass must have an act() method. This method designates the behavior of the actor once the program is run. In order to run a program, the user selects the "Play" button that is located with the control buttons at the bottom of the interface. "Play" indefinitely calls each class' act() method until the game is stopped programmatically or by pressing "Pause", which appears in place of the "Play" button when it is selected. Users can call one instance of each class's act() method by pressing the "Act" button. The "Reset" button removes all objects from the World and re-initializes each object. The "Compile" button compiles all classes.

Some educators have used Greenfoot to teach programming to undergraduates [15, 16, 17, 18]. Our work is more similar to that of Al-bow, who has used Greenfoot to teach programming to rising 9th and 10th graders and high school teachers [19, 20]. In Al-bow's programming sessions, students start by playing a pre-made game in Greenfoot and then in a series of exercises build a game by adding complexity one step at a time.

The instructional materials described in this paper teach programming principles through the use of game programming. An instructor uses the materials to guide the students through a series of exercises in which students create code to add functionality to a game. In each exercise students actively apply a programming concept (selection, repetition, etc.) to solve a problem and thereby enhance or complete a game.

Two things set our work apart from others. First, the modular nature of the instructional materials makes it easy to adapt them to different venues. Each of the modules can be used independent of the others, so they can be used in a one-day academy or as individual programming assignments in an introductory computing course. Second, all of the instructional materials are freely available for download and use by others.

IV. THE INSTRUCTIONAL MATERIALS

The instructional materials include five modules that can be taught individually or as a part of a weeklong lesson or a bridge program. Each module includes one incomplete game that is to be completed by students through a series of hands on exercises; and a complete version of the same game to be used as an example and a key. A PowerPoint presentation and a presenter's User Guide is also included, as well as the solutions to hands on activities that are completed by the students throughout the module. Assessment questionnaires and grading rubrics that can be administered to students are also included in each module.

A. Presentation and User Guide

A presentation is supplied with each lesson. The presentation introduces the lesson's concepts, the game, and its story. Throughout the presentation, students are taught concepts and then asked to apply those concepts in creating a portion of the game. These hands-on activities help engage students and reinforce what they just learned. Solutions to the hands-on activities are supplied. Presenters are also given a User Guide, which includes the learning objectives for the module and a slide by slide resource for the presenters that elaborates on each slide and suggests discussion topics for the group. This can help presenters who are unfamiliar with the program or concepts, which encourages a broader adoption of the materials.

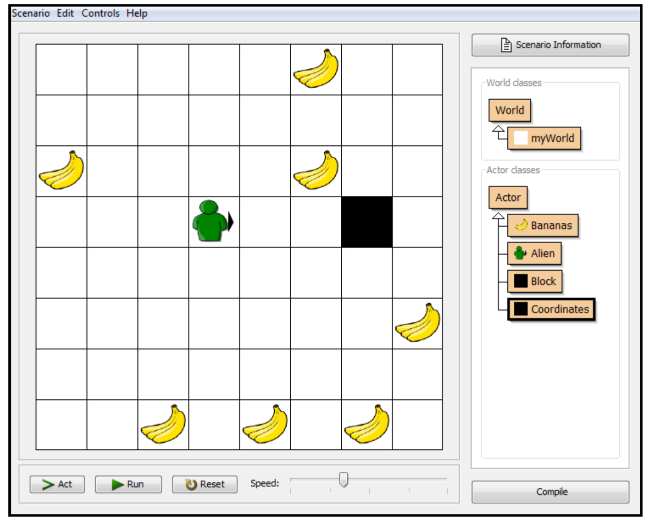

Figure 2. The Gathering Biofuel game.

B. Games

Two versions of each game are supplied. The student version is incomplete. Students complete this version during the hands-on activities. Comments are included in the incomplete version to highlight the section of code that must be modified or added by students. A second, complete version serves as a key and is used by the presenter to demonstrate the behavior of the game that is to be implemented by the students and to review the solution with students at the end of the hands-on exercises.

C. Assessment Components

In order to determine if the modules increase knowledge, content quizzes and grading rubrics are used. The questions test concept vocabulary and concept application. The grading rubric assigns point values for different answers. The quizzes are administered before teaching a lesson and after teaching a lesson. The scores on the pre-lesson and post-lesson quizzes are compared to see if there is a significant increase in scores, which indicates a significant increase in knowledge. In order to measure the reliability of the quizzes and rubrics, two different graders grade the pre-lesson and post-lesson quizzes independently. Consistency in grading can be tested by analyzing inter-rater reliability. Inconsistent grading triggers a review and modification of the quiz questions and/or grading rubrics.

V. THE MODULES

A story line unifies the five modules. The modules engage students in programming five independent games that help an alien return home. Sections A - E present the modules in the order in which they are used if the entire collection is to be used, for instance, as part of a week-long program.

A. Module 1: Gathering Biofuel

a) Learning Objectives. The goals are to familiarize students with the Greenfoot interface and introduce Java, Object Oriented Programming concepts (OOP), and the Java Applications Programming Interface (API).

b) StoryLine: An alien has stopped at Earth to gather bananas, which fuel its spaceship. The students learn how to populate Greenfoot's grid structure with bananas for the alien to collect.

c) Game: A screenshot of this game is shown in Figure 2. The game is based on the wombat tutorial supplied by Greenfoot [21]. The tutorial introduces the Greenfoot interface thoroughly, one of the main learning objectives of this module. This makes it a good choice as a basis for this lesson's game. In the supplied tutorial, a wombat traverses the screen and eats leaves that the user has added to the world. Users can add leaves for the wombat to eat by right-clicking the 'World' interface and selecting the appropriate method or creating a new object through Greenfoot's interface. Greenfoot's graphical interface lends itself well to teaching OOP concepts, which is another objective of this lesson. Greenfoot also has a documentation view that generates API documentation using Javadoc tools, which is used to teach the final objective.

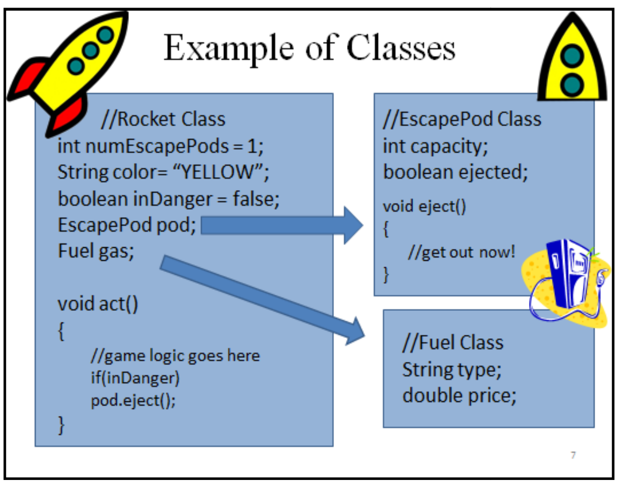

Figure 3. Sample slide that illustrates an example of classes.

What are two components of a class? Scoring rubric: (Cumulative) 1 pt each – "Methods" and "Variables"

Figure 4. Sample quiz question and scoring rubric from Module 1.

d) Hands-on activities: Students perform two hands-on activities in this module:

- create a banana object and set its location; and
- rotate an image by incrementing a variable and calling a method.

e) Sample instructional materials: Figure 3 shows a sample slide that illustrates the concept of a class. A sample question and scoring rubric from the assessment quiz for this module is shown in Figure 4.

B. Module 2: Accessing the Fortress

a) Learning Objectives: This lesson focuses on teaching students about arithmetic, Boolean and relational operations and simple if statements.

b) Story: The alien had its spaceship taken by the Spaceship Acquisition Crew (SAC.). The students must help the alien get the spaceship back from the SAC fortress by solving the puzzle to unlock the fortress door.

c) *Game:* A screen shot from this game is shown in Figure 5. In order to unlock the fortress door, the player must solve a 4x4 Sudoku grid. The student must implement the puzzle that must be unlocked in the game. Using arithmetic and Boolean operators, the student programs the population of the Sudoku grid with numbers, the mechanics to solve the puzzle, and the logic that checks to see if the puzzle is solved. The student accomplishes these tasks in a series of hands on exercises throughout the presentation.

d) Hands-on activities: Hands-on activities include:

- work with integer arithmetic, Boolean operators;
- work with if statements, Boolean, relational operators;
- write get and set methods; and
- import images.

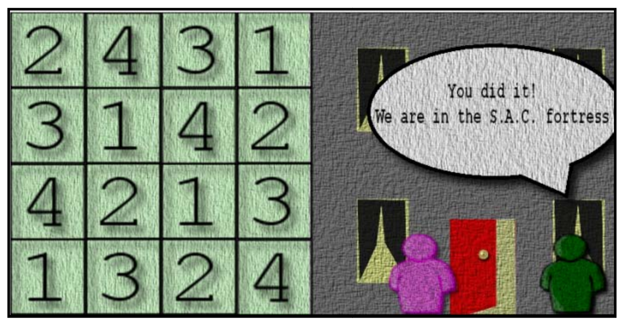

Figure 5. An image of Accessing the Fortress game with a solved puzzle.

```
/*
 *Hands on exercise
 *Write an if statement with the following condition
 *If newNumber equals 1
 *Then setImage (new GreenfootImage("one.png"));
*/
```

Figure 6. Sample hands-on exercise for Module 2: Create an if statement with relational conditions.

e) *Sample instructional materials*: A sample corresponding to one of the hands-on exercises for this module is shown in Figure 6. Comments in the students' partial game mark the spot and provide instructions for students to add content to the game. A sample question and scoring rubric from the assessment quiz for this module is shown in Figure 7.

Problem 4. 1 point awarded for each correct answer. Total of 3 points
int x = 2;
int y = 3;
boolean isJavaCode = true;
//Will the following expressions evaluate to true or false?	

Expression	Solution
x == y || x != y	true
x < y && x == 3	false
!isJavaCode	false

Figure 7. Sample quiz question and scoring rubric from Module 2.

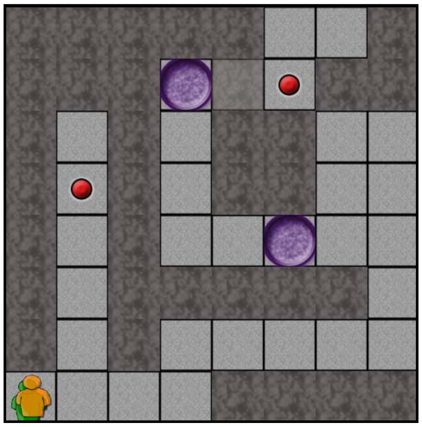

Figure 8. The Beginning of Fortress Maze. Two Players are on the bottom left; the small circles are buttons; the large circles are portals.

C. Module 3: Getting Through the Fortress Maze

a) Learning Objectives: Students learn selection and repetition structures and how they affect a program's flow of control.

b) *Story:* After the alien and student crack the code to get into the fortress, they need to work together to get through the maze that the SAC created to confuse intruders.

c) *Game:* This game requires two players. The players must disable the traps in order to access the buttons that open the hidden door to exit the maze. Figure 8 is an image of the game; in the maze, the traps are two moving portals, the large discs, which transport a player back to the beginning if they touch a player. Each player has a skill that, if used in cooperation with the other player, can disable the portals. One player can emit a field that will stun the portal so that it will not move. The other player emits a field that will disable a portal, but only if it is stunned. The cell between the topmost portal and button is a hidden door. It acts as a wall, but when a player 'steps' on a button the door is opened, but it will close once the player steps off the button. Once the portals are disabled, a player must step on the button to the left, which will allow the other player to walk past the hidden door to the exit, the cell in the upper right of the board. Once the player on the button steps off to head to the exit, the hidden door will close, but the player who is already past the hidden door can step on the button to the right and allow the remaining player to pass through to the exit. These rules are explained in the presentation and also in the game itself.

Students use the concepts learned in this module to implement core mechanics in this game. In hands-on activities throughout the lesson, students use switch statements to populate the game board with walls, portals, buttons, and the hidden door. Students use while-loops to implement the stun mechanism that is needed to remove the portals and if-statements to implement the mechanism that closes the hidden door once a player steps off the button.

d) *Hands-on activities*: Activities include:

- write complex conditional statements, nested ifs;
- use a switch statement; and
- work with the while loop.

e) *Sample instructional materials:* Figure 9 shows sample slides explaining the while statement. Figure 10 shows a sample quiz question and scoring rubric.

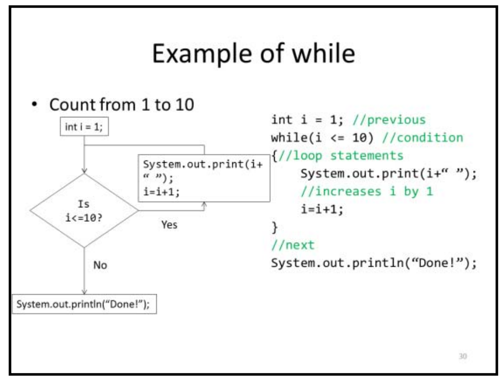

Figure 9. Sample slides used in Module 3 to explain the while statement.

Name 3 repetition structures used in Java. Score: (cumulative) 1 point each: while, do-while, for

Figure 10. Sample quiz question, scoring rubric for Module 3.

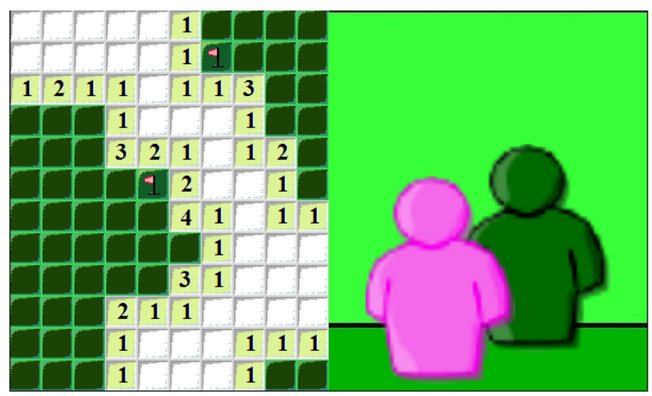

Figure 11. A game of AgentSweeper. The dark squares are active squares; the numbered squares are inactive squares bordering agents; the white squares are inactive squares not bordering agents.

D. Module 4: Agent Sweeper

a) Learning Objectives: Students learn about arrays and matrices, how to populate, access, modify elements.

b) Story: The students and the alien have managed to escape the maze and now need to avoid disturbing the sleeping guards so they can get to the alien's spaceship.

c) Game: Like the game Minesweeper, AgentSweeper requires the students to 'flag' all the sleeping agents before they can 'win' the game. Students click on the game board and use the numbers to determine where possible sleeping agents are located. Students can flag spaces where they believe agents are located. Once all the spaces are flagged or revealed as empty, the board will reveal where the agents are. This allows the alien to get through. A screenshot of the AgentSweeper game is shown in Figure 11.

Through the hands-on activities, students use for-loops to populate the matrix that represents the game board. Students also create and populate an array that holds the images of the agents that are revealed when the game is solved. In addition students implement the mechanism that counts and stores the number of agents that are bordering each square, which is revealed when an active square is selected.

d) Hands-on activities: Hands-on activities for this module include:

- use images in Greenfoot;
- create an array; and
- create, initialize, manipulate a matrix

e) Sample instructional materials: A sample solution to a hands-on exercise for Module 4 is shown in Figure 12. The solution is displayed on a slide and reviewed with students at the end of the exercise. A sample quiz question and scoring rubric are shown in Figure 13.

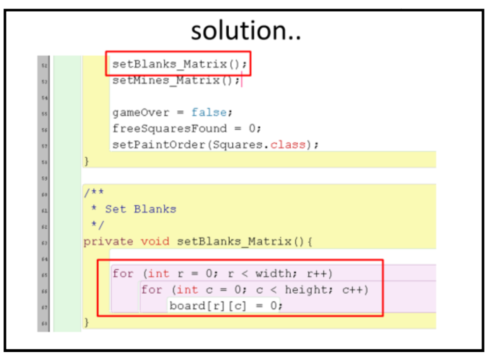

Figure 12. Sample solution to hands-on exercise in which students are to fill a matrix with zeroes.

What repetition structure can be used to fill an array/matrix?
Scoring:
2 points - for/nested for
1 point - while, do-while, or something along the lines of having to set the values in the array/matrix manually
0 points - anything else

Figure 13. Sample quiz question and scoring rubric for Module 4.

E. Module 5: Alien Flies Home

a) Learning Objectives: This lesson expands on the idea of classes and objects, and students learn about inheritance.

b) Story: Now that the alien has its ship back, it must navigate the asteroid field to arrive at its home planet.

c) Game: The student controls the alien spaceship in order to dodge the asteroids or blast them away. The asteroids periodically release power-ups that can help the alien regain health or gain a shield that blocks asteroids. The game board is illustrated in Figure 14.

In this lesson, the student creates her own class and implements her own power-up to help the alien reach home. By extending the Power_Up class, students can use the functionality already created and create their own methods to add another power-up, like one that increases firepower every time it is picked up.

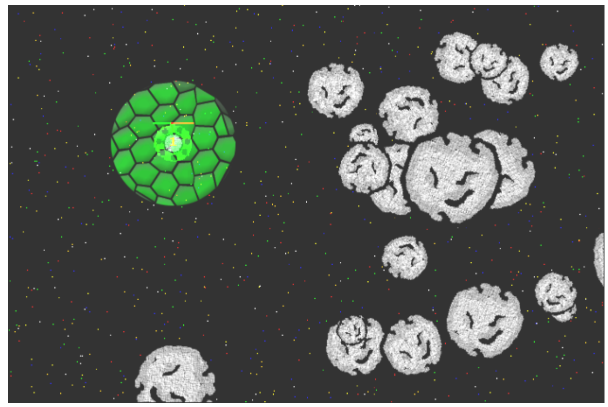

Figure 14. The alien flies home with a shield protecting its spaceship.

d) Hands-on activities: Hands-on exercises for this module include:

- create private variables;
- create a constructor;
- practice with nested if statements;
- manipulate images in Greenfoot; and
- detect collision in Greenfoot.

e) Sample instructional materials: A sample slide illustrating inheritance is shown in Figure 15. A sample quiz and scoring rubric for this module is shown in Figure 16.

VI. Results, Conclusions

In order to gauge the usefulness of the modules, the assessment seeks to answer the questions, "Does the completion of the modules increase knowledge?" and "Does the completion of the modules increase interest?"

These materials were used at Lamar University's INSPIRED High School Computing Academy in the summer of 2011. Students were taught game programming using these materials, as well as animation and web page development. Eighteen students participated in the academy: ten boys and eight girls. Analysis of the quiz assessment results shows that the students experienced a significant growth in knowledge of the computing concepts covered in all five modules [22]. Additionally, 81 percent of students reported an increase in interest in computer science courses [22].

The materials were also used in four afternoon sessions of a Lamar-hosted two-week residential academy for high school students interested in mathematics in the summer of 2012. Twenty-four 10th and 11th grade students participated: ten boys and fourteen girls. The sessions were taught by undergraduates who were not authors of the instructional materials. Assessment results show that the participants experienced a significant increase in computing knowledge in all five modules in this academy as well (t=5.279, p<0.000). A score of p less than 0.05 is considered significant. Also, 71% reported an increase in interest in computing, and 62% reported that they were more likely to take a class in computing in the future.

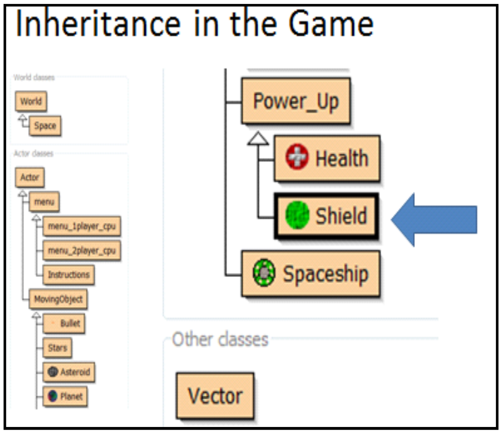

Figure 15. Sample slide from Module 5.

An object is defined by a class.
A class is the model or blueprint from which an object is created.
Score: 1 point awarded for each correct answer. Total of 2 points

Figure 16. Sample quiz question and scoring rubric from Module 5.

The results thus far demonstrate that these materials can be used to increase knowledge and interest in computing of high school students in different venues. The collection could also be used in a summer bridge program for entering freshmen. Because each of the modules has its own game and exercises that are independent of the other modules, they can also be used individually in one-day academies or as individual programming assignments in introductory courses.

The materials are available for download from: http://javagonegreen.blogspot.com/p/teaching-materials.html.

Assessing the Impact of Video Game Based Design Projects in a First Year Engineering Design Course

Joseph Ranalli* and Jackie Ritzko
Penn State Hazleton
Hazleton, PA 18707
*Corresponding Author: jar339@psu.edu

Abstract—**Introductory engineering design courses are an opportunity to engage and encourage first-year engineering students. In one such course, we implemented a novel student design project using a commercial video game. The game, Kerbal Space Program, is a simulation of rocket travel and provides a reasonably realistic representation of rocket propulsion and orbital mechanics. Teams of students were tasked with designing a rocket that could fly to the home planet's moon and return safely. The efficacy of the project was assessed using a pre- and post-activity survey, and results are compared with those from a larger-focus research project on the effectiveness of toys in the classroom.**

Keywords—games; engineering design; engagement

I. Introduction

Engineering students' first experience with the engineering discipline often occurs within introductory engineering design courses. As a result, these courses play an important role in retention and engagement of students in engineering. A variety of strategies have been employed in the past to improve retention and engagement of students. This article details a preliminary study conducted as part of a larger programmatic investigation on the efficacy of toy-based engineering design projects to increase retention of students in engineering disciplines. The contribution we made was to investigate the potential of video games as toys within this context.

Student retention is believed in part to be related to student attitudes about engineering, confidence in engineering skills, and interaction with peers [1,2]. Our approach uses team-based, hands-on projects to engage students. Another aspect of our approach is to use projects that provide students with engineering related coursework that does not have the heavy math and science focus common to the majority of their first-year curriculum. This allows them to build confidence in engineering apart from their still-developing quantitative analysis skills. The impact of these strategies was assessed by pre- and post-activity survey on self-efficacy of learning in engineering, engineering career interest and student perception of program usefulness.

This study is funded in part by a grant from the National Science Foundation (Grant No. 0756992) to the Pennsylvania State University for the STEP proposal Toys and Mathematical Options for Retention in Engineering (Toys 'n MORE) awarded to Principal Investigator Dr. Renata Engel.

II. Background

Video games are a ubiquitous form of entertainment in modern society. They can be now found on a variety of platforms including home computers, standalone gaming consoles and smartphones. The level of computational power used by these systems has grown substantially over recent years, to the point that video games may now contain sophisticated simulation environments for a variety of different types of physics. The combination of popularity and wide availability of these games has created a situation in which over 65% of college students report at least occasional video game use [3]. By leveraging the advanced computational platforms available for video games, there is an opportunity to engage students and harness an existing student leisure activity for educational purposes. A common aspect of many games is the development of a community of practice. As players collaborate, learning as a social process builds connections to what is being learned and situations where the learning can be applied [4].

Games and game-like activities have been used in a variety of classroom settings [5]. Educators have considered games as an environment for content delivery, where learning objectives are integrated with the game itself. Games may also be used as a practice environment for drilling and repetition in a (theoretically) more enjoyable task. Consideration has been given to "gamification," where common game reward structures are integrated into traditional learning to provide motivation. Lastly, games can be considered simply as a reward activity for students.

Previous studies have considered the ability of video games and other virtual environments to be used for engagement or learning purposes in an educational setting. In a physics classroom, virtual manipulative tools were shown to be effective as compared to hands-on experimental activity by students [6]. Coller and Shernoff [7] utilized games and game programming as an avenue to address numerical methods in an engineering simulation environment. They showed higher levels of student intrinsic motivation and overall engagement when working within the context of the game, as compared to traditional classroom activities. Other studies have considered the impact of mobile, augmented reality games in pre-college educational environments [8]. A study by Virvou et al showed gains in student learning through gaming especially in students whose previous mastery of the material was low, but caution

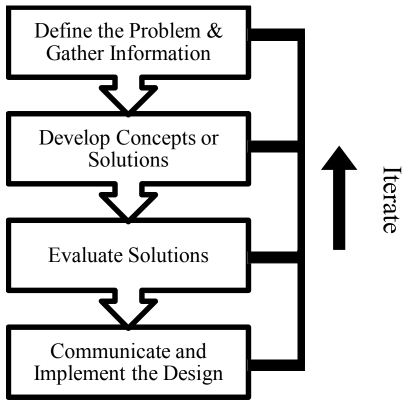

Fig. 1. The four-step engineering design model used in the course

that students will compare the production value in the games being used in the classroom with those commercial games that they encounter [9].

In this study, we considered the effectiveness of a commercial spaceflight simulation video game in the engineering design classroom. The game was used as an environment where students could practice engineering design by using the simulation to facilitate the production and testing of concepts throughout the design process. The game also produced a somewhat realistic depiction of the physics of rocket propulsion and spaceflight, providing students an environment to explore these concepts as they played.

III. Description of the Work

This study was part of the Toys ‘n MORE research program, which focused on measuring student engagement and retention through a series of toy based interventions in introductory engineering design and other courses. This program spanned several sections of the course, as well as several different university campuses. The interventions were implemented individually by each instructor, resulting in some variability in the projects for each course, though with the common theme of using toys in some way. One example of the Toys ‘n MORE program using LEGO Mindstorms robot design was reported by Sholtz and McFall [10].

The course in question was Introduction to Engineering Design, a course intended for first-year engineering students. The course covers topics of “engineering design processes, methods, and decision making using team design projects,” as well as engineering communication and graphics. The formalized design process used as a guide for students was a four-step model, shown visually in Fig. 1. In this course, students worked in groups to complete two team design projects. Survey data was compared for two groups: all students completing the Toys ‘n MORE version of the course (909 students from 2009-2012) and three course sections of students who completed a project using the video game simulation (58 students during the 2012/2013 school year).

A. The Video Game Project

The project we implemented to investigate student response to video games in the classroom was based around a commercial video game entitled Kerbal Space Program [11].

Fig. 2. Sample screenshot of a rocket under construction

Fig. 3. Sample screenshot of a rocket in-flight

This game is still under development, but at present is sufficiently complete to provide a comprehensive spaceflight experience. In the game, players can construct rockets from a variety of parts. Some examples are solid rocket motors, liquid rocket engines and fuel tanks, guidance systems, fins and other steering components, radial and axial staging separators, landing parachutes and structural supports. After constructing a rocket, the game provides a simulation environment where these designs can be launched and flown (requiring manual piloting) into orbit in a virtual outer space that includes other planetary bodies. A pair of screenshots from the game is shown in Fig. 2 and Fig. 3. For our study, the demonstration version of the game was used, because it was freely available and used a smaller set of components. While still allowing students the freedom to explore in their designs, this limitation did help provide focus.

The project assigned to students was to investigate the rocket parts and develop a rocket that would be able to reach space, fly into lunar orbit and return to safely land on earth. This flight plan mimicked the real-life flight of Apollo 8. Note that the earth, moon and sun were the only astronomical bodies that could be visited in the demonstration version. Landing on the moon was provided as an optional extra-credit goal, due to the additional piloting challenges that we felt would turn the learning focus away from the design. Besides practicing engineering design within the simulation, students did need to develop insight into some basic orbital mechanics principles, like the relationships between velocity and altitude. The latest versions of the game include built-in tutorials that could also be used to help acclimate students to the simulation. Students were given some instruction on these topics, specifically on how to create an orbital trajectory that would approach the moon.

Two specific learning objectives were addressed by this project. First, students were expected to be able to apply a four-step engineering design process to successfully complete a design goal. The second learning objective was for students to be able to demonstrate effective and professional teamwork behaviors throughout the process. The design process-related outcome included identification and articulation of design problems and challenges, identification of specifications for the design, and development and testing of multiple concepts in reaching a final design.

The video game we used fit well with the design learning objective, in that it required a workflow where students would piece together components and conduct test flights to evaluate the performance. Within the game's simulation environment, students encountered a broad set of challenges that their designs had to be modified to address. Example design decisions that students had to make were decisions about the type of rocket engine to use, the amount of fuel to carry, the rocket staging arrangement. In test flights students were able to observe how their choices impacted thrust-to-weight ratio, ease of control and flight stability, and how these parameters affected their ability to achieve their design goal. The application of the design process became a natural part of the playful activity. Another strength of this approach was the opportunity for students to iterate very rapidly on their designs.

The student deliverable for the project was a written report. They were instructed to focus on reflections about the implementation of the design process (e.g. concept generation and testing) and the measurable performance of their design. They were also asked to discuss their approach to teamwork in developing their design. Student grades were based primarily upon the stated learning objectives; their articulation of their design within the context of the engineering design process and their use of teamwork were the primary criteria. After completing the project, students received a detailed rubric providing the basis for their grade with an emphasis on the learning objectives. This was done to enable them to identify the shortcomings and receive feedback to improve their application of the design process on subsequent projects in the course.

B. Survey Data Collection

Student response to the learning activities was assessed using a survey adapted from the Longitudinal Assessment of Engineering Self Efficacy (LAESE) instrument [12,13] and a second technology self-efficacy instrument [14]. The pre- and post-activity survey was implemented for the entire Toys 'n MORE program. The survey was made up of seven demographic questions and 41 items related to aspects of engineering self-efficacy that mapped into nine subscales:

- Teaming self-efficacy (3 items)
- Technology self-efficacy (3 items)
- Communication self-efficacy (4 items)
- Engineering self-efficacy I (5 items)
- Engineering career expectations (7 items)
- Engineering self-efficacy II (6 items)
- Feeling of inclusion (4 items)
- Efficacy in coping with difficulties (6 items)
- Math outcomes efficacy (3 items)

Sample questions from three of the subscales are shown in Table 1. Note that the subscales detailed in Table 1 are those that had statistically significant results.

The pre-surveys were administered on the first day of class. This was to accommodate the fact that students were introduced to the game as a free-time activity at the beginning of the course so that they could play with the game freely and get a context for the upcoming project. The project was discussed with students at that time, but the formal assignment and expectations were provided in the 4th week of the course. Students had four more weeks to work on their designs and reports. The post-surveys were administered in the 8th week, after the projects had been completed.

TABLE I. SAMPLE QUESTIONS FROM SELECTED SUBSCALES

Subscale	Sample Questions
	Prompt: How confident are you in your current skill and ability to… (Not at all confident = 0 to Completely confident = 10)
Tech. self-efficacy	…design and build something new that performs very close to your design specifications? …quickly grasp the limits of a technology well enough to judge whether a project should use it?
Comm. self-efficacy	…organize a message so that it is clear and logical? …write reports that communicate clearly to the intended audience?
	Prompt: For each statement, indicate your level of agreement. (Strongly Disagree=0 to Strongly Agree=6)
Engr. self-efficacy I	-I can succeed in an engineering curriculum while not having to give up participation in my outside interests. -I will succeed (earn an A or B) in my physics courses.

IV. Results and Discussion

Results are considered for two separate groups of students. The first group represents students taking a Toys 'n MORE version of this course at our campus that did not include the video game. This group was made up of 909 students who took the course between 2009 and 2012. These students performed a hands-on design project that involved toys, but did not use the video game. The second group was the 58 students who took the course in Fall 2012 and Spring 2013, and who did both a toy-based design project and the video game-based project.

Due to the small sample size for the video game group, only three of the subscales were found to show statistically significant changes (two-tailed test significance less than 0.05). For two of those scales: Technology self-efficacy and Communication self-efficacy, an increase in mean rating was observed, while the third, Engineering self-efficacy I, showed a decline. The larger toy-only group showed statistical significance in the following subscales, with all showing an increasing trend from pre- to post: Teaming self-efficacy, Technology self-efficacy, Communication self-efficacy, Engineering self-efficacy II, Feeling of inclusion and Coping efficacy. These results are shown in detail in Table 2.

While some favorable results were seen for the video game group, there are some obstacles to interpretation. There is a relatively small sample size, with lower initial means. Additionally, the video game sections of the course had a different instructor than the rest, and one section had a slightly high number of sophomores. What we do conclude is that on the whole, the toy project provided benefits to students in some of the measured areas, and that the video game preliminary data shows gains, but would benefit from additional investigation.

Some subjective observations from the implementation of the project are worth considering. Students were extremely enthusiastic about the game. They frequently arrived at class early in order to play. In the first section using the game, students were given more time with the game and were primarily allowed to discover the orbital mechanics through free exploration. Some students began to express difficulty with this approach, and supplemental instruction was provided. The second group of students were provided with some orbital mechanics instruction early in the project, and qualitatively seemed to have a better experience with the task.

Another important qualitative observation is related to the engineering design process learning objectives. Because of the somewhat specific nature of the defined task (producing a rocket to orbit the moon), students seemed to have difficulty understanding how the game fit into the context of the four-step design process. An intervention was used during the second implementation of the project to provide a more concrete explanation of how the design process was relevant to playing the game. After this intervention, students offered informal feedback that they now saw how the process fit into their natural gameplay activities and felt that the game was a good example of the process.

One design process feature that the game demonstrated particularly well was iteration. All of the student groups identified iterative elements on their way from testing of multiple prototypes to the design of their final rocket. No groups were successful from their first launch and all had to make improvements on the basis of observations of the design weaknesses. We felt this was one big advantage over hands-on classroom design projects in which expense and time constraints can preclude students from building and testing multiple prototypes.

TABLE II. SUMMARY OF SURVEY RESULTS

	Toys-Only Group (n = 909)			**Toys and Video Game Group (n = 58)**		
Subscale	Pre-Mean	Post-Mean	Diff	Pre-Mean	Post-Mean	Diff
Team self-efficacy	7.09	7.56	+0.47	NS[a]	NS	N/A
Tech self-efficacy	7.44	8.00	+0.66	7.26	7.80	+0.54
Comm self-efficacy	7.51	8.03	+0.52	7.32	7.94	+0.62
Engr self-efficacy I	NS	NS	N/A	4.77	4.53	-0.24
Engr career expect.	NS	NS	N/A	NS	NS	N/A
Engr self-efficacy II	4.91	4.98	+0.07	NS	NS	N/A
Inclusion	4.37	4.69	+0.32	NS	NS	N/A
Coping efficacy	4.90	4.98	+0.08	NS	NS	N/A
Math outcomes	NS	NS	N/A	NS	NS	N/A

a. NS - Not statistically significant

V. Conclusion

The use of video games in the classroom is thought to have a great deal of potential to increase student engagement. We tested the use of Kerbal Space Program, a video game simulation of space travel, in a first-year engineering design project. Students were found to have enjoyed the project and were enthusiastic about the opportunity to play games in class. Some recommendations about the use of this game can be made on the basis of our experience. Students needed some guidance to understand the link between the video game and the academic content that it was meant to illustrate. However, once students began to feel comfortable with this relationship, they did observe features (such as rapid iteration) that the game was able to uniquely demonstrate. Survey data collected for the project showed that the game brought student gains in technology and communication self-efficacy ratings, and a decline in engineering self-efficacy. We believe that the outlook for this type of project is favorable as a demonstration of the engineering design process or similar activities, and that greater benefits to student participants can be realized with more experience.

***Abstract* — This paper presents an assessment of an educational game for teaching the efficient use of electricity. Developed with Adobe Flash®, it is a virtual board game where participants choose a car that starts the path and reaches the same final goal, going through a number of track steps defined in terms of a dice that each player rolls in turn. The car moves if the participant is able to correctly answer a question that is randomly generated by the software. The objective of the game is to answer questions related to energy efficiency promoting a healthy and attractive learning process for participants on concepts related to energy efficiency such as: the rational use of energy, the basic concepts of forms of energy generation, among others. The main objective of this paper is to assess the impact of the application of this virtual game in the teaching and learning process of high school students. Therefore, the game was applied in the discipline of physics in a class of junior high public school in the state of São Paulo. Initially, the class that had 43 students was divided into 10 groups of 4 students, and 1 group of 3 students. Each student group competed with one another. The idea was that each of them should indicate a student who was the representative of this group until only 4 group leaders were selected for the finals. At this stage, each student could interact with a group of up to ten students that acted as advisers. The adopted assessment process is based on the model proposed by Savi [7]. Then, at the end of the game, the students answered a prepared questionnaire based on the model proposed by Savi. According to Savi, although there are significant studies that show the importance of educational games for the process of cognitive development and learning concepts of students, there are few papers that present forms of assessing the potential of these resources. Thus, the assessment criteria proposed by Savi are based on the model of training evaluation by Kirkpatrick [3], taken as a reference to measure the efficiency of processes of continuing education courses for professionals. The authors assert that the metric of the evaluation proposed to assess the game is based on the first level of the model proposed by Kirkpatrick.**

Keywords: educational game; game-based learning; education; energy efficiency.

I. INTRODUCTION

Through playing activities to explore the reality, students can reflect and incorporate different environmental and cultural aspects we live with. Anyway, the game lets you transform the reality through imagination and allows the establishment of a network of constructive meanings [1].

When playing, children are given the opportunity to fully develop experiences, discoveries, creations, and skills. Playing is essential for the physical, emotional and intellectual development of the child.

Playing behavior is not only a necessity for children, but it is also inherent in human beings, since various activities that are performed in our everyday adults lives are imbued with playfulness: myths (fantasy games) in language (word games), religion, food, among others [2].

It was developed an educational virtual game under a partnership with a company established in the energy industry sector in Brazil – *Centrais Elétricas Brasileiras S. A. – Eletrobrás* – whose goal is to provide learning situations in the classroom in which questions about the efficient use of electricity can be discussed and problematized. In this paper, it is presented a review of the game developed in a real classroom situation. It was used, as instrument for data collection, a questionnaire based on the model of Kirkpatrick [3] for training evaluation, the ARCS model proposed by Keller [4], Gamez [5] in the field of Game User Experience, and the taxonomy model proposed by Bloom [6].

II. EVALUATION MODEL

According to Savi *et al.* [7], although there are significant researches that suggest the importance of educational games both for the process of cognitive development and learning concepts of students, there are few works that have forms of assessing the potential of these resources. Thus, the assessment criteria proposed by Savi is based on the training evaluation model by Kirkpatrick, fixing the attention on the degree of satisfaction and the perceived value by the students as for the learning experience they had to interact with along the game.

The evaluation model of training programs developed by Kirkpatrick, taken as a reference in processes of measuring the effectiveness of continuing professional training courses, is based on four hierarchical levels:

1. **Reaction:** It refers to the degree of impression that the training professionals had from the program. That is, we seek to understand how the training program motivated, awoke professional interest in learning the content, and developed the skills and competencies proposed in the training program.

*Students of electrical engineering

2. **Learning Process:** It is related to knowledge built by the professional during the training program.

3. **Practical Application:** For this search criterion, it was aimed measuring the professional capacity, developed during the training step, in applying the gained knowledge in practice.

4. **Results:** It refers to the positive effects of the training program for the organization in which the professional works.

The authors affirm that the evaluation metrics developed for assessing the educational game are based on the first level of Kirkpatrick model.

So, to specify the degree of motivation of students, as well as the value they attribute to the experience they had in the educational game, the authors build categories based on the ARCS model proposed by Keller, on the user's field of expertise (UserXperience - UX), proposed by Gamez, and on Bloom's taxonomy.

In the ARCS model proposed by Keller, it is assumed that the motivation to learn is a fundamental element for the whole educational process and that, to be established, it is necessary for the student to interact with the game, to have the expectation of success, and to assign value to the results obtained in this interaction. Thus, some categories may be established: Attention, Relevance, Confidence and Satisfaction.

- **Attention** is understood as a cognitive response given by the students to instructional stimuli used in the teaching and learning process. Therefore, it is essential that the instructional game has the merit of encouraging students not only at the beginning, but throughout the whole interactive process mediated in the act of playing.
- **Relevance** is considered a value assigned by the student from which he or she recognizes the importance of the educational activity for their learning.
- **Confidence** is understood as a sense developed by the student, during the development of the educational activity, from which he or she feels capable of overcoming the challenges that are proposed. In this sense, the educational game will be motivator if players feel confident enough to overcome the proposed obstacles.
- **Satisfaction** is interpreted as being the positive feelings of accomplishment and reward perceived by students during the execution of the proposed activities. Therefore, the game should be a source of satisfaction, that is, feelings of accomplishment and reward for students.

With respect to the contributions of the user's field of expertise (UserXperience - UX), the categories are based on the idea or perception that a given user formulates or feels after using a particular product. In this way, Savi *et al.* highlight that UX takes into account the thoughts, feelings and sensations triggered through the user-product interaction, as well as the present or previous expectations with respect to its use.

Thus, the authors, influenced by the categories proposed by Gamez, select those that showed to be more suitable for assessing educational games:

- **Immersion:** It refers to the level of involvement that the student has with the game, in order to divert the focus from the real world into the context that the game creates.
- **Challenge:** Considered by the authors as being the main aspect of good educational games, the challenge needs to be established to motivate students to get involved with the proposed activities. To this end, the game needs to have rhythm, that is, submit a schedule in which the rate at which new challenges, problems or tasks arise is appropriate. It is also necessary that the challenge level is proportional to the skills of the players and then increase as the game develops, in order to increase motivation.
- **Competence:** The student should feel able to confront challenges proposed by the game. If the proposed challenges are above the student's capacity, there will be a sense of anxiety, discouragement and, consequently, of demotivation.
- **Fun:** The game should generate a feeling of pleasure, satisfaction, joy, and contentment. This will establish in the student the desire to play again and recommend its use to other students.

Savi *et al.* use the first three levels of Bloom's taxonomy to evaluate potential aspects of the game in providing learning concepts to students. Bloom has proposed taxonomy based on specific areas of cognitive, psychomotor and affective domains. For cognition, understood as processes related to learning process, that is involving the construction of new knowledge and the development of intellectual skills. The levels used by Savi *et al.* are listed below:

- **Knowledge:** It is related to the ability to remember information and previously discussed content. In general, the purpose of this category is to identify whether the apprentice is able to bring to mind the knowledge and the information learned.
- **Understanding:** It is related to the ability to understand information or facts, to give meaning to the content that you are being informed about, using them in different contexts.
- **Practical Application:** It is related to the capacity or ability of the learner to use, in different situations, information or knowledge in real situations. In this sense, the learner should be able to apply rules, methods, models, concepts, principles, laws, and theory into practice.

Fig. 1 presents the assessment model proposed by the authors of the current paper to be used when evaluating educational games.

Based on this assessment model of educational games, a basic questionnaire was set which, after playing the game, students were invited to answer.

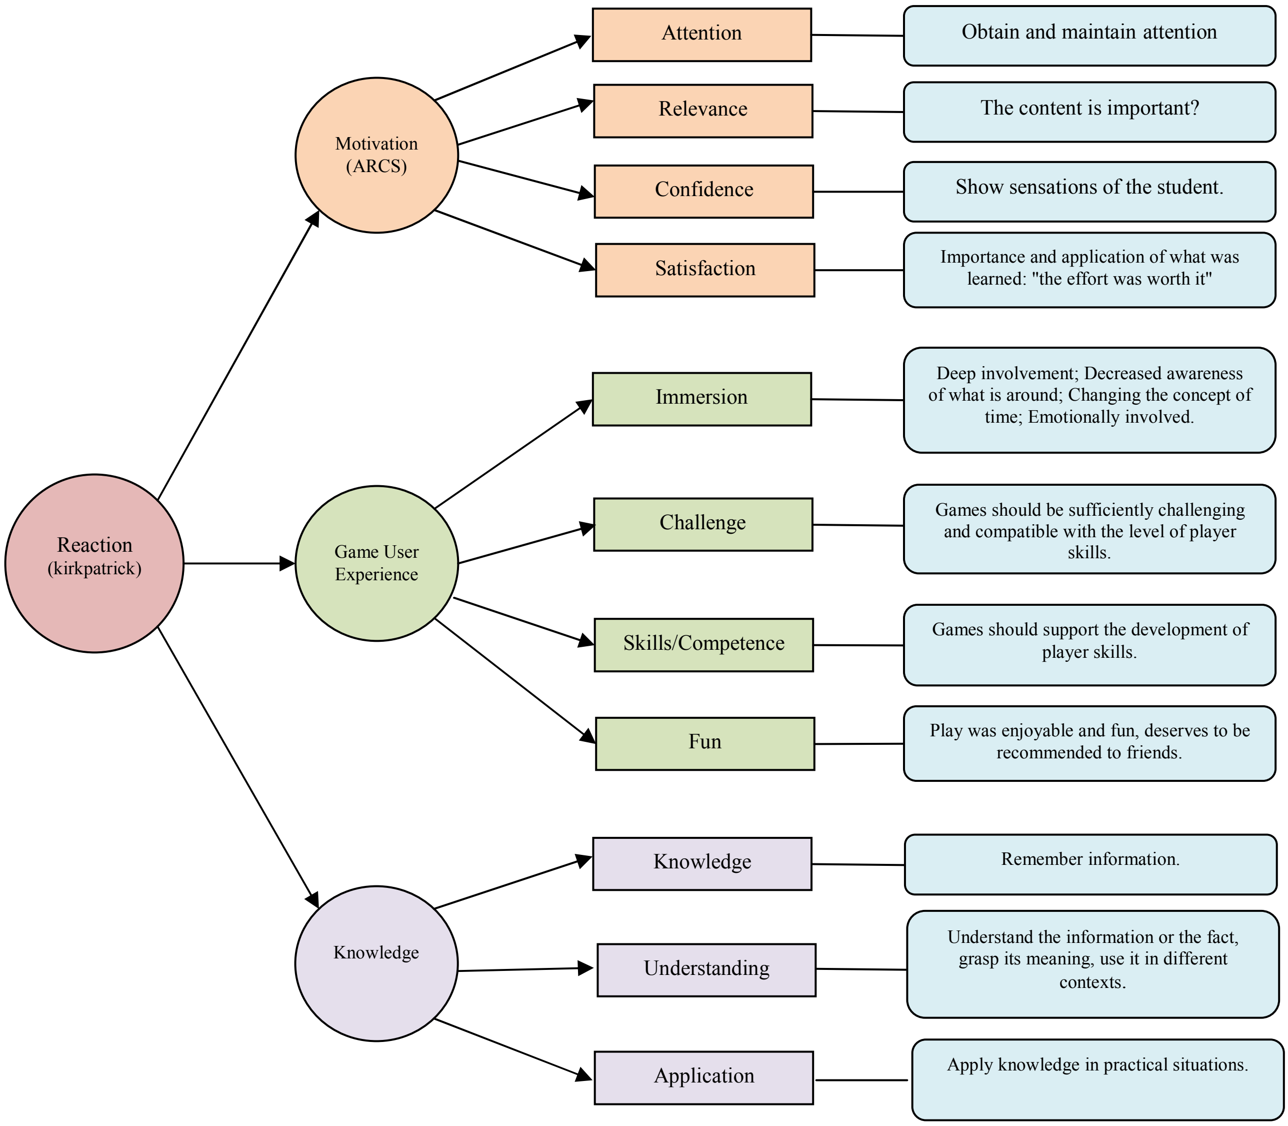

Fig. 1. *Proposed assessment model of educational games*

III. METHODOLOGY

The survey was conducted in the context of a school with high school students. The game was applied in the discipline of Physics in a class of junior high public school in the state of São Paulo, considering that the concepts involved in the questions are part of the contents taught in this discipline. The selection of the school took place in the context of a continuing education course for Physics teachers taught at UNESP, campus of Guaratinguetá. In this course it was held an invitation for the participants to apply the virtual educational game within their classes. The high school teacher had the autonomy to choose the school and consequently the class of students with whom he or she would work.

The class had 43 students who were divided, randomly, into 10 groups of 4 students and 1 group of 3 students. Each student group competed with one another. The idea was that each group should indicate a student who was the representative until only 4 group leaders were selected for the finals.

A pre-test was not applied to the students once we sought an instrument that did not limit us to a process-product research, but offered more general data, such as motivation, social interaction, among others.

As the students had no access to any reference materials during the execution of the game, it was allowed that, in the last stage, each student interacted with a group of up to ten students who acted as advisers. At the end of the game, the students answered the assessment questionnaire.

IV. EDUCATIONAL VIRTUAL GAME

The game, developed in Adobe Flash®, aims to provide learning situations of concepts for the rational use of energy, energy efficiency, and renewable and non-renewable energy sources to high school students. Fig. 2 shows the initial screen of the educational game.

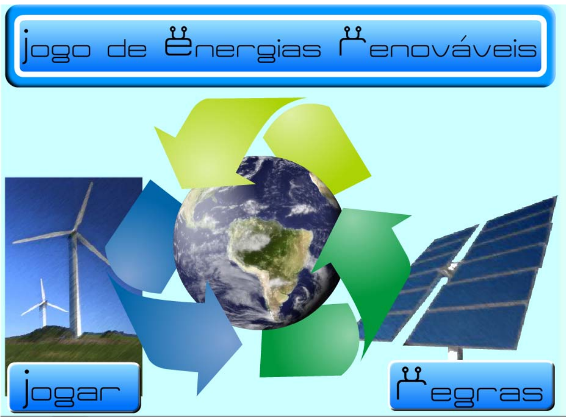

Fig. 2. Initial screen of the educational game.

The game is composed of an autorama track consisting of thirty houses to be travelled through. The board is set up (*jogar* button) during the booting stage of the game with two, three, or four lanes. In each board lane, the player has five houses called as REVES (for the setback condition: see below). The position of these houses is performed randomly by software during the game startup, as well. Fig. 3 shows the game set up with four lanes, that is, the game is set to four participants.

The game starts when a player rolls the dice on the virtual board and advances the number of track steps according to the value obtained. In each of these steps, the participant is asked questions with four alternatives of which only one is correct. If the answer is correct, the order of turns is not changed. If, on the other hand, the player mistakes the answer, he or she must spend a turn without playing. Such a condition is displayed immediately on the screen of the game. Fig. 4 shows the screen containing a typical question presented to players during the game.

The player who can position his or her cart in the step at the end of the track first wins the game. Thus, each player rolls the dice clicking on the icon shown on the screen, and goes through the number of houses obtained after the release. Then, the students may answer a question on one of the following topics: rational use of energy, energy efficiency, and renewable and non-renewable energy sources.

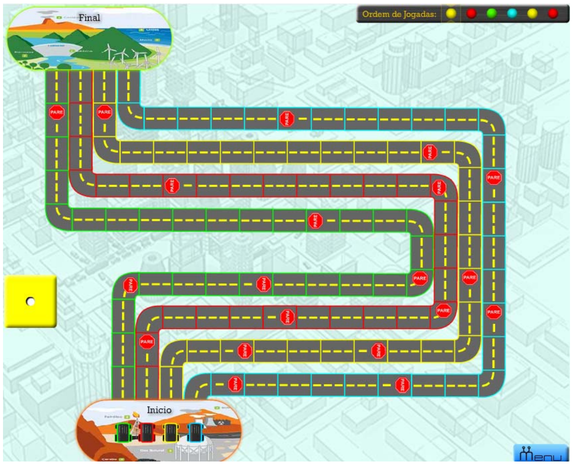

Fig. 3. *Board set with four lanes.*

If the answer is correct, the player rolls the dice the next round and the game continues normally. If the answer is wrong, the player loses a turn to throw the dice in the next round.

During the game, each player may suffer one or more setbacks. That is, an unfavorable situation related to the misuse of energy resources at his or her disposal. In that case, as in the case of mistaking an answer, he or she must spend a turn without playing, or even retreat already covered steps. All questions, as well as the setbacks, are randomly generated by the software.

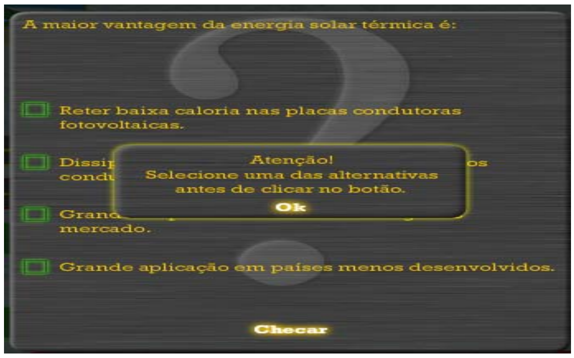

Fig. 4 Question screen.

The game ends when one of the players reaches the step called as the END. At this point, the player must answer a challenge question that has eight alternatives of which only one is correct. The game is ended when one of the players correctly answers the question. Otherwise, the game goes on until one of the other participants answers this challenge question correctly.

V. RESULTS

As pointed out before, a basic questionnaire was proposed, based on the assessment model of educational games. The assessment instrument was organized in three sections, corresponding to the MOTIVATION, GAME USER

EXPERIENCE and KNOWLEDGE categories. Based on data collected from the responses provided by the students, individually, from the completion of the assessment questionnaire, it was noted that, in relation to the section of the proposed assessment instrument for MOTIVATION category, all students have highlighted that the game has some features that triggered their attention, no student pointed out any aspect of the game that has generated lack of motivation, and a significant number said that already had some knowledge about the content involved in the game. Furthermore, the significant majority of students replied that not only liked the game, but also felt motivated by it, and found that the addressed topics were current and interesting.

The results obtained from the analysis of the questionnaires are shown in the form of Tables (Tables I, II, and III, in the sequel). With respect to the MOTIVATION category, the employed assessment tool has adopted the following aspects: attention, relevance, confidence, and satisfaction. The proposed questionnaire for the assessment of this category is presented below:

- **Attention:**
  - (1) Was there anything interesting at the beginning and during the game that called your attention?
  - (2) Is there any lack of motivation in the game?
- **Relevance:**
  - (3) Is the content of the game related to things you already knew?
  - (4) Did you like the game so much to the point of wishing to learn more about the addressed topics?
  - (5) Is the content of the game relevant to your interests?
- **Confidence:**
  - (6) Was the game more difficult to understand that you would like it to be?
- **Satisfaction:**
  - (7) Did you feel good when finishing the game?

Some points could be detached from data on Table I. Firstly, with respect to the *attention* aspect, one can see that most of the students (35) acknowledged that there was something interesting in the game that caught their attention. With respect to the *relevance* aspect, one can see that most of them (40) enjoyed the game so much to the point of becoming interested in learning more about the covered topics. It is interesting to notice that, with respect to the *confidence* aspect, most of them had no difficulty understanding the game. Finally, with respect to the satisfaction aspect, most of them felt good when the game was over.

TABLE I. *STUDENTS OPINION ON THE MOTIVATION CATEGORY.*

MOTIVATION							
	Attention		**Relevance**			**Confidence**	**Satisfaction**
Question	**(1)**	**(2)**	**(3)**	**(4)**	**(5)**	**(6)**	**(7)**
Strongly Disagree	0	10	0	0	0	40	0
Disagree	0	3	7	2	0	3	5
Agree	35	0	16	40	21	0	35
Strongly Agree	8	0	20	1	22	0	13

With respect to category GAME USER EXPERIENCE the employed assessment tool adopted the following aspects: immersion, challenge, competence, and fun. The proposed questionnaire for the assessment of this category is presented below:

- **Immersion:**
  - (8) Have you noticed the time going by when playing the game?
  - (9) Have you concentrated so hard on the game to the point of not realizing what was going on around you when playing?
- **Challenge:**
  - (10) Have you felt anxious at any point during the game?
  - (11) Have you felt bored at any point during the game?
  - (12) Has your knowledge gradually increased with overcoming the proposed challenges of the game?
- **Ability/Competence:**
  - (13) Have you felt that the game was appropriate to your learning level?
  - (14) Has the game granted a great collaboration between you and your colleagues?
  - (15) Has this collaboration helped your learning process?
- **Fun:**
  - (16) Did you like playing the game for a long time?
  - (17) When it ended, were you disappointed because you wanted to go on playing?

TABLE II. *STUDENTS OPINION ON THE GAME USER EXPERIENCE CATEGORY.*

GAME USER EXEPERIENCE										
	Immersion		**Challenge**			**Ability Competence**			**Fun**	
Question	**(8)**	**(9)**	**(10)**	**(11)**	**(12)**	**(13)**	**(14)**	**(15)**	**(16)**	**(17)**
Strongly Disagree	0	6	2	36	0	0	0	0	0	0
Disagree	0	10	28	7	4	6	3	0	1	12
Agree	34	25	10	0	30	37	30	30	42	30
Strongly Agree	9	2	3	0	9	0	10	13	0	1

The results presented in Table II indicate that students have been significantly involved in the game to the point of their thoughts not become dispersed with others questions that would not involve the approach of the game. The questions were appropriate to the level of the students, because they felt challenged with the same and with the problems proposed in different stages of the game. In this regard, the assessed students emphasized the fact of the game require different skills and competencies. Another aspect highlighted by the interviewees was that the game allowed them to experience moments of fun and at the same time, contributed to make learning more enjoyable.

As for the KNOWLEDGE category, the employed assessment instrument adopted the following aspects: knowledge, understanding, and practical application. The proposed questionnaire for the assessment of this category is presented below:

- **Knowledge:**
  (18) After the game, are you able to remember the several pieces of information related to the theme presented along the game?
- **Understanding:**
  (19) After the game, have you felt more capable of better discussing about the subjects related to the theme of the game
- **Application:**
  (20) Do you feel you can apply the knowledge acquired in the game in practice?

TABLE III . *STUDENTS OPINION ON THE KNOWLEDGE CATEGORY.*

KNOWLEDGE			
	Knowledge	**Comprehension**	**Application**
Question	**(18)**	**(19)**	**(20)**
Strongly Disagree	0	0	0
Disagree	0	0	0
Agree	37	32	21
Strongly Agree	6	11	22

From these data, we observed that the different questions proposed demanded different levels of cognition of the students. From the students' own perception, the proposed issues not only demanded knowledge of basic information related to the rational use of energy, as also challenged them in relation to the understanding of different contexts and the application of knowledge to solve certain problems.

VI. CONCLUSION

More than motivate and provide moments of fun for the students, the educational game involved students in processes of social interaction that provided a deeper understanding of the issues addressed.

In the opinion of the authors, the virtual game is not an educational resource that suffices by itself. The game has no innovation in terms of bringing in itself mechanisms for self-learning. However, depending on the way the teacher uses it in the context of the classroom, it can become an interesting resource, not only as a pre-test, but as a motivational tool for learning, a trigger of social interactions, from which an entire conceptual discussion can be established. Thus, the teacher can use the game to assess students' prior knowledge before beginning the process of teaching and learning, or even identify the concepts that need to be further emphasized after the teaching process. So the game is not the end, but the means from which the teacher will be able to evaluate students, verifying: doubts, knowledge level of the class, pre-conceptions about the previous theme, among others.

In this sense, we finish this article calling the attention to the importance of both the role of the teacher as the key element to manage the process of teaching and learning, and the use the game as a ludic and motivating instrument in the learning process.

ACKNOWLEDGMENT

We thanks the *Centrais Elétricas do Brasil S. A - Eletrobrás* the support for the development of this work.

Towards the Establishment of an Agile Method for OERs Development and Delivery

Mauricio Massaru Arimoto and Ellen Francine Barbosa
University of São Paulo (ICMC/USP)
São Carlos, São Paulo, Brazil
{mauricio, ellen}@icmc.usp.br

Abstract — **Open Educational Resources (OERs) have been emerged as an important mechanism for democratization of access to education. In fact, the free and open distribution of these resources contributes with the dissemination of knowledge and facilitates the access to information, benefiting the society as a whole. Similar to software, the development of OERs requires the application of appropriate methods and practices to ensure the productivity and quality of the resulting products. Agile methods seem to be an interesting approach in this perspective. However, initiatives to foster the development and delivery of quality and reliable OERs, according to agile principles and with reduced costs, are still incipient. In our work we discuss the establishment of an agile method for the development and delivery of OERs. The proposed method is based on the main characteristics, practices and principles of well-known agile methods for software. To illustrate our ideas, the method is discussed in terms of its application in the development of an OER in the FLOSS (Free / Libre and Open Source Software) domain.**

Keywords—open educational resources; open content; agile methods.

I. Introduction

The dissemination of information together with the adoption of computer and communication technologies have provided new ways of thinking, teaching and learning. Thus, issues associated to innovative educational processes are increasingly in evidence, attracting more and more interest from researchers and practitioners around the world.

In this context, the development of OERs (Open Educational Resources) has been widespread and investigated by the scientific community as a way to facilitate the access to education [7], [16]. Essentially, an OER encompasses: (1) *learning resources*, such as learning objects, full courses and educational modules; (2) *tools*, such as supporting systems for the development, (re)use and delivery of learning content; and (3) *implementation resources*, such as intellectual property licenses to promote the publication, reuse and dissemination of the educational content [9].

An important characteristic associated with the development and delivery of OERs refers to the dynamic and evolutionary aspect of knowledge, from which the resources should be continuously evolved in consequence of previous learning experiences. Furthermore, the elaboration of an OER may involve collaborative aspects in which developers, locally or remotely distributed, interact and cooperate to its construction [4].

To ensure that OERs effectively contribute to the teaching and learning processes, it is necessary to use appropriate approaches and methodologies that support the design and development of tasks and associated activities. In this perspective, agile methods constitute an interesting development alternative, providing flexible and suitable approaches for elaboration of products in constant evolution, such as OERs. Nevertheless, initiatives that consider the aspects mentioned above are still incipient.

In our work we discuss the establishment of a method which aims effectively support the agile and collaborative development of quality OERs. The proposed method is based on the main characteristics and practices of agile methods, taking into consideration the intrinsic aspects of OERs development. To demonstrate the practical application of the method, we discuss its adoption in the development of a short course in the FLOSS (Free/Libre and Open Source Software) domain, referred to as FLOSS OER.

This paper is organized as follows. In Section II an overview of OERs and agile methods is presented. In Section III we describe the main characteristics of the proposed agile method for OERs. In Section IV we illustrate the instantiation of the method in the development of FLOSS OER. Concluding remarks and further works are presented in Section V.

II. Background

A. *Open Educational Resources*

According to Atkins et. al. [1], Open Educational Resources (OERs) can be characterized as teaching, learning and research resources that reside in the public domain or have been released under an intellectual property license that permits their free use or re-purposing by others. They include full courses, course materials, modules, textbooks, streaming videos, software, and any other tools, materials or techniques used to support access to knowledge.

The OER movement originated from developments in open and distance learning and in the wider context of a culture of

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

open knowledge, open source, free sharing and peer collaboration [15]. The movement starts from the idea that knowledge is a public good and that technology, and the Internet in particular, provide a great opportunity for everyone to share and reuse this knowledge [8].

The term "open" provides to the user, through a license, permission to perform four main actions (4R) [16]: (1) *Reuse*: the right to use the content in its unaltered/verbatim form (e.g., make a backup copy of the content); (2) *Review*: the right to adapt, adjust, modify, or alter the content itself (e.g., translate the content into another language); (3) *Remix*: the right to combine the original or revised content with other content to create something new (e.g., incorporate the content into a mashup); and (4) *Redistribute*: the right to share copies of the original content, your revisions, or your remixes with others (e.g., give a copy of the content to a colleague).

The dissemination of OERs in higher education depends on many factors, from government initiatives until the effective collaboration of students [17]. Fundamentally, the quality of OERs should be guaranteed [18]. In this direction, there is a need for flexible approaches and methodologies that support the development of effective OERs, with reduced time and costs.

B. Agile Methods

Agile methods have emerged as an alternative to traditional methods, defining a new approach for software development, focusing on agility, flexibility, communication skills and ability to deliver products and services with added values to the market in due time [2].

Similarly to traditional development methods, the main goal of the agile methods is to produce high quality software. However, one aspect that differentiates the traditional from agile methods is that the latter are focused on people and prioritize a fast supply of the system and an effective collaboration of those involved in the project [2], [3].

Among the several agile methods existing in the literature, we can highlight Scrum and eXtreme Programming (XP) as the most well-know and widely used ones. Scrum [12] focuses on planning and project management. It prioritizes work based on business value, improving the usefulness of which is delivered to the customer and increasing their gains more quickly. XP [5] focuses on projects whose requirements are vacant and those changes often. It is based on a set of values and best practices that are mutually supportive in the software development.

III. An Agile Method for OERs development and Delivery

In many aspects of development, the production of OERs is similar to software development. In the case of software, processes, methods and tools have been established in order to contribute to the development of quality software products [4]. Similarly, the use of appropriate mechanisms to ensure the productivity of the development process and the quality of the resultant products are also critical to OERs.

In this section we describe our proposal of an agile method for OERs. The method is based on agile methods for software, particularly Scrum and XP. Besides that, Web 2.0 technologies are also considered as a way to encourage the effective participation of developers and users in developing the OER, also supporting the collaborative and distributed development of these resources. According to Gimenes [18], Web 2.0 technologies can significantly improve the production of OERs and the access to information, besides providing a way to facilitate computer communication and collaboration between educators and learners. There is also an emerging culture of Open Educational Practice which draws in ideas of Web 2.0 technologies [13] to emphasize the social praxis behind of the OERs [6].

Initially, an analysis of the agile methods was conducted in order to verify the main characteristics, similarities and differences among them. This analysis served as the basis for the proposition of the agile method for OERs. From the analysis conducted, we noticed that each method has some particular characteristics. On the other hand, there is also a series of common characteristics shared by them (Table I).

TABLE I. COMMON PRACTICES AMONG THE AGILE METHODS FOR SOFTWARE

Practice	Description
Iterative Development	Occurs in small cycles (sprints or iterations). The goal is to produce and integrate parts of the software constantly throughout development.
Incremental Development	Occurs incrementally through repetitive cycles, adding new features or evolving the features already implemented.
Flexibility	Due to the iterative and incremental issues, the development becomes flexible to accommodate changes in requirements and software design.
Collaboration	Developers, customers and users are involved in the software development. The customer provides quick feedback and facilitates communication among stakeholders.
Testing	Testing is conducted at the beginning of the project and extends throughout the development process.
Planning	The focus is on the continuous and short-term planning, since the degree of uncertainty is much higher in the long-term planning.
Estimative	Estimative are made with transparency and communication. Instead of treating the estimative as facts, it is considered that there an uncertainty in relation to the estimated value for each increment of the software.

It can be inferred that Scrum and XP have different but complementary approaches. While the focus of Scrum is on the planning and project management, XP focuses on the software development practices.

A correlation between practices of the investigated methods was also carried out. Table II summarizes the main practices observed in Scrum and XP. For instance, in XP, the current versions of code are integrated every day in order to reduce integration errors (incompatibility), and to identify implementation errors as fast as possible. In the case of Scrum, the integration occurs only at the end of each sprint (iteration). In XP, developers create tests for each feature before implementing them (Test Driven-Development – TDD). In Scrum, tests occur in parallel with the implementation within the sprint.

The characteristics and practices observed in the investigated agile methods were also used as foundation for the establishment of specific method for OERs. The most important practices from the perspective of OERs were incorporated and adapted to its context of development.

Figure 1 illustrates the sequence of development of the proposed method. In summary, the OER project starts from the needs of the instructor and/or learner (customer). These needs are reflected in resources that are prioritized by the customer during the iteration planning. From this, the development team selects and estimates the resources that are capable of being created during the current iteration.

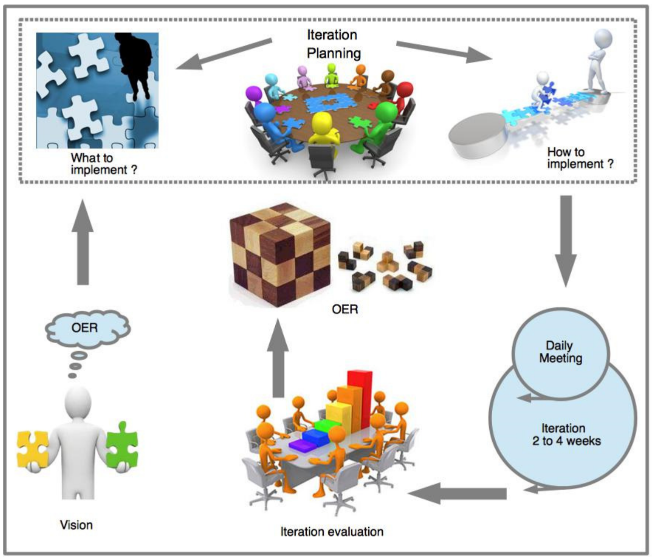

Fig. 1. Agile method for OERs: development flow

The development project is divided in cycles or iterations. Each iteration ranges from two to four weeks. Every day, the team makes a quick meeting to monitor the project progress and present the main obstacles to accomplish the work. At the end of each iteration, the team comes together to evaluate the work done within the iteration. Afterwards, a retrospective of the iteration is conducted to gather lessons learned and improve the next iteration. The process repeats until all resources are met, culminating with the final version of the OER.

The method consists essentially of agile development practices and associated roles. Issues of the collaborative development of OER are considered, including the adoption of Web 2.0 tools. Next, the proposed method is described in terms of its practices, roles and life cycle.

A. *Practices*

Iterative and Incremental Development

The OER development occurs incrementally by short repetitive iterations, which lasts approximately between two and four weeks. Periodically, the customer has the opportunity to use and evaluate the OER release, providing feedback to the development team. A release represents a functional module of the OER that will add value to the customer. New resources and enhancement requests are created as development progresses in the process. The resources are constantly integrated throughout the development until reach a final version of the OER. At the end of all iterations planned for the OER, a stable and robust version to be used and shared with others is delivered.

Collaborative Development

All those involved in the OER project must interact and constantly cooperate throughout development, either personally or through collaborative technologies. Thereby, problems and difficulties related to the specification, modeling and implementation of the resources may be solved more quickly, reducing development time and effort.

Metaphor

The development of OERs usually involves people from different areas (educators, designers, web designers, testers, programmers, among others). Therefore, it is important that the OER functioning be described using a common language and easy to understand (without the use of technical terms). This allows a more effective communication between the various parties involved, as well as assists in creating a simple project for the OER development.

Stories

All resources of the OER are briefly described as stories (into small paper cards), highlighting only the main ideas of each resource. Each story contains an estimative and its priority of creation. To describe the resources, we suggest a very simple format proposed by Cohn [19], which shows the benefit associated with each resource: As an <user/role> I would like to <resource> for <the importance degree of resource for teaching/learning>.

Iteration Planning

In the iteration planning, the team comes together to analyze and decide the set of resources of the OER that must be created within the iteration. The manner in which the work will be conducted has to be planned, as well.

The iteration planning can be divided into two parts. In the first part, the goal is to decide about the iteration target; something that generates value or benefit to the customer. Thereby, the resources to be created during the iteration are defined. Initially, the customer shows the resources according to its priority order, indicating what should be done with each one. Then, team estimates the effort needed to elaborate them and comes into agreement with the customer about what will be delivered at the end of the iteration.

In the second part, the goal is to decide how the work will be conducted during the iteration to maintain a commitment to the iteration target. Team decides how to elaborate the planned resources. In this context, the team divides resources into individual tasks. Once the tasks are established, developers select the amount of work they undertake to develop and deliver at the end of the iteration, and estimate the time (in hours) required to complete them. Thus, it is possible to obtain a detailed plan of what will be created within the iteration.

Daily Meeting

Team members conduct short and daily meetings (15 minutes in average) to discuss the completed work, the main obstacles and problems found and the next work to be performed. Daily meetings are a way to disseminate knowledge and information about the status of the project, allowing continuous monitoring of project progress. Meetings are held personally with the participation of all involved. If a team member is not available, synchronous communication tools (text mode or videoconference) can be used.

Real Customer Involvement

The customer, represented by the instructor, domain expert or instructional designer, actively participates throughout the OER development, being of fundamental importance in the definition and description of resources, as well as in the clarification of related doubts and issues.

Small Releases

Each release of the OER is composed of a small set of resources. First, a release must contain the value-added resources, i.e, those resources that are essential for teaching and learning from the customer's perspective. As development progresses, resources with lower priority are allocated to be created.

Complete Team

The team has a multidisciplinary characteristic, including professionals with different knowledge and skills, such as educators, designers, programmers, among others. Team members work cooperatively, constantly interacting and contributing to the development of effective OER.

Pair Development

Each stage of OER development, including modeling, instructional design, creation and adaptation of the resources, can be conducted by pairs of developers working side by side. This practice acts as a peer review, in which content can be revised constantly at the same time it is created, preventing errors and problems go undetected and being found as soon as possible and faster. It also acts as a way of balancing and dissemination of knowledge among team members, since the pairs of developers are exchanged during the OER development.

Collective Ownership

All team members have access to the various files that compose an OER, including text files, multimedia files and source code. Thereby, any member can make changes he/she consider relevant. However, it is necessary to manage and maintain a repository of versions and run the tests and verifications necessary every time a change is made.

Iteration Evaluation

The development team presents the work performed, demonstrating the OER or the set of resources that have been created. Users and customers have the opportunity to manipulate the OER release to check whether resources are in agreement with what was planned. Based on this, they can identify new perspectives for the OER, request changes and/or the addition of new resources and suggest improvements in a relatively short period of time, minimizing the cost of change. This evaluation occurs periodically to each delivery of the OER release.

Iteration Retrospective

After the iteration evaluation, the team has the opportunity to talk about the project. The aim is to analyze the problems and mistakes to decide what can be done to improve the performance of the next iteration. This retrospective works as a cycle of continuous improvement in which the team collects lessons learned to improve future iterations.

B. Roles

The team must include multidisciplinary characteristics and bring together all the knowledge and skills needed for agile development of OER. In this sense, we defined seven categories of roles, as shown in Table III.

TABLE III. AGILE METHOD FOR OERS: ROLES

Customer/ User	Collaborates effectively with the team, pointing out the problems, needs and key characteristics for the OER. He/she also assists in the understanding of the work to be done. Such role can be represented by the instructor, domain expert and instructional designer.
Project Manager	Manages the progress of the project, solving/minimizing the problems and obstacles faced by the team. He/she also specifies the OERs metadata and defines the validation mechanisms to be adopted.
Instructor Designer	Models the associated resources and designs the OER interfaces. He/she also acts in the validation and verification of the OER.
Instructor	Identifies the instructional needs. Plays a fundamental role in relation to the supervision and monitoring of the OER, helping to identify and record problems and improvements.
Domain Expert	Provides support for the determination of relevant parts and components of the OER, clarifying the main related doubts. He/she also helps in the resource modeling and in the validation of the instructional project.
Developer	Develops the resources associated with the OER, including content editing and integration of multimedia components. He/she also presents to the customer the work done during the iterations. He/she can assume different roles within the team such as instructional designer, tester and programmer.
Tester	Establishes implements and executes the validation and verification activities throughout the development process to ensure the quality of the OER. He/she also assists the customer to prepare the testing for the acceptance of the OER.

C. Life Cycle

The life cycle for the agile development and delivery of OERs is flexible, allowing the team to make changes they consider relevant during the development to optimize the project outcome. The cycle is composed of five phases, as shown in Fig. 2.

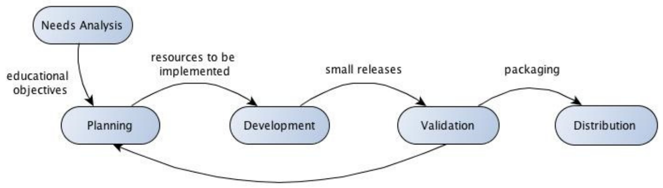

Fig. 2. Agile method for OERs: life cycle

Needs Analysis Phase

In this phase the needs to be addressed by the OER are established, including contextualized and clear definition of the educational objectives as well as the prerequisites and skills needed to use the OER. The resources of the OER are identified and summarized. At this stage, the first terms and metadata for associating resources may already be identified.

Planning Phase

In this phase the basic structure for the development of OERs is established. The resources of the OER are allocated to be created in the current iteration according to their order of priority. Customers and developers prioritize the resources to be implemented and establish the schedule for its creation.

The metadata management strategies must also be defined. The metadata specification should be standardized in order to provide reuse and facilitate the location of OER. The standardization of metadata also allows the use of OER in different educational environments and platforms. Besides that, licensing policies of OER should be defined. The use of open licenses is essential to provide reuse and benefit others users.

Development Phase

In this phase the OER is developed throughout repetitive and shorter cycles. The resources are elaborated through several iterations, culminating with the delivery of functional versions of the OER at the end of each iteration.

OERs can be developed from scratch or by combining existing resources. This phase can be divided in three steps following the development cycle proposed in [14]:

1. *Search* for resources that can adequately meet the needs, by using the Internet through search engines, databases and specific sites or searching materials previously used such as lecture notes, presentations, projects, exercises, assessments, etc.
2. *Create* a new OER in a fully way or combine the resources that were found during the search to compose a new OER.
3. *Adapt* the OER to meet the particular educational needs. In general, the composition of a new OER require adjustments to adapt it to a new context or domain, for example, translate the material into another language, make small fixes, add improvements, etc.

Validation Phase

In this phase the OER is prepared to be delivered for the learning environment. Instructors and learners are involved in the process in order to check how the OER meets the objectives initially proposed.

Extensive evaluating activities and inspections on the OER are needed, considering some quality characteristics such as: accuracy of the content, appropriateness of the content to the pedagogical objectives, resources accessibility for users with special needs, availability/location of the resources, stand-alone resources which can be reused in different contexts, among others.

Distribution Phase

In this phase the OER is available on platforms and repositories. The aim is to provide effective access to the OER according to its context and semantic meaning. The OER is packaged together with the associated metadata, in agreement with packaging standards. Such resources must be delivered according to licenses such as Creative Commons, providing few or no restriction on uses of these resources.

The distribution of the OER can be assisted through Web 2.0 tools, such as microblogging and social networking. The use of technologies such as RSS Feeds is useful to link related educational contents, and facilitate access to this OER. Moreover, media sharing can be accomplished through open tools such as Slideshare, Flickr and Youtube.

Web 2.0 tools, in particular, should be used throughout the process to provide the opportunity for those involved to effectively contribute to the development, making it more collaborative and serving as alternatives for customers/users to describe their needs.

IV. APPYING THE METHOD IN THE FLOSS DOMAIN

In this section we discuss the practical application of the proposed agile method in the development of a short course in the FLOSS domain – FLOSS OER.

Figure 3 shows the conceptual map illustrating the resources planned for the FLOSS OER during the *Needs Analysis Phase*. In this phase we also define the educational objectives, the prerequisites and skills to use the resource and the primary metadata.

The educational objective of the FLOSS OER is to clarify how specific characteristics of FLOSS may affect their use by individuals, companies, and governments. For this, some aspects need to be discussed: (i) problems related to proprietary software, and how FLOSS may become a good alternative; (ii) the emergence of the FLOSS movement, including history and perspectives; (iii) the peculiarities of the FLOSS development and the opportunities and difficulties in the interaction with their community; (iv) some major FLOSS licenses and their implications and consequences; and (v) major business models associated to FLOSS, with examples of successful approaches.

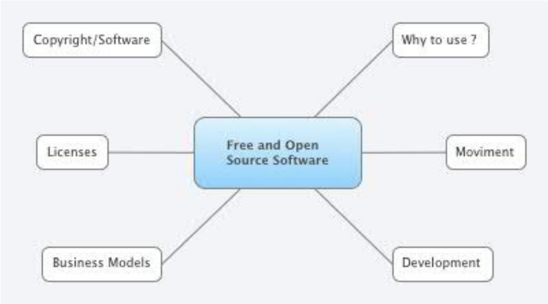

Fig. 3. Conceptual map of the FLOSS OER modules

In relation to prerequisites and skills, FLOSS OER was initially designed for graduate and undergraduate students in Computer Science and correlated areas. Specific knowledge and skills are not required.

In the *Planning Phase* we planned the iterations required to develop the resources, the media components, the metadata standardization and the licenses policies of the resources.

Four iterations were planned for the development of FLOSS OER. Two weeks of duration for each iteration was scheduled. In this paper, we focus on the first iteration planned. Figure 4 shows the conceptual map illustrating the *Licenses* resource, prioritized by the customer to be implemented in the first iteration.

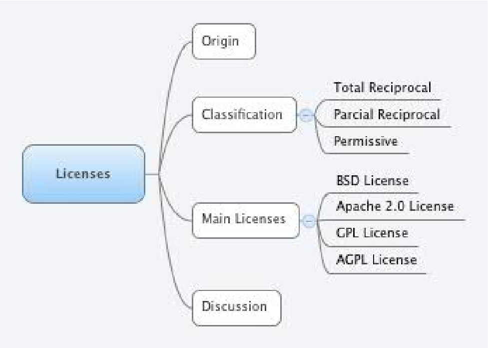

Fig. 4. Conceptual map of the Licenses resource

The *Licenses* resource was divided into small pieces (resources or topics) which were broken into smaller pieces (resources or concepts). It was chosen since licenses correspond to a key aspect regarding the FLOSS domain.

The media components planned to compose FLOSS OER were: text documents, hypertext, slides and podcast/streaming videos.

To formalize the resources description, an open metadata standard was adopted – *Learning Object Metadata (LOM)* [IEEE Standard Learning Technology Committee, 2002]. LOM was selected since it establishes an adequate set of elements to describe educational resources such as OERs. Furthermore, its hierarchical structure allows managing different kinds of metadata. Figure 5 shows an excerpt of the XML file containing the primary metadata for the FLOSS OER.

License policies of the FLOSS OER were defined in accordance with *Creative Commons Licenses* [21]. In this case, the OER will be delivered according to the license *Attribution-NonCommercial-ShareAlike – BY-NC-SA*.

Fig. 5. FLOSS OER: primary metadata

In the *Development Phase*, we firstly searched for open materials which could be reused and adapted to our purpose. Open materials available from the FLOSS Competence Center (CCSL) [20] were used as a basis for developing the FLOSS OER.

Resources, topics and concepts were designed and implemented as a set of slides, integrated to HTML pages, text documents and multimedia files. Figure 6 shows some components of the FLOSS OER and their integration.

To edit the content associated to the FLOSS OER, some open tools were used: (i) *LibreOffice*, for creating the set of slides and text documents; (ii) *LaTeX*, for creating text documents; (iii) *XMind*, for creating conceptual maps; (iv) *SlideShare*, for providing the set of presentation slides; and (v) *Youtube Movie Maker*, for creating and delivering video. To support the communication among the members of the development team, we use asynchronous (electronic mail) and synchronous communications tools as (instant messaging system and videoconference).

In the *Validation Phase* the resources developed in the target iteration were evaluated by two specialists. The produced content as well as the educational goals were taken in consideration. Besides that, customer and users were involved to verify if the resources were in accordance with the objectives initially proposed. Criteria as accuracy and appropriateness of the content to the pedagogical objectives were considered.

Requests for changes and improvements were collected to be implemented in the next iteration. The next activities also include the development of the other resources planned for FLOSS OER.

Although preliminary, the results obtained so far reveal the feasibility of the practical application of the proposed method in the agile development of OERs. The next iterations planned to the development of FLOSS OER should be performed in short-term, acting as a validation mechanism to the method as well.

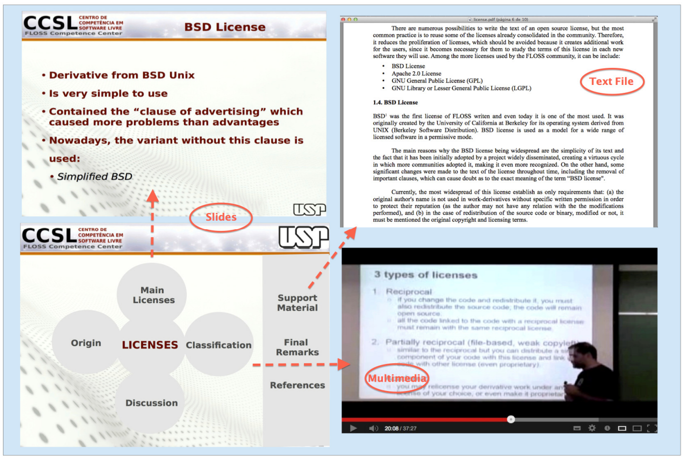

Fig. 6. Components of the FLOSS OER

V. CONCLUSIONS AND FUTURE WORK

In this paper we presented a preliminary version of a method for the agile development and delivery of OERs. The method was based on the main characteristics, principles and practices of agile methods for software, taking into account intrinsic aspects of OER development. The method has been applied (and validated) in the development of an OER for the FLOSS domain. It is worth to notice that the proposed method is also being developed in an incremental way, i.e., according to an agile approach.

The main contribution of this work is to encourage the adoption of systematic and (at the same time) flexible methods to develop and deliver OERs in a collaborative and agile manner. The idea is to create and deliver reliable and quality OERs, capable of being reused in different contexts of teaching and learning.

As a further work, we intend to keep evaluating and evolving the proposed method through the complete development of FLOSS OER. OERs for different knowledge domains should be produced in short term as well.

Aspects related to the distributed development of OERs should be also investigated and incorporated to the method, mainly regarding the geographical dispersion of the involved team. In this context, the monitoring activities and modules that comprise the OER and support for communication between teams are essential aspects to be considered.

Besides that, we intend to investigate the establishment of a repository/platform to support the creation, delivery and sharing of OERs, considering the aspects identified in the proposed method. A detailed analysis should be conducted to identify different tools to be used in order to effectively support the method in the development and delivery of OERs.

ACKNOWLEDGMENT

The authors would like to thank the Brazilian funding agencies (FAPESP, CNPq and CAPES) and the INCT-SEC project (CNPq 573963/2008-8, FAPESP 08/57870-926) for their financial support.

***Abstract*—The demand for digital learning content has been increasing in the last years and the advent of the Learning Objects (LO) concept has the goal of mitigating some of the difficulties related to authoring such kind of digital content, by proposing a reusable model and an open metadata standard classifications for them. Nevertheless, digital learning content authoring is often an expensive and time-consuming task that requires many distinct professional skills. One attempt to overcome it is the adoption of Learning Object Repositories (LOR), in order to smooth LO manipulation experiences for teachers and content authors. Some of its keys characteristics are: to promote LO dissemination and reuse to users in a unified spot; and, to serve LO through flexible searches and enforce a metadata standard classification. This paper proposes an innovative repository model to support LOR and their use in web-based courses in the context of an specific LMS, the Moodle environment. The model is flexible, enhances digital content searches and can be fully integrated with an institutional LMS. Moreover, it offers a social environment for peer evaluation and, more important, information about the student performance, resulting in an efficient evaluation of the available contents.**

Keywords—Learning Object Repository; Learning Object; Authoring; Reputation; Dissemination; Repository and LMS integration; MOOC.

I. INTRODUCTION

The increasing availability of Web based courses has raised some demands in distinct distance learning fields. One of these consequences is that educational digital content production, storage and dissemination is continuously growing. Another related factor is the integration of these materials within *Learning Management Systems* (LMS).

Considering LMS in general, we could say that these family of tools are becoming ubiquitous in education [1], among them Moodle (*Modular Object Oriented Distance Learning*) is one of the most popular, since it is free software with a huge community of developers (http://moodle.org).

However there are several other LMS, some of them free (like Sakai, Claroline and Dokeos), others commercial (like Blackboard and Desire2Learn) [2]. This ecology of systems emerged another important question: "how to distribute learning contents?"

These digital contents have been frequently described by many authors during last years. In a general way, these materials are named by *Learning Objects* (LO) [3] and [4]. It could be found divergent definitions for LO, by usually a LO is a digital content tailored for educational purposes, that can be used, reused and combined for learning in education within interactive learning environments or just mediated by computers.

Nevetheless, LO adoption has some intrinsic issues that must be taken into account. Although the LO undelrying idea is to reduce production cost by cooperation [5], some researches relate several difficulties faced by teachers considering them. Some of them could be cited: *i*) high costs associated with LO authoring; *ii*) time-consuming processes; *iii*) lack of procedures and standards for sharing those materials; and *iv*) negative practical experiences for reusing their materials in an LMS environment [5].

Several organizations and government institutions have proposed and supported researches that aim to overcome these difficulties. Few years ago a new field emerged from these researches, considering LO and repositories, the reason why it was called *Learning Objects Repository* (LOR). One of the main goals of researches that address thos area are interested in facilitating the dissemination and reuse of LO in Web based courses [6], [7] and [8].

The use of LOR has reduced the problem of authoring since it provides for teachers ready to be used content that was already tested for other teachers. These content could be referenced and reused indefinitely to compose new sophisticated materials, from the composition of others LO.

Nowadays, there are a few hundreds of LOR systems, indexed by LOR public directories, like OpenDOAR and ROAR. Some of them are:

- DSpace (http://www.dspace.org);
- Fedora Commons (http://www.fedora-commons.org);
- EPrints (http://www.eprints.org);
- Merlot (http://www.merlot.org);
- Ariadne (http://www.ariadne-eu.org);

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Despite the progress already achieved, there are still a series of barriers that hinder their usage by teachers. Some of them are: lack of integration between LMS used by teachers and LOR systems; high learning curve for users and difficulty for creating packages; and logical dependencies among associated LO [9].

Another difficulty associated with LOR is the big amount of LO available. The teacher must select an adequate content considering the student knowledge and their context.

This paper presents a model to circumvent these problems and the deployment of this model to a particular LMS, the Moodle environment. The proposition is an innovative LOR, named *iRepository* (*Interactive Repository on the Internet*), which can be integrated with Moodle. Besides the usual LOR resource, *iRepository* brings important information from the content use by its users. Since it is integrated with Moodle, it has access to any internal data, including the assessments made by students. From these data it can produce a better evaluation of its LO, informing the teacher, e.g., what are the better ranked questions considering an specific school year of an specific subject.

The *iRepository* intention is to overcome some barriers highlighted before, promoting to the teachers the use of qualified LO. It is an evolution of previous work [10], *iDCR* system (*Interactive Digital Content Repository*). Both of them are integrated with Moodle data and provide reputation and recommendation for both LO and its authors.

Nonetheless, *iRepository* presents an improved method of reputation using the outcomes from the students with any item of the repository. In addition, *iRepository* provides a model to LO versioning [11].

This paper is organized as follows. Section II presents previous work of our research group that is related to the proposed model. Section III shows related work about LOR research field. Section IV exposes *iRepository* proposed model that justify this current work and next, section V presents its implementation supported by Moodle LMS. Last section discusses some possibilities for future work.

II. Previous Work

The research group hosting this project, *Laboratory of Informatics in Education* (LInE), has performing researches about the aforementioned difficulties. In order to increase interactivity while doing an assignment using Moodle environments, it were released the *iAssign* package [12]. On the other hand, to promote the cooperation between teachers it were done a proof of concept of a LOR integrated to Moodle 1.9, named *iDCR* - *Interactive Digital Content Repository* [10].

iAssign is a Moodle package conceived to integrate *Interactive Learning Modules* (*iLM*), that usually are Java applets (Fig. 1) into Moodle. Such integration provides means for Moodle users to have interactive intense experience with the learning content produced with the iLM. *iAssign* is available to Moodle from version 1.9 on and it is distributed as a free software (http://www.matematica.br/ia).

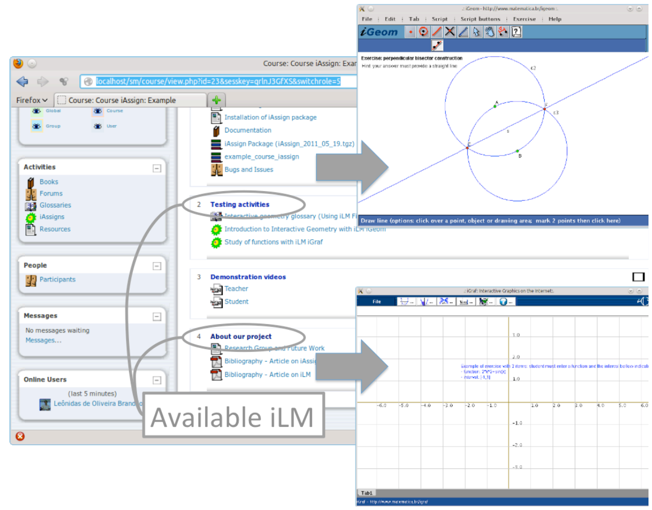

Fig. 1. The *iAssign* interface for Moodle 1.9 linking with two *iLM* (adapted from [12])

The second package, *iDCR*, had no public version made available. It was built to be integrated to Moodle 1.9 and by the time of its deployment, Moodle 2.0 was released and the adaptation of *iDCR* to Moodle 2.0 would lead to a lot of changes. The group leader decided by aborting that project and the *iRepository* is an evolution of *iDCR,* whose implementation is compliant to Moodle 2.0.

The *iRepository* and *iDCR* model allows communication with LMS internal data. This means that it can store LO in any level of aggregation, from a single text to a complete course. Both also provide reputation evaluation functionalities defined by the content's authors.

iRepository extends *iDCR* model in some aspects. The former presents evaluation of each content considering its use. If the content has automatic assessment, some measures could be performed to inform teachers how effective they classified it whenever it has been when used with a specific level of education.

III. Related Work

There are several work related to LOR and associated technologies. An interesting work is MEDUCA (http://gilt.isep.ipp.pt/meduca/) platform and the MELOR (http://gilt.isep.ipp.pt/melor) reposity [13]. The MELOR is based on DSpace and the MEDUCA platform integrates the MELOR repository to a Moodle environment. It is specialyzed in health learning and introduces a new layer of control to manage the submission, indication of referee and aproval to any submited LO.

Comparing this work with our, we could say that they use an external (and existing) repository, integrated to the LMS by web-service communication mechanisms. iRepository is integrated to Moodle and communication between them is transparent. In addition, they do not consider any information related to the student performance while consuming the content stored in the repository. Our proposal provides means for using information related to the student performance, as well as the ones related to the content's author.

The LORSE [14], is a multiagent system based on JADE (Java Agents Development Framework) to support teachers and students to reduce time in the process for searching learning objects in several LOR, such as MERLOT, Connexions, and Fedora Commons repositories. The approach of this work is also to integrate a LOR with the LMS, in this case the authors used the free system dotLRN (http://www.dotlrn.org).

The difference of this work with *iRepository* is the same when considering MEDUCA: they do not use internal information about the student usage of the repository items.

Another related work is [15]. Their goal is to provide information to LO based on crowd knowledge. They extended Fedora Commons repository and integrated it to a web site. In their extension, it is possible to put tag under the standard ISO/IEC 24751 (http://www.iso.org/iso/catalogue_detail.htm?csnumber=41521).

This work integrates the LOR with the learning environment (here a web site), but they do not have or use information related to the assessment of LO.

IV. Proposed Model

Considering Web-based learning, a common difficulty faced by regular teachers after finding suitable LO in a repository is how to integrate an specific LO to their electronic lessons. The proposed model supports most of the international standards for digital content description; it provides means for storing and retrieving LO from several levels of granularity (from a single text to an entire course); it supports versioning control and history tracking of LO; it supports the evaluation of LO reputation based on its use and its author and works as a peer-to-peer service provider. Nevertheless, since it integrates the repository with the internal assessment of an LMS, it has a bridge between the repository and the LMS database which is responsible for several of the provided functionalities.

In order to give some hints about how these functionalities are provided, some of *iRepository* key characteristics are described below:

A. Improved LO classification and searching

iRepository support major international standards addressed for digital contents, such as IEEE Learning Object Metadata (IEEE LOM) and Dublin Core. As a result, *iRepository* search engine will be more accurate. The LO could even be indexed in external LOR that supports same metadata standards, such as Ariadne (http://www.ariadne-eu.org) and Merlot (http://www.merlot.org).

B. Fine and course granularity of LO and dependency control

Since *iRepository* must be integrated to the LMS, an LO can be, for instance, a complete Web course or it could be an atomic LO, such as static texts or interactive activities. It is desirable that teachers could create and organize LO in such a way that they represent a logical arrangement of associated digital contents as a single self-contained package. Ongoing project supports granularity from a single text document to a complete course. It can facilitate author's composition, versioning, and distribution of more complex LO.

C. LO history tracking and versioning control

It's expected that LO contents could change over time – by adding, removing, or updating some of its core files as well as changing their metadata.

iRepository project keeps track of any change made by an author in such a way that all the LO's versions and data histories are automatically tagged and stored in the repository. This information can also be retrieved and checked by authors. They may also create new materials from any previous LO version.

D. LO reputation evaluation by other content authors and by content effective use

Usually a repository provides peer evaluation and reputation for LO and/or its author. This is an important indicator to the LO quality, and could be used in ranking searches: the indicators will be considered in search engines to promote good rated LO to the top of the search results.

In *iRepository*, a more interactive evaluation scheme is provided by the regular use of any item in the repository. This could provide information for accurate recommendation of digital content to a teacher during the search for a specific subject. The recommendation of content is, potentially, based on a large amount of the student experiences. For instance, it could involve: the number of correct answers to the item or mean time used by the students to answer that item.

E. Peer-to-peer service provider

iRepository has an architecture that provides peer-to-peer communication interface between distinct instances of the repository, as a federation of repositories. Any *iRepository* instance not only serves its environment, but also may be configured to exchange data with any other external instance. This feature could even bring new interesting possibilities in future, such as off-site LO backup, network balancing and inter-institutional collaboration projects.

The integration of these features could make *iRepository* an environment propitious to implement Item Response Theory [16]. The questions (or any assignment with automatic assessment) could be used to estimate the difficulty of the question.

V. Implementing The Model

In order to validate the model described in last section, we proposed an implementation prototype, supported by Moodle. There are many reasons for driving us towards the choice of this environment. The primary reason is that Moodle is a free software, allowing anyone to contribute. A second reason is its internal architecture, that is organized in such a way that a contributor can extend several of its features. A third reason is that the Moodle communities of development and of users. Moodle is used in more than 200 countries, by more than 40 millions of users [2].

The Moodle architecture allows a new package to extend some existent features. Usually it could be a plugin, a block or a filter. Mostly, *iRepository* is a Moodle block.

A. *Improved integration with Moodle Modules*

In this project the repository can exchange data with others modules besides *iAssign*, in a generic manner. This means that *iRepository* can register some information useful to evaluation of any of its item (LO). This is very important to promote a better scheme of content reputation. For instance, this can be used to identify a specific content for a specific curricular level or it can help teachers to find questions that present different levels of difficulty.

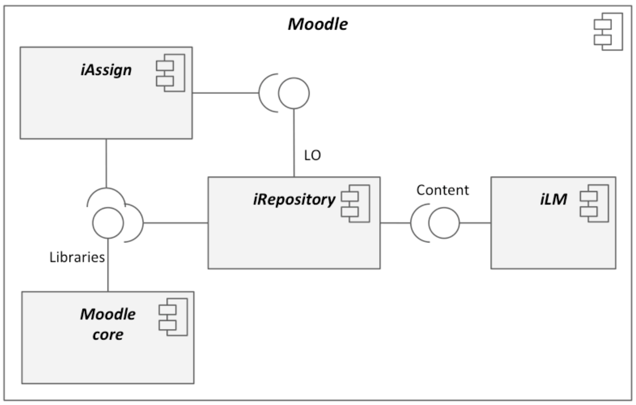

Fig. 2. UML Component Diagram for *iRepository* Moodle Environment

Fig. 2 shows a UML component diagram about an overview integration process between *iRepository* and Moodle Modules, using *iAssign* as an example. The last will act as a LOR client that have just to call repository methods to retrieve, update or store any content. Integration of iRepository with any Moodle package will be simple as is: the implementation of some inferfaces to retrieve, update and store content.

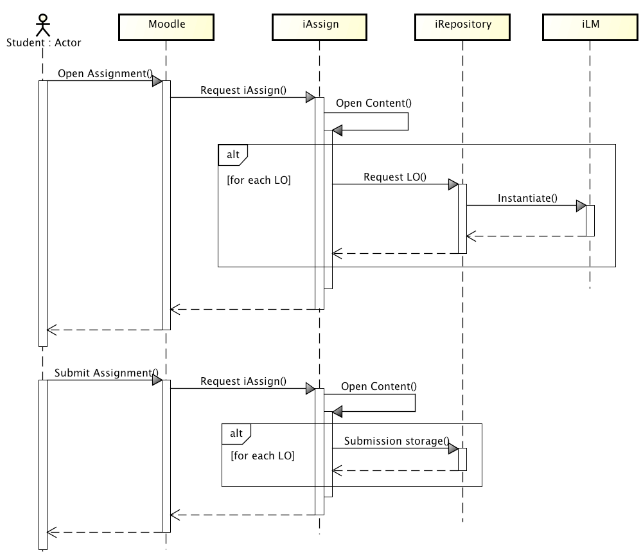

Fig. 3. *iRepository* as a LO provider for an *iAssign* and *iLM* modules

Fig. 3 shows a sequence diagram describing *iRepository* acting as an interface for *iAssign* and *iLM* modules. A student requests a Moodle *iAssign* activity. Each of its LO component (e.g. *iLM* module) is instantiated by the *iRepository* and returned back to the *iAssign*. After its submission to Moodle by the same student, *iAssign* can retrieve again its LO components and store each of them in the *iRepository*. The entire process is tracked and information related to te LO use from several point of views can be collected to be used further.

B. *Smooth learning curve for teachers and content authors*

Seamless interoperability between Moodle and *iRepository* is one of the key benefits of developing this new repository. Teachers and content authors do not have to switch between Moodle and any external LOR (e.g. Fedora Commons or DSpace), nor have to sign-up and login on distinct systems.

The *iRepository* is integrated with Moodle system in such a way that the its user actions can be called and executed through the LMS interface, following a familiar structure to the end user. Considering a regular teacher, not expert in technology, this feature could be sensitive to promote its use.

Authorization module for *iRepository* also shares Moodle user accounts, roles and privileges, so is not necessary to setup additional accounts besides Moodle's. The main interface of *iRepository* is presented in Fig. 4.

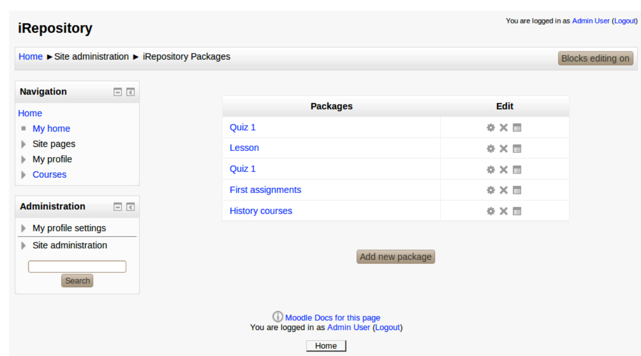

Fig. 4. *iRepository* main interface to Moodle

C. *The MOOC feature*

The previous features of *iRepository* results in interesting features from *MOOC* (*Massive Open Online Course*) besides preserving features of traditional e-learning courses.

Considering that *iRepository* allows the concept of federation of repository, can track the effective use of content item, and that several activities in Moodle allow automatic assessment (including *iAssign*), the proposed repository can leverage Moodle use to a higher position.

It can bring to Moodle's authors a kind of information typically gathered by MOOC: a massive collection of data related to the students outcomes. This data can be transformed into information to improve contents and courses. This kind of approach could be a partial answer to a question by [17]: "At this time MOOCs are fashionable and institutions are flocking into the business. Even though nobody has yet figured out how to make MOOCs profitable or at least financially sustainable". The use of any content item in several courses will provide important information about its quality: when use it? under what level of skills?

Also, it can produce a feasible model to implement *IRT* (Item Response Theory) [16].

VI. Conclusion and Future Work

This paper describes a project related to an innovative LOR that is integrated with Moodle environment, the *iRepository*.

In face of literature about educational authoring content, the *iRepository* was designed to reduce the difficulties of a regular teacher with e-learning environments.

There are several LOR available, each one with a huge number of learning objects. However these LOR environments are rarely used by teachers, e.g., in the last two years, in four courses with teachers or prospective teachers of Mathematics, no one had used a single LO to teach. In two of these courses, all the attendees were teachers with at least two years of experience and had about 15 students per class.

Although the proposed model is platform and system independent, an instance of it has been deployed to Moodle as a plugin. The Moodle was chosen because of its philosophy of open source code and its large amount users. This plugin will be available at Moodle Web page, so any interested user will be able to download and install it.

A future work must be an evaluation the *iRepository* with regular teachers. Another improvement would adopt agents to implement ontologies and semantic networks for accurate search results and interoperability among systems.

Development of Educational Techniques for Computational-Experimental Analysis

Nathaniel Rogers, Kumar Singh and Fazeel Khan
Department of Mechanical and Manufacturing Engineering
Miami University
Oxford, OH USA

***Abstract*— A curriculum wide initiative to enrich course content and increase student engagement in experiential learning through the adoption of new learning modalities is underway in the Department of Mechanical and Manufacturing Engineering, Miami University, OH. The projects entail the development of online learning modules which interweave experimental and computational analysis. The modules incorporate multimedia content which has been prepared with undergraduate and graduate student participation. The ComEx website has been designed to enable easy uploading/updating of material. The distinctive feature of the ComEx studios is the thematic linking of the content which allows them to be used for multiple classes with a progressive advancement in technical content. This paper presents details of the studio model: motivation, methodology, implementation and assessment. The learning modules can utilized by faculty to introduce new lab derived content, which may be related to their research, into a traditional class only course format. Additional benefits of the modules include the ability to independently review specific topics in preparation of advanced courses or for a research project. Assessment of the efficacy of the modules is being performed by students surveys completed online, and by four external (faculty) reviewers. Continuous improvement of the modules is underway.**

Keywords—Learning modules; Matlab; Experimentation

I. Introduction

Miami University has an enduring and nationally recognized tradition of excellence in undergraduate education. U.S. News ranked Miami 3rd for undergraduate instruction among national universities in 2012. Preservation of this heritage has been achieved through the provision of myriad student resources, creation of a vibrant liberal arts culture, and, perhaps most importantly, through the creation of instructional methodologies that are informative, immersive, and permit an exploration of the quintessential *'what if'* ideas during the course of study. One tool the Department of Mechanical and Manufacturing Engineering (MME) has developed in response to this last challenge has been a set of online ComEx studios in five areas (name is derived from the computational-experimental nature of the activities). Each studio is comprised of at least two multimedia learning modules which are to be used in conjunction with MME courses or in research preparation. The project is described in more detail in the following section.

The use of online instructional material in engineering is by no means a novel approach, but it is revealing to examine the format and scope of some existing practices in order to contrast the objectives and methodology of the ComEx project. The use of simulation tools in various subject areas such as fluids, dynamics, and noise/vibration has been demonstrated in [1-3], with more advanced 3-D simulation methods being presented [4] in the context of power systems and manufacturing environments. The provision of various toolboxes and the ability to prepare graphical user interfaces (GUIs) in Matlab has been utilized, as in this project, by other faculty [5, 6] to create interactive learning tools in which the effect of changing various input parameters can be readily explored by students. Simulation tools can also be used to create virtual labs, which can enrich a course by animating and aiding in the visualization of key concepts. Such exercises are essential for sustaining student interest, exciting creativity, and instilling a sense of appreciation of the engineered world. Some examples of virtual labs have been demonstrated by [7-9] in areas such as robotics, materials testing, and mechanics of materials. The incorporation of assessment methods has been highlighted by several authors, see for example [8,10-15], and some significant observations have included a favorable impressions of the ability to complete online modules at one's own pace and the effectiveness of the modules, while some criticism was directed at the inability to receive immediate guidance and lags in virtual lab activities.

The ComEx grouped approach to the deployment of learning modules stands in contrast to the single course module structure seen in the majority of the aforementioned studies. Each studio serves as a repository for a group of courses which can be connected along thematic lines across the curriculum. An additional distinguishing trait is that the learning modules within each studio are structured such that students are introduced to a given experiment and provided several sets of emerging data which are then used towards the testing of analytical models associated with the experiment. This paper presents a brief outline of the five studio areas using the Materials studio as an example. The section following that is devoted to an explanation of the assessment process and its application towards continuous improvement of the modules focusing on the deployment of an interactive Java based applet as a case in point. Details of the assessment process and some significant findings have been included. The paper concludes

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

with a discussion of the modifications planned for future semesters.

II. Project Structure

The ComEx project, projecting a two year development plan (key components being: creation of modules → assessment → revision), was initiated with support from the NSF-TUES. The motivation for the project emerged from a departmental student questionnaire which was designed to gather information on the level of student competency in being able to select, apply, and validate mathematical models against experimental data. Such skills are essential in myriad fields of engineering such as dynamics, thermodynamics, fluids, and manufacturing to name just a few, to ensure that product design and performance can be optimized by computer simulation methods while minimizing often prohibitively high experimentation costs and process lead times. This theme of computational-experimental juxtaposition established the guidelines for the organization, content, and presentation of the ComEx project. Key features of the project include:

1) Thematic grouping: The five ComEx studios are titled, i) Computational Core, ii) Design and Manufacturing, iii) Thermo-Fluids, iv) Materials, and v) Dynamics, Vibrations and Controls. With the exception of the Computational Core, all of the other studios feature a set of learning modules that span a set of courses. The Core studio has been populated with several tutorials and examples in a variety of mathematical platforms which students can adopt in their analyses. The ComEx homepage is shown in Fig. 1.

2) Longitudinal Utilization: The learning modules within each studio draw upon content from specifically selected courses. For example, the Materials Studio serves as an umbrella for the sophomore level Engineering Materials, the junior level Mechanics of Materials, and senior/graduate level Advanced Mechanics of Materials courses. The activities are designed to progressively introduce more advanced concepts and allow students to build upon previously learned concepts.

3) Content Expansion: The ComEx studios are designed to augment courses that lack a lab component by affording instructors the ability to use the multimedia content to familiarize students with specific experimental processes. The Materials Studio provides details of composite sample preparation and a video of the tensile testing performed to characterize the deformation properties. The data from multiple such tests is made available for download and can be used for various types of analyses.

Fig. 1. Image of the ComEx homepage.

III. Assessment

This section provides an overview of the project assessment mechanisms, and an example of how some of the first cycle assessment data has been used to implement changes to the project in preparation for the second cycle. The Ohio Evaluation and Assessment Center [16] at Miami University was contracted for creating and administering surveys in collaboration with the faculty using the studios. Input has been gathered from the following two sources.

1) External reviewers: Four senior faculty with prior experience in pedagogical research have served as external reviewers on this project. After completion of the first round in Fall 2012, a second round of assessment will be conducted in Fall 2013.

a) Process: The reviewers were provided student survey data from the first semester the ComEx studios (Materials and Dynamics/Vibrations) were used in MME courses. The two reviewers who visited the department also spoke with several students who had completed the learning modules, as well as the students involved in their preparation. Furthermore, they were asked to review the modules which had thus far been brought online, and complete a 25 question survey (with space for comments) which addressed various facets of the project. In addition to high priority characteristics associated with content delivery, user engagement etc, the questionnaire probed for evidence towards the attainment of the following outcomes:

- Recognize engineering concepts within multidisciplinary fields
- Apply knowledge of engineering and mathematics.
- Prepare systematic methodology for testing hypothesis.
- Select and utilize specific numerical approaches for simulating physical systems and phenomena.
- Engage in independent learning and research.

Some of these outcomes enable the fulfillment of certain ABET program accreditation requirements, thereby, incentivizing their adoption by departments and encouraging their use across the curriculum.

b) Findings: A sampling of the questions and results from the reviewer survey are provided in Fig. 2. The data in general suggested good progress towards the attainment of the project goals, and the comment, "ComEx would seem to be a nice environment that helps extend across curriculr borders such that one could begin a project or problem in one class, that can then be used in othe courses," captures very well the aspiration of the ComEx studios to be interwoven into the engineering curriculum. Two of the key reviewer suggestions pertained to making the student experience more interactive, and making the user experience more consistent across the various learning modules. Details of the efforts directed at fulfilling these requirements are presented in Section ABC to demonstrate continuous improvement through the use of assessment data.

2) Students: Online student self-assessment surveys based on their experience in completing a learning module(s) have been conducted each time a module has been used. The process began in Spring 2012, however, at that time the project website had not been completed which engendered a tepid response vis-à-vis the clarity and cohesiveness of the activities. An improvement of scores in these categories is anticipated.

a) Process: The online surveys are designed not only to elicit data for a given module, but sections of the form gather longitudinal data to gage the cumulative experience as students advance to higher level courses. In Spring and Fall 2012, 55 and 26 students, respectively, in a 200-level materials course responded to the survey. Data in other studios has been collected as well, but the presentation and discussion of data in this paper has been limited to one studio for brevity.

	Strongly Disagree	Disagree	Undecided	Agree	Strongly Agree
The ComEx exercises/activities will improve students' understanding of the technical processes and approaches related to the module content.				2	1
The ComEx exercises/activities require students to review and/or apply previous learning from other engineering courses.				1	2
The ComEx exercises/activities will improve students' skills in using computational tools (Finite element software, Excel, MATLAB, etc.).				1	2
The ComEx exercises/activities introduce students to computational or experimental technology that may be unfamiliar to them.			1		2
The ComEx exercises/activities will strengthen students' interest in the content of this module.			1	1	1
The ComEx exercises/activities provide access to the learning modules within the institution and enable utilization by other institutions.				3	

Fig. 2. Excerpt from the reviewer survey form. The numbers indicate the responses received from three reviewers. Data from the fourth reviewer was not available at the time of this writing.

b) Findings: Some representative data from the 29 question form is shown in Figs. 3 and 4. As stated in the Project Description section, an important feature of this project was the introduction of new content in an independent learning format. In the context of the materials learning module, this meant learning about the preparation, testing, and analysis of composite materials. It is reassuring to see in the data that students were able to recognize this characteristic of the assignment. Mirroring the observation of the external reviewers, several students also suggested a more streamlined incorporation of supporting images and improved clarity in the instructions.

IV. Continuous Improvement

An example of the use of assessment data for introducing changes to the assignments can be seen in the development of new Java applets.

		Level of Agreement				
		Strongly Disagree	Disagree	Unsure/Neutral	Agree	Strongly Agree
a.	This ComEx module improved my understanding of the technical content necessary to be successful in this course.	SD	D	UN	A	SA
b.	This ComEx module improved my understanding of the technical processes and approaches related to the course content.	SD	D	UN	A	SA
c.	This ComEx module required me to apply previous learning from basic science (physics, chemistry and mathematics).	SD	D	UN	A	SA
d.	This ComEx module required me to apply previous learning from other engineering courses.	SD	D	UN	A	SA
e.	This ComEx module improved my skills in using computational tools (Excel, MATLAB, etc.).	SD	D	UN	A	SA
f.	This ComEx module introduced me to current or emerging computational or experimental technology that were unfamiliar to me.	SD	D	UN	A	SA
g.	This ComEx module strengthened my interest in the content of this course.	SD	D	UN	A	SA
h.	This ComEx module provided the opportunity to learn and apply new concepts (experimental and/or computational).	SD	D	UN	A	SA
i.	This ComEx module provided the opportunity to review content I had previously learned.	SD	D	UN	A	SA

Fig. 3. Section of student survey form.

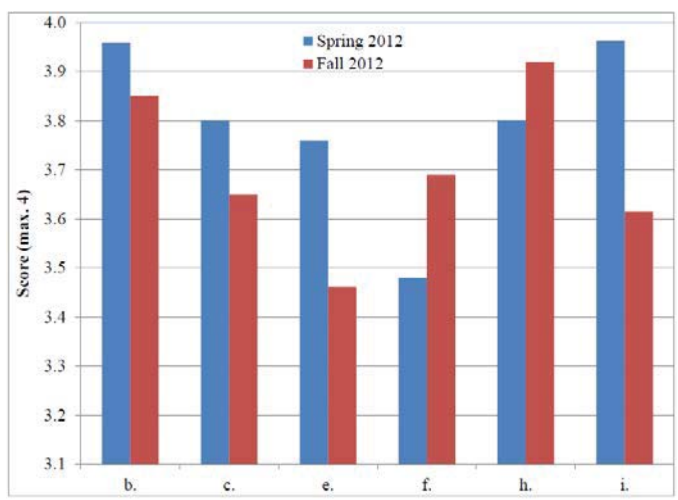

Fig. 4. Results of student survey (Fig. 3) for Composite Materials Characterization learning module. Data from six questions most relevant to the discussion presented here has been illustrated.

With the aim of making the modules more interactive, as suggested by the reviewers, and enabling students to investigate the effect of various parameters on process/model output, a simulation tool with a graphical user interface (GUI) has been developed for the Composite Materials Characterization module in the Materials studio. An image of this GUI is shown in Fig. 5. Students can change materials, from fiberglass to carbon fiber for example, and immediately perform a comparative analysis. For more advanced analyses, typical of a senior level course in advanced mechanics of materials or behavior of materials, a more advanced deformation modeling GUI is shown in Fig. 6. Both of these will be bundled into the Materials studio learning modules to achieve vertical integration of content.

In light of the intent to disseminate the ComEx content to other institutes, the development of the GUIs is also worth mentioning on account of the nature of the method of deployment. A GUI developed in a specific mathematical software typically requires local availability of that software for execution.

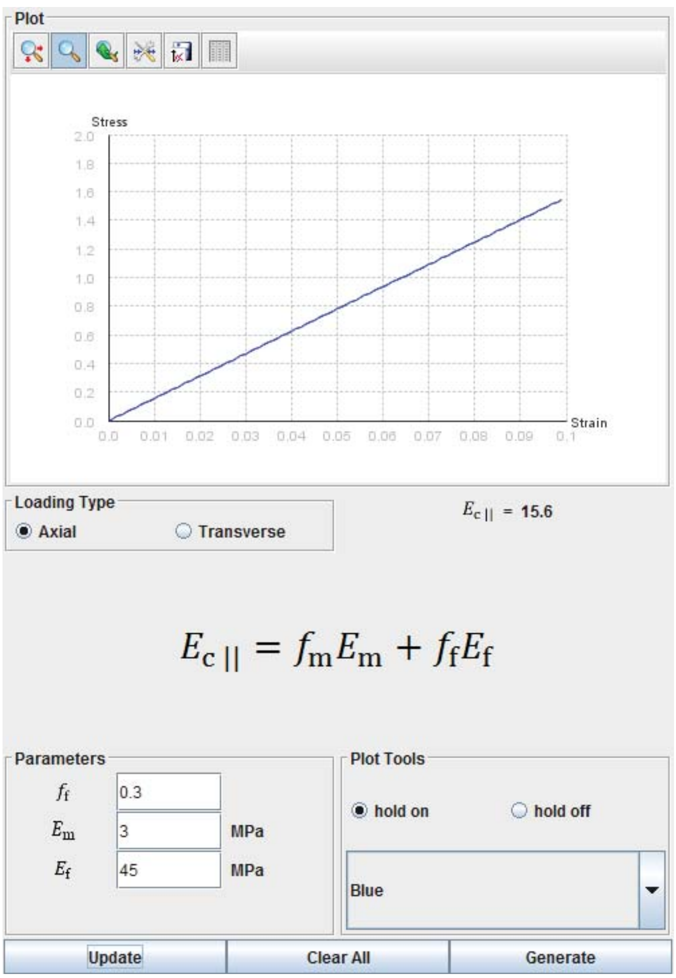

Fig. 5. Screen-capture of the Java based composite simulation tool.

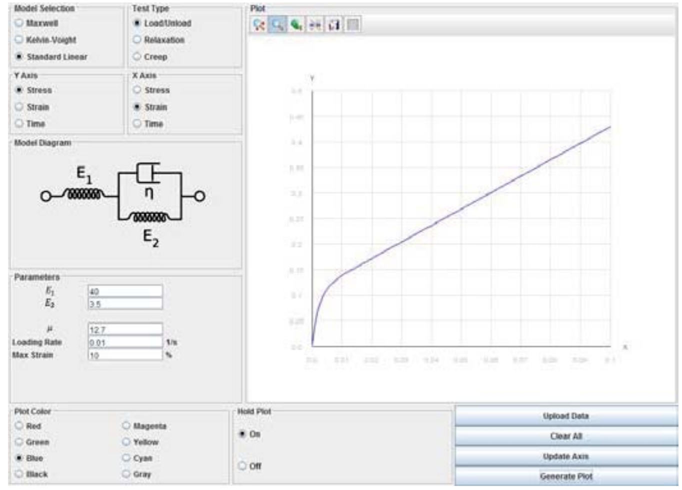

Fig. 6. Image of more advanced Java based interactive material property simualtion tool.

Since institutional preferences for software for faculty and research needs vary greatly among institutes, development of a universally operational GUI must shed it reliance on a specific software. Therefore, the preparation of the GUIs shown in Figs. 5 and 6, which even entails the solution of a first order linear differential equation, has been accomplished in a Java applet format which can run directly off the webpage. However, it is pertinent to add that more complex mathematical formulations (coupled or higher order differential equations etc.) may not be amenable to reduction to this environment, and the simulator shown in Fig. 7 does require the use of Matlab. The Java based GUIs can be used in sophomore and senior level courses in materials science and mechanics of materials, while the Matlab based tool is best suited for graduate students or use in research.

Other revisions to the modules include changes to the instructions, inclusion of more data sets for comparative studies, and greater consistency in style among the four subject specific studios.

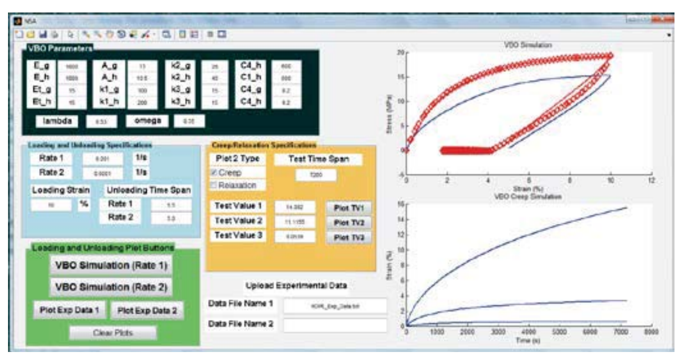

Fig. 7. Matlab based GUI enables determination of material parameters by enabling experimental data to be uploaded and juxtaposed against the numerical output. Multi-function capability allows various tests and experimental parameters to be input into the model.

V. Conclusions

The ComEx project was launched to address the need for greater proficiency in the use of computational methods in design and/or process analyses in areas of industrial significance. The computational methods are investigated in tandem with experimental data and packaged as learning modules with specific subject themes designed to allow progressive utilization across the curriculum. The learning modules have been found to be effective vehicles for the introduction of new content. A regular internal and external assessment process has been used to improve the quality and efficacy of the learning modules. Future work will comprise of increasing the number of learning modules, improving student interaction, and focusing of dissemination tasks.

***Abstract*— In this paper, authors apply the Linked Data Design Issues to describe and retrieve information that is semantically related to open educational resources related to the Engineering Education, that are accessible via the OCW Higher Institutions. Linked data have the potential of create bridges between OCW data silos. To assess the impact of Linked Data in OCW, the authors present an interface of faceted search for open educational content. The authors demonstrate that OCW resource metadata related to engineering open courses can be consumed and enriched using datasets hosted by the LinkedOpenData cloud.**

***Keywords*— OpenCourseWare; Open Educational Resources; OCW; OER; Linked Data; Faceted Search Engine; Serendipity; LOCWD**

I. INTRODUCTION

The key idea the Open Educational Resources (OER) movement is that open educational content should be maximally shared [1]. Heterogeneity leads to problems of interoperability and accessibility of open content among institutions and within them. The lack of interoperability shows some disadvantages in the discovery, reuse, re-mix and adaptation of OER. OER Community must find a way to exchange quick and easy access to open educational materials.

Materials in OCW repositories are not usually described by metadata. Heterogeneity leads to problems of interoperability and accessibility of open content among institutions and within them. The lack of interoperability shows some disadvantages in the discovery, reuse, re-mix and adaptation of OCWs. OCW Community must find a way to exchange quick and easy access to OER.

Considerable work has been devoted to increase the interoperability between Learning Object Repositories that rely on different metadata schemas e.g. IEEE LOM. However, learning object metadata is typically not linked across repositories and not is possible navigate or interoperate between different data sources available on the Web. In this work, this problem is addressed through Linked Data by that describes how linked data has been integrated to data extracted from OCW repositories to navigate OCW resources.

Based on the perspective of Linked Open Data, free open OCW data also fosters interoperability and creates a basis on which the use, re-use, remix, and adaptation of open educational tools or commercial applications can be built more easily. In Section 2, we describe the OpenCourseWare domain, and the notions of Linked Data and Linked OpenCourseWare Data Vocabulary, which ensures that an OER of type OCW can be safely discovered and reused. In Section 3, we present Serendipity, our implementation as well as an experimental evaluation of it. Finally, in Section 4, authors present the conclusions.

II. THE OPENCOURSEWARE DATASET

A. Data Source and Coverage

There is not a standardized way to implement OCW initiatives. The internal organization, structure and technological infrastructure of an OCW project are diverse, and respond to the vision of each university. Current OCW initiatives are Silos of OER. These silos of OER have no way to link to a particular item, and so hinder the free flow of information [8]. In this respect, OCW data is locked away in independent data silos, making it much less useful than it could be.

In this work, the data source is provided by higher education institutions associated to OCW Consortium (www.ocwconsortium.org/) and/or OCW – Universia (ocw.universia.net/).

Our dataset contains data about the main OCW concepts: (i) OER, the OER are teaching, learning, and research resources that reside in the public domain or have been released under an intellectual property license that permits their free use or re-purposing by others. (ii) OpenCourseWare, OCW is a type of OER.; (iii) repositories that contains OER and OCW courses; (iv) educational organizations; (v) users, creators or authors; (vi) branch of knowledge to which an OER belongs; and, (vii) open licenses or similar license that generally allows more liberal use, reuse, redistribution, re-mix and adaptation than a traditional copyrighted work.

B. Use of Linked Data from OCW content

Semantic Web technologies and, more precisely, Linked Data are changing the way information is stored and exploited. [5, 6]. The term "Linked Data" refers to a set of best practices for publishing and connecting structured data on the Web [4]. In summary, the Linked Data Design Issues, outlined by Tim Berners-Lee back in 2006, provide guidelines on how to use standardized Web technologies to set data-level links between data from different sources [3, 7].

The motivation behind creating the Linked OpenCourseWare Data (LOCWD) is threefold [9]: *Firstly*, data about OCW resources such as those stored in the Serendipity system are important for Educational decision makers, teachers, self-learners and other interested persons. We are particularly interested in courses related to engineering (see Table I and Table II). *Secondly*, although there are several open educational datasets, none provide the level of details that LOCWD does, nor are they available as linked data. And, *thirdly*, the current technology solutions used by OCW and OER sources are limited to offering data via diverse Web pages (not as raw data, but as embedded data within web pages) and very few services through APIs.

The selected open educational content were converted to Linked Data using the LOCWD vocabulary [9]. The resources described in Linked Data/RDF were stored in a RDF-Store. At this point, each resource was identified by a URI with a dereferencing option, and thus display the results retrieved as Linked Data.

III. CURRENT USAGE

It's difficult to develop tools for consume data from multiple OCW silos. Searching OCW/OER across multiple silos means invoking each one's user interface, and receiving the results in separate groups. This severely impedes the development of applications to OER/OCW that wish to combine data from different sources. However, the use of linked data approach on OCW repositories provides the framework for its evolution into a more interoperable and integrated system to sharing, connecting and discovering data and metadata of OCW initiatives.

The authors have personalized a faceted search engine that consumes data from LOCWD: Serendipity. The first version of Serendipity is based on flamenco.berkeley.edu. With Serendipity we explore the potential of LOCWD in supporting discovering process to give assistance to use, reuse and remix OER and OCW resources. See fig 1.

A. *Serendipity a Faceted Seach for OpenCourseWare Content*

Serendipity is an interface of faceted search accessible from http://serendipity.utpl.edu.ec/. It is based on data extracted from OCW sites. Serendipity provides a search interface for allowing users to browse OpenCourseWare content in such a way that they can rapidly get acquainted with the scope and nature of the content, and never feel lost in the data. This interface exposes OCW metadata in such a way that users can build their queries as they go, refining or expanding the current query, with results automatically reflecting the current query. This interface also combines free-text search, it avoids complex search forms.

Faceted search, also called faceted navigation, is a technique for accessing content organized according to a faceted classification system, allowing users to explore a collection of information by applying dynamic and multiple filters. A faceted classification system classifies each information element along multiple explicit dimensions, enabling the classifications to be accessed and ordered in multiple ways rather than in a single, pre-determined, taxonomic order.

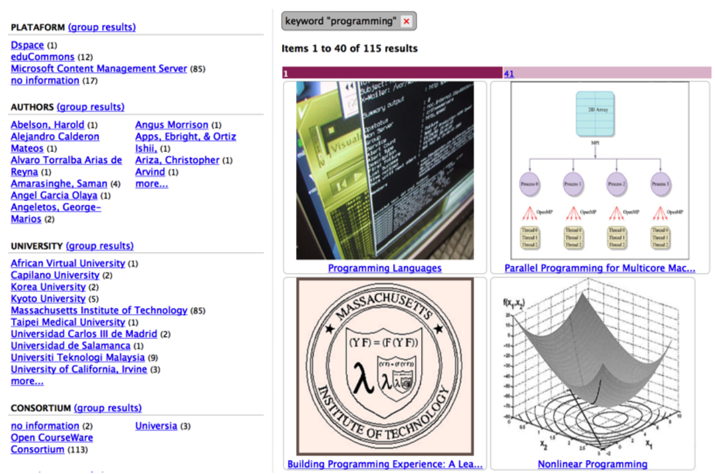

Fig. 1. **Explore OCW in an integrated and incremental manner**, from any of the repositories of institutions that publish OpenCourseWare.

B. *Data and Facets in Serendipity*

In Serendipity, facets correspond to properties of the OpenCourseWare content.

Any of the following cases might prompt to a teacher, student or self-learner to use Serentipity faceted search: (i) Users need to filter content using multiple category or taxonomy terms at the same time. (ii) Users want to combine text searches, category term filtering, and other search criteria. (iii) Self-learners don't know precisely what they can find on OCW site, or what to search for. (iv) Self-learners want to clearly show users what subject areas are the most comprehensive on your site. (v) Self-learners are trying to discover relationships or trends between OCW. (vi) OCW sites has too much content for it to be displayed through fixed navigational structures, but you still want it to be navigable. (vii) Self-learners want to use a faceted classification because a single taxonomic order or a single folksonomy is not suitable or sufficient for OCW content. (viii) Users often get empty result sets when searching your site. (ix) In cases that "advanced" search forms are not fun to use.

Fig. 2. Link from current OCW in Serendipity To Other LinkedData Source

C. *Navigation of OCW engineering courses*

In the search of OCW courses related to engineering, Serendipity demonstrates the following key features: Grouping search results by facet, displaying a total number of OCW per facet value, refining search results by facet value, update of the facet menu based on refined search criteria, displaying of the search criteria in a Bread Crumbs (navigation guides), ability to exclude the chosen facet from the search criteria, ability to improve ease of discovery open academic resources, ability to improve ease of consumption and reuse of OCW. ability to reduce redundancy in search of OCW, and Connect OCW Data with LOD data. Querying DBPedia, authors obtained additional information about universities such as name in different languages, label, comment, latitude, and longitude. From Geonames were extracted data about locations like continent, country, capital, city or state. To find and create external links, in this work were made directly SPARQL queries (see Fig 2). With Serendipity, we demonstrated that OCW resource data can be enriched using datasets hosted by the LinkedOpenData cloud.

We have verified that the data published in Serendipity is consistent and corresponds to the information obtained in various OCW sites and OCW Consortiums.

IV. Conclusions

The key idea the OER and OCW movement is that open educational content should be maximally shared. Any open educational data initiative should focus on providing data access permissions so that: provide non-discriminatory access/use/reuse/create derivate works/adapt/share to raw data, information and knowledge about the educational resource.

A lot of open educational resources ends up focussed on usage of open licenses, but not enough attention is paid to structure. Simply putting educational resources online under an open license is obviously not enough. Doing open educational resources data well depends on releasing key datasets in the right way. Moreover, with the proliferation of OCW/OER sites it has become increasingly hard to discovery and track what is happening in Open Educational Context.

In summary, we have shown that our implementation provides better results than other similar systems. Besides, we have also shown that our implementation, which benefits from linked data technologies, can be more appropriate to deal with interoperability and integration of OCW repositories.

Acknowledgment

This work has been partially funded by Madrid Regional Government through the project eMadrid (Ref:S2009/TIC-1650) 'Research and Development for e-learning technologies', Universidad Técnica Particular de Loja and scholarship provided by the "Secretaría Nacional de Educación Superior, Ciencia y Tecnología" of Ecuador (SENESCYT). ***Abstract*—We use the "borderlands of education" as a metaphor for studying processes of educational exclusion in engineering and the social forces that create them. Latinas in engineering education occupy intersecting borderlands. On the path to higher education, they face numerous societal obstacles. As women, they are on the margins of the masculine space of engineering. Though Latinas in engineering comprise a very small group, through their voices and experiences, we illuminate broader structural problems within engineering education.**

Keywords—Latino; Latina; Hispanic, engineering; underrepresented minorities, women in engineering

I. Introduction

We use the "borderlands of education" as a metaphor for studying processes of educational exclusion in engineering and the social forces that create them [1]. Latinas in engineering education occupy intersecting borderlands. On the path to higher education, they face numerous societal obstacles resulting from a legacy of racism. As women, they are on the margins of the masculine space of engineering. Though Latinas in engineering comprise a very small group, through their voices and experiences, we illuminate broader structural problems within engineering education.

How do Latino and Latina students navigate engineering education? We examine quantitative data to illuminate trends among Latinos and Latinas in engineering education. Using a large longitudinal data set with comparative information by race/ethnicity, we report six-year graduation rates disaggregated by ethnicity and gender. Similar to other researchers who examine retention longitudinally, we found that the paucity of Latinos and Latinas in engineering is related to recruitment more than retention. Our data shows that Latina transfer students are particularly successful and that geography and institution type affect academic persistence.

How do Latinas describe experiences of belonging in engineering education? We draw on qualitative research to examine the experiences of Latina students in undergraduate engineering education. We use the framework of "microagressions" in our analysis and describe how Latinas form counterspaces within the borderland of engineering education. This qualitative research, incorporating the rich, detailed perspectives through the women's voices, adds value to our understanding of the quantitative reality of engineering as a segregated space in academia.

Is there potential for radical change in engineering education? What might radical change look like?

II. Methods and Contributions

A. *Studying Engineering Education: Problems of Aggregation*

Research in STEM education tends to conflate racial/ethnic categories, aggregating and constructing a category called, "minorities". Disaggregation for social analysis, particularly in STEM higher education, is often difficult by discipline, because of the low population numbers. Much nuance, however, is lost in the aggregation of social groups. A notable example of the power of a single individual's story is the work of Foor, Walden, and Trytten [2] who described in-depth the story of female, multi-minority engineering student from a socio-economically disadvantaged background. In a similar methodological vein, Riley and Pawley [3] explore the experiences of a lesbian Latina engineering minor to critique myths of gender and race in engineering education.

In general, there is a paucity of disaggregated data on underrepresented groups, especially women of color, in STEM. Most studies aggregate by group, for example considering "women" or "underrepresented minorities," thereby assuming all women or all African Americans and Latinos share the same educational experiences. Because there are deep limitations to using a single category of analysis, feminists suggest the need to use an intersectional approach to best understand the multiple positions that combine unique gendered, racialized, social class, and sexuality perspectives that individuals inhabit [4]. An intersectional approach does not gloss over differences; rather, such an approach considers that not all women, for example, share the same experiences. The core of the intersectional paradigm suggests that relations of power are central in defining identities, and that identities may shift.

Similarly, many excellent studies also aggregate by field combining Science, Technology, Engineering, and Mathematics into STEM [5, 6], to the exclusion of studying a single discipline in depth. While there are important

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

methodological and theoretical arguments for aggregating these fields (because of shared foundational course requirements, or because of historical similarities in these disciplines), there are also disadvantages. Aggregating by discipline can lead to hollow findings due to a lack of specificity. Glossing over differences buries diverse intracultural differences by discipline, leading to a silencing of voices that ultimately hampers our ability to understand the social positions of those on the border in engineering education. Engineering education is uniquely different from other categories aggregated in STEM.

B. *Importance of mixed methods*

One of the primary reasons that a book on the topic of Latinas in engineering has not been produced to date is because of the low numbers of women in the field of engineering, preventing systematic data analyses. Our large, multi-institution, longitudinal dataset provides quantitative data allowing us to disaggregate by race and gender. For the qualitative data collection, we used focus groups, given that this methodology provides rich descriptions of the participants' shared experiences. We focused on one large public university with a fairly diverse student body so that we could identify sufficient numbers of women of color in engineering and we used a case study approach to allow for intensive analysis [7, 8]. Together, our analysis of the voices of Latina engineering majors, obtained by our focus group research, breaks new ground in the literature on STEM education and provides an exemplar for future research on subpopulations in these fields.

III. Key Findings

A. *Quantitative*

Among Latinos and Latinas the proportion of bachelor's degrees awarded in engineering in the U.S. has marginally increased between 1991 and the present [9]. Of all engineering degrees earned in 2005, for example, 7.2% were awarded to Latinos and Latinas [10] and increased to 8.0% in 2010 [11]. Latinas have made gains in engineering, from comprising only 4% of the Latino engineering population in 1977 to 25% in 2005.

A serious issue in research on underrepresentation is the lack of data-driven studies. Although there is no national, longitudinal data for academic persistence tracking the trajectory from matriculation to graduation among Latinos, the Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD) [12, 13] database provides a unique resource for investigations of this type at ten institutions. MIDFIELD includes records for more than 130,000 first-time-in-college (FTIC) students matriculating in engineering and over 40,000 transfer students articulating in engineering at eleven U.S. institutions with nine of these in the Southeastern U.S. Race and ethnic categories are student-selected from institutional records. Results from the study of the MIDFIELD database are expected to generalize to the same type of institutions, large public universities with above average enrollment of engineering students, and therefore are relevant to institutions producing most engineering graduates nationally [14]. Since this dataset includes whole population data, statistical inference is unnecessary—all reported differences are accurate for the institutions and subpopulations studied.

Of the total MIDFIELD population, this analysis focuses on the over 84,500 FTIC students and over 27,500 transfer students who have sufficient data to calculate six-year graduation rates during the period from 1987-2010. Graduation is defined as having graduated by the sixth year from matriculation, following a standard of reporting by the Integrated Postsecondary Education Data System (IPEDS) [15].

The MIDFIELD data set allows for the examination of longitudinal trends over time, however, the former trajectory of transfer students (prior to entering a MIDFIELD institution) is unavailable. MIDFIELD permits analysis of transfer students once they enter a MIDFIELD institution and no information is available about a student's previous major. A student's progress is measured from a curricular progression standpoint to estimate how long they took to graduate. For example, if a transfer student comes in with sufficient credits to begin taking junior level courses and finishes in three years at the MIDFIELD institution, the student would be considered to have an effective five year time to graduation.

Note that this dataset permits calculation of true graduation rates following the same students from matriculation to graduation. Such calculations are not possible with other datasets such as that of NSF that provide enrollment and graduation data for given years but provide no way to track individual students.

B. *Recruitment, Not Retention, is the Challenge for Latino Engineers*

Latinos and Latinas who enter engineering education persist (i.e. do not switch majors or drop out) at numbers comparable to Whites and Latina transfer students are the most successful of groups. Table 1 shows the number and percentage of engineering matriculants and transfers who graduate in six years in Engineering. Of all Latinos who matriculate in engineering, 50% of the women and 48% of the men graduate in six-years. This exceeds the overall six-year graduation rate of 46.9% reported for FTIC Latinos in all majors at public four-year institutions in the U.S. by College Board College Completion Agenda: Latino Edition [16].

Often originating at community colleges, transfer students provide a potential source of many engineers and a more diverse population of engineers [17]. This potential is particularly true for Latinos in our dataset where 40% of the Latino students who are ever engineers are transfers, higher than the 30% for White students. For comparison, in national data from the U.S. Department of Education, in Fall 2007, 34% of White and 40% of Black college students were in community colleges while 51% of Latino college students were in community colleges [18]. As seen in Table 1, the high graduation rates of engineering transfer students may be due to these students having already successfully passed many lower division courses. Transfer students have firsthand experience with the rigorous curriculum of the major; they have already surmounted many hoops, are more knowledgeable about the major, and thus more invested in a commitment to success.

Latino transfers in engineering are particularly successful. Latino males have graduation rates in engineering only surpassed by Asian males. Latinas, are the most successful among all transfer students, having the highest six-year graduation rate in engineering. This success may be related to what several researchers describe as the “personal agency, or internal drive”, of women of color in college that contributes to their persistence [19] including Latinas in information technology [20] and Chicana and Latina transfer students in science and math [21]. Valenzuela called this "mi fuerza" or "inner fire to succeed" [19, p. 88].

TABLE I. NUMBER AND PERCENT OF ENGINEERING MATRICULANTS AND TRANSFERS GRADUATING IN ENGINEERING BY RACE/ETHNICITY AND GENDER. ORDERED BY TRANSFER GRADUATION RATE.

		Engineering Matriculants		Engineering Transfers	
		N	**% graduating in Engineering**	**N**	**% graduating in Engineering**
Latino	Female	494	50%	191	72%
Asian	Male	3799	57%	1687	63%
Latino	Male	1860	48%	848	63%
Asian	Female	999	57%	397	62%
White	Male	52501	53%	16159	57%
Black	Female	3404	46%	1004	55%
White	Female	12713	54%	3328	55%
Native American	Male	270	39%	136	53%
Black	Male	5617	38%	1834	49%
Native American	Female	84	43%	26	46%
TOTAL		81741	48%	25610	57%

C. Qualititative

Latinas are attracted to engineering for a variety of reasons. Given that there are so many more men who are engineers, it is not uncommon that often it is a male role model inspiring Latinas. Some Latinas described a long-time affinity toward math and science. Some feel a transnational affinity to their parental homeland and a desire to improve it materially and believe that work in engineering can make a difference abroad.

How do Latina women experience the climate of engineering undergraduate education? Our findings suggest that Latinas in engineering redefine ideas of success, which paradoxically, focus on learning how to fail. They described how they overcame inhibitions of failure, given forced curves, and effectively learned not to be psychically devastated by receiving a low grade, given they had been high achievers in high school. They also discuss how they cope socially, in the face of some adversity, in order to persist in undergraduate engineering courses.

Racialized microaggressions are “brief and commonplace daily verbal, behavioral, or environmental indignities, whether intentional or unintentional, that communicate hostile, derogatory, or negative racial slights and insults toward people of color” [22, p. 271). Researchers have found instances of microaggressions in the experiences of women of color in STEM classrooms including feeling unwelcome, unsupported, or invisible [19, 23, 24]. Microaggressions can be experienced by women in engineering in many forms. They can be experienced at the institutional level (such as through biases in the curriculum, structure, and type of assignments, and even in accepted canons of the knowledge base), at the interpersonal level (in the form of snubs, dismissive gestures, or seemingly innocent comments that are perceived as hurtful, inappropriate, or insulting), and as jokes and humor that subtly deride women’s place in engineering. Although there is somewhat of a shared experience among undergraduate engineering women, microaggressions are processed differently depending on race/ethnicity.

Latina engineering students experience detractors, people who second-guess their commitment to pursuing engineering. For example, students described with mixed emotion the sense that outsiders insinuate they are not a good fit for engineering and outsiders express shock or surprise that they are studying engineering. Some Latinas described the sense of feeling excluded in terms of a double oppression, first as a woman, second as a person of color. Some women felt displaced when men asserted sentiments such as “you’re only here because you are a woman.” For women of color, this displacement is compounded by assumptions of being an affirmative-action baby—highlighting not only subordinate status, but also a hint that they might not be academically qualified. In this example, a Latina student shares her response to such assumptions:

> In high school . . . my guy friends actually ended up going into engineering. [A] lot of them didn’t get into [this institution], . . . they were very, well, jealous of it really [chuckles], because they really wanted to come here. [They would say] “You’re a girl and you’re Hispanic, and you’re going into engineering. Dude, why would they not take you?” And I was like, “No, it’s because my GPA is higher than yours, my SAT scores are higher than yours, and I’m more involved in school than you.”

This Latina student explains how she has to establish her credentials because assumptions are made that she is unqualified based on her minority status as a woman of color in engineering. Another Latina had a similar experience. She related, “I’m in the honors program here. And one of my friends was like, well, the only reason you got in was because you’re Hispanic. And I [thought], ‘I do better than him in every single class, but somehow he is still better than me.’”

Some women suggested that at the interpersonal level, men in their academic work groups simply ignored them; they felt invisible. One Latina student laments that when she offers a solution she is ignored but when the same response to a problem is proposed by a male student, then others listen. “I don’t think they do it on purpose. It just—it shows.” Her deflated tone in the focus group, accompanied by her final comment, “it just shows,” suggests that she sees the disparity in how she is treated by male students, even though she does not clearly articulate it as an injustice.

Women's voices are unheard because there are so few, thus stereotypes about who is capable, and who is not, are reproduced. As one Latina suggests,

> I don't know if it's necessarily because they're [men], but I think it's the people that speak up in class, you know, they're the ones asking questions, and you think, "Wow. They must be really smart." And because of the ratios in our classes, most of the time it is guys, so you make that connection that, you know, you make that connection that guys really are smarter than that girl. But I think it's because we're so outnumbered.

Insightfully, in this quote this Latina reflects that her own perceptions of who is smart germinate from who is most likely to speak openly in class. Given that the classes are primarily filled with men, this produces a particular effect—one that perpetuates the stereotype that men are smarter, faster at composing responses, and more confident in their intelligence. The perception of the women that men are "smarter" or better at technical topics echoes the influence of "stereotype threat" -- As a result of stereotype threat, women are less likely to have confidence in their own abilities; they second-guess themselves and take longer to produce answers. These patterns of behavior reinforce false ideas about biologically determined intelligence, that men are innately more capable. A higher percentage of women would somewhat diffuse majority male voices. The situation can be so caustic for some women that they avoid group work altogether. This type of exclusion can be harmful academically given the importance of group work in engineering education and practice.

When Latinas were asked about stereotypes, they reflected in terms of gender, not ethnicity, and described stereotypes that emerge because of their low representation as women in engineering. The fact that men are responding in greater numbers, more quickly, contributes to the stereotype that women are not as smart. Women are keenly aware of this numerical bias, and address it in terms of stereotypes that challenge them. Thus the low numbers of women represented institutionally directly affect them through stereotypes.

Latina women differed from other women in focus groups in their emphasis on "learning how to fail." Latinas explained her early frustrations and learned that a key to persistence was adapting to the curve method of grading, "Learning to fail, learning that you're not good at everything. That was a huge shock to the system." Latinas adapt to the climate in engineering education by attempting to carefully navigate setbacks. Students explained how they learn to stand up for themselves when they feel ignored or marginalized. "Yeah… speak up. Because most of the time when you're right, and you know you're right, guys will fight you until the end. They'll [say] 'no, I think you did this wrong.' So just stick with your guns, I guess." As this Latina suggests, "sticking to your guns" is a warlike metaphor to suggest that it is a battlefield for some women. And yet, even with this powerful metaphor, her assertion trails off with, "I guess," suggesting she is not convinced of this potential. In these subtle comments we perceive the complexity of being one of few Latina women in the classroom, and the difficulty in having the confidence to have faith in your own work, knowing that others may put you down even before they themselves do the work. Among those who persist, they describe isolation, depression, and obsessive behavior as common territory for engineering students.

For one Latina, the consequence of this competition and sense of isolation, meant not having friends in her major. "I'm mostly friends with people that are not engineers. This is probably a gross stereotype, but they just want to talk about school and classes." Another adds, "Most of the people here just talk about classes instead." Another concurs, "Yeah, you'll meet them at a party, and then [chuckles] they'll be like, 'Oh, class . . . that test was so hard!' And you're like, 'Are you serious?' [She and others laughing]. 'It's Friday night and we're both drinking, an' you're telling me about the test' [laughs]." Another exclaims, "I'm like, 'What is this—we're at the party!'" Latina women describe their social life as bracketed between students with whom they can talk about their academics vs. "real friends." Latinas reported being more likely to join engineering societies that offer support to women of color (such as Society for Hispanic Professional Engineers [SHPE]). However, they cite professional development, not social opportunities, as the most likely reason for joining. The idea of having one peer group for academic interactions and one for social interactions was also found by researchers for women of color in college [25, 26] including Latinas [23]. Since academic peer support has been found to be an important contributor to persistence [19], the difficulty in finding such support is problematic for Latinas.

Our findings demonstrate that Latina engineering students continue to experience many of the same challenges faced by women and yet respond in unique ways. This work demonstrates a pattern across geographic location and through time as our findings are consistent with those of Hacker [27], Seymour and Hewitt [5], and Tonso [28] beginning decades ago.

IV. Radical Strategies for Recruitment

To fulfill the potential of Latinas in engineering, we propose radical systemic changes as well as targeted intervention and recruiting strategies. We highlight a few of these here.

A. Moving Engineering Off of the Borderlands

Over the last few decades, there have been numerous and valiant efforts to enhance the diversity of the engineering and STEM workforce and educational population. Despite these efforts, diversity in engineering has not changed significantly. Such stasis points to the need for significant fundamental change. As Heywood argues, most reform efforts have operated within a *convergent framework* where the past is seen as a guide to the future resulting in incremental changes [29]. To enact meaningful change, he advocates for *divergent visioning* as a more promising strategy. Others have called for revolutionary educational reform [30, 31]. We agree that revolutionary divergent visioning is needed -- the field of engineering education cannot remain a segregated elite enclave.

The re-envisioning of engineering, we argue, should include sweeping modifications to existing curricula with the intent of moving engineering off of the borderlands of education. Currently, engineering is largely absent from K-12 education. Exposure to and preparation for engineering must happen at the earliest levels of education. Doing so ensures that engineering will be familiar to young people, Latinas included, so that they can be accessed early, enveloped in the process of understanding the field, and guided towards pursuing engineering as a career. There are hopeful signs in this regard, particularly the promise of new science standards in K-12 education in California which will include engineering for the first time [32].

We propose that engineering should become a part of the core of the education of all college-educated students. Several leaders have called for the need for engineering to be recognized as part of the essential education of an educated person in the 21st century in the tradition of liberal arts. In today's world, engineering should not be the purview of a small minority. Given our societal infusion with ever-increasing technological capacities, a greater majority must share, understand, and begin to shape it.

Faculty and academic leaders need to be champions in re-envisioning the core. As institutions reflect on and modify their mission statements, they should consider their role in meeting the needs of students in an ever-changing technological world. Technical literacy transcends academic boundaries and should reach into its current borderlands. If engineering moves out of the borderlands of education and into the core, there are implications for all faculty. Also, this should be a reciprocal arrangement: engineering faculty and students need to be more broadly educated; similarly those in other fields (social science, science, arts and humanities) need to possess engineering/technical literacy so that they can work together to solve interdisciplinary problems.

B. Innovative Pedagogical Strategies in Engineering Education

Traditional engineering education has changed little in the last few decades in terms of pedagogy and content. Efforts to change have been motivated by "rewards" such as funding from NSF and "punishments" such as ABET accreditation requirements. Both sets of structural changes slowly continue to chip away at the rigid format of engineering curricula. Promising changes in pedagogy such as more collaborative and active learning, teamwork, and community service learning all could be beneficial for all students including Latinas. In addition, culturally responsive teaching and targeted approaches that address gendered and raced inequities may be helpful. Finally, reimagining the structural format and content itself of engineering curricula yields possibilities for radical change.

Even more radical changes may be necessary to reform engineering education. This involves self-reflection by engineering educators and could expand to questioning the engineering "canon." Is there an engineering canon? If so, is it negotiable? Who decides and who should participate in this decision making process? This extends into fields such as ethics and philosophy of engineering. What significant differences would appear in engineering curricula if these questions were considered? Considering curricular questions in light of the recognition of the gendered and racialized nature of engineering could lead to new breakthroughs.

C. Community College Pathways

For Latinas and Latinos, interventions to encourage and support engineering must consider community colleges since they "are the chief points of entry for Hispanic students who go to college" [33]. These institutions could potentially play a key role in advancing Latinos and Latinas in engineering, particularly for low-income students who may benefit from taking prerequisite classes at community colleges.

Enrolling in a community college is not a guarantee of transferring to a four-year institution. Researchers have shown that rates of four-year college graduation are less for students who start in community college than those for students who matriculate directly into four-year institutions [34]. The pathways from two-year to four-year institutions for Latino/as are often difficult with few students successfully making the transition [35]. In 2008, only 25.7% of fulltime Latino students at two-year colleges graduated in three years or less. This lagged behind Asians at 31.5% and Whites at 28.5% [16]. Many of the two-year institutions where Latinos go are Hispanic Serving Institutions (HSIs) [36]. In fact, 53% of HSIs are two-year institutions. HSIs are particularly important for engineering since forty percent of Latino engineering degrees were awarded by HSIs [37].

Geography plays a significant role in the institutions that graduate engineering students. O'Connor showed that Latino students who aspired to a bachelor's degree were more likely to enroll in community college than their Black or White counterparts [38]. However, Latinos who lived in states with high Latino populations, were more likely to go directly to a 4 year college than a 2 year college compared with White or Black students. She suggests that this may be linked to the preference of Latino students to live at home along with the higher availability of community colleges outside these four states. Because Latinos are not a monolithic group, and because Hispanic-Serving Institutions serve different populations that vary geographically, a more nuanced analysis that explores variation by Latino ethnic group is necessary to inform the development of specific and effective engineering recruitment strategies. Interventions designed to increase the number of Latinos in engineering education may have the best results if these efforts are targeted at HSIs, with special consideration in states with the largest populations.

V. CONCLUSIONS

In our collective disciplinary efforts to broaden the reach of engineering education and diversify our population of students, increasingly it is important to closely examine variation by disaggregating students. Researching minority populations in engineering is of value to better understand their experiences and conditions of their persistence. We advocate for more studies that use multi-methods of investigation, quantitative and qualitative, to understand small populations in engineering. We also suggest that there is value and a need for more book-length projects in engineering education. Much research remains, and particularly more qualitative investigation is needed to understand the in-depth experiences of underrepresented groups in the borderlands of education.

Abstract—**Diversifying engineering programs is a major goal for almost all universities because expanding the diversity of students will broaden and enrich the knowledge and experience associated with the science, technology, engineering and mathematics community. This study looked to explore those factors that contribute to minority students' success and more precisely what contributed to their success the most so that recommendations could be made on how universities can improve their minority student retention. In order to do this, African American, Hispanic American, Asian American, and Native American undergraduate engineering students of various disciplines were interviewed using theoretically grounded qualitative methods. The transcripts were coded for patterns using NVivo qualitative analysis software and the patterns found are described in detail within this paper. These patterns gave us insight into the factors that contribute to minority students' success and therefore lead to recommendations on ways for college campuses to encourage and foster their minority students' success. The insights reported in this paper will hopefully help universities make changes that will greatly improve the success of their minority students in engineering majors.**

Keywords—diversity; retention; minority students; narrative

I. INTRODUCTION

Among minority races, interest in obtaining an engineering degree has grown, but given low retention and graduation rates of these students, completing a degree appears more difficult than for majority students. Nationally, the graduation rates in engineering of underrepresented minority students are lower compared to majority students [1]. According to St. Omer, by the year 2050 minority students will constitute the largest segment of the college population [2]. If the graduation rate of minority students remains the same, then the number of minority engineering students who fail to graduate will continue to increase. Over the last decade research has been conducted to identify factors contributing to this lower rate of degree completion. These studies have shown that the main factor affecting minority student persistence tends to be limited access to the resources and support needed to graduate.

Examination of the research reveals that lack of interaction with student organizations and technical societies, as well as with peers and faculty can have a significant impact on higher-education degree completion [3]. However, among minority engineering students at predominately white institutions, limited social networks reduce their access and utilization of these resources.

Two undergraduate engineering students enrolled in an honors research project to answer the research question "**what can institutions do to support retention and graduation of minority engineering students?**" In collaboration with their faculty advisors, the student researchers interpreted the narratives of undergraduate minority engineering students to respond to this research question with a set of recommendations. This paper is written in the voice of the students, both the honors research students through their theory-based interpretations and the research participants through their quotations.

II. METHODOLOGY

The factors contributing to successful graduation of minority engineering students at a large predominately white public research university were investigated through a study consisting of interviews of 138 undergraduate minority students. The engineering students belonged to one of four ethnic groups: Asian American (AsAm), African American (AfAm), Native American (NAm), and Hispanic American (HAm). Most of the students were juniors and seniors, and those who participated as sophomores were often interviewed again in a later academic year. All research participants successfully graduated with a bachelor's degree in engineering. We believe that the lessons to be learned from successful students are more valuable toward promoting future success than those derived from attriting students. The interviewers were given an outline to follow during the interview that included questions about the student's background, college experiences, and motivating factors. The individual interviews were open-ended questions, partially concerning what barriers the students encountered, but mostly what programs, processes, and practices helped on their paths to graduation. The interviews were transcribed and then coded using NVivo qualitative analysis software.

Analysis for this paper used a theoretical perspective grounded in an intersection of social capital [4] and heuristic knowledge theories [5]. Padilla defines heuristic knowledge as that obtained through experience in local context. As Padilla states, heuristic knowledge is most commonly passed from experienced students to new, inexperienced students either through individual or group interactions [5]. The social networks embedded in social capital are one way for students to acquire that heuristic knowledge [5]. Social capital is defined as the "aggregate of actual or potential resources linked to possession of a durable network of essentially institutionalized relationships of mutual acquaintance and recognition" [4 p.33]. Bordeiu further suggests that the quantity of social capital a particular student obtains depends on the amount of network connections the student assembles

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

and the amount of capital possessed by each network to whom the student is connected [4]. Examining the students' strategies with this dual lens, we will build a model for how minority students identify and build their social networks to gain heuristic knowledge supporting success within the context of a specific academic institution.

The findings presented here are supported by quotes from the participant interviews. Student's responses are designated with their race/ethnicity and sex. Words or excerpts that appear in *italics* represent the actual language of the students. Words or phrases inside parentheses ( ) have been added by authors to add context or clarify participants response. Words or phrases inside square brackets [ ] replace or delete identifying information and are used to ensure anonymity of participants and other entities.

III. RESULTS

Developed from the data to follow, Figure 1 illustrates our model for how minority students' social networks contribute to the development and use of relevant social capital. This figure visually depicts how heuristic knowledge builds social capital. Minority student research participants are at the core of the social network. Oval and diamond shape nodes represent examples of the larger institutional bodies defined in the rectangles. Each arc connecting the participants to nodes represents a channel of communication. Through these communication channels, heuristic knowledge is transmitted from these university constituents to students. Students who build larger social networks enable more of these channels of communication and thus accumulate stronger social capital.

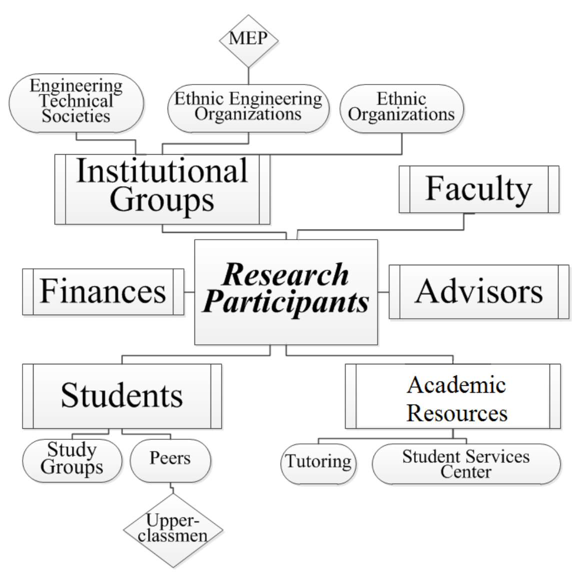

Figure 1. Model for minority student social networks of institutional bodies enabling accumulation of social capital

A. Institutional Groups

According to the minority engineering students in our study, supporting and accepting communities come in the form of ethnic organizations, and ethnic or technical engineering societies. Research reveals that minority students are culturally uncomfortable in predominantly white institutions, however, when available, ethnic-specific subcultures help students of color cope with this issue [6].

Students from all ethnic groups find that organizations like these help nurture their success during their academic career. Unlike the assumption that extracurricular and co-curricular involvement "diverts or distracts students from their academic studies" [7 p.402], our study, along with others, reveals a direct positive relationship between academics and involvement outside of the curriculum [7]. Belonging to an organization, program or society allows students to interact and socialize, to gain a support system outside their classroom. Specifically, ethno-centric organizations help minority students by providing the opportunity to build relationships with students and faculty of similar culture. For students of color at higher-education institutions, being involved in ethnic organizations was a way to "retain and nurture a sense of ethnic identity on campus" [5 p.134], which enhances the "interest, determination and aspiration of the students" [2 p.10]. Witnessing others' success encourages them to pursue their goal of graduation. One student describes the encouragement that the African and African American studies (AFAM) program gave her in pursuing her degree.

It gave me a sense of pride…helped to cure any type of inferior complex…that helped honestly in seeing other students that are successful in engineering that are black. AfAm Female

Also, involvement gives minority students access to other networks such as study groups, teachers, and upperclassmen, all contributors to success [3]. This student describes how being involved in Engineering Club (E-club) allows her to branch out, meet faculty and learn how to work within groups:

I think it's a really great way to meet people and get to know people and get to know some of the people in the college and some of the staff…so it's a really good way to get involved and it teaches you how to work with people and trying to get the best out of what little money you've got and all that stuff. HAm Female

One concern expressed by AsAm students is over-involvement with outside activities creating interference with their academics. Even with this concern, they still find that the organizations they join are a positive aspect of their college career. A minority student describes the conflict he feels regarding his involvement with his fraternity:

It gave me a lot of stress. I don't know, again it helped me work with people. It helped me prioritize and time management. Also it's an outlet it balanced engineering, a lot of times I'd get overburdened with engineering and I'd want to just give up and something that took my mind off of it for at least a couple of hours a day or hours a week. AsAm Male

Like the AsAm student describes, research has found that over-involvement outside of the classroom can sometimes lead to lower achievement in academics [7]. Further research found that students who are devoted to academics and are not involved in out-of-class activities tend to isolate themselves from peers, which can cause "smaller than-average changes in personalities and behaviors" [7, p. 392].

One of the largest support programs at this university is Multicultural Engineering Program (MEP). This program for underrepresented students includes a freshman engineering orientation class, a scholarship program, tutoring services, and other opportunities. Most participants in our study were involved with MEP. However, AsAm students use MEP only as a resource for tutoring. Students from the other minority groups are more engaged with MEP, enrolling in the class where they had the opportunity to meet successful minority professionals and diverse institutional groups. The most active students find MEP to be most beneficial, allowing them to interact with ethnic peers while simultaneously gaining heuristic knowledge about other organizations and societies. One student emphasizes how helpful MEP is in increasing their involvement at the University:

And that program has been so important to getting me involved right now, I'm in the E-Club and I'm in all of these different clubs, and DLC, and I would've never gotten involved in any of that. NAm Male

B. Peers

Foor and Shehab concluded, "the ability to find or create supportive peer communities is critical to student success" [8 pg.1]. We believe this interaction is most important for gaining heuristic knowledge when the peer community includes both upperclassmen and lowerclassmen. Many students discussed the help they receive from fellow students in their classes as well as the advice they receive from upperclassmen. The need for a relationship and help from peers is relatively equal across all four minority groups. When this NAm student was asked what advice he would give to a student entering the College of Engineering, he responded,

I'd say talk to as many kids as you can because it doesn't matter how much you think you know, there are still some things you don't know and it helps to know the people that have some idea about it, especially the older kids. NAm Male

Rarely is help from upperclassmen associated with class work. Instead, relationships with upperclassmen provide advice from someone who has already been through what these students are about to go through. The idea that the upperclassmen have recently completed what the younger students are hoping to achieve, makes them a more desirable advisor than teachers or the advising staff.

Many students recognize the need for interaction with peers. Museus found that involvement in organizations was often valued because it "provided undergraduates with opportunities to spend time with peers who they perceived as similar to themselves" [6, pg.580]. Interaction with peers is especially important because most minority students feel more comfortable asking classmates than professors or TA's when in need of help with their coursework. The help classmates can offer includes homework help as well as social outlets to relieve the stress of school. Huang supports this assertion that college students who are too focused on their academics become isolated from their peers, which hurts their social development [7]. When an AsAm student was asked where he goes for help, he responded:

Academic matters, usually this group of engineering friends. I mean we have the same classes and we always study together and end up taking the same classes together. And then in my fraternity, I've got a lot of guys who are like electrical engineers or computer engineers taking the same classes so I ask them. AsAm male

C. Study Groups

Although competition is high in the discipline of engineering, faculty should encourage cooperation as well. This cooperation can come in the form of study groups. Students who join small peer groups committed to academic success perform better in school, have a higher desire to learn, and more easily excel in their engineering courses [9]. Also, "research shows that students who work in groups develop an increased ability to solve problems and evidence greater understanding of the material" [10 p.4]. In our analysis, study groups exhibit similar importance on students' success. All participants saw cooperative learning as key to their success. Study groups facilitate student success by allowing them to interact with peers facing the same issues. Also, the impact of witnessing strong work ethics within these peer groups encourages the student to succeed. When asked if interaction with his peers contributes to his success, one student responded,

Some of them work really hard to get where they're going and that motivates me to do, you know, to try and do my best. NAm Male

There are numerous benefits for all members of peer study groups. Some in the group benefit through their role as peer instructors [9]. Furthermore, some students find that their peers can describe a solution to a problem better than their instructor. The student can work at their own pace, and when needed ask their peers a question. For example, these students describe the benefits of working in peer study groups.

I don't usually go to office hours too often. I'll see if I can find the answers through my peers. They can describe it, because they're just learning it too. So they can kind of describe in a better manner than somebody who has done this their whole life saying, 'Why don't you understand? It's so easy.' It's easy for you, but not for us new guys. AsAm male

It's a little bit tougher to get one on one help, so in study groups it's a lot better because you can work at your own pace and with people that are your peers. AfAm male

Although study groups most commonly enhance heuristic knowledge, and accumulate social capital, study groups intermittently have negative effects on the development of a successful engineer. The minority students recall feeling like an outsider when their study group is predominantly white. When speaking of the white majority, one AfAm female said that for this majority "*they [have] more people for them to associate with of their own kind*". Also, study groups can bring on adverse effects including underrepresentation of effort from certain teammates or study group partners [11].

D. Academic Resources

Although the details differ among minority groups, they agree that many of the resources offered to aid students, such as tutoring and student services centers, are rarely helpful. AfAm students report that student services centers are only helpful to meet advising requirements. However, they did find that the tutoring offered by the engineering college is a great way to show teachers your commitment to learning and to meet classmates that can help. One minority student accredits tutoring for his survival in the College of Engineering:

Basically, you have to really show the teacher you are trying, you know kind of get to know them and let them know you, and you know where you are coming from and all that. You have to have some people in there helping you out, and you know working with you taking their time and stuff like that, groups are great, stuff like that, getting tutoring was real good. AfAm Male

AsAm students, on the other hand, mention neither tutoring nor any other student service when discussing what helps them as an engineering student. However, when asked directly about helpful resources, most describe tutoring and service centers as helpful resources, but not critical to their success.

NAm students also report that the provided academic resources are part of formal requirements for advising and information dissemination. One engineering student describes a perspective shared by multiple students on how the advising resources provided within the engineering student services center do not meet the students' individual needs:

Well I noticed the last time, whenever I was here last fall because I was over in the honors advising center and then I got switched over to [engineering student services center]. But I like the honors advising college because you know they sat down with you and it's like they took the time to try to see what you want to take and give you advice about you know whether or not you should take even though you weren't the engineering and so whenever I went over there it was pretty much OK, let me see what you have and OK I think that will work and then they sign you off. NAm Female

However, many NAm students discuss the benefit they receive from the engineering tutoring available. NAm students find the tutoring beneficial because it is free and accessible to all engineering students. In particular, they value information provided by the college about available tutors and subjects. The following student found tutoring especially helpful:

Here is a list of the people that are actually hired to tutor. They are available but they (are) paid, basically. So if I have to, and I have done that once with a programming course. I got a tutor and it was excellent. NAm Male

HAm students have the most positive outlook on both university services centers and tutoring, and use these resources more than the other minority groups. In particular, most HAm students find the tutoring required by the MEP program to be very helpful. Some did report that tutoring was only as good as the preparedness of the student tutors. This HAm student offers the following advice for incoming students of similar background:

Definitely find a tutor as soon as you fail your first test. Or if you are having trouble within the first week, definitely find a tutor, find a group of people that will help you and motivate you, that is the key to surviving. HAm Female

While all four minority groups express wide ranges of opinions on academic resources, we were able to find trends among the groups. First, although services centers are considered helpful in the enrollment process, they lack in all other services they supposedly provide. Second, tutoring appears to help students who participate, however the students only value tutoring if the tutor is competent in the academic subject.

E. Finances

Financial resources appear in the model because they allow or limit a student's access to social networks. In particular, students from financially disadvantaged families must choose between working part-time jobs and engaging the social networks that facilitate college success. HAm students in our data set discuss financial issues and the need for scholarships more than others. Many HAm students believe that financing college tuition and other expenses is the biggest barrier to overcome, even more so than academic challenges:

Academically, I've always been able to succeed with the help of the professors or whatever, so that's really the money has been the only problem or the only challenge I have seen in front of me. There's nothing else that seems to stop me to go anywhere so. HAm Male

Some of our AfAm students find that financing college is often difficult and can be the determining factor in whether they stay in engineering or even in college. Those who work during the academic year to pay their college expenses, feel they have fewer opportunities to build social networks that could make them more successful. One AfAm engineering student comments on how financial concerns have affected him and his friends:

Me and my friends started off as Engineering. One of them he left after his freshman year. Uh, it's more of a money issue with him. I just worked. That is one thing I wished I didn't have to do is work while in engineering. I probably would have you know a better grade or whatever. AfAm Male

However, all minority students do not equally express such financial struggles. For example, many AsAm students appreciate the extra money scholarships and financial aid offers, but they don't discuss financial support as a challenge that must be overcome to continue to persist in engineering.

I really didn't have too much of an issue being able to get here. A lot of that was because they (my parents) could afford OU and I actually had a few scholarships to help out with that. AsAm Male

Huang recognized that employment limits campus involvement and therefore the benefits associated with involvement [7]. Although our students express different levels of financial need, most students recognize the help scholarships or other financial aid provides and recognize that financial difficulties prevents graduation for many students. One AsAm study participant provides this advice for other minority students:

Definitely apply for all the scholarships you can because I've seen how other people who are paying for school and it seems like they're the ones that tend to drop out more often. AsAm Female

NAm students differ from the other three minority groups because many receive financial support from their particular tribe. For some it has allowed them to focus more on school, and less on trying to find other outlets of support. The following students express some positive attributes of receiving tribal support:

I mean it's a blessing. We really benefited just from the fact that we had Native American background and things like that. [Those scholarships] helped us out. NAm Male

"*Yeah I get a tribal grant, a thousand dollars a semester, it's to kind of to keep it where I don't have to work during school, and pay bills, it helps me out a lot.*" NAm Male

While the need for financial help is present among all the minority students interviewed, many express frustration with the financial aid process. Within each group interviewed, there are individuals who discuss the need for financial aid but who found it difficult to locate scholarship and financial aid resources. On the other hand, those who are more involved and connected seem to be more aware of financial aid available. Below a student describes how his attentiveness to emails has made him more aware of scholarship availability:

They keep on sending me emails and I have been noticing that there are more opportunities for Hispanic where you can get different scholarships. HAm Male

F. Faculty

The importance of professors to students' success is broadly understood. "Peer and faculty networks include resources such as guidance, support, information and encouragement with coursework, and information and contacts for post-graduation endeavors" [3, p.4]. However, not all minority students report feeling comfortable with professors. HAm students in our study appear to be the most comfortable with their professors and gain the most help from them. Many discuss feeling comfortable talking to their teachers about school and coursework and other topics as well. The following quotes from a HAm student describe how he feels his professors are encouraging:

Sometimes they point out if they knew of a position they think I might be able to (apply for, or when) the company needed some help or (there were) some work opportunities. And they send me an email and tell me who to go talk to or something like that or a letter of recommendation, they are always helpful

You know just friendly, just kid about classes and if we're really going to pass and everything and graduate. Or if we understood the material they were teaching us. HAm Male

This feeling of natural comfort with professors was not as strong for the other participants. For example, many NAm students discussed that while they knew the importance of getting to know their professors well, they did not always feel comfortable doing so. The following quote from a NAm student talks about the benefit he received when he finally did find a teacher he knew on a more personal level.

Every other instructor that I have ever had has been strictly just an academic relationship. I am in your office because I have a problem with homework or I have a question from a test or something presented in class. Very rarely does it go beyond that (except) with a guy that I work with; we have had some real personal conversations. That is something that I really like, that he feels I am somebody that he can talk to like that. I am not just a student or I am not just somebody that works for him. NAm Male

The reluctance to get to know professors often seems to come from a feeling of intimidation. Many students find that some of their professors seem superior and unwilling to help. One AsAm described this feeling often in her college experience:

I don't know. Sometimes some of them come across as they're better than me. If I ask a question they are like oh, that is a stupid question…This one professor. He was kind of a jerk. You'd go in and ask a question and he didn't really know the answer and so he kind of blew me off. AsAm Female

All the participants recognize the benefits a relationship with a professor provides. Museus reports that AfAm students find that the biggest advantage of involvement with student organizations is the opportunity to form relationships with professors [6]. The students in this study report only few issues with the structural considerations of office hours, but more so with the attitudes from faculty that students encounter when attending office hours. Students also encounter some faculty with teaching styles that they feel are ineffective.

G. Advisors

The college advisor is instrumental in helping students achieve their degrees [9]. Minority engineering students in this study describe the value of a personable advisor who is knowledgeable of the engineering curriculum and truly cares about the students' future. However, many participants in our study mention limited access to this kind of advisor, thus creating a roadblock to their success. Faculty-led student advising is often variable and dependent on the perspective and experience of the faculty member. Some advisors do not advocate extra-curricular involvement, nor do they suggest how to access and utilize resources for success. These students express what they believe is important in the faculty-student advising relationship:

That little bit of encouragement goes a long way. You can do this and this is how we're going to do it...I mean just have that background voice saying this is where you need to go to get this information and not just brush you off. AfAm Female

I didn't like it when I came. ... I felt like [advisors] could have helped me a lot more in my decisions about my classes and where to take them and what teachers…. They helped a *little bit but I would have wished the college of engineering stepped in to guide us in a different way.* AsAm Male

Another key attribute of a good advisor is communication and the opportunity to form a relationship [12]. Many of our students find their advisors to be unapproachable. One HAm student mentions that their advising appointment "*wasn't anything too personal, and [it was] basically what I went in for and left*" (HAm Male). Many students express that they "*would feel more comfortable meeting with an advisor of the same ethnicity"* (NAm Male). The availability of an advisor with similar ethnicity and cultural perspective creates opportunities for students to find community [9].

IV. Recommendations

Critical cultural theory-based qualitative research forefronts the voices of the less-empowered members in an organizational culture. As faculty mentors, we recognize that student voices need to be included in the discourse of retention in engineering education. Thus, after their analysis of student experiential narratives, our undergraduate researchers offer these student-perspective recommendations for engineering faculty and administrators to consider.

From the view of the undergraduate researchers, all of the following recommendations would benefit engineering students. They believe that implementing anywhere from one to all of these suggestions will broaden access for more students to the social networks and social capital that enabled graduation for these minority student research participants. An additional focus of these recommendations is for institutional actions to address or remove issues that the research participant students encountered in their experiences. Supporting students' social networks using these recommendations will help future students attain heuristic knowledge and increase their retention as undergraduate engineering students.

A. Encouraging Peer Interaction

Study groups expand a minority-engineering student's social network and all the students in our analysis find it easier to communicate with their peers than faculty. Study groups are a way of forming relationships with people who will further the student's success. These relationships are an important aspect to a student's social network in college because the more connections that are made, the easier it is to form study groups in the future and therefore gain beneficial advice and help. An AfAm undergraduate female believes that "*professors should always encourage people to work in groups, and to do group work, even if not for the homework.*" Therefore, we recommend that professors encourage students to participate in study groups; we suggest this be done in a variety of ways. Professors should be encouraged to hold optional study sessions outside of class time. The advantages of these sessions are that faculty are present to monitor and supervise: 1) the exclusion and silencing of minority students within majority groups; 2) students not fulfilling their individual responsibilities within the group; and 3) groups lacking structure and focus. These sessions could be held once a week or even just once before the test. These sessions support collaboration within the class and help students get to know each other outside of class time. According to Springer in *Effects of Small Group Learning*, study sessions outside of class had greater effect on students than inside. It is also beneficial because the professor is there for consultation and guidance when needed [11]. These study sessions encourage developing social networks with their classmates and with their professors without the extra time commitment of being involved in an organization.

B. Faculty

Since minority students can more easily approach minority faculty, increasing the diversity of faculty will enable easier communication for both advising and teaching. Also, MEP and the freshman-engineering seminar class should include testimonies from teachers and upperclassmen about their success stories. These resources are meant to be a place where success is encouraged and taught. Knowing how others achieved success advocates this idea.

The students who experience successful teaching know the techniques most helpful to their success; therefore, we recommend that the university hold student-led workshops. These workshops would encourage professors to teach with students in mind. Finally, we believe that outside of office hours, faculty should have an "open door policy". Professors would encourage students to stop by when their door is open to just say hi, get advice, and get to know the professors. This takes away the pressure to only go to the professor's office for homework help and makes the professor more accessible on a personal level.

C. Accessibility of Information

Easy access of information about the college of engineering is vital for minority engineering students' success. Because every engineering student at our studied university has access to the Internet, we believe all information regarding anything associated with the college should be posted on a central webpage there. If all student support information is centralized, then students will know where to go to look for needed resources. Students should be able to easily access the different tutoring times within the college of engineering, as well as the tutors names and numbers. Ranking the tutoring programs from students' reviews, specific to subjects could help students pick out the tutoring services that would be most helpful. Also, accessibility to information regarding institutional groups should be available on the website as well. Possibly this webpage should provide a link to each institutional group's websites, or if a website is unavailable, someone to contact about this group. All scholarships available to minority students should be posted on the website, because sometimes scholarships can be hard to locate on the Internet. Not only should all of this information be online, but the student services center should also make all information available at the actual building the service center is located.

D. Mentoring

Connecting younger students to older students is one of the most important aspects to creating an academically-centered social network. Establishing one centralized mentoring program that is well-organized and advertised fosters the beginning of an academic branch for a young engineering student's social network. This mentor program would allow students to be immediately coupled with at least one older student. Connecting this mentor program with engineering organizations could encourage the younger students to get involved with their mentor's organization and meet even more people therefore expanding their social network.

E. Scholarships

Universities must recognize the positive impact scholarships and scholarship requirements have on undergraduate minority engineering students. If possible, the number of scholarships given to minority students should be increased, helping the students to stabilize their college financial situations. Covering more of students' financial costs can give students more time for school by reducing their amount of time spent having a job. Tied in with these scholarships should be requirements of students to attend different events, programs, and classes within colleges of engineering. Although students may find these participation requirements to be a hassle, participating in different events, programs, or classes could help the student become more involved which could expand their social network. Receipt of these scholarships should come with more information on the benefits of the program, the advisors and mentors that are leading it, and most importantly, success stories from others, which could instill more motivation for minority students to actively participate. For example, attaching participation requirements to scholarships is a technique the American Indian Scholars (AIS) Program tried and found successful [9]. When NAm students received a scholarship from AIS, they were required to volunteer at an event sponsored by AIS, which helped connect them to other Native students. From our research, we believe that expanding scholarship programs with participation conditions will reduce the financial burden for students and enhance social networks, which could increase those students' chances of graduating.

When Padilla looked at how financial barriers affected minority students, he recommended that minority students should be educated on financial aid options and processes in order to be successful [5]. Padilla's findings are similar to ours. We recommend that universities should make scholarships more well-known by having all applications online and on one webpage. Emails with dates that can be automatically added to the students' calendars would serve as reminders of the scholarship due date.

F. Advisors

In order to increase the positive impact advisors have on students, advisors must meet with students more frequently. More frequent meetings would mean more time spent together, hopefully creating a connection between advisor and student. The advisor must be able to encourage students academically, and give them guidance on strategies to utilize other resources to complete their studies. At each advising session the advisor can give a list of specific tutoring services or other outside resources that can be of use if needed. Further, taking time to personally email the student during the semester to see how their classes are going might allow the student to comfortably approach the advisor for advice and questions. Also, by identifying the student's strengths and weaknesses, the advisor should suggest the discipline that best fits the student [9]. Advisors must also connect what the students are studying to the real world, pushing these engineering students to have the desire to reach this real world [10]. Providing an ethnically diverse group of advisors within colleges of engineering could also help students to feel more culturally understood and comfortable with the advisor [10].

The Elephant in the Room

First-year Engineering Students Discuss Diversity

Lorie Groll, Teri Reed, P.K. Imbrie
Dwight Look College of Engineering
Texas A&M
College Station, USA

Lydia Kavanagh, Carl Reidsema
School of Engineering
University of Queensland
St. Lucia, Australia

Abstract— This work in progress presents a developmental model representing the ability of students to negotiate shared meanings with cultural others in order to build sustainable and mutually beneficial partnerships .The goal of this research is to locate students within this continuum and provide a student-centered starting point in the ways students construct meaning around cultural differences. This paper uses a qualitative inquiry and analysis methodology with a focus on first-year engineering students at a large Midwestern public university and a similar large public university in Australia. The data collected were interviews and focus group discussions probing their experiences with cultural differences. Initial findings demonstrate that in order for students to be able to acknowledge and express their understanding of differences, they need and want models, tools and techniques to be able to communicate their thoughts about cultural differences and to negotiate bridges of mutual understanding. Student interviews in the US reflected more polarizing messages while focus groups in Australia generated more minimizing messages. Engineering educators encourage students to approach and explore both their own cultures (self-knowledge), internal dialogues and other cultures (perceived through the student's own cultural lenses), and the language they use to describe others.

Keywords—cultural humility, cultural differences

I. Motivation

The engineering education literature on the attributes that students need to develop in order to participate in the multicultural, global workforce has grown exponentially over the last 15 years. Yet many engineers still struggle to see the importance in understanding and appreciate cultural differences relevance to engineering projects. Engineering is an applied science to benefit people from varying cultures. A firm understanding and appreciation of cultural differences impacts not only how engineers will interact with other teammates and stakeholders but also directly impacts the engineering process from conception to delivery and whether or not the product and partnerships will be sustainable [1]. Industry has stated the appreciation of diversity and other attributes necessary to create and build sustainable, multicultural partnerships are in high demand but the least frequently seen in those graduating and just entering the workforce [2,3].

In 2006, Lohman, Rollins, and Hoey discussed the difficulties of defining, developing and assessing these attributes [4]. Many of these attributes are represented within ABET's general criteria 3, student outcome h, "the broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context", the least researched area of the ABET criteria [5].While other academic disciplines have used a variety of theoretical models to define, guide pedagogical practices and assessment practices, within engineering education theoretical models used to understand this attribute have largely been classification models focusing on knowledge, skills and attitudes alone [6,7].

Engineering educators need to understand the attributes of first-year students' communications, discussion and negotiations of cultural differences. Therefore locating students within a developmental continuum is necessary to create and assess appropriate curricular activities and pedagogical approaches. This research is part of a project that seeks to offer a multi-faceted portrait of the ways that first-year engineering students communicate and share meaning around cultural differences. Initial findings show that these students collectively and individually fall within the first half of Bennett's Developmental Model of Intercultural Sensitivity (DMIS). These results indicate that first-year engineering students need structured, active learning opportunities that focus upon developing appreciation of and being comfortable with cultural differences. These attributions are integral progression in terms of developing their cultural humility.

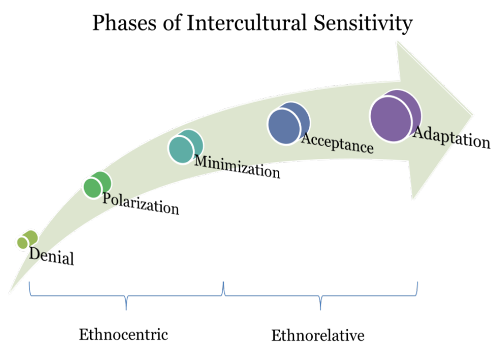
II. Introduction

The research considers Bennett's DMIS through the lenses of Politically Attentive Relational Constructionism (PARC) [8, 9]. DMIS offers six phases of development.: Denial, Polarization, Minimization, Acceptance, Adaptation, and Integration [8]. These six phases are illustrated in Figure 1. The first three are considered ethnocentric viewpoints and the final three are considered ethnorelative viewpoints [8]. PARC is a cluster of communication theories that asks people to consider interactions from the viewpoint of "person-in-the-world-with-other-moving-toward-a-future/past" (p. 41) [9]. Communication is not just a list of skill to be mastered but rather a relational endeavor embued with caring and hinging on the ability to create and sustaing prosocial connections with others [10]. Through this communicative and relational lens, the DMIS becomes a means of considering the development of communication with cultural others through a socioculturally mediated process, a Vygotskiyan approach to development [11]. As such, those who use language that predominately denies the recognition or existence of otherness would be in the Denial phase. Those whose language describing otherness is

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

judgmental characterized by the usage of words like "weird" and "strange" or within a context of "liking or disliking" end up in the Polarization space. Students whose language minimizes differences, "it's all good, in the end we are really all the same" land in the Minimization space. Students whose language describes otherness with words of neutrality are located in Acceptance. Students whose language predominately indicates an ability to connect to otherness and negotiate differences are located in Adaptation. Research has not indicated that the final stage of Integration exists and so the language patterns for Integration have not been identified [12, 13]. Together these theories offer insight into critical aspects of the negotiation of cultural differences: the communicative character of the understanding of otherness, the relational origin of the negotiation of meaning, political nature of encounters with cultural others, the historical and socio-cultural context of the encounter as well as the notion that these attributes are a part of a lifelong, developmental process.

Fig. 1. Phases of Intercultural Sensitvity [8]



III. Methodology

The focus groups and interviews were conducted between May and November of 2012 at a large Australian public university and a similarly large Midwestern public university. Seventeen first-semester, first-year engineering students from the Australian campus participated and 27 first-semester, first-year engineering students from the US campus participated. Students' genders and ethnicities were varied, though most grew up as a member of the majority ethnicity in the countries where these students spent their formative years.

Focus groups were initially conducted to understand how students communicated about cultural differences in a group setting. Because students were so reticent to talk about obvious differences such as race, the researchers wanted to hold individual interviews as well to see if students remained hesitant to discuss obvious cultural differences.

This portion of the research focused on a qualitative inquiry and analysis. While the methodological approach of the larger work uses Bruner's functional approach of narrative analysis to understand the ways students construct stories to create meaning around their encounters with others, the research presented here focuses on themes in the specific language students used to describe the notions of diversity and otherness [14]. Once the focus groups and interviews were transcribed, researchers read and reread the transcripts for thematic elements. This work focus on speech acts and how those speech acts would work to build mutual understanding or could potentially create misunderstandings. These speech acts were then categorized based upon their appropriateness to a developmental level. Speech acts that indicated a lack of understanding or awareness of how cultural differences might be impacting the interaction were classified under Denial. Speech acts that indicate negative judgments around otherness were classified under Polarization. Polarizing speech acts are divisive and may either favor or disparage students' culture of origin. Minimizing speech acts lump all peoples experiences together and minimize the impact of cultural difference. Accepting speech acts indicate an understanding of how culture impacts an interaction and, as the word indicates demonstrates acceptance of difference. Adaptating speech acts demonstrate ways mutually understandings are negotiated cross-culturally. As all qualitative work is, this work is necessarily interpretive and requires the acknowledging that the researchers are inherently a part of the interpretive process and the relational construction of knowledge.

IV. Discussion

Students vacillated between polarizing speech and minimizing speech when describing otherness. Frequently though, students found themselves without words. The following two vignettes are exemplars of the two most frequent phases demonstrated, Polarization and Minimization.

A. *Polarization*

This vignette shares a particularly obvious example of polarizing speech. A young Chinese man enrolled at the US university sits across the table from the interviewer intently discussing diversity. In earnestness, the student has shared how he initially thought his Resident Assitant (RA) was "gay" because he hugged him on his way back from the shower wearing only a towel, but in the end it turned out he [the RA] was not. The student shared, " [My RA] was in fact very nice". The polarizing speech is demonstrated by juxtaposing the term nice with a term to describe someone's sexual orientation. This student's language choice communicates the message that the idea of nice and a homosexual orientation are mutually exclusive. The interviewer keeps a non-reactive mask in place as the young man continues his story. He explains how this RA has made his experience in the US so much more comfortable. How he has introduced him to all kinds of new places and new religions. When asked what kind of diversity the young man has observed, with all sincerity he runs his right hand across his left forearm and asks if we can talk about skin color.

B. *Minimization*

An important example of minimization is shared in this next vignette. Seven students of multiple ethnicities enrolled at the Australian university are clustered around a table sharing pizza and conversation about cultural otherness. Two women, one domestic and one international, and five men, four domestic and one international are discussing the cultural differences they encountered upon arriving at the university. A young woman shared her reaction at seeing a woman in a "full burqa" for the first time. The students went on to discuss other differences they had observed. They concurred that what they liked best was that despite the different ways of dressing and acting, in classes and with their engineering teams what they discovered was in the end they were more alike than they were different. They all wanted their team to succeed so they would do well in the class. The minimization was typical. With first year students, there is a collective echo of the notion that at the end of the day we are all human and that is what is important.

This part of the discussion was not surprising: the surprise came after the focus group was coming to a close. A young Malaysian man who had been a quiet but supporting part of the conversation, nodding along with his fellow students', agreeing that in the end they were more alike than different asked if he could stay after the group to share some more of his experiences with cultural differences since arriving in Australia. He wanted to share that he did not really feel like a part of the team and that he did not know how to connect with them across the cultural differences. He shared he did not feel like he was included; and he did not feel like he could share this in front of the other students. He did not have the communication attributes to engage his classmates in a productive conversation on how he experienced things differently than they have without believing that he might be further isolated.

C. The Elephant in the Room

The researchers would like to say that these types of interactions were novel, but unfortunately, they were not. While these two vignettes are more colorful than most, they are examples of the ways first-year students communicate difference creates barriers to engaging and building mutually beneficial relationships with cultural others. Polarizing and minimizing messages permeate the conversations. These polarizing and minimizing speech acts impede students' ability to connect cross-culturally in meaningful ways. At the same time, inadvertently committing a cultural faux pas and unintentionally offending others was a pervasive concern for students on both sides of the Pacific. This mix of polarizing and minimizing communication patterns and fear of making a mistake impedes students' growth toward cultural humility. No one wants to talk about the elephant in the room for fear of looking foolish or worse.

V. IMPLICATIONS

This work provides a glimpse into how students communicate their understanding of cultural others. Students need tools and opportunities to discuss cultural differences and negotiate new meanings with cultural others within the engineering curriculum. Completion of this work will lead to locating first-year engineering students along this developmental continuum. Knowing where students are and what these phases look like in terms of students' constructions of meanings allows engineering educators to create student-centered, active learning approaches for student growth such as asking students to consider their relationships with various stakeholders when introducing the notion of user centered design, asking students to

VI. ACKNOWLEDGEMENTS

Thanks to all who contributed to this small vignette within the larger story of negotiating cultural humility. This work was made possible through an Early Career Research Grant, a joint venture between the two universities. Bouquets of thanks go to the experienced researchers on both sides of the Pacific. They shared their time, knowledge and expertise willingly to make this an important learning experience and lesson in humility for the interviewer. Their generosity of spirit makes negotiating cultural differences so much easier. A special thanks to the students who willingly shared their time and their stories with the researchers, their joie de vie is infectious.

Common Configurations for Engineering Student Support Centers

Walter C. Lee & Holly M. Matusovich
Department of Engineering Education
Virginia Tech
Blacksburg, VA, United States

***Abstract* — In response to the persistent issues of retention and diversity, many colleges offer Engineering Student Support Centers (ESSCs). However, little is known about ESSC design or how these centers function alongside the engineering curriculum and within the larger systems of engineering education. Based on the current literature, there is a need to better understand ESSC design and how such centers influence the institutional experience of undergraduate engineering students. Our research seeks to address this gap by examining ESSCs of varying structure and configuration at multiple institutions. The overall study will use a multi-case study approach, which includes interviews and open-ended surveys with center administrators and engineering students. Preliminary results from the first phase of the project reveal a variety of ESSC structures and will assist us in representing the assortment of centers in the later phases of the study.**

Keywords—recruitment; retention; student support; diversity

I. Introduction

In response to the persistent issues of retention and diversity in engineering [1, 2], many colleges offer Engineering Student Support Centers (ESSCs). ESSCs serve a variety of purposes and are found in various structures. Common structures include Minority in Engineering Programs (MEPs) and Women in Engineering Programs (WEPs). However, little is known about ESSC design or how these centers function alongside the engineering curriculum or within the larger systems of engineering education as much of the existing research is around individual programs (i.e. summer bridge programs) and typically focuses on program outcomes and student satisfaction - e.g. [3, 4]. Since few studied have examined ESSCs holistically (i.e. as individual entities) [4-7], the literature offers very little insight into the design of such centers or the advantages and disadvantages of the numerous approaches. Through previous studies, researchers have found: engineering faculty to be less supportive of programs and activities offered by MEPs that physically segregate students based on race or gender [5]; low financial cost and the ability to help numerous students academically and socially to be important factors when determining which activities to offer through a WEP [6]; female faculty to be more supportive of WEPs than male faculty [6]; and the impact changing the mission and physical space associated with an MEP can have on the relationship a center has with underrepresented students [7]. While these findings are useful, they underline the extent of our knowledge about the design of ESSCs and the scarcity of research that has investigated the diversity in structure and function of ESSCs across universities. That is to say, previous studies have not simultaneously examined the similarities and differences between an assortment of ESSCs with respects to how they are designed and influence the undergraduate experience. Based on the current literature, there is a need to better understand ESSC design and how structure and configuration impact the influence an ESSC has on the institutional experience of the undergraduates being served. Understanding the implications of the various structures and configurations will allow colleges to ensure they have an ESSC that best meets the needs of their students.

Our research seeks to address this gap by closely examining ESSCs of varying structures and configurations at multiple institutions. This work-in-progress describes the overall project and then focuses in more detail on the first outcome of the initial phase of the study - identifying and describing current ESSC configurations.

The overall study will use a multi-case study approach [8, 9], which will include data from interviews and open-ended surveys with center administrators and students respectively. Through this project, we will answer the overall research question: How do individual student support centers function alongside the engineering curriculum to promote positive institutional experiences for undergraduate engineering students? The project is a multi-phased qualitative study that will result in (1) descriptions of current ESSC practices, (2) descriptions of how students and center administrators experience and view these practices, (3) the identification of supports and hindrances to programmatic changes, and (4) strategies to overcome revealed barriers.

Specifically, this paper focuses on answering the following sub-question: What kinds of student support centers do engineering colleges commonly offer? This important first step will enable us to determine which types of ESSCs to include in the subsequent project phases for

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

closer examination. In this phase, we examine the common ESSC types, providing examples of how centers are structured at multiple institutions. Since there has been minimal research in engineering education regarding ESSCs holistically, this paper fills a needed gap by examining how colleges have attempted to support engineering students, particularly those from underrepresented populations.

II. Overall Research Project

To engage in examining ESSC structures, we will use a qualitative multi-case study approach including interviews, open-ended surveys, and document artifacts to gather a variety of information. We will interact with center administrators and undergraduate students at multiple institutions. Research findings will be grounded in Tinto's Longitudinal Model of Institutional Departure [10]. Tinto defines the institutional experience as a combination of: (1) academic performances, (2) faculty/staff interactions, (3) extracurricular activities, and (4) peer interactions. Tinto's model asserts that these experiences influence the level of academic and social integration a student achieves. Tinto's model further suggests that higher levels of integration lead to greater institutional commitment and retention. Looking at college students in general, research using Tinto's model has supported the underlying premises of the model [11-13]. The results of this study could potentially confirm or result in a modified version of Tinto's Model specifically geared towards ESSC design.

III. Current Status

To ensure the cases selected for the subsequent phases of the research study are representative of the common ESSC structures, we completed a preliminary Internet search to develop a database of common ESSC types. To gauge the commonness and variety of ESSCs offered across institutions, we compiled a list of universities and investigated whether or not they had a student support center specifically for engineering students and, if so, in what format.

To ensure we included a variety of schools, we intentionally sought out schools ranked high in engineering as well as schools graduating a large amount student from underrepresented groups by using the following lists:

1. Best Undergraduate Engineering Programs Rankings from the 2012 U.S. News & World Report (where doctorate is highest degree)
2. Best Undergraduate Engineering Programs Rankings from the 2012 U.S. News & World Report (where doctorate not offered)
3. Bachelor's Degrees awarded to Black or African-Americans (2010-2011) from the ASEE School Profiles
4. Bachelor's Degrees awarded to Women (2010-2011) from the ASEE School Profiles
5. Bachelor's Degrees awarded to Hispanics (2010-2011) from the ASEE School Profiles

From lists 1 and 2, we selected schools ranked in the top 10. From list 3-5, we selected schools ranked in the top 15. This resulted in a list of 50 universities from multiple regions of the US with a range (based on the Carnegie Classification) from very small to large, public to private, and undergraduate focus to very high research activity. Many institutions were represented on multiple lists, so the total number is less than adding the number of schools from each list together. For example, Georgia Tech has a highly ranked undergraduate engineering program and enrolls a large population of women and underrepresented students.

IV. Preliminary Findings

The results from searching the websites of each of the 50 universities revealed five ESSC formats across institutions and they are listed in Table I. The formats included:

- Minority/multicultural engineering programs (MEP), which focus on ethnic diversity without a specific focus on gender diversity
- Women in engineering programs (WEP), which focus on gender diversity without a specific focus on ethnic diversity
- Diversity in engineering programs (DEP), which focus on engineering students in general while targeting underrepresented populations; this includes centers that focus on broadening participation by targeting students from underrepresented populations or under-resourced high schools communally
- Women & minority engineering programs (WMEP), which separately focus on ethnic and gender diversity but under common leadership (i.e. one director); and
- General engineering support (GES), which focus on engineering students in general without a specific focus on broadening participation or diversity

It should be noted that 8 schools offered both a WEP and MEP separately so the percentages in Table 1 will not add up to 100% (i.e. each university that had a WEP also offered a MEP).

In looking for patterns in type of ESSC by school, we found that each large, public, research-intensive university (n = 16) offered an ESSC in some format. ESSCs were not as prevalent in schools under different Carnegie classifications and no patterns were found by setting (i.e. residential or non-residential) or geographic region.

TABLE 1: COMMON ESSC FORMATS

ESSC Format	Universities Identified
Minority Engineering Program (MEP)	10 (20%)
Women in Engineering Program (WEP)	8 (16%)
Diversity in Engineering Program (DEP)	10 (20%)
Women & Minority Engineering Program (WMEP)	3 (6%)
General Engineering Support (GES)	3 (6%)
No ESSC Identified	25 (50%)
Total	50 (100%)

Half (n = 25) of the institutions included in the Internet search do not offer an ESSC. At first we were surprised because a large part of our sample are schools that graduate a large number of women, Black/African Americans, and/or Hispanics. However, through closer examination, we found that a majority of the schools without ESSC were highly ranked non-PhD granting universities, Historically Black Colleges and Universities, or schools with very high Hispanic populations. There are several exceptions that we believe warrant further examination to understand if support is offered in a way that we were unable to identify during our Internet search. For example, perhaps these schools have strong support centers for students in general that were not identified through our initial search criteria.

V. Future Work

Our preliminary findings suggest that we should sample schools from these five configurations for subsequent phases of the project. However, to verify that we have not missed important alternative configurations, we are developing a survey to be administered nationwide. This survey will include schools in our present sample for confirmation of our classifications as well as a broader sample, allowing us to verify and/or modify the ESSC classifications identified herein. ESSCs will also be surveyed with regards to the specific programs, activities, and services they provide and invited to participate in the larger study. Once a more complete picture of the ESSC landscape is developed, centers that represent the variety of formats will be selected and more closely examined.

Engineering Culture and LGBTQ Engineers' use of Social Change Strategies

Mike Ekoniak
Virginia Tech, mekoniak@vt.edu

Abstract – **In this paper, I describe the theoretical framework for an investigation of the ways that engineers who identify as LGBTQ navigate engineering cultures. Previous work by Cech and Waidzunas, Bilimoria and Sewart, and Riley describe strategies that LGBTQ engineers use within highly heteronormative engineering cultures. The strategies described in the previous work fall into what Cox and Gallois refer to as *social mobility* strategies. Because Cox and Gallois assert that these strategies ultimately prove inadequate, I call for investigation of the use of *social change* strategies within the context of engineering.**

Index Terms – Diversity, LGBTQ, Sexual Orientation, Social Change

INTRODUCTION

Within engineering education, there is significant discussion of women and racial and ethnic minorities as underrepresented or marginalized groups in the field. A significant corpus of research on the subject, as well as engineering-specific community resources exist [1]–[7]. Lesbian, Gay, Bisexual, Transgendered, and Queer (LGBTQ) individuals in the engineering community are another, less visible (both literally and figuratively), marginalized group in engineering on which there is considerably less research or resources available.

Cech and Waidzunas' [8] 2009 conference paper and follow-up [9] journal article on the subject argue that engineering culture has "a strong propensity for dualistic styles of thought" where from the beginning of their training "engineers learn to differentiate between people-focused / technological-focused, detached objectivity / emotional connectedness, etc," These dualisms are valued differently in engineering culture, with technological-focus, and objectivity more highly valued than people and emotions. Furthermore, they noted that previous work on gender inequality showed that in engineering culture "technical/social dualism is often mapped directly onto a corresponding masculinity/femininity binary, having consequences for women within the profession." They extend this framework to LGB engineers and show that a similar dualism exists in engineering culture: the "heterosexual / homosexual binary." The main conclusion of their work was that in order to cope with this environment, their LGB participants utilized various strategies such as passing, covering, and compartmentalization, where students essentially feel the need to hide their sexual orientation or downplay its salience in engineering contexts.

Donna Riley [10] noted that within engineering workplaces, even in companies with LGBT-friendly policies, engineering workplace culture can undermine efforts to create a warm climate. For participants in that study, fear of the social repercussions of being out in the workplace can make work a "fearful and isolating place" for LGBT individuals, many of whom use covering, passing, and compartmentalization to cope with workplace culture.

Bilimoria and Stewart [11] conducted interview research with LGBT science and engineering faculty in academia with the goal of modeling the effects of academic workplace climate on the careers of LGBT faculty. Similarly to Cech and Waidzunas' [9] findings with engineering students, they found that engineering faculty work in a climate where heterosexuality is assumed, and that non-heterosexual identity is invisible. Informants in the study reported both direct and indirect hostility towards LGBT sexual orientation. This climate leads many faculty to remain closeted for fear of negative social or career consequences, and consequently experience their academic work environment as an isolating and fearful space.

THEORETICAL FRAMEWORK

In this work, I adopt social identity theory as a theoretical framework, specifically the work of Cox and Gallois [12]. The heart of their social identity perspective of sexual identity development lies in the fact that members of non-dominant groups have a harder time building self-esteem through social comparison (positive distinctiveness) than dominant groups. "Because of the inequalities in the power relations between groups," non-dominant groups must employ certain strategies so that the social comparison process builds positive distinctiveness rather than negative. These are referred to as Identity Enhancement Strategies, and are used by non-dominant groups to overcome the fact that dominant groups, through their position of power, determine the dimensions by which social comparisons are made and ensure that the chosen dimensions cast the dominant groups in a positive light. The Identity Enhancement Strategies that Cox and Gallois posit may aid the process in gay and lesbian individuals are: Social Mobility Strategies, and Social Change Strategies.

Social Mobility Strategies rely on the fact that (some) social groups have fluid boundaries. By joining a dominant group, a member of a non-dominant group can increase self-esteem. In the case of homosexual identity, this can involve capitulating, passing, covering, and blending. Capitulation, in this case, would be where a homosexual individual discards all aspects of homosexual identity. Passing is where an individual lives with a homosexual identity in one social circle and a heterosexual identity in another, hoping that the circles do not intersect (Don't ask, Don't tell is an example of passing). Covering is when an individual is "prepared to disclose their sexual orientation if asked, but does not actively demonstrate it." Finally, blending is when an individual views their sexual orientation as irrelevant to all other aspects of life, and avoids disclosing it while acting as a member of the dominant (heterosexual) group. (In the preceding sentences, I used homosexual as an example identity for illustration, but any non-dominant sexual identity could be substituted). Cox and Gallois posit that when individuals interact in social situations, sexual orientation can move from being seen as a personal identity to becoming a salient identity in group situations. As this happens, it becomes less possible to use social mobility to enhance self-esteem because as sexual orientation becomes more salient in group dynamics, it becomes more apparent to the individual using social mobility strategies that they have not, in reality, joined the dominant group. Cox and Gallois are also careful to point out that because social mobility maintains the status quo comparison between the dominant and non-dominant social groups intact, "the most that can occur via social mobility strategies is for individuals to leave the subordinate group and join the dominant group. Social mobility is a strategy for individuals, not for groups."

The other type of strategy described by Cox and Gallois is Social Change Strategies. There are two types of social change strategies, social creativity and social competition. Both strategies can increase positive self-esteem in the non-dominant group. Social creativity takes three forms: creating new dimensions for comparison with the dominant group where the non-dominant group is evaluated positively (homosexuals are artistic); redefining the value of existing dimensions; and comparing with other non-dominant groups (homosexuals are superior to polygamists). It is important to note that while social creativity increases self-esteem, there is no fundamental change in the social structure. Social competition, on the other hand, aims to effect change in the relationship between non-dominant and dominant groups where both groups accept the shift in status differential. Examples of social competition include lobbying for official government recognition such as the right to marry, or holding civil rights protests.

Each of the coping strategies used by LGBTQ engineers described in the previous work [8]–[11] in an engineering context can be as what Cox and Gallois called Social Mobility Strategies. While the previous work on sexual identity found ample evidence that LGBTQ engineers use these Social Mobility strategies, there is a lack of reported evidence of the use of Social Change Strategies.

As an initial inquiry, I am using in-depth open-ended qualitative interviews to explore 3-5 case studies of LGBTQ-identifying engineers to look for evidence of the individuals' use of social change strategies within engineering schools and workplaces. As this research is ongoing, the exact demographics of the participants are unknown. This work will contribute to a fuller understanding of the ways that LGBT engineers navigate engineering cultures, with a larger goal of identifying new directions for research on sexual identity in engineering. Preliminary results will be shared at the conference.

***Abstract*—We want our students to understand and apply the concepts in each course. Therefore, we work hard to help our students master often-difficult concepts; however, our evaluation of their conceptual understanding often occurs simultaneously with evaluation of other learning goals through use of traditional problem-solving tests. Seldom do we measure pre-to-post learning gains. Often, instruments that would facilitate pre-to-post learning evaluation are not available. Creation, development, and use of such instruments would likely promote constructive conversations between engineering students and faculty members. Assessment instruments that have been designed to evaluate only conceptual understanding are often referred to as concept inventories, following a convention established by the Force Concept Inventory. Concept inventories have a range of possible uses, e.g., a pre-course diagnostic to understand conceptual understanding of students at the beginning of a course, early course formative assessment to guide instructional planning, summative assessment to evaluate conceptual understanding at the end of the course, and pre-post assessment to aid evaluation of instructional strategies. Concept inventories have been used at both course and program levels. What distinguishes concept inventories from typical engineering course assessment methods is focus on a small set of key constructs, focus on a specific domain of academic content, and focus on conceptual understanding or qualitative reasoning, as opposed to computational problem solving. Considerable scholarship informs selection of the situations, formulation of the question, and development of plausible distracters.**

During the workshop, participants will (i) be provided an overview of research on conceptual understanding, (ii) be provided an overview of the historical development of concept inventories, (iii) engage in activities to describe effective uses and some misuses of concept inventories in their courses, (iv) learn how to access existing concept inventories via the developing ciHUB.org platform, (v) discuss psychometric properties of existing instruments, (vi) learn how psychometric analysis can aid development of concept inventories, and (vii) have opportunities to become active members in a growing community of users.

Keywords—assessment; assessment instruments; conceptual understanding; formative assessment

I. Introduction

Most engineering faculty members will agree with this statement: "Students should understand engineering concepts." However, a much smaller percentage actually assesses the extent to which their students have developed conceptual understanding, apart from performance on course exams. Unfortunately, course exams assess complex combinations of knowledge and skills, so separating out development with respect to conceptual understanding is difficult. Also, small numbers of engineering faculty members track gains in conceptual understanding from the beginning to the end of their courses. In cases where faculty members have tracked pre-to-post development, many have been surprised at the small size of the gains that were achieved [1, 2].

Instruments to assess conceptual understanding have been developed or are under development for several engineering subjects [3-6]. Other subjects could benefit from development of such instruments. Therefore, this workshop at FIE 2013 provides an excellent opportunity to engage many engineering faculty members in constructive conversations about applying and developing these instruments, often referred to as concept inventories.

II. Assessing Concept Understanding

Although conceptual understanding of the course subject may be necessary to solve problems on course exams, many other areas of student learning and development contribute to their ability to solve these problems. As a result, scores on the exams may indicate the extent of mastery of conceptual

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

understanding, but they may also indicate the extent of mastery of many other sets of knowledge and skills. In order to assess and evaluate conceptual understanding, many instrument developers have turned to questions that do not require students to complete calculations. Instead, questions, sometimes referred to as concept questions, pose a scenario for students and ask them to reason qualitatively to develop or select an answer to the question. Further, many of the concept questions are often multiple choice questions that allow a faculty member to identify potential misconceptions. An appropriately developed, appropriately organized, and appropriately refined set of concept questions may form a concept inventory.

In the case of multiple choice questions, selection of the situation on which each question is based, formulation of the question, and development of distracters is based on research about how students understand the concepts that are the focus of the concept inventory. For a particular concept, research often reveals that many learners have completely incorrect understanding while many other learners have partially correct understanding. Use of this research allows development of distracters that can reveal much about alternative conceptions that learners hold and suggest approaches to repairing these alternate conceptions.

III. Brief History of Concept Inventories

Concept inventories, which began in 1985 with the Force Concept Inventory (FCI) [7, 8] in physics, seek to produce valid, reliable data on conceptual understanding and foster constructive conversations among STEM educators. The FCI provided a snapshot of student conceptual understanding of force and motion that fostered a "cascade of CI development initiatives" in many different subjects [9]. Use of the FCI in many different settings illustrates how a well-developed instrument can evaluate instructional strategies [1], catalyze educational change in a science field [10], and influence education in other STEM fields.

IV. Workshop Overview

Workshop facilitators will use a set of interactive activities and short lectures so that participants will:

(i) Be provided an overview of research on conceptual understanding,
(ii) Be provided an overview of the historical development of concept inventories,
(iii) Engage in activities to describe effective uses and some misuses of concept inventories in their courses,
(iv) Learn how to access existing concept inventories via the developing ciHUB.org platform (http://www.ciHUB.org),
(v) Discuss psychometric properties of existing instruments,
(vi) Learn how psychometric analysis can aid development of concept inventories, and
(vii) Have opportunities to become active members in a growing community of users.

V. Workshop Facilitators

A. *Jeffrey E. Froyd, Texas A&M University*

Dr. Jeffrey E. Froyd received the B.S. degree in mathematics from Rose-Hulman Institute of Technology and the M.S. and Ph.D. degrees in electrical engineering from the University of Minnesota, Minneapolis. He is a TEES Research Professor in the Office of Engineering Academic and Student Affairs at Texas A&M University, College Station. He has been an Assistant Professor, Associate Professor, and Professor of Electrical and Computer Engineering at Rose-Hulman Institute of Technology. He served as Project Director for the Foundation Coalition, a National Science Foundation (NSF) Engineering Education Coalition in which six institutions systematically renewed, assessed, and institutionalized innovative undergraduate engineering curricula. At Rose-Hulman, he co-created the Integrated, First-Year Curriculum in Science, Engineering and Mathematics, which was recognized in 1997 with a Hesburgh Award Certificate of Excellence. He has authored over 70 papers on faculty development, curricular change processes, curriculum redesign, and assessment. Prof. Froyd is a Fellow of the IEEE, a Fellow of the ASEE, an ABET Program Evaluator, the Editor-in-Chief for the IEEE Transactions on Education, and a Senior Associate Editor for the Journal of Engineering Education. He has served as the general chair for the 2009 Frontiers in Education Conference and a program co-chair for three other FIE conferences.

B. *P. K. Imbrie, Texas A&M University*

Dr. P.K. Imbrie, the Director of Undergraduate Programs and an Associate Professor in the Department of Engineering Technology and Industrial Distribution at Texas A&M University. He holds B.S., M.S. and Ph.D. degrees in Aerospace Engineering from Texas A&M University. An advocate for research-based approaches to engineering education, curricular reform, and student retention, Dr. Imbrie conducts research in epistemologies, assessment, and modeling of student learning, student success, student team effectiveness, and global competencies. He helped establish the scholarly foundation for engineering education as an academic discipline through lead-authorship of the landmark 2006 JEE special reports "The National Engineering Education Research Colloquies" and "The Research Agenda for the New Discipline of Engineering Education." He co-led the creation of the First-Year Engineering Program's Ideas to Innovation (i2i) Learning Laboratory, a design-oriented facility that engages students in team-based, socially relevant projects. Directly building on the enhancements to the first-year experience, he led the First-Year Honors Program toward an enabling environment that attracts and retains the highly motivated and academically successful student with a broader and more enriched educational experience promoting scholastic achievement, breadth of knowledge, global awareness, and leadership development. He has been involved with various research projects sponsored by NSF, NASA, and AFOSR, ranging from education-related issues to traditional research topics in 3D stress measurements using photo-stimulated luminescence spectroscopy (PSLS) and environmental effects on titanium-based metal matrix composites. Prior to joining Purdue, Dr. Imbrie was involved with NSF's Foundation Coalition, during which time he established himself as one of the nation's experts on collaborative learning and teaming. He is co-author of a text on teaming called *Teamwork and Project Management*.

C. Teri Reed, Texas A&M University

Dr. Teri Reed is assistant vice chancellor of academic affairs for engineering (TEES), assistant dean of academic affairs for the Dwight Look College of Engineering, and associate professor in the Department of Petroleum Engineering at Texas A&M University. She received her BS in petroleum engineering from the University of Oklahoma and spent 7 years in the petroleum industry during which time she earned her MBA. She subsequently received her PhD in industrial engineering from Arizona State University. Dr. Reed's teaching interests include statistics, interdisciplinary and introductory engineering, diversity and leadership. Her research interests include statistics education, concept inventory development, assessment/evaluation of learning and programs, recruitment and retention, diversity, and equity. She has received funding from the National Science Foundation, Department of Education, various foundations, and industry. Professor Reed is a member and Fellow of the American Society for Engineering Education (ASEE), and a member of the Institute of Electronics and Electrical Engineers, the Institute of Industrial Engineers, and the American Society for Quality. She serves as an ABET Engineering Accreditation Council evaluator for ASEE and is the co-chair of the Undergraduate Experience Council. Dr. Reed served as a reviewer of the United States' National Academy of Engineering's (NAE) 2008 report Changing the Conversation: Messages for Improving Public Understanding of Engineering and 2010 report Standards for K-12 Engineering Education? and was an invited participant in NAE's Committee on Curriculum Reform and the NAE workshop Curriculum: Understanding the Design Space and Exploiting Opportunities. She recently joined Texas A&M University from Purdue University, where she received one of Purdue's highest honors given by the University President in the fall of 2012, the One Brick Higher Award. She has two boys, one is a first-year student at Purdue and the second is a sophomore at Allen Academy in Bryan, Texas.

Building an Inclusive REU Program

A Model for Engineering Education

Chuck Stone, Maureen Durkin, Tim Ohno,
Idemudia "JJ" Airuoyo, Kory Riskey, and Erich Meinig
Colorado School of Mines, Golden, Colorado, USA
cstone@mines.edu

***Abstract*—Faculty, staff, and students from Colorado School of Mines' Renewable Energy Materials Research Science and Engineering Center (REMRSEC) will discuss several strategies that have allowed REMRSEC to host a successful Research Experiences for Undergraduates (REU) program over the past five years for more than 100 students. The REU has consistently attracted highly qualified, diverse applicants and participants from a broad range of educational institutions that include Doctoral/Research Universities, four-year liberal arts colleges, historically black colleges and universities, Ivy League schools, tribal colleges, and two-year colleges. The program has received a significant amount of national recognition and international visibility due to its strong mentoring component that spans a variety of engineering and science disciplines while engaging students in authentic research tasks. Audience members attending this panel discussion will learn how our REU has successfully connected faculty mentors and undergraduate student researchers together in experiential education activities outside the students' primary research endeavors that include extracurricular activities, field trips, hands-on laboratory investigations, interactions with other REUs, professional development opportunities, student-driven "snapshots" sessions, and weekly technical seminars.**

Keywords—community; inclusive; mentoring; renewable energy; research experiences for undergraduates; REU program.

I. INTRODUCTION

This panel session features a spectrum of speakers from the Colorado School of Mines' (CSM) Renewable Energy Materials Research Science and Engineering Center (REMRSEC) who will discuss several strategies that have allowed REMRSEC to host an extremely successful Research Experiences for Undergraduates (REU) program over the past five years for more than 100 students. The REU has consistently attracted highly qualified, diverse applicants and participants from a broad range of educational institutions that include Doctoral/Research Universities, four-year liberal arts colleges, historically black colleges and universities, Ivy League schools, tribal colleges, and two-year colleges. The program has received a significant amount of national recognition and international visibility due to its strong mentoring component that spans a variety of engineering and science disciplines while engaging students in authentic research tasks. REMRSEC's interdisciplinary team of approximately 30 science and engineering faculty from Mines, as well as staff from the Center for Oil Shale Technology and Research, the Colorado Energy Research Institute, and the National Renewable Energy Laboratory, mentor students in a ten-week summer research program addressing fundamental materials issues related to the science and technology of renewable energy. These highly interdisciplinary studies focus on multiple areas that are open to all chemical engineering, chemistry, computer science, engineering, materials science, mathematics, and physics majors. Audience members will learn how our REU has successfully connected faculty mentors and undergraduate student researchers together in experiential education activities outside the students' primary research endeavors that include extracurricular activities, field trips, hands-on laboratory investigations, interactions with other REUs, professional development opportunities, student-driven "snapshots" sessions, and weekly technical seminars.

II. PANEL SESSION FORMAT

Our panel format will allow our diverse group of speakers (energy educators, engineering research faculty, graduate student mentors, REU leaders, and undergraduate student researchers) the opportunity to present a holistic view of our program. The panel will feature viewpoints of faculty and administrators who developed the REU structure, its curricular themes, and multifaceted research components, as well as students who have participated in the program over different summers. The first half of each 15-minute time block will allow panel members to share their remarks, while the second half of each 15-minute time block will be open to audience members to discuss best practices at other institutions. These multiple perspectives will provide panelists and audience members a rich landscape of successful REU qualities, as well as factors that contribute to robust energy engineering and energy education programs. We hope this session will extend our methods to existing and new REUs in an effort to provide more students with high-quality undergraduate research experiences that will give them clearer perspectives on academic coursework, a better appreciation for graduate studies, and the need for a highly-trained workforce in the field of energy engineering.

The panel session will address the following key areas in six, 15-minute time blocks:

A. Recruiting Strategies and Tactics that Resonate Well with Underrepresented Populations

The REMRSEC REU has been successful in recruiting women, underrepresented minorities, non-traditional students,

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

and persons with disabilities in research. Underrepresented minorities are African Americans, Hispanics, American Indians, Alaska Natives, and Native Hawaiians or Other Pacific Islanders. Since the REU began in 2009, female participation has ranged from 29% to 59%, while underrepresented minority participation has ranged from 12% to 29%. Strategies to foster interest in the REU have included faculty attendance and student presentations at conferences targeted for underrepresented groups. A majority of our applicants freely interact with our faculty and staff via email communications, conference calls, personal phone calls, and campus visits.

Throughout the recruitment and selection process, as well as the entire REU program, students have a consistent point of contact through Chuck Stone, our REU Program Director. Stone tirelessly promotes our student recruitment efforts, establishes collaborative research groups on- and off-campus, and facilitates successful student-mentor interactions. He travels to about six scientific meetings each year to discuss research opportunities in renewable energy, advertise our REU summer program, and recruit underrepresented students. He follows-up on all contacts, completes direct mailings to interested students, and promptly responds to all telephone and email inquiries. He also signs offer letters and responds to acceptances. Upon arrival at the CSM campus for the REU experience, Stone introduces participating students at our Orientation Session and Welcome Luncheon. During the Orientation, Stone provides an overview of the REU program; introduces faculty mentors, post-doctoral scholars, and graduate students; discusses the role of REU alumni mentors, external collaborators, and visiting scientists; and highlights key features of REMRSEC. He also introduces REU students to the members of the project management team, the administrative support staff, and their own research teams. Although direction of the students' research is transferred to each project's primary faculty mentor, Stone continues to be an important point of contact and acts as a resource to both students and faculty mentors throughout the summer.

B. How to Encourage Faculty Mentors and Prospective Students to Structure Preliminary Research Teams

Each year, the REU recruits approximately 30 CSM faculty to mentor REU students. During our recruiting period, students are openly encouraged to contact REMRSEC faculty and staff to discuss research opportunities. A typical applicant may speak to three different research teams with work efforts that require analytical, computational, experimental, or theoretical expertise. Stone serves as an unbiased advocate and coach for those applicants that contact him seeking to best match their interests and skills to appropriate research teams. Since he is uniquely aware of each research team's activities, and always leaves the final student selections to individual faculty mentors, Stone helps match strong, deserving students to the most appropriate research endeavors. Renewable energy projects typically address the performance of next-generation photovoltaic devices; microstructural design of composite membranes; hydrogen storage in clathrate hydrates; social and ethical implications of climate change, renewable energy, sustainability & education; hybrid energy systems for oil shale production; and optimizing computational tools for energy science. In the end, the goal is to create a "win-win-win" situation for each student, each faculty mentor, and REMRSEC's unique research agenda.

Most REMRSEC research teams consist of a primary faculty mentor, postdoctoral scholars, graduate student researchers, and CSM undergraduate students. A visiting scientist may also be on the team. When an REU applicant is selected to participate in our REU, he or she is assigned a near-peer mentor (usually a CSM undergraduate student) within the team, and often begins interacting with team members six to eight weeks prior to the start of our REU. This gives a participant valuable lead time to get to know team members, an opportunity to contribute to group discussions, survey reports on team activities, and preview relevant papers on the research topic. Consequently, most REU students are able to make preliminary headway in their research pursuits before they arrive on campus. These types of preliminary interactions make students feel they are already an integral part of the research enterprise before our REU begins, and prevents many students from declining our invitation, even after they have committed to our program. Yes, students can be fickle at times and change their minds when least expected!

C. Community-Building Activities within Students' Research and Social Environments

REU students are encouraged to connect with each other as much as possible outside of their research teams and individual projects. Opportunities for community building include weekly technical seminars that span photovoltaics, energy storage materials, the role of catalysts in fuel cells, computational energy science, and challenges & opportunities with biofuels. These technical seminars expose students to a renewable energy curriculum that provides them with appropriate depth and breadth in the subject. Students demonstrate an appreciation for how and why an advanced degree in an engineering or science discipline is beneficial to further advances in renewable energy. Each week, hands-on laboratory investigations expose students to processes and techniques used in engineering and physical sciences. Professional development sessions cover Ethics and the Responsible Conduct of Research; Learning, Teaching, & Working Across Generations; Being a Role Model, Finding a Mentor; Careers in Renewable Energy; and Graduate Schools & Fellowship Opportunities. Student "Snapshots" Sessions allow participants to informally share their research results in a weekly open-learning environment. Additional community-building activities include field trips to the nearby National Renewable Energy Laboratory, visits to local renewable energy businesses and a sustainable energy museum, outdoor concerts at Red Rocks Amphitheatre, evenings at Colorado Rockies baseball games, afternoon soccer matches and ultimate Frisbee competitions, mountain biking, horseback riding, summiting 14ers (mountains with elevations over 14,000 feet), overnight backpacking trips, whitewater rafting excursions, shopping at the local farmer's market, exploring downtown Denver, and sightseeing throughout the Rocky Mountains. In addition, all students are housed in the same on-campus residence hall, which also fosters community.

D. *Nurturing Collaborations with Other Nearby REU Programs*

REMRSEC REU students participate in research discussions, laboratory tours, social activities, and an end-of-summer joint poster session with other nearby REU students in the Advanced Metallurgical Design for Transportation, Infrastructure, and Energy REU at CSM; the Advancing Polymer Materials by Integrating Chemistry and Chemical Engineering REU at CSM; the National Nanotechnology Infrastructure Network (NNIN) REU at the University of Colorado, Boulder; and the Science Undergraduate Laboratory Internship (SULI) program at the National Renewable Energy Laboratory.

For the past two years, the Advanced Metallurgical Design and Advancing Polymer Materials summer REUs have been established on the Mines campus. Since the REMRSEC REU is the older and more established program of the three, the faculty managing these two other REUs have looked to our REMRSEC REU for guidance. In turn, the REMRSEC REU has included these other REUs in its various community-building and professional development activities, allowing students in all three programs to benefit from additional networking structures.

E. *Post-REU Tracking and Measuring Long-Term Student Outcomes*

During the summer of 2012, REMRSEC surveyed its past REU participants in its 2009, 2010, and 2011 summer programs. Questions addressed issues like the influence of the REU on career aspirations and what former REU students are currently doing. The survey had a 64% response rate (54 students) and provided data that has helped the REU program understand its strengths and areas for further development.

F. *Retention with the Fields of Renewable Energy, Energy Engineering, and Energy Education*

One of the goals of the REMRSEC REU program is to encourage people from underrepresented groups in science, technology, engineering, and mathematics programs to learn more about renewable energy research in hopes of motivating them to stay in the field. Our survey data indicates some success with this goal, with almost 1/3 of the students continuing to graduate school.

III. Summary

The thrust of this panel, and the very nature of it, is that we have a model program at one institution. Students in our REMRSEC REU participate in research discussions, laboratory tours, social activities, and an end-of-summer joint poster session with two other REUs at CSM (the Advanced Metallurgical Design REU and the Advancing Polymer Materials REU) and two other nearby groups at the NNIN REU at the University of Colorado, Boulder and the SULI program at the National Renewable Energy Laboratory. Although we considered inviting personnel from these four groups to join our panel, these partner REUs are still maturing and are not yet vested in the model program we describe. In the future, we would like to offer a panel session featuring presenters from different institutions, in addition to the breadth of perspectives from our REMRSEC REU stakeholders. This discussion could focus on strategies for effectively assessing and evaluating REUs as well as describing best practices for tracking short-term and long-term student outcomes. First, however, we see benefit to the engineering education community in featuring a singular (yet still collaborative) model, which has inclusion as a core value and outcome.

***Abstract*— Every classroom constructs its own culture through the interactions of all participants, students and instructors. This culture, often covert or invisible, has a direct impact on students' opportunities to learn. Therefore, it is critical that instructors understand their classrooms' interaction patterns and their effect on student learning. We suggest that discourse analysis may serve as a tool to enhance instructors' understanding of their classrooms and to serve as an intervention particularly useful for junior faculty as they are beginning their teaching career. To this end, this paper (1) describes the theoretical foundation of discourse analysis and (2) demonstrates its application, effectiveness, and applicability in STEM classrooms, particularly at the introductory level, the time when students make their first steps in negotiating 'academic literacies'.**

***Keywords*— discourse analysis; qualitative methodology; academic literacies; first-year engineering courses**

I. Introduction

In the last few years, an increasing number of scholars have called upon the engineering education research community to expand the predominant quantitative and positivist paradigm to include a broader and more diverse range of epistemologies, theories, and methodologies [1]-[8]. Broadening engineering education scholarship will allow access to a larger spectrum of possible research questions and ensuing understandings about ways engineering is taught and learned. By including a range of research perspectives, the engineering education research community may delve deeper into the fundamental questions about engineering students' learning experiences and extend the current discourse about student learning from a purely cognitive enterprise to a socially constructed endeavor [8, and the literature cited therein].

This paper presents discourse analysis method as a way of exploring the question of students' learning experiences situated in various socio-cultural contexts. We maintain that discourse analysis, albeit underutilized to date in engineering education research, allows for understanding classroom culture as it is being created through the interactions between all participants, students and instructors. Specifically, the focus on the classroom use of language provides a lens to understand students' learning opportunities [8]-[14].

To this end, we situate our discussion in the research on 'academic literacies' while also co-opting this term to embrace ideas that go beyond the traditionally defined boundaries of the engineering education research field. Epistemologically, literacies are considered social practices, in which students negotiate, often conflicting, academic and experiential discourses [8],[14],[15]. Literature on the subject maintains that it is through this process of negotiation that students work towards finding their professional identities [8]. We propose, however, that the term 'academic literacies' need to encompass students' understanding of 'the rules of the game' in each classroom context, i.e., the micro-actions and micro-discourses embedded in each classroom's activities that serve as opportunities to learn [2]. We argue that in the absence of knowing 'how to play each classroom's game,' students do not take advantage of opportunities to learn, preventing them from further learning particular academic discourse needed for realization of professional identities.

Thus, in this paper we draw on the work of Courtney Cazden (2001) to describe the academic literacies developed in classrooms by focusing on micro-actions and variations in discourse features [10]. As such, in addition to describing qualitative features of the classroom discourse that form the cognitive basis of students' professional development, we employ quantitative methods to measure the ability of all students to gain access to learning. By using this mixed-methods framework, we demonstrate how the effectiveness of comprehending communication may be measured through the ability of all participants, at any given moment, to actively share in the co-creation of classroom culture and for students "to know what they are talking about and feel confident that all the parties involved refer to the same things when using the same words" [16].

In Cazden's framework, the classroom culture is created by all participants through actions such as obtaining speaking turns, gaining the floor, active listening, pacing and sequencing, classroom routines, etcetera [10]. We demonstrate how these actions, which serve as a source of quantitative data, along with qualitative observations can be used to generate a holistic picture of the classroom's culture. Specifically, we do so in the context of introductory mathematics courses, which serve either as a gateway to a technical degree or a requirement for a non-technical one. In all cases investigated, the courses are situated at the critical time in students' overall development as they are making their first steps in negotiating 'academic literacies' [14],[15]. Therefore, understanding the cultures of those specific classrooms becomes of particular importance. Moreover, we illustrate how discourse analysis method may be used as an early intervention for junior faculty as they are beginning to shape their pedagogical identities and skills.

We conclude with a description of how discourse analysis method allows for identifying what students have better opportunities to succeed in the specific classroom cultures investigated and how faculty perceive their post-intervention evolution with an emphasis on the ways in which they can then take concrete steps to make overt the classroom culture, otherwise invisible to students, and reshape it to expand learning opportunities for all participants.

II. Discourse Analysis Method

A. Methods

We investigated three introductory mathematics classrooms at three different undergraduate institutions: one at an engineering school, another at a liberal arts college, and the third at a business school. All classrooms were led by an early-career instructor (either in his second or fourth semester of teaching). Three classroom meetings of each course were videotaped and one videotaped session from each was chosen for transcription and further analysis [17, and the literature cited therein]. Analysis began with the creation of broad categories typical of discourse analysis studies: the number of interactions initiated by the instructor and students, the amount, "density," and quality of instructor's and students' discourse, etc. This was achieved by breaking transcribed discourses into message units, interaction units, and instructional units (defined below). Multiple passes through the data allowed for enumerating and qualifying various items of interest (e.g., quantity and quality of faculty feedback, type of questions, etc.), which revealed specific interaction patterns. To summarize our findings for each classroom, we used three representations: graphical visualization of the numerical data; short narratives describing a typical student's experience; and a 'taxonomic map' of the classroom's culture. These representations allowed a holistic understanding of each classroom's unique culture and, moreover, identification of these cultures' aspects that students ought to have understood to take full advantage of learning opportunities.

B. Nomenclature

In what follows, we present the discourse analysis terminology used throughout the paper.

Interaction units are defined as "turn-taking" between classroom participants [2]. For example, the following episode contains three interaction units. For visual identification, interaction units are separated by horizontal lines:

Instructor: *First, tell me the type of curve it is. It has a name, right? We know that?*
Student: *Parabola.*
Instructor: *It's a parabola.*

Instructor: *And it opens up or down?*
Student: *Up.*
Instructor: *Up.*

Instructor: *So, the coefficient of the x squared term is positive or negative?*
Student: *Positive.*
Instructor: *Positive.*

In this episode, the instructor begins each interaction, the student then responds, and the instructor follows up with feedback. This is a typical example of what is called the IRF pattern (Initiation-Response-Feedback). Many interactions, however, do not fall into such a neat arrangement. For example, an instructor may ask a student a series of questions to elicit a desired response. A turn-taking may then be considered to be "complete" either after each student's response, or after the instructor moves on to a new line of questioning or to a different student altogether. The way interaction units are identified is subject to the information sought in specific classroom discourse.

A message unit is defined as "the smallest unit of meaning." In practice, this can be interpreted as the smallest portion of speech that evokes a complete image or thought. For example, in the previous example, message units, delineated by slashes, may be defined in the following way:

First tell me / the type of curve it is. / It has a name, / right? / We know that?

Finally, the largest unit of analysis identified in discourse analysis is that of an instructional unit. An instructional unit is usually defined as a change of interaction pattern and/or of content. For example, in a class session that has three instructional units, a teacher may start by lecturing, then allow time for group work, followed by the group report-outs. In this example, the lesson moves in a very linear way and the instructional units, sometimes known as lesson phases, are clear to all participants. Other classrooms may follow a different pattern. For example, an instructor may choose to shift from topic to topic based on student feedback or spiral around a central class theme; yet other classrooms may have loose instructional units whose transitions are obscured by frequent, off-topic interruptions.

To some extent, identification of interaction, message, and instructional units is subject to the specific analytical practices used by an analyst. The robustness of the results lies in the analytical consistency and high inter-coder reliability.

C. Analytical Representation

The results of the analysis may be represented in several different ways. Used together, these representations allow for a comprehensive in-depth description of quantitative and qualitative results. For example, data can simply be represented in terms of raw numbers of interaction, message, and instructional units. Alternatively, a series of bar charts or other graphical representations may be used to capture major patterns in classroom discourse. A short narrative of what an analyzed class might look like from a student's perspective may serve as yet another illustration of classroom discourse.

This particular portrayal of data usually supplements quantitative results and allows for a detailed description of qualitative findings. Finally, a taxonomic map allows for a visual depiction of the classroom culture with ensuing understandings about a type of student that might thrive in a given classroom environment. A taxonomic map can also be used to understand the processes necessary to support students' success in each classroom culture and serve as an intervention for instructors' professional development.

In this particular study, the taxonomic map incorporated both quantitative and qualitative features along with some open questions. This allowed us to use the taxonomy to generate a conversation with the instructors about their classroom culture and the processes they follow to co-create interactive contexts in their classrooms. In our dialogue with participating instructors, we were able to identify important aspects of each classroom that students need to understand in order to successfully take advantage of learning opportunities.

Ultimately, discourse analysis has several benefits when used in the appropriate context. Breaking down a classroom's discourse into countable units allows an analyst to quantifiably answer questions about the procedures and processes that govern classroom interaction. Those objective results can reveal an overall picture of the classroom's culture, and various methods of data interpretation may be used to help the instructors understand that culture from many angles so that they can overtly communicate their unique interaction "rules" to students.

III. Our Study

To give context for our results we first offer a description of the format and content of each of the three classes analyzed. Next, we present the results of the study by first explaining emerging catgories for all three classrooms and sharing an illustration and interpretation of one taxonomic map. We also include a cross-class comparative analysis of our findings for each classroom and present them as models-in-use, i.e., examples, but not generalizations, of similar classes.

A. Abbreviated Class Narratives

All three mathematics classes investigated were introductory in nature and prerequisite either for attainment of a major or as a distribution requirement. As well, early-career faculty, all men, taught all three classes. Set in the context of different institutions, however, each class had its own unique structure, pattern of interactions, and overall discourse. Below are much abbreviated narratives about each observed class.

At the *engineering school*, the classroom was significantly larger than the other two with 72 students and an approximate ratio of 50/50 men to women. This class ran 100 minutes and was held in an auditorium, with a single large white board at the front of the room. The distinctive feature of this class was that three mathematics instructors were always present in the room. For each lesson, one of the instructors was designated as a "main lecturer," while others chimed in to either clarify an answer to a question or to expand on the material presented. The lesson analyzed for this study was presented by the most junior instructor in his fourth semester of teaching at the school. The lesson took the form of an interactive lecture that began with a discussion and clarification of the course format and expectations, quickly transitioning to the presentation of the main topic, differential equations. Guided by students' questions, the instructor briefly reviewed and clarified content presented in previous lessons and homework assignments. When students had no further questions, the instructor moved to introducing new content: linearization, phase plots, and phase planes. The instructor frequently solicited and entertained students' questions, often taking him away from the lesson's focus. However, he quickly realigned himself with the class agenda while still responding to students. (His colleagues occasionally spoke up as well.) On several occasions, students' questions were only briefly or partially answered under the premise that the full answers would be included in later portions of the lecture. The interactive nature of the lesson was established by frequent exchanges between instructor(s)' lecture and student questions/comments. These exchanges were either instructor-to-individual student or instructor-to-student group. There were no student-to-student interactions during the lesson, that is, we did not observe any partner- and/or small-group work. Throughout the entire lecture, the instructor allowed for no deviations away from the main lesson's content.

The *liberal arts college* classroom was the smallest of the classes observed with only 14 students, all women. The lesson ran 75 minutes and took place in a room that had individual desks arranged in two rows, all facing a "smart" interactive white board. The instructor was in his second semester of teaching at the college. The content of the analyzed lesson included convergence of power series. The instructor taught the lesson in a traditional lecture format. There was some individual and pair work. The instructor began the class with a review of a quiz taken by students during the previous class session. He then moved into sharing the results of a student feedback survey regarding the course. The instructor then transitioned into the day's lesson by stating the lesson goal, representing functions as power series, and recapping what the class had learned about the topic up to that point. He gave an example of a function the class was familiar with, and asked questions beyond the students' knowledge to justify the importance of what was to come during the lesson. Although the instructor frequently solicited questions, they were usually met with silence; yet, for simple questions that required (dis)agreement, students seemed to respond through nodding of their heads or other non-verbal cues. During a short period of individual work, the instructor asked students to solve a problem on their own. As students did so, the instructor checked individual student progress and answered questions, making sure to stop by each desk. At the end of this individual seatwork, the instructor brought the students back together and stepped through the problem with the entire class. The instructor concluded the lesson by solving an additional example problem. The interaction during the presentation of both sample problems consisted of lecture interspersed with instructor's questions, infrequently followed by students' answers. Throughout the entire lesson, the instructor's focus remained on presenting the relevant material allowing for no social language and little teacher-student interactions.

Similarly to the classroom in *liberal arts college*, the class in *business school* was relatively small, 17 students, with a male to female ratio of 12:5. The class was 80 minutes and was held in a classroom arranged in two semicircular arcs centered on a series of white boards at the front. A new faculty member, in his second semester, taught the class. Similarly to the lesson in liberal arts school, the class took a form of a lecture with a group work component. The lesson began by the instructor reviewing a recent quiz with a detailed presentation of each problem on the board. The lecture then moved to a discussion of a simple and compound interest. At each step, the instructor made a point to differentiate between an asset's present and future values based on certain interest rates and initial investments. Following the presentation of the new concepts, the instructor asked the class to work on a problem in small groups. During this mini-session of problem-solving, the instructor walked around the classroom answering students' individual questions. The instructor did not solicit questions from student groups; rather, he spoke only to the groups that had specific questions. In the final few minutes of class, the instructor quickly presented the process of solving the problem at hand and demonstrated the correct solution. Students in this course frequently interrupted both the instructor and one another. These interruptions ranged from questions about problems that had already been discussed earlier in the lesson to questions about grading. Some students' questions were unrelated to the course and were of a personal or social nature. These interruptions required the instructor to suspend the flow of the lesson, go back to previously presented material and/or discuss content tangential to the lesson's objectives.

B. Comparison of Variables

After multiple passes through the data coding the *quantity and quality* of each set of units (interaction, message, and instructional) from the transcribed classroom discourses, we arrived at ten emerging categories. These categories were: (i) overall interaction units (both initiated by the instructor and students); (ii) overall message units (both those of the instructor and student); (iii) questions asked by instructor; (iv) instructor feedback; (v) student name use; (vi) instructor use of "I" vs. "We"; (vii) social content vs. pedagogical content; (viii) interruptions; (ix) student participation (i.e., "density" of student message units); and (x) theoretical vs. "real life" application content. The above categories served as a basis for ensuing quantitative and qualitative analyses within and across the classes. Below we describe most prominent categories as a way to understand social interactions of the classrooms studied.

1) Number of interaction/message units

In what follows we report quantitative data and analyses; statistical methods are not used in reporting our analytical findings as data demonstrated refers to specific units counted in one class at each school. Fig. 1 compares the number of interaction and message units per instructional hour initiated by the instructor with those started by students in each class. With only 80 interaction units/hr commenced by the liberal arts instructor in comparison to 124 and 135 in the engineering and business lessons, respectively, this seems to be the least "interactive" class. The number of interaction units/hr initiated by the students in each class, with only 16 in the liberal arts college in comparison to 23 and 83 in the engineering and business schools, respectively, supports the description of least "interactive" class as well.

When paired with the message units "density" data (the number of message units per instructional hour), however, the following picture emerged. With the 1749 instructor's vs. 134 students' message units/hr, the lesson in the liberal arts college remained the least "interactive" of the three. The corresponding numbers in the engineering and business school lessons were 1507 vs. 361 and 1974 vs. 449, respectively. This indicates that the low density of interactions in the liberal arts school does not correspond to a decreased number of message units, i.e., the density of the information shared by this instructor was quite significant, in fact, even larger than that at the engineering school. What this implies, however, which is what we qualitatively observed as well, is that the liberal arts classroom had the least student participation, solicited or otherwise. This qualitative observation bears out in the quantitative finding that only 7.1% of all message units in this class came from the students.

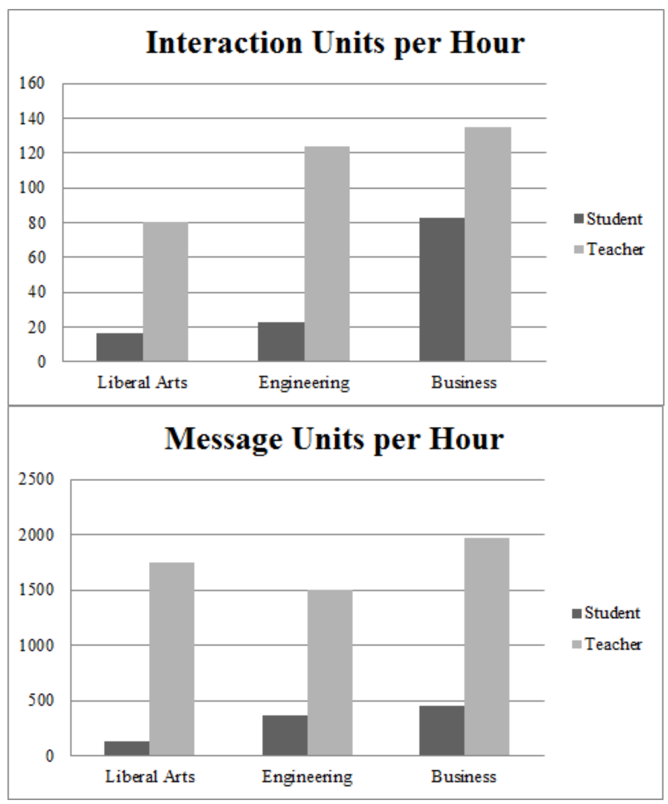

Fig.1. Number of interaction and message units per instructional hour initiated by the instructor and students in each class.

In the business and engineering courses, 81.5% vs. 80.7% of all message units were faculty discourse. This implies a high students' participation rate, which was both observed qualitatively in the two classes and bears out in the quantitative findings, i.e., 18.5% and 19.3% of all message units in these classes, respectively, come from the students.

2) Student vs. teacher initiated interaction units

In comparison to the classrooms at the liberal arts and the engineering colleges, the classroom at the business school boasted the largest density of both interaction and message units initiated by the instructor and the students. In fact, students initiated 38.1% of all interactions in this classroom. This is in comparison to 16.7% in the liberal arts and 15.6% in the engineering lessons, respectively. By this measure, the business school class was the most interactive of the three in terms of the student initiations. Measured by the instructor's message unit density, the overall information shared by the instructor in this class was comparable to that of the instructor at the engineering school.

The classroom "interactivity" may be also measured by the participation rate, i.e., the number of students participating in the classroom discourse. From this perspective, the lesson in the liberal arts college remains to be the least "interactive" with only 20% of students engaging in the overall classroom discussion (3 out of 14). On the other hand, using these quantitative data, the lesson at the business school continues to be the most interactive with 70% student engagement (12 out of 17), and the class at the engineering school having intermediate level of student participation at 38% (27 students out of 72).

3) Interruptions

Classroom "interactivity" measured simply by the interaction unit density, whether initiated by the instructor or the students, or by the students' participation rate, however, is a poor measure of what goes on in the classroom. This is because interaction units initiated by the students are not the same qualitatively. The quality of contribution to the classroom discourse differs greatly from classroom to classroom and from student to student. For example, the lesson at the business school had the highest number of student-initiated interaction units, but most were categorized as interruptions. An example of such interruptions, indicated by dashed horizontal line, is demonstrated below:

Instructor: *Okay. / So, i equals prt. / I'm going to leave it here. / And we're going to move on to compound interest. / Because/ this is, this is a pretty, / a pretty straightforward idea. /*

\- -

Student Larry: *Professor, /what did you do for RIM? /*

Instructor: *Um, we'll talk about it after class, / because/ we have to get through a lot. / But/ not much. /*

Student Elsa: *What? /*

Instructor: *I worked for Blackberry/ – the, the company that makes Blackberry phones. / Um, but/ I only worked there a semester during grad school. /*

At 30 such interruptions per hour, or one interruption every two minutes, the quality of this lesson's "interactivity" is pedagogically questionable. The quantitative data, taken with the qualitative observation, indicate that the class seemed to have developed a culture wherein students had learned that interruptions are acceptable. Some students had come to understand they would receive a response, either from faculty or a fellow student, notwithstanding the time, content, and suitability of the questions.

In comparison, interruptions were either small in number (6 per hour) or non-existent at the engineering and liberal arts schools, respectively. Combining these data with the qualitative observations, we find that these two lessons were highly focused on the subject matter with the emerging culture of the speaking rights belonging to the instructors who nevertheless welcomed students' content-centered input.

4) Questions

In terms of the questions asked in each classroom, the instructors presented a differing number of inquiries (85 in the engineering school, 75 in the liberal arts, and 143 in the business school classes). The instructor in the liberal arts school asked 85% of all questions during the class session, while the percentage of all the questions asked by the instructors at the engineering and business schools were, respectively 65% and 63%. These quantitative findings combined with the qualitative observations of the three classrooms indicate an interesting set of cultural paradigms.

In addition there were interesting qualitative differences observed in the type and format of the questions. The instructor in the liberal arts school tended to ask multiple questions before receiving an answer – sometimes as many as four questions were asked in sequence before a student responded. The students seemed to expect multiple questions, each increasing in focus in terms of content solicited. To ensure "the correct" response, therefore, a student may have developed a strategy of waiting until the last question to better understand what the instructor wanted to hear:

Instructor:

So, / what we see/ here in black/ is the actual curve 1 over 1 minus x./ Right…/and it makes sense, / because/ it seems like / it has an asymptote at x equals 1./ Um, so it seems like/ it's the right curve./

Instructor: *So, / can anyone tell me/ what they think this thing /in red is?* ***[4 sec silence]*** */ Any ideas?* ***[4/5 sec silence]*** */ First tell me / the type of curve it is./ It has a name, /right?/ We know that?/*

Class: *Parabola./*
Instructor: *It's a parabola./*

At the engineering school, the quality of questions asked seemed to indicate high instructor expectations in terms of both students' preparation for the class and the instructor-student dialogue for constructing new understandings:

*Instructor***:** *So, let's try to figure out /what is the behavior /around the equilibria/ in this system of equations. / Is there anything we have to do /preliminary to that investigation?* ***[1 sec]*** */*
Student B: *Find the equilibria. /*
*Instructor***:** *We definitely need /to find the equilibria / so systems of equations. / This is an example /of a system of equations. / And let's find the equilibria.* ***[6 sec]*** */*

---

*Instructor***:** *Okay. / So, how do we/ go about doing that? /*
*Student M***:** *Set x-dot equal to zero / and y-dot equal to zero? /*
*Instructor***:** *Yeah. / So, if I'm at equilibrium, / and I'm not moving, /neither x nor y could be moving/ at equilibrium. / So, I have to solve / now / two equations and two unknowns. /*

The predominant culture of high density of interaction units and multiple student interruptions at the business school seems to indicate that students in this context needed to ask and respond quickly before another student interrupted the flow of the discourse.

5) Instructors' use of students' name

Interestingly, quantitative measure of students' class participation is correlated with quantitative measure describing the number of students called by name. At the liberal arts college, with the lowest number of students and the lowest percentage of student participation, no student was called by name. In contrast, at the engineering school, the instructor used the names of 10 students of the 27 participating; the instructor at the business school called all 12 participating students by name. We may attempt to infer an unspoken message that students in each of the three classes may have received as a result of either being called by name or not. Remaining nameless, may decrease the responsibility for participation in the class, while being called out prevents one's ability "to disappear," i.e., a student must be present and participating in such an environment.

6) Feedback

Differences in quantity and quality of feedback message units were also significant. In fact, in the business school, students received instructor feedback 216 times (i.e., 27 times every 10 minutes) compared to only 54 and 90 feedback responses at the liberal arts and engineering schools (i.e., 7 and 9 times every 10 minutes), respectively. In the engineering classrooms, feedback messages were more numerous but brief in quality (e.g., "*Yeah!*" or "*Yes!*" or "*Absolutely!*") in comparison to the class in the liberal arts school, while in the business classroom, the feedback was personal and positive (e.g., "*It gets…yeah, / right. / Wow. / I can't believe you just, / you just, uh, understood that. / It's um… /").*

7) Type of Content

One of the most interesting categories was the number of message units dealing with the type of content in the three classes. In the liberal arts college, the class contained mostly message units coded as mathematical theory (e.g., "*This function has the same slope at 0,/ the same y value at 0 /and what else?/"),* while at the engineering school most message units contained visualization-related content (e.g., "*Who has, / who has a Matlab window open? / It's just 2 by 2, / but/ we're that lazy. / What are the eigenvalues and eigenvectors? /*"). Yet, in the class at the business school, most message units were based on real life applications (e.g., "*The next year, / we're going to get interest/ on our original investment/ and interest on the interest. /*"). What is significant in this finding is that each class reflected the values and missions of the three institutions.

8) Taxonomic Maps

Discourse analysis allowed us to look at the three mathematics lessons by de-constructing them into distinctive coding variables and then restructuring the variables to uncover the hidden interaction of each context.

A taxonomy is map of the identified patterns that constitutes the "rules of the game" for each class. An example of such map is presented in Fig. 2. This map summarizes various quantitative and qualitative findings while placing them in the context of students' experiences. In addition to the summary, such a map prompts a participating instructor to think about the questions related to classroom culture (e.g., "Who creates classroom culture and how?") and ensuing student experiences. Empty blocks are left specifically for the participating instructors to fill in during and following the debriefing session with the researchers.

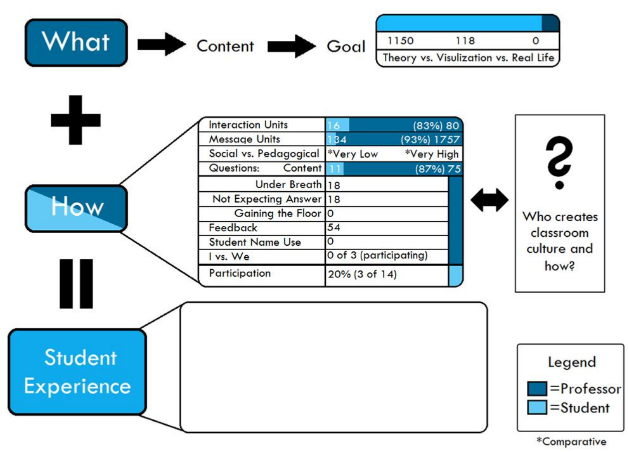

Fig.2. An example taxonomic map.

The liberal arts classroom was one in which students' responsibility for the classroom interaction was minimal and the instructor was in control of the lesson. In sharp contrast, in the business school, students participated actively, however, much of the participation was in the form of interruptions changing the topic. In the engineering classroom, students were expected to co-construct the classroom content and culture. Each classroom had constructed its own distinct culture through the interaction of instructor(s), students, group dynamic, and text Students who were able to understand the culture and live within its rules, gained more learning opportunities.

Although not in the scope of this paper, we also investigated the patterns of pedagogical units (change of topic) of each instructor and the variation of interaction types within pedagogical units. This topic will be discussed in our future work.

IV. Concluding Remarks

To complete the research-to-practice circle, our methods and results were shared with participating instructors during a follow-up meeting the subsequent semester to determine the research and program's efficacy. The main question discussed during these meetings was about a type of student that may thrive in each class and how the instructors may actively work to change the classroom culture to benefit all students. We also helped instructors identify 'academic literacies' that students must develop in their classrooms in order to succeed. Two instructors found that their classroom discourse changed drastically due to their participation in the research. The third instructor felt his participation in the program confirmed what he had already known about his classroom discourse.

One semester after the program completion, participating instructors were presented with an opportunity to reflect on the efficacy of the program and its effect on their teaching. The two instructors, who originally found the program beneficial to their teaching, remained positive about their participation and found that their teaching improved dramatically:

> *Discourse analysis helped me see exactly how my lessons were falling short of my intended learning outcomes for them. I've since used the results of the analysis to better pace my lessons, improve the time I wait for student responses to questions, and adjust my lesson outlines to better foreshadow upcoming new material.*
>
> \- Instructor from Liberal Arts School

While the original study design did not include a longitudinal piece, in the future we intend to conduct follow-up interviews with participating faculty over a course of several semesters post-program to allow for a rigorous analysis of the impact and efficacy of the discourse analysis "intervention" on participants' classroom teaching.

Our findings indicate that discourse analysis, a rigorous yet straightforward method of researching classroom interaction, may be used by any educator who wants to uncover, understand, and shape their classroom's culture to offer all students the most effective opportunities to learn .

Acknowledgment

We would like to thank Babson/Olin/Wellesley Mellon Presidential and Olin College Innovation Grant Programs for supporting this project. We would also like to extend our gratitude to Gisselle Castellon, Wellesley College student, for her help in data collection and analysis.

Abstract—**The increasing application of student-centered teaching approaches to solve real problems, driven by the market´s demand for professionals with better skills, has prompted the use of PBL in different areas, including in Computing. However, since this represents a paradigm shift in education, its implementation is not always well understood, which adversely affects its effectiveness. Within this context, this paper puts forward a model for assessing the maturity of teaching processes under the PBL approach, the PBL-Test, with a view to identifying points for improvement. The concept of maturity is defined in terms of teaching processes adhering to PBL principles, taken from an analysis of the following authors: Savery & Duffy (1995), Barrows (2001) Peterson (1997) and Alessio (2004). With a view to validating the applicability of the model, an empirical study was conducted by applying the PBL-Test to three skills in the Computing area. Results showed that although the model has shown it needs further enhancement, it has already been possible to identify improvements in PBL teaching processes that clearly affect the effectiveness of the approach.**

PBL; Evaluation of Teaching Processes; Process Maturity.

I. INTRODUCTION

Professionals in highly dynamic areas such as Computing, face the need to be familiar with and know how to apply new concepts, methods and techniques for specific situations that may arise in the labor market, if they are to keep up with the pace of rapid change in this market. In seeking better ways to formally train these professionals, the instructional teaching method called Problem-Based Learning (PBL) has been adopted with very favorable results as in [1, 2, 3, 4]. In general, PBL makes use of real problems to start, motivate and focus on the acquisition of knowledge. In addition, it encourages professionals to add to their skills and it fosters positive attitudes in the professional environment. It is considered to be a student-centered educational strategy, which helps to develop reasoning and communication. These are skills which are essential for professionals to possess if they are to be successful in the labor market [1].

PBL is becoming increasingly effective in a variety of disciplines in higher education [5]. Many studies have shown the efficiency of the PBL method in helping learners to absorb the content of learning. In [6], the authors conduct a systematic mapping of the use of PBL when teaching computing, from 1997 to 2011. They analyzed 52 studies in this field, taken from sources such as IEEE, Scopus, Science Direct and ACM databases. This study shows that this method has been adopted with the objective of improving the effectiveness of teaching and learning processes.

Despite the potential benefits of the PBL approach, it is also evident that its use implies a profound educational change and a new culture of teaching and learning [7, 8, 9, 10]. Thus, managing a process of teaching and learning based on PBL is a great challenge, especially with regard to implementing a methodology which adheres to PBL principles [7]. Thus, if such adherence is absent or partial, this could have an adverse effect on the effectiveness of this approach.

Faced with this challenge, this paper seeks to answer two important questions: "*How can it be certified that a process of teaching and learning is adhering to the principles of PBL approach?*" And "*At what level of maturity is the process of teaching and learning in a formal training course which uses the PBL approach, in accordance with PBL principles?* '.

As to the first question, Oliveira et al. [6] stress that there is a wide variety of educational methods, referred to as being PBL. According to Norman and Schmidt [11], "*anyone who knows more than one institution in which PBL is used will verify that in each of them, the methodology is applied in a different way.*" Very often, teaching organizations/ institutions start to work with PBL without their having the necessary theoretical foundation on which to bring about educational change. Therefore, the method ends up being confused with practical experiments or other methods of active/ collaborative learning, thus jeopardizing the success and authenticity of the methodology [3].

Additionally, some intrinsic characteristics of PBL, such as the unpredictability and flexibility in the practical assimilation of learning, entail that the teaching coordinators lose control of the actions and constantly improvise [11]. Experiences undergone as in [2, 3, 4] show that adopting this method is made difficult when there a lack of appropriate support from content, processes and human capital in order to implement PBL. PBL demands flexibility, continuous assessment and cooperation. It is against this background that this paper argues that for PBL to be adopted effectively, it is of fundamental importance that the learning and teaching processes be in conformity with the basic principles that guide the practice of this approach.

As to the second question, in view of the variety of PBL formats, it is important to check at what level of adherence these formats are. This visibility enables faults in the process of teaching and learning to be identified as well as the corrective actions or improvements needed in this process.

In this context, this article proposes a model for assessing the maturity of processes of learning in the PBL approach, deemed a PBL-Test. The concept of maturity is defined, based on the teaching processes that adhere to PBL principles. These principles have been set out by authors such as Savery & Duffy [7], Barrows [8] Peterson [9] and Alesssio [10]. With a view to validating the applicability of the model, an empirical study was conducted by applying the PBL-Test to three formal training courses in Computing. Results showed that although the process of analysis of the model may already shows signs it needs to be further improved, the model is a valuable tool for evaluating the maturity of teaching processes in the PBL approach, thus demonstrating its applicability.

II. The Principles of PBL

PBL is based on educational principles and on results from research in cognitive science, which show that learning is not a process of passively receiving and accumulating information, but one in which knowledge is constructed [6].

In [7], Savery & Duffy set out a set of eight instructional principles for PBL, namely: (SD.1) *Anchor all learning on activities to a larger task or problem*; (SD.2) *Provide support for engaging the student on the task or problem*; (SD.3) *Design an authentic task*; (SD.4) *Design the task and the learning environment to reflect the complexity of the environment for which the students should have the skills to interact in, at the end of the learning*; (SD.5) *Give the student ownership of the process used to work out the solution*; (SD.6) *Design the learning environment to support students' thinking while challenging them*; (SD.7) *Encourage the testing of ideas against alternative views and contexts*; (SD.8) *Give opportunity for reflecting on learning and what has been learned*.

In the review of the literature conducted for this research, which includes the systematic mapping of the use of PBL in teaching Computing [6], no records were found of other authors who have set out principles for PBL, using this nomenclature for this purpose. However, the authors Barrows [8], Peterson [9] and Alessio [10] define criteria and characteristics that are key to PBL, which, for comparison purposes, in this paper, are also referred to as *PBL principles*. These studies were chosen with a view to having practical guidelines for this teaching approach that, to some extent, derive from or complement the principles suggested by Savery & Duffy [7] for PBL.

In Peterson [9], the author draws attention to three important criteria that foster more effective learning when PBL is used: (PT.1) *Learning takes place in an environment where students are immersed, in practice, in activities in which they receive feedback from their fellow students and teachers*; (PT.2) *Students receive guidelines and support from their peers such that this encourages multi-directional teaching involving other students, teachers and monitors, unlike conventional teaching which is usually unidirectional (teacher to student)*; (PT.3) *Learning is functional, with real problems as the starting point*.

To Barrows [8] the features essential to PBL are: (B.1) *The student must take responsibility for his/her own learning*; (B.2) *The problems used in PBL should be scantily structured and allow free research*; (B.3) *Learning should be integrated into a wide range of disciplines and subjects*; (B.4) *Collaboration is essential for the learner to develop the security needed to be responsible for his/her own learning*; (B.5) *What students learn during their self directed learning should be applied when resolving the problem through interactive discussions, in order to promote in-depth understanding*; (B.6) *A more accurate analysis is essential about what concepts and lessons were learned in working with the problem*; (B.7) *Students should be able to assess their own learning progress and to evaluate that of their peers*; (B.8) *The activities conducted in PBL should be the same as those performed in the real world*; (B.9) *Assessments should measure the learner's progress as per the PBL objectives*; (B.10) *PBL should be the pedagogical basis of the curriculum and not a part of the didactic curriculum*.

The author Alessio [10], in her study on the perceptions of students and the performance of PBL, stresses three key characteristics of PBL: (A.1) *Learning in context, in which real-life problems are presented*, (A.2) *Extending knowledge through social interaction, in which students work together in small groups, and* (A.3) *Metacognitive reasoning and self-directed learning*.

The model for evaluating the maturity of PBL put forward in this paper is at bottom based on PBL principles. Given the variety of definitions, the study included a mapping of the principles and characteristics of PBL previously mentioned with the aim of identifying the correlation or possible differences between them (Table 1). This mapping enabled both the concepts of PBL to be more clearly understood and for it to be seen that the values and proposals suggested by Savery & Duffy, compared with those of Peterson, Barrows and Alessio, express practically the same ideas. To the extent that there are differences, these complement each other. Thus, it was concluded that two other principles can be added to the list of PBL principles described by Savery & Duffy, and which, as per the study by Santos [12], were described as follows:

- *Principle 9 - "PBL lays down a process of multi-directional teaching and learning*" (Peterson's Principle 2): which foresees collaboration through social interaction between students, and between teachers and students, unlike conventional teaching in which learning is largely unidirectional, from teacher to student, and;
- *Principle 10 - "PBL is supported by planning processes and continuous monitoring*" (includes Barrows' Principles 7 and 8): an effective PBL methodology is strongly oriented to process, since it needs to be planned. This ensures that theory and

practice go hand-in-hand and are aligned to each other, while learning should be monitored by instruments that can evaluate its effectiveness [1].

Therefore, the result of this mapping indicates that the PBL may be defined in 10 basic principles as shown in Table I. The correlation between the principles/ characteristics of the authors Savery & Duffy, Barrows, Peterson and Alessio is also presented in this Table, using the indices of the respective principles. For example, considering the principle PR1, Savery & Duffy says "Anchor all learning activities to a larger task or problem." Peterson reinforces this principle when he affirms that "the learning is functional - based on solving the real problem," corroborated by Alessio when he says that "PBL include learning in context, where real life problems are presented".

TABLE I. PBL PRINCIPLES

PBL Principles	Correlation
PR1. All learning activities are anchored on a task or a problem;	SD.1, PT.3, A.1
PR2. The learner should feel he/she owns the problem, and is responsible for his/her own learning;	SD.2, B.1
PR3. The problem should be real;	SD.3, B.2, B.3, B8, PT.3
PR4. The task and the learning environment should reflect the reality of the professional market;	SD.4, PT.1
PR5. The learner needs to own the process used so as to work out the solution to the problem;	SD.5, A.3
PR6. The learning environment should stimulate and at the same time challenge the learner´s reasoning;	SD.6, PT.1
PR7. The learner should be encouraged to test his/her ideas against alternative views and contexts;	SD.7, B.5
PR8. The learner should have the opportunity and support to reflect on the content learned and the learning process;.	SD.8, B.6, A.3
PR9. The learning is collaborative and multidirectional;	B.4, PT.2, A.2
PR10. PBL is supported by planning processes and continuous monitoring.	B.7, B.9

It is important to stress that the mapping undertaken in Table 1 was based on an interpretive analysis from the meaning and descriptions of the principles discussed in the studies mentioned above, which are subjective in nature. However, the practical and research experiences in PBL of the authors of this paper have contributed to adding reliability to this process, as shown by cases in [2, 3, 4].

III. THE PBL-TEST MODEL

Based on the principles set out in Table 1, the PBL-Test consists of a model for assessing the maturity of the teaching processes based on PBL. This model includes an assessment tool and is structured into five maturity levels. Additionally, the model lays down conditions and steps for its implementation.

A. Definition of the PBL-Test Model

The PBL-Test includes an assessment tool, which consists of a form which contains questions, comprising: a header section, comprising data to be collected, viz., name of participant, training program, the participant's status (student, professor or tutor), and period of his/her training; a section consisting of 10 objective and standardized questions, made up of exclusive alternatives as shown in Table II.

TABLE II. PBL-TEST QUESTIONS.

PR 1 - Problem (s) at the core of the educational proposal.
0.0)The learning activities are carried out regardless of tasks or problems. 0.5) Not all learning activities are associated with the resolution of a problem or task. 1.0) All learning activities are initiated, directed and motivated to solve a specific problem or task.
PR 2 - Learner as the owner of the problem.
0.0) Totally passive posture on the part of the learner about the problem. 0.5) The learner engages with the problem, usually on delivery of partial results required by the teacher or tutor. 1.0) The learner is fully involved with the problem, demonstrating engagement in seeking to solve it.
PR 3- Authenticity of the problem or task.
0.0) The learning tasks do not reflect real-world situations. 0.5) The problem or task is real, but the client and his context aren´t. 1.0) The actual learning tasks are defined and monitored and the client and restrictions are real (scope, delivery time and effort spent).
PR 4 - Authenticity of the learning environment.
0.0) The learning environment is defined by the teacher. 0.5) The learning environment is a simulation of the real world. 1.0) The learning environment is real, with the same challenges as those in the labor market.
PR 5 - Driving the solving the problem process.
0.0) The solving the problem process is fully driven by the teacher or tutor, without the learner understanding the process. 0.5) The teacher or tutor defines the solving the problem process, but the student knows how to apply it and to identify strengths and improvements. 1.0) The student defines the solving the problem process, and can describe its steps, strengths and the improvements needed.
PR 6 - Complexity of the problem or task.
0.0) The problems or tasks require little training in the subject matter. 0.5) The complexity of the problem or task doesn´t require much effort with regard to looking for information or alternative solutions that will resolve them. 1.0) The complexity of the problem or task stimulates thinking and sets challenges on how to develop ideas for solving the proposed problem.
PR 7 - Evaluation and analysis of how the problem was resolved
0.0) How to resolve the problem is proposed by one of the team members, from their knowledge and/ or individual experience. 0.5) Solutions are proposed by one or more apprentices, towards the best solution. 1.0) The solutions are built from an investigative process and questioning of ideas among all members of the team, towards the best solution.
PR 8 - Reflexion on the content learned and the learning process.
0.0) The students have no opportunity to reflect on their learning. 0.5) The students have the opportunity to reflect on their learning, but it is not oriented towards their self-awareness during the learning process. 1.0) The student is encouraged to think, and thus to demonstratie skills of self-awareness on the content learned and the learning process.

PR 9 - Collaborative and multidirectional learning.
0.0) Learning is unidirectional (teacher/tutor -to-student). 0.5) Learning occurs in groups, but there is little collaboration and interactivity among peers, teachers and tutors. 1.0) Learning is collaborative and multidirectional, involving discussions and greater interaction among peers, teachers and tutors.
PR 10 - Continuous Assessment.
0.0) The assessments are not aligned with the educational objectives in the teaching plan. 0.5) The educational objectives were not clearly defined and evaluations are applied to award a grade that classifies the learner as pass or fail. 1.0) Assessments are continuous and aligned with educational objectives planned. They are applied in order to monitor the learning progress and provide feedback to the learner.

The answers to each question are related to how one PBL principle was applied. Each question is associated with three statements that correspond to the following scale of values: 0 (Does not meet the principle), 0.5 (Partially meets it); 1 (Fully meets it). On this scale, the score for each question is related to one these values.

The score of each participant is defined as the sum of points obtained in each question. After collecting the responses of all the participants, the score for the course/ training program evaluated is determined. For simplicity, we chose to calculate this score by using the arithmetic average of the final scores of all participants, equally. The scale range was from 0 to 10 points, given that each of the 10 questions can obtain the maximum value of 1 point (Meets the principle completely). The points calculated are associated with classes of quality indicators, which determine the maturity levels of the model.

According to [13], a level of maturity can be defined as a "plateau" of improvement achieved by a given organization. Therefore, the levels of maturity in the PBL Test model set levels of evolution for processes, by characterizing stages of improving the implementation of the PBL teaching and learning processes in the teaching organization/ institution.

As can be seen in Table 2, the PBL Test model is structured into five maturity levels.

TABLE III. LEVELS OF MATURITY IN PBL

Category	Overall Average	% of Principles Evidenced
Level 0: Insufficient	Overall average < 7	< 70%
Level 1: Initial	<= 7 overall average < 8	< 80%
Level 2: Satisfactory	<= 8 overall average > 9	< 90%
Level 3: Good	<= 9 overall average > 10	< 100%
Level 4: Excellent	Overall average = 10	= 100%

The PBL Test is used to obtain a certain level of maturity which is achieved when the score set for the level in question is reached: *Level 0 - Insufficient*: indicates that the teaching process evaluated does not adhere to PBL principles; *Level 1 - Initial*: indicates that the teaching process evaluated adheres weakly to PBL principles; *Level 2 - Satisfactory*: indicates that the teaching process adheres to a significant extent to PBL principles; *Level 3 - Good*: indicates that the teaching process evaluated adheres strongly to PBL principles; *Level 4 - Excellent*: indicates that the teaching process evaluated is fully adhering to PBL principles, which may be deemed "authentic" or "pure" PBL.

The classification of the level of maturity is directly related to the final score obtained by the arithmetic mean of the final score given by those who take part in the training program evaluated. On a scale of 0 to 10, we chose the value 7 as the average, given that at least the first three principles must be met in full (tasks anchored on a problem, the learner feels he/she owns the problem and the problem is real) and none of the other principles was zero.

This division into levels enables the current state of the teaching process to be visualized with regard to implementing and adhering to PBL principles. But we note that it is important not only to define at what level the teaching process is, but rather also what must be done to ensure that it evolves over time.

B. *Application of the PBL-Test Model*

The conditions for applying the model can be summarized in the following questions: *Who applies the model?* The coordinator or manager of the training program; *What is assessed?* The process of PBL teaching and learning; *Who does the evaluation?* The coordinator or manager is the person who should evaluate and consolidate the results obtained from applying the questionnaire; *Who takes part in the evaluation?* Students, teachers and/ or tutors; *When should the model be applied?* During each cycle of assessing the training program, i.e. during the steps of the PDCA cycle (Plan, Do, Check and Act); *How should the model be applied?* As a survey that uses the evaluation questionnaire given in the model. This may be applied via online Web-format, or face-to-face.

Ideally, we recommend that the PBL-Test be applied over four steps, as shown in Fig. 1.

Figure 1. Steps of applying the PBL-Test model.

Initially, the participants of the evaluation (Teachers, Students, and Tutors) should be introduced to the model, informed what the objective of applying it and given guidance on how to answer the questions in the evaluation questionnaire.

The next step is to apply the evaluation questionnaire. This should be completed by the students, teachers and/or tutors of the training program being evaluated. To reduce the influence responses that are repeated, we recommend that the order of the questions be altered each time that data is accessed/ collected. The ideal is that all the actors of the teaching process evaluated take part in the survey. However, it is known that this is not always possible. In these cases, we recommend that the minimum number of respondents should be at least 1 student, 1 teacher 1, and 1 tutor. Where there is no tutor, or the teacher takes on both roles, the teacher can substitute for the tutor. With the results at hand, the responses obtained are scored and the overall average of the training program is calculated. Finally, the maturity profile of the PBL teaching process of the training program evaluated is checked, taking the levels of maturity for the proposed model into account. It is recommended that the coordinator or manager of the training program be responsible for the activities of applying the model.

Given that one of the objectives of applying the model is the continuous improvement of the processes of PBL teaching and learning, we also recommend that this be inserted as an activity of the Check phase of the PDCA cycle of Deming or that it be applied to each evaluation cycle of the training program. In other words, the teaching process as a whole should be planned, executed, verified (controlled) and improved in every cycle. In this context, the model is inserted as a tool to support managing the PBL teaching process, thus making a contribution towards defining and monitoring continuous improvement actions (Act).

IV. APPLYING THE PBL-TEST IN SOFTWARE ENGINEERING EDUCATION

With the aim of validating the PBL-Test model initially, an empirical study of an applied nature and quantitative approach was conducted, which used the data collected from responses to the questionnaire described in Section 3 and consecutively an analysis was made of these data based on the criteria described in Table III (PBL maturity levels). The Ex-Post-Facto method or "method applied after the occurrence of the facts" was used as a technical research procedure [14].

To undertake the study, we selected three training programs, referenced in this article as Course A, Course B and Course C. All programs selected are higher education ones in Computing: Course A is at the Masters level, lasts 1 year and the class has 16 students, 10 teachers and two tutors; Course B at the undergraduate level, lasts 6 months, has a class of 11 students, 1 teacher and 1 tutor; Course C at the undergraduate level, lasts 5 months, and there are 10 students, 5 teachers and 1 tutor. These formal training programs were selected because they use PBL as a teaching approach. Specifically in the case of Course B, the coordinator was not sure that it should be included in this context, but the fact of there being strong signs of using PBL in the teaching-learning process prompted us to apply the PBL-Test in this program.

For data collection, we made the evaluation questionnaire proposed in the PBL-Test model available on SurveyMonkey in September-October 2012, given that this made both the collection of data and the analysis of results easier. We invited the students, teachers and tutors of three courses to be participants, and thereby a sample was obtained comprising 23 volunteer collaborators, distributed as follows: 6 participants were from Course A (2 students, 1 tutor and 3 teachers); 8 from Course B (7 students, 1 tutor and 0 teachers), 9 from Course C (5 students, 2 tutors and 2 teachers).

From the point of view of the principles, Table IV presents the arithmetic averages of the participants' evaluations of each PBL principle, in each of the three training programs.

On analyzing the results, we found that all the courses evaluated used the PBL approach, since they received scores of above the average of 7.0. Taking the maturity levels of Table 2 into account, Courses B and C were classified within the level of adherence to PBL principles in the category of "Initial", while Course A stood out by being classified in the category of "Satisfactory".

TABLE IV. AVERAGE OF EVALUATIONS PER PBL PRINCIPLE.

Principle	Course A	Course B	Course C
1	0.9	0.8	0.9
2	0.8	1.0	0.7
3	0.9	0.3	0.6
4	0.8	0.3	0.7
5	0.8	1.0	0.6
6	0.8	1.0	0.7
7	0.7	0.6	0.6
8	1.0	0.9	0.8
9	1.0	0.9	0.9
10	1.0	0.9	0.9
Overall average:	**8.6**	**7.7**	**7.3**

On evaluating the principles most perceived as having been met, the result gives evidence of the PBL approach by showing adherence to two of the principles that characterize this approach: the problem is the core of the pedagogical purpose and the student takes ownership of the problem. Moreover, we found that the programs had a very positive concern with the educational methodology, namely, they sought to maintain: adherence to the principles that targeted reflection on the learning and the learning process (Principle 8); collaborative learning based on multidirectional interactions between students, teachers and tutors (Principle 9); and the process of continuous assessment (Principle 10).

On the other hand, the reality and authenticity of the problem (Principle 3) and of the learning environment (Principle 4) were the aspects that showed the greatest need to improve in the evaluations of courses B and C. Course A reinforces its greater maturity by remaining adherent to these principles. It is worth noting another deficiency in perception regarding the analysis of alternative solutions (Principle 7), pointed up by all three training programs, which probably arises from the effort and length of time this approach requires. All of these deficiencies represent improvements in PBL teaching processes that clearly affect the effectiveness of the approach.

From the point of view of the participants, Figs. 2, 3 and 4 represent the distribution of the sample, by case study, and list the subjects taking part in the experiment and their respective responses to each PBL principle. The "PR" index refers to the principles of Table I, "P" to the participants and their parameters (P - Professor, T - Tutor or S - Student).

As per Fig. 2, the absence can be observed of non-adherent responses (0-zero) related to any principles questioned on Course A, which is thus a behavior that is statistically divergent from the other training programs. This behavior can be understood as there was a larger number of mature participants involved in the assessment, a higher educational level (Masters) and the predominance of active subjects within the educational process, such as tutors and teachers (1 tutor and 3 teachers). Another factor that deserves consideration is the total adherence to all the principles, scored by participant P06. This reinforces the students´ positive perception of this course, although in smaller number.

Question/Principle	Participants						
	P01 (T)	P02 (P)	P03 (P)	P04 (S)	P05 (P)	P06 (S)	Total
Q5 - PR 1	1	0,5	1	1	1	1	5,5
Q6 - PR 2	1	0,5	1	1	0,5	1	5
Q7 - PR 3	1	0,5	1	1	1	1	5,5
Q8 - PR 4	0,5	0,5	1	0,5	1	1	4,5
Q9 - PR 5	1	1	0,5	0,5	0,5	1	4,5
Q10 - PR 6	1	0,5	1	0,5	0,5	1	4,5
Q11 - PR 7	1	0,5	0,5	0,5	0,5	1	4
Q12 - PR 8	1	1	1	1	1	1	6
Q13 - PR 9	1	1	1	1	1	1	6
Q14 - PR 10	1	1	1	1	1	1	6
Total	9,5	7	9	8	8	10	51,5
General Average of the Course A:	8,6						

Figure 2. Distribution of Course A.

As per the data reported in Fig. 3, what can be seen is a statistically consistent and better behaved distribution in relation to other training courses. Thus, we regarded the behavior of the participants' responses as tending to be in harmony on this training course. Given that that this course had the largest number of students (7 seven) and only one tutor, it is worthy of note that the effective presence of students in the assessment may represent a positive aspect, since the PBL methodology is based on student-centered processes.

Question/Principle	Participants								
	P01 (S)	P02 (S)	P03 (S)	P04 (S)	P05 (S)	P06 (S)	P07 (T)	P08 (S)	Total
Q5 - PR 1	1	1	1	1	0,5	0	1	1	6,5
Q6 - PR 2	1	1	1	1	1	1	1	1	8
Q7 - PR 3	0,5	0,5	0	0	0,5	0,5	0,5	0	2,5
Q8 - PR 4	1	0,5	0	0	0	0,5	0,5	0	2,5
Q9 - PR 5	1	1	1	1	1	1	1	1	8
Q10 - PR 6	1	1	1	1	1	1	1	1	8
Q11 - PR 7	1	0,5	1	0,5	0,5	0	0,5	1	5
Q12 - PR 8	1	1	1	1	1	0	1	1	7
Q13 - PR 9	1	1	1	1	1	0	1	1	7
Q14 - PR 10	1	0	1	1	1	1	1	1	7
Total	9,5	7,5	8	7,5	7,5	5	8,5	8	61,5
General Average of the Course B:	7,7								

Figure 3. Distribution of Course B.

The data presented in Fig. 4 show the greatest variation in scores between the other training courses analyzed, thus demonstrating a behavior that is not as statistically balanced. This class has a well distributed sample on account of the presence of all the roles involved in a PBL process, in acceptable proportions - 5 students, 2 teachers and 2 tutors. Attention is drawn to participant P09 because of the non-adherent score (0 - zero) in more than one PBL principle and this may therefore reduce the maturity average of the group. At this point, it may make sense to exclude points of dispersion from the analysis, so as to have a more precise statistical approach from the results of the questionnaire.

Question/Principle	Participants									
	P01 (T)	P02 (P)	P03 (S)	P04 (P)	P05 (S)	P06 (P)	P07 (S)	P08 (S)	P09 (S)	Total
Q5 - PR 1	1	1	1	0,5	1	1	0,5	1	1	8
Q6 - PR 2	0,5	0,5	1	0,5	0,5	0,5	1	1	0,5	6
Q7 - PR 3	0,5	0,5	0,5	0,5	0,5	0,5	1	1	0,5	5,5
Q8 - PR 4	0,5	0,5	0,5	0,5	0,5	0,5	1	1	1	6
Q9 - PR 5	0,5	0,5	1	0,5	1	0,5	0,5	0,5	0,5	5,5
Q10 - PR 6	0,5	0,5	1	1	1	0,5	1	0,5	0,5	6,5
Q11 - PR 7	1	0,5	1	0,5	1	0,5	0,5	0,5	0	5,5
Q12 - PR 8	1	1	1	0	1	1	1	1	0	7
Q13 - PR 9	1	1	1	1	1	1	1	1	0	8
Q14 - PR 10	1	1	1	1	1	1	1	1	0	8
Total	7,5	7	9	6	8,5	7	8,5	8,5	4	66
General Average of the Course C:	7,3									

Figure 4. Distribution of Course C.

In general, we note that in the sample collected from the selected training courses there was a significant variation between the behavior of the subjects analyzed as to the composition of the training subjects. In this context, it is understood that a more rigorous assessment of the influence of each role of a participant as well as identifying atypical behaviors in the evaluation may result in an analysis that is able to verify and validate the maturity of PBL processes more precisely. This supplies greater consistency to the PBL-Test model. This is work in progress, which will give rise to future articles.

V. CONCLUSIONS

This article put forward a model for assessing the maturity of teaching processes under the PBL (PBL-Test) approach. This model basically consists of an evaluation questionnaire, which uses a points scale (1, 0.5 and 0) to calculate the result. This reflects the PBL maturity (Level 0 to Level 4) of the course evaluated and is supported by a process of applying a questionnaire and analyzing the results. To validate the proposed model, an initial experiment was conducted in three formal IT skills programs. Although this sample is a starting point for further analysis, the results demonstrate the applicability and potential contribution of the model for improving the quality and the PBL teaching management process, to the extent that it points out the principles that are or are not met in the teaching process. It also indicates the state of adherence of the teaching process as a whole. In general, some shortcomings were found in the PBL processes on the courses evaluated and in the influence of their participants and we acknowledge that the PBL-test model needs to be evolved.

Finally, it is important to emphasize that the proposed PBL-Test aims to be an evaluation instrument the maturity of PBL according to their principles, but does not evaluate the effectiveness of PBL approach with regard to the development of learning and skills in the students involved, a central theme work on authentic assessment, discussed by the authors of this article in [15].

***Abstract*— Due to success at adapting and implementing team-based learning (TBL) for use in sophomore-level electric circuit theory courses, an initiative is underway to encourage other faculty to use TBL in their courses, and instruct them in how to do so. The purpose of this work-in-progress paper is to describe an online training course that is being developed to assist engineering instructors in learning to use TBL as well as other forms of group-based student-centered active learning in the classroom. Currently, the course consists of five units, each of which culminates in a quiz that must be taken successfully before moving on to the next section. The content sections consist of Powerpoint slides plus detailed instructor commentary for further explanation. Also included are selected illustrative video clips taken during an exemplary classroom session.**

Keywords—team-based learning; online faculty training; student-centered active learning.

I. INTRODUCTION

Research has shown that traditional lecturing is an inefficient way to facilitate conceptual learning [1], and that student-centered active learning can result in a deeper understanding of the concepts in question [2]. Furthermore, when active learning is conducted in an extensively group-based learning environment, students also develop various professional skills, such as problem-solving, written and oral communication, independent learning, teamwork, etc. [1]. Team-Based Learning [3] (TBL) is a form of group-based learning that has been used successfully in many academic settings both outside [3] and within engineering [4-8].

Author R. O. has been successfully implementing and adapting TBL for use in sophomore-level electric circuit theory courses [7, 8] for three years. Because of this success, an initiative is now underway to encourage other engineering faculty to use TBL in their courses also. Experience has shown, however, that TBL as described in the literature [3] needs to be modified somewhat in order to be used most effectively in engineering courses. Thus, engineering faculty unfamiliar with TBL must surmount a significant learning curve in order to successfully implement the strategy. To streamline this process we have developed an online training course that shares our knowledge of and experience teaching with TBL [9]. An online delivery format was chosen over a live, face-to-face format to provide prospective trainees greater scheduling flexibility and to permit inclusion of illustrative video clips and detailed instructional explanatory text. This work-in-progress paper describes the course delivery format, course content, unit mastery quizzes, and the results of an evaluative survey taken of volunteers who agreed to pilot the course. Information from that survey is being used to make improvements to the course.

II. DELIVERY FORMAT

The course is accessed through the Blackboard^{TM} course management system, and it is designed to be self-paced and self-explanatory. The home page contains introductory information and explains how to proceed through the course. It states that the course is self-paced, and that it consists of five learning units, each of which includes a textual content section based on Powerpoint slides with detailed instructor commentary, and culminates in a mastery quiz which must be passed with a score of at least 80% before the trainee may move on to the next unit. There is no limit to the number of times a quiz may be taken. The home page also directs the trainee to the learning units.

Currently, the mastery quiz for each learning unit is generated from a pool of multiple-choice questions. The software uses an instructor-defined algorithm to select a subset of those questions to generate a quiz. Thus, a trainee will see a slightly different quiz each time he repeats it. For example, the quiz for the first learning unit currently consists of twelve questions from a pool of fifteen. To satisfy the 80% requirement, the trainee must answer ten of those questions correctly. To provide prompt feedback and remedy incorrectly answered questions, the software refers the trainee to corresponding slides in the textual content section.

III. COURSE CONTENT

In order to facilitate learning of the principles of TBL, it has been helpful to first place TBL in the context of other group-based learning methods, such as problem-based and project-based learning [10], and to place group-based learning methods in the context of student-centered active learning generally [11]. Thus, the course consists of five learning units, which are described briefly in this section.

Unit 1: Introduction and limitations of lecture-based learning

The introductory portion of the unit states and discusses the four course aims and seven learning outcomes. The aims of the course are to provide trainees with: a) an awareness of and appreciation for student-centered active learning; b) knowledge of some lecture-based active learning activities; c) knowledge of the differences among different group-based learning strategies; and d) practical ideas for adapting TBL to engineering courses. The learning outcomes are that at the end of the course, trainees should be able to:

- Discuss the limitations or shortcomings associated with the traditional lecture style of teaching.
- Define and describe student-centered active learning.
- Describe some teaching and learning activities for the lecture-based learning environment.
- State and discuss the principal shortcoming of lecture-based active learning.
- Compare some of the features of problem-based learning (PBL) and project-based learning (PjBL).
- Describe textbook-defined TBL and compare it to PBL and PjBL.
- Describe some recommended practices concerning the use of TBL in basic engineering courses.

The second part of the unit addresses some of the reasons why traditional lecturing is a poor teaching and learning strategy. These include a) the natural decline in attentiveness that occurs during a passive lecture session; b) the use of relatively inefficient learning styles, e.g., listening; c) the lack of constructive alignment between learning outcomes and traditional lecturing; and d) the inability to develop professional skills.

Unit 2: Student-centered active learning for the lecture

Short of converting to a group-based learning environment, the instructor can insert pauses in the traditional lecture to interrupt the inevitable decline in attentiveness and engage students in various learning activities. This unit discusses some of those activities, which include using short quizzes to check readiness for class, using guiding questions throughout the lecture, consolidation pauses for students to compare notes and prepare questions, short reflective essays, and "think-pair-share" exercises.

Unit 3: Group-based student-centered active learning

Extensive use of learning groups enables students to maximize use of highly efficient learning styles, such as doing things, discussing them, and teaching each other. It also enables students to develop certain professional skills, such as problem-solving, teamwork, oral communication, and interpersonal skills. While we consider TBL to be the group-based method of choice for basic engineering courses, in order to fully appreciate its virtues as well as its limitations, it is important to know how it compares with the other popular group-based methods, i.e., PBL and PjBL, which are the subject of this unit.

Unit 4: Textbook Team-Based Learning (TBL)

This unit essentially describes TBL as is done in the textbook by the original developers of the method [3]. Discussed in depth are the three phases of TBL (preparation, application, and unit assessment); the four essential principles of TBL, which relate to group formation and management, student accountability, group assignments, and feedback; and a comparison of TBL to PBL and PjBL. The unit also includes six video clips, taken during an exemplary TBL classroom session, that illustrate various aspects of the TBL strategy.

Unit 5: Practical recommendations for using TBL in engineering courses

TBL as described in [3] was originally developed and optimized for senior and graduate level courses in psychology and business. When it was first used by author R.O. in the sophomore-level electric circuit sequence, it was observed that some of the textbook aspects of the strategy did not work well in those classes; subsequently, four beneficial changes have evolved, which have improved its use in the electric circuit sequence. Those changes are discussed in this unit as practical recommendations. Briefly, they relate to the use of learning outcomes, including one related to learning the principles of TBL; to the use of shorter preparation assignments and more frequent readiness testing in the preparation phase; to the use of a specific problem-solving scheme during the application phase; and to the use of formative assessments in the unit assessment phases.

IV. Evaluation

The online training course is currently being piloted by several faculty volunteers. In addition to completing all course requirements as described above, pilot volunteers also complete an evaluative questionnaire that is helping to improve the course. The questionnaire contains multiple-choice and open-ended questions related to the following: a) length of time needed to complete each learning unit; b) ease of navigation within the course site; c) clarity of writing and ease of comprehension of the textual course content; d) quality and usefulness of the illustrative video clips; e) usefulness and difficulty of the mastery quizzes.

To date two volunteers have piloted the course and completed the evaluative questionnaire, the results of which suggest that Unit 4 is disproportionately long, that parts of Unit 4 in particular are unclear and/or difficult to comprehend, and that several mastery quiz questions, particularly some of those in the quiz for Unit 4, are ambiguous. Limited though the evaluative data is at this point, it is clear that Unit 4 needs work. Thus, for the next version of the course, Unit 4 is being divided into two units, the material therein is being rewritten, and the associated mastery quiz questions are being examined and rewritten as needed.

V. CONCLUSION

The purpose of this project has been to provide engineering faculty with an on-line training course that will help them obtain the knowledge and skills needed to incorporate various forms of student-centered learning, especially TBL, in their own practice. A “first edition” of the course is being piloted and evaluated by several faculty volunteers. Using feedback from them, the course is being revised and a “second edition” is now being developed. Eventually, the course will be made available to other engineering faculty wishing to improve student engagement and learning in their courses.

***Abstract* - As the field of Engineering Education continues to grow so does the number of research studies. In this ever developing field, it is important to understand the practical applications and implications of this growing body of work. This paper discusses the initial practical applications of one study designed to examine the motivation and identity development of Graduate Teaching Assistants (GTAs). Our hope is that by sharing the initial practical applications of our work in the work-in-progress format, we can better define the appropriate applications of this particular study but also contribute to the conversation of research to practice in Engineering Education.**

Keywords - teaching assistants, motivation, identity, application

I. Introduction

Engineering Education is a growing and developing discipline and research field; as Jamieson and Lohmann [1] have discussed, to continue to move Engineering Education forward with meaningful progress, we need to continue to connect research and practice. This work-in-progress addresses that key issue by presenting the initial practical applications from a large research study about GTAs who are the future of Engineering Education both in terms of research and practice. At this time, this research is in the analysis phase, and we hope that by presenting our findings in this format, we can gain further insight into our research and applications. We also hope to further contribute to the ever developing conversation of research to practice by focusing our research on future faculty who will be instrumental in connecting the two areas in the years to come.

GTAs serve a variety of functions in engineering classrooms. Many times they are the primary instructor for a lecture or lab or they may be an assistant in the classroom, helping to mentor students and support faculty [2]. Regardless of their specific role, GTAs are often in direct contact with undergraduate engineering students, creating the potential for GTAs to have a significant impact on a student's educational experience. To create GTA development programs to best prepare GTAs for their roles and optimize student experiences, it is important to understand the experiences and needs of GTAs from their own perspective. This work-in-progress paper addresses the possible applications of a research study currently examining GTA teaching experiences in first-year engineering programs. The ultimate goal of that work is to identify the key factors affecting GTA motivation to teach and identity development as teachers. This paper focuses on the specific applications of the findings.

II. Theoretical Framework

This research is based in a theoretical approach that combines motivation and identity. As previously described [2], the theoretical approach uses Self-Determination Theory (SDT) [3] as the motivational perspective and Possible-Selves Theory (PST) [4] as the identity component. In the proposed model, PST serves as the foundation for understanding an experience where views of one's future possible self influence how we experience something. The SDT constructs of competence, relatedness, and autonomy can then be examined keeping in mind the individual's view of their future self. In our work, as defined by Ryan and Deci [3], autonomy includes an individual's feelings of decision making power and control, competence addresses having appropriate knowledge, and relatedness encompasses feelings of belonging to a community. By using a combined theoretical perspective such as the one described above, a holistic understanding of GTAs' experiences can be developed taking into account both identity and motivation which are both fundamental to who we are and how we act in certain situations.

III. Methods

Overall, this research employed a multi-phased mixed methods design incorporating qualitative interviews and a quantitative national survey with GTAs teaching in a variety of first-year engineering programs. For the qualitative portion, 12 interviews, representing five different first-year engineering programs, were coded using an *a priori* approach where the major constructs of the theory served as the codes [5]. The quantitative portion, which had 33 participants representing seven different first-year engineering programs, was analyzed using basic descriptive techniques due to the size of the sample.

The main outcome from the project so far is a set of teaching profiles that represent different clusters of GTA participants based on SDT and PST constructs: specifically identity, competence, autonomy, and relatedness. The clusters were developed by statistically clustering the quantitative data and subsequently examining the qualitative data in a mixed methods approach. The profiles combine both the qualitative and quantitative findings from the study through connecting and mixing. Essentially, the profiles represent possible types of graduate students that are working as GTAs in first-year engineering programs. It is not our intention to suggest that all GTAs only fit into specific groupings. Rather our intention is to show that there are similarities and differences in students that choose to be GTAs and thinking of them by profile could help researchers and supervisors alike to develop strategies to help prepare GTAs for their teaching roles. Additional information about the methods (i.e., details on the analysis, reliability, and validity concerns, etc.) will be provided in future publications.

Below we discuss the first teaching profile developed as an example of the initial findings from this work. We also provide detailed examples of how that profile can be applied towards reconsidering structures for GTA teaching appointments and towards revising traditional GTA training programs.

IV. Strong Identity Profile

Based on the analysis, we discovered that the most salient construct for determining the profiles was identity. With this in mind, here we discuss the strong teacher identity profile that emerged from our work.

Based on the interviews, individuals who make up the strong teacher identity profile believe that teaching is integral to who they are. They also believe that teaching is something you do beyond the confines of a classroom taking place in many aspects of life. For this group of GTAs, teaching is a natural fit and is something they feel they were meant to do. As Wesley, a first time GTA, said:

> *"Just being conservative, but um, it's all, it goes along with the fact that [being a teacher is] part of who I am. [...] I always knew I had to you know, teach in order to be happy…"*

From this quote, we see that Wesley has a strong connection to teaching, believing it is something he has to do in life. Additionally, in keeping with PST, these GTAs more often than not want future careers to involve teaching in some direct capacity. Many cite being future faculty members as part of their ideal job after graduation.

V. Applications of the Profile

Based on the profile described above, these individuals want to teach in the future and see it as a strong part of who they are. For these types of GTAs, programs should be developed that help foster advanced teaching experiences for these individuals so they can continue to develop their skills as teachers. The current development programs that are reported most commonly in the Engineering Education literature are universal in the sense that they do not consider individual identity or motivation needs. To supplement the current training, we suggest that strong teacher identity GTAs take part in programs such as the Preparing the Future Faculty [6] or get involved in Engineering Education PhD programs or certificate programs to further supplement their teaching in the classroom. In these types of programs, students get to hone their teaching practices, but they are also exposed to educational theory and literature further supporting their interest and knowledge about teaching. Looking towards early career faculty development literature also provides examples of how GTAs could continue to develop and progress in their teaching abilities. A recent example would be the work by Felder, Brent, and Prince [7] who explore instructional development programs, best practices, and recommendations with regard to adult learner motivation.

We also suggest that GTAs meeting the strong identity profile be given increased responsibilities in their programs and be considered for advanced roles where they can serve as role models and mentors to other GTAs providing support and encouragement as needed. By serving in advanced roles, GTAs would not only impact the learning of their students, they would also impact the learning and development of their fellow GTAs. This impact could ultimately help to contribute to improving the quality of Engineering Education as a whole. In K-12 teacher education, similar approaches have been taken where K-12 teachers are involved in leadership roles to help with overall education reform at the school and district level (e.g., [8-9]).

We would like to clarify that the recommendations above are targeted at the strong identity profile, but they may also be suitable for GTAs in other profiles as well. These recommendations serve as a starting point for understanding GTA experiences but are by no means the only recommendations for supporting their experiences. To fully understand a GTA's experience, we suggest they take the survey we have created related to motivation and identity to better understand themselves and their own beliefs. These initial results should be used as a starting off point as we believe the profiles are fluid and GTAs can easily move between them given teaching appointments.

VI. Conclusions and Future Work

The overall purpose of the study is to better understand the teaching experiences of GTAs involved in first-year engineering programs examining their motivation and identity. However, this paper serves to set the stage for applications and implications from that work. By presenting this research in a work-in-progress format, we are able to open this topic of research to practice for formal discussion. We plan to use the results of presenting this paper to influence the applications and implications of this research beyond the first profile and beyond first-year engineering programs. In the future, we plan to expand this research beyond engineering examining the motivation and identity of GTAs in a variety of disciplines. Additionally we hope to develop this research providing information about the connection between GTA motivation and identity and student motivation, identity, and achievement. Finally, we believe that the audience for this work includes anyone who is a TA, uses TAs, or is new teacher in general.

Institutional Benefits Policies and Family Formation among Engineering Faculty

Joyce B. Main
School of Engineering Education
Purdue University
West Lafayette, IN, USA
jmain@purdue.edu

***Abstract* - This work in progress examines family-related benefits policies across doctoral institutions and the family formation patterns of engineering faculty. The nationally representative data come from the 2004 National Study of Postsecondary Faculty surveys of institutions and faculty. Data show that a little over half of engineering faculty members provide financial support to one or more dependents. Yet, many doctoral institutions do not provide childcare benefits or parental leave for full-time faculty and instructional staff, highlighting the need to examine the role of institutional structures and benefits policies in the career progression of engineering faculty with dependents.**

Keywords- faculty, engineering, child care, benefits policies

I. INTRODUCTION

The complexity of the issues surrounding the underrepresentation of women in science and engineering has inspired a sizable body of research encompassing every stage of the life course from preschool through post-doctoral employment. The importance of family formation cannot be overstated in the career progression of women faculty. Women with dependents experience unique barriers to career formation when they assume primary responsibility for childcare and household labor [1]. Many academic institutions were developed based on traditional gender norms (men as breadwinners and women as caregivers), and therefore, female faculty with dependents may face disproportionate challenges in the workplace compared to their counterparts [2,3]. This study is a comparative examination of institutional benefits policies as a potential source of variation in the career progression of faculty with dependents using a nationally representative dataset. How do the career patterns of male and female engineering faculty with dependents differ based on the availability of institutional family-related benefits?

Previous research investigating the influence of family formation on academic career progression find that female doctorates with children are less likely than male doctorates with children to enter tenure-track positions and are more likely to obtain part-time academic or non-tenure track positions [4,5]. Among those who are on the tenure-track, women with children are less likely than men with children to earn tenure. Both men and women, however, do not consider tenure-track faculty positions at research institutions to be "family-friendly" [6]. While engineers are often included in these analyses, engineering has unique characteristics that warrant a closer inspection. Chief among these is the relatively lower representation of women in engineering relative to other science disciplines. Attracting and retaining women as engineering professionals and as tenure-track faculty members in engineering are of critical importance. The nation's scientific, technological, and economic progress is partially dependent on the size and diversity of the engineering labor force [7]. Further, the representation of women faculty in science and engineering is positively associated with increases in the persistence of women undergraduates [8-10]. Research results will therefore aid key stakeholders in postsecondary institutions shape benefits and institutional policies to support work-life integration among employees. These policies also have the potential to be adapted to address caring for aging parents.

II. DATA

The nationally representative data come from the 2004 National Study of Postsecondary Faculty (NSOPF) institutional-level and individual-level surveys, which were conducted in 2003 via web-based questionnaire or telephone interview. Institution-level data include information regarding types of benefits available to full-time staff, such as childcare, paid maternity leave, and paid paternity leave. The institution-level data are comprised of 920 Title IV-participating degree-granting institutions across the 50 states and District of Columbia. The stratified sampling generated 1,070 eligible institutions and 920 institutions completed the survey, resulting in a weighted response rate of 84 percent. The weight also adjusts for changes or merges between institutions. The 920 institutions therefore represent a population size of 3,134 institutions across the United States.

The individual-level data include 26,100 survey responses from faculty and instructional staff sampled from the institutions resulting in a 76% weighted response rate. Faculty and instructional staff include permanent, temporary, adjunct, visiting, acting, and postdoctoral appointees employed full or part-time in tenure or non-tenure track positions. Individual-level data include demographic characteristics, such as gender,

This research is funded by the American Educational Research Association Grants Program.

race, marital status, and number of dependents. Information regarding employment status at the time of survey such as faculty rank, length of service, and field are also available.

The sample for this study is limited to full-time engineering faculty at doctoral institutions. Approximately 78% of engineering faculty members are full-time [11]. When data were collected in fall 2003, women comprised 9.5% of engineering faculty [11]. The institution sample is limited to doctoral institutions. Weighted proportions of faculty with dependents and of institutions offering family-related benefits to all, some, or none of full-time faculty and instructional staff are estimated. Weights are applied to adjust for the differential probability of selection of institutions and individual faculty, such that the results are generalizable to the population.

Fig. 1 indicates the proportion of male and female tenure-track engineering faculty in doctoral institutions with dependents. A dependent is defined as an individual 24 years old or younger for whom the faculty member provides financial support. Among male tenure-track engineering faculty in 2003, 41% indicated no dependents. Meanwhile, 59% reported one or more dependents. In comparison, 47% of female tenure-track faculty members indicated no dependents while 53% reported one or more dependents.

Although over half of the engineering faculty reported supporting at least one dependent, benefits associated with childcare, paid maternity leave, and paid paternity leave were not commensurately available. Among doctoral institutions, 31% provide childcare benefits to all full-time faculty and instructional staff (Fig. 2). Meanwhile, 59% of institutions do not provide any type of childcare. In regard to parental leave, nearly half of institutions offered paid maternity leave while only 32% offered paid paternity leave. In contrast, tuition remission is available to all faculty and instructional staff at 54% of the institutions.

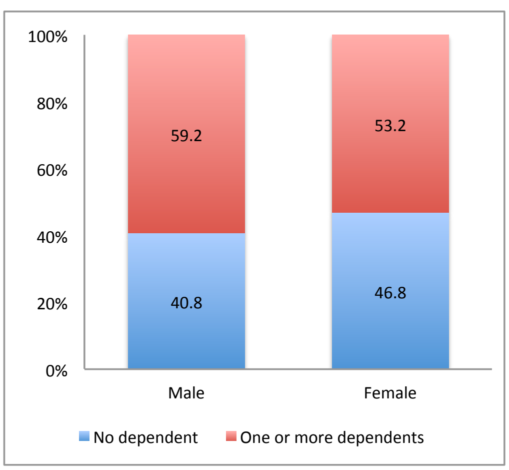

Fig. 1. Proportion of male and female tenure-track engineering faculty with dependents

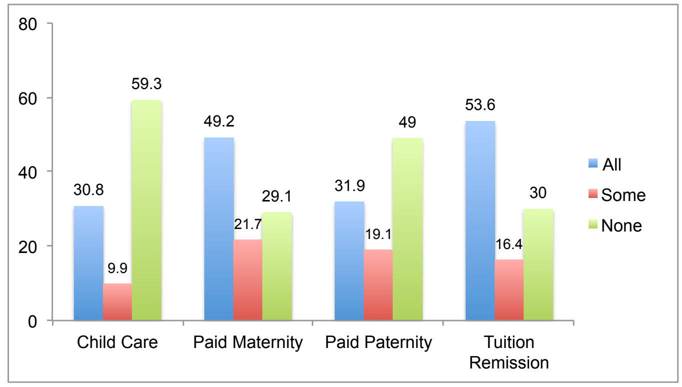

Fig. 2. Proportion of doctoral institutions offering family-related benefits to all, some, or no full-time faculty and instructional staff

III. FUTURE WORK

The disparity between the proportion of engineering faculty with dependents and the availability of benefits associated with dependent care highlight the need to examine how policies influence academic career progression. Further, the relatively smaller proportion of doctoral institutions providing paid paternity leave suggest that work/life issues for men should also be investigated [12]. While the data provide a comprehensive national perspective, the data are limited in that they were collected in fall 2003. Future work entails analyses of the career progression of female and male engineering faculty as a function of the availability of family-related benefits policies. Data from more recent faculty cohorts will also be analyzed from the National Science Foundation Survey of Doctorate Recipients.

***Abstract*—Many universities require engineering majors to take some form of a professional development course. Generally, the goal of these courses is to prepare students for the engineering profession. Another important aspect of these courses is to provide a mechanism to satisfy accreditation criteria on student outcomes that are difficult to implement in other technical courses. At the University of Oklahoma, most engineering disciplines take the course titled: ENGR 2002 – Professional Development. Historically, this course was effective in satisfying accreditation requirements on student outcomes, but was not well received by the students. Details of the reasons for this dissatisfaction and changes made in the re-design of this course are discussed in this paper. The new version of ENGR 2002 includes many innovative practices in team-based learning and peer learning that are shared in this paper. All of the vital elements of the four projects included in the course are provided to support others who would like to implement similar projects. Course surveys, completed by 148 students, were used as the primary assessment method. Additionally, standard course evaluations were used to compare this course to other engineering courses and show improvement from the previous version of ENGR 2002. Many student comments are included in the paper to show their reaction to different aspects of the course. One student made a comment that echoed our sentiments regarding the teaching of this course for the first time in the fall 2012 semester: "from being in this class it is noticeable that people need to take it to work on public speaking skills or working with groups." From our experience, many students grow a great deal in terms of communication effectiveness and ability to function on a multi-disciplinary team as a result of this course, and we believe these skills are essential to become a great engineer.**

Keywords—professional development; team-based learning; ethics; entrepreneurship; peer learning; rubric; ABET

I. Introduction

Many universities require engineering majors to take some form of a professional development course. Generally, the goal of a professional development course is to prepare students for their engineering career. Many universities require their engineering students to take non-engineering courses, such as technical writing, communications, and leadership to help satisfy this need. Some universities have even developed specific courses in engineering ethics [2] and engineering entrepreneurship [3, 4] to better serve their students. This paper discusses a unique professional development course, titled ENGR 2002, developed by the University of Oklahoma (OU) that includes all of these topics.

In addition to providing engineering students the type of well-rounded education needed for them to be successful in their careers, a professional development course can provide a mechanism to satisfy accreditation criteria on student outcomes that are difficult to implement in other technical courses. At OU, most engineering disciplines take the two credit-hour ENGR 2002 course. Historically, this course did an excellent job of satisfying difficult accreditation requirements, but was not well received by the students. To address this issue, the College of Engineering at OU formed a task force of leaders in different engineering disciplines to formulate a solution. The task force researched the problem and discussed with industry partners the areas of competency that should be emphasized in ENGR 2002. They arrived at similar conclusions that are presented in a recent study [1]; The EAC of ABET competency that is most important for engineers in industry is the ability to work in teams (EAC of ABET outcome d) [5]. The second and third most important competencies were shown to be data analysis (b2) and problem solving (e) in this study. Outcomes b2 and e are thoroughly taught in technical engineering courses so they are typically not difficult for engineering departments to assess. The study stated that the next three most important competencies were: communication (g), life-long learning (i), and ethics (f). With this information, the task force set out to modify ENGR 2002 to emphasize these four competencies (d, g, i, and f). The following additional outcomes are also assessed in ENGR 2002: (a, b, h, j, and k). Later in the paper, each project is described and the EAC of ABET outcomes that are emphasized are listed.

The next step for the task force was to analyze student feedback to see how the structure of the course could be modified to increase their interest level and overall satisfaction. There were four findings that became the foundation of the new ENGR 2002 course structure. First, the course relied too heavily on in-class lectures and a top-down learning model. In response to this finding, the course was switched to a team-based learning model with lecture time minimized and the time allotted to work in teams maximized. In a similar finding, the second thing that the students liked most about the old version of the course was the final group project. In response, this project was modified to overcome some of the issues the students had with various details. In addition to enhancing the final project, three more group projects were added to the course. The third finding was that the students disliked the multitude of quizzes and assignments in the old version of the course. The new team-based model we implemented for the course put the vast majority of the work required in the course to be performed in group projects. The last finding is that students had a difficult time aligning schedules to work on the final group project. To address this issue a lab/discussion session was added to the course. The students now have two 105 minute blocks in their schedule for the two credit-hour course. Attendance for the second class period of the week is usually optional, but it provides the students a time block in their schedules to work on the course projects. The new course was implemented in the fall 2012 semester. After the semester, a thorough assessment process was conducted that led to numerous changes to the spring 2013 version of the course.

II. Course Structure

The primary goal of this paper is to provide as much detail as possible to allow others to implement this course. From the experience gained and insights learned in teaching nine sections of this course over the fall 2012, spring 2013, and summer 2013 semesters, it is our belief that this course could be easily implemented in any engineering curriculum at any university. In order for this paper to be better used to implement the course, a week by week schedule will be used as a means to describe the course. Before discussing the projects and weekly schedule, the structure and some of the unique practices are discussed. Each section is composed of nine teams of four to five members that are programmatically selected to have diverse engineering disciplines and leadership styles. Each team selects a leader, who ideally only serves as a leader for one project to allow everyone the opportunity to gain leadership experience. In order to encourage participation in the team-based learning model of the course, a peer evaluation process is utilized that accounts for 10% of the overall grade. A peer evaluation template is filled out after each project that rates the team leader and members.

Each project includes a presentation that the students in the class grade with a provided rubric. The rubrics are kept simple so that students and faculty can easily judge the presentations while they are observing them. Details of the rubric are provided for each of the four projects in their corresponding sections of this paper. The average rubric scores from the students in the class equates to one judge. Three to five additional judges (including the instructor and the teaching assistant) also grade each presentation. The rubric scores from all of the 4 to 6 judges are averaged and normalized so that the team with the highest presentation score gets a 100% grade. The rubric scores from the four projects in the course results in 48% of the overall grade. Over the first two offerings of the new version of ENGR 2002, there has been strong correlation amongst the judges rubric scores. The correlation is shown to the students to provide them with a sense that the grading process is fair. In the assessment section of this paper, data shows the students strongly support this grading process. Furthermore, in reviewing survey data and student comments, we found that one of the greatest strengths of the course is the peer learning that occurs during the grading process.

The remaining 42% of the grade is broken down as: 10% for attendance and participation, 5% for a FE style ethics quiz, 10% for a final quiz, and the remaining 17% for various writing assignments. For the first two offerings of ENGR 2002 only 5% was assigned to the final quiz and the other 5% grade was given for participation in the course assessment process.

III. Project 1 Overview (Outcomes: d, g, h, i, j, k)

Project 1 is titled "Greatest Achievements of the 21st Century". The student's objective for this project is to study different engineering achievements of recent history and make a case for which one is the greatest of the 21st century. The students are allowed to select their own criteria to measure "greatness". Details of the schedule during this 3-week long project are described below. Week 1 is the most complicated and critical week in ENGR 2002 because it sets the stage for the entire semester. For the students to embrace the course, they need to be given clear justifications for the course and detailed explanations of expectations.

A. *Project 1 Weekly Schedule – Spring 2013*

Week 1 – The students are given a questionnaire to determine their major and there leadership style. The questionnaires are then turned in and the teaching assistant enters them into a spreadsheet while the instructor goes over the syllabus. Once the data is entered a LabVIEW program is executed to produce teams with high levels of different leadership styles and majors. While the program is running and the students see their names shuffling around into different teams on the screen, the instructor explains that the reason for assigning teams in this way is to give the students experience working with different types of engineering majors and personalities. The nine teams of four to five students assemble and select a team leader. The instructor then introduces project 1. The teams work the rest of the class period to finalize the three engineering achievements they will study. During this process the instructor and teaching assistant engage with the teams individually to help them get started. The students also turn in a timeline and task list by the end of the class period.

Week 2 – First, project management information is presented by an engineering professional with considerable experience in managing projects. The students are given a tutorial of how to make Gantt charts and information about project timelines and roles. The teams finalize their selection of the greatest engineering achievement of the 21st century from their list of three and create a Gantt chart and assign roles that they must adhere to in the completion of the project.

Week 3 – Each team presents their work; while all other teams score the presentation with the rubric they are provided.

B. *Project 1 Presentation Rubric – Spring 2013*

The following are the items judged with the presentation rubric. To keep the grading simple, each item in the rubric is worth 10 points for all of the projects.

- **Timeline and Roles** - A project timeline was prepared and team member roles were identified and adhered to. If timeline and roles were not kept, explain why.

- **Achievement Comparison** - The team made adequate comparison with 3 achievements and justified their rankings in a logical way.
- **Technical Details** - Describe how the product/technology was envisioned and brought to market. Which company and/or visionary team led the development of the project from start to completion?
- **Technical Details** - How will it (or does it) benefit or inspire society? What other positive or negative unintended consequences did the achievement generate?
- **Conclusion** - The team made a succinct and convincing conclusion statement highlighting all of the main points.
- **Overall Delivery** – It was presented clearly in a logical, organized, and easy to follow sequence. Topics were presented by all team members.

C. Project 1 Writing Assignment – Spring 2013

Each team is also required to write an abstract over their project. The abstract is graded by engineering faculty members skilled in writing. Each team receives detailed feedback from the graders.

D. Project 1 Lessons Learned

After each project description, a section will be dedicated to reviewing the lessons that were learned and changes made between the fall 2012 and spring 2013 courses. Many of these changes resulted from student feedback during the fall 2012 assessment process, which is discussed later in the paper.

- We found that project 1 was extremely effective in the fall 2012 semester at laying a foundation for the rest of the course. The great achievement theme was interesting to the students and the required items were not very difficult to complete. This allowed them to ease into the course and become comfortable in working in a team structure.
- Since we were limited to 105 minutes for 9 presentations, allotting the correct amount of time for each presentation was critical. In the fall 2012 semester, we used 8 to 10 minutes for the presentation length and had problems with going over the allotted time in some sections of the course. We found that having a presentation length of 7 to 9 minutes was the optimal length. We also instituted more severe penalties on the rubric score sheet for not staying in this time window in the spring 2013.
- Writing was emphasized in the fall 2012 course, but the feedback needed for them to learn to become better writers was lacking. In the spring 2013 we received support from an expert in technical writing to help provide feedback on writing assignments and redesign our writing exercises.
- In the fall 2012 semester, the writing assignment over the greatest achievement they selected was a short essay. To add a writing component to the course that is important to many engineers, we changed this to an abstract (or executive summary) writing assignment. This allowed us to be able to explain the importance of writing a good abstract and give them resources to assist them. We also turned this assignment into an Abstract competition, where the best abstract would receive bonus points. To provide better writing feedback and fair grading we found qualified faculty members to serve as the judges for this competition.

IV. PROJECT 2 OVERVIEW (OUTCOMES: A, B, D, G, H, I, J, K)

One important aspect of project 2 is that it is the only project that is highly technical. It is important to add a technical element into engineering courses to keep students interested. This project also allowed us to assess ABET outcomes A and B, which are not included in the other projects. Another important element of project 2 is that it is a video project. By forcing the students to experience a different form of communication that is growing in popularity, we were able to keep the course from being too repetitive. In the fall 2012 semester we titled project 2 "As the Pendulum Swings – The Movie". The objective was to experimentally validate the equation of the period for a pendulum. This was the one portion of the course in the fall 2012 semester that required a significant change.

From studying the student responses, we determined that the primary reasons that changes were needed were due to two factors. First, they didn't like watching a video of the same scientific principle numerous times during the peer grading process. To address the first item, we redesigned project 2 so that the students could choose any scientific principle to validate experimentally. The students were encouraged to build something to facilitate their experiments. Some examples of things that students built were a trebuchet, an aluminum foil-based capacitor, and a tennis ball launcher. The students also were required to select a unique application of the principle (discussed later). The second reason that changes to project 2 were needed was that students needed more guidance on how to make a video and what was expected of them. We added a lecture module describing how to make a video and used the example videos from the fall 2012 semester to give them guidance on what was expected. We showed them pendulum videos from the fall 2012 semester and told them that a good example of a unique application would be the Burj Kahlifa, which uses a massive pendulum as a tuned mass damper to stabilize the tall building. It is interesting to note, that we came up with the example of the Burj Kahlifa because it was selected by a team as their greatest achievement of the 21st century in the fall 2012 semester. From informal feedback, project 2 appeared to be very successful with these changes implemented and survey data (shown in Table I) supported this observation.

A. Project 2 Weekly Schedule – Spring 2013

Week 4 – The teams are reshuffled and no students are allowed to work with the same people as project 1. Next, research fundamentals are presented by an expert in performing research and navigating the OU library. This presentation prepares them for the more detailed research that is required in the remaining projects of the course. We also introduced the IEEE citation style guide at this point and required the students to properly cite all references in their work. Project 2 is introduced and the previously described fall 2012 video examples are shown and the Burj Kahlifa is highlighted as a possible application. A tutorial is then provided to give the students a basic understanding of how to make a video. For the remainder of the class the teams selected a team leader and chose a scientific principle to validate. Students who were team leaders in project 1 could not be team leader again. With the peer grading experience in mind, we didn't allow more than two teams to select a scientific principle in the same area.

Week 5 – Leadership fundamentals are presented. Then the teams work on their projects. The instructor should try to provide as much support as possible for the students during this project. We purchased a set of tools, materials, and measuring devices that the students could check out. Making arrangements with labs that might be needed to perform the experiments is also beneficial to the students.

Week 6 – Each team shows their video; while all other teams score the rubric they are provided.

B. Project 2 Video Rubric – Spring 2013

The following are the items in the video rubric.

- **Scientific Principle Validation Explanation –** The video explained the scientific principle in an easy to understand and thorough fashion.
- **Scientific Principle Validation Experiments –** The experiments performed were done in a clear fashion and were sufficient to adequately validate the scientific principle.
- **Applied Scientific Principle to a Product** - The video showed how this scientific principle is cleverly applied in an existing product to solve some type of problem.
- **Overall Video Content** – Video is logical, organized, and easy to follow sequence. The video is exciting and interesting.

C. Project 1 Writing Assignment – Spring 2013

For the team writing assignment for project 2, the students were given a scenario where they were the engineering team who first proposed the idea of applying this scientific principle to the unique application that was described in their video. With this in mind, the students were told to write a white paper to convince an audience of potential clients that the scientific principle is valid and persuade them to use this solution for the problem or activity being addressed. This required the group to learn about the technical details of the application.

D. Project 2 Lessons Learned

Changing the structure of project 2 to allow the students to be creative and come up with their own ideas was a big success. The students were much more excited and engaged in the project as a result. The videos were also much better than in the previous semester. The most important lesson we learned in this project is that the peer learning element of the students grading the presentations must be a central focus in the creation of projects. In the new version of project 2, the students learned about several different scientific principles and many unique applications that they were not aware of prior to the class. For future semesters, we are not going to allow any group to select the same scientific principle so the students of each section will learn about 9 different topics. We also purchased additional measurement devices that they can use.

V. PROJECT 3 OVERVIEW (OUTCOMES: D, F, G, I, J, K)

Project 3 was titled "Ethical Disasters". This project was similar in style to project 1, except the focus was on engineering ethics and professional licensure. Each team selected two ethical disasters that have a strong engineering focus. They performed a thorough literature review, obtaining reliable articles. During their presentation, they discussed the ethical and criminal issues related to the disaster and the societal, economical, and political impacts of the disaster. They also commented on key reasons for unethical conduct. The students then picked which of the ethical disasters they felt that "every engineer should know about" and justified their selection.

A. Project 3 Weekly Schedule – Spring 2013

Week 7 – The teams are reshuffled again with the students working with a new group of people. Ethics and professional licensure information is presented, which includes the steps involved to become a professional engineer. To tie professional licensure to ethics, the NSPE code of ethics is used. The students are told that they would be given a quiz similar to the ethics questions that are on the FE exam. For the remainder of the class, the teams select a team leader and chose two ethical disasters to study. Students who were team leaders in projects 1 or 2 could not be team leader again. Again, for the peer grading experience, we didn't allow more than two teams to select the same ethical disaster.

Week 8 – A guest speaker from industry with a strong ethics background and practical examples is brought in for a presentation on engineering ethics. For the remainder of the class the teams work on their projects.

Week 9 – The students take the ethics quiz at the beginning of class. Then, each team presents their work; while all other teams scored the presentation with the rubric they were provided.

B. Project 3 Presentation Rubric – Spring 2013

The following are the items in the presentation rubric.

- **Ethical Disaster # 1 - Overview:** Clearly Describe the Disaster and show the references that were used. Did the ethical disaster have a strong engineering focus?
- **Ethical Disaster # 1 - Details:** Discuss the ethical and criminal issues, and the societal, economical, and political impacts. Describe the reasons for the unethical conduct
- **Ethical Disaster # 2 - Overview:** Same as previous
- **Ethical Disaster # 2 - Details:** Same as previous
- **Most Important Ethical Disaster** – Select the ethical disaster that is the most important ethical disaster that every engineer should know about. (Justify the selection).

C. Project 3 Writing Assignment – Spring 2013

In the fall 2012 semester, an individual writing component was included where students compared different engineering disciplines code of ethics, such as NSPE, IEEE, and ASME. In the spring 2013 semester, the writing assignment was replaced with the ethics quiz. Since additional writing assignments were added in the spring 2013 semester it was decided that the ethics code comparison assignment should be removed to avoid increasing the student's workload.

D. Project 3 Lessons Learned

We received many comments from the students in the surveys that made it clear that studying the ethical disasters was a good way to emphasize the importance of ethics in the engineering profession. One student stated: "I think it's important to know about the mistakes that other engineers made and make sure they don't get repeated. Our mistakes cost lives so we should be reminded of that every day."

VI. Project 4 Overview (Outcomes: D, G, H, I, J, K)

Projects 1 through 3 focused on researching and presenting information about things that other engineers and scientists have done. Project 4, titled "Great Idea" leveraged the knowledge gained in the previous projects and allowed the students to come up with a unique engineering solution to a market problem. The project 4 presentation is the student's opportunity to pitch their great idea to "potential investors" (The class and the judges). The presentations start with the showing of the elevator pitch video (discussed later). For the rest of the presentation the students had the freedom to do any communication style they preferred.

A. Project 4 Weekly Schedule – Spring 2013

Week 11 (*Week 10 was spring break*) – The teams are reshuffled, trying to keep a minimal number of students working with the same people as project 1, 2, or 3. Also, students who have not served as leaders are put in different teams so they have the opportunity to be the leader for this project. Next, a guest speaker discusses the importance of engineers being involved in entrepreneurship. Project 4 is then introduced and an explanation of the "elevator pitch" is provided. For the remainder of the class, the teams select a leader and watch kickstrater.com videos. They must write a summary over one of the videos they liked and explain why they think it will be successful or not. Having the students watch kickstarter.com videos together was a method to get them thinking like entrepreneurs.

Week 12 – A presentation is given over idea protection. This is ideally presented by a lawyer who has experience in patent, copyright, and trademark law. Next, a technical ideation presentation is performed over the paper "The Innovator's DNA" [6]. The students are then assigned an individual writing assignment, which is due in week 13. The assignment requires the students to read the paper discussed in the technical ideation presentation and reflect on their discovery skills. The teams are also required to finalize their great idea by the end of this week.

Week 13 – A presentation from an entrepreneurship professor is provided to help the students with their business plans.

Week 14 – Half of the teams present their great idea during the first class of the week and the other half do their presentations during the second class. The presentations are increased to a maximum of 15 minutes and there is time at the end for questions form the judges. Business professors and graduate students are brought in as guest judges for this project.

B. Project 4 Presentation Rubric – Spring 2013

The following are the items in the presentation rubric. Additional details are provided in the project 4 assignment for each of these items.

- **Elevator Pitch** – Did the elevator pitch convince you to have a second meeting? The students were required to write an elevator pitch that clearly identified four major sections: Who, Why, What, and the Goal. An online template (http://www.alumni.hbs.edu/careers/pitch/) was used and the teams were required to meet the following specifications: 200 to 500 words and 56 to 120 seconds. The students made a video of one of their team members delivering the elevator pitch and it is shown at the beginning of the presentation.
- **Research** and study the "Market Problem" with regards to your "great idea". Assess how much this problem costs the market. The "cost" can be financial or other negative impacts of this problem.
- **Ideate** a technical engineering solution to the market problem. How will you reduce the 'pain' in the market (i.e. reduce the negative effects of the problem)?
- Describe your **technical solution** in detail?
- Address any **ethical**, **safety**, **regulatory**, or **intellectual property protection** issues that might arise in the implementation of this solution.
- **Conclusion** - Communicate why clients' would want to pay for your solution.
- **Overall Presentation Quality and Responses to Questions** – All members presented clearly in a logical, organized, easy to follow sequence.

C. Project 4 Writing Assignment – Spring 2013

The writing assignment for project 4 was a project proposal document, which is an abbreviated version of a business plan. The same elements that were required in the presentation are also in the business plan specifications. In the spring 2013 semester the students are given until the end of week 15 to complete the business plan. It was due at the end of week 14 in the fall 2012 semester, but we realized an extra week was needed for this assignment.

D. Project 4 Lessons Learned

In the spring 2013 we made several changes to project 4 after receiving valuable student feedback.

- First, in the fall 2012 the students were given 6 market problems that they could pick from if they couldn't think of one on their own and they had to choose something in the first week of the assignment. We observed that the students that seemed the most engaged in the project were those that selected their own idea instead of using one of the provided market problems. For this reason, we didn't provide any options and allowed an extra week to come up with an idea.
- The guest speaker in the fall 2012 mentioned kickstarter.com and it spurred a lot of interest amongst the

students. This is the reason we added in this element in week 11.

- The elevator pitch was also added in the spring 2013 semester because it is such a key entrepreneurial concept.
- The last thing that was changed was the length of the presentation and the style restrictions were removed. In the fall 2012 semester the project 4 presentations were of the same format as project 1 and 3. We realized that there was not enough time to cover everything, so we decided to split the presentations into two class periods to give more time. We also decided to allow the judges to ask questions at the end of the presentation.

VII. ASSESSMENT

To help determine the effectiveness of the modified ENGR 2002 course, an assessment was performed during the last class period (week 16) in the fall 2012 semester. The first assessment tool was a survey, where 148 students ranked different aspects of the course on a scale of 0 to 10, where 10 was the most positive answer. Following the survey, we had a team discussion about different aspects of the course. Many valuable ideas were obtained from this discussion time. In the last assessment exercise we asked for comments about different aspects of the course.

A. ENGR 2002 Survey

The following instructions are listed on the survey:

"DO NOT answer 5 on any of the questions. We want to avoid neutral responses. Answer every question for participation credit. You are free to answer the way you really feel (good or bad). The responses will have no impact on your grade."

For the first question of the survey the students were told to: *"rate each of the projects from 0 to 10. 10 would mean you really liked the project and 0 would mean you really didn't like the project."*

Table I shows the results of this survey question for the fall 2012 and spring 2013 semesters. For this question, additional survey data were obtained in the spring 2013 from two sections of the course that were taught by an instructor from fall 2012 (77 students) to assess the change in project 2. The average scores are shown along with the percentage of positive responses (6 to 10). The shaded cells in Table I show the dramatic improvement in project 2 that resulted due to the changes that were made between the two semesters.

TABLE I. FALL 2012 AND SPRING 2013 STUDENT PROJECT RATINGS

Project Number	*Fall 2012 Rating (0-10)*	*Fall 2012 % Positive*	*SP 2013 Rating*	*SP 2013 % Positive*
1	7.4	89.2%	8.2	95.4%
2	5.6	55.4%	7.5	89.2%
3	7.1	81.0%	7.7	90.8%
4	7.5	87.8%	7.5	83.1%

The next section of the survey asked various questions about the course. *"For each of the items below the students were told in the survey to "rate from 0 to 10. 10 is the most positive response and 0 is the moset negative"*

The **bolded underlined** data are the results from all sections in the fall 2012 semester (148 students). The original quiz had a blank where this data is located for the student to write their response.

- **7.6 avg. (+91%)** The CoE task force designed the content (Project themes) and group-structure of the new version of ENGR 2002 that was taught this semester. Do you like what they did?
- **8.4 avg. (+97%)** The Instructors (Landers, Sluss, and Davis) worked together to implement the task force recommendations. Do you like what they did?
- **8.1 avg. (+89%)** The rubrics used for the presentations were a good way to assign a grade.
- **7.9 avg. (+88%)** The class collectively serving as one of the judges was a good idea.
- **7.6 avg. (+88%)** You learned new things by watching/scoring other group's presentations.
- **8.1 avg. (+89%)** The attendance/participation grade served as good motivation to stay engaged in the class.
- **7.5 avg. (+86%)** The peer evaluation grade served as good motivation to stay engaged in the group.
- **8.9 avg. (+97%)** The attendance/participation grade should be continued next semester.
- **8.0 avg. (+84%)** The class collectively serving as one of the judges should be continued next semester.
- **8.2 avg. (+89%)** The peer evaluation grade should be continued next semester.

B. ENGR 2002 Comments

Following the survey we asked the students to comment on different aspects of the course. Some of the comments about what they liked about the projects are shown below:

- **Project 1** – "I had to do a lot of research … and in the process I learned … new things that were not only limited to science and engineering."
- **Project 1** – "I was introduced to several engineering innovations that I was not aware of previously. Also, it sparked my interest in keeping up with new fields of research and invention."
- **Project 2** – "It involved math and testing rather than just plain research."
- **Project 2** – "… the movie aspect forced you to be more creative and made the process much more fun.
- **Project 3** – "I found it very interesting to learn about several, historical engineering disasters where these codes

of ethics could be applied. This project tied everything together and made me realize just how important it is to approach ethics with a very high level of respect."

- **Project 3** – "I liked the learning about history aspect, and it gives someone the ability to realize the consequences of actions before they put themselves in a position where they do it to themselves."
- **Project 4** – "It required an understanding of everything we have done in this class. We had to apply the research skills, ethical skills, business plan skills, and ideation that we learned in this class. Also, this project required the teams to be more original and actually come up with new ideas."
- **Project 4** – "… introduced the creative and business aspects that are associated with becoming an engineering entrepreneur. The process of developing a unique solution to a current or foreseeable market problem is no simple task and is somewhat time-consuming. This creative exercise helped to teach the students just how much it takes both for ideation and research to develop a product or service that is truly unique and that solves a problem. By including a business plan in the project deliverables the business aspect was introduced, allowing students to further research their target markets, methods for marketing, product development and integration of consumer feedback and how they would integrate these aspects into their overall product development plan."

Student evaluations were also used to assess the course. The only question in OU's evaluation that provides evidence of an improvement in course effectiveness is the following question: "In general, the instructor taught this course effectively". The students respond on a 1 to 5 scale, where 5 is the most positive response. The average score for the 99 students in the four sections in the fall 2012 semester, which were taught by three different instructors, was 4.46. This was 27% higher than the average score of all courses in the College of Engineering in the fall 2012 semester for this evaluation question. It is also 60% higher than the average scores received for all ENGR 2002 sections in its previous version in spring 2012.

VIII. CONCLUSIONS

The ENGR 2002: Professional Development course at OU, in its new redesigned format, shows signs of success according to the assessment that has been performed. The numerous comments from the students that support the structure and material of the course gives us confidence that we are on the right track. To fully assess the effectiveness of ENGR 2002 we would need to survey the students (and possibly their supervisors) after they are practicing engineering at their job to see if the things they learned have been useful. In conclusion, student comments that speak to what we are trying to accomplish will be shared:

- "It forced me out of my comfort zone. What I mean is that it forced me to do a lot of public speaking and work with a variety of people with differing opinions/ideas, which are two things that I sometimes struggle with."
- "It teaches you valuable skills that you would actually use in your future career such as working in teams, writing technical papers, and presenting your research."
- "Getting comfortable with presenting project findings to a large group of people was highly beneficial personally as I have never been comfortable presenting in front of a group particularly over something that I have researched or developed. Now I am much more confident and comfortable with presenting and can better prepare for future presentations either for a potential thesis defense or for future jobs."
- "There was a lot of information and skills gained in this class that aren't developed in technical classes. This is a great way to get our minds thinking in not just a strictly technical viewpoint. It helps open our minds to other aspects of what an engineering career is really like."
- "It was good experience to work in multi-disciplinary groups and be able to lead and follow. It helped people that are introverted be more outspoken and extraverted take a lesser role."
- "The course is unlike any other required for engineers and from being in this class it is noticeable that people need to take it to work on public speaking skills or working with groups."

Abstract—This paper reports on self-rated career management knowledge, use, and confidence for women in computer science and engineering before and after participating in a CRA-W Cohort of Associate Professors Project (CAPP) professional development workshop. We find that months after their workshop, three years worth of participating women gave higher ratings for their knowledge and use of skills such as time management, networking, and productive mentoring relationships, as well as confidence in their promotability. These findings suggest that professional development interventions can have long lasting positive effects on mid-career women in computing, and that the type of group mentoring, role models, and community offered by CAPP can help compensate for women's reduced access to career mentoring.

Keywords—women; computer science; computer engineering; professional priorities; professional development; networking; leadership; soft skills; productivity; visibility

I. Introduction

Mentoring is the gold standard for advancing professionals. Its positive effects are well documented (for example, see [13]). Even among the studies of mentoring women faculty in academic settings [10, 14, 15], there is evidence for the importance of mentoring in faculty professional development [3, 4, 6, 7, 11, 12]. Positive impact is not a given, however. The most effective mentoring methods might vary by circumstances, including stage of faculty development [7, 11, 14], although the evidence is clear that high quality mentoring has a positive impact on professional development of diverse people.

Unfortunately, members of underrepresented groups, such as women in computing, have less access than majority men to informal mentoring [1, 2, 5, 8]. Likewise, senior women's scarcity means that even in formal mentoring programs, junior women face challenges finding someone demographically similar with whom to form a close personal bond. Demographic similarity is not required for successful mentoring, but it can offer understanding of the particular challenges associated with underrepresentation, such as low professional self-confidence, limited professional networks, and lack of insider information, which can hinder academic women's career achievement.

To level the playing field and help more women succeed in computing research careers, the Computing Research Association Women (CRA-Women) offer professional development workshops that help mid-career women advance their careers in computing. These Cohort of Associate Professors Project (CAPP) workshops develop women's careers by building community, offering intentional role modeling, and providing group and brief individual "mentoring"[1]. The group mentoring focuses on knowledge of strategies for professional visibility, time management, working productively with a mentor, effective communication. Armed with this information and with enhanced professional networks, our model for change predicts that these women will gain confidence in their promotability and become leaders in their fields.

This paper describes evaluation findings from three years of these CAPP workshops. Analyzing data from surveys of 127 participants, we find that after CAPP, participants reported more knowledge and use of career skills, and more confidence that they will be promoted in a timely fashion. This evidence suggests that professional development in the form of role modeling, group mentoring, and networking can build women's confidence that their careers in computing will advance. CAPP appears to achieve its goal of developing women leaders in computing research.

These findings suggest that employers of women researchers in computing can benefit from either sponsoring participation in CAPP programs, or organizing similar workshops for in-house professional development.

II. Description of the Project

CAPP aims to increase the percentage of Computer Science and Engineering (CS&E) women researchers at the rank of full

professor, or the top of their organization's technical ladder. It provides professional development, a supportive community, and mentoring to cohorts of women researchers. As the project website describes, senior CRA-W Distinguished Professors or Researchers actively participate as role models, mentors, and advisers to the CAPP participants.

The CAPP project began in 2004 and repeats at two-year intervals. Each cohort participates in an initial professional development workshop, a series of smaller meetings in conjunction with technical conferences/seminars, and ongoing electronic support activities. Pre- and follow-up evaluation surveys are administered for each iteration of the workshop. The follow-up surveys are generally fielded a year or more after the workshop.

In total, 127 participants responded to either the pre-survey or the follow-up survey, 88 responded to both, with some missing data in both surveys. We include only first-time responses from the very few repeating CAPP participants in our analyses, and our analyses focus on the matched pre and follow-up surveys for the 88 respondents to both. We conducted qualitative analyses on open-ended questions regarding participants' professional activities and concerns, and quantitative analyses on questions regarding knowledge and use of career management skills as well as their relationship to confidence in promotion.

The extent of CAPP's reach into college and university computing female faculty may be estimated by comparing the number of CAPP participants during the three study years with the number of mid-career women in research universities. This approach approximates CAPP participants as accounting for approximately 21% of all female associate faculty from research CS&E departments in the U.S. and Canada[2].

For statistical analyses, we merged answers from 3 iterations of the surveys into one data set with matched pre and follow-up responses. In addition to descriptive statistics, we tested pre- and follow-up responses for significant changes in three categories of self-rating questions using paired samples t tests. Each survey item has an individual sample size due to missing data. Sample sizes for descriptive statistics range from 55 to 107 responses. Sample sizes for paired samples t tests range from 60 to 86 responses.

III. PROFESSIONAL ACTIVITIES & CONCERNS

CAPP participants are at mid-career and already have engaged in many well-known activities for advancing careers. For example, pre-surveys show that more than 70% of them collaborated on research or writing with someone inside and someone outside their institution or lab. More than 70% also served on a conference committee. All of these activities were within the year prior to CAPP. Unfortunately, only 37% had been mentored within that year.

Perhaps because so few had been mentored, participants came to the workshop wanting to learn a variety of things. More than 85% wanted to learn about networking and the promotion process, but more than 90% expressed interest in learning the less specific "skills that will help make me more promotable," "common mid-career issues," and "career management strategies for my stage". Without guidance from a mentor, these women may have worried that they did not know what they did not know. Certainly, our findings show that they initially were less than confident in their own promotability, despite believing that their accomplishments were appropriate for their career stage.

Overall, it appears that CAPP participants got what theuy wanted from the workshops. Their positive evaluations included free comments that they had learned about other computing subfields and other people, and felt more comfortable seeking advice, more energized, and more connected. Specific significant changes from before and long after the CAPP workshop are described in the following sections.

IV. PRE AND FOLLOW-UP SELF RATINGS

Prior to their first CAPP workshop, the average participant indicated that she knew something about time management strategies, ways of making herself professionally visible, how to work productively with a mentor, effective communication strategies, her organization's expectations for promotability, and its typical schedule for promotions. The average participant reported that she used that knowledge somewhat effectively, except in the case of working with a mentor, where she used this knowledge "not very effectively". Participants were also moderately confident that they met their organization's expectations for their current career stage. They were only slightly confident, however, that they met the criteria for timely promotability or that they had a professional network that would support their career growth.

A year or more after the workshop, the same respondents rated their knowledge, use, and confidence better than they rated it before the workshop, as shown in Figures 1, 2, and 3. To identify the statistical significance associated with the increases in ratings from Pre-CAPP to Follow-Up, we use t-test, paired sample t-test, and regressions to compare ratings from different time periods. Data sets used for comparisons in this chapter are of both equal and unequal sizes, due to missing data problems. Hence, using all three types of analysis render the most robust results [9]. Statistically significant results from these tests provide empirical evidence for the effectiveness of CAPP project.

In particular, knowledge of time management and being professionally visible rose from "some" to "quite a bit," on average. Effective use of knowledge about working productively with a mentor rose from "not very effectively" to "somewhat effectively." Confidence in being promotable and promoted in a timely way, as well as having a network supporting career growth, all increased to "moderately

[2] Based upon the survey responses, there were approximately 127 CAPP participants during our study years, with about 83 holding associate professor positions. We compared this number with the 2011-2012 Computing Research Association (CRA)'s Taulbee Survey, which reported a total of 291 female associate faculty members in CS&E [15]. We assumed similar numbers in the non-responding Taulbee population of departments. The result was 83/(291*.72)= 21%.

confident." All test results shown in Figures 1 – 3 are statistically significant at .01 level.

The t-tests confirm that the observed changes in pre and follow-up means are very likely to be real changes. Participants rated themselves higher on knowledge and effective use of information that contributes to career advancement. They also felt more confident that their careers would advance than they felt prior to the CAPP workshops.

A. *Self-Ratings of Knowledge*

There are five items in this category. Participants provided self-ratings of their knowledge of these areas on a 1-4 scale (1: none; 2: almost none; 3: some; 4: quite a bit). As Figure 1 shows, there was a significant increase in the four evaluated strategies – time management, professional visibility, working productively with a mentor, and effective communication. They did not however, show any significant improvement in the fifth item - their knowledge of their own organization's expectations for promotability. Of course, this last content was not covered during CAPP, but learning about it was encouraged.

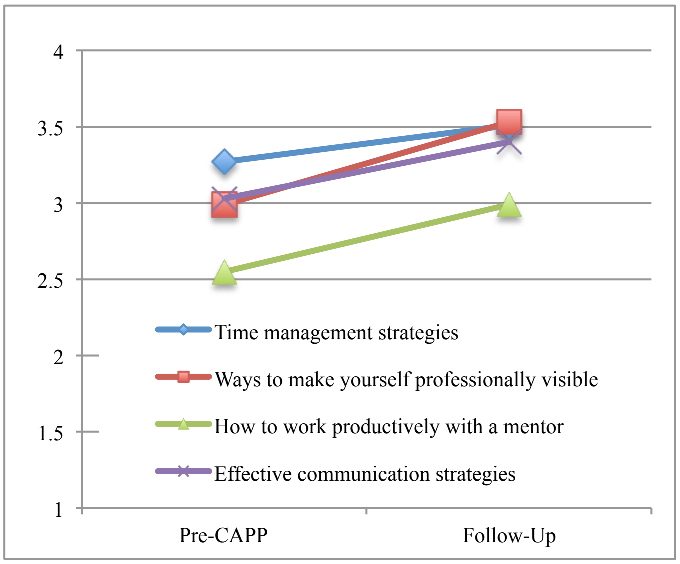

Fig. 1. HOW WOULD YOU RATE YOUR **KNOWLEDGE** OF THE FOLLOWING AREAS?

B. *Self-Ratings for Effective Use of Knowledge*

Participants provided self-ratings for how effectively they use their knowledge in certain areas on a 1-4 scale (1: don't use what I know, 2: not very effectively, 3: somewhat effectively, 4: very effectively). The pre and follow-up mean ratings shown in Figure 2 illustrate the improvements in use of knowledge reported by CAPP participants.

Paired Sample t test results confirmed that self-ratings of effective use of knowledge increased significantly in time management, professional visibility, working productively with a mentor, effective communication, and the respondent's own organization's expectations for promotability.

The means ratings for effective use of knowledge are across-the-board lower than ratings of knowledge in the same areas. All differences are statistically significant at .01 level, with means of use of knowledge lower than means of knowledge in each of these four areas: time management, professional visibility, working productively with a mentor, and effective communication. This indicates that our participants believe they know about these areas better than they use their knowledge.

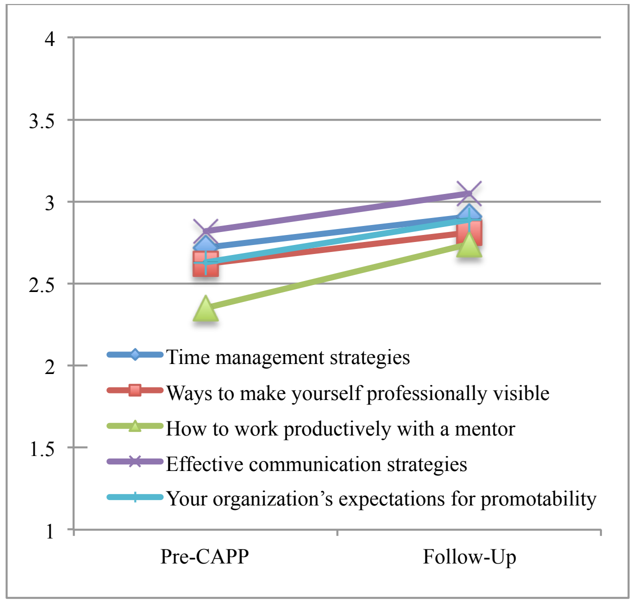

Fig. 2. HOW EFFECTIVELY WOULD YOU SAY YOU **USE YOUR KNOWLEDGE** OF THE FOLLOWING AREAS?

C. *Self-Ratings of Confidence*

Participants provided self-ratings on how confident they are in following areas on a 1-4 scale (1: not at all confident, 2: only slightly confident, 3: moderately confident, 4: very confident). Figure 3 below shows clearly that participants significantly increased self-confidence from before to after CAPP. The most dramatic increase is in their confidence related to professional networking. As with the other self-ratings, t-tests confirmed that these changes are statistically significant.

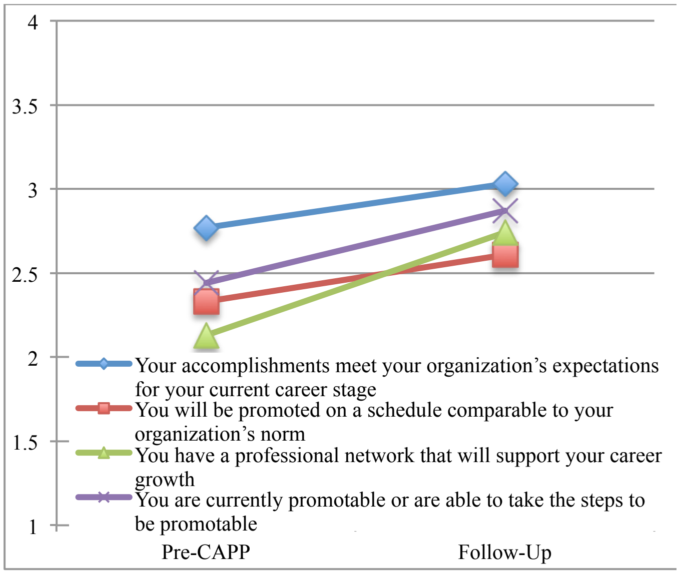

Fig. 3. HOW **CONFIDENT** ARE YOU THAT…

D. *Relationships among Knowledge, Use, and Confidence*

In this section we measure relationships between changes in knowledge of subjects addressed at the CAPP workshop and changes in effective use of that knowledge. We also investigate their contribution to changes in confidence regarding promotability. Finally, we consider whether the amounts of knowledge, use, and confidence are more important than the degree of change.

To create the Change in Knowledge index, we combined the difference in ratings for time management, professional visibility, productively working with a mentor, and effective communication strategies, and then calculated an average Change in Knowledge. We did likewise for Change in Use of that knowledge. The correlation between these two variables is moderate and statistically significant (r=.31, sig. at .01 level), meaning that an increase in knowledge is somewhat associated with an increase in effective use of that knowledge.

Much stronger correlations were evident between the follow-up Knowledge and Use indices (actual average ratings for these categories, not average changes) (r=.52, sig. at the .01 level). Evidently, level at follow-up is more important than changes in level.

E. *Explaining Confidence in Career Advancement*

The CAPP model for change is that improved confidence in professional advancement results when mid-career women researchers in computing gain knowledge from group mentoring by role models, and formation of a supportive community. To test that model, we regressed Change in Confidence on Change in Knowledge and Change in Use.

Our regression results for the change indices, shown in Table 1, find that this model is weak, but statistically significant. Together, Change in Knowledge and Change in Use predict five percent of the variance in Change in Confidence (sig. at .05 level). Change in Use is the stronger predictor of Change in Confidence (beta=.19), but neither variable has a statistically significant effect.

Level of Knowledge and Use, rather than Change in Knowledge and Use, is a better predictor of post-CAPP confidence. We regressed indices constructed similarly to those above on an index of follow-up Confidence level.

The regression results for measures of levels, also shown in Table 1, find that this model explains 26% of the variance in Confidence level (R^2 significant at the .01 level). Clearly other factors play a role in Confidence level, but Knowledge and Use each also contribute significantly. As with the Change analysis, level of Use is a better predictor of Confidence than is Knowledge. In this case, a one unit increase in Use is associated with .38 units increase in Confidence, and a one unit increase in Knowledge is associated with a .21 unit increase in Confidence (both are significant at the .05 level).

V. DISCUSSION

Many studies support the effectiveness of career mentoring, role models, and community membership as contributors to career success. Unfortunately, women in computing have less access to these beneficial conditions than do their male colleagues. To compensate for this inequality, CRA-W CAPP workshops seek to develop women's careers by building community, offering intentional role modeling, and providing both group and brief individual "mentoring". This paper investigates whether this approach succeeds.

CAPP's group mentoring conveys information about strategies for professional visibility, time management, working productively with a mentor, and effective communication. Armed with this knowledge and with professional networks enhanced by the workshop, participants are expected to take more effective action toward advancing their careers. The expectation is that this type of mentoring compensates for women's relatively lower access to career mentoring and increases their confidence in their promotability, which should help advance women to leadership positions in their computing research field.

Our analyses of pre- and long term post-CAPP survey data lends support for this model. Perceived knowledge, effective use, and confidence were greater for the average participant long after CAPP workshops. This improvement was especially evident with respect to working effectively with a mentor and feeling confident in having a supportive professional network.

The evidence also supports the model of career development knowledge contributing to effective use of that information, and together contributing to mid-career women computing researchers' confidence they are promotable. The change associated with the workshop, however, is less influential than the participants' actual levels of knowledge and use of career advancement strategies. In other words, women with access to career information, who also use it effectively, have less need for the CAPP experience. As long as this access remains low for many women in computing, however, professional development workshops like CAPP meet an important need.

***Abstract*— Teamwork has been considered as one of the important learning outcomes for engineering graduates. Industry sees higher education as being where graduates should be prepared with these professional skills. Every year, a lot of engineering students graduate in China and how best to train these students to be good team players is an urgent and important need. This paper describes a planned, improved mechanism for teamwork teaching on a joint degree programme between a top Chinese university and a key British university. A previous experiment about teamwork teaching to Chinese engineering students was conducted in a Personal Development Plan (PDP) module that takes professional skills as its main objectives. This work describes an improved approach to teamwork teaching based on the experience derived from the previous practice and a summary of students' feedback about PDP that was collected from several questionnaire-based semi-structured interviews. The improved approach will be conducted in both the PDP module and a technical module – Software Engineering.**

Keywords—teamwork; students' feedback; engineering education; China; technical module; improved mechanism

I. Introduction

Current levels of complexity in technology make it impossible to complete an engineering project on one's own; it should be designed and implemented by a group drawn from different disciplines or from different countries. Chinese engineers must welcome this challenge and learn how to work well with others on a common technical goal. Industry sees higher education as the place where graduates should be prepared with these professional skills.

This paper describes a planned, improved mechanism for teamwork teaching on the joint degree programme (JP) between Beijing University of Posts and Telecommunications (BUPT) and Queen Mary, University of London (QMUL). This programme aims to mix the best of teaching approaches from China and the UK; it recruits the best students who have achieved well above the top line in the Chinese national university entrance examinations. This programme puts more emphasis on professional skills training than other Chinese degree programmes.

The background of Chinese engineering students is very different from that in most Western countries: emphasis is traditionally on individual and competitive learning of complex mathematics and physics rather than working together. The large population in China results in high levels of competition. Students' learning is motivated by factors such as high marks, degrees or certificates, rather than by intellectual inquiry, interest, gaining competence or self-improvement. Therefore they put more effort into the learning of "hard" technical skills, essential for degree application and job hunting – and importantly to them, which are always given marks. This means they often sacrifice the "soft" professional skills, which are difficult to assess and demonstrate in a short period of time. Cultural influence, like face saving, compliance, harmony and group thinking, also makes it complex and difficult to teach technical teamwork to Chinese engineering students.

A previous experiment about teamwork teaching to Chinese engineering students was conducted in the Personal Development Plan (PDP) module that takes professional skills as its main objectives in 2011. The experiment results have been analysed in an earlier paper [1].

This work describes an improved approach to teamwork teaching in the PDP module based on the experience derived from the previous experiment and a summary of students' feedback about PDP that was collected from several questionnaire-based semi-structured interviews [2]. For the first time it attempted to put some tests and checks in the group project of a technical module: Software Engineering (SE).

II. Related Study

Many studies report successful practices in classroom-based teaching of teamwork [3-5], the most popular practice being to assign group projects in technical modules. Many approaches to design and manage group projects can be found from the literature, for example [6, 7]. Researchers often comment on the teacher-controlled factors that influence students' team experience [8, 9], and many computer systems have been developed to help the process of group formation, administration and teamwork assessment [10-12].

However, other researchers and educators argue that teamwork skills cannot be learned through *ad hoc* project experience without teaching; it is a learned skill, and should be taught, practised and assessed as other academic skills in a project module with teamwork as its main objective [13], a specific programme that teaches interaction skills [14], or a minor in Engineering Communication and Performance [15].

III. MECHANISM PLANNED

A. PDP Experiment

The experiment will be conducted in the Year 1 PDP module. Students will be asked to produce and deliver a presentation in English for a foreign audience in groups. The topic can be a famous Chinese engineer or scientist, introduction to the JP for a visiting student, 'Inside Beijing' - tips for travellers, 'Hidden China', or a day in the life of a JP student.

1) Four group formation methods:

It was found in the previous experiment that self-selected groups did not perform better than groups formed by other methods; in fact they were worse [1]. This was contrary to the finding of Phuong-Mai and colleagues: it was better for Asian students to form groups based on existing friendship to enhance cooperation [16]. However due to the small sample it did not show any statistically significant difference between the four team forming methods in academic results and team performance in the previous experiment.

This work will select a bigger sample to find the statistical difference of the four different team-forming methods. The Year 1 JP students (20-22 classes) will be grouped by four different methods, with each method grouping 5-6 classes (30-36 groups): i) self-selection; ii) random assignment; iii) academic merit (grouping students with the same ability range); iv) fair system (mixing the academic rank with good, middle and bad together). The hypothesis that will be tested is: *self-selected groups do not perform better than groups formed by other methods for Chinese students; they are even worse*.

2) Introduction of teamwork skills

In the previous experiment, it was found that the introduction of teamwork skills was helpful and welcomed by students. But the students also expressed demands for more skill training and instructor interaction. In this experiment, a brief introduction of teamwork skills will be given at the beginning of the task, and then several workshops will be organized to discuss and practise specific team skills. The instructor will attend some group meetings to give advice and guidance.

3) Team policies

In the PDP interview[2], students reported that in groups already-confident students were more likely to take the role of leader and presenter to further develop their confidence, while the shy students had no opportunity or space to come forward. The definition of confidence varies: it can be the confidence to speak in public, it can also be the confidence to assert one's right (say NO to others politely), to deal with unexpected problems, difficulties and conflicts in relating with others, and to search and learn new knowledge and skills to solve a problem. These attributes are required in team work, but are often lacking in Chinese people.

In order to overcome this weakness, an explicit policy should be made. Firing members of the team after two formal warning letters beforehand is allowed. The sacked members are allowed to form their own groups or join other groups if accepted, otherwise they will work on their own to finish the work. Students are, therefore, encouraged to deal with problem members instead of tolerating their misconduct.

Random checks and mine/ours strategies will be used: the instructor nominates one or two students to represent the group to present their work, and asks questions about the work strategy, individual contribution, and individual suggestions on choosing topics. In this way, the dominant students will share work and knowledge with others to reach the team goals.

It was found that the Chinese students preferred single leadership, and did not know how to set up or accept shared leadership in the previous experiment. In this experiment, students are asked to select one leader who coordinates the whole group's work and keeps team work on track. Other members take separate shared responsibilities in specific tasks.

4) Agreement of expectations & Teamwork evaluation

Students will be asked to work out an agreement of expectations for their group at the beginning, and evaluate their team performance in the middle. These two mechanisms were adopted from Barbara and Richard's work [6], and were found effective and culturally appropriate in the previous experiment.

5) Peer rating

Many educators continually invent and improve peer evaluation approaches [17, 18]. In this experiment, students will still be asked to rate team members including themselves upon team citizenship instead of academic contribution. Because the peer rating system suggested by Barbara and Richard [6] did not have detailed grading criteria and the grading consistency is a concern in the previous experiment, in this experiment the Comprehensive Assessment of Team Member Effectiveness (CATME) [12] will be used. At the end of the task, each student fills the CATME peer rating form online. An individual mark will be calculated by the weighting factor of the peer rating results (Individual Mark = team mark * (individual peer rating mark / average group peer rating mark)).

6) Give sufficient detailed feedback quickly

Immediate feedback will be given in class to comment on the overall work of all groups: good examples and common problems. The anonymous peer rating results and a short comment on each group's final work will be given together with the mark later.

B. Technical Module Experiment

The previous experiment of teamwork teaching to Chinese engineering students was done in the PDP module, which takes professional skills as its main objective. This research initiated a pilot study on the supplementary strategies on teamwork teaching in the group project in a Year3 (Y3) technical module – Software Engineering (SE), in which teamwork skills are also one of the course objectives. Many educators have done a lot of research on teamwork teaching in SE [19, 20].

In this Software Engineering module, students were grouped into 9-10 to do a group project – developing a Technical Conference Management System. In the middle of the project, students were asked to do two tests: Team

Knowledge Test (TKT) [21] and Self Assessment of Communication Skills [22]. These tests will help students to enhance their awareness, knowledge, understanding and self-reflection of teamwork and communications skills. In the TKT test, students were asked to mark what they think is correct and what they would choose to do. The difference between knowledge and behaviour will be examined. These students are the same cohort of students as in the previous experiment two years ago. A similar TKT test was conducted with the current Year1 (Y1) students. This allows a comparison of the team knowledge level between Y1 and Y3 students to investigate any progress in the process of group work practice. After the project, students will be asked to complete the Team Process Check (TPC) [21] online to evaluate their team performance. The correlation between TKT result and TPC result will be tested. The coursework mark is marked out of 100 – 90% are group marks and 10% are given for individual participation and achievement presented by weekly reports. Since the peer rating mechanism had not been shown to be effective, valid, reliable and culturally appropriate in the PDP module, it was not introduced in SE. Because this is a senior core course that takes a reasonably high percentage in the degree Honours calculation, more caution should be given in changing the evaluation criteria. In senior years, the course content becomes more difficult and students are all busy preparing postgraduate applications and job hunting. If the overhead for students in teamwork learning is too high, the efficacy of the study suffers as student responses become hurried and superficial. A questionnaire was circulated to students to complete, and students' perspectives of the teamwork teaching and learning in this senior technical module will be collected.

IV. CONCLUSION

This study aims to improve teamwork teaching in Chinese engineering education. An improved approach to teamwork teaching has been designed with increased introduction and instructor interaction, single leadership and a more precise peer evaluation method. The four team formation methods will be compared statistically in promoting team performance and productivity. A pilot survey and tests were performed in a technical module (SE). Students' teamwork knowledge, communication skills and team performance were examined. The gap between declarative knowledge and skill based behaviour will be identified. Maybe because these teamwork tests were not graded in the final course mark, the response rate was very low. However it at least reflected a more realistic situation in teamwork teaching in technical modules. The questions will be studied using data collected from questionnaires: how do the senior students rank the importance of teamwork learning? How would they like to incorporate it in the technical modules?

Improving Student Writing Through Multiple Peer Feedback

Mike Ekoniak, Molly J. Scanlon, PhD and Mahnas Jean Mohammadi-Aragh, PhD
Virginia Tech, mekoniak@vt.edu, mscanlon@vt.edu, and mjm@vt.edu.

Abstract - **This paper describes the design of a study to examine the effects of various types of feedback and revision on student writing quality improvement in a first-year engineering course. We apply the previous work of Cho and MacArthur that showed that multiple peer feedback is superior to single peer and single expert feedback in improving student writing quality. We extend their work to examine the effects of in-class instruction on giving peer feedback, and also examine the effect of giving (rather than receiving) feedback on student revisions. Preliminary findings from this study will be presented at the conference.**

Index Terms – communication, peer feedback, revision, writing

INTRODUCTION

It is widely recognized that effective written communication skills are essential for engineers. [1] This is reflected in the ABET accreditation criterion 3g, that students should develop "an ability to communicate effectively." [2] In addition, International organizations like The Chartered Institute for IT consider communication to be an essential transferrable skill for any student of information technology. [3] However, many engineering instructors are reluctant to integrate writing assignments into their curricula and writing instruction is often relegated to a technical writing service course rather than in the context of engineering courses [4]-[5].

Best practices of writing instruction include a recursive understanding of writing as a process and review of an earlier draft to allow for revisions before the paper is submitted for evaluation. [6]-[7] Revision is considered a fundamental component of improving written work, yet writing assignments in engineering courses are often submitted unrevised. Many engineering instructors feel that they do not have the requisite skills to effectively provide feedback or that within a content-packed course, revision is not possible given the limits of instructors' time, the large class sizes, and the lack of pedagogical training for teaching assistants.

One way to address these concerns is to use peer feedback. Recent research by Cho & MacArthur [8] showed that feedback from multiple peers (MP) in a psychology research methods class was more effective in improving students' writing than feedback from a single expert (SE)—typically the instructor—or a single peer (SP) reviewer. When compared with single-expert and single-peer feedback contexts, multiple-peer (MP) feedback revealed improved student understanding of comments and included non-directive recommendations for revisions, which resulted in more complex repair decisions (global issues like organization and thesis focus vs. local issues like sentence structure and grammatical structure) and new content revisions as well as improved paper quality overall.

The purpose of this study is to examine the various ways that peer review affects student writing quality in a first-year engineering course. We will attempt to reproduce the results from Cho & MacArthur's study in this context, as well as extend it to explore the impacts of different types of peer review instruction. We also compare the effects of the act of peer reviewing vs. the act of receiving feedback.

Research questions include:
1. How do different forms of feedback (SE – single expert, SP – single peer, MP – multiple peer) affect improvement in students' writing quality in an engineering course?
2. How does the form of peer review instruction affect student perceptions of the helpfulness of feedback received?
3. How does training on feedback best practices for writing peer review affect the quality of peer review comments?
4. How does acting as a peer reviewer impact writing improvement?

SETTING

This study will take place in a second-semester course of a first-year engineering program at a large research university located in the southeastern United States. This course includes mainly first-year students intending to major in electrical and computer engineering and computer science, although a small portion of the students are more advanced or intend to major in other disciplines. Approximately 400 students are enrolled in the course.

The Contemporary Issue Report (CIR) is a major assignment in the course. The CIR asks students to select and report on a contemporary issue in electrical and computer engineering or computer science. Students are given a template based on IEEE formatting and citation styles and an example of a report that was written by the instructors. This assignment has been given for three semesters, but past semesters did not include any peer review or opportunity to revise the submission.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

ANALYTICAL FRAMEWORK

To define improvement in writing quality, researchers utilized a rubric with categories in writing mechanics, writing quality, and technical quality. Student work was evaluated against these categories and was assessed as unacceptable, marginal, proficient, or excellent. Writing mechanics were evaluated based upon students' use of assignment template and grammar, mechanics, and spelling. Writing quality was evaluated based upon the paper's structure, conceptual engagement, support, and references. Technical quality was evaluated upon students' ability to engage the problem, link the problem to their field, and discuss solutions, tradeoffs, ethics, and societal impacts of the contemporary issue.

METHODS

In order to confirm and extend the previous findings of Cho and MacArthur, students in this study will be divided into a total of six feedback group conditions. In the prior work, there were three feedback group conditions:

1. Single Expert Feedback (SE),
2. Single Peer Feedback (SP),
3. Multiple Peer Feedback (MP).

Students in all conditions still reviewed others' work based on a general writing rubric.

To extend this framework we further divided the students in this study. Half of the peer feedback condition students received in-class training from a writing instructor on how to give effective feedback, and the other half received their feedback training via a handout developed by the writing instructor. This extends Cho & MacArthur's work to determine the efficacy of two types of instruction on feedback best practices. Within the SE group, students will be divided such that some give no feedback to their peers and some give feedback based on the handout. In this study, our experts consist of both workshop instructors and graders who are advanced engineering students. The peer feedback will not be exchanged in this group so that we can examine the effects of giving peer feedback independently from receiving it. These new parameters mean that this study has a total of six feedback conditions rather than three. The division of students into groups is summarized in Table 1.

TABLE I
DESCRIPTION OF TREATMENT GROUPS

Feedback Condition Group	Received Feedback Parameter	Peer Feedback Instruction Parameter
A	Single Expert	No Instruction
B		Handout
C	Single Peer	Handout
D		In-class + Handout
E	Multiple Peer	Handout
F		In-class + Handout

Student work products in this course are collected for research purposes under IRB approval. Only work products of students who actively consented to this collection are analyzed in this study. In order to ensure equity, we will identify any significant difference between treatment groups in students' mean assignment grades and normalize them.

ANALYSIS

A random sample of student drafts and final papers will be taken from each feedback condition to be evaluated by the researchers. This evaluation will consist of three steps:

1. Assess initial draft according to rubric
2. Code peer or expert feedback on initial draft
3. Assess final submission according to rubric

Feedback will be coded according to the parameters of quality peer feedback included in the handout and in-class instruction. Quality peer feedback guidelines instructed students to write comments that were specific, encouraging, and that offered suggestions for improvement. The evaluation rubric was included in the handout and students were encouraged to use the rubric's values to guide their feedback (e.g. peer feedback should focus more weight on issues of argumentation and source synthesis—worth a combined 20% of the grade—than grammatical errors or typos that are worth only 5% of the grade).

By comparing the level of writing quality improvement between the six feedback conditions, we will be able to verify that multiple peer feedback results in the highest level of improvement. We will also be able to examine the effects of peer feedback instruction on both feedback comment quality and overall paper improvement. Finally, by comparing group A to group B, we can determine the extent to which writing improvement from draft to revision is affected by giving others feedback rather than just receiving feedback, a result that could allow students to become better readers of their own writing during draft stages.

ACKNOWLEDGMENT

This work in progress received feedback from multiple people. We would like to thank Dr. Marie Paretti and her research group in the Department of Engineering Education at Virginia Tech for their feedback on methodology.

AUTHOR INFORMATION

Mike Ekoniak is a PhD student in the Department of Engineering Education at Virginia Tech. He received his BS in Computer Engineering from Kettering University. His research interests include engineering identity, sexual identity and engineering culture, writing in engineering courses, and engineering diversity.

Molly J. Scanlon is an Assistant Professor of Writing at Nova Southeastern University. She received her PhD in Rhetoric and Writing from Virginia Tech. Her research interests include visual rhetoric and writing in the disciplines.

Jean Mohammadi-Aragh is a visiting Assistant Professor with a joint appointment in the Department of Electrical and Computer Engineering and the Bagley College of Engineering Dean's Office at Mississippi State University. She earned her Ph.D. in Engineering Education from Virginia Tech. Her research interests focus on technology in engineering education, first-year engineering experiences, human computer interaction, and scientific visualization.

An Empirical Study: Team Charters and Viability in Freshmen Engineering Design

Veronica Conway Hughston
Workforce Education and Development
The Pennsylvania State University
University Park, Pa
vcc1@psu.edu

Abstract—*While the concept of teams has been diffused into engineering education as an instructional activity for nearly two decades, questions remain about how best to provide instruction so that it supports student teams' effectiveness without compromising technical content. Additionally, employers in industry, government, and higher education have an insatiable need for engineers proficient in work that requires multi-disciplinary teams. The issue is further compounded by the sky-rocketing cost of education—students and families want an acceptable rate of return on their tuition. Administrators must determine how to increase value-adding coursework. Engineering education and team literature is replete with theoretical and descriptive studies focused on adding separate team-building courses to the already full and expensive mandatory class lists. Students and their families do not want to pay for more credits; they want more for their investment. To this end the current study looks at one facet of planning, team charter enactment, in relation to team effectiveness—operationalized as team viability within an existing freshmen design engineering course at a large Mid-Atlantic university.*

Keywords—*team effectiveness; teamwork mental model similarity; team charter; team viability*

I. Introduction

This study seeks to understand and measure the relationship among team charter enactment, teamwork mental model similarity, and team viability. Team charters are codified agreements on how team members will work together to accomplish team goals. Teams that share a "common view" or "lens" are said to have a similar team mental model. Current research highlights team mental models as predictors of increased teamwork and team performance. Team viability, the desire to take on future work as a team, is critical to engineering freshmen because they are likely work with the same students on future team projects. The extant engineering education literature offers little on empirical team effectiveness studies—that is, no engineering studies have looked at the use of team charters in the classroom, yet data indicate the use of team charters in engineering classes [1], [2], [3]. Articles mention team charters or codes of cooperation as parts of larger team-based assignments; however, they give no details or explanations on their use. This investigation addresses gaps in the extant engineering student team effectiveness literature.

II. Contribution

A. Situation Being Addressed

Teams have become commonplace in engineering education over the last 20 years. Yet questions remain: Are students effectively working in teams? Are educators and administrators consistently offering empirically tested instructional activities? What instructional activities can educators use in the classroom to ensure students not only deliver the team-based project assignment, but work effectively in the team context? Where is the demonstration of such learning?

B. Goals of Proposed Practice

This study aims to determine whether team charter enactment is a direct antecedent of team viability. Additionally, the study reviews the mediational effect of teamwork mental model similarity on team viability. Team viability is a predictor of team effectiveness [4]. Hence, successful use of team charters should improve team effectiveness. This work in progress seeks to understand and measure the reciprocal relationship among team charters, teamwork mental models, and team viability.

A secondary goal is to provide educators with an empirically tested team effectiveness instructional activity that may be easily executed within their current team-based classes. Results will help instructors provide students with a foundational team skill that is applicable in their work as they matriculate from freshmen to world-class engineers.

C. Research Foundations

Three areas of team-based research provide the foundation for this proposed practice: team charter, teamwork mental model, and team viability.

Team charters have been shown to increase the quality of work [5], develop cognitive and practical skills [6], clarify goals and operating principles [7], and improve team effectiveness and performance [5], [8], [9], [10], [11]. Additionally, team charter enactment has minimized many of the common pain points for student teams: poor communication, lack of decision-making processes, social loafing, and unresolved conflict [8], [10]. Once students acquire team chartering skills they will be poised for success in future similar team interactions [6], [10].

Teamwork mental models are "organized mental representations of the key elements within a team's relevant environment that are shared across team members" [12: 877], including: objectives, "team roles, behavioral expectations, and interaction patterns" [13: 65]. Members who have similar teamwork mental models have been shown to demonstrate better team performance [14]. More concretely related studies include findings that team-shared mental models had a positive effect on team coordination in geographically dispersed software engineering teams [15]; and shared team mental models (degree and structure) were shown to improve performance between measured time periods [16]. Additionally, a recent study of shared knowledge among engineering design teams revealed that the level of shared knowledge changes most during the early phases of team development. This is represented more by teams with more complex and longer team project life-cycles [17]. Hence, designating time toward planning is vital.

Team viability, the desire to want to work as a team in the future, has been consistently linked to team effectiveness and performance [1]. Team viability is of critical importance to team-based learning, which is an integral part of engineering education. Negative team experiences can distort a student's attitude towards future team experiences [21]. Today's freshmen will be required to work together in a team environment in future engineering courses as sophomores, juniors, and seniors. Therefore, helping them proactively plan for "how" to work as a team, team charter creation, should reduce counterproductive intrateam interactions such that members desire to work together again in the future as a team.

III. Description

The study is being designed for implementation in team-based freshmen engineering design and/or problem-solving courses. Motivating factors for this study are threefold: a) provide much needed empirical team-based research in the engineering education discipline; b) offer useful and actionable research for faculty and instructors to apply in the classroom with minimal interruption to the delivery of technical content; and c) provide students with a team skill that can be used throughout their academic and professional career.

IV. Research that has Supported the practice

Team effectiveness instruction was delivered, via in-class facilitation, to a class of Engineering Leadership minors at a large Mid-Atlantic university during spring 2012. Teams took part in an industry-sponsored semester-long design project. The deliverable was a business plan and team presentation. Each team had members in the United States and at least one European country. Due to distance and resources members relied on email, Skype©, and other virtual communications to complete their work. The course is a major component of the Leadership minor in the engineering college. Feedback from the students, teaching assistant, instructor, and faculty were overwhelmingly positive. The session was requested by the instructor and faculty member for future classes. During the spring 2013 session two students from the spring 2012 class served as guest presenters. Their topic was lessons learned in 2012 and how to be successful in the project phase of the class. When asked where they developed their presentation content, they replied, "the team effectiveness session you did from last year." Two of the most helpful strategies learned, per the two students, were: "just being given time to sit down and plan out how we would get the work done"; and "the team calendar was really helpful".

Additional pre-pilot study work has been accomplished at a small public southern university during summer/fall 2012. A team charter lesson and assignment were used in a U.S. Department of Education-funded STEM retention program. The project was put in place to increase STEM student retention between the freshmen and sophomore years. Seventy-two STEM freshmen received team charter instruction, subsequent homework assignments, and feedback from peers, instructors, and the team charter lesson facilitator. Feedback was collected via class discussion and an anonymous survey. The survey included open-ended and Likert-type questions. The feedback was overwhelmingly positive. Ninety-three percent of participants reported, "Developing the team contract assignment was helpful to me as a team member". Eighty-nine percent stated, "I plan use the team contract idea from the discussions in future team projects." Similar responses were given in response to questions regarding participants' belief that the lesson increased their competency to be successful, and was helpful in strengthening their knowledge and interest, in STEM (96.5% and 89.5%, respectively).

V. Work Remaining to be Done

Future work includes executing a quasi-experimental study in multiple sections of a freshmen engineering design course. The study will be the first test of team charter quality, shared teamwork mental model, and team viability. This work in progress builds on recommendations in the existing literature [16] by offering "better team-based instruction" that seeks to improve team mental model similarity.

In summary, the proposed work aims to provide engineering educators with an empirically tested, low-cost (time and resources) instructional activity that can positively impact student team effectiveness.

Drafting Program Educational Objectives for Undergraduate Engineering Degree Programs

Ramakrishnan Sundaram
Gannon University, sundaram@gannon.edu

Abstract - **This paper outlines the process to draft Program Educational Objectives (PEOs) appropriate for undergraduate engineering degree programs at ABET-accredited institutions of higher education. In the ECE department at our University, the existing PEOs were deemed to have language that was very similar to that used in the ABET student outcomes. Therefore, it was imperative to distinguish the PEOs from the ABET student outcomes since the PEOs must quantify the expected attainments of graduates a few years after graduation. First, PEOs must reflect the Mission Statement of the institution and serve as a yardstick of student achievement three to five years following graduation. The objectives represent the expectations of the department from its graduates. Active participation by the faculty in defining the PEOs yield clear and concise objectives and promotes ownership of the goals of the Department and ABET process. However, not all faculty members are necessarily familiar with the assessment language and the process to evaluate the PEOs. In order to ensure a meaningful contribution from all faculty members involved in defining the PEOs, this paper presents a framework to define the PEOs that (1) adhere to the Mission of the University (2) achieve consistent and measurable expectations.**

Index Terms – Program Educational Objectives, Accreditation, Assessment, Bloom taxonomy

INTRODUCTION

Program Educational Objectives (PEOs) for undergraduate engineering degree programs must clearly define the vision of the program for its graduates three to five years after graduation. These objectives represent the expectations of the department from its graduates and must be crafted such that measurable objective evidence can be obtained through alumni surveys. In addition, there must be in place internal and external review procedures to periodically review and revise the language, assessment, and evaluation of the PEOs. The focus of this paper is on defining the process to draft the PEOs. The framework that we propose is first to provide an assessment language that is similar to the cognitive learning pattern of *Bloom's Taxonomy for Knowledge, Comprehension, Application, Analysis, Evaluation and Synthesis* during the different stages completed by our graduates in their career path. Faculty members should recognize that the students in the undergraduate degree program are viewed as *learners* who must acquire the intended skills over the duration of the baccalaureate program. These students are then expected to *demonstrate* the application of these skills three years following graduation. They are expected to assume more responsibilities in management or to *lead* in their profession and/or society six years after graduation. Ten or more years after graduation, these students should become *contributors* with significant influence on policy and decision making in their chosen profession and/or society. The assessment language at these different stages of our graduates' career path is different. Hence, it is important to use the proper set of assessment language intended for the PEOs that focuses only on the immediate or first three years to measure the direct impact of our program on young careers, not the six-year or the ten-year longer term objectives which would measure learning experiences and contributions beyond the direct impact of our program. Second, the framework requires faculty to extract key words from the Mission Statement of the institution which emphasize the broad and specific intent of undergraduate education along with a set of key words that the faculty see as attributes to gauge graduates in becoming the individuals the PEOs intended. Third, capture the distinction between educational objectives and student outcomes, and formulate each objective recognizing the need for measurability.

The faculty of the Electrical and Computer Engineering (ECE) department at our institution met on different occasions for discussion and a final work session for almost six hours to complete the steps of the process in order to revise the existing set of PEOs. The PEOs of our fully accredited undergraduate ECE program (accreditation period from 2005 to 2011) were deemed to have language that was very similar to that used in the ABET student outcomes. Therefore, it was imperative to distinguish the PEOs from the ABET student outcomes since the PEOs must quantify the expected attainments of graduates a few years after graduation. For instance, the ECE program at one pre-eminent institution [2] develops the PEOs according to three expected outcomes from graduates five years after graduation – *professional expertise, innovativeness, and leadership*. At another institution [3], continuous education program assessment is addressed by bringing together a working team of departments and education specialists using a Web-based assessment process to gather and evaluate the data. There are also institutions that stipulate

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

the PEOs of the program without empowering the faculty to develop, own, and adopt a consistent set of measurable PEOs.

Section 2 provides a broad overview of the PEO assessment cycle at our institution with internal and external review processes. Section 3 describes the framework to formulate the PEOs. Section 4 discusses the PEO assessment and evaluation process, summarizes the mapping of these PEOs to the ABET student outcomes, and the preparation of the alumni survey. The conclusions and future issues appear in Section 5.

SECTION 2: PEO ASSESSMENT CYCLE

The following requirements are stipulated by ABET in its Self-Study Questionnaire [1] as part of Criterion 2. Program Educational Objectives.

A. Mission Statement of the Institution
B. Program Educational Objectives (PEOs)
C. Consistency of the PEOs with the Mission Statement
D. Program constituencies
E. Process for revision of the PEOs

In order to fulfill the requirement of consistency between the PEOs and the Mission Statement of the institution, key words and phrases are identified in the Mission statement that would directly relate to the language used to formulate the PEOs. For example, the following Mission Statement of our institution has words and phrases underlined to indicate their significance in the drafting of PEOs.

This Institution is a Catholic, Diocesan, student-centered University which provides for the <u>*holistic development*</u> *of undergraduate and graduate students in the Judeo-Christian tradition. As such, it offers each student outstanding teaching and a* <u>*value-centered education in both liberal arts and professional specializations*</u> *in order to* <u>*prepare students for leadership roles*</u> *in their careers, society, and church. The University faculty and staff are committed to excellence and continuous improvement in teaching, learning, scholarship, research, and service. The University's* <u>*environment is to be one of inclusiveness and cultural diversity*</u>.

Figure 1 displays the overall Quality Assessment cycle with Level 1 representing the PEO Assessment highlighted. as the focus of this paper. The assessment cycle for Level 1 is once every three to five years to gauge the relevancy of the PEOs to the requirements of the program constituents because the PEOs are measured three to five years after graduation. Student outcomes assessment, identified as Level 2, is in a different cycle but provides the major input to address the attainment of the PEOs. The Level 1 PEO Assessment cycle is shown in Figure 2.

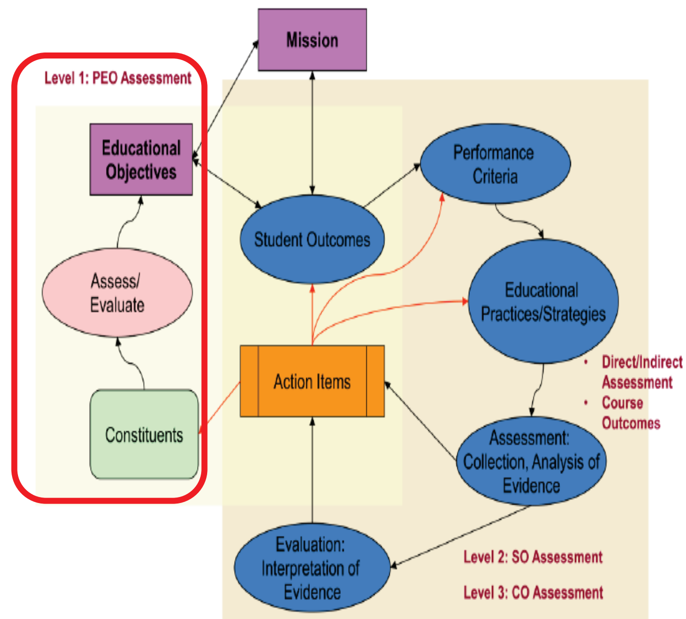

FIGURE 1
QUALITY ASSESSMENT CYCLE

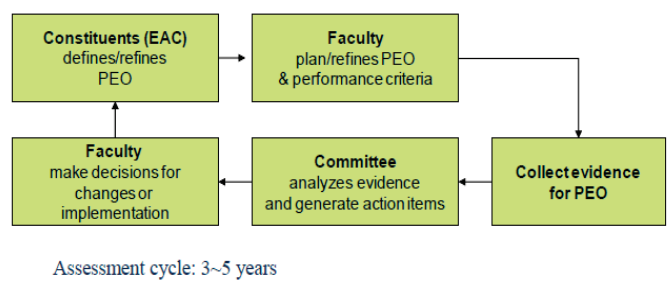

FIGURE 2
LEVEL 1 PEO ASSESSMENT CYCLE

The program constituents for the PEO assessment process comprise the faculty, staff, students, and the local industry represented by its members on the Engineering Advisory Council (EAC). The toolsets used in the PEO assessment process are as follows:

- Alumni survey (*external*)
- EAC review (*external*)
- Executive summary report for student outcomes (*internal*)

SECTION 3: FRAMEWORK TO FORMULATE PEOs

The first step was that faculty members as *individuals* had independent PEO ideas, leveraging our multi-cultural and multi-discipline resources. Then, the faculty members, objectively as a team, had long workout sessions to revise and commit to these new PEOs, thus promoting PEO ownership as a Department. At the beginning of the workout session, the faculty identified and agreed to the following keywords of the Mission Statement of our institution –

professional development, value-centered, leadership roles, cultural diversity, and *lifelong learning*. In addition, the faculty identified the categories in which objective evidence shall be obtained to measure each key word keeping in mind the proper set of assessment language. Faculty members then formed break-out groups of two to draft the PEO suitable for each key word. Finally, the faculty reconvened as one group to review and revise each objective as well as to arrange the objectives in the order of chronological impact and accomplishment before reaching agreement for adoption.

The framework for the review and revision of the PEOs at the departmental level involving all the faculty members comprises the following broad stages.

1. Provide the assessment language
2. Use the key words and phrases extracted from the Mission Statement of the institution to identify attributes to gauge graduates
3. Capture the distinction between the educational objective and the student outcomes
4. Formulate each objective to be measurable

The assessment language is patterned along the lines of the *Cognitive domain* of *Bloom's taxonomy* [4]. The Cognitive domain (or *What should I know*?) corresponds to the recall or recognition of specific facts, procedural patterns, and concepts that serve in the development of intellectual abilities and skills.

There are six major categories from simple to complex - *Knowledge, Comprehension, Application, Analysis, Synthesis, and Evaluation* - to be mastered. Although these categories are covered within every course at all levels (first year to senior year), the focus of the pattern of learning at each level is as follows:

TABLE I
FOCUS OF LEARNING

Level of Course	Focus of learning
First year	*Knowledge*
Second year	*Comprehension*
Third year	*Application & Analysis*
Fourth year	*Evaluation & Synthesis*

SECTION 4: PEO ASSESSMENT & EVALUATION

Figure 3 illustrates the components and the flow of the process of PEO assessment and evaluation. The two primary approaches to PEO assessment are (1) internal review, and (2) external review.

The internal review consists of assessing the attainment of student outcomes, through senior exit surveys and embedded course assessment processes, to determine if the skill sets necessary for attainment of PEOs are being provided within each course and across the curriculum. The external review comprises the assessment of data gathered through the alumni survey to determine how well our graduates are performing in the workforce three to five years following their graduation. This measures the level of attainment of each PEO.

The PEO evaluation process determines the relevancy of each PEO to address and successfully meet the needs of the program constituents. The program constituents are faculty, students, alumni, and industry. The evaluation of the PEOs by both the EAC and the faculty members helps address the needs of program constituents. Action items generated at faculty and EAC review meetings are expected to lead to changes in the PEOs and have significant impact on the shaping of our educational practices.

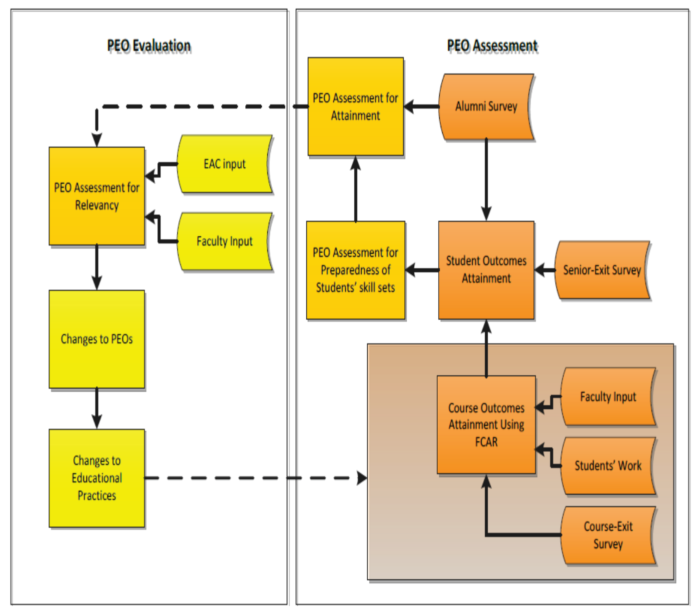

FIGURE 3
PEO ASSESSMENT AND EVALUATION PROCESS

The mapping of the student outcomes to the PEOs is intended to help us determine if our educational practices within each course and across the curriculum prepare our graduates to meet the intended PEOs. Table II illustrates the mapping.

The PEOs used to complete this mapping are as follows:

PEO 1. Sound preparation for adaptation in the exciting, rapidly-changing areas of technology and a passion for lifelong learning

PEO 2. Ability to understand how engineering solutions affect our society and respond to ethical and public issues, including safety, social, and environmental concerns.

PEO 3. Ability to apply personal values to daily and professional life, develop the skills necessary for exercising informed literary and aesthetic judgments, and appreciate diverse cultures and societies

PEO 4. Ability to communicate effectively in both oral and written forms and work efficiently with multi-disciplinary/multi-cultural teams which foster leadership qualities

PEO 5. Foundation in problem formulation and problem solving skills to include the following:

- Sound preparation in general science and applied mathematics
- Strong preparation in electrical engineering and applications
- Strong preparation in computer and software systems development
- Effective use of computer-aided design and analysis tools
- Quality experience in engineering design

TABLE II
RELATIONSHIP OF STUDENT OUTCOMES TO PEOs

Student Outcomes	PEO 1	PEO 2	PEO 3	PEO 4	PEO 5
ABET Criteria:					
SO1: Ability to apply knowledge of mathematics, science, and engineering	X				X
SO2: Ability to design and conduct experiment, as well as to analyze and interpret data					X
SO3: Ability to design a system, component, or process to meet desired needs	X				X
SO4: Ability to function on multi-disciplinary teams			X	X	
SO5: Ability to identify, formulate, and solve engineering problems	X				X
SO6: Understanding of professional and ethical responsibility		X	X		
SO7: Ability to communicate effectively				X	
SO8: Board education necessary to understand the impact of engineering solutions in a global and societal context	X	X	X	X	
SO9: Recognition of the need for, and an ability to engage in life-long learning	X		X		
SO10: knowledge of contemporary issues	X		X	X	
SO11: Ability to use the techniques, skills, and modern engineering tools necessary for engineering practice	X				X
ECE Program-Specific Competencies:					
SO12: Knowledge and ability to apply mathematics including probability, statistics, and discrete mathematics	X				X
SO13: Develop systems containing hardware and software components	X				X
SO14: Analyze and Design of complex electrical and electronic devices	X				X

The language of the PEOs listed above does not make the clear distinction between PEOs and ABET outcomes. The implementation of the process described in this paper resulted in the following set of PEOs.

PEO 1. Demonstrate *professional ethics* and *personal values* in daily and professional life that exercise informed literary and aesthetic judgments by leveraging diverse cultures and societies

PEO 2. Demonstrate *teamwork and leadership qualities* and/or the attainment of *leadership roles* in a global work environment

PEO 3. Demonstrate *technical competency* in applying comprehensive engineering knowledge throughout their chosen profession

PEO 4. Demonstrate *passion for life-long learning* through engaging in the rapidly changing and emerging areas of technology, and/or continued professional development

This set of PEOs is also mapped to the ABET outcomes as in Table II. Table III summarizes this mapping.

TABLE III
SUMMARY OF REVISED MAPPING

PEO #	Student Outcomes
1	SO6, SO8, SO10
2	SO4, SO7
3	SO1-3, SO5, SO8, SO11-14
4	SO1-3, SO5, SO7, SO8-14

The alumni survey provides the data for assessment of the PEOs as part of the external review. The survey addresses the following question:

How well are our graduates really doing in the workforce?

The survey is administered through secure access on the Web [5] and has quantitative and qualitative sections in the following categories.

- *General information*
- *Employment History*
- *Preparedness of Gannon Education*
- *Soft Skills and Broad Education*
- *Liberal Studies*
- *Intern Experience and Professional Societies*
- *Rate education based on the PEOs*

Table IV lists the questions asked in the quantitative section of the alumni survey for the category titled *Preparedness of Gannon Education*.

TABLE IV
QUANTITATIVE SECTION - I

Preparedness of Gannon Education

	Questions
1	How well do you feel your undergraduate training helped you to develop the ability to apply technical knowledge in the solution of specific work-related problems?
2	How well did your undergraduate training prepare you to design and conduct experiments?
3	How well did your undergraduate training prepare you to analyze and interpret research data?
4	How well did your undergraduate training prepare you to design a system, component or process to meet task needs?
5	After graduation, how prepared were you to function effectively on a multi-disciplinary team?
6	How well did your undergraduate training prepare you to develop your leadership skills?
7	How well did your undergraduate training prepare you to identify, formulate and solve engineering problems?
8	Compared to engineering friends and colleagues from other colleges and universities, how well do you feel the Gannon Engineering program prepared you to handle the technical aspects of your job?

The qualitative section for this category asks the graduate to comment on any special strengths or weaknesses they saw in the technical preparation they received at Gannon.

Table V lists the questions asked in the quantitative section of the alumni survey for the category titled *Soft Skills and Broad Education*.

TABLE V
QUANTITATIVE SECTION – II

Soft Skills and Broad Education

	Questions
1	Do you feel your Gannon education helped you to understand the ethical responsibilities of your profession?
2	How well did your Gannon education prepare you to give oral presentations?
3	How well did your Gannon education prepare you to write technical reports and other written communications?
4	Do you feel you have the ability to use the most modern engineering tools and techniques effectively?
5	Do you feel your education at Gannon was broad enough to give you a perspective on how a particular engineering solution might impact society?

SECTION 5: CONCLUSIONS & FUTURE PLANS

This paper describes how the process to draft PEOs is and implemented in our ABET accredited ECE degree program. The key requirements to guarantee success of this process are as follows:

- Engagement and commitment of the entire engineering department to the discussion, ratification, and eventual adoption of the PEOs
- Active participation by the faculty in defining the PEOs to promote ownership of the goals of the Department and ABET process
- Adherence to the Mission of the University
- Distinguish PEOs from student outcomes
- Draft PEOs with measurable outcomes

From Global to Local: Investigation of Necessary Engineering Skills for KBE Transformation in Qatar in the Context of Global Engineering Attributes

Reem Khair, Mahmoud Abdulwahed, Abdelmagid Hamouda, Mazen O. Hasna*
College of Engineering, Qatar University, Doha, Qatar
** Corresponding Author: m.abdulwahed@qu.edu.qa*

***Abstract*— this paper provides the findings of a study on investigating the required contextual engineering skills in Qatar in light of the global engineering skills. A set of 20 attributes were identified in the literature, and surveys were implemented to measure the importance of these skills in Qatar. The targeted groups spanned from students, practicing engineers, senior industrial engineers, and academicians. The basic logic behind surveying various engineering groups was mainly to evaluate the capabilities of the current engineering labor force as well as evaluating the potential of the future engineering supply (current students). The main findings indicated the consensus of participating groups on the importance of enhancing communication skills. High perceptual gaps were identified in communication skills, business and entrepreneurship and practical skills. Remedy actions that were proposed so that the future supply of engineers is featured by required and desired level of selected skills.**

Keywords— Global Engineering Skills; Engineering Education; Transformation; Knowledge -based Economy (KBE); and Statistical Analysis.

I. INTRODUCTION

Engineering in particular and other relevant STEM (Science, Technology, Engineering & Mathematics) fields in general are the most critical areas for a nation to focus on while seeking for- or maintaining a knowledge based economy status [1] [2] [3], [4], [5], "unpublished"[6]. For that reason, Engineering and Technology are at the core of realizing the Qatari government strategic vision that aims to transform its economy from being hydrocarbon based into a knowledge based one by 2030. To respond to the requirements of the KBE age, a clear necessity in producing and managing the right engineering technical and non-technical skills is recognized. Given the increasing complexity and interdisciplinary nature of the engineering profession, equipping engineering graduates with a set of non-technical skills such as communication, decision making, management, leadership, emotional intelligence, cultural awareness, and social ethics is required. A global literature review on skills outcomes of engineering degrees in the US, Europe, and Asia Pacific showed that students lack enough competencies in these soft skills [7]. Similarly, certain core engineering competencies such as problem solving, design, and analytical thinking became essential in the 21st century work force even for those who would study and work in non-engineering disciplines [8].

A number of key thematic areas for an engineering education that is fitting with a KBE requirements are identified: 1- Engineering Entrepreneurship, 2- Engineering Leadership (technical and societal), 3- Engineering Design, 4- Engineering Creativity and Innovation. Focusing specifically on futuristic characteristics of next generation of engineering graduates, a list of 20 attributes of future engineers has been identified in the literature in support of the four engineering KBE themes identified earlier; where ten attributes belong to the technical aspects, and the other ten belong to the non-technical aspects. These skills are communication skills [9][10][11][12], teamwork [10] [13] [14], leadership [1][2] [9] [13], business and entrepreneurship [1][2] [15], "unpublished" [16], creativity and innovation [12] [13] [14], adaptability [1][2][17], strategic thinking [1][2][17], lifelong learning [1][2] [17], cultural and diversity [1][2] [18], ethical awareness [1][2], "unpublished" [19][20], practical skills [1][2][10], technical breadth [21][22], theoretical understanding [1][2], science principles' knowledge [1][2], critical thinking [1][2][23][12] [17], problem solving [2][3] [12], analytical thinking [9][10] [17], engineering design skills [24][25], wide variety of IT skills [22][26] and research skills.

Generally, these attributes were derived from global studies on future engineers in USA, UK, Europe, and Australia, such as the UK study: "Educating Engineers for the 21st Century: The Industry View" and the US study: "The Engineer of 2020: Visions of Engineering in the New Century". Yet, no similar efforts were done in the Middle East. For assessing the current status of Qatari engineering graduates attributes, an instrument in a form of Questionnaire has been implemented. The core part of the instrument was utilized to collect data from four different samples: 1- Senior engineers in the local industry, 2- Engineering academics from Qatar, 3- Undergraduate engineering students in Qatar, and 4- Postgraduate engineering students in Qatar (mainly professional working engineers). The following section provides further details on the conceptual framework of the study, the methodology, data analysis, and main findings of the investigation.

II. CONCEPTUAL FRAMWORK OF ENGINEERING EDUCATION FOR A KNOWLEDGE BASED ECONOMY (KBE)

To have a productive engineering education system in place, the efficiency of inputs should be developed and controlled in such a way that leads to the effectiveness of outputs. This will be only possible if it is supported by the use

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

of innovative, quality and value added processes. Fig. 1 below illustrates the proposed conceptual framework of engineering education and its role in supporting and building up a KBE as discussed in what follows.

Fig. 1. Illustration of a closed loop of engineering education and its role in supporting building up KBE.

According to the Organization for Economic Cooperation and Development (OECD), a science system can support KBE development by contributing to three key functions which are knowledge production, knowledge transmission, and knowledge transfer [27]. Knowledge production means developing and creating new knowledge mostly in a form of research. Knowledge transmission means educating, developing and upgrading human capital. This is a key enabler in raising the awareness of today's students while building in the desired capabilities of tomorrow's engineers. Furthermore, knowledge transfer means publicizing knowledge and providing solutions to real life problem. This element addresses the practical implication of engineering in all real life aspects. To reflect a comprehensive role of education system in KBE, another key function is added which is the knowledge acquisition. To have an innovative and effective processes, education system should reflect the two way communication between academicians and other key entities in the system such as students. To complement the knowledge transmission function, a well-grounded knowledge acquisition process should be endorsed. In this process, students are the recipients of current available technical, social, environmental, economic and technological information while academicians are the providers.

In parallel to these functions that are based on knowledge, a focus should be given to developing and enhancing certain set of soft and core engineering skills. A literature review on required modern and future engineering skills was done indicating that engineers need to be equipped with both soft and core skills "unpublished" [28]. These skills are very important as they eventually capitalize the produced engineering workforce who directly supports the KBE development. In this aspect, academicians and elite students are considered to play a vital role. To support the main objective of this paper, research efforts can be steered further towards modernizing engineering education, revising and restructuring engineering curricula in such a way that support the development of these skills. Such modernization may include shifting from classical teaching towards more constructivist learning approaches, such as technology enabled learning [29][30][31][32], research based learning [33], meaningful mathematics [34], experiential and project based learning approaches [35], continuous assessment and effective feedback provision [36]; "unpublished" [37], etc. These modern teaching and learning approaches may equip students with better skills than traditional approaches. Before shifting into curricular and pedagogical major changes, an assessment of the current inventory of these skills would be recommended. Initial assessment is provided in this paper.

Finally, all inventories of knowledge and skills formed through these processes are acquired and employed in engineering workforces, who are eventually utilized to serve in building up systems, products, Research and Development (R&D) activities, patents and services. These outputs are required to back the development of all KBE pillars. These pillars are defined by the World Bank as Economic Incentive and Institutional Regime (EIR), innovation and technological adoption, education and training, and Information and Communications Technologies (ICT) infrastructure [38]. All these pillars if enabled, support a smooth transition to knowledge based economy and society driven by innovation and knowledge. It is worth noting that defined framework is a closed loop system. It means that continuous feedback from all downstream are fed again as inputs to the system so that all processes are adjusted to cope with the new requirements.

III. METHODOLOGY

This section looks at the framework and methodologies used in this study. Mainly, surveys and pilot interviews are the two techniques aimed to collect the relevant data. Data which are needed to identify needed skills were collected through four different surveys. It may seem reasonable that these surveys were designed to target different engineering groups, classified as engineering practitioners; engineering academics; undergraduate engineering students; and postgraduate engineering students (mainly professional working engineers pursuing their graduate degrees). As the general objective is to identify the level of awareness and satisfaction in regards to major attributes needed to support Qatar vision 2030, all surveys were administrated locally in Qatar. Basic content analysis was utilized to analyze the pilot interviews, and different statistical techniques (descriptive statistics, hypothesis tests and inferential statistics, etc.) were utilized for analyzing the surveys. Having the surveys anonymously administrated, a total of 190 valid responses were received by which 121 were submitted electronically and the remaining 69 were paper based. Following this, data were organized in one database and then, statistically analyzed using SPSS. Rating of skills was based on a likert scale from 1 to 5, where "1 = Strongly Disagree", and " 5= Strongly Agree".

TABLE I. MEAN VALUES OF GROUPS' PERCEPTION IN EACH OF THE ENGINEERING SKILLS. "I" REFERS TO "IMPORTANCE", AND "S" REFERS TO "SATISFACTION"

IV. DATA ANALYSIS

Surveys were designed to: 1- identify the level of awareness of various engineering population with regards to skills needed for transforming Qatar's economy to a KBE; and 2- help in measuring the degree of difference between their perception of how much these skills are important and to what extent they think they are equipped with. The following subsections provide further details on the data analysis.

A. Descriptive Statistical Analysis

Three descriptive measures were used to support the analysis of obtained data related to engineering skills; namely, the mean, the mode and the Pearson Correlation. Firstly, the average perception of each attribute was computed for every respondent group (for both level of importance and satisfaction). Results obtained are presented in table I below. It was noticed that there was a common perception between all groups in viewing majority of the attributes. Yet, to some extent this entire commonality was slightly disturbed when addressing few of them. Major irregularities are highlighted below.

Unlike the strongly agreement in view of Bachelor Engineering Students on the importance of Communication Skills, Expert Engineers expressed a neutral perception in this regards. Irrespective to this inconsistent view, both groups believe that they were not equipped enough with this type of Skills. Additionally, a noticeable difference was observed with regards to Practical skills. While both Junior Engineers and Academician agreed that these skills are very important to be presented in the future engineering supply, both Bachelor level Students and Expert Engineers disagreed with this. Alongside with this differed perception, both latter groups expressed that they are not satisfied with the students/engineers' capabilities in these skills while former groups are somehow satisfied. Moreover, the shared view on Cultural Diversity Awareness was not totally alike. Even though all groups agreed that they are skilled and equipped with this attribute, Academic Engineering Staff did not view it as an important skill as the other groups did.

The targeted groups were also asked to rank the most important six engineering skills according to their own perception. As these data are classified to nominal and non-parametric, Mode Analysis would be the suitable measure to reflect the overall conclusion of this question. Table II summarizes the main findings from Mode Analysis. It can be noticed that a mutual agreement was given to communication skills being the most important skill for engineers of 2030. Only 50% of the identified engineering skills appeared in the top 6 ranking given by all engineering group. Commonly, communication, teamwork and problem solving appeared in the ranking of all groups.

TABLE II. SKILLS RANKING GIVEN BY EACH ENGINEERING GROUP PRESENTED BY THE MODE

Group	Ranks					
	Rank 1	*Rank 2*	*Rank 3*	*Rank 4*	*Rank 5*	*Rank 6*
Bachelor Students	Commu-nication	Team-work	Creativity and Innovation	Problem Solving	Engineer-ing Design Skills	Lifelong Learning
Junior Engineer	Commu-nication	Leader-ship	Teamwork	Problem Solving	Teamwork	Problem Solving
Expert Engineer	Commu-nication	Team-work	Teamwork	Problem Solving	Problem Solving	Wide Variety of IT Skills
Academician	Commu-nication	Critical Thinking	Teamwork	Critical Thinking	Technical Breadth	Problem Solving

B. Inferntial Statistical Analysis

The second part of the analysis aims to identify if there is a statistically significant difference between the ranking of all groups with regards to awareness and satisfaction levels.

Mann-Whitney U test was used and repeated six times as it is designed to test only two independent samples (all possible combinations of two groups chosen from the set of 4 groups is 4!/(2!(4-2)!) = 6 combinations).

TABLE III. STATISTICAL SIGNIFICANCE DIFFERENCE IN SKILLS IMPORTANCE BETWEEN EVERY TWO GROUPS

b. Group 1 indicates Bachelor Students, Group 2 indicates Master Students, Group 3 indicates expert engineers and group 4 indicates academicians

Using SPSS, the Mann-Whitney statistics was computed for every combination of groups. Summary of results is summarized in table III and table IV. The main findings of Mann-Whitney hypothesis test are detailed below:

- A statistically significant difference was found between Bachelor level Students and Academicians in regards to all soft skills. It was found that Bachelor level Students felt more strongly than Academician that all soft skills are important to be in Qatari Engineers in light of Qatar 2030 vision. At the same time, a statistically significant difference was found with regards to their level of satisfaction over few of these soft skills. It was noticed that Bachelor Students were more satisfied with the level of capabilities in communication, teamwork, and creativity and innovation.

- Similarly, a statistically significant difference was found between both groups in regards to 50% of core engineering skills which were: technical breadth, theoretical understanding, analytical thinking, engineering design skills and research skills. For research skills, both Bachelor level Students and Master Students perceived it with more importance when comparing it with the perception of Expert Engineers and Academicians. Moreover, a statistically significance difference was found between both groups when ranking the level of satisfaction of their capabilities in 80% of core skills. Noticeably, Bachelor Students were more satisfied when it comes to their capabilities in theoretical understanding, science principle knowledge, critical thinking, problem solving, analytical thinking, engineering design skills and research skills. On the contrary, Academician felt more strongly than Bachelor level Students that the students/engineers' are equipped enough with practical skills.

- With reference to communication skills, a statistically significant difference was found between Expert Engineers and both Bachelor Students and Master Students. More precisely, it was noticed that both groups felt more strongly than Expert Engineers that this attribute is of importance for future engineers.

- Moreover, there was a statistically significant difference between Bachelor Students and Master Students when viewing practical skills, adaptability, critical thinking and analytical thinking. It was shown that Bachelor level Students have a stronger appreciation that adaptability, critical thinking and analytical thinking skills are important for engineers of 2030. On the contrary, Master Students felt more strongly than Bachelor Students that practical skills are important. At the same time, Master Students were more satisfied with both communication and practical skills they have when comparing it to the average level of Bachelor Students satisfaction.

- There was a statistically significant difference when viewing both leadership and cultural diversity awareness attributes by Master Students and Academicians. Noticeably, Academicians viewed these skills with less appreciation when compared with Master Students view.
- There was no statistically significant difference between Expert Engineers and Academicians in terms of soft skills. However, a statistically significant difference was found when viewing the practical skills (one of engineering core skills). It is worth mentioning that academician felt more strongly than expert engineers that they are equipped with practical skills.
- There was a statistically significant difference between Bachelor Students and Expert Engineers in viewing 40% of soft skills; namely in communication, team work, lifelong learning and ethical awareness. In all mentioned skills, Bachelor Students had stronger belief that these skills were important for engineers of 2030. At the same time, for 80% of core engineering skills, a statistical significant difference was observed between both groups when it came to their level of satisfaction. It was noticed that Bachelor level Students felt more strongly than the expert engineers that they were equipped with these skills (theoretical understanding, science principle knowledge, critical thinking, problem solving, analytical thinking, engineering design skills, and research skills).

V. MAIN FINDINGS AND DISCUSSION

In this section, the main findings are highlighted where two main aspects will be of focus. Firstly, major inconsistencies when perceiving both importance level and satisfaction in competency level between groups are highlighted. Secondly, attributes that were perceived with low confidence in competency are identified and methods for bridging these gaps are proposed. This will then be used to adjust the engineering curricula so that the workforce is prepared to support KBE activities as described in Section II.

A. Attributes perceived by groups with unequal level of importance/satisfaction

Two main attributes exhibited some sort of irregularities in regards to groups' perception; namely, communication and practical skills. For communication skills, a mutual understanding on the importance of these skills was demonstrated by all groups. It is worth noting that bachelor students were the group who strongly agreed that communication skills are very important for the future supplies of engineers. Additionally, the same group believed along with expert engineers that they are not equipped enough with these skills. One major note arises here; engineers-in-process who are the potential future engineers are aware that communication skills are necessary to confront professional, technological, social and economic future challenges.

Second attribute that was perceived differently by groups was the practical skills. It was observed that, bachelor students and expert engineers believed that practical skills are not important to be in future engineering supply while junior engineers and academician felt the opposite. Following the same trend, both former groups expressed that they are incompetent in the level of practical skills they have. Underestimating the importance of these skills is an issue of concern and needs to be investigated clearly. Being practitioner in engineering and believing that practical skills are not important may be explained by the fact that the current expert engineers are equipped enough with such skills such that they did not recognize its importance as they do not lack it anymore . Not recognizing the importance of these skills by Bachelor Students may be due to their view of practical skills as purely working experience and that it can only be achieved after graduation and once leaving the education system. However, practical skills cover the ability to use wide range of tools and techniques, as well as laboratory and workshop equipment (including both hardware and software related to their specific disciplines). At this end, both raising the awareness of practical skills' importance and filling in its competency gap are important. Not only statistical results revealed the existence of this gap, but also, evidence from engineering employers had shown that employers struggle while filling vacancies due to the shortage of fresh engineering work force with relevant skills and practical experience. Specifically, Engineering employers find it more difficult to recruit people with technical and practical skills than other skills. To this extent, it remains the educational institutions responsibility to raise the awareness of industries in investing intensively in graduates during their transition phase (from acquiring knowledge to applying it) while working on enhancing students capabilities in engineering practical elements.

B. Attributes perceived by students with low confidence in competency level

The basic logic behind surveying various engineering groups is mainly evaluating the capabilities of the current engineering labor force as well as evaluating the potential of the future engineering supply (current students). For that reason, those skills which were perceived with low or neutral agreement by fresh and in-process engineers are found to be a valuable input for the conducted research. The three highest perceptual gaps between importance and satisfaction were detected in the following skills: "Communication", "Business and Entrepreneurship", and "Practical Skills". Table V summarizes possible reasons behind the perceived gap in competence and provide some possible enhancement solutions that can fit in the framework proposed in Section II. These remedy actions can be used to adjust the existing engineering curricula or by or by introducing extra-curricular activities. Eventually, what is of our interest is to equip the new engineering workforce in such a way that supports the in development of innovation and knowledge driven economy.

TABLE V. INVESTIGATION ON ENGINEERING ATTRIBUTES WHICH WERE PERCEIVED WITH NEUTRAL OR LOW SATISFACTION LEVEL IN COMPETENCE

	Possible Sources of weakness	Possible enhancement solutions
Communication skills	• Students' low confidence towards communication in foreign languages; • Deficient teaching methods; • Lack of opportunity for engineering students to practice communication skills; • Absence of advanced communication specialized courses in engineering curricula.	• Involve active learning as part of engineering courses • Encouraging student exchanges with countries abroad • Encourage extra-curricular activities (such as seminars, presentations, contribution in newsletters with academic articles) by attributing part of the overall grades towards it • Organize specialized seminars, workshops, and tutorial sessions on both basic and advanced communication skills. • Encourage active participation by students in actual communication situations;
Business & Entrepreneurship	• Traditional engineering curricula tend to be focused on how-to-do-it (technical knowledge and skills), with little or no emphasis on entrepreneurship; • Limited view of engineer prevailing career path which is rather oriented towards technical, academic or managerial functions within large companies; • Lack of enterprising spirit among new engineers due to unrealized importance.	• Provide awareness and educational seminars on entrepreneurial attitudes not only to transfer knowledge, but also to develop the building-up of skills and attitudes in favor of entrepreneurship; • Raise the enterprising spirit in engineers from their freshmen year by facilitating the exposure towards successful entrepreneur stories; • Introduce entrepreneurship courses customized to engineering students and integrate it as part of the general engineering core requirement; • Allow engineering students to take relevant courses from school of business as electives.
Practical Skills	• Unappreciated view of courses that contain practical elements due to low or absence of assigned credit hours; that is, it is not attached significantly to grades causing careless attitudes towards its importance and results in ineffective utilization of its benefits; • Lack of activities which contain direct engagement with local/international industries.	• Increase weight of credit hours assigned to courses that address practical skills elements; • Facilitate more opportunities to students for industry exposure outside the study time (during semester breaks); • Integrate experimental sessions that involve use of software and hardware related to specific discipline in theory classes.

C. *Issues of concern*

Surprisingly, when viewing results of analysis and especially when looking at means related to the level of awareness among defined groups, it was observed that the lowest importance rank for around 80% of listed attributes was given by Academic Engineering Staff. This group had the least awareness level with a mean of means equals to approximately 5, which reflects a little agreement on the importance of all the attributes. Being the influential guiders, and facilitators of the educational process, this issue mandates a prompt response due to its significant impact on building up the desired future supply of engineers.

VI. CONCLUSION

This paper provided analysis and investigation of needed skills in engineering workforce in Qatar in light of the country's vision of transformation into a KBE by 2030. Literature was reviewed to identify the futuristic engineering skills that support the KBE development. Then, a framework that illustrated the engineering education and its role in supporting building up KBE was proposed. Both the importance of engineering knowledge and skills were acknowledged in the proposed framework. This study was based on surveying various engineering groups. The main logic behind this was mainly to evaluate the capabilities of the current engineering labor force as well as evaluating the potential of the future engineering supply (current students) with regards to the identified skills. Among these 20 skills, communication skills, teamwork, and problem solving were most frequently ranked important between the main groups of surveyed stakeholders; Communication skills were ranked highest consistently by all groups. This guided us to the conclusion that these skills are of high priority to be promptly included in the engineering curricula when compared to the other skills. Additionally, the highest perceptual gap of importance versus satisfaction was identified in "Communications skills", "Business and Entrepreneurship", and "Practical Skills". The paper provided a set of potential reasons behind these findings as well as a number of recommendations for implementation in the curriculum. As a sum up, the current engineering education system should be adjusted to incorporate the prioritized skills (skills that are commonly ranked as very important). It should also allow the inclusion of proposed remedy actions to overcome identified irregularities. This can be done by either changing the current engineering curricula to address these gaps or by introducing extra-curricular activities.

ACKNOWLEDGMENT

Data analyzed in this paper were collected through a senior project by Amal Al-Enazi, Bayan Al-Amoudi, Fatima Al-Emadi, Reham Abdullhadi, and Sara Adel Al-Khawaja; their effort is greatly acknowledged. This work is conducted under a research project investigating the attributes of future engineers in Qatar. Funding of this project is provided by Dolphin Energy, and is greatly acknowledged.

Abstract— This paper explores what is included in the worldview of the modern engineer and how this compares to the concept of sustainability. Worldviews are important to humanity because they are interwoven throughout civilizations. Societies do not contain but one homogenous worldview, however, they do essentially contain a dominant worldview characterized by the collection of values, beliefs, habits, and norms. This dominant worldview forms the frame of reference for a collectivity of people, such as a nation or culture. In this paper, we attempt to articulate modern worldviews, the contemporary engineering worldview, and the sustainability worldview. We use the concept of worldviews to address the compatibility of sustainability and engineering. Our synthesis suggests that the two ideologies are misaligned and incompatible in many respects. We suggest that for sustainability to gain prominence within an engineering context, engineers and engineering educators must first become conscious of these inconsistencies. Through the philosophical synthesis presented in this paper, it is our goal to begin rethinking how we educate engineering students about engineering and sustainability.

Keywords—*engineering; engineering education; sustainability; values; beliefs; worldviews*

I. Introduction

This paper explores what is included in the worldview of the modern engineer and how this compares to the concept of sustainability. This work complements calls for change in the engineering profession, coming from works such as the National Academy of Engineering's (NAE) The Engineer of 2020 [1]. NAE suggested that the engineering profession must evolve in order to "contribute to success" in context of the way the world "will be, not as it is today". The report continues, "The entire engineering enterprise must be considered [for reinvention] so that the changes made result in an effective system" [1].

The prominent question for engineers and engineering educators is the direction in which engineering must change as a profession. Riley (2008) noted that engineering has been attempting to reconfigure its image for quite some time, noting "leaders in the engineering community in the United States and other countries have been seeking to cast engineering as a profession in service to humanity" [2]. Riley continues, "I personally find it difficult to recruit high school students to engineering by holding out dreams of working on humanitarian or even environmental causes, when I know that most students will be working either on military endeavors focused on the facilitation of war or on corporate endeavors focused on increasing profits, often on the backs of poor communities" [2].

Matutinovic (2007) suggested, "The process of radical institutional change is contingent upon prior change in the dominant worldview, while its dynamics resemble that of a paradigm change in political and scientific arenas" [3]. Using this suggestion as a starting point, in this paper we explore what an operational understanding of "modern worldview" entails. We begin by first examining the literature on the term, "worldview". We next explore literature pertaining to "Western", "modern", and "dominant" worldviews. We proceed to explore the relationship between what we call the dominant Western worldview, the engineering worldview, and sustainability and qualitatively assess their compatibility.

A. Research Questions

This paper is guided by the following research questions: What is the relationship between the Western worldview and engineering? How does the Western worldview influence engineering praxis? What are contemporary understandings of sustainability? Are there any discontinuities between the Western dominant worldview, engineering, and sustainability?

B. Study Overview

To answer this study's research questions we start by conceptualizing several terms essential for our synthesis, followed by a literature review exploring articles where *engineering* and *worldview* or *sustainability* and *worldview* were discussed. We use worldview analysis as a framework for deconstructing the worldviews of sustainability and engineering [4]. This work is *not* empirical in the sense that it collects its own data. It is, however, empirical in the sense that it draws on observations and empirical work produced by others. This paper should be looked at as a starting conversation for engineers and engineering educators to become conscious of how their underlying beliefs influence the sustainability implications of their work.

In the following section titled Conceptual Overview we conceptualize the terms worldview, Western worldview, and worldview analysis. In the subsequent section titled "The Engineering Worldview" we provide an overview of what engineering is according to the literature, providing connections to the "worldview", namely, the Western/modern one. Following this section, we present an overview of "The Sustainability Worldview". Lastly, we

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

discuss the relationship between the Western dominant, engineering, and sustainability worldviews.

II. Conceptual Overview

A. Worldview Analysis

Starting in the mid-19th century, "worldview analysis" or the study of religions and ideologies became a serious scholarly endeavor in fields of anthropology and sociology, before establishing itself as the academic field of Religious Studies in the 1960's. Prior to this, people "had little inclination to explore the thoughts and values of other" [4] as studying such ideologies "was only thought appropriate for believers" (p. 2). Worldview analysis, unlike those theological studies prior, strives to take on the perspective strictly as an observer (as opposed to a believer) in order to examine "experience, ethics, beliefs, ritual, and institutions" (p. 4) with no preconceived notions of what is right or wrong.

Despite the novelty of worldview analysis, Devall and Sessions write, "For the last five hundred years, some of the assumptions of the dominant worldview have been questioned and criticized in the west by philosophers, poets, religious spokespeople and others from different philosophical backgrounds" [5]. Therefore, opposition to the dominant modern worldview is not entirely novel. However, the formalized mode of questioning dominant worldviews through "worldview analysis" is.

B. Defining Worldview

Smart (2000) wrote, the importance of worldview to humanity is that "civilizations are importantly interwoven with them" [4]. Society does not contain but one homogenous worldview. Albeit, as Devall and Sessions suggest, civilizations essentially contain a "dominant worldview" characterized by "the collection of values, beliefs, habits, and norms which forms the frame of reference for a collectivity of people, such as a nation" [5]. Devall and Sessions go on to suggest that the overall components of any worldview are as follows:

- "[G]eneral assumptions about reality, including man's [sic.] place in Nature"
- Methods for "approaching problems", the methods being "generally agreed upon"
- A common societal "definition of the assumptions and goals of their society"
- "[C]onfidence among believers in the worldview that solutions to problems exist within the assumption of the worldview"
- And "[p]ractioners within the worldview present arguments based on the validity of data as rationally explained by experts"

As our individualistic worldview that becomes an intricate part of our very being, it may become unwavering. Ray and Anderson (2000) suggest, "Most of us change our worldview only once in our lifetime, if we do it at all, because it changes virtually everything in our consciousness". They continue, "Changing a worldview literally means changing what you think is real" [6].

C. Contemporary Dominant Western Worldview

Western civilization has been constantly evolving. Florman (1987) highlights this when he notes, "The Renaissance, the Protestant Reformation, the Age of Exploration, the Age of Science, the Age of Reason—all these terms are historians' shorthand for vast and complex changes that occurred in Western civilization" [7]. Thus, we title this section "Contemporary Dominant Western Worldview" simply to highlight that the worldview is not stagnant. Further, while associating the dominant worldview explicitly as "Western" allows comparison of a dichotomous Western versus non-Western, this comparison is not the intent of this paper. Many individuals may find that their worldview is more comparable or heavily influenced by non-Western worldviews not emphasized in this paper. To reiterate, our focus in this paper is on the *dominant* intricacies of the contemporary Western worldview.

Devall and Sessions, pulling from Catton Jr. and Dunlap, summarize a few "basic assumptions of the Western worldview" [5]. These are:

- "People are fundamentally different from all other creatures on Earth, over which they have dominion
- People are masters of their own destiny; they can choose their goals and learn to do whatever is necessary to achieve them
- The world is vast, and thus provides unlimited opportunities for humans
- The history of humanity is one of progress; for every problem there is a solution, and thus progress never need cease" (p. 43)

Ehrenfeld describes similarly what he calls humanism as "a part of the lives of nearly everyone in the 'developed' world and of all others who want to participate in similar development" [8]. In this ideology, and as similar to Judeo-Christian religions, Ehrenfeld writes, "the idea of using a Nature created for us, the idea of control, and the idea of human superiority" are all ideas associated with Western civilization since its conception. He goes on to list the primary assumptions of humanism, which are as follows [8]:

- "All problems are soluble by people
- Many problems are soluble by technology.
- Those problems that are not soluble by technology, or by technology alone, have solutions in the social world
- When the chips are down, we will apply ourselves and work together for a solution before it is too late
- Some resources are infinite; all finite or limited resources have substitutes
- Human civilization will survive"

In a critique towards humanism and similar ideologies, Quinn suggests "what is lacking in modernity, in its most succinct formulation, is the principle of wholeness or integrity," which tends to result in "no harmony, no value, no meaning" [9]. Quinn continues, "With the loss of quality, the remaining standard of value for modernity is quantity" [9].

D. Modern Dominant Identity

Note that worldview is not synonymous with identity, although the two, in theory, ought to be highly correlated. Therefore, we find it appropriate to include what is considered the modern dominant group's identity, as this is more often discussed in engineering literature than "worldview". As of 1989 the dominant identity "[w]ithin the United States, the generally accepted norm by which people are evaluated or against which they measure themselves is how close one comes to being anglo, middle class, male, Christian, heterosexual, English speaking, young, and mentally, physically, and emotionally unimpaired" [Highlen, Speight, Myers, and Cox as quoted in 10]. Almost 20 years later, Foor, Walden, and Trytten write, "The cultural rules which govern social spaces reflect and sustain the ideologies and sensibilities of the dominant class. In the U.S., those sensibilities are white, male, Christian, heterosexual, married, and middle-class." [11]

Despite the dynamism we have seen residing in the dominant worldview, the dominant identity within the U.S. seems to be relatively stagnant. But, consider that here we are using the term dominant, and not addressing *how* dominant. That is, not everyone in the population are followers of the dominant ideology, but that there is one particular ideology that is more commonly adopted than all others.

Meyers and others [12] suggested that engineering identity corresponds to a student's sense of belonging in the engineering profession. While the authors do not shed light on how identity relates to what they call "professional persistence", their results suggested a positive relationship between the two.

III. THE ENGINEERING WORLDVIEW

Florman (1987) suggests that changes in the Western worldview have included "a quickening interest in engineering progress" [7]. Quinn writes, "Architecture, products, and transportation are virtually all Western in origin" [9]. Thus, since the conception of Western civilization, engineering has been linked to this/these Western worldview(s).

Today there are many striking similarities between the profession of engineering and the dominant worldview. The latter, in the words of Quinn, include "pursuits and goals" such as "greater reliance on science and **technology**, the refusal to set limits on production and consumption, the fragmentation of human labor into separate and autonomous spheres of operation, the **reductionist** approach to understanding life and the interrelationships between phenomena, and the concept of progress as a process of continually transforming the natural world into more valuable [through exploitation] and more human-made environment" [emphases added, 9] – many ideas that resonate with me as an engineer. For example, compare this to what Simon writes: "[T]he engineering worldview, is quintessentially **reductive** and deterministic… Characteristics of this ideology include the reification of a hierarchical and dualistic relation of mind and body and the insistent imposition of **mechanistic** models on non-mechanistic scenarios" [emphases added, 13].

As most literature does not use the term "engineering worldview", and rather than relying on this singular account, we must enhance our understanding of what engineering as a profession is today. A direct connection between engineering and one dominant worldview has become more complex in recent years, especially due to initiatives calling for specific changes. Note in this essay we discuss what engineering *is* at present rather than what, ideally, the engineering profession *could or should become*, according to existing calls for change.

In 2002, Stonyer wrote that "professional engineering education is located in the intersection of three discourses - the scientific discourse, the managerial discourse and the liberal education discourse" [14]. The first component, scientific discourse, is defined by Stonyer as "thinking based on reason--induction, deduction, logic, analysis, and synthesis" [14]. In terms of the managerial discourse, Stonyer writes, "Engineering practice is, to a large degree, regulated and controlled by corporate/commercial decisions that define and limit, how and where engineers use their engineering skills and knowledge" [14]. And, lastly, in terms of the liberal education discourse, "the confident, well-educated professional engineer… is capable of making informed decisions and acting in ways enhancing and progressing social good" [14].

More recently, a study by Pawley in 2009 assessed faculty responses to the question, "What is engineering?" Three explicitly "universalized narratives" surmounted, with faculty defining engineering as "applied science and math… problem-solving… and making things" [15]. The first characterization presupposed that engineering "helped society more than science", the second that engineers solved "problems that mattered" (leaving the question is, "Mattered to whom?" best answered as, "Society."), and the last "connected engineering to the physical construction of highly technical and mechanized products" [15].

Figueiredo offers a 2-by-2 matrix to help conceptualize engineering, breaking the profession into four disciplines. He explains: (1) "basic sciences views engineering as the application of the natural and exact sciences," (2) the "social dimension… sees engineers not just as technologists, but as social experts… creat[ing] social and economic value, (3) "design… values systems thinking much more than analytical thinking… is founded on holistic, contextual, and integrated visions of the world, and (4) practical realization is the "art of getting things done" [16].

What we see here are a few recurring themes, with one sticking out that seems highly relevant: the engineering profession serves society. Pawley's results suggest engineers perceive engineering help society more than science, Figueiredo thrusts engineers in the realm of the social sciences where they actually create social and economic value, and Stonyer discusses that engineers are limited, even controlled, by corporations. Then, if engineers directly serve society, we must ask what the driving forces of society are. Given that we have already associated the dominant societal forces with the modern dominant worldview, it seems reasonable to assume that there exists an intricate relationship between the modern dominant worldview and engineering.

IV. THE SUSTAINABILITY WORLDVIEW

Eckersley writes, “The dominant worldview of material progress, which gives priority to economic growth and a rising standard of living, is being challenged by a worldview based on sustainable development, with its aim of balancing social, economic and environmental goals to create a high, equitable and lasting quality of life” [17]. Hence, sustainability is deliberately and explicitly decoupled from engineering. But before explaining the division further, we must first look at how the concept of sustainability came to be and what sustainability means today.

The need for sustainability in the modern West has grown alongside technology. Riley writes that transcendentalism, dealing “with humans’ relationships to nature… [and] directly with the ecological problems of our time has emerged since the 1960s, set off by Rachel Carson’s work *Silent Spring* and Aldo Leopold’s call for an evolving land ethic” [2]. Where within an engineering worldview “the facts of ecology in general, do not fit” as ecological issues are too complex [18], we find a new worldview emerge.

As reported by the Brundtland commission following their eighth and final meeting of the World Commission on Environment and Development (WCED) in Tokyo of February 1987 address, “When the century began, neither human numbers nor technology had the power radically to alter planetary systems. As the century closes, not only do vastly increased human numbers and their activities have that power, but major, unintended changes are occurring in the atmosphere, in soils, in waters, among plant and animals, and in the relationships among all of these” [19]. The committee then questions how these difficulties might be addressed in “political agendas” [19] and/or through “concrete and realistic action proposals” [19]. Albeit, the committee suggests these agendas and proposals should be situated in the “institutions we have created”, as the committee self-admits, “we were not called upon to deal with the environment alone, but with development and the environment” [19].

Thus the WCED pioneers introduced the “concept of sustainable development” with the premise that the “will for change must be created” [19]. Inherent in the very core of this concept are “recommendations” based “on the realities of present institutions” [19]. At large, today, sustainable development is reiterated verbatim from the Brundtland report as “an approach to progress which meets the needs of the present without compromising the ability of the future to meet their own needs” [19].

We find ambiguity inherent in the term “sustainability”, as we question how it might ever be possible to quantify “needs”. Milhelcic and others write, building off the Brundtland reports ambiguous definition of sustainability, a “diverse set of constituents have developed different visions of sustainability based on their different needs and aspirations” [20]. This leads to a redefinition of the term, during the 2002 World Summit on Sustainable Development, as “the design of human and industrial systems to ensure that humankind’s use of natural resources and cycles do not lead to diminished quality of life due either to losses in future economic opportunities or to adverse impacts on social conditions, human health and the environment” [20].

Confusion also arises today as we often hear people use the word “green”, and do not realize that this should be distinguished from “sustainability”. Ansari writes, the word green “represents a rather wide and loosely defined spectrum of thought, attitudes, philosophy and practice, centered around the common theme of concern for and protection of the environment” [18]. Then, green engineering is limited to “pollution prevention and industrial ecology alone” [20]. Green engineering is therefore “not sufficient to achieve sustainability because even systems with efficient material and energy use can overwhelm the carrying capacity of a region or lead to other socially unacceptable outcomes” [20]. Despite the wide definition appropriated to sustainability, its goal in creating a “more sustainable world” has had noticeable impact. Eckersley posits that a “shift in worldviews” from “material progress” to “sustainable development… may be taking place.” [17]

V. CLOSING DISCUSSION

Progress in the dominant modern worldview is “measured as the size and rate of increase in Gross Domestic Product” (GDP) [17]. Consequentially, in a dominant worldview where “progress needs never cease” [5] should we optimistically believe that GDP will grow without end? As “engineers are perennially the agents of technological progress” [7], and technological progress is the means through which GDP continues to grow, does it seem feasible to propose that engineers have the ability to accomplish the challenge of continual progress?

Once sustainability became “real”, people attempted to mesh it with the engineering worldview. But sustainability brings with it alternative assumptions about how the world should be approached, views contrary to those of the engineering worldview, and an idea that progress can be environmentally, socially, and economically savvy all at the same time. It should not be surprising that there are some who confuse sustainability with “weak” and “strong types, where in the former acts “that are harmful to the environment damage both society and the economy,” and therefore environmental considerations become the most prominent in an engineer’s decision making process [21]. In the latter case economic considerations come to the fore whereas environmental and social considerations cede to the background. [21]

Ansari suggests that there are different “shades of green” at different ends of the spectrum [18]. One shade he calls the green worldview “assumes ecology to be a basic theoretical and empirical discipline rather than an offshoot of other fundamental branches of science” [18]. This is in contrast with the “engineering worldview” that uses “physics and chemistry as the basic theoretical and practical framework for problem solving" [18]. In turn, each worldview has largely variable solutions, one that considers ecology paramount, the other only minimally. Somewhere in the middle of these two extremes lies the sustainability worldview, which we may be the bridge connecting the green and engineering worldviews. The challenge then is how to construct such a bridge.

The WCED writes, "The radical change in human attitudes foreseen by acceptance of the concept of sustainable development depends upon a vast campaign of public education and re-education, a worldview debate around life-and-death issues. Changing the attitudes of people everywhere is a fundamental prerequisite if the priorities of human society and therefore of human government are to be rewritten." [19] While the Brundtland report suggests that a worldview debate should occur, where our modern society questions what we value, the committee does not provide us context on *how* to spark such a debate. Nor are we provided a metric that shows us if society is progressing towards the "Sustainability Worldview".

Munir Fasheh (1990) seems to be touching on the difficulty of such change when discussing hegemony. Fasheh writes, "Hegemony does not simply provide knowledge; rather, it substitutes one kind of knowledge for another in the context of a power relationship" (p. 24) [22]. Thus, hegemony is itself a "form of domination". From these statements, pertinent questions regarding hegemony of engineering education arise. Who gets to be an engineer? What ideologies must they value? Do engineers get to value solving problems unfamiliar to possessors of the dominant worldview? These are difficult questions, especially given that the hegemony of the dominant Western worldview within the university seems to be beyond scrutiny. The university is the keeper of knowledge. To *officially* become an engineer you must pass through the university first. As a result, ethno-centric forms of engineering tend to be overlooked as something other than engineering [23].

Sustainability has become an ideal simply "bolted-on" to engineering education, rather than the driving ideology for the dominant modes of engineering practice [24]. If our common goal is radical change of the entire engineering enterprise, as reports by NAE such as the Engineer of 2020 suggest [1], the questions contemporary society must concern themselves with first are the direction of change and how to implement it. Our suggestion is that this requires a complete rethinking of the engineering worldview, paired with specific attention to the influence of the broader, societal, dominant worldview driving engineering practice.

Urban Sustainability – an Engineering Course for General Education

Making the Case for Engineering to be Active in General Education

Shirley T. Fleischmann, PhD
School of Engineering
Seymour and Esther Padnos College, GVSU
Grand Rapids, Michigan, USA
fleischs@gvsu.edu

Abstract— *This paper will address two closely related topics. The first is the design and successful delivery of an engineering course for General Education at the university level. The focus of the course is how the built environment influences the social, economic, and natural environment. Engineering decisions about the materials used to create the built environment affect structural integrity, energy performance, and the sense of place in cities. These factors, in turn, affect the quality of life for all citizens - so the topic of this course is of interest to students of all disciplines. As such it offers an opportunity to introduce non-engineering students to the way that engineers think and make decisions. The second topic is an exploration of why engineering departments are not typically major players in General Education. We in engineering have often secluded ourselves from the rest of the university. The effect of this is that students outside of engineering view the subject matter as out of reach when many of the main ideas are really central to the shared life of our nation. One way to overcome this barrier is to offer engineering courses meant for students of all academic disciplines.*

Keywords—engineering and liberal arts; general education; urban; sustainability

I. INTRODUCTION

Three distinct personal experiences against a background of nearly 30 years of teaching experience in engineering, and a report published in 1989 converged to lead me to the development of the course described in this paper. The report was issued by the American Association for the Advancement of Science and was titled "Science for all Americans" [1]. On page 13 of that report they simply state "Most Americans are not scientifically literate...and the latest study of National Assessment of Educational Progress has found that despite some small recent gain, the average performance of 17-year-olds in 1986 remained substantially lower than it had been in 1969." There has been considerable effort dedicated to STEM education in the years since that report, however as our national dependence on technology has increased dramatically, the general level of technical literacy has not kept pace.

The three experiences follow:

Experience 1: In 2005 I met Dr. David Billington of Princeton University and was inspired by a series of courses developed by him and by his colleagues. Courses such as "Engineering in the Modern World" and "Structures in the Urban Environment" were intended for students of all academic disciplines and offered an opportunity for students of all disciplines to understand engineering ways of thinking. The courses were well received at Princeton and, it seemed to me, greatly needed at other universities as well.

Experience 2: In the summer of 2006 I joined a group of undergraduate students traveling abroad with an archeology professor from a neighboring university. During our 3 weeks in Greece lectures were delivered on-site and often involved a short introduction, an opportunity to explore, followed by time to report, reflect, and discuss. This was an extraordinary learning experience and I wondered how I could incorporate a similar approach into my engineering teaching.

Experience 3: During the same summer I participated in the building of an energy efficient home for a low income family – a home that my students and I were able to design and that earned a Silver ranking in the LEED-H (U.S. Green Building Council's LEED for homes) pilot program. We were able to obtain energy data for the house with a family living in it. With that data as well as the experience of designing and building the house, I gained an entry into the home-building industry as well as opportunities to make presentations to neighborhood associations, civic clubs such as Kiwanis Clubs, and engineering education conferences such as this one.

II. ESTABLISHING A NEED FOR THIS COURSE

As I presented what we had learned from this house, I was surprised by how little - even well educated people - knew about the topic of energy. I was also surprised by how eager those same people were to learn, and how grateful they were for explanations that they could understand. The need for education about energy for all citizens was clear. When energy education is applied to housing and to creating urban environments that people can care deeply about we have a "vehicle" with which to deliver this education. It is also the mission of universities in this country to prepare citizens for modern life. This is where schools of engineering can and must contribute to the education of students from all discipline areas. Pages 12-13 of "Science for All Americans" [1] provides a list of 6 major points in establishing a need for scientific literacy for everyone. The last point is: "The life-enhancing potential of science and technology cannot be realized unless the public in general comes to understand science, mathematics, and technology and to acquire scientific habits of mind; without a scientifically literate population, the outlook for a better world is not promising." In 2002, 13 years later, The National Academy of Engineering published "Technically Speaking: Why Americans Need to Know More About Technology" [2] in recognition that the critical task of assuring technical literacy for all citizens was far from finished. Numerous articles have been published more recently about the need for STEM education at all levels – even as a necessary part of liberal arts education. In 2008 The Chronicle of Higher Education published an article titled "Engineering and the Liberal Arts: Strangers no Longer"[3], addressing the approach at Smith College, Union College, Olin College, and Duke University to integration of engineering into liberal arts education. Yet in spite of the mandate included in that article, the integration of engineering into the liberal arts is far from universal. When my sabbatical approached in 2007 it was time for me to take action – beginning with the course described in the rest of this paper.

III. COURSE STRUCTURE

Approaching non-engineering students with an engineering class has its own challenges which will be discussed more fully later in this paper. However, the popular saying, "a spoonful of sugar helps the medicine go down" applies in this case. The engineering content is embedded in the urban design and social aspects content of the course. There are two major engineering topics that are addressed. The first engineering topic is structures – more specifically stresses due to gravity loads and wind loads on common structural elements found in buildings. The second engineering topic is energy - beginning with units of energy, purchased forms of energy, and how energy is delivered to buildings. The energy studies then are applied to heating of air and water and end up with heat load analyses for buildings. Engineering topics and the calculation exercises are presented in two small course-packs. In addition to the course-packs there are three text books which are listed in the next section. The approach is to weave the engineering topics into the larger social and economic context of cities. A combination of assigned calculations, journaling, and instructor-led walks through urban areas near our campus enable me to hold the interest of the students and inspire them to look for applications of what they learn. Before every walk a prompt is provided to define what we will be looking for and a walk report is required after the walk. This part of the course was inspired by the experience in Greece and it has been very well received by students who tell me years later that they still return to some of the areas of the city that we explored together. In order to encourage students to explore our city beyond the requirements of the course, up to 3 restaurant reviews can be submitted for extra credit. The restaurants must be unique to our city. That is, no chain restaurants are allowed to qualify and students must order and eat something in the restaurant in order to submit a review. I am careful to point out good and unique places to eat as we walk. The variety of activities keeps students a little off-balance and requires them to stay engaged. This is a 3 credit hour course that meets twice each week for 75 minutes in each session. This allows time for the walks.

Text Books: The texts are: *The Death and Life of Great American Cities* by Jane Jacobs, *The Tower and the Bridge* by Dr. David Billington, and *Suburban Nation – the Rise of Sprawl and the Decline of the American Dream* by Andres Duany, Elizabeth Plater-Zyberk, and Jeff Speck. Billington's book presents a history of building materials progressing from stone and wood to the use of iron and eventually concrete and steel and finally reinforced concrete and post or pre-stressed concrete. In parallel with Billington's book and structures calculations the students are also reading Jane Jacobs book which addresses how cities really work. At the beginning of her book on the page titled "Illustrations", she notes "The scenes that illustrate this book are all about us. For illustrations, please look closely at real cities. While you are looking, you might as well also listen, linger and think about what you see." We take her advice literally. The course is taught on an urban campus and a series of instructor guided walks through selected parts of the city have proven to be the favorite part of the course. As we cover structures, structural elements can be pointed out, but mainly the walks at the beginning of the course are used to tie the ideas of Jane Jacobs' book to the reality of our own city. Later in the semester when we cover energy topics the walks also include the houses that I have personally worked on in the neighborhood next to our campus…and the walks include stories about the people who live in the neighborhood.

IV. THE ORDER OF ENGINEERING TOPICS MAKES A DIFFERENCE

As noted earlier, there are two major engineering topics, structures and energy. It works better to do structures first-mainly because structures are far easier to visualize and so the engineering content is not so formidable. Solutions for stresses in columns and beams are algebra based and college algebra is the math level required for the course. Energy is not as easy to visualize and it is based on thermodynamics – which even engineering students often find difficult. The energy equation is a differential equation and this is beyond the math level of most students. For this reason a series of spreadsheets with the solutions are provided and the emphasis shifts to looking for patterns in the solutions. By the second part of the course students are more comfortable with the engineering content and some discussion of the energy equation (also known as The First Law of Thermodynamics) is possible.

V. WEAVING CONTENT AREAS: EXAMPLE 1

This arrangement of covering structures first and energy second works well with the non-engineering texts that are used. We begin with Jane Jacobs' book and Billington's book. One of the major points of Jane Jacobs' book is that sorting a city by use -putting all of one kind business in one place and destroying fine-grained diversity in a city – is deadly. On our second day of class, with the reading assignment in Jane Jacobs' book completed, we take our first walk to Calder Plaza in Grand Rapids. It is a beautiful example of how sorting by use kills the vitality of a city. All of the government buildings are arranged around an impressive and beautiful plaza – and unless there is a festival, there is no-one on the plaza. The lone restaurant at plaza level struggles to survive and seldom has any customers – even close to noon. Far from being a lively city center it is orderly, quiet, and both economically and socially dead.

On our walk back to school we pass the tallest purely residential tower in West Michigan. It is built on the banks of the Grand River. The exterior is entirely glass and with the exception of the top 2 floors, contains no structural steel. It is entirely re-enforced concrete and post-stressed concrete. It is surrounded by the river on one side, two major limited access highways on two sides, and by the park area around the Ford Presidential Museum on the remaining side. We can clearly see this tower from our classroom and in most semesters I have been able to arrange for a tour of the building, however on this first walk we stand in park and look up 434 feet to the top and note that the Eiffel Tower, completed for the 1889 World Exhibition in Paris stands more than twice as high at 984 feet. The Washington Monument completed in 1884 is also taller at 500 feet. And the John Hancock Tower completed in 1970 is 1100 feet tall. We note this to give everyone a sense of scale since the structures calculations in the course-pack use the Washington Monument as an example of a column, the Eiffel Tower as an example of a wind-loaded cantilever, and the John Hancock Tower as an example of a column-cantilever. We will tour the residential tower after the students have completed many of the structural calculations, after I have added similar calculations for residential tower as part of the lecture material, and after they have read more companion material in the assigned texts. From The Death and Life of Great American Cities they will gain perspective on how such a building with the use that it has will fit into the social, economic, and cultural life of the city. From The Tower and the Bridge they will gain a sense for the history of building materials progressing from wood and stone to iron to steel and both re-enforced and post-stressed concrete. They will also read about the designers of these structures and how they viewed their work within the context of their culture and their time. From Gustave Eiffel who designed the Eiffel Tower to Fazlur Kahn who designed the John Hancock Tower to Swiss bridge designers such as Christian Menn who designed bridges in post-stressed concrete, students gain a perspective on how culture and technical progress are intertwined.

By the time we tour the residential tower they will understand why columns are much larger on the ground floor than on the 30th floor; they will understand how the transfer girders that we see in the lower parts of the building work to transfer load. Beyond simply enjoying the view and the luxurious surroundings in the building they are able to place the building in the full social, historical, economic, and cultural context. The walk report will require that they use the criteria set forth by both Dr. Billington and Jane Jacobs to evaluate this building. They will also be able to do a very simple structural analysis and be able to explain why post-stressed concrete might have been chosen over structural steel as the main material.

VI. WEAVING CONTENT AREAS: EXAMPLE 2

In the second half of the semester we switch texts to Suburban Nation – The Rise of Sprawl and the Decline of the American Dream. We also switch engineering content to the energy studies. The Suburban Nation text is more contemporary and the focus is on a contrast between traditional town development and the urban sprawl that has developed in our country since World War 2. Many of the ideas in Jane Jacobs' book are echoed in this book – particularly the way in which sorting by use destroys social and economic vitality. Many students have grown up in sprawl and by now in the course are able to see the contrast to traditional town development. The isolating effects of sprawl on community, the lack of shared public space, and the effects of increased dependence on automobiles are clearly presented in the book. As we examine social consequences of sprawl and the differences in the style of houses and much of the built environment, the highly energy dependent nature of our lifestyle is apparent and the energy calculations are a natural extension. We begin with units of energy – in particular the units of purchase most commonly encountered for buildings (kWhr of electricity and CCF of natural gas) and we link them to costs so that students can calculate the anticipated electric or gas bill based on rates of energy use. The steady state heat load calculation for buildings can be easily developed and the concept of “R-value” for various types of materials as linked to physical characteristics can be presented. At this point in the class I have many examples of insulation, window sections, and other building materials to pass around. One of the spreadsheet exercises involves the house that I worked on – Green House on Watson. Prints for the house are in the course-pack as well as a detailed case study. In the spreadsheet exercise students can examine the effect of increased temperature difference, infiltration rate, and insulation value of windows, walls, and attics on heat load required to support a given temperature difference between inside and outside. This is related to the cost of heating by various means - natural gas, electric, and fuel oil furnaces - at various levels of efficiency.

Our walks now include the houses that I have personally worked on – most especially the houses featured in the case studies. The neighborhood close to campus is predominately low-income and many of the houses are rental units and, being older houses, many are poorly insulated and highly energy inefficient. The spreadsheets help students to see how poor energy efficiency can result in a \$400-\$500 monthly natural gas bill while the houses are not warm. This is a social justice issue. The most vulnerable in our society, the ones with the fewest options of where to live will bear the greatest energy cost…and with that the greatest social cost. Most students have never encountered the reality of having to choose between paying an energy bill and either eating or medical care, yet that is a reality for all too many of the people who live near our school.

In the walks through these neighborhood areas I am able to point out many of the social and economic consequences of choices made in the past that affect not only energy performance of the houses but the quality of life for the residents today. I have many stories about my experiences with the people who live in the neighborhood and so the class material takes on a human form. While many areas are run-down, there are signs of renewal and the older patterns of traditional town development still underlie what can be seen today. The neighborhood near our school provides a nearly endless supply of illustrations for what we cover in the classroom. All of this has captured the interest of many students and has inspired them to think more deeply about *how* we have chosen to live – and how those choices have affected other people. This is exactly what general education in a university or college should do. The engineering perspective that provides a sense of numbers and potential for improvement is essential in this.

The journals, walk reports, and short papers are essential for reflecting on the learning that is taking place. In the first weeks of the course most students do little more than repeat what they have read or what they have heard in class. When we read a portion from the text, then go out to see how that idea plays out in the city, and then return to write about our observations and discuss them, the students begin to “claim” the material of the course. There are heavy reading assignments in the first few weeks – to bring them up to speed, but after a few weeks of repeated experience with reading, observing, and reflecting, most students are able to recognize and articulate how built environments affect social environments and vice-versa. By mid-term when a short paper requiring a personal observation of this interplay of built and social environments is assigned, most students are able to bring the main ideas from the texts together…and then walks become far more than an opportunity to escape a classroom.

VII. SO WHY ARE SO FEW ENGINEERING SCHOOLS AT THE GENERAL EDUCATION TABLE?

I have been teaching engineering at the university level for more than 30 years. In my own experience and through conversation with many engineering educators at other institutions there has been little enthusiasm for developing courses in general education. The engineering courses starting in 1974 at Princeton University broke new ground and they have offered workshops in an effort to spread this approach to other schools. Approaches such as “Converging Technologies” at Union College and described by J.D. Klein and R. Balmer in a paper titled “Engineering, Liberal Arts, and Technological Literacy in Higher Education” [4] are beginning to gain attention. However we are far from recognizing engineering as a major part of a liberal arts education. Is it because schools of engineering are professional schools and general education is still perceived to be the business of the liberal arts? But then why is it that the schools of business – also professional schools – do participate in general education in many universities?

As I pondered this question I noted the content of my own course. The urban sprawl mindset of sorting by use has penetrated deeply into our view of the world. Sprawl results in isolation on the basis of income because most housing developments are made up of similarly valued homes. The design of many of these homes includes a garage and many people enter and leave their homes by car and through the garage. Once in the car (a private space) they travel to work or to shop or to enjoy recreation – often with other people of similar income. Older people who can no longer drive are forced to move out of the suburbs and into retirement communities and so isolation on the basis of age also occurs. In the communication age we find it harder and harder to communicate or understand people of a differing income level, age, or culture because we seldom encounter them. This is in part a result of how we have chosen to live with great emphasis on private space at the expense of the shared (public) domain.

In universities we are sorted by discipline in a way similar to the sorting by use as seen in sprawl. It takes great effort to cross disciplinary lines. In large universities different disciplines occupy different buildings – often on different campuses. Even within our modern buildings we have fabulous private office space and very little shared space.

We are further specialized by engineering discipline and what we do is often a mystery to even other academics. The paper by Klein and Balmer [4] includes a subheading titled "Engineering, Liberal Arts, and the Two Cultures" in which they further discuss the divide between the separate cultures of engineering/science on the one hand and liberal arts on the other. My own observations echo their discussion.

Within our culture at large there is a prevailing attitude that engineering is far beyond the understanding of most people and certainly our wonderful electronic tools add to this mystique. As a result, students outside of engineering are normally hesitant to sign up for an engineering course. There is a real fear that the level of mathematics required is beyond the student of normal intelligence. Engineers are responsible for the production of the wonderful technology that everyone depends on but few really understand. This is not healthy for a culture so dependent upon technology.

VIII. CONCLUSION

One of the principle ideas presented in Jane Jacobs' book and also in the Suburban Nation book is that sorting by use kills the vitality of a city and that mixed use, mixed income, and fine-grained diversity is essential to the ongoing health of cities. The truth of this is clear if we observe cities. It is as important to academia as it is to cities. One way to promote mixed use and fine-grained diversity is for academic disciplines to work together. This is the challenge to higher education. If we find a way to meet this challenge, not only will students outside of engineering benefit, but we will benefit from the shared perspectives of other academic disciplines and our students will benefit from our enriched perspective. One way to engage the diversity that we seek is to work together with our colleagues in other parts of the university to create general education courses that prepare students to contribute to all of society.

A parting thought:

"Engineering has really been the transforming force in society for the last 200 years. Liberal arts schools that do not deal with engineering are leaving out an important component of liberal education."

Dr. David Billington, New York Times, Nov 4, 1990

He was… and is still correct. We have work to do.

***Abstract*— In recent years, many studies and reports have highlighted concerns and problems with engineering doctoral degree recipients. Criticisms have come from professionals in both industry and academia, as well as from current and former Ph.D. students. Given the dissatisfaction of a variety of stakeholders, there have been calls from professional societies, disciplinary bodies and federal agencies to improve doctoral granting programs across the U.S. and to educate Ph.Ds. who are equipped with skills and attributes necessary to meet the highly-competitive and rapidly changing 21st century workforce [1, 2]. Within this context, this study focuses on the perspectives of working professionals from both academia and industry. Preliminary findings were obtained from one-on-one interviews with forty engineering Ph.D. holders who are from industry and/or academia. They recommended practical measures for engineering doctoral students to obtain desired characteristics upon graduation. Using the preliminary results, the work in progress precludes the design of an instrument to evaluate on-going changes to different aspects of doctoral education. The instrument will serve as a useful tool to understand the degree and scope of changes in engineering doctoral program. Portions of the instrument informed from these recommendations are provided.**

***Keywords*— engineering doctoral education; recommendations; instrument development**

I. INTRODUCTION

The Doctor of Philosophy is typically the highest degree an individual can earn within a field. It conveys a level of academic accomplishment that only a select group of individuals have chosen to pursue. Admissions criteria for doctorate programs draw a picture of an individual who is intelligent, curious, driven, and dedicated. Students from around the world choose to pursue graduate training in the U.S. because of the high caliber of programs and training and expertise produced by doctoral programs. Such pursuits have resulted in advances in science and engineering that were unimagined only a few decades ago [3]. However, recent years have witnessed a number of changes within the system of U.S. doctoral education. Criticisms of the current system, combined with economic and global changes, have forced universities and academicians to reevaluate the purpose of the PhD.

For example, employers of Ph.D. holders in non-academic sectors (e.g., industry, government, and non-profit organizations) have criticized doctoral recipients for being narrowly trained and educated and for lacking teamwork and management skills [4]. Similarly, many academics criticize recent Ph.Ds. for their limited teaching abilities, grant writing skills, and lack of familiarity performing interdisciplinary work [5, 6]. Even current and past doctoral students have criticized graduate programs for providing limited information about employment opportunities after graduate school [6-8].

A review by Campbell et al. [9] identified a number of the major concerns within graduate education. Of primary concern is the disconnect between the training that graduate students receive and their future professional roles. The assumption that graduate students will pursue academic careers is no longer valid as an increasing number of students are pursuing work in non-research universities, industry, or other arenas [10]. However, while the career goals of doctoral students have changed, the focus of graduate engineering education has remained the same. Graduate programs that focus only on research, to the exclusion of other skills, are not preparing students for the responsibilities of the positions they will fill in the future [9]. It is imperative that engineering graduate educators begin to consider the attributes of a successful engineer at the doctoral level and implement curricula and training that develop these skills in their students.

Considering multiple concerns of engineering graduate education, there have been calls from professional societies, disciplinary bodies and federal agencies to improve doctoral granting programs across the U.S. and to educate Ph.Ds. who are equipped with skills and attributes necessary to meet the highly-competitive and rapidly changing 21st century workforce [4, 5]. Therefore, in recent years, some engineering and science doctoral-granting programs have developed in-house workshops and seminars to equip Ph.D. students for their future roles as professionals [11, 12]. However, there is a need for additional studies to identify improvements and assessments of these improvements within doctoral programs. One way to identify what needs to be improved in engineering doctoral programs is to examine the perspectives of engineering Ph.D. holders who work in industry or academia.

Such employers can reflect accurately the types of work that they do and can provide recommendations for improving engineering doctoral programs. In this study, forty engineering working professionals were interviewed. Their perspectives on ways to improve current engineering doctoral education were explored. Findings identified from these engineers were then translated into measurable outcomes to assess the improvements made in the doctoral programs.

II. Research Method

A. Data Collection

This study is part of a larger research study which examines topics such as, the desired skills and characteristics of engineering Ph.D. recipients, the ways that current graduate education practices in engineering have or have not prepared the Ph.D. recipients for their current roles and functions at their workplaces in academia or industry, and practical measures that might help students to acquire desired characteristics for engineering Ph.D. holders. Researchers focus on the topic of practical measures to prepare students for desired characteristics. Semi-structured one-on-one interviews with 40 engineering Ph.D. holders working in industry or academia were conducted by the research team.

The original interview protocol included 16 questions. Here, researchers explored the results from the interview question, "What can be done at the graduate level to ensure engineering Ph.D. students are acquiring the desired characteristics to be successful in academic and industrial careers?"

B. Data Analysis

A code book has been developed following a process described by MacQueen, McLellan, Kay, and Milstein [13]. The use of a structured codebook helped to ensure consistency among team coders. Open-coding was used to classify the responses to the interview question. An inter-coder reliability test demonstrated a percent agreement higher than 75% among coders. The code book was used to code all of the forty transcripts.

III. Preliminary Findings

The researchers are in the process of identifying the themes and patterns of the data. In this report, the list of codes obtained through the interview question was summarized. Codes here will be later translated into items that will become part of an instrument to assess changes implemented in current engineering graduate programs. Preliminary results include all codes that emerged from the 40 transcripts. These codes can be grouped into recommendations to students, faculty members, and the doctoral program itself.

These codes emerged from the transcripts cover different aspects of doctoral students' training. For students, the recommendations focused on diverse professional skill sets, experiences, or activities that would prepare students for their future careers. Interviews from the working professionals also stressed on the opportunities to which advisors or faculty members should pay special attention in the process of training and mentoring of doctoral students. Finally, the last set of recommendations indicated some areas that would require formal and informal support from administrators or other stakeholders of doctoral programs.

Sample recommendations to students include:

- Develop business skills.
- Develop good communication skills.
- Develop leadership skills.
- Engage in regular research group activities.
- Engage in interdisciplinary activities.
- Learn how to run a research program.
- Present orally.
- Participate in discussion-based learning.
- Participate in experiential learning activities.
- Teach and/or learn about teaching.
- Understand connections between engineering and society.

Sample recommendations to advisors or faculty members include:

- Allow doctoral students to make mistakes.
- Allow doctoral students to work independently.
- Introduce doctoral students to the realities of the work environment.
- Encourage students to critique their work.
- Encourage students to engage with industry.
- Engage students in publishing.

Sample recommendations to other higher education doctoral program stakeholders include:

- Align programmatic activities with the institutional mission.
- Change the reward system for faculty.
- Encourage faculty to acquire more industry experience.
- Set high expectations for passing Ph.D. milestone exams.
- Teach students about finances.
- Engage with non-academic stakeholders.

The recommendations from the perspectives of professionals who have worked in industry and/or academia provide practical measures to improve current doctoral education. Some of these suggestions were based directly upon their lived experiences through their own doctoral education and their past and current work experiences.

IV. Discussion

Some of ideas proposed by the working professionals directly address the criticisms discussed in current literature. For example, one of the main criticisms is that current doctorate training focus on preparing the doctoral students for academic positions [9]. Some of the recommendations identified in this research seem to respond directly to the concern that many Ph.D. recipients' career choices have shifted to non-academic positions, especially the ones in industrial fields. These recommendations focused on developing students' professional skills, such as, business skills, leadership skills, etc.

It should be noted that many recommendations refer to different skills or experiences that students should possess upon graduation. However, the working professionals also stress the important roles of advisors or faculty members and the doctoral program itself. The successful implementation of the recommended measures for improving doctoral students' training experiences demands the engagement of multiple stakeholders.

These codes will be translated into short statements to be used for developing a survey instrument. The survey will be divided into portions for students, faculty members and other stakeholders, such as administrators of engineering doctoral program (e.g. a department head).

Several sample statements for the part of students' survey are shown in Table 1.

Table 1. Sample statements in a survey for students

In my doctoral training,	Not at all 1	2	3	4	Very Much 5
1. I was exposed to opportunities to understand the connections between engineering and society.					
2. I learnt about how to teach through my own workshops, seminars, or other venues.					

The design of the survey can be used to access the changes that are taking place in current engineering doctoral programs from the perspectives of different stakeholders, including the students, faculty members, administrators, industrial representatives, etc. Researchers envision that the instrument will be used within workshops and seminars and will include specific benchmarks and metrics focused on different areas identified in the interviews.

V. Implications and Future Work

Preliminary results confirm that revisions to graduate education are needed, especially given the likelihood that the vast majority of engineering Ph.D. holders will obtain jobs in industry after graduation. Although many recommendations refer to students, interviewees noted that advisors, faculty members, and higher education administrators need to engage in efforts to reform doctoral education for engineering students.

The survey developed from this work will reflect different components for soliciting perspectives from students, faculty members, etc. By understanding these different perspectives, potential results obtain via this survey can be used to access the degree and scope of on-going changes in preparing students for diverse career options and related professional skills. The tool might serve as foundations for advising, mentoring, and for students' self-reflections of doctoral progress.

Abstract— This paper describes a new required course in the Georgia Tech computer engineering curriculum, ECE 3030, *Physical Foundations of Computer Systems*. Traditional introductory courses take a constructive approach to logic design and computer organization. 3030, in contrast, introduces the major physical concepts underlying computation. It shows how they determine basic properties of computers such as speed and energy consumption. It also explores design trade-offs by showing how changes that improve one type of property inevitably, due to physics, cause another useful property to degrade. The course emphasizes CMOS but many of its principles apply to other logic technologies as well. Students do not directly design logic or learn assembly language---for example, delay and energy consumption are studied for inverter chains. However, they have time in the course to study in detail the basic physical phenomena that underlie design choices in digital systems. Those principles help students absorb material in later classes such as VLSI design. 3030 introduces certain topics to students much earlier in the curriculum than is traditional. We believe that an early introduction to principles is important not just for students who become logic designers but for all computer engineers.

Keywords—logic design, computer architecture, delay, energy, reliability.

I. INTRODUCTION

This paper describes a new required course in the Georgia Tech computer engineering curriculum, ECE 3030, *Physical Foundations of Computer Systems*. This course, which is recommended for the junior year but is early in the prerequisite chain, provides a very non-traditional introduction to computer engineering. Traditional introductory courses take a constructive approach to logic design and computer organization. 3030, in contrast, introduces the major physical concepts underlying computation. It shows how they determine basic properties of computers such as speed and energy consumption. It also explores design trade-offs by showing how changes that improve one type of property inevitably, due to physics, cause another useful property to degrade. The course emphasizes CMOS but many of its principles apply to other logic technologies as well.

The course uses basic device physics to understand the delay and energy consumption of logic gates and logic networks; it demonstrates the inherent trade-offs between performance and leakage current; it studies basic problems in sequential system design including clock distribution and metastability; it describes various forms of memory, the causes of the memory wall and remedies for it; it analyzes heat transfer in server farms; and it considers the technologies behind batteries, semiconductor manufacturing, and other important topics. Students do not directly design logic or learn assembly language---for example, delay and energy consumption are studied for inverter chains. However, they have time in the course to study in detail the basic physical phenomena that underlie design choices in digital systems. Those principles help students absorb material in later classes such as VLSI design.

3030 introduces certain topics to students much earlier in the curriculum than is traditional. We believe that an early introduction to principles is important not just for students who become logic designers but also for all computer engineers. Computer architects need to understand the rationale behind the limitations of memory and leakage current. Embedded software designers need to understand the physical costs in time and energy for programs.

A. Course Goals

ECE 3030 is a first attempt at a re-thinking of the computer engineering curriculum. Mix up device physics and architecture; do it early in the curriculum; concentration on the knobs that control design decisions rather than particular designs.

Engineering is the simultaneous satisfaction of competing design constraints. The key design constraints in logic design are performance, energy, cost (area), and reliability. Logic design without consideration of performance is just the first two weeks of a mathematical logic course in the philosophy department.

Most students won't work on a large-scale chip project, either microprocessor or SoC. However, they will use those chips and need to understand their limitations. Thinking about the design space early gives them a new perspective on

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

engineering that they don't get in high school or many early engineering courses.

We have two goals for this course. The primary goal is to related device characteristics to logic design and computer architecture. Transistor and wire characteristics drive some of the most basic design choices in computer systems: caches and memory systems, pipelining, power management. But it is very difficult for a student to pick out those relationships from the coverage given in a traditional device course. We concentrate on a few key characteristics---gate capacitance, leakage, and wire resistance/capacitance---to identify the key advantages and limitations they provide.

A secondary consideration is to relate physics to the mathematics of computing. We want to be sure that students do not assume that all problems can be solved with clever devices and circuits. No amount of circuit trickery will, for example, make P = NP. The Turing model also provides the fundamental framework for the structure of modern computers---memory, discrete values, and discrete time---even though Turing was not concerned with implementation. The story of the early days of computer design is the search for ways to build physical devices that could provide useful memory and perform discrete computations.

Our course was inspired by *Feynman Lectures on Computation* [3]. However, we quickly realized that the book was better as an inspiration than a basis for court development. The book talks about simple VLSI design but it doesn't talk about computer architecture---Feynman is ultimately interested in fundamental limits on computing bits, not designing complex computer systems. One clear example of his view of the subject is that he does not talk about metastability, a critical topic for reliability that is rooted in circuits and physics. We did, however, use *The Feynman lectures on Physics* [2] as a key source for physics concepts.

We have identified some key concepts that underlie much of the course. These topics appear at several points and at different levels of abstraction. Highlighting these concepts provides structure for students and keeps the course from becoming a bewildering list of equations.

- **Boltzmann's constant** surprised us by emerging as a key concept. It appears in all the basic device equations. But it also underlies heat transfer; heat management devices such as heat sinks are important topics. Boltzmann's constant also appears in the Arrhenius equation, a model for the rate of chemical reactions that is used to model on-chip reliability.
- **Impedance matching** also pops up in several contexts. The simplest example is driving pins from on-chip. An exponentially tapered buffer chain is the optimal solution to this problem. But impedance matching also underlies two key topics: driving large clock trees and transistor sizing in any long logic path such as an adder carry chain.
- **Leakage vs. performance** is a key design trade-off in modern CMOS. Device characteristics that provide high performance also increase leakage current. Leakage could at one point be kept to manageable levels using circuit techniques; designers must now deal with the effects of leakage at all levels of abstraction.
- **Reliability** has multiple root causes and therefore crops up in a number of contexts. Heat produced by power consumption is one important cause of failure; heat can be dealt with at the circuit, architecture, and packaging levels. We also explore fundamental trade-offs between performance and reliability.
- **Scaling** is the driving force behind modern semiconductor development. Ideal scaling of the 1970's and 1980's had a few negative consequences but largely led to simultaneous increases in integration and performance. However, limits on devices cause scaling to deliver mixed benefits in modern technology. Those problems can be dealt with at many levels of abstraction.

B. Course Structure

We have developed the course as a series of modules. The first two-thirds of the course are spent on the basic concepts while the last third introduces some more advanced topics. We follow a roughly bottom-up structure, although we do introduce heat transfer early to remind students of the importance of power consumption.

- **Electronics and computation.** We spend the first week on historical background, without any hard-core physics or math. This module illustrates both what we mean by computation and the underlying technologies required to build useful computers. Mechanical computers such as the Babbage Analytical Engine demonstrated important concepts but were fundamentally limited by the performance and size of gears and shafts. Memory is a key technology for computers. The many intermediate steps on the way to dynamic RAM---mercury delay lines, magnetic cores, *etc.*---show that the form of the computer was not at all obvious. We also mention the Turing machine as a mathematical foundation for computing. The Turing machine motivates two critical concepts in computing: memory and discrete-valued computation. We also mention computational complexity to show that some problems cannot be swept under the rug by fancy physics or circuits.
- **Thermodynamics**. This is a short module covers thermodynamics and atomic structure using Boltzmann's constant as a unifying theme. We use some simple examples, including heat transfer and Johnson noise, to motivate the importance of these concepts. However, this module would feel at home in a physics course.
- **Heat transfer**. Heat transfer is the first module in which we talk in detail about computer design. We like heat transfer as an opening topic because it let students know that we will talk about computers at all scales. We introduce the scale of heat generation in a modern server farm. We then describe Newton's Law of Cooling followed by an introduction to thermal resistance and capacitance. We use these concepts to work some simple problems in heat sink selection. We also talk about

power/ground distribution, which for server rooms is itself a massive problem.

- **Scaling**. Dennard's scaling theory [1] gives an extremely useful synopsys of the relationship between device and logic characteristics. That theory casts logic characterisitcs (delay, power, area) as functions of device parameters, then derives relations on how those device parameters scale with feature size. Dennard shows, for example, that gate delay actually decreases as feature sizes decrease. However, the story of the last 20 years is steady erosion in the assumptions underlying Dennard scaling, with leakage being one of the most important drivers of scaling failure. This discussion of ideal scaling therefore sets up the discussion of topics for the remainder of the course.
- **Device physics.** We survey the classical MOSFET theory and the extensions for leakage with an eye toward their use in logic circuits. We concentrate on the classical MOSFET model [4]. We also relate some key device parameters, such as gate capacitance, to Dennard scaling. To motivate leakage, we use a simple model focusing on subthreshold behavior of MOSFET including the concept of the subthreshold slope.
- **Inverter analysis**. We use an inverter as a fundamental logic element and proxy for electrical behavior of other logic gates throughout the course. We first introduce the transfer curve and show how it suggests the boundaries of the logic 0 and 1 ranges. We use the inverter transfer curve to introduce the concept of noise margin and regenerative property. This helps us to explain the difference between a "logical" and a "physical" inverter. We then show how to approximate the transistor as a resistor and develop the RC delay model. We also compute dynamic energy consumption.
- **Interconnect**. We first show how to measure the resistance and capacitance of layers of on-chip material. After introducing the general concept of a transmission line, we concentrate on the RC case. We perform an intuitive definition of Elmore delay and show how RC sections both delay and distort a pulse.
- **Combinational logic**. We reduce the continuous signals we have used so far to an event-based model. We analyze the delay of a chain of inverter using a piecewise linear simplification of the transfer curve and an inertial delay model for the gate. This allows us to not only compute delay but also to show the importance of transistor sizing.
- **Sequential machines**. Turing's model requires us to discretize time. We introduce registers and clocks as the mechanism for turning continuous time into discrete time. We then use our simplified inverter model to analyze the behavior of static registers. This model is sufficient to allow us to model metastability, our first major foray into reliability. We also introduce clock trees and show how they are an example of exponential buffer tapering.
- **Memory**. Turing's model requires bulk memory for the tape. We introduce simplified versions of the DRAM circuit. A simple model is sufficient to explain why DRAMs do not get faster, unlike logic gates, creating a phenomenon known as the memory wall. Because the DRAM cell is read by charge sharing, smaller bit cells results in smaller voltage swings. This motivates the complex bank architectures seen in modern DRAMs. We also discuss flash memory, magnetic disks, and optical CD-ROM storage. For all these technologies, we give simple performance models.
- **Computer architecture**. The students now have all the pieces necessary to understand a complete computer. We consider the effects of technology on modern architectures: the memory wall motivates caches; high clock speeds complicate clock distribution; leakage current causes power problems which in turn cause thermal problems. We also use planet-scale computing to study design trade-offs. Even when signals propagate at the speed of light, an Earth-sized computer has a clock speed slightly slower than an Intel 4004.
- **Batteries.** Mobile devices rely on batteries with limited energy. We survey the design space for batteries: energy, current, recharge characteristics, *etc*.
- **Leakage.** This module spends more time on the device characteristics that cause leakage. We also survey circuit and logic techniques to manage leakage current.
- **Fundamental limits on reliability.** This is a fairly theoretical analysis of reliability based on a barrier model of transistors. We start with a very optimistic assumption: the probability of correct operation can be 0.5. We then go through a series of physical effects that cause us to spend more energy on a computation resulting in a value of energy per computation about 10,000 times larger than our original estimate.
- **Manufacturing.** We survey basic technologies for manufacturing, primarily lithography and testing. We also survey new techniques for 3-D chip manufacturing.
- **Image sensors and displays.** We discuss image sensors for two reasons: a great coincidence of physics allows us to use the same material for sensing light and computing; and multimedia has driven demand for high-performance and low-power mobile computing over the past decade. We also look at several different types of displays, including LCDs, electronic ink, and digital light projection.
- **Emerging technologies.** At the present, this model concentrates on carbon nanotube logic and phase-change memories. We may introduce quantum computing at some point, but an adequate treatment of that topic would require a great deal more quantum mechanics.

C. Grading Criteria

We base students' grades on homework and tests. We have found that questions must be carefully designed to allow students to answer them with the limited amount of information they have. This course emphasizes breadth of material over depth, so we cannot expect students to introspect as much as in some other classes. For example, although we discuss caches and average access time to motivate the limitations of DRAM, some students do not have previous experience with caches.

We had originally hoped to have students read some important papers in the field. However, we have found that virtually all papers require too much background information. At present, we only have students read Dennard's paper on scaling, and do not ask them to read the device modeling material at the start of that paper.

D. Experience and Lessons Learned

We are in the midst of teaching the course for the third time. After being not at all sure how to approach this course, we believe that we have found a reasonable shape for the material. A great deal of work remains to fill in details, however.

A constant challenge is fitting the material to students' background. We have spent a great deal of effort finding simple approximations to complex topics. Students have very little background in either circuits/devices at the low end; they have a little more knowledge of logic design and computer organization, but are still not sophisticated.

We would like to develop material on a few more topics:

- A module on networking that relates the physical phenomenon of latency and throughput to similar concepts in logic/architecture.
- A more thorough treatment of advanced technologies, emphasizing the basic characteristics we need from a technology in order to be able to use it to compute.

E. Acknowledgments

A hearty thanks to Profs. Mary Jane Irwin, Kevin Skadron, William Dally, and Yuan Xie for material we incorporated into our lectures.

Automatic Generation of Characterization Circuits – An Application in Academia

Azam Beg
College of Information Technology
United Arab Emirates University
Al-Ain, UAE
abeg@uaeu.ac.ae

***Abstract*—Circuit characterization is an essential topic in most integrated circuit design courses in an electronic and/or computer engineering curricula. In such courses, a standard set of basic circuits (called *standard cells*) needs to be characterized based on different design criteria, for example, noise margin, power, performance, etc. So the students usually need to go through the manual, iterative process of creation of circuit descriptions (defined by *Spice netlists*) – a process that is not only time-consuming but also prone to errors. For the students to be able to conduct a large number of experiments while focusing on the design issues rather than on the tedious task of creating different circuit variants, an online tool is being proposed. The tool can be used in different courses that cover the topics of nano-sized CMOS (*complementary metal oxide semiconductor*) digital design, VLSI (*very large scale integrated*) circuit design, low-power digital circuit design, circuit reliability, etc.**

Keywords—online circuit generation, digital CMOS circuit, VLSI design, standard cell, cell characterization, Spice simulation, testbench, low-power design, circuit reliability

I. INTRODUCTION

Standard cells include basic building blocks that are used to build larger circuits. Examples of basic digital blocks in a *standard cell library* are inverters, NAND gates with two or more inputs, NOR gates with two or more inputs, etc. Other cells include flip-flops and input-output pads [1].

Circuit characterization is an essential topic in courses[1] on digital design. Various aspects of the topic fall under different headings in the course syllabi, for example, performance estimation, power consumption, and circuit simulation. Additionally, the recent scaling of transistors to 22 nm and lower dimensions have brought to limelight the need for teaching the effects of variations in circuits due to dissimilarities in dimensions and dopant densities of transistors.

The circuits may originate from HDL (*hardware description language*) models, from schematics, and/or from Spice netlists. Regardless of how the circuits are initially created, their designers may have to create many, many circuit variants. A few dozen or a few hundred design variations may be needed just to meet a given design criterion, such as power consumption or performance. A few thousand or hundreds of thousands of (Monte Carlo) iterations may be needed to study the behavior of a circuit under parameter deviations, such as random changes in switching (threshold) voltages, manufacturing variability in device dimensions, etc. [2], [3]

Depending on the type of characterization being done on a circuit/cell, a set of input stimuli and the means of measuring the circuit behavior (current, delay, etc.) have to be included in the Spice netlists [4].

Creating the Spice circuits and their *testbenches* (that comprise of carefully crafted commands for stimuli, commands for measuring current, voltage, and timing) is a time-consuming and error-prone process. So a student (or any circuit designer, in general) may spend a significant amount of time just creating the netlists, instead of expending her energy on the larger issues of the design and analysis. This paper presents an online tool, named *SpiceGen*, that not only creates but also their testbenches.

In Section II, we briefly review related work on simulation of electronic components and circuits. Section III gives an overview of SpiceGen and its structure. Section IV presents the contents of a sample course on CMOS digital design and how SpiceGen can be utilized for the course. Two examples of student activities based on the tool are illustrated in Section V, followed by the description of classrom-deployment of the tool, in Section VI. Conclusions are given at the end of the paper in Section VII.

II. RELATED WORK

Over the years, curriculum for teaching of integrated circuit design has been addressed by many researchers [5]-[9]. Circuit simulation has for short-channel effects (SCE) modeling in MOS (Metal-Oxide Semiconductor) transistors [10], gate level-design [11], [12], and circuit theory [13], [14].

A Spice-driven website for teaching power electronics covers experiments on just a single component (a power diode) [15]. Hashimoto *et al*'s cell library generation tool has used for

simulated annealing for creating cell layouts for 130, 180, and 350 nm technology nodes [16]. An offline tool called AutoLibGen [17] has allowed characterization of cell library with 65 nm node, but not the state-of-the-art nodes.

The author (of this paper) has conceived and developed an offline tool for automatic creation of Spice netlists for basic gate characterization. He has successfully used the tool for his research work in the past two years; now the web-based version of the tool is being presented with an emphasis on academic usage. None of the known online systems have the circuit construction capabilities that this tool offers.

III. SPICEGEN OVERVIEW

The flowchart in Figure 1 shows the overall structure of the SpiceGen tool. The Spice netlists and the corresponding testbenches generated by the tool depend upon many variables, the primary ones being:

- *Standard cell type*: one of 19 basic gates, such as inverter, NAND2, NOR2, etc. (termed as *unit-under-test*/UUT)
- *Technology size*: 16 nm or 22 nm
- *Supply voltage* (V_{DD}) and *operating frequency* (f_{max})
- *Variation type*: transistor dimensions and/or threshold voltage (V_{TH})

SpiceGen customizes the netlists and the testbenches based on the type of characterization being done. Currently, the three options are:

- DC/voltage transfer curves for measuring (and balancing) gate/cell rise and fall times, and *static noise margin* (SNM) (see Figure 2)
- Delay and power measurement (see Figure 3)
- Maximum operating frequency measurement with a ring oscillator of *n*-stages (see Figure 4)

Apposite *driver* (waveform-shaping gates) and *load* are included in the netlists. Customized stimuli based on V_{DD} and f_{max} are also added. Depending on both the UUT-type and the characterization-type, tailor-made measurement (".meas") commands are incorporated into the netlist.

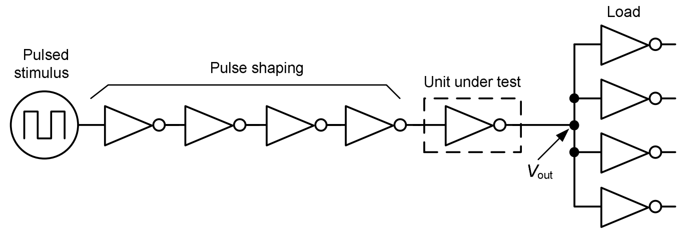

Figure 3. Test setup for measuring the current and delay of an inverter

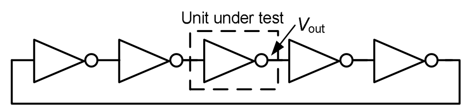

Figure 4. Five-stage ring oscillator for measuring the maximum operating frequency of an inverter

A screenshot of the tool's user-interface is shown in Figure 5.

IV. CMOS DIGITAL DESIGN – A COURSE AND REQUIRED TOOLS

Digital design courses are common components of the electronic and computer engineering curricula. The following is a list of topics in a sample course on CMOS digital design:

1) Basics of MOS transistor physics

2) Introduction to digital standard cell-based design

3) Design of common standard cells: INV, NAND, NOR and XOR gates; and flip-flops and memories

4) Design of arithmetic circuits: adders and multipliers

5) Cell simulation and characterization: noise margin, propagation delay and power dissipation

6) Introduction to HDL and synthesis

7) Introduction to placement, routing and assembly

8) Advanced topics: low-power techniques, near-threshold and sub-threshold operation, reliability, and effects of parameter variation

When feasible, commercial EDA tools (such as Cadence and Synopsys) are employed in a course similar to the one described above. The vendors offer these tools to the universities at a "nominal cost" of US $5-10K per year. However, complicated legal requirements and the need for skilled EDA support personnel are known challenges that accompany such tools. An additional issue is the inability of the students to run the tools on their own machines. So some institutions opt for more *portable* and free, open-source tools such as Alliance VLSI CAD System [18] and Electric VLSI Design System [19]. SpiceGen, the online netlist creation tool presented in this paper is anticipated to be a valuable addition to the other freely available EDA tools for tutelage, due to former's unique *push*-button capability of highly customized and automatic testbech generation. SpiceGen can be easily utilized for a course such as the one described in the beginning of this section. The tool can be used for hands-on work related to these topics in the course: (2)–(5), and (8). The users can use commerical or free Spice simulators (e.g., HSPICE, Ngspice, etc.) for circuit simulation.

V. SpiceGen Usage Examples

To exhibit the pragmatic applications of SpiceGen, we present two examples of how the students in a CMOS digital design course can use SpiceGen.

Example 1

The students are asked to study the measure the current (and the power) of a 22 nm inverter operating at 0.8V and 1 GHz frequency. The inverter sizing is W_{pMOS}/L_{pMOS} = 3/1 and W_{nMOS}/L_{nMOS} = 2/1. (Same sizing is also used for latter examples).

The students in this case choose the circuit configuration of Figure 3. SpiceGen automatically creates the complete Spice netlist as shown in Figure 6. The netlist as mentioned earlier includes the UUT, the stimuli, and the requisite measurement commands. By simulating the circuit netlist, one gets the input and output voltages, and the current for the inverter – the device-under-test (see Figure 7). The need for better fall- and rise-time balancing of the output is evident from the magnitudes of the positive and the negative current peaks. The average current is also included in the simulation log file.

Example 2

The students are assigned to study the effect of changing V_{DD} on power and energy consumption of a 22 nm inverter. V_{DD} ranges from well below V_{TH} to above-nominal voltage (0.8V), i.e., from 0.2V to 1V.

Nine different circuit variations (similar to the ones in Figure 3) are needed in this case. Simple settings in the SpiceGen user-interface let the users quickly create all needed netlists in an error-free fashion.

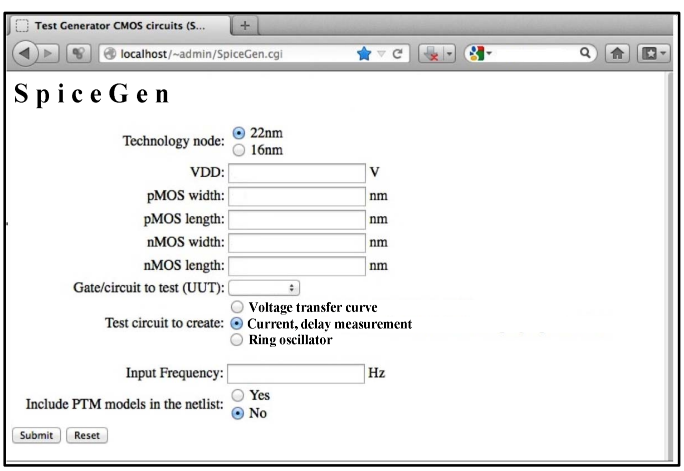

Figure 5. SpiceGen's user interface

.ends inv
```

Figure 6. SpiceGen-generated netlist for measuring the current of an inverter

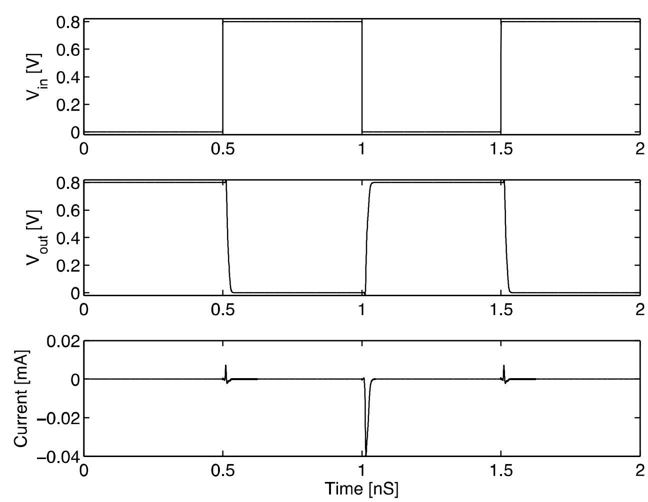

Figure 7. Simulation results of the netlist of Figure 6: inverter's input voltage, output voltage, and the current

After the circuits are simulated in batch-mode, the log files contain the currents and the delays of the respective circuits. A student can see that the inverter power consumption drops as V_{DD} is decreased (see Figure 8). She also observes that the gate delay has an inverse relationship to V_{DD}. Consequently, the *power-delay-product* (PDP) of the gate bottoms out at near-threshold voltage of 0.5V.

VI. SPICEGEN IN THE CLASSROOM

During the Spring 2013 semester, we deployed SpiceGen online and used it in an 18-student class. We allocated one lecture for introduction and hands-on practice. During this class, the students generated different circuits and simulated them with an open-source (Ngspice) simulator; this was followed by two home assignments. After the assignments were turned in, we conducted a survey about the tool, and found very favorable student responses, in terms of ease of use and the ability to conduct many experiments in a quick fashion. For further evaluation of and for any improvements in the tool, we intend to use it again in the Fall 2013 semester in two more courses; soon afterwards, we plan to publish a comprehensive report including a how-to-use guide and student responses.

VII. CONCLUSIONS

SpiceGen has promising applications in the teaching of different courses related to the design of CMOS circuits. We have seen encouraging response to the initial deployment of the tool for classroom use. In other institutions, dedicated courses on low-power circuits and on circuit reliability are also highly likely to benefit from the tool.

One way of expanding SpiceGen's capabilities is to integrate it with an online Spice simulation engine – an option we are presently considering.

Issues of Recruitment and Retention for a New Engineering Provider

Dale A. Carnegie, Craig A. Watterson
School of Engineering and Computer Science
Victoria University of Wellington
Wellington, New Zealand
dale.carnegie@vuw.ac.nz

***Abstract*— As a new provider of engineering, Victoria University of Wellington (VUW) faces a significant number of challenges in attracting and retaining quality students. As the primary funder of Universities, the New Zealand Government is providing conflicting funding directives, desiring an increase in student numbers, but penalizing poor course completion rates and banning funding on foundation or bridging courses. This paper details the development of a successful engineering programme, focusing on the modern "digital" aspects of engineering, in the face of these challenges.**

***Keywords*— engineering retention, pastoral care, student support, teaching and learning**

I. Introduction

New Zealand (NZ) lags behind many of its OECD partners in terms of the number of engineering graduates it produces [1]. This is reinforced by industry demands to the Institute of Professional Engineers NZ (IPENZ) to lobby for increased numbers of university engineering graduates since industry is being forced to recruit internationally for engineering capable employees. In response, the NZ Government in 2007 supported Victoria University of Wellington (VUW) to formalize the provision of a professional engineering degree. Initially this was a Bachelor of Engineering (BE), but soon afterwards this was extended to include both the Master of Engineering (ME) and the PhD. The decision was made to focus on, and extend upon, existing expertise in the areas of Electronics and Computer Systems (ECEN), Networking (NWEN), and Software (SWEN). This provision of an exclusive set of "digital" engineering specialisations was unique in New Zealand as existing tertiary engineering education providers offered only subsets of these specialisations. As background, approximately 50% of the University's funding comes from central Government grants and so changes in government policy can have a profound effect on university enrolment numbers, and type. Students are charged tuition fees, set by the central Government at approximately US$5000 per year per student and this comprises about 20% of the University's income.

This paper outlines the challenges faced in establishing a new engineering degree and how we overcame them, especially in the face of a major shift in Government funding to the universities and strong (and sometimes hostile) competition from existing established providers. Compounding issues include the effects of a radical change in student assessment at High (secondary) School which has dramatically altered the mechanisms of student learning and made it difficult to assess student ability for determining entry into our Engineering programme.

This paper will be divided into two parts. The first is the issue of recruitment – how to get a new programme known to the target students, their influencers and other stakeholders. We discuss how knowledge of our brand of engineering was established and differentiated in the minds of students from other engineering providers even though these topics are not presented at High School. This work is informed by marketing surveys, interviews with teachers and careers advisors, and an examination of the efficacy of various marketing tools. Following static results from traditional marketing approaches, an innovative "Geek" orientated marketing programme, combined with intensive High School outreach activities that targeted both students and teachers was implemented.

The second part of this paper details the retention issues that we have faced. Specific challenges begin with the University's policy of open entry into our engineering degree. In order to ensure the quality of our graduating cohort, students are required to achieve at the above-average level of B (65%) over their first year courses in order to progress in the BE programme. These first year courses include 2 computer science courses and a core first year engineering course for all engineering students, and selective mathematics and physics courses depending upon the specialization – ECEN students require calculus, algebra and core physics, NWEN and SWEN students require discrete mathematics, statistics and introductory level physics.

Given the variability in student ability, and the Government's decision to NOT fund any foundation courses at Universities, we currently suffer a first year student attrition rate of 60%, which can no longer be tolerated given the Government's current funding penalty schemes.

II. Recruitment

A significant barrier to the recruitment of students into University Engineering programmes is the absence of a specific engineering topic in High Schools. Target students in their final year of High School will typically take courses in physics, mathematics with calculus, mathematics with

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

statistics, chemistry, and potentially biology. Typically they would have some engagement with these courses over at least three years of High School, and hence they become very familiar with the concept of Science. Some "technology" courses are presented, but these encompass everything from electronics, through to fabric technology. Engineering is not explicitly covered and students entering university often only have a vague and incorrect idea that engineering study entails building skyscrapers or bridges.

Our recruitment initiatives then, had the dual challenge of firstly informing students about what "digital" engineering entails (i.e. that there was more to engineering than the mechanical, civil, structural specializations) and secondly that VUW should be their institution of choice rather than one of our established competitors. It is fair to state that we learnt from our mistakes.

In our first year (2007) we went with traditional forms of advertising; newspapers, adshel posters, and hiring out a movie theater for a sponsored recruitment evening. This was complemented by outreach activities where students in groups of 20 were taught to populate, solder and code a microcontroller board. This hands-on exercise really helped to reinforce our message of "digital" engineering rather than bridge or skyscraper engineering.

We exceeded our business plan enrolment expectations in this first year, but faced a static enrolment figure in the following 2 years. In 2009 we decided to trial in-game advertising under the assumption that this would directly target our intended market. Under this arrangement, VUW Engineering advertising was embedded in "Massive" on-line games of our choice. The advert featured the VUW logo, and the caption "Don't just play it. Create it". We were charged by the number of 10 second cumulative views of the advertisement. Enrolments did not significantly increase in 2010 and we undertook the first of our annual student surveys to determine why. The response rate was 88 out of a total of 105 students for that year, and only 1% indicated that the in-game advertising was a contributor to their decision to enroll in Engineering at VUW [2]. Surveys have been conducted every year since to determine our marketing effectiveness. Students are asked to select each category that was a contributor to them finding out information on VUW's engineering program. There is surprisingly little variation year to year. Table I below presents the results from the 2012 student survey. There were 142 responses, 128 male, 14 female.

Newspaper advertising does not appear to be a direct influencer, with scores between 2 and 4% every year. However, the students are not the target of these advertisements; they are intended to influence and inform the parents. We do not yet have any mechanism to gauge the effectiveness of our marketing campaign to students' parents, and we are reluctant to completely abandon this traditional marketing technique since parental influence consistently ranks as one of the top contributors.

The TV advertising was undertaken by VUW central on a limited budget and did not have significant prime-time airing. It was a 30 second advertisement featuring a student and the presenting author of this paper promoting the robotics and rehabilitation work undertaken at VUW. It appears to have some limited impact, with scores ranging between 6 and 10%. Since such advertising is conducted by VUW central, and does not form part of our budget, we are happy to continue supporting such initiatives.

TABLE I. SUMMARY OF 2012 STUDENT RESPONSES {ALL: MALE: FEMALE} TO ADVISING ON HOW THEY FOUND OUT ABOUT VUW'S ENGINEERING DEGREE

Activity Description	Percentage of all students selecting option	Percentage of male students selecting option	Percentage of female students selecting option
Friends	69	58	79
Attending VUW Open Day	52	54	50
School careers advisors	47	39	50
VUW Website	32	30	50
School Visits by VUW Eng. Staff	22	22	14
Parents	21	19	36
High School teachers	19	31	21

Attending Eng. Outreach Activity	7	7	7
Geek Engineering website	4	4	7
Newspaper Advertisements	4	2	7
Programming for Girls Challenge	0	N/A	0
Other (TechHui, Google, Robotics comps, local uni)	14	14	21

Given the total failure of the In-Game advertising, a more effective marketing campaign needed to be implemented. We undertook two new initiatives. The first began with a thorough demographic study comprising our existing year one and year two engineering students and final year High School students. We were rather surprised to find a strong association with the label "Geek". When the authors of this paper attended High School, being called a Geek was a derogatory term, but now it seems to be almost a badge of distinction, embraced by both males and females.

Consequently, we undertook the design of both print and on-line material centered on this Geek theme. The print material took the form of a tongue-in-cheek, 24 page A5 size booklet that embraced and exaggerated the Geek concept. The front and rear covers of this booklet are illustrated in Figure 1. Internally the book contains information on digital engineering, the degree programmes offered, student and project profiles and career information, but all written in a student-friendly style – with NO corporate branding. This booklet was extremely successful, well over twice as many copies being distributed compared to the standard university information booklets (4500 have been distributed so far with another run of 3000 underway).

The intent of the website www.engineering.geek.co.nz was to again provide a student-focused repository of information on Engineering degrees and careers, hold information that would be useful for a High School teacher, feature cool projects and information, and generally be an evolving resource.

The effectiveness of the on-line website is somewhat questionable, rating a mere 4% in student responses. A significant challenge is the substantial resourcing required to keep this website up-to-date, fresh and relevant. However, our anecdotal evidence is that the hard copy booklet has been exceptionally popular with the High School teachers, careers advisors, and students themselves. For the 2013 survey we will ask a specific question regarding the impact of this booklet.

Fig. 1. Front and rear cover of our Geek Engineering recruitment publication.

As mentioned, the survey results consistently indicate the importance of High School teachers and careers advisors in influencing students' study decisions. To profile VUW's digital engineering in the science, mathematics and technology laboratories, seven informational posters and an additional flashy, non-informative poster for the careers advisors (Fig 2b) were developed. The informational posters covered:

- Ohm's law: series and parallel resistive circuits (Fig.2a)
- The battle between Tesla and Edison: DC vs. AC
- Conductors and superconductors
- Resistors, capacitors, diodes, transistors
- How Facebook works
- How the Internet works
- Digital data storage: (esp. music and images)

Fig. 2. (a) Information poster of Ohm's Law as an example of High School science laboratory poster (b) Careers Advisor office recruitment poster

These posters are designed to begin the association of Victoria University with Engineering in the minds of our prospective students, and hence inform them that there was an alternative to the well-known existing providers. They also serve to instruct High School teachers as to the nature of "digital engineering" and the specialisations VUW offers. This is vital since the lack of knowledge of digital engineering amongst the students' influencers meant that students were remaining ignorant of the opportunities and careers available to them in these areas. The High School teachers and careers advisors were also invited up to the University for the launch of our new marketing, with all attendees being given a copy of all the posters for their laboratories, our outreach Arduino microcontroller kit with suggested experiments to run in their laboratories and an invitation to keep in regular contact with us.

The overall results of our revamped recruitment initiatives were a very significant 36% increase in enrolments in 2012 compared to 2011. This increase was maintained for 2013 with a significant increase in computer science enrolments. We are noting a new trend in enrolments – students applying for multiple institutions. Our initial engineering applications increased by nearly 40% compared to 2012, however many of these students did not complete the enrolment process. We are in the process of endeavoring to contact these students to determine the reason for them not progressing to full VUW enrolment, but we strongly suspect that they accepted an offer from another institution. This trend has initiated a change to our recruitment process – historically we made no effort to market during the summer period when we expected all applications to be in. We will now personally contact each applicant and guide them through the enrolment process so that we do not lose them to other institutions.

As the primary changes since 2011 were the Geek initiatives and the posters, it is reasonable to attribute the bulk of this increase to these initiatives. Whilst we are thrilled with this result, further work is necessary to both improve the quality of students entering our programme (a slight decrease in quality was noted for 2013 enrolments) and to provide a better balance of equity; indigenous students and female students are very poorly represented.

In an effort to attract female students, VUW runs a programming camp for girls, mainly those mid-way through High School. This is a medium term recruitment effort – it will take 3 years before these students are eligible to enter VUW engineering; however an immediate goal is to ensure they continue with the engineering enabling subjects of mathematics and physics in their senior years at High School.

In future, we are hopeful of establishing a special relationship with six targeted High Schools in our immediate catchment region. We would like to run some lessons for these students, provide them with laboratory kit and training, and potentially have top students enroll in a VUW first year engineering course in parallel with the completion of their last year at High School. Perhaps being credited with a University course will make these students more likely to consider VUW as their preferred Tertiary Engineering education provider rather than one of our competitors.

At the time of compiling this paper, one of our student honors projects (4th year BE), MechBass went viral, (http://www.youtube.com/watch?v=5UYMnzXQEtw) with over 500,000 views. Successes such as this will certainly be the focus of 2013 recruitment activities.

III. Retention Background

Recall that in order to progress in our Engineering programme, students must attain an above average, B grade (65%) or above over the required first year courses. Progression figures are indicated in Table II. In this table, the first column indicates the student's first year of enrolment. Subsequent columns indicate the percentage of students who gain the B or above grade average over all the required subjects in that year. For example, of the students who first enrolled at the University in 2007, 22% of them passed this requirement in 2007, 10% in 2008 and 1% in 2009. The final column indicates the total percentage of students who successfully achieve this requirement. As Table II indicates, throughout our 6 years of offering the BE degree, we have faced an attrition rate of approximately 60%. Initially this was only of a moderate concern, after all we are offering a professional degree with essentially open entry, a high attrition was to be expected.

However, the NZ Government then introduced a set of conflicting directives [3]. First, all Universities are directed to enroll a fixed number of students for the following academic year. If the University cannot enroll at least 97% of this figure then it can be financially penalized. Similarly, if the University enrolls more than 103% of this number then it can also be fined. VUW responded to this by endeavoring to manage entry on the basis of High School grades, with students lower than some threshold placed on a wait list. This threshold was too high, and in order to meet the minimum 97% level, many waitlisted students were admitted. Engineering was unhappy with this since our analysis of their High School grades [13] strongly suggested that these students were unlikely to succeed in our Engineering program. Worse, this minimum attainment figure is being raised to 99% for 2013.

TABLE II. Percentage of students progressing past Part I (B average or above in required first year courses)

Entry	2007	2008	2009	2010	2011	2012	Total(%)
2007	22	10	1				34
2008		23	18	1	1		43
2009			28	9	5		42
2010				30	13	2	45
2011					22	21	43
2012						33	

The next directive from the Government was that a percentage of the Universities' funding would be "success based" with indicators of success being [3]:

- Successful course completion,
- Student retention,
- Qualification completion,
- Student progression.

Student retention measures an institution's success in retaining their students through to the completion of their qualifications. This is calculated by considering the fraction of students that either continue with their studies or graduate.

The qualification completion is calculated as being the number of qualifications (Diplomas, Bachelor/Master/PhD degrees) completed at an institution in a year multiplied by the number of courses that is required of that qualification, and divided by the total number of courses provided. This calculation does not differentiate between students who repeat courses because they have previously failed it and high performing students who take more than the minimum number of courses for their qualification.

Student progression is measured by the fraction of students who enroll in a higher qualification within 12 months in New Zealand after graduating. This does not count students who wish to take a gap year or enroll in an institution outside of New Zealand. The dollar figure of the penalties on these three criteria is still being determined, and hence the University has not produced a strategy and resources to mitigate any penalties that may be imposed.

However, successful course completion is penalized on course by course basis. In 2012 the ruling was that if any course did not pass at least 55% of students enrolled, then that course would receive no Government funding. This pass rate figure increases to 60% for 2013 and rumors are it will increase to 62% in 2014. This has devastating implications on our Department's budget, especially when large first year subjects are at risk.

An obvious solution is the introduction of a foundation or bridging level course to help prepare the students for the rigors of Tertiary Engineering study, particularly in the mathematics and physics. For reasons we still struggle to understand, such foundation level courses are explicitly excluded by the Government, they refuse to fund these at universities.

So we are under pressure from the University to expand our enrolment numbers, especially to help them attain their minimum 99% enrolment goal. However if we enroll weak students, then not only do we consider that unethical, we risk financial penalties unless we introduce grade inflation which we are not prepared to consider. This is a significant challenge for a programme that must expand (at least by 50%) in order to ensure its continued existence.

IV. Retention Solutions

Literature in the field of engineering education identifies many issues relating to students retention and success, for example Veenstra, Dey and Herrin [4] note nine specific factors affecting students in their retention model; High School Academic Achievement, Quantitative Skills, Study Habits, Commitment to Career and Educational Goals, Confidence in Quantitative Skills, Commitment to Enrolled College, Financial Needs, Family Support and Social Engagement. As this extensive list indicates that no single retention factor exists, rather there are a multitude of factors which contribute to student success and failure. A search through engineering education literature illustrates that the problem of engineering student success has not gone away in the last twenty years despite extensive research into the field. There are no miracle solutions that can be easily applied to the varying contexts of tertiary engineering institutions, however, many helpful ideas that can be trialed and adapted in the search for improvement.

New Zealand research into many of these areas [5-9] has informed our initiatives discussed below, which have focused on a programme of information gathering and intervention for our local context, Also, in line with international research by Tinto [10,11] that recommends putting student welfare ahead of purely institutional goals and that institutions commit to developing a supportive social an educational community, and New Zealand research by Zepke et al. [12] that also recommends monitoring student performance and establishing an early warning system, we proceeded with the trial introduction of a pastoral care agent located within the engineering programme. Discussion on this position is detailed later in this section.

Since 2011 we have engaged in a series of student surveys at the beginning and conclusion of the academic year. We also conducted student focus groups run by external experts from the Centre for Science and Technology Educational Research at Waikato University, and High School grade analyses. We found a number of factors that contributed to the attrition rate.

- Poor mathematics preparation
- Poor physics preparation
- A self-belief that they are academically prepared for university study
- Difficulty transitioning to university study, especially breaking poor study habits developed in High School
- Fear of accessing help and support services
- An unwillingness to engage in mathematics and physics courses, deeming these irrelevant to engineering study
- A frustration that first year university was less about immediate engineering and more about setting a mathematics and physics foundation

Again in 2011, we endeavored to overcome the poor mathematics and physics preparedness by forming a success predictor based on a combination of High School grades and an in-house developed mathematics diagnostic test [13]. Subsequent analyses and experience has led us to trust this success predictor. In 2011 we used this predictor to identify students who were at risk of failing (not achieving a B average). An individualized email was sent to these students, outlining our specific concerns and suggesting the most appropriate form of assistance for them to access. This initiative was spectacularly unsuccessful. Only 2 students out of the 60 notified actually accessed any help.

The surveys and focus groups identified reluctance, and in some cases an actual fear of accessing help, a finding that surprised us. It also identified that many students fully believed they were adequately academically prepared for engineering study. One cause of this is a radical change to assessment in New Zealand High Schools. Most students now participate in a National Certificate of Educational Achievement (NCEA). Problems with this form of assessment and are discussed in brief below with a more detailed discussion residing in [13].

A student will typically take five subjects in their final year of High School and undertake level 3 NCEA assessment. NCEA divides each subject into a number of modules. For example, Chemistry at level 3 is presented as modules in titration, redox, organic, aqueous systems etc. There are 6 chemistry modules in total, some being internally assessed, others by an end of year examination. Other typical subjects for a potential engineering student include Physics (5 modules), Mathematics with Calculus (7 modules), and Mathematics with Statistics (5 modules).

Grades are awarded for each module, not for the entire subject. An artefact of this NCEA module scheme is that students can mix and match modules according to their levels of interest. So for example, in theory it is possible for a student to “pass” level 3 Mathematics with Calculus without attempting the differentiation module. High Schools have also been known to regularly manipulate averagely performing students away from the perceived difficult subjects of Physics and Mathematics with Calculus in order to preserve or enhance their league-table standing.

A significant problem with NCEA is that only four grades can be awarded: {Not Achieved; Achieved; Merit; Excellence}. Although it is difficult to quantify, it appears that the “Achieved” grade actually spans an ability range of 40 – 70% (where historically 50% was the threshold for a passing grade). Consequently, students can enter university with a large number of Achieved grades from High School and yet be unable to cope with even introductory University courses, especially in mathematics. We find that many students aren’t motivated to attain the Merit and Excellence grades, and the absence of an actual percentage mark has resulted in many students “cruising”, doing just enough to attain an Achieved grade. An added barrier to students developing study habits that will assist them at university is that NCEA permits the re-taking of failed assessment items. It takes our students several years at university to comprehend that they will only be given one attempt at any University course assessment.

A consequence is that students do believe they are more able than they actually are. To quantify this, students were asked to rate how well prepared they felt they were for university study on a scale of 1 to 10 where ‘1’ indicated ‘not at all prepared’. On average, they rated their preparedness at 5.9 (± 2.2). The modal response (illustrated in Figure 3) is clearly ‘reasonably well prepared’, but the deviation is broad. Past analyses [14] reveal similar results indicating no significant change in High School mathematics curricula or delivery over the past 3 years. This survey was conducted in the first two weeks of first year university study, and interestingly conflicts with evidence obtained during interviews conducted by our pastoral care staff member (discussed later).

We were able to appoint a pastoral care agent in 2012 who was tasked with working with the marginal students to increase retention between first and second year engineering. Working with the NCEA High School data and the diagnostic scores, an early risk identification was made. To assist with identifying risk, programmers within our Department designed the "Big Sister" grade system that collated all assessment grades in near real-time over all first year subjects and graphically flagged a problem when a student began failing assessment. Big Sister can also identify when an assessment item for a specific course has been too difficult – it will again graphically indicate the number of students who struggled with, or failed, that assessment item. If that number is large, the problem is more likely to be in the assessment item itself than any individual student shortcoming.

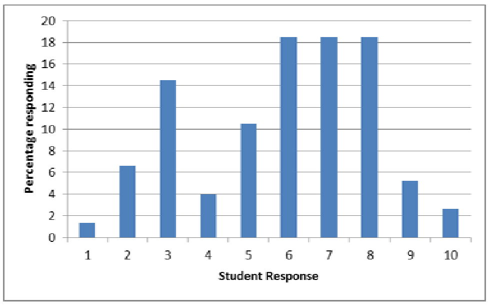

Fig. 3. 2012 Student response to academic preparedness, '1' = not at all prepared for university study, '10' = extremely well prepared.

Our Pastoral support person now personally engages with the identified student, invites them to a 50 minute, open ended interview where field interview notes are taken. The interview process is designed to identify the specific barriers to that student's success. These barriers turned out to be academic (as previously discussed), transitional (issues in transitioning from High School to University), personal, financial, or expectational. Indeed, a significant finding from these interviews was that we were not meeting many students' expectation of engineering study.

Of the 80 identified students interviewed in 2012, practically ALL of them stated that NCEA had not prepared them for the rigors of engineering study at university. This is in stark contrast to the earlier survey results (Figure 3). One of our challenges is to help students gain this realization earlier when there is still a chance to alter their study habits in order to pass the first trimester courses.

We are informed by our Pastoral Agent that the current generation of students is far more removed from our generation than we were from our lecturers 20 odd years ago. The current student expects immediate gratification, they are not prepared to blindly accept our assurance that physics and mathematics will be essential for future engineering work. They want to create and build immediately.

These findings motivated a complete revamp of our introductory engineering course (ENGR101). These changes were sweeping in nature. Historically the first lectures in this course were a soft introduction to engineering. High profile researchers did guest lectures showing the students what projects would be available to them in later years. This was intended to motivate the students, give them a goal to strive for. Now, substantial academic material is presented, and tested after one week. This serves as a shock for the students – an emphatic realization that university is considerably harder than High School and that they cannot just relax back and believe they can catch up later.

The text book was custom constructed so that it now contains information on study habits, learning skills, handling university life, as well as the core engineering content. The laboratory sessions have become more student guided rather than following a "set recipe" and are capped by the construction of an autonomous robotic vehicle to at least partially satisfy the requirement for instant results.

These changes, combined with the pastoral intervention have increased the B and above pass rates in ENGR101 from 52% to 63% (2012 compared to 2011). Student surveys indicate the students engage with this course far more than in previous years, better understand how engineering is differentiated from science, and indicate an increased satisfaction that their expectations of engineering study are being met. Following on from this success, an additional, second trimester engineering first year course is under planning, with expected delivery in 2014.

The results of the survey question asking students after their first trimester of 2012 whether engineering study at VUW was meeting their expectations are provided in Table III. The figure in parentheses indicates the responses provided in 2010. There has been a significant increase in the number of students for whom we are meeting all their expectations (20% in 2012 compared to 6.8% in 2010). There is no statistically significant variation between the 2012 male and female responses (the 2010 survey did not differentiate between genders). Informal student feedback has changed – in 2010 we were frequently hearing student dissatisfaction with the programme and students were withdrawing from BE study. This seldom occurs now except for very weak students who cannot handle the mathematics requirements of the engineering degree.

When asked qualitatively, which courses they found most difficult, nearly every ECEN student who had to take the core first year physics course rated this as being the most difficult. Further enquiries revealed that a significant contributor to this difficulty was poor underlying mathematics. Neither the physics nor the mathematics courses are run by our Department and changes are difficult to effect since these courses form the core for mathematics majors and physics majors respectively. Engineering students, whilst comprising a sizeable portion of first mathematic enrolments, are not in the majority and the University is not prepared to let us run our own courses in these subjects. However, we are engaging with the Department of Mathematics for them to provide an offering with an engineering emphasis – where real world examples are provided, proofs and theorems are de-emphasized and effort is made to cover the essential mathematics tools that engineers will require. We are also advocating that Engineering staff deliver at least a part of these courses. The reality is that first year mathematics will have to be substantially overhauled to accommodate our requests and we are hoping to have many of these changes in place in time for the 2014 academic year.

An obvious solution that we have not yet discussed to this high attrition rate is to restrict entry into the programme. However, this is where the Government's mixed funding messages intervene. New Zealand universities receive most of their funding from the Government. The bulk of this funding is based on the total number of students enrolled at the institution and any reduction in numbers results in reduced funding and potential financial penalties as discussed previously.

TABLE III. 2012 (2010) FIRST YEAR STUDENT RESPONSES WHEN ASKED IF VUW WAS MEETING THEIR EXPECTATIONS OF ENGINEERING STUDY

	% responses all students 2012 (2010)	% male responses	% female responses
All Expectations Met	20 (6.8)	20	21
Most Expectations Met	66 (78.4)	66	64
Some Expectations Met	14 (14.8)	13	14
No Expectations Met	1 (0)	1	0

V. CONCLUSIONS

In 2007 VUW established its Bachelor of Engineering degree and immediately faced the issues of strong competition from existing providers and general ignorance by students, parents, teachers and careers advisors as to what our "digital" offering of engineering entails. Following moderate marketing success from traditional modes of advertising, an innovative Geek oriented campaign was launched complemented by a dedicated campaign to involve High School teachers and careers advisors with our programme. These initiatives combined to provide a 36% increase in enrolments from 2011 to 2012. Future initiatives such as the Programming for Girls camp, and exploiting the viral MechBass bode well for increasing success in recruitment.

The attrition rate between year one of the degree where students must attain a B grade average or higher and year two is approximately 60%. Whilst such attrition rates are not atypical for professional degrees, they are no longer tolerable at VUW given the Government's position of imposing financial penalties for the University should it not attain 99% of its target number of students, and further penalties if any individual course does not pass at least 60% of its enrolled students. We are not in a position to impose restrictive entry requirements to the degree, and cannot create foundation level courses.

Given these constraints, we have created the Big Sister student assessment tracking system, developed a predictor based on NCEA level 3 grades and a bespoke diagnostic test and employed a pastoral care agent to use these tools to provide an early indication of student difficulty. Our pastoral agent identifies at risk students, actively intervenes, determines through interviews the source of the difficulty and then directs (hand-holding or coercive as appropriate) that student to the appropriate form of assistance.

Our first year core engineering course was substantially altered in response to our increased understanding of student expectations, and a "shock" test (or "epiphany" test as our first year course coordinator more delicately calls it) is delivered to jolt students out of poor study habits developed during High School NCEA assessment. A noted decrease in the quality of our 2013 intake has increased the number of students identified by our diagnostic test as requiring additional assistance. Mathematics continues to be a very significant issue and we are fully engaging with the Mathematics Department with the hope of them offering substantially altered first year courses in 2014. Also in 2014 we are hoping to have a follow-on course from the now very successful ENGR101.

First trimester results indicate an increase from 52% to 63% in the number of students achieving a B grade or above in ENGR101. Overall retention figures show the largest percentage of students attaining the B average in their first year of study (33%) and a significant increase in the number of 2011 students who have now attained that average (a further 21% gained the required grade in their second year). This certainly indicates some success with our first year initiatives – with further increases expected next as our discussions on a revamp of first year mathematics reach fruition.

Integration of Funded Faculty Research, Capstone Experiences and Industry Requirements

Aurenice M. Oliveira, Trever J. Hassell, and Wayne W. Weaver
Michigan Technological University − oliveira@mtu.edu, tjhassel@mtu.edu, wwweaver@mtu.edu

Abstract — **This paper presents a senior design strategy integrating funded faculty research and industry requirements. Students participating in this type of senior design are directly involved with all the aspects of a complete system development cycle focusing on user needs and requirements. All the aspects of the project represents higher quality and larger scale than typical senior design projects, and in this way better resemble industry projects. The case study presented herein is a practical industrial project sponsored by a faculty member the construction of a research quality electric machine dynamometer and test-bed.**

Keywords—capstone; industry requirements; ABET; faculty research; test-bed.

I. Introduction

Capstone or senior design projects are challenging and important components in Engineering and Engineering Technology undergraduate education and usually teach students valuable skills in design, prototype construction, testing, teamwork, and project management related skills [1], [2], [3], [4], [5]. However, a high percentage of the capstone projects deliverables do not result in an operable system that follows industry standards and guidelines, or cover a complete product or system development lifecycle with focus on sponsor and user needs [4]. A complete engineering project lifecycle includes planning and analysis, build and test, implementation and maintenance phases, among others. Usually, capstone engineering and technology projects are product-oriented, focusing only on the build and test phases of development [4]. This approach serves as an additional element in the gap between engineering curriculum and what skill sets employers expect new engineering graduates to have. As pointed out in [6], employers have indicated that new engineering graduates have technical competences but several lack professional skills necessary to manage a real engineering project lifecycle, work with others collaboratively, write and present proposals, among others. In [2]-[3], based on a comprehensive national study, the authors list the 22 primary topics covered in engineering and technology capstone projects. The topics range from written/oral communication to CAD design and layout, but it doesn't include any topic related to user needs or user testing. As a consequence, the focus is on the product end of the system development lifecycle neglecting the user-centered analysis, design, test, and implementation phases of the development lifecycle [4].

In this paper, the authors discuss a hands-on senior project consisting of collaboration among faculty, undergraduate and graduate students of the Electrical Engineering Technology (EET) program in the School of Technology and the Electrical and Computer Engineering (ECE) department in the College of Engineering at Michigan Technological University. The project gives the students the opportunity to be directly involved with all the aspects of a complete system development cycle focusing on user needs and requirements. In the EET program at the Michigan Technological University, students are required to complete a two-semester senior design project, which are typically industry-sponsored allowing students to work on real-world projects. More recently, however, some of the capstone projects were sponsored by faculty members instead of industry partners. This initiative serves to support some funded faculty research projects, and allows undergraduate students participating in the project to interact with graduate students, faculty members of the college of engineering and school of technology, and customers. Design, construction, system integration, software, and testing all involved other researchers instead of just the capstone team, which in turn, created new project management challenges such as team work, communication, documentation, scheduling, among others; resembling a larger scale project in industry.

The case study presented here is a practical industrial project sponsored by a faculty member the construction of a research quality electric machine dynamometer and test-bed. The project followed practical industry project standards and all the aspects of the project presents higher quality and larger scale than typical senior design projects, and in this way better resemble projects in industry. The test-bed will be used for externally funded research projects in several areas such as electric drives systems, electric propulsion systems, power electronics, and ac microgrids, among others. The test-bed was designed and built with the forethought to enable a wide variety of electric machine configurations and applications, as it provides a platform for testing of innumerous projects. In addition, the test-bed will be used for undergraduate and graduate education.

This project allows students participation in the research of possible solutions and the selection of the one that best meets the sponsor criteria and user needs, then they design, construct, and present a finished product. In addition to the application

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

of knowledge learned in previous courses, students develop technical and soft skills such as: how to research and comply with current Occupational Safety and Health Administration (OSHA) standards for test-beds, learn how to use AutoCAD for test-bed layout and electrical schematics, practice industrial type circuit construction, components selection and acquisition, learn and use industrial communication protocols as well as team and time management. The students also further develop critical thinking and accountability.

The assessment methodologies for this senior design course uses indirect and direct measurements to assess the applicable ABET a-k criteria [7]. The assessment results indicate improvements in the student comprehension of key concepts, and increased students' confidence to start their careers in the industry.

II. RESEARCH PROJECT BACKGROUND

The goal of the capstone project that we present here as a case study was to design and construct a dynamometer test-bed with the capability to test electric machines of moderate sizes. Dynamometer systems are used for testing and verification procedures in several applications including automotive, industrial, and manufacturing. Dynamometers have the capability to simulate a wide range of loads a system may experience, precise controllability, and unit testing prior to the unit under test reaching the customer. Additional motivation for having a dynamometer test-bed comes from the increasing penetration of electric propulsion in modern automobile [8] and Michigan Technological University growth in hybrid vehicle education and research [9], [10]. Electric Vehicles (EV) and Hybrid Electric Vehicles (HEV) both use electric machines for either full or partial traction of the vehicle. A dynamometer test-bed was developed with the purpose of research into various electric propulsion drives systems, including the flexibility to accommodate various types of machines. Such a test-bed would be a great asset to have in our power electronics research lab. In addition to the EV or HEV applications, a dynamometer test-bed could also be used to model a load in a small ac Microgrid. This load could mimic the load cycle of hydraulic pump systems or a heating, ventilation, and air condition (HVAC) system of a small building.

A. Design Requirements

The faculty sponsoring this project had specific industry type requirements that had to be followed by the team, including:

1. Testcell safety system following OSHA standards – also, devices must have adequate guarding to protect users from injury, use of cable tray to protect cables, safety relays;
2. Efficient use of space – cell must be as compact as possible to fit in the available room;
3. Wired communication with laptop for configuration;
4. Variable frequency drive (VFD) must communicate via Modbus RTU receiving its commands from the testcell PC;
5. VFD step-up transformer, since VFD operates at a higher input and output voltage than the testcell infrastructure voltage supply.
6. High accuracy torque/speed monitoring;
7. Testcell infrastructure controls must be PLC-based and independent of the VFD and inverter controls;
8. PC-based controls: user interface controller station with National Instruments LabVIEW GUI, dSPACE embedded controllers, Allen-Bradley Micrologix communication adaptor, and operator pushbuttons station;
9. Inverter with opto-isolated (fiber-optic) gate drive and fault signal output for electrical isolation and noise immunity;
10. Signal isolation to isolate any control signal input signal to the one that will be connected into the dSPACE embedded controller;
11. Electro-magnetic interference (EMI) isolation;
12. Easy operation;
13. User manual.

III. TESTCELL DESIGN AND CONSTRUCTION

The electric machine test-bed is a collection of various commercially available and custom made components. It is designed to enable a wide variety of electric machine configurations and applications, as it provides a platform for testing of innumerous projects. The current configuration of the test-bed features two identical 20 HP ABB induction machines in a back-to-back testing configuration. The "dynamometer" is controlled via an ABB (full 4-quadrant) variable frequency drive. The "prime mover" machine is driven from a custom IGBT inverter controlled via a dSPACE embedded controller. Both shaft torque and speed can be measured via a compact digital torque meter. The power wiring of the test-bed is controlled by a Motor Controller and Safety System Enclosure (MCSSE). The MCSSE includes a standalone programmable logic controller (PLC) system controlling the power flow throughout the system. The test-bed machine mounting tables, shown in Fig. 2, were built in modular fashion to accommodate various electrical machine types and sizes.

Fig. 2. Testcell – start of the project

Table I. Project Major Tasks

Phase	Task
I:	Cell Architecture Design
	Testcell Safety Research
	MCSSE Design
	MCSSE Parts Selection and Procurement
	MCSSE Construction
	Isolation Transformer
	Cabling and Connectors
	Embedded Controller/PC Station
II:	Initial Micrologix Program
	Expanded Micrologix Program w/ added
	Testcell Power/Control Wiring
	ABB VFD Drive Configuration
	ABB VFD LabVIEW Program
	Motor Coupling/Torque Sensor Specifications
	Testcell User Manual
III:	Signal Isolation and Interface Board
	Signal Gain Tuning
	Electric Machine Parameter Estimation
	System Performance Characterization

The capstone projects in the Electrical Engineering Technology (EET) Program at the Michigan Technological University are comprised of two academic semesters. However, this particular project, since also involved a graduate student, was completed in three phases: Phase I, during the fall semester of 2011, Phase II, during the spring of 2012, and Phase III, during the summer of 2012. In Table I we highlight the project major tasks in each phase. The graduate student participated on the team both as a technical advisor and as a project engineer. With this dual role he contributed both to the completion on the EET senior design project and a successful commissioning of the testcell system. The fact that not all students were involved in the last phase of the project didn't impose any problem for the overall students' experiences. Phases I and II consisted of all the construction, system integration, and documentation for the test cell. Phase III was for additional parameter estimation and performance characterization. All the students participated in Phases I and II.

At the start of the project at the beginning of fall semester in September of 2011, some previous work was already done to: acquire donations for the electrical machines and VFD, testcell electrical machine table was designed and constructed, mounting hardware attached to the wall, various components for use in the testcell purchased. The various components are comprised of DC power supply, several inverters, and electrical power meter with accessories.

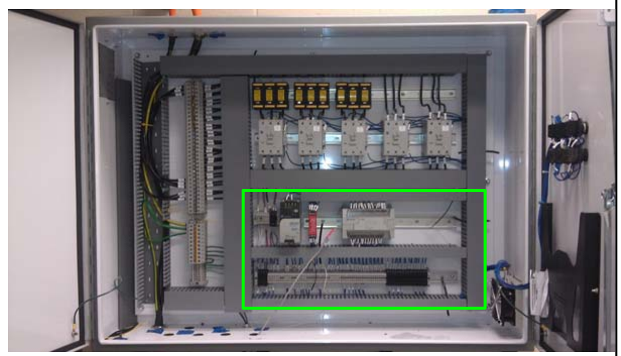

Fig. 3. Testcell infrastructure: subpanel

During Phase I of the project, the team researched and designed an architecture approach, ordered, and constructed the Motor Controller and Safety System Enclosure (MCSSE). The first task completed was the design of the test power architecture shown in Fig. 1. The testcell at the start of the project is shown in Fig. 2, and the infrastructure enclosure MCSSE and subpanel is shown in Fig. 3. The completion of these tasks included knowledge of the operation of the individual components and specific placement of the contactors to control electrical energy flow. The team researched and selected the components to be used in the MCSSE, which included the Allen-Bradley Micrologix controller, contactors, fuses/fuseholders, safety relay, terminal blocks, enclosure fan, DIN rail mounts, DC power supply, and wire way. The team also was responsible for the enclosure layout scheme and placement of the components on the back panel. The wiring schematic used to construct the MCSSE and testcell cabling was developed and guided the team with good practices in assembling the sub-plate and enclosure. Along with the enclosure and subpanel, the team ordered the materials necessary for the complete testcell power cable routing. Several other components were also researched and ordered, including the isolation transformer, operation station computer, dSPACE embedded controller, PLC, safety relays, and high voltage shielded power cables and connectors.

During Phase II of the project (spring 2012), the team continued to research and order several components needed to complete the testcell. This would include the motor flexible coupling, torque sensor, motor coupling guard, embedded controller, and control signal isolation modules. The conduit used for the ESPB enclosures/operations was bent, and the wiring of the high voltage and communication cables was completed. The team also installed the analog control signal wiring between the work bench and controller station. Also during phase II the team programmed the initial Micrologix program that allowed running the testcell system. The graduate student worked very closely with the EET team member who was responsible for the VFD communication LabVIEW program. They specifically set up the drive with the appropriate parameters to allow communication between controller station and VFD. The team also completed the power and signal routing, and complete the safety items necessary for operation of the dynamometer. Table II summarize the main objectives and deliverable of the EET students.

During the summer semester of 2012, Phase III of the project, the final items were completed to have a fully functional system. These final items included control signal gain tuning, electrical machine parameter estimation, baseline system data collection, and testcell performance testing. The completed testcell system is shown in Fig. 4 and Fig. 5. The test-bed is primarily comprised of off the shelf commercial products. The components are integrated together to form a functional electric machine dynamometer test-bed. The one-line system is classified into two distinct portions; the "prime mover" and dynamometer. In Fig. 5, the top branch of the circuit, prime mover, consists of the A (DC power supply) and B (DC-AC Inverter). The lower branch of the one-line diagram is classified as the dynamometer and consists of E (isolation transformer), F (variable frequency drive), and the second induction machine, Motor 2.

The current test-bed configuration includes two 20 HP ABB induction machines in a back-to-back testing configuration. The dynamometer is controlled by a four quadrant ABB Variable Frequency Drive (VFD). In addition, a DC power supply and a couple of voltage source inverters (VSI) were available for use in this project. All of these components served as the essential components in the testcell system; however system integration including some form of safety system was needed to safely control the behavior of the testcell. The testcell architecture was designed for two machines "back to back" testing. A one-line schematic is shown in Fig. 1. The two identical induction machines are mechanically coupled together via flexible motor couplings and torque sensor. There is only one source of electrical energy for the motors, a 208 Vac 50 Amp 3 phase receptacle, which is supplied from a power panel in the test-bed room. This source would supply two "loads"; the magna DC power supply/inverter and an ABB frequency drive. The Magma DC power supply powers the APS inverter, which in-turns supplies power the "Prime Mover" electrical machine, M1. Because the frequency drive operates at a different voltage than the main source power a transformer is needed. The frequency drive would then supply the "Absorber" electrical machine, M2. The high level control scheme of the testcell safety system puts the system in one of five states; "Ready", "Enabled", "Powered", "ON" and "Fault". These states dictate what, if any, combination of contactors and indicating lights are on.

TABLE II. TEAM OBJECTIVES AND DELIVERABLES

Phase I – Fall 2011	Phase II – Spring 2012
Project proposal	Incorporate PLC control of start/shut down procedure
OSHA Report	Fault detection
Components: Researched, selected, ordered	Sensor Integration
AutoCAD	Communication (ModBus) integration
Functional System	User documentation
Report/Presentation	Final Report/Presentation

IV. BENEFITS

The team members received numerous benefits from involvement with this type of capstone project that they would not get in a traditional senior design project. The first major benefit was working on a real collaborative multi-disciplinary project among faculty, undergraduate and graduate students of the EET program in the School of Technology and the ECE department in the College of Engineering. Another very important benefit team members received is determining real system design requirements. Although not unique to this senior design project, but very important, is that students obtain skills in both technical report writing and oral presentation. Each semester the team was required to write progress reports and to give presentations. These reports consisted of many aspects of the team's progress as well as procedures the team followed regarding safety. What is different in the reports and presentations from the traditional class room report and presentation setting, is the audience. The audience consisted of professionals from industry as well as faculty members and fellow students. The team was given feedback from these individuals and was expected to change or explain any issue that was presented. This demonstrated to the students the level of expectation for formal report writing and presentation skills, and gave them prior experience to the expectation level they will encounter in industry. Students were also exposed to industry tool such as CAD design and layout, dSPACE embedded controller, National Instruments LabVIEW VFD control, PLC programming, Allen-Bradley Micrologix Program, communication (ModBus) integration, sensor integration, fault detection, OSHA safety standards. Graduates will be able to use the technical knowledge from the use of the development tools they were exposed to during all phases of the project as well as some experience to complex system level problem solving.

Potential industry employers and faculty sponsors also benefit from this collaboration. Potential employers will benefit from hiring graduates exposed to project following industry type requirements. The faculty sponsoring this project will use the test-bed as a research platform for externally funded research projects in several areas such as electric drives systems, electric vehicle propulsion systems, power electronics, ac MicroGrid, among others. The test-bed was designed and built with the forethought to enable a wide variety of electric machine configurations and applications, as it provides a platform for testing of innumerous projects. In addition, the test-bed will be used for undergraduate and graduate education; the test-bed is currently being used for two specific laboratory classes: Introduction to Power Electronics and Introduction to Motor Drives.

V. ABET Capstone requirment and assessment

Capstone senior design experiences are both a graduation requirement for engineering and technology majors and a requirement for ABET accreditation of these programs. The capstone or senior design experience is typically the last bridge for students between their undergraduate engineering curriculum and the engineering profession. The ABET-ETAC Criteria−5 [7] states "The Integration of Content - Baccalaureate degree programs must provide a capstone or integrating experience that develops student competencies in applying both technical and non-technical skills in solving problems." The integration of capstone experience and externally funded faculty research projects is an effective way to actively engage students in challenging engineering design problems. In addition, the senior capstone experiences are a primary source of documentation of the achievement of the ABET Criteria 3 – Program Outcomes [11]. Criteria 3 requires that engineering technology programs must demonstrate outcomes (a-k), and includes: (a) an ability to select and apply the knowledge, techniques, skills, and modern tools of the discipline to broadly-defined engineering technology activities; (d) an ability to design systems, components, or processes for broadly-defined engineering technology problems appropriate to program educational objectives; (e) an ability to function effectively as a member or leader on a technical team; (g) an ability to communicate effectively. The project example that we discussed in this paper successfully satisfies all these requirements, as previously discussed in this paper. Project participants have the opportunity to determine real system design requirements, work with graduate students and faculty members, to obtain both professional report writing and presentation skills, and to be exposed to industry leading development tools and hardware. Moreover, a broad range of educational and professional benefits results for students participating in projects that integrates capstone experience and externally funded faculty research, which focuses on a real world problem.

The assessment methodologies for this senior design course used indirect and direct measurements to assess the applicable ABET a-k criteria. The success indicators were based in direct and indirect quantitative measures such as written reports, oral presentations, student surveys (midterm and end of semester), and instructor/students meetings. The assessment results indicated improvements in the student comprehension of key concepts, and increase in students' confidence to start their career in the industry. In Table III, we summarize the key skills acquired and applied by the students based on the EET curriculum and specifically project related. In Table IV (on page 6), we show the summary of student achievement of the student learning outcomes (SLO) for this capstone and quality of instruction as required by ABET for the capstone group of fall 2011/spring 2012. The results show the correlations between the project objectives and capstone requirements. All the SLO had acceptable results with exception of SLO 2 (organize research and data for synthesis), which is attributed to the lack of experience of the undergraduate students in working on research level projects. We intend to emphasize this objective during the next capstone cycle. The direct measurements included technical reports and technical presentations open to faculty, students, and Industrial Advisory Board members. The technical reports and the presentations have standardized scoring rubrics (which will be presented during the FIE meeting presentation). The students also developed a user documentation manual for the test-bed. The capstone team technical presentation scored slightly higher among three industry sponsored capstone projects presented at the same time. The overall quality of the project received positive comments for all the members. The test-bed has been used for classes and serving as project demonstration for visitors from industry, prospective students, among others.

TABLE III. CURRICULUM AND PROJECT RELATED SKILLS

EET Curriculum	Project Related
Wire Specifications	General Safety Practices for test-beds
Electrical Machine Operation	AutoCAD
	ModBus
	Component Selection Process
	Industrial Type Circuit Construction
	PLC Hardware and wiring

VI. FINAL REMARKS

The integration of funded faculty research and industry requirements in a capstone project can provide distinctive benefits to undergraduate students, graduate students, and faculty involved in the project. All the aspects of the project consisted of higher quality and larger scale than typical senior design projects, and in this way better resembled projects in industry and better prepared students to enter the workforce. In particular, students participating in this type of project developed useful project skills, and had the opportunity to be directly involved with all the aspects of a complete system development cycle focusing on user needs and requirements, in addition to follow practical industrial project standards. For the cases that we investigated there is no significant difference in the students' perceptions whether their capstone project is sponsored by faculty or industry as long as the project gives the students the opportunity to develop a broad range of skills. However, students' participating in these types of faculty sponsored projects have the potential for more employment opportunities due to the projects similarities with industry projects. Most of the industry sponsored projects in our program have a relatively small budget as compared to our case study, which can limit the complexity of the industry sponsored projects.

Table IV. Summary of Student Achievement of Course Objectives and Quality of Instruction

Student Learning Outcome (SLO)	*Relates to Program Outcome(s)* [a]	*Assessment Instrument for This SLO*	*Standard*	*Results*
1. Be able to research on applied electrical engineering technology.	3a, degree 2 3b, degree 2 3f, degree 2	Weekly meetings, project development phases;	70% of students will score 70% or better.	80% of students scored 70% or better
2. Organize research and data for synthesis.	3a, degree 2 3b, degree 2 3c, degree 2 3d, degree 2	Weekly meetings, project phases	70% of students will score 70% or better.	67% of students scored 70% or better
3. Prepare written reports.	3g, degree 3 3k, degree 3	Weekly memos, Bi-month reports, End of semester report, Final Report.	70% of students will score 70% or better	87% of students scored 70% or better
4. Prepare and present oral reports.	3e, degree 3 3g, degree 3 3k, degree 3	Weekly meetings; University Expo Capstone Conference, Final oral presentation.	70% of students will score 70% or better	80% of students scored 70% or better
5. Work in teams.	3e, degree 3 3g, degree 3 3h, degree 3 3i, degree 3	Weekly meetings, project development phases, oral presentations, written reports/memos.	70% of students will score 70% or better	100% of students scored 70% or better
6. Coordinate and work to meet scheduled deadlines and facilities, manage resources, etc.	3e, degree 3 3g, degree 3 3i, degree 3 3k, degree 3	Project development phases, and scheduled deliverables.	70% of students will score 70% or better	87% of students scored 70% or better
7. Learn general safety practices for test beds	3c, degree 3 3d, degree 3 3f, degree 3 3j, degree 3	Project design, construction, testing following OSHA requirements.	70% of students will score 70% or better	94% of students scored 70% or better
8. Be able to make industrial type of circuit construction.	3a, degree 3 3b, degree 3 3c, degree 3 3f, degree 3	Project design, construction, testing, and scheduled deliverables in line with sponsor requirements and approved by sponsor.	70% of students will score 70% or better	100% of students scored 70% or better
9. Learn how to make component selection and ordering.	3c, degree 3 3d, degree 3 3k, degree 3	Project design and budget requirements approved by sponsor.	70% of students will score 70% or better	100% of students scored 70% or better

a. In the second column, "Relates to Program Outcome(s)…", the degrees are a way of prioritizing course outcomes. Degree 3 implies that the course places significant emphasis on that outcome, degree 2 implies moderate emphasis, degree 1 implies some but minimal emphasis.

A Builder and Simulator Program with Interactive Virtual Environments for the Discovery and Design of Logic Digital Circuits

Arturo Miguel-de-Priego
Chincha, Peru
amiguel@pucp.edu.pe

***Abstract*—This paper describes the features and applications of a computer program for building and simulating digital circuits with standard and custom integrated circuits, virtual environments and other useful and practical elements such as interactive tutorials and schematic circuits. By using virtual logic modules users can insert integrated circuits into breadboards, trace wires, change switches and check outputs in displays, almost like in a real life laboratory. Also students can use virtual environments to test circuits as if they were in the real world. Users can design digital applications with more components and reuse their designs to show additional examples and study more applications while saving time and money. This program supports several instructional methods. In inquiry-based learning students can be guided to experiment with integrated circuits and logic symbols in order to discover truth tables for basic logic functions and then search for patterns, principles, abstractions and applications. In project-based learning students can try solutions for virtual environments such as traffic light controller, water tanks, kinematics experiments and elevators, and then build solutions in the real world with more confidence. Earlier versions of this software have been used on many high schools and universities in Europe and Latin America.**

Keywords— logic circuit design; project-based learning; self-learning; virtual environments; inquiry-based learning.

I. Introduction

Digital technologies are embedded on many devices and systems and it is required for all engineering students to understand digital systems and computational tools [1]. Introductory digital logic courses are designed to teach the fundamental principles, design techniques, and practical applications of digital circuits [2]. A typical approach is teaching basic principles with standard TTL/CMOS integrated circuits. Then, instruction continues with programmable logic design techniques, high-level hardware description languages, and microcontroller design and programming.

In Peruvian institutions logic design courses typically include data representation, Boolean algebra, transformation and simplification techniques, combinatorial and sequential circuits, finite state machine, technological issues, and occasionally programmable logic and hardware description languages. In order to validate the theory learned in class, students design their logic circuits by using many manual techniques and then they draw schematic logic circuits in order to build digital circuits on a testing board or breadboard. On the breadboard students insert chips and wires to connect the circuits and test their designs. When building the circuit the students usually face an error-prone and time-consuming task because of mechanical and electrical issues such as broken links or damaged chips. Also misconceptions can arise even after completing the course [3].

Many research-based studies [4] recommend effective methods for teaching and learning. For example, it is recommended that the curriculum and instructional objectives are designed to promote higher levels of thinking, and to apply constructivist methods such as project-based learning [5, 6] and inquiry-based learning [7].

Industrial design tools have limitations for educational use because of they require prior knowledge of the topics, and for novice students many software features can be overwhelming.

This paper describes a computer program for building and simulating digital circuits with support for project-based learning by using virtual environments, circuits and instruments. It was designed for an initial course in digital circuits, either in high school or college. This tool allows users to create logic circuits with various types of representations such as schematic diagrams, standard integrated circuits, application-specific integrated circuits (ASIC), programmable logic devices (PLD), and flowcharts. This feature helps students to learn design concepts and methods from several perspectives.

The purpose of the program is to help teachers and students in an introductory logic design course, by providing tools for both virtual manufacturing and virtual testing of digital circuits with their environments. Thus they have more design and experiment opportunities and fewer limitations such as component availability and costs.

The distinctive features of the components of this program, as well as its editing and simulating characteristics, are described in Section 2. Using this application with instructional methods is illustrated in section 3. Experiences in high school and university classrooms are shown in section 4, and the conclusions and future work are stated in section 5.

II. Application Features

This program provides all the essentials for: making circuit diagrams, placing integrated circuits on breadboards, simulating with typical inputs and outputs and for advanced testing in virtual environments.

A. Virtual Laboratory

For making and testing virtual circuits this software provides integrated circuits (chips), breadboards, a DC power source, a timer board, input and output boards, virtual environments, and logic analyzers. By using the mouse chips are inserted into breadboards and all interconnections are made. The program prevents short-circuits and incorrect insertions of chips. The DC power supply provides the power lines (VCC, GND) for integrated circuits and other boards. The timer board provides four timing signals with frequencies of 1, 2, 5 and 10 Hz. Input and output signals are provided by simple switches, debounced pushbuttons, leds, and seven-segment displays. Fig. 1 shows all the interface boards and a chip inserted into a breadboard.

Chip models include standard TTL and CMOS chips, some ASICs, and basic microprocessors and microcontrollers. All chips are modeled without propagation delays. TTL and CMOS chips contain logic gates, adders, multiplexers, flip-flops, ALUs, memories, registers, decoders, etc. ASIC chips include traffic light controllers, chronometers, parking controllers, elevator controllers, radio-alarms, robotic-arm controllers, frequency meters, number guessing games, and others. Microprocessors contain academic and instructive models. Microcontrollers contain programs to illustrate typical interface applications and operations, as adding, selecting, coding, writing, reading, etc.

Virtual environments (scenarios) are environment models for the operation of the circuits. They can operate in standalone mode or interactive mode. In standalone mode, the scenarios show a predefined behavior where users can change directly input conditions and see the responses in order to understand the problem and determine solutions. In interactive mode, the scenarios are handled by circuit signals. Scenarios include crossroads, water tanks, elevators, car parking, robots, and chronometers. Some scenarios help to teach fundamentals of electrical circuits and laws of kinematics. This approach reduces risk, resource usage, design time and overall design cost. For example, Fig. 2 shows a traffic light controller and a crossroad with vehicle sensors; signals of interest are shown in two logic analyzers.

Logic analyzers have nine signal channels and provide two capture modes. In asynchronous mode, all signals are captured when a signal changes on any channel. In synchronous mode, capture occurs with a change of the signal on the last channel.

B. Abstract Representations

The tool includes logic symbols, flowcharts and programmable logic devices (PLD). These elements have propagation delays of 100 milliseconds, which is useful to analyze timing aspects and feedback circuits. Logic symbols comprise logic gates, flip-flops, decoder, multiplexer; programmable functions; function generators; and 4-bit adders, counters, comparators and registers. They can be used to verify logic circuits before designing with chips.

Flowcharts allow high-level descriptions of logic functions using algebraic expressions that can be placed on condition and assignment boxes. They can be used to describe the same logic functions with different logical expressions. These flowcharts can be used to introduce basic concepts about hardware-description languages.

PLD models are represented with their schematic form in order to make connections directly using the mouse. There are a basic programmable logic array (PLA) and a simple programmable logic device (SPLD). Both circuits are useful to illustrate circuit operations and to prototype custom logic functions. Fig. 3 illustrates a full-adder and a 4-bit binary counter. PLDs are useful to introduce programmable logic technologies.

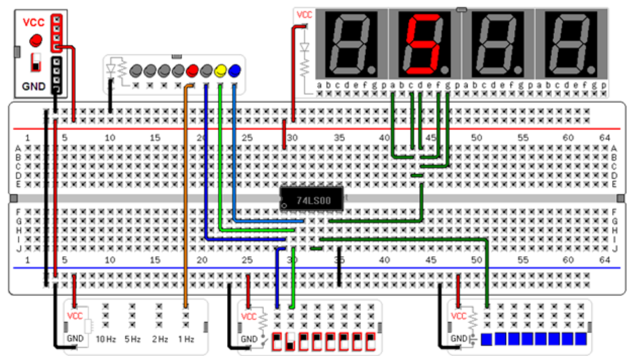

Fig. 1. Main boards and a simple test of an integrated circuit.

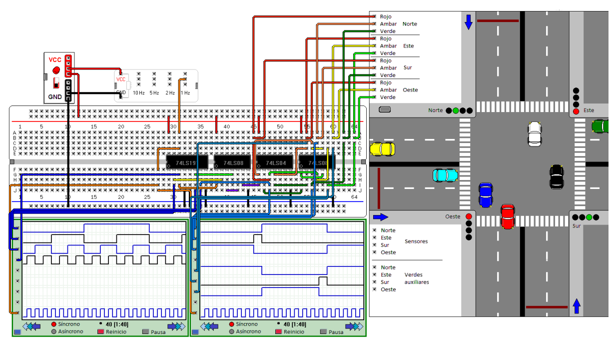

Fig. 2. A cross-road, logic circuit and logic analyzers.

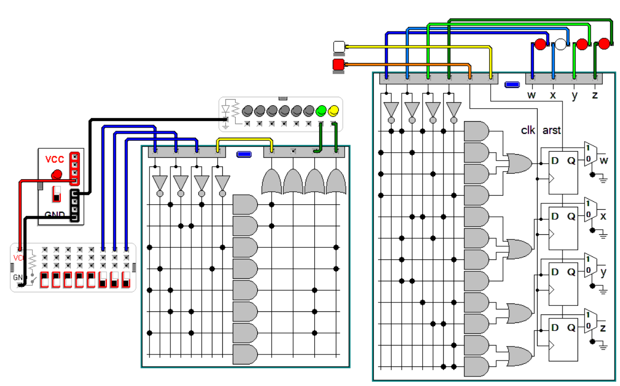

Fig. 3. A PLA-based full-adder and a SPLD-based 4-bit counter.

III. Support for Design and Instructional Methods

Following pedagogical recommendations [4], this program was designed to foster constructive and independent learning by providing multiple circuit representations as well as many analysis and design opportunities. It can be used in universities as well as in high-schools with many design and learning methodologies for custom teaching and learning. Also, this software gives more design opportunities by overcoming logistic and economical limitations.

A. Logic Design in University

A logic design process at university level is illustrated in Fig. 4. White boxes are typical steps for introductory logic circuit courses. By applying transformation techniques schematic circuits are drawn in order to build and test circuits. In a typical lab, students draw the schematic circuit on paper and then they go to the lab. Using this program, many errors and logic mistakes can be noted before going to the lab by building and testing the circuit in the computer, as indicated by green boxes. Blue and green bars show comparisons in design and testing time; students concentrate more time in design, and less in finding mechanical errors.

B. Course Content and Delivery

A custom curriculum is illustrated in Fig. 5. Horizontal cyan bars inside the boxes indicate a relative measure of how this tool can help to learn the concepts and to understand the applications in each item. Instruction starts by analyzing NAND gates and all small-scale integrated circuits, including latches and flip-flops. Concepts such as glitch, universal functions and programmable logic can be introduced in this learning stage. Medium-scale integrated circuits are studied next with counters introduced before adders and then instruction follows with comparators, multiplexers, decoders, and coders. In this analyze phase students practice with more design options and their learning styles can be supported by developing custom tutorials. This constructive approach also serves to know what it is possible to do with logic circuits.

In a design phase state machines and data-paths are studied in order to design practical and more complex circuits such as microprocessors and microcontrollers. In this way students develop a deeper abstract reasoning. Because many industrial circuits are made with programmable logic and hardware description languages by the end of the course all concepts can be revised using computer-aided design tools to show the state-of-the-art in circuit design.

Finally, in the engineering phase students and instructors working as teams bring practical solutions to real problems. As instruction progress students gain more learning responsibilities and instructors can dedicate more time for inquiry and assessment activities. Instructors can prepare customized tutorials to address student learning styles, misconceptions, and curiosity, as illustrated in Fig. 6 for a NAND tutorial. For example, students with global thinking can be trained with more abstract representations (flowcharts, programmable circuits) meanwhile students that favors serial thinking can be addressed by using step-by-step guides, from concrete things (integrated circuits) to abstract circuits (logic symbols).

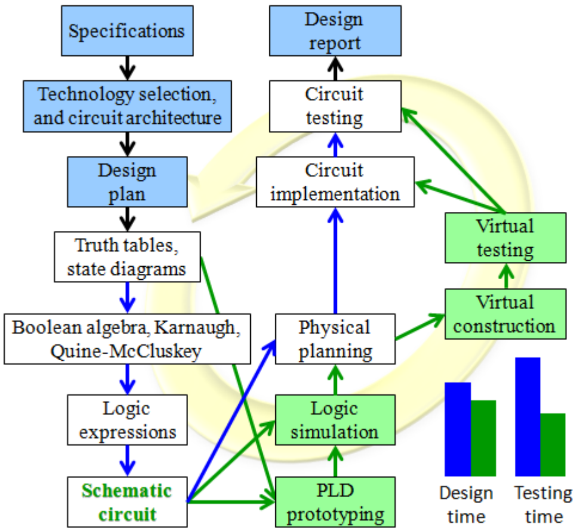

Fig. 4. A logic circuit design methodology.

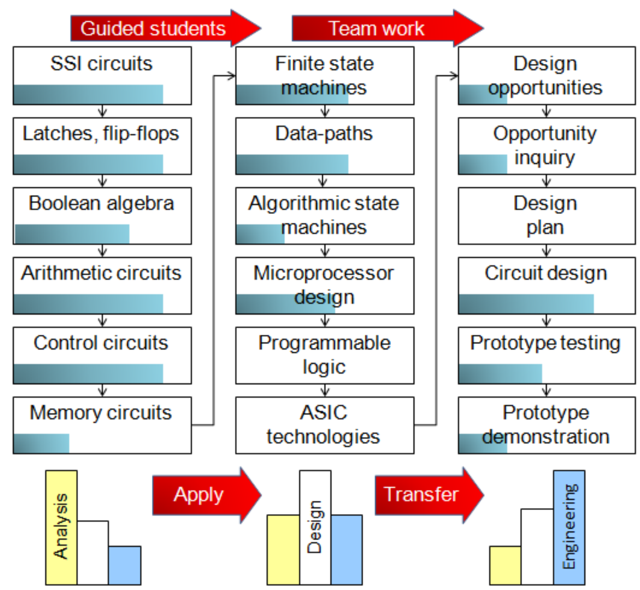

Fig. 5. A logic digital design course content.

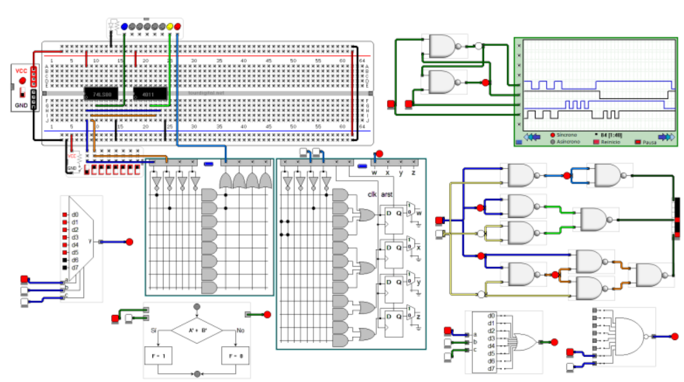

Fig. 6. A tutorial for NAND descriptions and NAND-based circuits.

C. Course Content and Delivery

At high-school this application can be used in inquiry-based learning to foster STEM (science, technology, engineering, mathematics) education. For example, by applying scientific inquiry, students can conduct experiments to discover pattern and basic principles about logic design. These concepts can be reinforced by using Boolean algebra. Engineering design can be applied to make optimal and practical circuits using the component library and virtual environments.

The 5E instructional method [8] can be used to guide the behavior and applications of logic circuits in an introductory class. This method has five phases: engage, explore, explain, elaborate, and evaluate. Fig. 7 and Fig. 8 show how the program can be used for the discovery and design of a NAND-based AND circuit:

1) Engage: Students see many circuits working in real and virtual versions, answer some surveys and post questions about logic design and circuit applications.

2) Explore: Students learn step-by-step how to build and test a NAND circuit on the breadboard, build the circuit in the computer, find output and input logic states and write a truth table for the NAND function. Then the students build the same circuit with real components, test the logic functions and verify each gate in the chip.

3) Explain: Students analyze the NAND truth table, experiment with flowcharts, look for patterns and write pseudocodes. They can use the flow diagrams to validate their circuit descriptions. Next the students prepare oral and written presentations to share their understanding on the matter and post some questions.

4) Elaborate: Students apply their understanding by discovering more NAND circuits and using other integrated circuits with similar functions. They examine a special circuit, deduce the circuit truth table and verify their table by simulation. Next the students think how to connect the new circuit and how to build and simulate the circuit. When the circuit works fine they build up the real circuit and verify it.

5) Evaluate: Students compare their initial understanding about logic circuits with their current achievements and then make plans for new designs.

This process is repeated to analyze a biestable circuit. Students see a video about water supply in the world and explore a water tank with a bomb pump. Then they simulate a NAND-based SR latch using logic symbols and a logic analyzer to see the circuit behavior on the time. Next they adapt this circuit to handle signals from the water tank.

Concluding this lesson, it is expected that students are able to know many basic gates circuit descriptions, understand how build many circuits to do the same functions, apply logic concepts to discover more functions, analyze schematic circuits, identify circuits on breadboards, design circuits to control water supply, evaluate and communicate their results for feedback and valorize their work and learning process.

As students know more functions and techniques, they can design more complex circuits, like the circuit in Fig. 9, where students bring solutions to a practical problem for an optimal use of water and energy. In the process, they learn about seven-segment displays, number systems, coders, and decoders.

In this approach, students can learn about logic design by walking through many ways and by studying circuits according to personal interest but maintaining a common concept core.

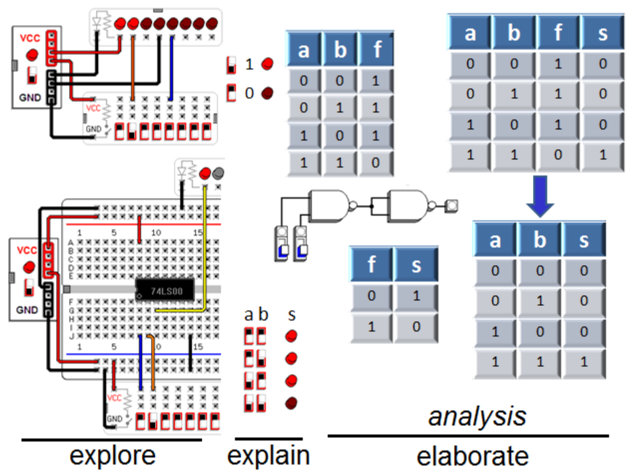

Fig. 7. Discovery and design of an AND function, part I.

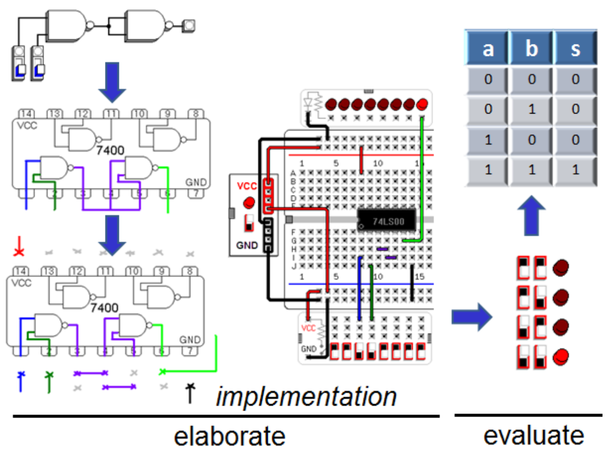

Fig. 8. Discovery and design of an AND function, part II.

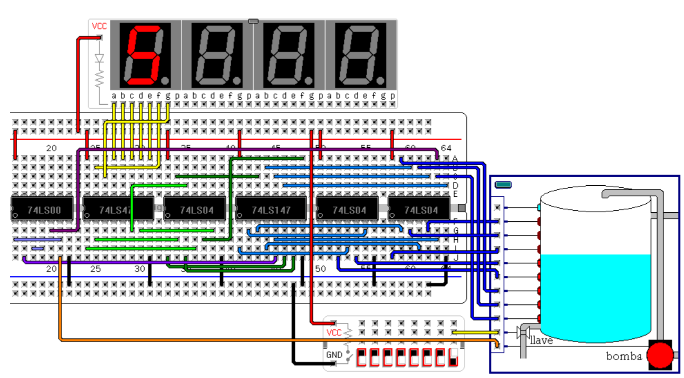

Fig. 9. A water level controller.

D. *Project-Based Learning*

In project-based learning (PjBL) students develop practical solutions to real problems [7]. PjBL begins with a search of design opportunities and concludes with a public presentation and demonstration of the product or prototype. This software can support many stages of the PjBL process for introductory logic design. For example, with teacher-made environments, students can find and analyze opportunities by determining operation conditions and by specifying problem sentences. With the virtual digital module and the breadboard students can simulate their designs and check results and also build and test other design alternatives. With interactive tutorials students can learn special items at their own pace. When the work is ready on the computer students build their circuits in the real world.

Fig. 10 shows a tutorial to aid students in understanding and resolving a kinematics problem. They use a tutorial to learn how gravity acts on falling bodies. Students deduce free-falling and compound laws, and prepare a design to calculate local gravity acceleration. They learn how to choose component values for resistors and other sensors. Fig. 11 shows a 4-stage up-down counter with frequency selector that can be used for kinematics experiments as well as athletics races, person counting, etc.

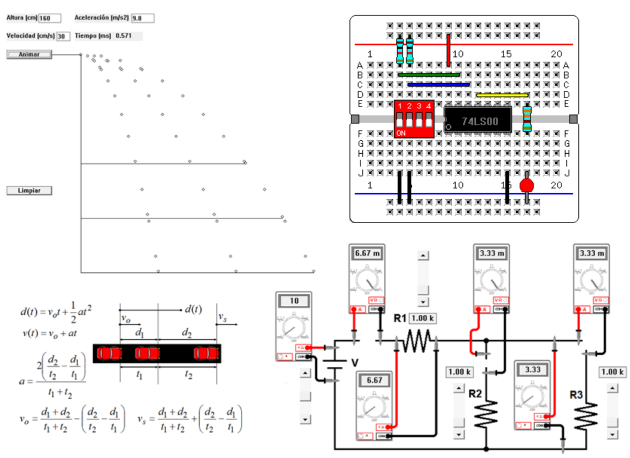

Fig. 10. Tutorials for kinematics and elecrical experiments.

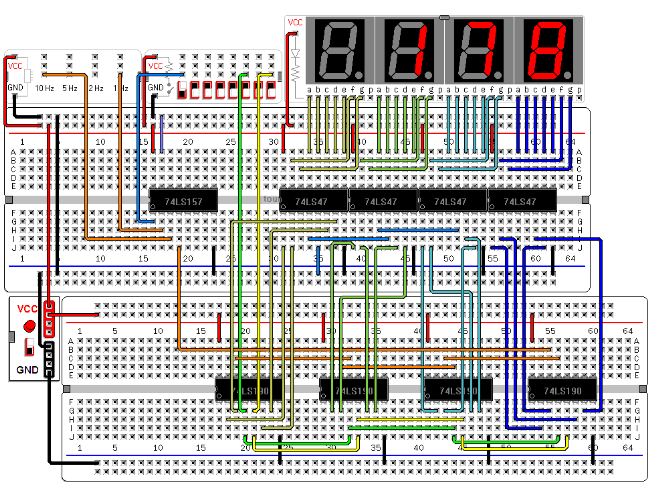

Fig. 11. A chronometer for kinematics experiments.

IV. Users of the Software

We have used this software as a support tool in workshops and lab-based classrooms in Peruvian high schools and universities. A number of extracurricular workshops have been developed at public high school José Pardo y Barreda, in Chincha, Peru. In those workshops students first explored electronic parts and instruments and then learned how to use the computer program. When their simulations worked fine they built the real circuits. The students developed more working applications compared to traditional instruction and a couple of projects won honorary places in national technological and scientific fairs. Fig. 12 shows some pictures from a workshop for instructors and students.

At a public university the students used this tool to learn circuit simulation with standard chips and then used industrial tools to learn about programmable logic devices. At the end of the course students showed their projects and prototypes in a local technology fair. Students at a private university have used the program before going to the lab. In a couple of university workshops the students used this tool to discover circuit properties and analyze logic functions.

Previous versions of this tool have been shared freely in the Internet [9]. The program page appears in the top search results with the Spanish words: *simulador digital, simulador circuitos digitales, enseñanza circuitos digitales*. This tool has been used by many instructors and students from schools and universities in Europe and Latin America. Many comments and observations have helped to improve the software functionality. Some users say:

- "The simulator has been very useful for getting a better understanding of the digital circuits".
- "The program is very helpful before building the circuits on the breadboard".
- "We do not have constant access to the laboratory, but we can experiment at house".
- "If I have had studied with these tools, I would have saved a lot of money."
- "It is a didactic, simple, and practical tool".

Fig. 12. A workshop session at the Jose Pardo y Barrera public school.

V. Conclusion and Future Work

It has been described a computer program for building and simulating digital circuits. The program allows users to create logic circuits with various types of representations such as schematic diagrams, standard integrated circuits, ASICs, programmable logic devices and flowcharts. Besides the typical applications in introductory courses the software facilitates the study of more complex circuits such as state machines, data-paths, microprocessors and microcontrollers.

This tool has special characteristics like delay propagation through symbols and logic analyzers with two capture modes that are useful in analyzing timing issues. The program features help students to reinforce design concepts and methods from several perspectives. While students work with the tool, instructors have time to focus in different teaching topics such as customize their methodologies according to the student learning styles in order to meet instructional outcomes.

The program supports many stages of the inquiry- and project-based learning for introductory logic design and it has been useful for students and instructors in introductory courses of digital logic circuits.

The next version of the program will be designed to support cooperative design on the Internet. Also this tool will incorporate artificial intelligence agents in order to guide students when they are designing circuits.

***Abstract*— This paper presents a model that enables the integration of SCORM packages into web games. It is based on the fact that SCORM packages are prepared to be integrated into Learning Management Systems and to communicate with them. Hence in a similar way they can also be integrated into web games. The application of this model results in the linkage between the Learning Objects inside the package and specific actions or conditions in the game. The educational content will be shown to the players when they perform these actions or the conditions are met. For example, when they need a special weapon they will have to consume the Learning Object to get it. Based on this model we have developed an open source web platform which main aim is to facilitate teachers the creation of educational games. They can select existing SCORM packages or upload their own ones and then select a game template in which the Learning Objects will be integrated. The resulting educational game will be available online. Details about the model and the developed platform are explained in this paper. Also links to the platform and an example of a generated game are provided.**

Keywords— SCORM; Game-Based Learning; Learning Objects

I. Introduction

Many studies show that pupils are more motivated to learn with educational games [1], [2]. They feel more engagement and learn easier. This is mainly because they have grown up with computer games, they feel comfortable using them [3] and even more with the increasing popularity of video games and the spreading of handheld devices such as smartphones and tablets.

Educational video games can be really improved with the introduction of new technologies. But the development costs are very high (even higher if we consider the opportunity costs of developing another kind of video game) and teachers or educational institutions usually cannot afford it. Therefore, teachers usually have to resort to existing games. However, most of them are focused on specific topics and cannot be reused in other academic subjects. The type of educational content used in the game (e.g. video, images or audios) or the content´s language are important parts of the game that need to be adequate for students bearing in mind their context (e.g. age, level, etc.).

On the other hand e-Learning standards such as SCORM (Sharable Content Object Reference Model) [4] are widely used nowadays in Learning Management Systems (LMSs) and Learning Object Repositories (LORs). They offer a good possibility for teachers to easily manage their contents, reuse them or export them from one system to another. Teachers can also create their own resources in these standard formats using different e-Learning authoring tools.

The research presented in this paper aims to build a bridge between both worlds to create adaptive educational video games. Teachers will be able to customize the learning contents inside the games and game developers will be able to create adaptive educational video games in an easier way and following a standard for the integration of the learning contents and the communication with them. Hence the intended audience of this research is the teaching community and the game developers' community.

This research is based on the possibilities that SCORM standard offers. SCORM packages can be integrated into web games the same way they are integrated into a LMS. The Learning Objects (LOs) or activities inside the SCORM package can be shown to the players when certain conditions are met or when they do specific actions. For example, when they need a special weapon they would have to consume a LO to get it. The LOs can communicate with the game the same way that they do with a LMS. For example, a quiz would assess that the pupil have passed it and so he can get an extra life in the game.

The rest of the paper is organized as follows. The next section reviews the state of the art in educational games and the SCORM standard. Section 3 introduces the possibilities of integrating SCORM packages into web games. Section 4 presents the model including its architecture and interface. Section 5 describes the SGAME platform that we have developed following this model. Finally section 6 presents some conclusions and future work.

II. Related Work

According to [5] Game-Based Learning can be defined as "the use of a computer game-based approach to deliver, support, and enhance teaching, learning, assessment, and evaluation". It is a growing trend in recent years. As educational games have potential to improve students' motivation [6], promote self-directed learning [7] and develop social and cognitive skills [8], [9]. In [10] we can find a broad literature review of the educational impacts and outcomes of computer and serious games, where 129 papers were analyzed.

The potential for educators to become involved in the development of educational games is substantial [9]. Interesting initiatives are providing frameworks to develop adaptive educational games, where teachers can create and evaluate their own games and simulations from scratch.

A good example of this can be the game authoring tools provided by e-UCM, a research group from Complutense University of Madrid with several related projects and research lines like Game-Tel [11] and e-Training DS [12]. There are other software tools available that make easier to create computer games, replacing part of the programming by mechanisms in which games are constructed from simple building blocks. Examples are StageCast [13] that is particularly aimed at young kids, the products by ClickTeam [14] or Game Maker [15].

Other initiative to involve educators in the authoring of games is to make it even easier for them introducing game templates. This concept comes from the non-digital world with the *Frame Games* described back in 1980 by [16]. Frame Games are board games which are designed so that they can be filled with arbitrary educational content (for example by putting it on blank playing cards). As an analogy in the digital world, game templates are a certain type of gameplay which can be configured and filled with content by an author [17].

On the other hand e-Learning standards are widely used to package and interact with LOs. One of the most used is SCORM. This standard was created by ADL (Advance Distributed Learning) from the US Department of Defense to promote interoperability, reusability and durability of digital educational contents. SCORM arose as an application profile that integrated several existing standards and specifications from the e-Learning field to simplify their implementation in systems and tools. It acquired the category of technical report by ISO (International Organization for Standardization) in 2009 (ISO/IEC TR 29163).

SCORM is intended to import and export LOs to and from LMSs and LORs. But as it offers a run-time environment to communicate with these LOs it can be used in other contexts. A good example of this kind of use is described in [18].

III. SCORM AND GAMES

As an introduction to the model we present in this section a summary of the SCORM standard and an analysis of the possibilities of integration in games.

A. *Inside SCORM*

SCORM standard has been introduced in the related work section, but now we will summarize the standard to understand the possibilities it offers for the integration of the SCORM packages in other scenarios different from a LMS. SCORM 2004 4th edition is composed of three technical documents that describe different aspects and provide guidelines for the creation and use of these SCORM packages.

- *Content Aggregation Model*: Specifies the structure and format of the file known as manifest and indicates how to tag or label the content (based on the Learning Object Metadata or LOM [19] standard) and how to package the Learning Objects (with IMS Content Packaging). The SCORM package is a zip file containing all the source files with the learning resources and the manifest file. A resource can be a SCO (Shareable Content Object) or an asset. A SCO is a content object that will use the SCORM API (Application Programming Interface) to interact with the Run-Time Environment when it is launched and while it is running. An asset is a content object that will not use the SCORM API but that can still be used for an activity. For example, it might be a text document or an image.
- *Run-Time Environment*: Defines how the contents have to be executed, the data model for SCOs and the way of doing this communication (IEEE 1484.11.2). SCORM specifies both an IEEE standard communication data model (IEEE 1484.11.1 known as CMI model) and a custom data model. The CMI data model contains several categories of data, among others:
    - Completion and success status.
    - Score.
    - Data about various types of interactions and their status including learner responses.
    - Entry and exit status, used to determine how the SCO was launched and how and why the SCO is being terminated.
- *Sequencing and Navigation*: Defines the order in which the content will be presented to the pupil together with the navigation options that are offered. It is based on the IMS Simple Sequencing specification to define flow conditions in the activities.

B. *Possibilities of integration*

According to the Content Aggregation Model a SCORM package is a zip file containing all the resources (SCOs and assets) together with a manifest file. All SCOs and assets inside the SCORM package can be integrated into a website (such as a LMS) so they can be integrated into a web game. In fact there is a required *type* attribute into each resource element of the manifest file to indicate the resource type, but this is always set to *webcontent* by recommendation of the SCORM standard.

Although there are no technological constraints to integrate these resources into web games we can find a huge limitation with the resource learning time. Due to the nature of games they cannot be interrupted for a long time. For example, although a one hour video can be a very good learning resource it should not be integrated into a game.

Fortunately LOM specifies an attribute for this called “typical learning time”. LOM also has other attributes that can be useful to determine if a resource should be integrated or not, those are “duration” (to indicate full duration for videos, audios or animations), “typical age range” and “difficulty”. But if these parameters are not specified in the manifest file the user will be the one in charge of deciding if a resource should be integrated or not.

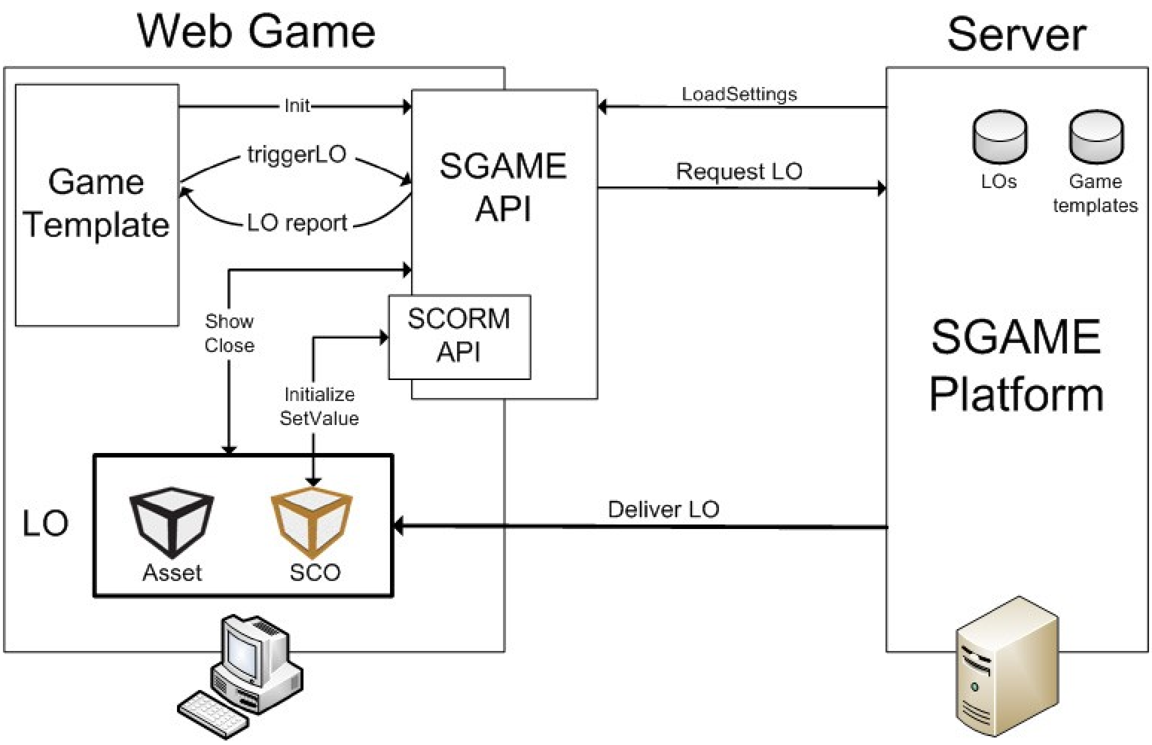

Fig. 1. SGAME Architecture

SCOs communicate their status to the LMS using the Runtime Environment, i.e. the API that SCORM defines for this communication. This status can be a score, a success flag or a completion status among others. By the integration of this API into the game it will be able to get information about the interaction of the player with the learning activity or LO. For instance, if the player answers a quiz correctly the SCO will communicate the success status through the API. The game gets this information assessing that the learning activity has been passed and the game is resumed giving the player a reward like an extra life or a better weapon.

This interface is only used by SCOs. Assets on the other hand do not communicate any status to the LMS so they also will not do it to the game. The game can show the asset but when the player closes it the only information that can be obtained from the interaction is the time period that the asset has been displayed.

Finally although for an LMS it can be very useful, the Sequencing and Navigation part is not useful for the integration into games. The game presents the LOs to the player when the conditions are met or the actions are performed, not in a specific strict order.

IV. SGAME MODEL

In order to allow the integration of SCORM packages into web games we have defined a model called SGAME, which name is the result of the contraction of the words "SCORM" and "GAME".

This model defines the architecture and the API that allow the integration. Both will be explained in this section together with the conventions that a game developer would have to follow in order to create a game compliant with this model.

A. SGAME Architecture

Fig. 1 shows the detailed architecture and interactions between the different components of the model that are carried out for integrating SCORM packages into web games. In the figure we can see the different pieces that take part in the process.

We have already introduced SCORM related concepts but before explaining this figure we should introduce the other ones.

- A *Web Game* (or game instance) is a game composed by a game template and a set of LOs. These web games are presented to the users as conventional games, but they show educational contents under certain events. Therefore, in a specific moment a Web Game can be showing the game to the player or a LO to be consumed.
- *Game Templates* are full games with specific events that may call external LOs to be shown when they are triggered. They use the SGAME API to request them.

Taking a quick look to Fig. 1 we can see two main parts, the SGAME Platform and a Web Game. The SGAME Platform is in the cloud so it can be accessed from anywhere and at any time. It stores the SCORM packages, the game templates and the web games. This server has a very simple functionality, extract the LOs from the SCORM zip files, i.e. SCOs and assets, and create the web games linking these LOs with specific events defined in the game templates. The Web Game runs on the user browser. It includes a Game Template and the SGAME API. It communicates with the SGAME Platform using the SGAME API to request and show the corresponding LOs.

Finally we will use an example to explain the interactions that take place to show a LO when playing one of these games. When a specific event occurs in the game, for example the player opens a chest, the Game Template calls the API to show one LO with the function *triggerLO* passing the identifier or name of the game event as a parameter. The SGAME API will call the platform that will deliver the LO together with its metadata, and it will be shown to the player. In the example a quiz with a couple of questions would appear and the player would have to answer them.

Whenever the player closes the LO the Game Template receives a LO *stats report* with information collected during the LO display time. In the example, the game would receive the number of questions that the student have correctly answered and will give the player 20 coins per each correct answer.

B. SGAME API

The SGAME API is the main contribution of this research. It is the one that enables the integration of SCORM packages into web games, i.e. the one that a game developer would have to use to create an adaptive web game or to edit his/her already developed games in order to convert them to a game template compliant with this model.

This API is quite simple. It only has two methods to communicate with the game template.

- An *Init* method with two options. Firstly a *togglePause* function to stop the game when showing a LO and resume it when the LO is closed. Secondly a *background image* for the display box where the LO is shown, this way the LO seems to be totally integrated in the game. Calling the Init method is not mandatory. It can be omitted if the game handles the pause/resume by itself. However, this way the LO will always appear with the default style, i.e. a white display box.
- A *triggerLO* method with the name or identifier of the game event. This is the main method in the API and will communicate with the SGAME Platform to request a LO and show it. Whenever the player closes the LO the game will receive two parameters: a true/false value called *success* indicating if the player consumed or passed the LO, and a *report* with some statistics about what the player did with the LO. The values will vary depending on the LO being an asset or a SCO:
    - If the LO is an asset the only information that we have about what the player did with the LO is the time spent (*tspent*). So the *success* parameter will follow a very simple algorithm: *true if tspent > tmin*, being *tmin* a percentage of the "typical learning time" if present and a minimum time (that we initially set to 15 seconds) if not. Anyway, the report contains this *tspent* for game developers who want to implement their own algorithm based on this data.
    - If the LO is a SCO it will automatically communicate with the Run-Time Environment that is also included in the SGAME API. Thus it gathers much more information: completion rate, number of attempts, success indicators, etc. In this case the *success* parameter will be extracted from this information and the *report* will contain all the information gathered.

C. Conventions

A game developer who wants to follow this model would have to follow the next conventions when creating games:

- Include an index.html file that launches the game.
- Include a file describing the events that can be linked to the LOs.
- Include the SGAME API.
- Implement a function to pause/resume the game when the LO is shown/closed.

V. SGAME PLATFORM: A CASE STUDY

Following this model we have developed a web platform that we have also called SGAME. In this section we will explain the main functionalities and an example of a generated game.

This platform is open to the public [20] and anyone can use it without registration being needed. In this version we have introduced three game templates. Two are existing games (Sokoban and Onslaught Arena) that are open source and we have modified to use the SGAME API, and another one called Natural Park that we have developed from scratch.

This platform is open source and the repository of the code can be found in GitHub [21]. Anyone can download it and it is open for contributions from the learning or game development communities. Furthermore, all the future works presented at the end of this paper will be also included in this repository.

A. Functionality

SGAME is an online e-Learning authoring tool to create educational web games by customizing the LOs and activities in them. Fig. 2 shows the main page of this platform.

The functionality is quite simple, the user has to choose a game template, some SCORM packages and click on the "create" button. A small form will be displayed to write a name for the created game and add an avatar to recognize it. After this the generated game is shown for the user to try it. The game will be always available in that URL so it can be easily shared. A "gallery" button to access a page with all the created games is also available.

In this screen users can also upload their own SCORM packages. This way they are not limited to use the existing ones.

Finally, there is a button where users will be able to add new game templates the same way as SCORM packages are added, although this functionality has not been implemented yet in the SGAME platform.

Fig. 2. SGAME platform

B. Example

Several examples of generated web games can be found in the SGAME platform gallery. We explain below one game example based on the game template Onslaught Arena.

This game is available online [22]. It is a medieval fantasy game where the user plays the role of a fighter that has to shoot different kind of monsters to get gold and weapons. Each time a player tries to get a new weapon (Fig. 3) a LO is shown (Fig. 4). The player will only obtain the weapon by accomplishing or consuming the LO.

In Fig. 4 we can see that we have also included a semaphore that will show a red, yellow or green light as a feedback for the player. The status of this semaphore depends on the "typical learning time" parameter of the LO metadata or on the information gathered from the Run-Time Environment API if the LO is a SCO. If the player closes the LO before the green light is on, he/she will not get the reward in the game, in this case the weapon. In this figure we can see a quiz where the player has to drag and drop the weapon names to their corresponding pictures. After finishing this learning activity he/she will be able to continue playing.

Fig. 3 Game example

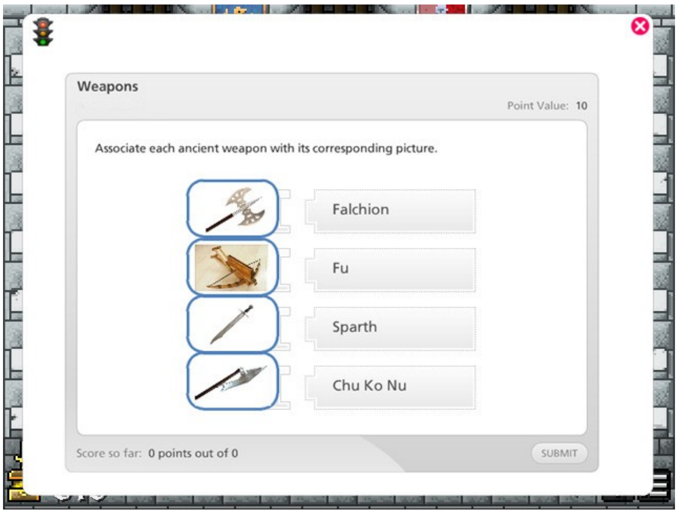

Fig. 4 Quiz shown in the game

VI. Conclusions and Future Work

In this paper we have presented SGAME, a model to integrate SCORM packages into web games. The main piece of this model is the SGAME API that games have to use to allow this integration. This API has been explained together with the model, architecture and interactions that occur when playing one of these generated games.

Following this model and to validate it we have developed an open source web platform (also called SGAME). We have also described it in this paper together with its functionality and an example of a generated game available online.

This model can bring closer the game developers community and the teaching community. The API is quite simple and can be easily integrated into existing web games or in new ones created from scratch. The possibilities that this model offers to the teachers are huge as they can customize games with their own learning content, this way adapting them for their students´ age, language, subjects and areas of interest.

The immediate next step in this research consists of extending the model to other standards such as IMS Common Cartridge. In the platform the next work will be to allow a more flexible integration of the LOs with the events in the game, maybe with a second step in the creation process where the user links each LO with a specific event in the game. Together with this, it would be very interesting to allow the edition of the metadata, as we have seen that the information included is very important. We could for example allow the user to specify the "typical learning time" of each LO inside the SCORM package in case it is not included.

Finally we would like to use the SGAME API in other contexts different than games to allow the integration of SCORM packages in them, for example in Android-iOS native applications.

Acknowledgment

We wish to acknowledge our gratitude and appreciation to all the GLOBAL excursion project partners, and each one of the project team members, for their contribution during the development of various ideas and concepts presented in this paper. We also would like to thank the SAAN project (TIN2010-19138) for funding this work.

An Educational Simulation Model Derived from Academic and Industrial Experiences

Daniela C. C. Peixoto, Rodolfo F. Resende, and Clarindo Isaías P. S. Pádua
Federal University of Minas Gerais, cascini@dcc.ufmg.br, rodolfo@dcc.ufmg.br, clarindo@dcc.ufmg.br

*Abstract***— Simulation games are gaining increased interest among academic researchers and practitioners where conventional teaching approaches are not adequate. In the Software Engineering field, simulation games are commonly used for enhancing the learning and understanding of complex themes such as software processes. This complexity is represented by intrinsic software development characteristics such as multiple feedback loops and cause-effect delays. One fundamental aspect for the development of a simulation game is the definition of its simulation model. A simulation model contains some dynamic features and phenomena of the system it represents. It typically involves a set of assumptions concerning the system operation and it is used to translate the underlying system model, with given inputs, producing its behavior pattern. In this work, we describe an approach to create an educational simulation model derived from academic and industrial experiences. We focus on the systematic activities executed during its development. The created model was applied in a Software Process Improvement simulation game, named SPIAL (*Software Process Improvement Animated Learning Environment*). A set of important issues were identified. Our work can help developers during the creation of simulation games for educational purposes.**

Keywords- simulation model; software engineering; simulation game; software process improvement

I. INTRODUCTION

Over the past years it was observed a movement towards more active and experiential based learning, especially using simulations and games [1]. In the Software Engineering field, we observed that it is very difficult to train students in the real situation of a software development organization, due to the very nature of software applications and the great diversity of organizational cultures. A number of simulation games were developed for enhancing learning and understanding of Software Engineering [2]. The use of simulation games represents a shift from "learning by listening" to "learning by doing" model of teaching [3]. Using simulation games, it is possible to increase students' interest [4]. In addition, the aspects presented within a simulation game can allow the application of concepts learned in the classroom in a more compelling environment [5], [6].

A fundamental aspect for the development of a simulation game is the definition of its simulation model. Simulation models are valuable tools to practitioners because they help them to understand complex issues of the represented system [7]. The Software Engineering concepts are difficult to model, mainly because of their intrinsic characteristics, mostly involving human behavior, such as, non-linear relation of cause and effect, feedback cycles, dynamic behavior and socio-cultural issues that can affect them [8], [9]. A Software Process Simulation Model (SPSM) focuses on a particular software process which can be represented as implemented in the present time or as planned for future [7]. Zhang and others [10] discuss one of the earliest software process simulation modeling in the Software Engineering field - the work of Abdel-Hamid and Madnick [11]. Since then, it has gained increasing interest among academic researchers and practitioners alike as an approach for [7]: strategic management, planning, control and operational management, process improvement, technology adoption, understanding, training and learning.

In this work, we described the activities carried out to design an educational Software Process Improvement Simulation Model (SPISM) based on academic and industrial experiences. This model is intended to raise the students' awareness for the effects and results of improving software development processes. These effects and results can be very difficult to estimate and predict. The created model was applied in a SPI (*Software Process Improvement*) simulation game, named SPIAL (*Software Process Improvement Animated Learning Environment*). SPIAL is a graphical and interactive game-based simulation environment focused on SPI [12], [13], [14]. SPIAL's evaluations suggest that it is a useful complementary approach to teaching or reinforcing SPI and Software Engineering concepts.

Our research result consists in an SPISM that incorporates some industry's process improvement issues and some Software Engineering best practices. Our main research motivation is to support game developers and instructors during the creation and selection of simulation games for educational purposes.

The remainder of this paper is structured as follows. Section 2 outlines the basic concepts of SPSM and a brief description of SPIAL. Section 3 presents an overview of the steps carried out during the simulation model design. Section 4 discusses the lessons learned during SPIAL and its SPISM development and Section 5 presents the final considerations and future work.

II. BACKGROUND

A. *Software Process Simulation Model*

A model is a simplified representation of a real or conceptual complex system [7]. Modeling means capturing and abstracting significant features and characteristics of the system. A simulation model is a computerized model which represents some dynamic features or phenomena of the modeled system

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

[7], [15]. A simulation model typically involves a set of assumptions concerning the operation of the corresponding system [16]. It is used to exercise the represented model with given inputs to observe its pattern of behavior. The simulation is a viable alternative when the costs, risks or logistics of manipulating real systems are prohibitive [7].

The diversity and complexity of software processes have been represented by different modeling approaches. The most widely used techniques in SPSM are **System Dynamics** and **Discrete-event** simulation as a representative for dynamic and discrete simulation categories, respectively. As presented by Zhang and others [10], from 1998 to 2007, 49% of the SPSM researches apply the System Dynamics paradigm and 31% Discrete-event simulation. The **System Dynamics** models represent the system as 'flows' (e.g. error generation rate) that accumulate in various 'levels' (e.g. the current number of errors). The flows can be dynamic functions or the consequence of other variables. As the time advance, in small spaced increments, the levels and the flow rates are changed [17]. Its focus is not on specific individuals or events, but on patterns of behavior and on average individuals in a population [18]. The **Discrete-event** model is efficient when the process is viewed as a sequence of activities. It is often used to represent entities with unique values for attributes (e.g. error rates or the impact of different programmer capabilities) [17].

The different aspects of software development projects need both mechanisms in order to be suitably simulated. For instance, the duration and effort of activities are rarely predicted without some uncertainty, and the size of artifacts or programmers experience may differ. In addition, several aspects vary over time, for example, the schedule pressures and programmer's fatigue. SPIAL's SPISM can represent both types of simulation approaches. It models the activities of a software development organization and also its dynamic environment.

B. SPIAL

SPIAL is a graphical, interactive, and adaptable simulation game [12], [13], [14] (Figure 1). The game goal is to improve the Software Engineering learning, using simulation. Several Software Engineering topics are explored within the context of Software Process Improvement project. These aspects were based on CMMI-DEV version 1.3 [19]. CMMI was chosen because it is the most widely known SPI reference model. CMMI defines 22 process areas. Each process area consists of a set of goals and these must be implemented by a set of related practices in order to satisfy the process area. Levels in CMMI describe an evolutionary path recommended for an organization to improve the processes it uses. CMMI supports two paths (or defines two forms of representation) using levels. One path, **continuous**, enables a selection of process areas customized to the organization goals. The other path, **staged**, enables the improvement of a set of related processes by incrementally addressing successive sets of process areas [19]. **Continuous representation** is defined using capability levels while **Staged representation** is defined using maturity levels. In SPIAL the simulation model can be tailored to simulate continuous or staged improvements.

SPIAL was developed with the goal to provide students with a more realistic experience in software development processes within the academic environment**.** SPIAL allows students to practice SPI techniques and the best practices of Software Engineering. SPIAL is a single-player game in which player takes on the role of a manager of an SPI group in a software development organization. SPIAL's scope covers both a development project and an improvement project. The player is given a process improvement task and he or she can interact with other stakeholders (high level management, project manager, team member, consultant, or customer) represented as non-player characters, i.e. a character controlled by the computer (see Figure 1). The type of improvement that is required is stated at the beginning of the game and it can include, for example, reduce defects, improve the productivity, and reduce costs. In order to complete the task, the player can make investments for improving specific process areas of a software development project. A good investment strategy will result in improvement of process areas and a bigger budget for further investments. The player can visualize project estimations, indications of process areas capability level and decide in which process area to invest. During the development project, the player can visualize the effects of his/her selections on the outcomes (productivity, defect, cost, and time-to-market measures) and, if needed, change his/her investments. The final outcome is a score that represents how close the results are to the initial proposed target. During the game, the non-player characters communicate the effects of the player's actions through bubbles over their heads.

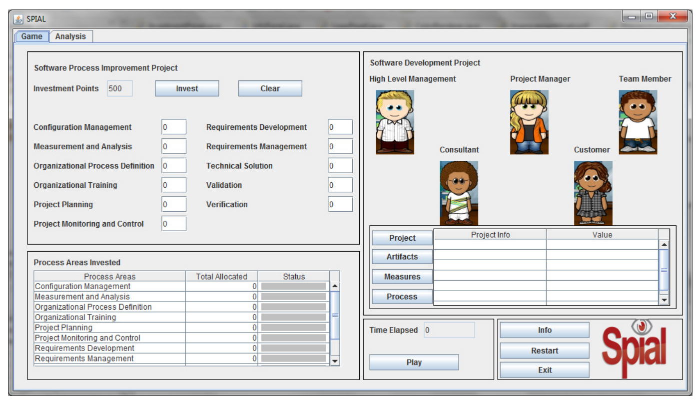

Figure 1. SPIAL Graphical User Interface.

III. SPIAL'S SPISM DESIGN STEPS

SPIAL's simulation model is interactive. It allows to build and enhance the comprehension of how complex development process and improvement program behave by experimenting and "playing" with different scenarios. In the course of SPIAL's SPISM design we adopted an incremental and iterative process, comprising the following activities:

A. Conceptual Representation

The set of concepts to be covered by the game should be defined according to the students' needs and the instructors' teaching objectives. It is not possible to address all the content of an introductory Software Engineering course. Our first task involved the organization of the conceptual content to be represented in the simulation model. The conceptual content was designed around SPI, Software Engineering rules, and Software Engineering processes explained ahead.

We investigated the domain of our simulation game. Since a simulation game should reflect what happens in the real world, we analyzed the main results reported by organizations in research papers regarding their SPI initiatives [12]. Through a systematic literature review [20], we gained an up-to-date view of the SPI area, allowing us to identify and characterize the actual results of SPI initiatives. In the SPIAL context, the results of this study provided the basis for the simulation model and requirements definition. We assessed 91 studies related to the results of SPI efforts [12]. Most of the data came from large companies which are mainly focused on improving their management project processes, requirement engineering processes, software review processes, and establishing organizational level processes. This encompasses mainly process areas of maturity levels 2 and 3 of CMMI. Considering all types of organizations, CMM/CMMI is the most frequently used improvement models. We observed that SPI initiatives do not bring "dramatic" changes (the works report improvements between 5 and 35%), and the main common reasons for launching SPI efforts are the reduction of the defect rates detected during development and after delivery, the improvement of productivity, the reduction of time-to-market, i.e. the time needed to deliver the product, and costs. A considerable percentage of data originated from interviews, observations or questionnaires revealing that most of the organizations have difficulties to measure and analyze their improvement quantitatively. Additionally, the studies have limitations in terms of rigor, credibility, and validity in their findings. They do not provide enough information about the software development organization context and the correlation between the process improvement and the effects in the organization environment. This lack of information prevented us of producing a better assessment.

As a result of this literature review, we adopted the latest version of the CMMI-DEV model as the subjacent theoretical background of our simulation model. This reference model guided the definition and validation of the mathematical framework represented in our simulation model. We observed that it would be impractical to represent all CMMI concepts in a simulation game. Therefore, we selected a subset of them to support our research hypothesis for improving student's Software Engineering knowledge. Based on the main results of the literature review, in the first SPIAL version, we considered an organization with maturity level 2 and an incomplete 3, with capability levels of process areas varying between 0 and 3. The player can invest on a set of 11 processes areas (level 2 and 3 process areas), making investments for improving specific process areas of a software development project.

In order to make our simulation model closer to what happens in development organizations, we also collected studies discussing software practitioner's motivators and de-motivators factors for SPI [21], [22]. This information was collected directly from software companies and represented in the simulation model. Examples include: The team is resistant to the change (to give up learned habits), the staff is committed with the change, and customer pressures is working as a barrier to process improvement.

In addition to SPI concepts and factors, we also collected 123 Software Engineering rules from text books [23], [24], and from other Software Engineering simulation games [5], [6]. Our goal with SPIAL was also to teach some best practices of Software Engineering area to students. The rules provide ways to reward and penalize students' actions during the game. This set of 123 rules includes rules that are imprecise (do not specify values) and rules beyond the Software Engineering area, including a wider range of business processes ones. For each rule, we mapped related measures and process areas. From this set, we selected the ones related to the SPIAL process areas, resulting in 57 Software Engineering rules. Three examples of rules and their mapping are:

Requirements deficiencies are the prime source of project failures. [23], [25] **Process area**: Requirement Development **Measure**: Defects.

Matching the tasks to the skills and motivation of the people available increases productivity. [5] **Process Area:** Project Planning **Measure**: Productivity

Rigorous inspections can remove up to 90 percent of errors from a software product before the first test case is run [24]. **Process Area:** Verification **Measure**: Defect

We also represented concepts of software development process in the simulation model. The software process works as the glue that ties coherently all the other concepts together. The simulation game play happens during the development of a software project that follows the prescribed process. The player can make investments for improving specific process areas and also observe their effects. In SPIAL first version, we modeled the Waterfall development process, with requirement, design, implementation, and test phases. The measures employed to evaluate whether the process has improved were defect, cost, productivity and time-to-market (see Figure 2). All these concepts and their relations were represented in a specific mathematical framework described in the next section.

B. Mathematical Framework Definition

Several techniques can be applied for the construction of a model. The SPIAL's SPISM was inspired by the mathematical model proposed by Birkhölzer and others [26]. The aim of their model is to provide an environment where the user, acting as a top-level manager, can interactively change the investments in the level of a software development organization, improving his/her understanding of the SPI results. It was developed following a top-down approach, considering 15 process areas of CMMI as states, and deriving 27 business measures from the company strategic goals (in their study at Siemens) [27]. The inputs are the investments that the user can make in each process area and the outcomes are the real value of the business measures. The simulation model focuses on the organizational level abstracting the specific aspects of software production processes.

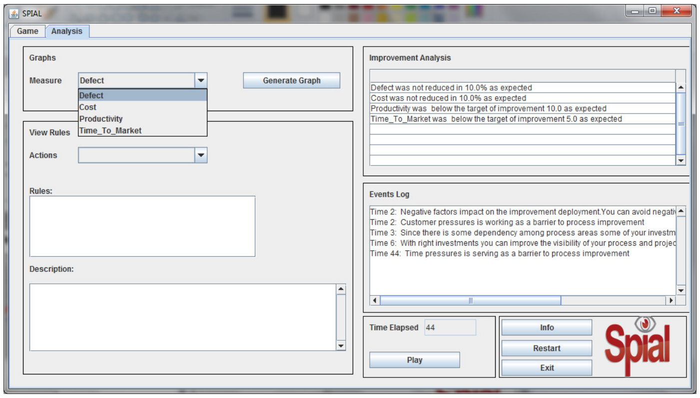

Figure 2. SPIAL Analysis Tab sheet.

The items listed below described the motivation to apply this mathematical framework:

- The original framework represents the overall direct and indirect effects of an SPI initiative. These effects can be very difficult to estimate and predict;
- The original framework integrates business measures that can be used as performance and informative feedback during the whole simulation game; and
- It seems that the original framework can be adapted to other SPI reference models, since the prerequisite to apply it is to have a simulation model with process areas characterized by capability levels.

We promoted some changes that turned the model more suitable to an educational environment. The reasons to adapt this model are:

- Besides the organizational-level, we simulate aspects of the project-level improvements, abstracting specific issues that have been extensively exploited by other Software Engineering simulation games (e.g. the project planning task).
- This framework has ten configurable parameters that constitute a considerable burden in populating the model with adequate values for them [26]. In its original application, these values were estimated by experts and turned out to be a tedious work. This could be a de-motivation factor for instructors and we tried to avoid this problem reducing the number of configurable parameters.
- We included Software Engineering rules and SPI motivators and de-motivators factors into the simulation model.
- In order to facilitate the students' evaluation of the causes and effects of their choices, we did not include advanced concepts in the initial version of SPIAL.

The SPIAL mathematical framework for such a model is a linear, time-discrete, state-space model (these categories are discussed by Pearson [28], and Kitagawa [29]):

$$\vec{x}_{t+1} = \vec{f}(\vec{x}_t, \vec{z}_t) \quad (1)$$

$$\vec{y}_{t+1} = \vec{h}(\vec{x}_{t+1}) \quad (2)$$

$$t \in \mathbb{N}, \vec{x} \in \mathbb{R}^n, \vec{z} \in \mathbb{R}^m, \vec{y} \in \mathbb{R}^p$$

Where t denotes the discrete time between each player interaction, $\bar{x}_t = (x_{1,t}, \ldots, x_{n,t})$ denotes the n-tuple of the internal state variables, $\bar{z}_t = (z_{1,t}, \ldots, z_{m,t})$ denotes the m-tuple of input variables, $\bar{y}_t = (y_{1,t}, \ldots, y_{p,t})$ denotes the p-tuple of the output variables, f and h denote functions that relate subsequent states.

In this model, the internal state variables represent the capability levels of the process areas of CMMI and the output variables correspond to measures that should be used by players to evaluate process improvement results, for example, productivity and cost.

The dynamic behavior of the model is described by the following equations:

$$x_{i,t+d_i} = level(y_{i,t} \cdot (1 + p_{i,t})), i = 1, \ldots, n \quad (3)$$

$$p_{i,t} = \sum_j \beta_{ij} \cdot x_{j,t} + \sum_j \gamma_{ij} \cdot x_{j,t} \quad (4)$$

with

$$level(arg) = \begin{cases} x_{i,t} + 1 & \text{if } arg \geq c_i \cdot d_i \\ x_{i,t} & \text{if } arg < c_i \cdot d_i \\ x_{i,t} - 1 & \text{if no investment is made during 100 clock ticks} \end{cases} \quad (5)$$

$$d_i = \alpha_i \cdot g_i \quad (6)$$

$$\alpha_i = \frac{\sum \mu_i \cdot \rho_i}{\sum \mu_i} \quad (7)$$

In equations (3) and (4) the term $p_{i,t}$ consists of the feedback from the other states. In SPIAL, 11 process areas are mapped with their dependencies (prerequisites process areas) and impacts according to CMMI. For example, the process area *Project Monitoring and Control* (PMC) depends on process area *Project Planning* (PP). Therefore, if PP is at capability level 0, investments in process area PMC will be quite ineffective. In the same way, improvements in process area *Measurement and Analysis* (MA) impacts positively on process area PMC, i.e., with higher capability levels of MA will ease the improvement of PMC. The effects of improvements can only be observed after a delay d_i period. We modeled the delay as a term affected by the motivators and de-motivators factors for SPI [21], [22], α_i, and by a predefined delay for each process area g_i. In α_i equation, the μ_i term represents the impact of a factor and ρ_i term is the probability of its occurrence. For values of α_i lower than zero, the state can react fast on changes, in contrast with values greater than zero where reaction is slower.

The *level(.)* function represents the capability level of each process area. Investments greater or equal than the cost of improvement needed during the improvement time $t + d_i$, will increase the process area capability level. We also modeled a decreasing of the capability level, after a predetermined simulation time without investments. In equation (4), β_{ij} and γ_{ij} serve as weights for the influence (dependence and impact) of the j-th process area on the i-th process area.

The actual value of each measure (the output) is calculated as a linear mathematical function.

$$y_{i,t} = mat(\sum_j \delta_j \cdot x_{j,t}) \qquad (8)$$

where δ_j denotes the weight of each process area on the measure value, which was derived from the Software Engineering rules. One *mat(.)* function was defined for each measure. For each time step, these functions are calculated based on the influence among the process areas and the impact of the motivators and de-motivators factors on the investments results.

The player operates with a budget A_t of investments points, which is characterized by the equation below:

$$A_{t+1} = A_t + \sum_{i=1}^{p} \theta_i \cdot x_{i,t+1} - \sum_{i=1}^{m} z_{i,t} \qquad (9)$$

Investment points are the amount necessary to maintain (or improve) a capability level of a process area. The budget of investment points consists of the previous balance, A_t, the previous investment, $z_{i,t}$, and the weighted sum of the internal states, $x_{i,t+1}$.

Therefore, making right investments will increase the budget of investment points and wrong investment will decrease this budget.

C. Simulation Model deployment

The simulation model represents aspects of the world to be simulated. The applicability of a simulation model depends on the model builder's ability to capture these aspects [30].

We decided to use an XML file to represent the SPIAL's SPISM. Editing the XML file, instructors can tailor a simulation model according to their course. This model allows the representation of: (i) an active role for players, e.g. as a project manager they can hire or fire employees; (ii) reaction to events; (iii) feedback and (iv) different participants to actions. We used some modeling constructs similar to those defined by SimSE [5]. Three SPIAL's SPISM elements are shown below followed by a corresponding XML excerpt. A complete list of these elements can be found in Peixoto and others [14].

Object types: The object types define the templates for all the objects. The object type consists of a name, a boolean value indicating whether a log will be generated for each object, and a set of attributes. For each attribute, its name, type, and two boolean values can be defined. The boolean values indicate the visibility of the object (i) during the game and (ii) at the end of the game. Unlike SimSE, there is no object type creation restriction.

```
<type name="ImprovementProject" log = "false">
<attribute name="InvestmentPoints" type="integer" visible = "true" visible-end="true"/>
</type>
```

Initial state: The initial state contains a set of objects that are active at the beginning of the simulation. Each object is an instantiation of a given object type, containing initial values for their attributes.

```
<object name="IProject" type="ImprovementProject">
<attribute-value name ="InvestmentPoints">500</attribute-value>
</object>
```

Rule(s): Rules specify the effects of the execution of an action. They modify the objects attributes that participated in the action. Each rule identifies the time of its execution, which can be: trigger, destroyer, or continuous. Trigger rules will be executed at the time the action is triggered. Destroyer rules will be executed when the action is destroyed. Continuous rules, on the other hand, will be fired every clock tick, representing continuous behaviors of the model. Rules also specify the order they will be executed in the "priority" parameter.

```
<rule name="investmentRule" description="Investment made in some process area" timing="trigger" priority="3" class="br.ufmg.dcc.engsoft.spial.rule.RuleDiscreteInvest"/>
```

The simulation game behaviors were implemented using Java classes. These classes must be referenced in the simulation model XML file. When the simulator parses these classes' names in the simulation model, it learns which classes should be instantiated in the Java code.

D. Model Calibration

One important issue for obtaining an effective and efficient simulation game is populating the model with suitable quantitative data. There is a considerable work in populating simulation models. The designers need to find data according to the simulation game domain. Also, this data should be suitable for an educational environment.

Despite all simplifications that we made in the simulation model design, still there were important issues in SPIAL calibration. One first barrier for the calibration of our model was the lack of specific values for the Software Engineering rules. Since most of these rules are quite imprecise, it is not possible to map them directly into the simulation model. In addition, most of the SPI industrial studies reported only qualitative evaluations. When the quantitative evaluations were available, the information was limited, or with validation problems, preventing their application in our model.

Since most of the parameters could not be deduced from the literature data, they were estimated for their initial usage.

The criteria to find a good parameter value corresponds to the ability of the model to reproduce a situation close to the ones presented in the industry; and its ability to allow students to understand its intrinsic behavior. We incorporated rules and SPI results by experimenting them with different values and we selected the values that were most suitable for an educational environment. We made sure that the real system is approximated sufficiently well by the simulation model and students would be able to check the effects of their actions.

E. Model Validation

The last activity was the validation of the model. We not only checked the simulation model but we also validated the simulation game results. Inspections and experiments were carried out.

First, an inspection was conducted by a specialist and communicability breakdowns were identified and corrected. This inspection applies an interpretative and qualitative method of the Semiotic Engineering domain [31]. The focus is on the analysis of how a software designer communicates with a user through the software's interface. According to the specialist, despite feedbacks given during the whole game, such as measurement charts and improvement analyses, important aspects to understand the core behavior were missing, such as the reason why sometimes investments do not produce any improvement. Then, experts in Software Engineering and SPI also inspected SPIAL. In their opinion, the game interface could be improved in a next release, but its behavior was acceptable for the inspected version, which covered an introductory Software Engineering course.

The educational aspects were verified in a pilot experiment. The aspects addressed in the experiment included the capability of students to understand, remember and apply Software Engineering concepts in the context of a CMMI based SPI initiative and students' impressions of the game. Our evaluation suggests that SPIAL is a useful complementary approach to teaching SPI and Software Engineering concepts. Students found it quite enjoyable, and they had fun during the game play. They learned new concepts and reinforced concepts taught in Software Engineering course [12], [13].

IV. LESSONS LEARNED

The following lessons were learned during the incremental and iterative development process employed for the creation of SPIAL and its SPISM.

A. Definition of simulation model concepts

Clear simulation model concepts make more realistic the expectation about the modeling results. Model builders are expected to have a deep understanding of the benefits, the results, and the educational goals of the simulation model.

The lesson learned is that sufficient time should be spent in the beginning of the modeling to understand all the basic concepts to be covered by the simulation game. These concepts should be coherently identified according to the modeling goals and the educational expectations. The model builder needs to be realistic and accepts that a simulation model can't represent all the issues about the reality of a software organization.

B. Identification of a reference framework

It seems to be difficult to find a suitable reference framework for the simulation model development. Starting a model development project without a well-defined reference model, has a high probability of undesired consequences. The definition of a reference model works as the subjacent theoretical background, helping in the model development and validation. The reference framework helps to clarify what kind of results the students can expect, the information that is required to be learned about certain area, the identification of relationships among the concepts, and the type of measures that can be used.

The lesson learned is the importance of having a core theoretical reference model in order to assist the simulation model definition and validation. During the preparation of experiments, this model can support the questions definition.

C. Decision of the model size

The more details are included in a model, the more difficult is the comprehension of the relationships and the model calibration. This is especially true for students that are not experts at the modeled subject. A suitable simulation model tries to represent a minimal set of variables that are sufficient to generate behavior closer to the realistic system. Too many parameters may prove to be an unpleasant work for populating the model with adequate values.

The lesson learned is that a simpler model for an introductory Software Engineering course is better than a complicated one, which would be difficult to model and validate. The validation is an important step for the simulation model development. Therefore, it is more efficient to model and validate small parts of the behavior and then integrate them.

V. CONCLUSION

This work presented the activities carried out during the design of a SPISM. The design comprised five steps: (1) Conceptual representation; (2) Mathematical framework definition; (3) Simulation model deployment; (4) Model calibration; and (5) Model validation.

Our experience with SPIAL's SPISM has highlighted some important aspects that can be used to enhance the field of Software Engineering education and simulation game development. The most concrete result is the SPI simulation model itself. The other results are the activities carried out and the lessons learned during the model development.

Although no rigorous empirical validation has been done, the simulation verifications carried out were in agreement with expectations of experts and students. SPIAL's SPISM reflects industrial aspects of a software development organization in a comprehensible manner.

We believe that simulation can provide strong support for teaching different type of disciplines, such as SPI. Unfortunately, no simulation model can replicate the world exactly, and predict the future with certainty. However, much of the students' guesswork can be reduced with this technology, forcing them thinking in a quantitative way.

As a future work, other phenomena that happen in the real world will be incorporated in the simulation model. This will provide to students experiences that resemble more closely those in industry. We will also carry out additional experiments in order to assess the simulation model results; for example, comparing them with an industrial grade SPI simulation model, validating SPIAL's SPISM with professor, developer and other roles, and comparing with other traditional educational approaches (e.g. reading from a textbook or hearing lectures).

***Abstract*—Game-based learning is to present the instruction by games in learning, with the main purpose of triggering learners' motives instead of instructing the courses. Thus, increasing learning motive by game-based learning becomes a common instructional strategy to enhance learning achievement. However, it is not easy to design interesting games combined with courses. In 2011, Echeverria proposed a design to combine characteristics of games with elements of courses by matching the virtual scenarios in games with proper courses. However, in the past game-based learning, students were gathered in regular places for several times of game-based learning. Students' learning was limited by time and space. Therefore, for students' game-based learning at any time and in any places, based on theories of design elements of online community game Aki Järvinen, this study treats Facebook as the platform of games. The development by online community game is easier, faster and cheaper than traditional video games. In 2006, Facebook allowed API program of the third party. Therefore, by Facebook, this study provides the platform for students to learn in social lives to explore students' activities in online community games. Questionnaire survey is conducted to find out if the design of non-single user game is attractive for students to participate in game-based learning.**

Keywords—Social Network game, Facebook, game-based learning.

I. Introduction

Game-based learning has been proven to be a kind of learning method that allows students to organize knowledge through the game content in the game process and in turn elevate learning motivation [1]. Compared to traditional education in which students passively receive knowledge, game-based learning allows students to actively participate in game activities [2], which not only strengthens but also maintains student learning motivation, making them willing to spend time on learning [3]. However, in view of the fact that it is not easy to design a system that combines game elements and course content, Echeverria proposed the design method for course knowledge systems, combining game elements and course knowledge. The fictional story of the story or the interaction with fictional characters corresponds to suitable course content, in turn combining the course and the game [4]. However, since traditional game-based learning tends to cause temporal and spatial constraints for students, in order to break through these constraints, so that students can conduct game-based learning at any time and place, this study uses Aki Järvinen's theory of social network game design elements as the basis to create the game in Facebook [5]. Other than using the 2006 feature of Facebook that permits third party development of apps, at the same time the development of social network games is relatively simpler than traditional video games, as well as faster and cheaper. Facebook provides a platform for students to learn as they socialize, and this is used to explore the activity process of students in social network games, further using questionnaires to explore whether the design of social network games can attract students to conduct game-based learning. In order to understand the gaming intentions of students, this study also uses SPSS to conduct reliability and validity testing on questionnaire questions, in hopes of understanding how social network games affect the learning intentions of students.

II. RELATED WORK

A. *Design of social network games*

Traditional game design usually focuses on game content and rules, but the design of social network games includes the element of interaction with friends, so interactive mechanisms are an important part of design for social network games. Thus, in social network game design, Aki Järvinen proposed five important design points [5]: symbolic physicality, spontaneity, inherent sociability, narratively and asynchronicity.

III. SOCIAL NETWORK GAME LEARNING SYSTEM

In order to establish the "social network games learning system" on the basis of curricular elements, and at the same time strengthen student impression of course content, the adventure game element is added. Students can engage in adventure and exploration to solve every question in the game step by step. Based on this, the story focus of the game will be on island exploration. When the user first signs into the system, he is asked to name his pet, and when the name is decided, the game begins.

The story of the game begins on a deserted island. The user's pet was abandoned and drifted to this island. The user needs to bring his pet to explore this unknown island, and try to survive under difficult circumstances. The detailed functions and processes of the game are as follows:

Finally, complete content and organizational editing before formatting. Please take note of the following items when proofreading spelling and grammar:

- Explore the island

To enable students to become more familiar with the course content through the game, this study uses the instructional materials conceptual diagram for operating systems. The sequence of concepts allows students to gradually increase their familiarity with concepts, but also allows them to use the conceptual diagram to enhance concepts they are less familiar with in the learning process. The areas on the deserted island are the different concepts on operating systems, and arrows are used to guide students in gradually finishing island exploration (based on the conceptual sequence in the conceptual diagram, answer the questions in each concept). However, since game design begins with the concept, before the game begins students still must understand the knowledge and principles of the concepts in order to explore the island with their pets. In order to give pets greater ability differences, the system design involves money and experience points (regardless of accuracy) from exploring the island, and when an area is successfully explored (with correct answers), they can also gain OS points. Student will be able to use OS points to trade for feed that can greatly increase pet abilities, and increase the probability of success in fights. However, if they do not successfully explore the region (with incorrect answers), other than being unable to proceed to the next unknown realm, they are also unable to gain OS points. Thus, these game mechanisms can stimulate students in wanting to defeat others in challenges, elevating the number of times one can successfully explore the island, ad can also enhance student familiarity with concepts.

- Feeding pets

Feed is the key to determining pet ability and characteristics. If the pets are not fed, it would increase the probability of failure when fighting wild animals on the island, so students must take note of the stomach fullness of their pets. However, in order to prevent students from feeding pets without restriction, the system only permits students to buy feed by answering the questions correctly to earn money to buy feed. The system also sets limits on the fullness of pets, students must return online to take note of the fullness value, feeding them at appropriate times to maintain pet movement. In addition, in order to elevate the fun of the game, so students can feel that their pet is unique, so the feed types will be diversified, and students can give pets different types of feed to improve different abilities. At the same time, when the pets reach certain levels, the preferences of feed would also determine how they develop.

IV. EXPERIMENTAL PROCEDURE

The experiment course is the 2012 Operating Systems, the course content used are the first three chapters on operating systems, which are "introduction to operating systems," "computer system structure," and "operating system structure." The purpose is to analyze whether the course knowledge system on social networking platform Facebook affects student learning motivation. The experiment is divided into four steps. The first step is the pretest motivation questionnaire, used to find out student learning motivation before conducting the course knowledge system. The second step is the game-based learning. The third step is the posttest learning motivation questionnaire; pretest and posttest learning motivation questionnaires are compared to analyze changes in student learning motivation after the course knowledge system. The fourth step is the game questionnaire, to find out more about student views toward social network games.

V. QUESTIONNAIRE ANALYSIS

98 students participated in this experiment, and 98 questionnaires were retrieved. Analysis is conducted after retrieval. Questionnaire evaluation is conducted using principal component analysis in SPSS. KMO measure of sampling adequacy and Bartlett test of sphericity are first conducted. The KMO value is 0.935, the Bartlett test of sphericity value is 1750.249, and significance is 0.000, which means that this data can undergo factor analysis.

Statistical testing involves using principal component factor analysis to extract common factors. The number of factors is determined by eigenvalues greater than 1 as the standard for extraction. The result is one single principal element, with accumulated explained variance of 69.501%, which means that the principal component analysis can explain 69.501% of the raw data .935 Bartlett test of sphericity Close to chi-square distribution 1750.249 Degree of freedom 105 Significance .000

Factor analysis shows that each question in the game questionnaire fall into the same dimension, and the corresponding factor loading of each question is greater than 0.6, which shows that it has good construct validity.

After validity analysis, this study uses Cronbach's α to conduct reliability analysis for internal consistency. The Cronbach's α coefficient is 0.956, since it is over 0.700, it means that the 15 questions in the game questionnaire have homogeneity, meaning this scale has reliable consistency.

VI. EXPERIMENTAL RESULT

The means show that in the posttest stage, learning motivation has a rising trend. In addition, the bar graph of pretest and posttest motivation questionnaire distributed among the students in Fig. 2 shows that after social network game-based learning, their learning motivation increased.

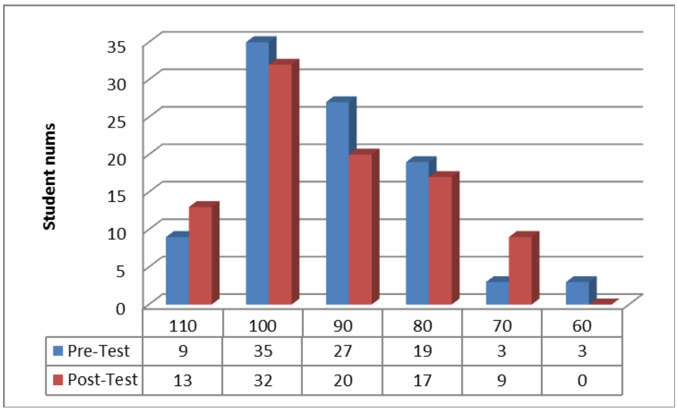

Fig. 1. pretest and posttest motivation questionnaire distributed among the students

The result of students filling out the game questionnaire, from which 98 valid questionnaires were collected. Results show that students approved the images, animation, and sound effects of the social network game, but there are still students who said they would be more attracted to complete the game if the game screens could be improved upon. In terms of game interaction, students believe that winning in fights in island exploration makes them happy, but still hope for improvements in interaction, and also hope to increase interaction with peers. This shows that when students play games, other than increasing their ability in games, they also hope peers can stimulate their improvement.

Results in the game questionnaire also show that students agree with the temporal and spatial convenience brought be building the game in Facebook, so that learning is no longer constrained by time and space. With the assisted learning from the game, it can improve upon boredom while learning, and can also help students review the knowledge they have learned, enhance their understanding of concepts, and in turn decrease their rejection for operating systems.

In addition, this study explores the reason for which students enjoy games on Facebook. Number 13 of the game questionnaire shows that one reason students think Facebook games are fun because of the people playing with them but not because of the game itself. Thus, when more peers are playing the same game, students would become more interested. On the whole, students approved the system, and are happy to recommend it to use by younger students.

Since students need to explore the island and answer questions to gain money and experience points, data shows that students spent a lot of time exploring the island. Further, concept completeness shows that out of 98 students, 54 completed all the concepts ("introduction to operating systems," "computer system structure," and "operating system structure"), which shows that without temporal and spatial constraints, students can have sufficient time to engage in game-based learning. Compared to games with time limits, it can enhance student conceptual learning effects.

VII. CONCLUSION

Statistics on the game questionnaire and experiment data show that students use time effectively to go online for the game, and there are even students who sign into the system early in the morning. This shows that the course knowledge systems on Facebook can indeed make students willing to enter the system to learn after school, to conduct game-based learning without the constraints of time and space. However, this study also finds that in game-based learning, if the same system is used continuously, long time use would result in lowered curiosity or even annoyance at the system, resulting in decreased learning motivation. Thus, the effective addition of new game elements can not only increase student learning motivation but can also help the game to be expressed in more diverse ways.

Questionnaire feedback from students shows that students like social network games because of their peers. Thus, an issue worthy of deep consideration in the future is how to effectively use the characteristics of social network games so that students can also interact with peers while engaging in game-based learning.

***Abstract*— Simulations allow students in an educational environment to experience tasks and the results of their decisions, which they will be asked to perform upon graduation. In the construction industry, many employees are hired that do not have the training or coursework at the university level that provides them access to such simulations. Simulation and gaming is not new to higher education but in the past was done in a very narrow vein and because of the complexity and development time required to produce them. Most have not been robust enough to engage students. Managing engineering and construction involves being able to make decisions that involve balancing time, cost, quality, resources, and identifying and solving a variety of issues related to the selection of equipment, labor, and tools. The skills required of today's construction engineering and management professionals are a combination of management skills and technical knowledge. This paper describes the development and implementation of Construction Industry Simulation (COINS) designed and developed at California Polytechnic State University, San Luis Obispo (Cal Poly) to prepare construction engineering and management students for the real world.**

Keywords—game based learning, simulations, engineering education

I. Introduction and Contribution

Construction Industry Simulation (COINS) is a computer simulation built to simulate the business environment for a construction company. The players, participants, play the role of contractors, competing in a market with variable demand for construction work. The simulation immerses students into the day-to-day operations of a construction company, requiring them to management specific aspects of the company with the goal of procuring and managing construction work in terms of its planning, scheduling, and resource allocation. Students have a choice between commercial construction company, a heavy construction company, or a company that does both. Players are required to set up a complete business strategy including the following tasks:

- examine available information
- determine the best portfolio of jobs to bid on
- create strategies to improve bonding limits
- set strategies to create negotiated work
- develop bid prices for desired jobs
- monitor their financial position as work progresses
- monitor and create strategies to improve company's appraisal metrics
- choose and modify their construction methods to meet due dates and reduce costs
- interpret their competitors' strategies
- respond to changing conditions and situations proposed to the company and driven by the decisions and actions of the company

A. *Projects and Activities*

Each period the simulation generates a list of projects available for the teams to estimate, schedule and propose on. The type of projects include the following: highways, bridges, site development, mass excavation, and underground utilities

All projects have nine (9) activities that the teams need to schedule, generate and cost estimate. The activities that must be scheduled and estimated include the following: clear and grub, rough grading, excavation, underground piping, concrete forming and placing, backfill and compaction, placement of aggregate base, asphalt-concrete paving, and finish grading.

In addition the simulation creates an Estimated Time and Cost Report for each job. Using the this information, each company must decide which jobs to bid on, the bid price, and which of the five methods to use for each of the activities.

Every activity has five (5) different construction methods that vary in time and cost. The Estimated Time and Cost Report gives labor and material costs and the amount of time required for every activity using each of the five methods. Heavy construction bids are generally unit price bids while commercial bids are lump sum.

II. Game PlaY Simulation

During the simulation, students experience three distinct phases playing through the simulation. These are:

Identify applicable sponsor/s here. If no sponsors, delete this text box (*sponsors*).

A. Phase 1 - Project Planning and Design

Students begin the simulation in Phase 1 by being presented with a list of potential projects to review. Considering market conditions, student teams proceed by selecting a project to plan and then designing a project control system for the project. This is accomplished by selecting methods for each project activity and balancing the schedule and cost considerations. In Phase 1, students compete against their peers as well as the simulation's virtual companies for award of the project. Award of projects is based on the team's accuracy and proximity to the simulation's internal estimate. Teams that are not initially awarded a project for their efforts must continue with the simulation, refining their plans, until their plans are awarded a project. Thus, the COINS simulation enables students to learn from their mistakes.

B. Phase 2 – Construction Engineering

When a student team is awarded a project, they enter Phase 2. In Phase 2 student teams must manage their project by monitoring and controlling the project activities, analyzing the schedule and costs in reference to the methods to the activities they selected for each activity. Throughout the duration of their project, students are presented with real-life scenarios which they must respond to, thus measuring, testing, and validating the design of the project control system. Therefore, students are able to utilize their knowledge and hone their skills at controlling the process through modifying their project control system. The simulation provides feedback to the students which they then can use to continuously improve their model throughout the duration of the simulation.

C. Project Closeout

Phase 3 begins after students have completed each activity for their virtual project. They have the opportunity to evaluate their performance using several predefined metrics, including Schedule Variance, Cost Variance, Cost Performance Index, and Schedule Performance Index.

D. Student Learning Process

III. Student Learning Process

As mention above, one of the first activities for the students is to determine what positions will make up their main office overhead. This is reevaluated each period, and hire/fire activity is performed by the team. A report is given to the company telling them how they are handling their personnel and it's requirements. Work scheduling is very important in the selection of the methods so projects can be completed by the contractual deadlines, and the costs reduced as much as possible. Each bid price submitted should cover all the firm's direct and indirect job expenses, its main office overhead costs, and the desired profit. At the end of each period the simulation will determine which company is awarded each available project. The lowest bid will not necessarily win since the computer takes into account several other factors:

- Is the firm's cash-on-hand adequate to provide enough liquidity with regard to the bid price?
- Is the bid price below a minimum amount, computed by the program? If so, then the bid will be disregarded as irresponsible and be rejected.
- Is the bid price higher than the unknown contractors, the presence of this simulated company assures a competitive, uncertain environment with realistic bid prices.
- Is the firm within it bond limits?

At the end of each period, teams receive a progress report for the previous two month period, giving a statement of the firm's work progress on each of its jobs during that time. It shows the amount of work completed as well as the expenses incurred for each activity in every one of the company's projects. The amount of work completed during a period depends not only on the methods selected for the various activities, but also on uncertainty factors during that time such as the weather conditions, labor availability, and the fluctuating cost of materials.

An end-of-period financial report is also provided to the participants showing the expenses incurred during that period. It lists amounts spent on direct construction services, bidding costs, delay fines, taxes incurred, and interest on borrowed money. It also shows payments to the contractor by the owner according to the payment requests and gives total cash-on-hand at the end of the period. Each firm may at any time apply for a loan to improve its financial situation. Loans granted are amortized over a one year time period. Changes in company ratios are also logged along with changes to the company's appraisal metrics.

- Is the firm within it bond limits?
- Financial Liquidity
- Financial Success
- Responsibility
- Pace
- Ethics
- Name Recognition

At the end of a period, the firms examine their Progress Reports and decide on the effectiveness of the methods chosen for the various work activities. If they wish, they may change them and specify different methods for the following periods. The choice of methods allows companies to utilize slower but cheaper methods if they fear budget overruns, or faster but more expensive methods if meeting contractual deadlines is the main concern. In addition, overtime may be used to speed up certain activities, greatly increasing the labor costs. Firm must be concerned with the amount of liquidated damages on each project as they vary from project to project.

At the conclusion of the simulation, the program provides each participating company with a final report, forecasting the expected results of any on-going projects or their position at that point in time. It also shows the final total worth of the firm. Teams should consider maximization of profit as one of their main objective, and one of the primary criteria used to evaluate each firm's performance. As the simulation progresses, evaluations of company ratio, and appraisal metrics can be used to determine successful completion of the simulation.

IV. Assessment of Student Learning

The simulation has a built-in grading module that can be used to obtain statistic on the various companies for comparison or to use in the classroom for grading the simulation. Each faculty can have their own method of grading. The following criteria can be used by faculty for assessing participation and student learning:

- Is the firm within it bond limits?
- Number of jobs bid
- Minus the jobs rejected (i.e., not enough bonding capacity, substantially low cost estimate, etc.)
- Number of times the number jobs you are the lowest cost
- Number of times the company retained earnings
- Company’s appraisal metrics

V. Discussion and Recommendations for Future Implementations

To assist in the development of COINS, the developers have developed an Industry Advisory Board (IAB) from the construction industry as well as a working group of educators to continue the development and ideas for changes. Because of the idea of module development COINS can turn on and off some of its modules, making it a better fit in different classes. For example, estimating can be turned to an automatic mode which in a construction accounting class helps the student focus on accounting and not on the estimating itself which can be very time consuming and complex. Periods can move much quicker giving the students more accounting to analyze and in a shorter time in which they can see the changes that occur within a company without being bogged down in the estimating/procurement of work. Billing can be turned on to auto mode and additional projects can be added to each team to create additional project or backlog. The game play between commercial and heavy/civil construction is also modulized so a faculty can play only commercial, heavy/civil or both can be played in one game. Future additions are also planned as modules, i.e. personnel additions, case studies, and wide use of equipment management.

Making In-Class Competitions Desirable For Marginalized Groups

Amy McGovern and Deborah Trytten

Abstract—**Inspired by research that indicates that direct competition is not always comfortable for female students, we redesigned an existing class competition to permit students to choose whether they wished to participate in either direct or indirect competition. We pilot tested it in the Spring of 2013 in a undergraduate/graduate class on introductory artificial intelligence at the University of Oklahoma. Although the results for female students are inconclusive due to their small number, we observed that international students embraced the indirect competitions. This suggests that allowing the option of indirect competition may also appeal other groups of students who can be marginalized in engineering. Our results indicate the international students prefer the less risky option of indirect competition.**

I. Introduction and Motivation

We have previously successfully introduced a game-based environment used to motivate students to learn about artificial intelligence and to create a significant learning experience [1], [2]. With our previous experience in games and and literature that demonstrates the games are motivating for students [3], we wanted to continue to use games to motivate students but to adjust the type of competition to make it more appealing for all students. Based on existing literature that demonstrated the first person shooter games were not motivating for women [4], we designed our game to not to contain any first-person shooting or blood. The game that we designed is called Spacewar and it is based on the classic game of Asteroids [5]. In the original version of our game, the students competed to have their spaceships survive as long as possible while being controlled by programs they wrote using artificial intelligence techniques.

In order to encourage creativity and early completion of projects and to promote active engagement in the subject matter, our previous work used a game ladder where all groups of students competed against each other. The competition was run each night by having all combinations of three students and three professor created agents play simultaneously. Scores from all runs were averaged to determine the winners. This competition provided extra credit for students who performed in the top three positions of the game ladder. Although the students who competed in the ladder enjoyed the competition, there were a number of students who chose not to participate. We hypothesized that this is based on the type of competition that was required to participate in the ladder.

Direct competition occurs when competitors are permitted to interact with and hinder other opponents (e.g. a stock car race or boxing match). Students using Spacewar were competing directly since damaging or destroying other spaceships was permitted and encouraged in the game ladder. Indirect competition occurs when competitors are judged independently against a single standard (e.g. a beauty pageant or golf)[6]. We were concerned that using direct competition in the class might be uncomfortable for the women students, so we redesigned the projects and simulation system to allow students to choose either direct or indirect competition.

This work in progress paper focuses on our pilot test in the artificial intelligence class in Spring 2013. We provide two separate but equal tracks for projects. Our hypothesis was that students who are members of marginalized groups (e.g., traditionally underrepresented groups and international students) will choose indirect competition over direct competition.

II. Related Work

Many computer games are focused on direct competition. The computer gaming industry has extensively studied girls' response to competition in games. Much of this research is proprietary but one company released some of their research results without peer review [7]. Their study shows that girls tend to be horizontal competitors with covert competition and a desire to establish relationships and friendships. Their social status tends to be determined by affiliation and exclusions. Boys are hierarchical competitors (also supported by [8]) and tend to favor overt competition with a desire to establish physical superiority and power. Often their social status is determined by achievement and physical domination. Gendered competition preferences of Germans in games were studied by Hartmann and Klimmt [4]. They demonstrated that more than women prefer competitive games and identified first person shooter games as particularly unappealing to women.

The literature on how other groups, such as racial and ethnic minorities or non-native speakers of English, might prefer to compete in games is thin. Amory and Molomo [9] have compared video game playing by South Africans by gender but did not consider race in their analysis. Similarly, Joyner and TerKeurst [10] found differences between British and Japanese gaming preferences. This data supports the well-established idea that gaming and competition preferences are culturally situated; an idea also established using a gender lens [11].

The role of gaming self-efficacy and feelings of competence was discussed as a factor related to girls' enjoyment

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

of computer games [12]. Kiesler, Sproull and Eccles discuss gender differences in poker playing behavior, where women prefer video poker and men prefer to play face to face. While both forms of poker risk money, face to face poker also requires deceit and assertiveness. Playing poker face to face requires direct confrontation with more experienced (usually male) players [11], which may require more self-efficacy and tolerance of risk taking. The link between gender and risk taking behavior was shown to be different in all female groups than in mixed gender groups. Female students in an all-female context were shown to exhibit patterns of risk taking behavior that were similar to males, where females in a mixed gender environment exhibited less tolerance for risk taking [13].

Joyner and TerKeurst created a model that considers interactions between motivating needs, interpersonal motivations, and entertainment preferences[10]. It is not unreasonable to hypothesize, that just as stereotype threat [14] can be demonstrated in many marginalized groups, marginalization could impact self-actualization, self-esteem, and a sense of belonging of a variety of marginalized groups in similar ways.

Competitive structures have been used previously in artificial intelligence [15] and other CS classes [16] although these efforts have not examined whether the competitive aspects had a differential impact on marginalized groups. [3] discusses the use of games in computer science classes but does not study the effect of competition on marginalized groups.

III. Method and Current Results

A. Spacewar2: The New Design

In order to accomplish our goal of having the two tracks be separate yet equal, we had to redesign Spacewar. The version that we pilot tested in Spring 2013 began with the goal of having the ships collect resources. Spacewar2 still has the students controlling spaceships in an asteroid filled environment. In the new version, the resources come in two forms: energy beacons and mineable asteroids. The energy beacons provide energy to the ships necessary for their navigation and survival. The mineable asteroids provide money.

At the beginning of the semester, the goal was to collect monetary resources. We introduced the question of what the students would like to buy with their monetary resources in a class discussion. After a passionate discussion, teams were given the power to buy additional ships, bases, and a variety of power ups to the ships and the bases. We included a balance of power ups that were offensive and defensive.

B. Competition ladder

Both the indirect and direct competition ladders rank the teams based on the amount of money brought back to the base. In the direct track, students compete against each other. The top three teams receive extra credit every day that the student remains at the top of the ladder (2 points for first place, 1.5 points for second, and 1 point for third). In the indirect track, students compete against known heuristics. Any student who can outperform the heuristic consistently can receive up to one point of extra credit per day. Student groups choose one of these two tracks on a project by project basis. Each competition is available for 10 to 14 days before the project is due, with extra credit being awarded daily. In either track, the student must outperform a specific heuristic that is provided ahead of time in order to receive extra credit.

Groups participating in the competitions by type

		Indirect	Direct
Project 1	**International**	5	4
	Female	3	2
	Non-URM	7	1
Project 2	**International**	8	1
	Female	4	1
	Non-URM	5	3
Project 3	**International**	9	0
	Female	2	2
	Non-URM	7	2
Project 4	**International**	7	2
	Female	2	1
	Non-URM	8	1

TABLE I. Number of groups participating in each competition. 'International' has at least one international student, 'Female' has at least one female, and non-URM groups have no under-represented minorities (URM) or international students.

C. Student Choices

The pilot test for this project was in Spring 2013. We had four class projects. For each project, we tracked which type of competition the students choose (indirect or direct), how early each group entered the competition (intermediate or final), and their success in the competitions and in earning extra credit. The competition ladders are published daily. This enables students to see the results of their work quickly.

The majority of students worked in pairs, which influenced their competition choices. At the start of the semester, we had 42 students enrolled. This included ten members of underrepresented groups (including women and members of racial and ethnic groups that attended high school in the U.S. and are underrepresented in engineering). This number was obtained through observation with discreet questions in case of ambiguity and likely under-estimates the true number of members of underrepresented groups due to group memberships which may not be physically identifiable (specifically biracial and Native American students). We had 13 international students. Most pairs stayed together for the semester but a few changed due to compatibility issues, affecting the counts very slightly.

Table I summarizes the choices of the student groups in the projects. Overall, more students are choosing the indirect competition over the direct competition. Although the numbers were small for the groups of international students or female students, there is a pattern. The international students primarily preferred the indirect competition. In project one, it was almost an equal split, but the remaining projects demonstrated that the international students chose indirect competition instead. Groups with female students had a more mixed picture, with their choices being approximately equal in projects one and three. Most of the females are grouped with White male students and most of the females are also not international students. This likely affected their views on risk taking. Although there are female international students, the numbers are too small to analyze separately.

Beginning with project 2, we asked them to explain their choice of competition in their write-up. Many of the groups

Student persistence in choice of competition	International	Female	Non-URM
Project 1 to Project 2			
Indirect persistence	5	2	3
Indirect to direct	0	1	2
Direct to indirect	3	1	0
Direct persistence	1	0	1
Project 1 through Project 4			
Indirect persistence	4	0	2
Direct persistence	0	0	0

TABLE II. STUDENT GROUP PERSISTENCE: CHOICES WERE ONLY RECORDED FOR TEAMS PARTICIPATING IN AT LEAST 2 COMPETITIONS.

who chose the indirect competition stated that they knew how well they would perform there because the heuristic was provided. The direct competition involved risk of not knowing if they would win. Although the payoff was higher for the direct competition, the risk was also higher. In informal discussions with groups of mixed underrepresented minorities and non-underrepresented minorities, this risk was a big factor in their decision making. In project 4, we changed the extra credit structure for the direct competition to address the risk factor (3 points for top place, trickling down to 1/2 point for the 4th place) but nothing changed in the student choices.

During this study, an interesting aside developed. The results of each competition are available publicly on the primary author's website. Students were asked to choose a name for their teams. We asked them to include some part of their name in the team name to make it more efficient to assign the extra credit. Two of the groups containing underrepresented minorities did not want to put part of their personal names into their team name. This may be a response to the additional visibility that can come from being a member of an underrepresented group (called spotlighting [17]) or it may be related to the risk-avoidance behavior also observed in the international students.

Student groups are permitted to change their competition preferences for each project. Table II examines the trajectory of the student groups' competition choices across projects. Interestingly, no group persisted in the direct competition for all four projects yet four international groups persisted in indirect competition. We also measured choices from project 1 to project 2 and there the choices of the underrepresented groups can be seen more clearly. They chose indirect or moved from direct to indirect at a higher frequency than the groups with no URM students.

IV. Discussion and Future Work

Although this change in classroom practice was designed to support women students, the primary beneficiaries appear to be the international students. While we don't typically consider international students within the framework of underrepresentation in engineering, these are students that can be marginalized in the classroom by lack of fluency with English (real or perceived) and social customs. The U.S. higher education system also places these students under more pressure since their ability to remain in the U.S. is dependent upon their academic success. International students may be strategically choosing to avoid an outcome with a high penalty (failing a course) by taking the less risky indirect competition route.

While international students may have benefitted most from this innovative practice, two groups of White male students also chose to persist in the indirect competition. As is often the case, this shows that course design changes that are made to support specific groups can be beneficial across the board.

Future work in this area should include a deeper and more comprehensive analysis of: student motivation, choices in competition selection, and direct queries of students to determine group membership and identity and decision making patterns. An analysis of choices made by marginalized students if teams are allowed to display or conceal their individual identities could also be fruitful.

Acknowledgments

The authors would like to thank Sonya Wolff for help with the class and Zack Tidwell for the concept of different types of competition.

***Abstract*—Two e-learning modules are being developed to improve self-regulation and lifelong learning readiness. More than 150 mechanical engineering students completed first versions of the two modules in 2012. An evaluation of the module results suggests that students are learning the module content and tend to enjoy taking the modules. The modules were also tested as an intervention for improving lifelong readiness as measured by the SDLRS. Comparing scores of the SDLRS taken before and after the modules showed a statistically significant gain ($p<0.1$). Comparisons were also made between the 2nd and 3rd year classes and between women and men. Suggestions for improvements to the modules have been identified.**

Keywords—e-learning; self-directed learning; learning styles; motivation

I. INTRODUCTION

Engineering work is changing due to globalization and the rapid advance of communication and other technologies. Engineering education is changing too with the advent of more online delivery. Personalized learning will grow as adaptive e-learning software develops. Are engineers and engineering students prepared for these changes? One of the most valuable skills that engineering students can learn is the habit of lifelong learning. To be effective in their careers and in school, engineers will need to become independent learners. Senior design and graduate projects are effective for developing independent learning ability. Are there other less expensive interventions that can accelerate student development?

Pintrich identifies four areas of self-regulation: cognition, motivation/affect, behavior, and context [1]. This project focuses on the first two areas—cognition and motivation. Our objective is to develop and test two e-learning modules that raise student awareness of their own cognition and motivation and subsequently provide strategies for improving learning.

II. METHODS

For the metacognition module we focused on learning styles. The goal for this module was for students to experience the difference in learning when material is presented in a way that targets different learning styles. The motivation module manipulated two aspects of motivation: task value and control beliefs. Again, the goal was for students to experience what it is like to learn with different motivation levels. In evaluating the modules, two aspects are of interest in this paper. First, did students experience what we intended? Second, did the modules have an effect on lifelong learning ability?

Lifelong learning ability was measured using the Self-Directed Learning Readiness Scale (SDLRS) instrument [2]. Other researchers have done factor analyses of SDLRS results. For example, Hoban, et al. [3] used the SDLRS to identify four dimensions of lifelong learning readiness: curiosity, self-confidence in learning abilities, responsibility for one's own learning, and the attitude that learning is a tool for life.

Starting in the spring 2012 semester we recruited students to take the modules along with the SDLRS as both a pre and post-test to the modules. Mechanical engineering students were recruited from both a second year manufacturing class and a third year design class.

III. DESCRIPTION OF E-LEARNING MODULES

Although learning styles have been widely used by educators, their usefulness is not without debate [4]. A number of classification schemes have been adopted. We chose the Barsch Inventory [5] for our e-learning module because it is simple and can be used free of charge with permission. It identifies four learning styles: visual, aural, tactile, and kinesthetic.

The learning styles module teaches about two biology topics—Punnett Squares and mitosis. Biological topics were selected because it seemed likely that few Mechanical Engineering students would have taken classes in the subject beyond high school ensuring that all would start at the same level. (This turned out not to be the case, however.) Four presentations were prepared for each topic—one for each learning style. Students are presented with information about one of the topics in their most preferred learning style and the other topic in their least preferred learning style. For the visual presentations, the module presents PowerPoint slides. For the aural presentations, the module directs students to Khan Academy videos; these combine both visual and aural. For the two topics selected, a purely aural presentation would probably have been ineffective. For the tactile presentation, the module

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

asks students to view a video and take notes. For the kinesthetic presentation, the module presents interactive flash animations that were created specifically for the module.

After the learning styles questionnaire, students take a pre-test on one of the biology topics, then proceed through a tutorial on the topic, and then take a post-test. This procedure repeats for the second biology topic. Next, the students learn of their Barsch Inventory results, and they go through a tutorial about learning styles and suggested strategies for different style learners, followed by a post-test. The module concludes with evaluation and reflection questions.

The motivation module follows a similar format as the learning styles module. It starts with the Motivated Strategies for Learning Questionnaire (MSLQ) [6]. Students are asked to consider the course in which they are assigned the module when answering the questions about motivation. This questionnaire is based on an expectancy-value theory for motivation and measures control beliefs, extrinsic motivation, intrinsic motivation, self-efficacy, task value, and test anxiety.

The module then has learning tutorials in which two components of motivation are manipulated: task value and control beliefs. To manipulate task value, the module has tutorials on two quite different topics that would have different levels of interest for students: osmosis and the Northern Lights. Before the task value tutorials, the module asks students to rate their interest in the two topics. We anticipated that the Northern Lights topic would be more interesting for most students, but it was not for all students, and it was not necessary for that to be the case. After completing the two tutorials that include pre and post tests, students answer questions about their reflections on task value. For the control beliefs manipulation, the module includes two topics about which we anticipated an engineering student would have different confidence levels. The module introduced the photosynthesis topic by stating that it would be difficult material for a mechanical engineering student. The introduction to the aluminum can manufacturing tutorial indicated that it would be easy for a mechanical engineering student to learn.

Next, the module informs the student about their scores on the MSLQ, and it describes where motivation comes from. It then gives learning strategies that address the components of the MSLQ [7]. Like the learning styles module, the motivation module concludes with a series of questions asking students to reflect on the module experience and finally evaluate the module with suggestions for improvement.

IV. RESULTS

A. Data Collection

Data was collected in the spring and fall semesters of 2012. In the spring 2012, there were both intervention and control groups. Unfortunately, in this semester, we lost many research participants from the beginning to the end of the semester and had relatively few matched pairs of pre and post SDLRS scores. Also, we noticed that pre and post scores on the SDLRS could vary widely which suggested that students rushed through it the second time. In the fall 2012 semester we took a different approach. We asked half of the students to take the SDLRS prior to the modules and the other half to take it after the modules.

B. Learning Style Module Evaluation

Learning style preference scores for the students who took this module reflect earlier studies with engineering students where the most preferred learning style is visual and the least preferred is auditory.

Pre and post-tests were used to gauge students' learning of key concepts from the biology topics tutorials. According to pre-test scores, students were much more familiar with the Punnett Square than they were with Mitosis. The average pre-test score on the Punnett Square test items was 55.0% (s=34.13%) and the average pre-test score on the Mitosis items was 30.0% (s=31.0%). Gain scores on the Punnett Square items (24.9%) were slightly different than gains on the Mitosis items (30.2%); however, the differences in gains were not significant. Further, gains were not statistically different between the groups based on whether they were utilizing their most preferred or least preferred learning style. Thus, it appears that the students were able to adapt to learning through their least preferred style and still gain from the experience.

Students were also given a post-test that assessed their understanding of differences in learning styles. The average score on this test was 71.2% indicating that by the end of the module, most students had an acceptable understanding.

Table I shows the questions used to obtain attitudinal measures. In this and subsequent tables, SA=Strongly Agree, A=Agree, N=Neither Agree Nor Disagree, D=Disagree, and SD=Strongly Disagree. The results for 163 students suggest that the majority enjoyed working with the module and felt that they learned something from it. Additional open response questions provided further insight. For example, many students responded that they have taken some type of learning styles instrument before and thus they were not surprised about their most and least preferred learning styles. However, many believed that the strategy suggestions would be helpful to their learning. Also, for many the biology topics were not interesting and the module was boring. Based on this feedback, we are developing content on additional topics, and we are investigating the feasibility of using a different and perhaps less familiar (to the students) model of Felder and Silverman [8] for the learning style instrument and tutorial presentations.

C. Motivation Module Evaluation

The motivation module concluded with a similar set of evaluation questions. Table II shows the results from this evaluation from the 152 students who took the motivation module. This module is longer and had more difficulties in terms of browser compatibility. That meant that some students had to take the module with more than one browser to get it to work, creating frustration. A number of open-ended questions were also asked in this module. The results suggest that the manipulations of task value and control beliefs may not be having the impact we are looking for. Also, students complained about the module being too long and boring. These are areas for improvement.

TABLE I. STUDENT RESPONSES TO ATTITUDINAL QUESTIONS ABOUT THE LEARNING STYLES MODULE (N=163)

	SA	A	N	D	SD
I thought the module was easy to use	39%	43%	15%	3%	0%
I understand differences in learning styles after completing the module	26	60	12	2	0
I enjoyed working with the module	14	44	26	15	1
I was surprised to find out my most preferred style	7	25	37	23	8
I was surprised to find out my least preferred style	3	23	33	29	12
I think the listed strategies of my preferred learning style will help me become a better learner	15	44	31	8	2
I will apply what I learned through completing this module to my learning in this class	12	48	29	5.5	5.5
I will apply what I learned through completing this module to my learning in other classes	14	50	25	6	5
Overall I would rate this module	E 7	VG 39	G 37	F 14	P 3

TABLE II. STUDENT RESPONSES TO ATTITUDINAL QUESTIONS ABOUT THE MOTIVATION MODULE (N=152)

	SA	A	N	D	SD
I thought the module was easy to use	14%	64%	15%	6%	1%
I understand different aspects of motivation after completing the module	15	67	13	4	1
I enjoyed working with the module	5	46	31.5	15.5	2
I was surprised by my motivation scores	10.5	42	31	15.5	1
I think the strategies for improving motivation will help me become a better learner	9	59	23	8	1
I will apply what I learned through completing this module to my learning in this class	8.5	57	21.5	11	2
I will apply what I learned through completing this module to my learning in other classes	8	60	20	10	2
Overall I would rate this module	E 6	VG 30	G 43	F 20	P 1

D. Assessment of Intervention

The intervention in this case is the taking of the modules. We believe that lifelong readiness will improve if the modules make students more aware of factors that affect their learning. To test this hypothesis, we compared SDLRS test scores before and after taking the modules. The average SDLRS score for the 258 students who took the test as a pre-test was 216 (50^{th} %ile for adults) while the average for the 79 students who took it as a post-test was 221 (57^{th} %ile). A two-tailed (with the assumption of equal variance) t-test of the difference between these two groups produced a p value of 0.074. The four factors from the SDLRS were also compared. Self-confidence, responsibility for one's learning, and curiosity were all higher in the post-test ($p<0.1$).

This is an encouraging result but we need to look more closely at the two groups of students. For example, the students who took the post-test had to follow through and complete the two modules. In other words, students doing the post-test may have already started with a higher level of traits such as responsibility and curiosity.

In a second analysis we compared the SDLRS results of the second year manufacturing class and the third year design class. In the second year course, the average pre and post scores were 215 and 219, respectively. In the third year course, the average pre and post scores were 218 and 223, respectively. The differences between the second year takers and the third year takers are not quite statistically significant ($p=0.16$). Interestingly, the only factor with a statistically significant difference between the older and younger students (combining both pre and post test takers) is self-confidence. A third analysis showed no significant gender difference for the SDLRS score or the sub-factors.

V. CONCLUSIONS

With the goal of improving student awareness and lifelong learning readiness, the project team has developed two computer modules that teach about learning styles and motivation. The modules take between 30 and 60 minutes to complete and thus represent a very short intervention. More than 150 students have taken the two modules. As an intervention, the evidence so far indicates the modules may be having a modest effect on lifelong learning readiness. We are examining additional data collected by the modules to identify ways to improve the modules.

On Mentoring Relationships: How to Become a Good Mentor

Waddah Akili
Principal, Geotechnical Engineering
3222 Evergreen Rd., Ames, Iowa, 50014, USA,
w.akili@isunet.net

***Abstract*- Engineering faculty have many types of relations with their students. In class, they are primarily the facilitators of learning. Also, act as advisors guiding students through their years of education. In some cases, the relationship between the student and the professor evolves into a mentoring relationship –which is the topic of this paper. This paper takes a practical look at the challenges and rewards of experienced engineers and educators becoming mentors for students or young practicing engineers. The author recommends an approach to mentoring that is deep in self-evaluation, one that considers the intellectual, social, cultural, and professional development needs of students and young professionals, and the need for taking little steps—one person at a time—that may make a big difference in student's performance and attitudes towards learning. It is argued that such an approach to mentoring will help encourage more underrepresented groups, such as women and minorities, to pursue careers in engineering. The paper, also, describes some attributes of mentoring and suggests how a faculty member might become a good mentor to students.**
.

Keywords-mentoring relationships, mentoring attributes, helping students meet their needs, how to become a good mentor.

I. Introduction

Mentoring is not a new concept. Many of us have benefited from a trusted mentor. Perhaps we called them a friend, family member, or an advisor, whose opinions and experiences we trusted. They created an intangible bond with us through their experiences, opinions, and the time they took to give us advice and counsel. As professional engineers, many of us have the same opportunity—by getting involved in two aspects that are vitally important to the engineering profession. The ***first*** is to make a positive impact on the life of a young, aspiring professional or student. The ***second*** is to help solidify the role of engineering in a fast paced, diverse landscape. How best to start? Begin by assessing what we have to offer as mentors. The main role of a mentor is to stimulate students or young professionals to think in new and creative ways. One of the biggest values to bring to mentoring is a broad perspective—and how that perspective can be of value to students.

From author's experiences, a key issue in "starting where they are" relates to our own preconceived notions about students and their abilities to evolve into the field of engineering. It is all too easy to consider general educational trends that indicate a woeful lack of most students' preparation in math and science. The logical extension of such thinking is: They don't have what it takes to succeed in engineering. Let us not waste our time and resources. In light of this, do we simply give up? Or do we rally our resources to help students do better? There is only one real option - how do we meet students where they are in their educational preparation, and how do we help them develop their core competencies so they could one day become engineers?

The paper takes a practical look at the challenges and rewards of experienced engineering educators becoming mentors for students or young practicing engineers. The author recommends an approach to mentoring that is deep in self-evaluation, one that considers the intellectual, social, and professional development needs of students and young professionals, and the need for taking little steps—one step at a time—that makes a big difference. Such an approach to mentoring will help encourage students, particularly underrepresented groups, to pursue careers in engineering.

The relationship between the mentor and the student may last for many years after student's graduation. Often it is difficult to define, in a clear manner, what mentoring is and how a professor can become a good mentor. The paper describes some attributes of mentoring and sketches out how a faculty member might become a good mentor to students.

II. How to Become a Mentor?

So how does one become an effective mentor of engineering students? Perhaps we could list the attributes of good mentors and simply say "go ahead and do that." But this approach is not without precedent. The National Academy of Sciences takes this approach in its book, *Advisor, Teacher, Role Model, & Friend* [1]. It advises new mentors to try to implement most of the following:

- Listen patiently to their mentees.
- Try to build long lasting relations.
- Don’t abuse your authority.
- Nurture self sufficiency.
- Establish “protected time” together.
- Share yourself.
- Be constructive.
- Don’t be overbearing.
- Seek the advice of your own mentors.

But such lists are not enough. Listing the instructions for being a good mentor is like trying to learn to ride a bicycle from an instruction book, where you are instructed to: Sit down on the seat, Grasp the handlebars, and Pedal with your feet. These are good instructions, but of little value without actually getting on the bicycle and trying it out [2]. Learning to be a good mentor requires dedication and effort, although knowing some of the rules, just as in learning to ride a bicycle, are useful and helpful, but not enough.

To start the journey toward becoming a mentor, he/she will need to thoroughly understand the role of mentoring. Look at a role they are already familiar with. Most of us have had a supervisor, a boss or coach who has made a positive difference in our lives. Those people wore many hats. They acted as: role models, cheerleaders, policy enforcers, advocates, and friends. As mentors they will wear these same hats. Mentors, presumably, understand the need to assume a number of different roles during the course of a mentoring relationship, but successful mentors also share the same basic qualities [3].

- A sincere desire to be involved with a young person.
- Respect for young people.
- Active listener.
- Empathy.
- See solutions and opportunities.
- Be flexible and open.

To start, new mentors should attempt to develop relationship with their mentees; exploring values, interests and goals. Soon will find themselves making a difference and having a positive effect on their life. What they may also be surprised to see is that they will be learning more about themselves. Mentoring doesn't just affect the young person. Mentoring is a shared opportunity for learning and growth. Many mentors say that the rewards they gain are as substantial as those for their mentees. Being a mentor enables them to:

- Achieve personal growth and learn more about themselves.
- Improve their self-esteem and feel they are making a difference.
- Gain a better understanding of other cultures and develop a greater appreciation for diversity.
- Feel more productive and have a better attitude at work.
- Enhance their relationships with their own children.

An effective mentor is willing to take time to get to know his/her mentees, to learn new things that are important to the young person, and even to be changed by their relationship. Undoubtedly the mentor has to accept the challenges and rewards of mentoring a young person. Also, he/she will experience the benefits that will last a lifetime [3].

III. The Mentor as a Friend

Some academics believe and advice strongly in maintaining a business-like relationship between mentors and mentees. They claim that a professor should not have any casual relationships with students, and such relationships “conflict with our fundamental obligations as faculty members” [4], and the ethics of the relationship require that the faculty member remains “dispassionate,” avoiding any appearance of partiality. The faculty member should “not seek to be their psychiatrist, friend, or lover.”[5]. While some of us may agree about the psychiatrist and lover part, many of us do not agree that friendship between students and faculty members has ill effects and should not be allowed. Too often we tend to be overly cautious and keep students at a distance, not offering them the encouragement and support they need.

I firmly believe that teachers, at all levels, should try their best to offer friendship as part of their professional role. There are times and situations where friendship is exactly what is needed in the mentoring relationship. Such a friendship does not have to be destructive or result in unjust impartiality [2]. A note of encouragement, a friendly gesture, asking underachieving student to chat, answering e-mail, paying attention to students’ extracurricular activities and achievements----are all indicators of friendship and do mean a great deal to students[2]. As pointed out by Richard Baker, “The key ethical point is that the professor-both inside and outside the classroom- should act as a friend” [6].

There is a clear difference between a “friend” and “pal”. The professor/mentor has a clear position and special power relationship with the student/mentee, and may be called on to evaluate performance and to do so “dispationately”.Therefore; a mentor can not be a pal, shooting hoops with students, spending time with them in “restricted” places such as taverns and bars, or joining them in night activities such as dancing, etc. A mentor trying to be a pal may destroy the fragile relationship between student and professor that is such an integral part of education [2].

IV. How to Get Started and Proceed Onward?

How best to start? Begin by assessing what you have to offer as a mentor. As a mentor your role is to stimulate students or young professionals to think in new and creative ways. One of the biggest values a faculty member can bring to mentoring is a broad perspective, and how that perspective can be of value to students. From author’s experiences, a key issue in "starting where you are", relates to our own preconceived notions about students and their abilities to evolve into the field of engineering. It's all too easy to consider general educational trends that indicate a woeful lack of most students' preparation in math and science. The logical extension of such thinking is: they don't have what it takes to succeed in engineering. For example, numerous international studies indicate that, compared to peers in other countries, U.S. students underachieve in math and science.

The French-based Organization for Economic Cooperation and Development (OECD), comprised of more than thirty member countries, conducted an international comparison in 2003 of mathematics, reading, and science skills among fifteen-year-olds [7]. More than 250,000 students in forty-one countries participated in the assessment. On the mathematics scale, the United States ranked twenty-fifth; on the science scale, the United States ranked twentieth; and on the reading performance scale, the United States ranked twelfth. Other educational indicators are equally alarming. Nearly half of all high school students in some of the nation's largest cities drop out before receiving their diplomas [8]. In some parts of the country, about a third of all high school students fail to graduate [9], and among those who do receive their high school diploma, many find that they are not prepared for the rigors of college academics. Equally alarming, more than a third of first-year college students received or planned on getting remedial help in math during their freshman year [9]. And finally, even though males and females take similar math classes and achieve similar scores in the K-12 environment, the participation rate of males in math is far greater than that of females after high school [10]. In light of these findings, do we wave the white flag and simply give up? Or do we wave a red flag to rally our resources to do better? There is only one real option. Yet, ***how do we meet students where they are in their educational preparation***, and how do we help them develop their core competencies to become engineers?

As faculty members, we must remember that not all students coming into the college or university environment will be developmentally ready for the academic challenges they face. Our role is to help students develop their potential and capabilities so they can earn an engineering degree. How do we develop them? The best way, in my opinion, is to approach one's development from intellectual, social, and professional vantage points. In my role as a faculty member, I work to develop the intellectual capability of my students. But the other elements—social and professional development and maturation—are equally important. All of these attributes carry equal weight because they come together in the same package. In increasing fashion, we must develop students not only intellectually, but in the other dimensions as well so they can lead, compete, and participate in, or contribute to, a complex and increasingly diverse workplace [11].

It is not just the students who stand to benefit from an effective mentor. Engineers, new to the profession, also, need mentoring, often until the point of professional licensure and even beyond. Effective mentoring of young engineering professionals is a two-way street. A young professional's energy, new ideas, thirst for information, and willingness to learn give any organization spirit and momentum. In mentoring a young professional, it's important to provide opportunities for the mentee to take part in team building, brainstorming and planning sessions, and to build relationships throughout the organization. Such processes and experiences are of significant benefit to the mentor as well. Mentoring is perhaps the best way to ensure that one's intellectual and experiential legacy can be tapped, improved upon, and be of continual benefit to the organization. Let us not forget that engineering is a profession in which learning occurs continuously [11].

It begins with formal education and continues through various developmental experiences, including a positive, long-lasting mentoring relationship. It was noted above that mentoring provides organizations with spirit and momentum. That is true. In addition, it is the personal nature of these relationships that give organizations their strength. Mentoring, however, is one part of the picture. Life experiences are another. We must continue to push for new ways to expose students to diverse experiences. That is how they will grow. It is one thing to watch and listen, and another entirely to be in the middle of a real-world situation experiencing it. Students gain from activities that include profession-related travel abroad, cooperative experiences, and community involvement projects that put them in contact with a wealth of opinions, new ideas, and alternate ways to approach an issue. How do we accomplish our lofty objectives? ***We start where we are and help the next generation through mentoring.***

V. Mentors' Attributes and Outreach

The most effective mentors, irrespective of their field of study and/or concentration, share similar attributes. What they have are abilities to listen, question, challenge, and offer feedback and support. These are the qualities central to faculty roles as mentors. What mentors also have are young people who stand before them with a variety of backgrounds, educational preparations, and aspirations. The mentors would strive to raise their capabilities and help them develop in a holistic fashion intellectually, socially, and professionally. Each student or young professional is a collection of his or her individual backgrounds, traditions, and aspirations. They, also, each represent an opportunity for teachers as mentors to use their resource as reservoirs of experiences in helping them prepare for an engineering career to last a lifetime.

A call to mentorship should not be an unusual thing to read. As educators and professionals, we have an obligation to help those who need to be nudged along the way. Mentoring a young professional or a student is part of the package of professional responsibility. We do not need another study to make this happen. Just look at each student individually, on a case-by-case basis. That's the secret. We just have to move beyond what engineering has historically been good at—systematic problem solving—and apply our special skills to solve a problem that could one day undermine the profession: a paucity of ideas and creative solutions that could only come from the mindset of those who are currently unheard throughout the profession[11].

In general, there are many qualities of good mentors. Some are not easily attainable, and do require firm commitment, self discipline, training, and patience. The author has noted in Table 1, some of these qualities that all mentors need, accept, affirm, abide by, and resort to when the need arises.

TABLE 1. QUALITIES THAT MENTORS SHOULD POSSESS

THE MENTOR IS:
• Approachable and welcoming in the office and outside. • Shares information, knowledge and experience openly. • Has good communication and listening skills. • Understands the field of engineering and related areas. • Has a network of contacts within the college, university and industry. • Is motivating, encouraging, positive and empowering. • Is willing to set aside/commit time to mentor someone. • Is committed to making a difference, one individual at a time. • Does not wait to be asked, approaches mentees when he/she feels there is need.

It's amazing the differences that a personal commitment can make to the life of another. We cannot expect to change the professional makeup of engineering overnight, and perhaps not even in years. But, with individual commitments, we can take positive steps, one person at a time [11].

VI. Mutual Acceptance and Satisfaction

The relationship between the mentor and the mentee can be mutually satisfying and rewarding to both party, but may also be the cause of anguish and pain. One may ask if the mentor/mentee system is a reliable one, or if some other system may be better? For example, consider a situation where every faculty member in a department advises every student in that department on equal bases. In time, would students not seek out one or more professors whom they have the strongest rapport and whose advice they begin to appreciate and value? Also, would the professors not begin to identify those students they most would like to advise and in whom they see their vision and aspirations become a reality? In other words, positions are subject to change and students will eventually migrate to those professors/mentors who they most desire to be their mentees.Therefore, the mentor/mentee system can neither be selected nor imposed, but rather a natural outcome of feelings and convictions of the two parties involved.

Unfortunately, the advising system in most universities is not ideal and may force a student to accept an advisor without mutual consent, or changing student's field of study may force a change in advisors, or the faculty member may leave the university or go on leave, thus forcing a change in advisors. The process is dynamic and the relationship that looked good at the beginning of student's journey can go sour with student's maturity or as a consequence of added responsibilities. It is therefore possible for students to face what is referred to as "toxic mentors" [2]. Students caught in a trap with a toxic advisor can either live with it or attempt to graduate as fast as they can, or try their level best to change their advisor. Neither is easy. Changing advisors is often difficult and almost impossible in some universities, due to rules and regulations on advising. An incompetent and /or an impatient advisor is often the cause of dropping out, or failure of students to accomplish their goals in engineering programs.

VII. Building Trust with Students

Underlying almost all aspects of learning is the element of trust. Trust between teachers/mentors and students is the affective glue binding educational relationships together. Not trusting teachers has serious consequences for students. Students are unwilling to submit themselves to the uncertainties of novel and unfamiliar approaches to learning. They do want to avoid risks and keep their deeply felt concerns private. The more profound and meaningful the learning is to students, the more they need to trust their teachers and mentors [12]. The importance of trust is experienced, time and time again, in students' critical incident responses, i.e., when students are off track and/or lose patience, and reach the stage where they can no longer exercise good judgment; then, they do need the care and attention of their mentors. At the center of the cluster of characteristics that make teachers/mentors more trustworthy in students' eyes are two components that may be described as teacher's *credibility* and teacher's *authenticity*.

Teacher's credibility: Teacher's credibility refers to teacher's ability to present himself/ herself as a person with something to offer to students. When teachers have this credibility, students see them as possessing a breadth of knowledge, depth of insight, and richness of experience that far exceeds students' own. Shor and Friere [13] describe credibility as the "critical competence" that students have the right to expect of their teachers and mentors. Almost all students continually stress their desire to be in the presence of someone who is knowledgeable, skilful and an expert in his/her field, i.e., meaning that he/she can help students come to grips with the contradictions, complexities, and problems they are experiencing.

Teacher's authenticity: Authentic teachers are those that students feel they can trust [14]. They are also those whom students see as human beings with passion, frailties, and emotions. They are remembered as whole persons, not as people who hide behind a collection of learned role behaviors appropriate to college teaching. In more specific terms, students see four types of behavior as evidence of authenticity: i) teachers words and actions are congruent**;** ii) teachers admit to error, acknowledge fallibility, and do make mistakes in public view of learners**;** iii) teachers allow some aspects of their personality (outside their role as teachers or mentors) to be revealed to students; and iv) teachers do respect learners by allowing them to express their views and by being open to changing their practice as a result of students' suggestions.

Steps towards trust buildings: Trust is not something bestowed on teachers and mentors just because they are teachers or mentors, it must be earned! Undoubtedly, it takes time, effort, and willingness on the part of the teacher and the mentor to earn the trust of the students. Teachers must remember that not only can they not expect students to trust them from the outset; they most likely have to face accumulations of mistrust nurtured by actions of cynical, arrogant, and indifferent teachers in students' past. This is likely to arise when the teacher is facing the students for the first time; and face also their accumulated educational histories and their memories of the teachers they have experienced in the past. Building trust is neither quick nor easy. It may be very dispiriting to realize that one's efforts to build trust with his/her students may often bring little immediate results. With patience and persistence, however, and with the advice of those teachers and mentors with experience, it is possible to build trust where none has existed before. Undoubtedly, students will remember the time they spent with a *caring* mentor who has done his/her level best to understand and be of help to them. There are those steps and /or precautionary measures that the teacher/mentor should be aware of and attempt to follow, if and when the need arises. These measures include:

First, Denial of one's credibility: Teachers' protestations that they don't really know any more than students do, and that they are simply there to help students realize that they already possess all the knowledge and skills they need. If students conclude that teachers' experiences have left them with no greater skill, knowledge, or insight than that already possessed by them, then there is nothing useful to gain from teachers. Teachers should be careful not to undermine their credibility in the eyes of their students.

Second, Be explicit about one's organizing vision: It is quite normal to have visions that guide the practice. However, when teachers deny having any visions, plans, or educational agenda, yet through their actions do make it apparent that such visions exist and do influence classroom activities. Not to be explicit about their plans, and agenda, at the outset, confuses students & is fundamentally wrong [12]. Should be avoided.

Third, The congruence of words and actions: Few things destroy students' trust in teachers and mentors more quickly than teachers who say they will do one thing and proceed to do something very different. Or, teachers who espouse one set of plans and principles then proceed to implement something else. Teachers ought to be careful and take necessary measures to safeguard them against falling in this trap.

Fourth, Be willing to admit that you make mistake: Teachers and mentors who acknowledge that they do not have all the answers and that, like their students, they sometimes feel out of control. Such acknowledgement helps reduce the tension students feel about their own need to be seen as perfect by their peers. While declarations of fallibility from teachers who earned credibility are appreciated by the students, the same declarations from those teachers who have not earned their credibility as yet - are basically unknown quantities- may produce the opposite effect of the one intended.

Fifth, Revealing aspects of one's self unrelated to teaching: Nothing wrong when mentors refer to enthusiasms, passions, and concerns outside his/her teaching and advising role. Revealing aspects of one's personhood gives students a sense that they are in the presence of an ordinary person; thus helps in bridging the gap that may have developed between students and their teachers. Often, teachers use incidents from their own daily lives to illustrate general principles, and talk about those passions that led them to develop an interest in their fields, Also, their own enthusiasms that sustain and renew these interests [12, 15].

Sixth, Show that you take students seriously: A caring teacher should listen to any concerns, anxieties, or problems voiced by the students. If none are forthcoming, the teacher should encourage students to speak out their minds and express their concerns - no matter how misplaced or trivial it may be- without interruption, rephrasing, or interpreting their concerns. Even if the teacher is confused about what a student is saying, he/she should be patient and chances are that the same concern will be expressed by another classmate in a clearer manner. When students suggest topics, exercises, and issue they wish to explore, even if these are outside the original scope, the teacher/mentor should consider seriously how to make some compromise to include some of what has been suggested by the students [15].

Seventh, shouldn't play favorites: Almost in every class there are those students that the teacher prefers to listen to more than others, people whose work he/she looks forward to receiving, and those whom he/she would welcome as personal friends. Conversely, there are those whom the teacher may dislike personally, and whom he/she thinks are "boring", insensitive, and do not give the course the effort and attention it requires. As a human being, it is normal to warm up for some and freezes in the presence of others. But if the teacher is to be trusted by all students, it is absolutely essential that he/she does not allow himself/herself the luxury of exercising these personal dislikes, and definitely needs to avoid playing favorites. Playing favorites destroys one's credibility in students' eyes very quickly [15, 16].

***The concepts of credibility, authenticity* and the suggested steps towards building trust between students and their teacher and /or mentor** are elusive, and made the more so by the fact that they are not standardized. It is not possible to develop ways of telling people how to be credible or authentic, since contextual features affect so strongly how students and teachers define credible and authentic behaviors. The most that could be done is to offer guidelines, give examples of how teachers/mentors in different environments try to build trust, and urge those, who wish to benefit from such experience, to try to implement some of the guidelines mentioned earlier. Teaching and advising with care is not easy, and all of the potential balances a teacher is encouraged to try to attain being credible and authentic in the right proportions is a difficult task. But *caring* teachers/mentors should not be discourage or neglect the need to build credibility in students' eyes, then, chances are that students will have little confidence in what the teacher/mentor asks them to do. And if the teacher behaves inauthentically, students will regard teacher's asking them to do it as a self-serving confidence trick.

VIII. Do What You Can?

Despite all the problems that may arise and the difficulties that an advisor or a mentor may face, mentoring is, in author's opinion, intensely personal, interactive, and rewarding. Mentoring can be achieved through a variety of methods. Here's how to "do what you can" [11]:

- Identify two to three students or young professionals who could benefit from your insights and experiences. Ask them if they have questions about the scope of engineering and how they might fit in.
- Help your students evaluate employment opportunities that they might not otherwise consider. Encourage them to think about many facets within the profession, and help them secure rewarding summer break experiences, or take a semester off and join a company as a trainee.
- Encourage students to become involved with local, regional, and national professional associations. Membership and involvement in such organizations provides students with priceless leadership opportunities and helps students develop a variety of valuable workplace skills.
- Remember that a student or young engineer may have a different or even a better idea in solving a problem. The young engineer may well bring a perspective that is much more than fresh—it may well be of the "why didn't we think of that" variety.
- Seek out students where they exist. Get involved with local high schools and help them establish an engineering club. Seek involvement with community organizations such as Big Brothers and Big Sisters or Habitat for Humanity [11].

There is little if any magic in all of this. And, we won't be successful with every student we mentor. But our efforts will be one hundred percent worthwhile as we strive to help make our profession more robust and vibrant for these complex and challenging times.

IX. University's Role in Enhancing Mentoring

The university can definitely enhance the quality of advising/mentoring available to students and increase the potential of having an adviser/advisee turn into a more effective, fruitful and lasting relationship. Some suggestions, based on the experience of some forward looking universities, may be helpful. [16].

i) The university, in general, and the college in particular, should devise policies that would allow students to have the option of selecting advisors, even if not all parties want this choice. The mentoring relationship is best fostered with sound advice and in a mutually comfortable environment.

ii) The university is, by all measures, the sole organizer for improving advising in all colleges. Training programs, short courses, seminars, etc. should be established and maintained on a college basis.

iii) The university should recognize faculty participation in an advisor training program, and encourage young faculty, in particular, to participate in such programs.

iv) The college and the respective department should establish lines of communications with advisees at all levels, asking for their opinions and views on their relations with their advisors, and how may advisor/advisee relations be improved? Such feed back would help all parties involved.

v) The university should establish a reward system for exemplary mentoring, based on feedback from mentees coupled with a statement from the nominee stating his or her philosophy on mentoring.

vi) Advising with care and mentoring should become part of the tenure and promotion process. Letters should be solicited from former students/mentees soliciting their opinions on the mentoring they received during their college years.

vii) Students at all levels should be asked to complete exit surveys, to assess their views with their advisors/mentors, and the pros and cons of their experience [16].

Implementing the above noted ideas will, no doubt, improve the advising process at any university. However, we have to be realistic. If a faculty member, particularly a senior member, does not desire to help students, there is little a university can do to improve the situation. As stated by Vesilind [2] "Mentoring does not come from a guidebook, a set of rules, or even incentives. Mentoring comes from the heart." On the other hand, those who chose to become mentors, mentoring makes a difference in their lives. It's an equal opportunity relationship that is voluntary and mutually beneficial. As a mentor, you will learn just how valuable your experiences and expertise are to another. You will discover new levels of patience and commitment not previously experienced. And you will marvel at the energy, sincerity, and fresh perspectives of the next generation of professional engineers.

X. Concluding Remarks

Mentoring engineering students provides mentors the chance to make a significant difference in someone's life. For the mentor, the benefits of helping a student realize his or her professional goals and aspirations are lifelong, too. Through mentoring, we help students discover themselves and their potential, show them how to apply their skills and special aptitudes, and guide them in defining and pursuing their own career goals. In turn, mentoring helps mentors discover new things about themselves. They will learn just how valuable their knowledge, experience, and expertise are to their mentees. They will also discover new levels of patience and commitment not experienced before. And will marvel at the energy, sincerity, and fresh perspectives of the next generation of professional engineers.

The paper addresses issues of concern to future mentors highlighting the attributes of good mentors and why and how mentors should try to offer friendship to their mentees as part of their professional role. An effective mentor should try to meet students "where they are" in their educational preparation regardless of previous set backs, concerns and incompetence. When students reach out to you, take their hand and guide them. They are saying that they trust your wisdom, your experience, and your leadership. Simultaneously, as a mentor, you will enhance your expertise, communication and leadership skills, while helping the student explore a career path and prepare for the transition from college life to the workplace.

***Abstract*— In this paper, a method for improving the teaching materials of programming education is introduced, and the evaluation of the effects of using the strategy is presented. By using this method, the teachers of programming education will be able to assess and improve their teaching materials irrespective of their knowledge and experience of their teaching materials already used. In this method, the teaching materials were improved based on the statistical analysis of the motivation of students. Specifically, the motivation of students was measured for each lower category of ARCS motivation model with the authors' original questionnaire. The lower category in a particular lesson that showed a statistically significant decrease from the previous lesson was identified, and the improvement strategies for the lower category were selected from the list of motivation strategies in the ARCS model. The teaching materials of programming education were then improved based on the strategy. In this research, five lower categories of particular lessons in a programming course were identified, and the teaching materials were improved. The improved teaching materials were used in the following programming course, and the effects of the improvements were seen in three lower categories out of the identified five lower categories.**

Keywords—Programming education; Motivation; Motivation strategies; ARCS motivation model

I. INTRODUCTION

Many ingenious contrivances have been made in e-Learning systems especially in the next generation e-Learning systems called Massive Open Online Courses (MOOC) in order to draw better outcomes from the learners [1]. In these systems, the emphasis was put on the learning-support mechanisms which adapt to the learners' learning outcomes, but not on the feedback to the teaching materials based on the motivation of the learners. There have not been many systems based on the quantitative analysis of the relation between the motivation of the learners and the teaching materials.

In this paper, a method for systematically improving the teaching materials of programming education using the analysis of students' motivation is introduced, and the evaluation of the effects of using the method is presented. In this method, the teaching materials were improved based on the statistical analysis of the motivation of students. Specifically, the motivation of students was measured for each lower category of ARCS motivation model introduced by J. M. Keller et al. [2] with the authors' original questionnaire that used the ARCS model as the background theory. The lower category in a particular lesson that showed a statistically significant decrease from the previous lesson was identified, and the improvement strategies for the lower category were selected from the list of motivation strategies in the ARCS model. The teaching materials of programming education were then improved based on the strategy. This method of improving teaching materials of programming education has been practiced in a university of fine art, and the effects have been evaluated.

S. W. Martins et al. proposed a strategy to improve students' motivation levels in programming courses [3]. Based on two-year experience, they assessed several aspects such as motivation, self-efficacy, and satisfaction with course activities, and demonstrated an alternative model to make introductory programming courses more productive and attractive. They asked their students to make biweekly reflections on their satisfaction with their own performance, tasks, materials and class rhythm, and this was used to introduce changes when necessary. Also, they used several instruments to evaluate cognitive aspects related to motivation. The instruments include the Inventory of Attitudes and Study Behaviors (IACHE), Course Interest Survey (CIS), and the Student Motivation Problem Solving Questionnaire (SMPSQ). However, the quantitative analysis was conducted in pre and post basis and the levels have not been evaluated on a weekly basis. If the monitored qualities change gradually from the beginning of the course to the end, the evaluation in pre and post basis is meaningful. However, the duration of the course would be more than one month long, and the monitored quality might have changed on a weekly basis. If that is the case the quality is better to be monitored on a weekly basis.

J. M. Jerez et al. presented their twelve-year experience of improving their programming course for telecommunication engineering students [4]. Their aim was to increase student

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

motivation by making the task of solving exercises more enjoyable, and they improved the teaching contents by analyzing the relation between telecommunication concepts and programming education concepts using concept maps. Basically, they changed the contents to be more suitable for telecommunication students, and the way of teaching from a teacher-centered perspective to a much more practical and student-centered one. Their analysis for improving the programming course was based on the opinions of teachers rather than opinions of the students. However, the opinions of the students are also considered to be important.

A. Forte and M. Guzdial also tried to improve motivation of their students in a CS course, and offered different contents for the students with different majors so that the students could learn CS in the context of their specialty [5]. They tailored their CS course by identifying discrete audiences and recognizing interests that lend themselves to learning about computation. In their approach, the high level contents of the courses were dealt with. For example, they offered different programming languages for the students with different majors. Though the improvement of high level contents are important, the improvement of low level contents such as each item in the syllabus are also considered to be important.

U. Nikula, O. Gotel, and J. Kasurinen approached the problem of rehabilitating the troubled first programming course in a more holistic manner [6]. Based on the opinion of the students who had dropped out of the course, they changed the teaching contents as a whole. For example, they changed the programming languages, virtual learning environments (VLE), teaching methods, support systems, and the assessment methods in a five-year period. After these broad scale changes, they suggest that the extrinsic motivators need to be established at the organizational level. Though they claimed that focusing on course elements rather than the course as a system has a serious risk of limiting the improvement efforts to local fitness peaks, establishing a systematic way of improving the local items in a programming course is also important.

Holistic approach is important to achieve significant improvement, but the approach is rather heuristic. For example, it is difficult to find a systematic way of changing the programming language in a programming course. The approach in this research is not holistic, but rather local in a programming course. Each item in the syllabus is the subject of improvement and the incremental improvements were supposed to be accumulated. The students' opinions are systematically collected, and the improvements have been made using motivation strategies.

II. THE PROGRAMMING COURSE

In this research, an introductory programming course in which computational figures were used as teaching materials was offered twice to the sophomore students in Osaka University of Arts. In the course, Processing language [7], which is a Java based language that facilitates the development of visual projects, was used.

The first programming course in which students' motivation was monitored was offered from June to July, 2012. There were 60 students in the course, and two classes per week

TABLE I. SYLLABUS OF THE PROGRAMMING COURSE

Week		Learning items	Details
First	**Second**		
L1-2	L1-2	1. What is Processing 2. Drawing figures 3. Variables and calculation	size, background, point, line, ellipse, rect, triangle, println, stroke, fill, smooth, strokeWeight, int, float
L3-4	L3-4	4. Repetition	**for**
L5-6	L5-6	5. Color	colorMode, RGB , HSB
L7-8	L7-8	6. Input Exam1	void draw, frameRate, mouseX, mouseY, save, mouseClicked
L9-10	L9-10	7. Conditional branch 8. Random Assignment1	**if**, random, mousePressed, rectMode, ellipseMode
L11-12	L11-12	9. Images 10. Font	Pimage, Image, image, filter, text, textSize, textAlign, Pfont, textFont
L13-14		10. Font (Cont'd) Assignment2	rotate, translate
L15-16	L13-14	11. Animation 12. Arrays	frameRate, algorithm of movement
L17-18		Assignment3 Exam2	2D animation

were conducted for 9 weeks (one class is 90 minutes). The questionnaire based on the ARCS motivation model was conducted once a week in order to assess the motivation of the students.

The second programming course was offered from October to December, 2012. There were 28 students in the course, and two classes per week were conducted for 7 weeks. The questionnaire based on the ARCS model was also conducted

TABLE II. THE QUESTION ITEMS IN THE QUESTIONNAIRE

	Attention
A1	Perceptual arousal: Did the learning content give you new and surprising incentives to learn during the programming education?
A2	Inquiry arousal: Did you feel that you wanted to learn more during the programming education?
A3	Variability: Could you study without getting bored because there were variations in the learning content?
	Relevance
R1	Familiarity: Did you feel that the learning content was familiar?
R2	Goal orientation: Did you understand the goal and the importance of the learning?
R3	Motive matching: Did you have chances to select the learning methods that were suitable to you?
	Confidence
C1	Learning requirements: Is the goal you should reach clear?
C2	Success opportunity: Did you feel that you had written your programs well?
C3	Personal control: Did you feel that you wrote your program well because of your efforts and ability?
	Satisfaction
S1	Natural consequence: Did you have occasions to use your newly acquired knowledge?
S2	Positive consequence: Were you happy when you did well?
S3	Equity: Was your accomplishment fairly evaluated with a consistent standard?

once a week. In this course too, the questionnaire was conducted once a week.

The syllabus and the teaching materials used in the courses were designed in accordance with the ARCS motivation model in order to raise the motivation of the students. The syllabus and the teaching materials used for the two courses are shown in Table I. Though the syllabuses for the two courses look the same, some modifications based on the analysis of the first class were made in the second class.

The students in the two courses studied the same contents from L1 to L10 (first 5 weeks). In the first course, the students were taught image processing in Chapter 9 in the teaching material, and font processing with “textFont” in Chapter 10 in L11-L12, and they were taught font processing with “translate” in L13-L14. These contents were taught all together in L11-L12. Also, in the first course, the students spent two weeks (from L15-16 to L17-18) to work on animation processing, arrays, and final assignments, but the students in the second course spent only one week (L13-L14).

III. THE MOTIVATION ASSESSMENT EQUIPMENT

The motivation of the students in the programming courses was analyzed using the authors’ original questionnaire based on the ARCS motivation model [2]. This model has four factors (*Attention*, *Relevance*, *Confidence*, and *Satisfaction*), and each factor has three lower categories, and therefore there are twelve lower categories in total. The lower categories and the corresponding question items of the questionnaire are shown in TABLE II. Though the question items in the table are in English, the actual questionnaire was written in Japanese.

The authors developed the questionnaire, and each question item in the questionnaire was designed to ask if each of the twelve lower categories in the ARCS model was satisfied. Each item was presented using a five-point Likert scale where answer 5 always corresponded to “agree” and answer 1 to “disagree”. The reliability of the questionnaire was verified using Cronbach’s alpha in the previous works of the authors [8][9].

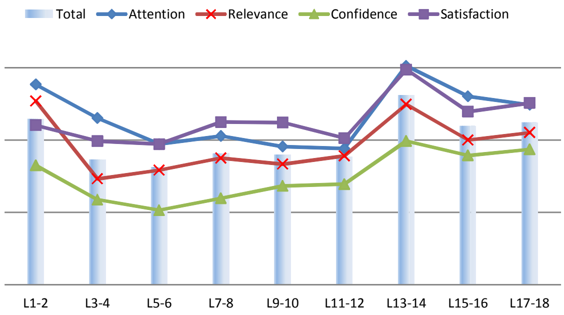

Fig. 1. Change of Motivation in the First Course

In the first course, the questionnaire was administered 9 times (once a week), and in the second course, it was administered 7 times (again, once a week).

IV. CHANGE OF MOTIVATION IN THE FIRST COURSE

The change of the average scores of the four factors is shown in Fig. 1 so that the overall trend in the first course can be understood. In this figure, the data are from the 26 students who attended more than or equal to 8 double-classes out of 9. The data of the students who were absent at most once was used for the analysis, and there were 218 effective data.

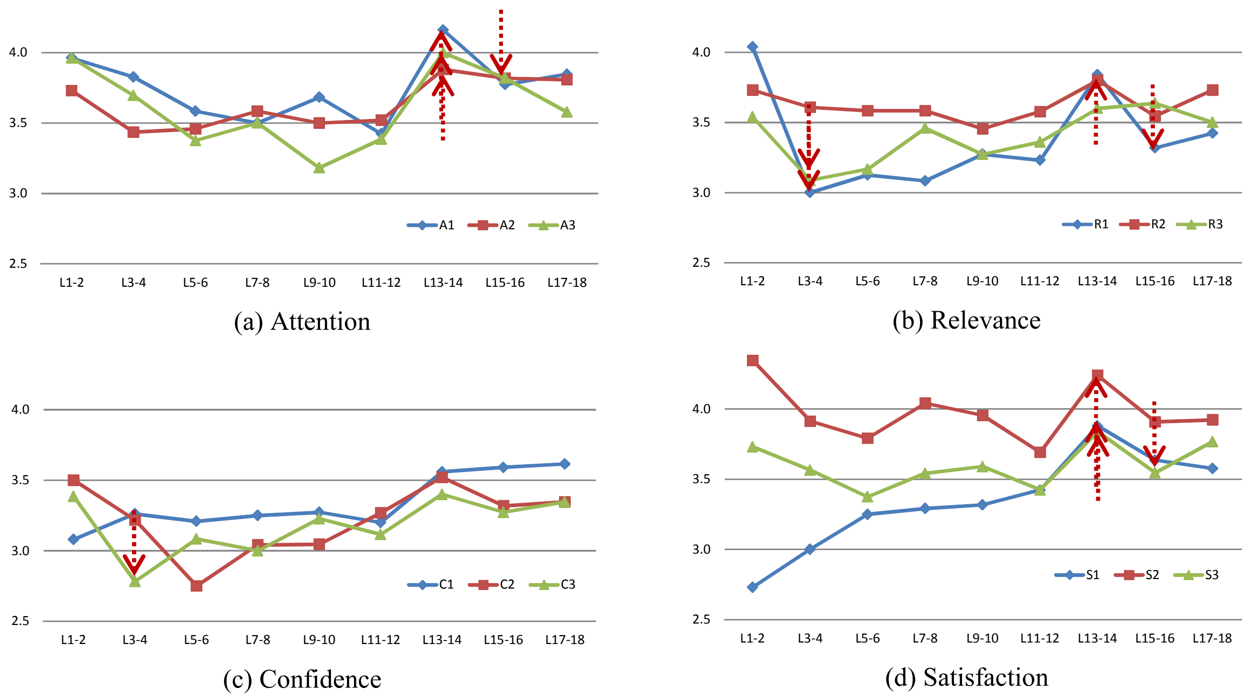

Fig. 2. The Change of Lower Category Scores

TABLE III. CHANGE OF MOTIVATION IN THE FIEST CLASS

	Attention			Relevance			Confidence			Satisfaction		
	A1	A2	A3	R1	R2	R3	C1	C2	C3	S1	S2	S3
L1-2	4.0	3.7	4.0	4.0	3.7	3.5	3.1	3.5	3.4	2.7	4.3	3.7
L3-4	3.8	3.4	3.7	*3.0	3.6	*3.1	3.3	3.2	*2.8	3.0	3.9	3.6
L5-6	3.6	3.5	3.4	3.1	3.6	3.2	3.2	2.8	3.1	3.3	3.8	3.4
L7-8	3.5	3.6	3.5	3.1	3.6	3.5	3.3	3.0	3.0	3.3	4.0	3.5
L9-10	3.7	3.5	3.2	3.3	3.5	3.3	3.3	3.0	3.2	3.3	4.0	3.6
L11-12	3.4	3.5	3.4	3.2	3.6	3.4	3.2	3.3	3.1	3.4	3.7	3.4
L13-14	*4.2	*3.9	*4.0	*3.8	3.8	3.6	3.6	3.5	3.4	*3.9	*4.2	*3.8
L15-16	*3.8	3.8	3.8	*3.3	3.5	3.6	3.6	3.3	3.3	3.6	3.9	*3.5
L17-18	3.8	3.8	3.6	3.4	3.7	3.5	3.6	3.3	3.3	3.6	3.9	3.8

It can be observed from Fig. 1 that the changes of the scores of the factors towards L3-4, L13-14, and L15-16 are significant. Decreases in Relevance factor towards L3-4 and that in Attention factor, Relevance factor, and Satisfaction factor towards L15-16 are significant comparing with other factors. On the other hand, increase in Satisfaction factor towards L13-14 is significant comparing with other factors.

The change of the score of the lower categories in the ARCS model is shown in Fig. 2. In order to find out if there is a significant change between lessons, t-test was conducted. Table III shows the scores of the lower categories with the results of the t-test (those scores that are significantly different from the previous ones are marked with asterisks). In Table III, the gray cells indicate that there is a significant difference between the score in the cell and that in the above cell with 5% significant level. Light gray cells indicate that there is a decrease in motivation levels, and dark gray cells indicate that there is an increase in motivation levels.

A decrease in motivation level is observed from L1-2 to L3-4 (Let's call it "Decrease phase 1"), and also from L13-14 to L15-16 (Let's call it "Decrease phase 2"). On the other hand, an increase in motivation level is observed from L11-12 to L13-14 (Let's call it "Increase phase 1"). Decrease phase 1, Decrease phase 2, and Increase phase 1 cover all the scores marked with asterisks. In the Decrease phase 1, the lower categories R1 (Familiarity), R3 (Motive matching), and C3 (Personal control) decreased. In L3-4, the students learned repetition with "for" statement instead of previously learned single statement of drawing figures. As a consequence, the students had to learn the new concepts such as syntaxes and algorithms, and they had problems in coping with familiarity to learning contents, selecting the learning methods, and confirmation of their own ability. These are considered to be the reasons why the scores of lower categories decreased.

In the Decrease phase 2, the lower categories A1 (Perceptual arousal), R1 (Familiarity), and S3 (Equity) decreased. In L15-16, the students learned animation programming with arrays. It is thought that the students who are familiar with high level games could not feel much new and surprising stimulus (which is the component of A1), and familiarity to the learning contents (which is the component of R1) with the simple animation and arrays. Also, for S3, while consistent evaluation standard is supposed to be applied, the instructor changed the evaluation standard from the one based on ingenuity of making still images to the one based on the movement of the animation. This can be considered to be the reason why the motivation of the students decreased.

The Increase phase 1 could be attributed to the fact that the students were allowed to work on free assignments in L14. The students could apply the knowledge and techniques they had learned to create the artwork they desired, and confirmed that what they had learned was useful. That is considered to be the reason why the motivation increased in this phase.

V. IMPROVEMENT OF THE TEACHING MATERIALS

In this chapter, the improvement strategies for R1, R3, C3 in the Decreasing phase1, and A1, R1, S3 in the Decreasing phase 2 that has been implemented are presented. These strategies are based on the Motivation strategy of ARCS motivation model [2]. Since the teaching materials and the learning items had been designed in accordance with the ARCS model so that the motivation of the students would be raised, modification of the teaching materials based on the motivation strategies would be effective. The keywords for the samplers of the strategies are shown below.

- The attention getting strategies for A1: A1.1 Audio-visual effects, A1.2 Unusual content or events, A1.3 Absence of distractions
- The relevance generating strategies for R1: R1.1 Human interest language and graphics, R1.2 Illustrations for concreteness, R1.3 Familiar examples and contexts
- The relevance generating strategies for R3: R3.1 Goal level options, R3.2 Scoring system, R3.3 Noncompetitive options, R2.4 Multiple participant opportunities
- The confidence building strategies for C3: C3.1 Exit control, C3.2 Pacing control, C3.3 Quick access, C3.4 Menu structure, C3.5 Attributional language
- The satisfaction producing strategies for S3: S3.1 Purpose and content consistency, S3.2 Exercise and test consistency

Based on these motivation strategies, some ways for improving each learning item that had shown decrease in motivation from a previous lesson were proposed. For "repetition (for sentence)" in L3-4, the improvements with regard to R1.3 Familiar examples and contexts, R3.1 Goal level

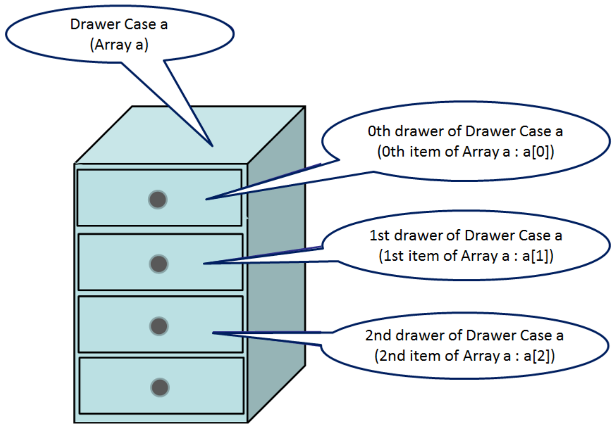

Fig. 3. Explanation of the Concept and Function of an Array

options, and C3.1 Exit control would be effective. For "movement (animation) and arrays" in L15,16, the improvements with regard to A1.1 Audio-visual effects, R1.2 Illustrations for concreteness, and S3.1 Purpose and content consistency would be effective.

Before starting the second course in October 2012, some modifications were made to the teaching materials that had shown decrease in motivation from a previous lesson. The explanation for the learning item "for repetition" in the Decrease phase 1 had been improved with the following strategies:

- An illustration that can be used to explain the concept of "for" statement had been placed in the teaching material (R1.3 Familiar examples and contexts)
- The number of the practice exercises had been increased from 2 to 6 so that the learners could chose the suitable exercises based on their understanding (R3.1 Goal level options)
- Page breaks had been inserted between explanation section and exercise section so that the teaching materials, which were PDF files, could be viewed more easily (C3.1 Exit control)

The explanation for the learning item "Animation and Arrays" in the Decrease phase 2 had been improved with the following strategies:

- Word balloons had been placed in the illustrations so that the concept of arrays could be better understood (A1.1 Audio-visual effects)
- The concepts of arrays had been explained with the illustration of a drawer case as shown in Fig. 3 (R1.2 Illustration for concreteness)
- Original code examples for arrays had been replaced with the ones with which the concept of arrays could be understood more easily (S3.1 Purpose and content consistency)

VI. CHANGE OF MOTIVATION IN THE SECOND COURSE

In the second course, the improved teaching material was used to teach programming. As in the first course, the questionnaire based on the ARCS model had been administered. In the analysis in the second course, the data are from the 10

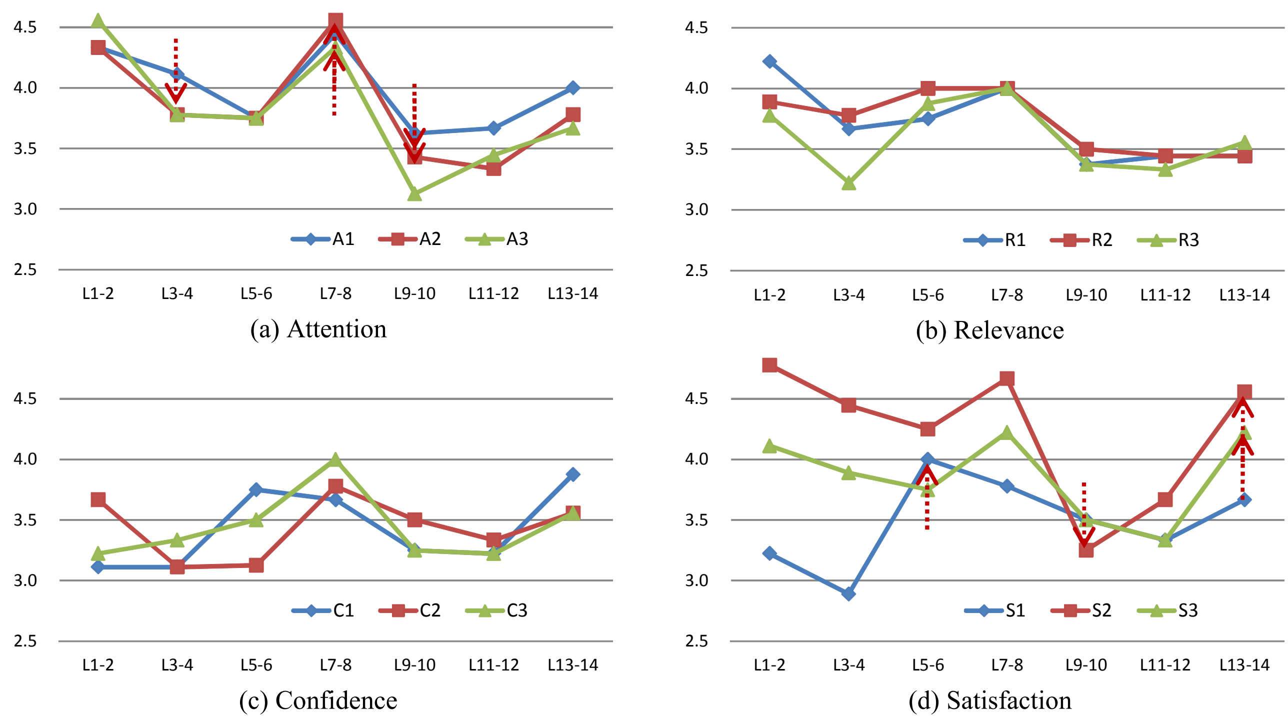

Fig. 4. The Change of Lower Category Scores in the Second Course

TABLE IV. CHANGE OF MOTIVATION IN THE SECOND CLASS

	Attention			Relevance			Confidence			Satisfaction		
	A1	**A2**	**A3**	**R1**	**R2**	**R3**	**C1**	**C2**	**C3**	**S1**	**S2**	**S3**
L1-2	4.3	4.3	4.6	4.2	3.9	3.8	3.1	3.7	3.2	3.2	4.8	4.1
L3-4	4.1	3.8	*3.8	3.7	3.8	3.2	3.1	3.1	3.3	2.9	4.4	3.9
L5-6	3.8	3.8	3.8	3.8	4.0	3.9	3.8	3.1	3.5	*4.0	4.3	3.8
L7-8	*4.4	*4.6	4.3	4.0	4.0	4.0	3.7	3.8	4.0	3.8	4.7	4.2
L9-10	3.6	*3.4	*3.1	3.4	3.5	3.4	3.3	3.5	3.3	3.5	*3.3	3.5
L11-12	3.7	3.3	3.4	3.4	3.4	3.3	3.2	3.3	3.2	3.3	3.7	3.3
L13-14	4.0	3.8	3.7	3.4	3.4	3.6	3.9	3.6	3.6	3.7	*4.6	*4.2

students who attended more than or equal to 6 double-classes out of 7. The data of the students who were absent at most once were used for the analysis, and there were 67 effective data. Since the number of lessons in the two courses was different, L11-12 and L13-14 in the first course corresponded to L11-12 in the second course, and L15-16 and L17-18 in the first course corresponded to L13-14 in the second course. In the second course, a clear increasing trend of motivation was not observed for any motivation factor.

The change of the score of the lower categories in the ARCS model is shown in Fig. 4. Table IV shows the scores of the lower categories with the results of the t-test. As before, the gray cells indicate that there is a significant difference between the score in the cell and that in the above cell with 5% significant level. Light gray cells indicate that there is a decrease in motivation levels, and dark gray cells indicate that there is an increase in motivation levels. Each arrow in the figure indicates that there is a significant increase or decrease in the level of the lower category.

In the first course, a decrease in motivation level was observed in R1, R3, and C3 from L1-2 to L3-4 (Decrease phase 1), and also in A1, R1, and S3 from L13-14 to L15-16 (Decrease phase 2).

In the second course, a significant decrease of motivation was not observed in R1: Familiarity, R3: Motive matching and C3: Personal control in Decrease Phase 1, and A1: Perceptual arousal, and R1: Familiarity in Decrease Phase 2. A significant increase in motivation was observed in S3: Equity in Decrease Phase 2. From these observations, it could be said that the improvement strategies for A1, R1, R3, and C3 had the influence on at least keeping, if not increasing, the motivation. Also, the improvement strategy for S3 was to change the program in such a way that the students could understand the value of the functions used in the programs more easily. Therefore, this modification of the teaching material is considered to be effective in increasing motivation in programming education.

For comparing R1 in L3-4 in the first course and that in the second course, a t-test was conducted, and the result showed that there was a statistically significant difference between them. The average score of R1 in L3-4 in the second course was higher. Therefore it could be said that the modification of the teaching materials using the strategy R1.3 (Familiar examples and contexts) was effective. The lower categories R1 and S3 in L15-16 in the first course had similar property as R1 in L3-4. Therefore, it could also be said that the improvement strategies R1.2 (Illustrations for concreteness) and S3.2 (Exercise and test consistency) were effective.

By comparing R3 in L3-4 in the first course and that in the second course, it can be seen that the average score in the second course was higher, though the t-test showed that there had not been a significant difference. From this, it could be said that the improvement strategy R3.1 could at least keep the motivation in the first course to the second course. The lower category A1 in L15-16 had similar property as R3 in L3-4, and therefore the improvement strategy A1.1 (Audio-visual effects) could at least keep the motivation in the first course to the second course.

Since the major goal of educational efforts in the programming courses is to make students understand better and obtain higher skills of programming, the same paper tests and skill tests were conducted in the first and second courses to see the change in the understanding and skills. Admittedly, any significant difference in the total averages of the test results was not observed.

VII. CONCLUSIONS

In this research, two programming courses with Processing programming environment was offered, and in that, the motivation of the students was monitored using the questionnaire based on the ARCS motivation model. In the first course, two decreasing phases of motivation and one increasing phase of motivation were observed. By analyzing the two decreasing phases thoroughly, the ways for improving the teaching materials were proposed. Based on the proposals, some modifications had been made on the teaching materials before the second course started. In order to verify the effect of the modification, the motivation of the students was monitored again in the second course. As a result, the effects of the modification of the teaching materials on the decreasing phases found in the first course have been confirmed. However, it was observed that there were significant decreases in scores for A2, A3, and S2 from L7-8 to L9-10. Therefore, we plan to further analyze the reason of the decrease in motivation.

Abstract—This paper describes a framework adopted to examine the fidelity level of the implemented curriculum in a computer engineering course. The framework allows education researchers to analyze how an applied hybrid instructional model impacts student learning methodically. This study helps to gain insights into how instructors' pedagogical and content knowledge has shaped the curriculum implementation. Factors that influence the intended, implemented, and learned curriculum are discussed.

Keywords—hybrid instructional model; fidelity; implemented curriculum; intended curriculum; learned curriculum; pedagogical and content knowledge

I. INTRODUCTION

Engineering education plays a key role in preparing students for real-world challenges in an increasingly globalized and technology-driven society. Empowered by continued technological advances, many institutions have introduced innovative instructional models to improve the effectiveness of teaching techniques. For years, instructors struggled to deliver the mandatory amount of content at a manageable pace for students' learning until recent years when online lectures became another delivery vehicle [1] [2]. Online lectures, also known as virtual lectures, are now conveniently utilized to convey the required content without overwhelming students, allowing them to study and review course materials at their own pace [3] [4]. In-class lecture periods are used for more interactive class activities, such as group problem solving to better engage students in active learning [4] [5] [6] . Despite the evident benefit in applying these new approaches, many students still struggle to adequately use these online lectures as planned and may drop out of the online course completely [7]. Motivating students to learn computer networking concepts often experiences additional difficulties because many students find the subject rather technical, dry, and boring [8]. Disparities between teaching and actual learning have led to concerns regarding the effectiveness of new instructional models [9] [10] [11].

Our current study addresses the emerging issues that instructors experience while implementing innovative teaching models. We adopt a framework to examine the fidelity of the implementation of a hybrid instructional model applied to an undergraduate computer engineering course [12]. We analyze the data collected from in-class surveys to examine what impacts, if any, the developed instructional model has on students' learning. Other information, such as students' learning experiences from working on the team projects were analyzed as part of the learning outcome assessment.

II. BACKGROUND

A. Setting

This study was conducted in an upper-division undergraduate computer engineering course, CEE425: *Data Communications and Computer Networking* at the University of Wisconsin-Stout (UW-Stout). A hybrid instructional model was applied in this course, which included both online lecture delivery and in-class activities. Online lectures were conducted through streaming videos that delivered the majority of the course content. Online quizzes were designed and administered to assess students' comprehension of the content after they had watched the scheduled online lectures. Similar to traditional in-class course settings, periodic homework assignments were given to evaluate students' understanding of the lecture materials. The lecture material was based on theoretical concepts from the assigned textbook, examples primarily from modern internet technologies, as well as industrial experiences provided by the course instructor. However, the instructor had limited availability to be on campus for delivering in-class course materials. Due to such scheduling conflicts, the course was required to have a unique schedule arrangement, which was not necessarily desirable to all enrolled students. The class met for 4 hours every other week while the online lecture material was delivered on a weekly basis.

The online lecture content closely followed the sequence of the computer networking topics arranged in the chapters of the assigned textbook. During the in-classroom lecture, the instructor typically clarified important concepts covered in the online videos, held a question-and-answer session for students, and then proceeded with introducing new lecture material that were not previously covered by online lecture. The course plan had two purposes: (i) to keep lecture content delivery continually without overloading online videos; (ii) to elicit students' questions during in-classroom sessions. Students spent the majority of in-class time solving problems related to the theoretical concepts introduced

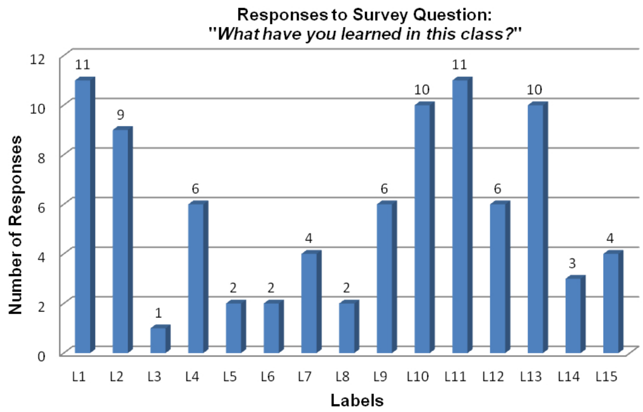

Figure 1. Self-Identified Learned Content and Skills

and performing hands- on lab exercises designed to help students become familiar with the lecture material. Furthermore, the course included an important semester-long team project assignment. For the project assignment, the class was divided into several small groups with 2 or 3 students in each group. Each team was given the flexibility to select a project topic related to computer networking upon approval of the course instructor. Initially, each team was required to submit a written project proposal for the approval. Allowing students to make their own choice of the project topic with minimum technical guidance was intended to encourage students to be creative when encountering real-world challenges. The exploratory process was expected to help students gather meaningful project information, for example, current status of the field of computer networking, the ongoing projects in the area, and issues in the field to motivate and inspire students to learn. The team project was also designed to prepare students to work effectively within a team setting that mimics real-world working environment.

B. Research Methods

Experimental design methods were used to adjust instructional techniques and advance both the goals of design and research simultaneously [13] [14]. The curriculum was developed to provide an introduction to fundamental concepts in the design and implementation of modern data communication and computer networks in terms of protocols and their applications. The instructional goals also aimed at helping students envision how data communication and computer networks are likely to evolve in the future [15]. It was important for this study to focus on designing instructional interventions that would better align teaching and learning goals throughout the semester [16]. Three surveys were conducted at the beginning, after the midterm exam, and at the end of the semester, respectively. The pre-course survey was to assess the level of student awareness of this hybrid instructional approach that combined online and in-class lecture with problem-solving lab exercises. The survey also evaluated the level of students' readiness for the hybrid teaching model, and if students understood how to make good uses of this new teaching approach, particularly

TABLE I. STATEMENTS OF SURVEY QUESTION: '"*What have you learned in this class?*"

online videos, in-class problem-solving lab exercises, and the team project. A similar survey was conducted at the end of the semester. The post-midterm survey focused on identifying and analyzing learning challenges and progress through self- reflections of students' course experiences. Thirteen students enrolled in the computer networking course and participated in this study.

Both quantitative and qualitative methods were used in the data analyses. A modified taxonomy model was applied to assess student learning outcomes while frequency counting was utilized to quantify the survey results [17]. The course instructor and the researcher discussed the course progress regularly. The results from the pre-course and post-midterm surveys were applied to adjust the instructional approaches. The close collaborations between the instructor and the researcher prompted the design of instructional interventions to improve teaching and learning. The correspondences focusing on designs of instructional interventions were descriptive and qualitative in nature. Student learning outcomes were assessed by both quantitative and qualitative methods.

III. RESULTS

Fig. 1 summarizes student responses regarding a survey question of "*What have you learned in this course?*". Students were provided with 15 statements regarding content knowledge and skills intended by the curriculum as well as the course instructor. These statements are denoted in Table I. Five statements, labeled as **L1**, **L2**, **L10**, **L11**, and **L13** were selected by the majority of the class. Their labels are shown with **Bold** fonts in Table I. In contrast, statement *L3*, *L5*, *L6*, and *L8* were selected by only one or two students. These labels are shown with *Italic* fonts in Table I.

Derived from the results of the pre-course survey, Fig. 2 illustrates students' prior knowledge and perceptions about computer engineering and engineering learning from their previous courses. The statements listed in the pre-course survey are described in Table II.

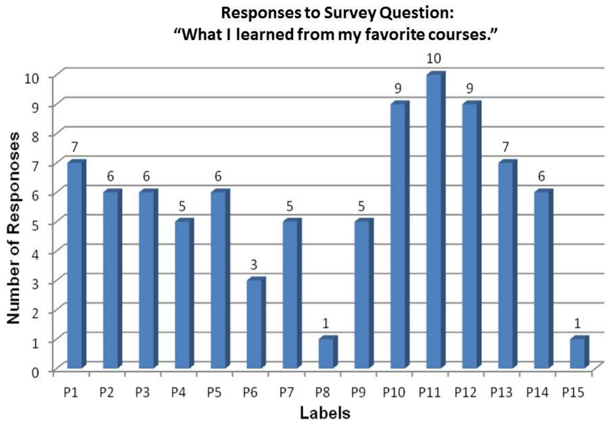

Figure 2. Pre-Course Assessments with Statements Described in Table II

TABLE II. STATEMENTS FOR PRE-COURSE ASSESSMENT

Label	Statement
P1	Fundamental computer algorithms and their analysis
P2	Math representations in computer science and computer engineering
P3	Creating and realizing abstractions/models
P4	Computer data structure principles
P5	Data manipulations in computers
P6	Modular design for partitioning a system into components
P7	Computer system architecture and its organization
P8	Data communications and computer networks
P9	Underlying physics of signals and data communications
P10	How to program accurately
P11	How to program efficiently
P12	How computer system executes programs
P13	How computer system stores information
P14	How computer systems communicate
P15	Other-FPGA board and basic signal processing

In general, students understood fundamental computer algorithms, and how a computer system executes programs and performs data stores. Students felt comfortable with programming tasks, and seemed prepared coming to the course. Labels with **Bold** fonts shown in Table II highlight student prior knowledge and skills indicated by the majority of the class. Several students indicated that hands-on learning experience was helpful. Only one learned computer networks from previous studies as indicated with the *Italic* fonts (*P8)* in Table II.

Fig. 3 shows students' responses to a group of survey questions regarding the usefulness of the semester-long team project. The survey questions are described in Table III. Overall, students reflected positively on the activity, and considered the team project as an important tool that fostered learning. The entire class made efforts and fulfilled the basic requirements by the course instructor. Yet, the quality of the final deliverables of the team project differed dramatically. One group, for example, implemented a functional network device to remotely turn on LED lights as a proof of the concept of a Smart Home function, which exceeded the instructor's expectation. Another group, on the other hand, failed to execute the plan for producing a functional deliverable that they intended to perform. Students' wide-ranging

T4	The team project strengthened my conceptual understanding of the course content.
T5	The team project helps me improve my problem solving skills.
T6	The team project helps me appreciate group learning.

ability to master and apply several fundamental elements of computer networking concepts was obvious. Regardless of various challenges that individuals faced in the team project assignment, most students commented that they learned a lot from the activity. Students made efforts to learn and have made commendable progress in the class, as illustrated in Fig. 1.

IV. INTERPRETING RESULTS

Research results from the current study clearly show that students responded to the instructional approaches positively overall, yet quite differently in some areas. Most of students grasped the course content and developed skills intended by the curriculum and the course instructor, and a few even succeeded in every category of content knowledge and skill as reflected by completing the quality team project. However, several students did struggle in this class. This study intends to find out if and how the newly developed course and the instructional model have impacts on student learning. To interpret the results, one needs to understand why students reacted to this hybrid instructional approach similarly in some areas, but contrarily in others. For example, for the team project evaluation, the entire class indicated that they have learned a lot from the team project. However, the class was divided regarding if the team project helped relate what was learned in the classroom to the real world. Our study resorts to a conceptual framework that would allow engineering education researchers as well as engineering course instructors to examine how the level of the fidelity of the implemented curriculum influences students' learning in a systematic way [12].

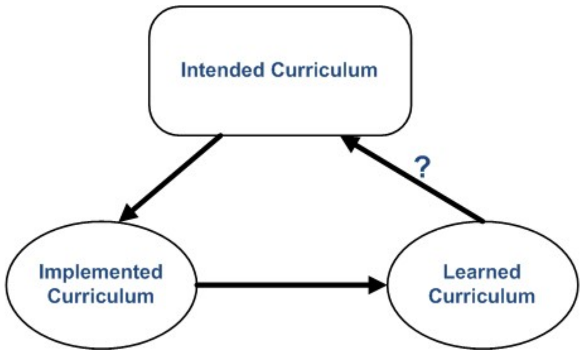

Figure 4. Framework Depicting Relationship between Various Curriculums

Fig. 4 shows the framework that sketches the relationship of three types of curriculum: (i) intended curriculum; (ii) implemented curriculum; (iii) learned curriculum. Table IV describes the adopted framework and displays main factors of each curriculum pertaining to this course.

TABLE IV. VARIOUS TYPES OF CURRICULUM

Type	Factors that influence curriculum
Intended curriculum	- Needs of society and workforce development - Advances in computer engineering - Understanding of teaching of learning technology - Values and beliefs about computer engineering
Instructor: Implemented curriculum	- Teachers pedagogical and content knowledge - Beliefs about learning engineering and learning - Perceived student needs - Constraints
Student: Learned curriculum	- Prior knowledge and skills - Motivation - Perceptions and effort support

A. Driving Forces behind the Intended Curriculum

It is very important that students are aware of rapid advances in both concepts and practices of computer data communication network. They need to be prepared for these changes and are held accountable to norms of the field. As mentioned in Section II, one of the course objectives is to help students develop the ability to anticipate how data communication networks are likely to evolve. Through learning basic concepts, protocol models, and status of computer data communication networks, students are expected to know about the internet, network tools, and applications of these tools. They need to have a deep understanding of computer system architecture and its organization, and should be able to design and configure network management systems.

B. Factors that Impact the Implemented Curriculum

Course instructors are the impelling causes behind curriculum implementation. Possible factors that affect the fidelity of the implemented curriculum are shown in Table IV. Instructors' pedagogical and content knowledge and their perceived student needs undoubtedly shape the pedagogies that have impacts on student learning. As mentioned before, the course instructor has supplemented many real-world examples based on his industrial experience, aiming to inspire students to learn actively. The instructor has made efforts to help students develop the ability to foresee how computer networking evolves based on their understanding of how the current system functions. Specifically, the team project in this course is an illustration that shows how the instructor's pedagogical and content knowledge as well as the perceived learning needs influence the design and the implementations of the curriculum. Students were given flexibility to choose the project topic, and were encouraged to explore new ideas and models. They were required to submit an outline of the project as well as an expanded proposal after getting the instructor's feedback for their initial draft. In-class problem-solving lab exercises used problems from both the textbook and real-world situations to prepare students for the team project.

Constraints influenced the implementation as well. The limited availability of the instructor affected some students even though the majority of the class adapted to the course schedule well. As a result, a few students became very critical regarding content delivery. The instructor modified the length of modules, dividing online videos into several 20-30 minute sections to take into account student attention span after receiving the feedback from students. The instructor also reinforced important concepts during the in-class lecture, and strengthened the connection of various learning activities purposefully. While the majority of the class indicated that online-videos were effective and helpful, and recognized that online lectures helped mitigate the scheduling limit in their survey responses, a couple of students never overcame the anxiety of not knowing what would be discussed during in- class lectures. Unfortunately, they failed to take advantage of online video modules and reported their frustrations in the survey.

C. Factors that Impact the Learned Curriculum

In this pilot study, the learned curriculum is defined as student learning outcomes. Fig. 1 displays knowledge and skills that students believed they learned in this course. To understand why some students mastered certain types of content and skills with an ease, but struggled to grapple with others we applied a taxonomy model that highlights the nature of content knowledge. The results are shown in Table V. The fifteen statements included in the survey question shown in Table I are re-categorized following the model by Anderson and Kratwohl [17] [18]. Individual statements are marked by four classes of knowledge: factual, conceptual, procedural, and metacognitive (knowledge of cognition in general as well as one's own and higher cognition), from concrete to abstract. A similar analysis was applied to the pre-course survey results of Fig. 2, and the results are shown in Table V.

The current study finds that almost all students have improved their learning significantly, particularly in learning concrete

TABLE V. TAXONOMY MODEL

Knowledge Type	Figure 1 Mapping	Figure 2 Mapping
Factual	L11, L12	
Conceptual	L1, L7, L10, L13, L14, L15	P8, P12, P13
Procedural	L2, L4, L9	P1, P10, P11
Metacognitive	L3, L5, L6, L18	P2, P3, P4, P5, P6 , P7, P9

knowledge such as the factual and the conceptual ones. They also did well in learning procedural knowledge. What lacks is the learning of abstract knowledge in advanced computer engineering courses. Many students seemed less comfortable in mastering meta-cognitive knowledge, such as math representations in computer science and computer engineering, underlying physics of signals and data communications, and data manipulations in computers in this course. We believe students' prior knowledge and perceptions influence their learning. Their struggles in learning abstract knowledge in up-division courses, which demands higher cognitive thinking levels, suggest interventions to help students advance cognitive thinking abilities should be reinforced. Designs of such instructional interventions need to be placed at the center of the curriculum implementation.

By applying the framework, we are able to interpret the results regarding student learning. We find that the learned curriculum is influenced by factors such as student prior knowledge, student perceptions about learning, and student effort. It was also affected by the implemented curriculum shaped by pedagogy and content knowledge of the instructor. Designs of instructional interventions are influenced by perceived student learning needs of the instruction.

V. DISCUSSIONS

The current study shows that the fidelity level of the implemented curriculum influences student learning. The team project, for example, along with the problem-solving lab exercises engaged students in active learning. The class recognized the benefits of having a semester-long team project intended and implemented to facilitate learning. Students commented that the team project, in which they learned the most, improved their problem-solving skills significantly. Similarly, they ranked the problem-solving lab exercises as one of the most helpful learning activities. Most students also appreciated the group learning opportunity. These were in line with the instructor's expectations. Complaints about lacking clear directions and topics in the team project assignment indicated that a few students were challenged by open-ended problems. Whether students lack skills or confidence, instructional interventions are needed to help students understand the necessity in developing abilities and confidence to solve open-ended problems. Students need to realize that tasks in real-world situations are often undefined and unclear. It is up to engineers (students in this case) to define what needs to be done in order to accomplish the overall project objectives. A couple of students complained that not enough time was provided for the team project even though it was assigned at the beginning of the semester. Interventions to keep students on task will be required in the future.

By applying the conceptual framework to examine the fidelity of the implemented curriculum, we find the intended and learned curriculum intersect under the team project. In other words, the instructional goals were well aligned with student learning goals. From a models and modeling perspective, we believe that both the problem-solving lab exercises and the team project activities emphasized the process of the developing knowledge and skills, instead of the process of getting a solution. Specifically, the team project has focused on representation fluencies, a crucial element in problem solving [19]. Past studies in this area have indicated that representations and the tools to produce them are among the most important artifacts that students project into and encounter in the real world [20] [21]. This is particularly important in computer engineering education where dynamic and multi-linked representations are come across almost all of the time. In the process of solving problems in this class, students need to define problems, recognize specific types of tools, and develop solutions. Students connected equations, tables, diagrams, etc. and turned these multi-linked representations into new types representations of computer topologies, both physical and logic. They then created program codes that functioned as planned. The final product of the team project was graded by several criteria including scalability and reusability. Through team work and semester long practices, the team project offered students an opportunity to encounter real-world issues, apply their knowledge, and develop skills. The holistic process includes cycles of exploring, defining, designing, testing, and revising for a specific goal [19]. The effectiveness of the team project and its pedagogical focus on enhancing representation frequencies also show that activities like this will be productive in facilitating learning of meta-cognitive knowledge, such as math representations and data manipulations. Instructional interventions for learning tasks that demand higher levels of cognitive thinking will be required all the time, however.

VI. CONCLUSION

The current research has answered the research question, and concludes that the fidelity level of the implemented curriculum influences student learning. That is, the fidelity level of the implemented curriculum minimizes the disparities between the intended and learned curriculum. The framework adopted in this study has helped us advance the goals of design, research, and practice simultaneously. We report three main findings:
(i) the framework depicting relationship of three types of curriculum provides us with a unique opportunity to gain insights into factors that influence each curriculum. It helps to ensure successful implementation of new instructional models; (ii) instructors should attend to all factors that influence the implemented curriculum, and work around constraints to balance student learning needs and constraints. Transitioning from one learning activity to another,

for example from the online-lecture to the in-classroom lecture, should be seamless and purposeful; and (iii) to maximize the potential of a hybrid instructional model, each learning activity needs to be carefully planned and designed to merge the implemented and learned curriculum into the intended curriculum that facilitates active learning. Efforts as such will have lasting impacts on student learning, particularly on learning of abstract knowledge. Furthermore, quality designs of instructional interventions will require cycles of iterations. This research could provide a foundation to additional research studies, including lower-division computer engineering and other engineering classes. Unquestionably, students from lower-division computer engineering classes would have different preparations, perceptions, and learning needs. The main findings of the current study centered on pedagogical and content knowledge of the instructor can be tested and applied in these expanded studies.

***Abstract*—The purpose of this paper is to provide significant evidence from the literature for the use of emerging methods to study engineering students' use of metacognitive strategies when studying. We will review current research methods used to study metacognition and provide evidence that observational methods are an appropriate methodological choice when attempting to study the actual metacognitive strategies students engage in when in naturalistic settings.**

Keywords—metacognition; methods selection; observations, naturalistic settings *(key words)*

I. Introduction

The use of metacognition has been identified as a critical aspect of learning particularly important in problem solving and conceptual change. Metacognition is defined as the knowledge and regulation of one's own learning processes [1, 2]. Much of the research in metacognition has focused on understanding how metacognition impacts learning [e.g., 3, 4] and has occurred in controlled settings. As a result, there is little research to understand *if* and *how* students engage in metacognitive practices in authentic learning environments (such as in the classroom or in peer collaborative settings) or how context affects engagement in these practices. Understanding how students engage in metacognitive practices in a *natural* setting and how students support one another in this engagement will allow for the design of interventions to support metacognitive development that take into account the influences of context.

This paper focuses on reviewing relevant literature on metacognition to develop and support the need for studying metacognition in a naturalistic setting as opposed to in a controlled environment. It also discusses the selection of appropriate methods for evaluating metacognition as many of the tools already in use have come under criticism. Choosing an appropriate setting and appropriate methods are an important first step in a larger project that examines how students engage in and support one another's metacognitive practices in a peer collaborative setting. The larger project is in the early stages of development and this paper provides support for the direction of future work particularly since choosing appropriate research methods is vitally important. The target audience for this paper includes educational researchers and practitioners interested in better understanding metacognition in a variety of fields. In this work in progress paper, we will discuss our initial argument for methods selection with a goal to gain additional insight from members of the engineering education community on moving forward with the larger study.

II. What is Metacognition?

Metacognition can be defined as a learner's knowledge about and regulation of their own cognition [1, 2]. Metacognition can be broken into two major branches: knowledge of cognition and regulation of cognition. Knowledge of cognition, or metacognitive knowledge, can be described as the knowledge that the learner has about his or her own cognitive processes [1, 2]. Regulation of cognition refers to the activities that a learner uses to regulate and oversee his learning [2].

Much of the research in metacognition focuses on the use of metacognitive strategies that are used in the regulation of cognition. These strategies include planning, monitoring, evaluating and awareness:

- Planning - activities that involve predicting the outcomes of learning, i.e. scheduling the activities used to learn [2].
- Monitoring - observation of a person's own level of knowledge as well as the act of testing and revising knowledge and activities used for learning [2].
- Evaluation - judgment of whether a person's own understanding is sufficient and the act of searching for conflicting information and connections to what is already known [5]; process of checking whether a particular learning pursuit is efficient and effective when compared to some criteria or standard [2].
- Awareness - detection of difficulties in understanding concepts and the detection of knowledge that is conflicting with expert beliefs [6].

Notice that these processes are all internal to the learner which can make measuring them challenging. We specifically address methodological challenges in the next section.

III. How is Metacognition Typically Studied

Researchers have used surveys, verbal protocols, and error detection studies to examine relationships between metacognition and learning. However, as described in this

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

section, each of these methods has drawbacks. Researchers have used self-report questionnaires in an effort to study the effect of engagement in metacognitive strategies on specific learning outcomes. For example, Jacobs and Paris studied children's use of metacognition while reading using the Index of Reading Awareness and found that a classroom based program focusing on metacognitive instruction improved young children's ability to use metacognitive strategies while reading [7]. In a self-report questionnaire, participants are asked to respond to a series of statements or questions by showing their level of agreement. Examples of self-report questionnaires that measure metacognitive engagement are the Index of Reading Awareness [7], the Motivated Strategies of Learning Questionnaire [8], the Metacognitive Assessment Inventory [9] and the Learning and Study Strategies Inventory [10]. Because metacognition happens in the learner's mind and learners may not have conscious access to their metacognitive abilities, metacognitive constructs can be difficult to define in concrete ways. This lack of specificity causes issues of construct validity when using self-report questionnaires [11].

Interviews and think aloud protocols are also popular methods for the study of metacognition. Interview protocols, such as the one developed by Zimmerman and Martinez-Ponz [12], allow for gathering information on knowledge, monitoring, strategy use and regulation. In a think-aloud study, participants are given problem and asked to think-aloud while they develop a solution to this problem. Think-aloud protocols have been used to gather information about the problem solving strategies used during problem-solving by asking the student to think out loud while they attempt to solve a problem [11]. Chi, De Leeuw, Chiu and Lavancher used think aloud protocols to study the effect of self-explanations on problem-solving and found that those that used more monitoring strategies were more effective problem solvers [13]. Interviews and self-report questionnaires can be problematic because participants may not have conscious access to discuss their engagement in certain metacognitive practices [14]. And by asking participants to 'think out loud' during a think-aloud study, the researcher is potentially changing the way in which a participant may have engaged in a metacognitive practice in a natural setting.

Error detection studies, in which participants are given a problem solution or reading passage with deliberate mistakes and asked to identify the areas that make understanding difficult, have also been used in gathering data on student engagement in comprehension monitoring activities as well [14, 15]. Palincsar and Brown used an error detection method to study student's comprehension monitoring when using the Reciprocal Teaching method and found that student's that engaged in Reciprocal Teaching were able to detect mistakes in reading more accurately than students that did not engage in Reciprocal Teaching[15]. Error detection studies have been cited with issues of ecological validity due to the fact that participants do not typically encounter problem solutions or reading passages with deliberate mistakes [14].

Self-report questionnaires and interviews are used to report the perceived metacognitive practices that students engage in. Think-aloud protocols are used to study the metacognitive practices that students engage in while in a controlled setting but have the potential to change the thought process of the participants. These flaws make it difficult to use these methods to understand what metacognitive practices participants actually engage in while in naturalistic settings.

IV. USING OBSERVATIONAL METHODS TO STUDY METACOGNITION

The use of observational methods to study metacognition may be one approach to understanding how students engage in metacognitive practices in natural settings. A 2002 Special Edition of *Educational Psychologist* highlighted the importance of studying Self-Regulated Learning, of which metacognition is a critical component, in context using qualitative methodology [16]. In this issue, several researchers highlighted the use of observational methods as critical to the study of SRL in context [17, 18]. Bryce and Whitebread have used observational studies to better understand engagement and development of metacognitive skill in young children [19, 20]. These studies cited that the use of observational techniques was specifically appropriate due to concerns of lack of conscious access to what skills children engage in.

One caution is that observational methods are quite time intensive and require significant resources. Baker and Cerro suggest that this method be limited to research and not be used for practical purposes due to time and resource limitations [14]. By developing observation protocols and coding schemes, similar to that of Whitebread [21], that reduce the time intensive nature of data collection and analysis, observational methods have the potential to become a more widely used research method for studying metacognition.

V. FUTURE WORK

This literature review is part of a larger study that seeks to understand if and how engineering students are engaging in metacognitive practices while study in study groups as well as the contextual factors that impact metacognitive engagement. Observational methods, including video and audio recording, will be used as the primary method of data collection for this study.

The results of the larger study will also be used to support work in understanding how intentional factors such as motivation and learning strategies impacts conceptual change in thermodynamics. Metacognition, which is included in learning strategies for the *hot cognition* framework [22] used for this second study, has been shown to play a significant role in conceptual change [23-25].

VI. CONCLUSIONS

The use of observational methods has proven to be useful when studying metacognitive engagement in young children. Using what has been learned by Bryce and Whitebread, we can pursue using observational methods as a tool to understand how engineering students engage in metacognitive practices while learning.

VII. ACKOWLEDGEMENTS

This paper is based in part on research supported by the National Science Foundation under Grant Number EEC-1150384. ***Abstract*—An alternative to the traditional classroom structure that has seen increased use in higher education is the flipped classroom. Flipping the classroom switches when assignments (e.g. homework) and knowledge transfer (e.g. lecture) occur. Flipped classrooms are getting popular in secondary and post-secondary teaching institutions as evidenced by the marked increase in the study, use, and application of the flipped pedagogy as it applies to learning and retention. The majority of the courses that have undergone this change use applied learning strategies and include a significant "learning-by-doing" component. The research in this area is skewed towards such courses and in general there are many considerations that educators ought to account for if they were to move to this form of teaching. Introductory courses in computer programming can appear to have all the elements needed to move to a flipped environment; however, initial observations from our research identify possible pitfalls with the assumption. In this work in progress the authors discuss early results and observations of implementing a flipped classroom to teach an introductory programming course (CS1) to engineering, engineering technology, and software engineering undergraduates.**

Keywords – flipped classroom, introductory programming, learning with video, computing self-efficacy

I. Introduction

The ability to write and understand computer programs has become an essential skill for engineers to learn. The increased reliance on computer programming to address engineering needs has rapidly increased the number of programming-based courses required to receive any engineering degree. There has been a trend towards trying out newer strategies to enhance and improve how first and second year engineering students understand the principles of programming. Among the many strategies, the *flipped classroom* or *inverted classroom* [3, 4] has gained use being applied heavily at various secondary and post-secondary institutions.

The simplest form of a flipped classroom involves replacing traditional in-class lectures with video tutorials that students are expected to watch prior to class. The students are then required to come prepared for class, which is spent solving hands-on problems that are related to the video. Some variants of the flipped classroom model have students completing assignments, projects and homework in-class based on the watched video lectures. Inspiration and rapid increase of using the flipped classroom approach and many of its variants stem from the emergence of massive open online courses (MOOCs) [5], which have now been established around the world. This movement was spearheaded by the MIT OpenCourseWare [6]; aimed specifically to provide learning and knowledge to anyone who had a desire and motivation to gain new knowledge. The emergence of MOOCs as a ready-to-use learning platform and the popularity of the flipped classroom model have had a combined effect that has led to a vast migration of traditionally taught courses at many educational institutions.

This work in progress is a first attempt at a thorough evaluation regarding the effectiveness of the flipped classroom approach, specifically how CS1 or introductory computer programming is taught. Several authors have experimented with flipped classrooms in order to teach computer programming, but past assessments have focused on upper division courses. Gehringer and Peddycord [1] share their experience with using the flipped model to teach a junior level computer architecture class. Mason, Shurman and Cook [2] compare the effectiveness of a flipped classroom in an upper division engineering course that emphasizes problem solving. Both studies note that a major detractor of the flipped classroom approach is the introduction of the model in later years can be a difficult prospect for the student who has already had two or more years of learning in the traditional way. That leads to the current study, which will investigate the following research questions:

1) *Can a flipped classroom be an effective model for teaching CS1 to first and second year students?*
2) *How does the flipped classroom impact student computing self-efficacy?*
3) *What associated value do students have toward a flipped classroom approach?*
4) *What variants of the flipped classroom approach effectively help students learn?*

This paper will present our preliminary findings with the intention of shedding light on how a flipped classroom model compares to a traditional lecture-style approach in an introductory programming course.

II. Course Design

The course used in this preliminary study was taught to students enrolled in engineering, engineering technology and software engineering programs. The three sections of the course were designed to be the first foray into learning a programming environment. Two of the three sections underwent the flipped model (experimental) with the third section being taught using a traditional approach (control). The course was structured in such a manner that one experimental section used the flipped classroom model for the first half of the semester and then switched to a traditional approach after taking the midterm. The second experimental section started out traditionally and switched to the flipped approach after the midterm. The control section was traditional throughout. Students were randomly enrolled into any of these three sections.

The course content included an introduction to the Python programming language and covered sequence, selection, iteration, flow-control, branching, object creation and manipulation, as is common to most CS1 courses [8]. The hands-on activities for all the sections centered on creating game-based algorithms using Python and the PYGAME library [7]. PYGAME provided the instructors with the necessary hooks needed to make the course hands-on. This was intentionally chosen to transform the course with considerably more applied learning elements. All in-class assignments were game-based and the videos necessary for solving the in-class assignments were specifically recorded to achieve student success. A total of 22 videos were recorded; 11 were needed prior to the midterm. The final exam was given after all the videos had been watched and all assignments were completed. A total of ten assignments were given to each student; five before the midterm and five after the midterm. A student, depending on the section they were enrolled in, either did the first five or the last five assignments in-class. All students took the same midterm and final across all the three sections.

III. Courses Assessment

The common assessments across the three sections were a midterm and a final. Both were timed tests and contained a finite number of problems specific to the course. In addition to the common assessments, students were also given pre-post surveys to identify computing self-efficacy [10] and associated value toward the course.

A. Summative Assessment

The project evaluated the performance on assignments between the students who were in the flipped model classrooms with students who were in a traditional lecture-based classroom. Summative assessment included the performance on: 1) assignments before taking the midterm, 2) performance on assignments after taking the midterm, 3) the midterm, and 4) the final. Table 1 shows these represented as columns and the rows represent the instructional model that was being applied prior to taking any of the column items. The flipped row indicates the results from the experimental sections when they were flipped. The traditional row indicates the results for the experimental sections when they were traditional. The control row represents the class that used a traditional approach throughout the entire semester. Different pre and post-midterm assignments were used in this course explaining the absence of these scores in the table.

TABLE 1. Average Assignment, Midterm, and Final Scores

Model	Assignments Pre-midterm	Assignments Post-midterm	Midterm	Final
Flipped	81.4	65.5	71.4	81.7
Traditional	69.1	66.3	59.2	63.4
Control	-	-	69.4	62.3

Our summative assessments suggest that the flipped model produced higher average scores in the course. This was consistent across both experimental sections eliminating any possible group differences that may have resulted from the randomized student placement. The control section had lower scores in both the midterm and final in comparison to the flipped sections.

B. Computing Self-Efficacy & Value Toward a Flipped Classroom Approach

A pre and post computing self-efficacy survey was used to evaluate any impact the flipped classroom model had on student confidence [9]. The survey was administered to students in both the experimental and control sections. An overall analysis of students' computing self-efficacy from both classes revealed an increase from pre ($M = 53.3$) and post-scores ($M = 71.8$). A paired-samples t-test of the 39 students confirmed this difference to be significant [t (38) = -3.459, $p \leq 0.001$].

A formative evaluation of value was conducted to measure the students' associated value towards the course and also their attitude towards the flipped approach. Experimental classes were asked questions pertaining to the flipped classroom approach. Initial analysis revealed a lack of positive value toward the flipped model.

A correlation analysis between computing self-efficacy and students' perceptions of value toward the flipped classroom model was shown to be not significant. This suggests that the course improved computing self-efficacy, but that the flipped classroom pedagogical approach was not likely to have been the reasoning for this increase. There can be many factors that could be the reason for the flipped classroom approach playing a less important role in the mind of the students. The critical reasoning suggested by the students as part of the open-ended survey were:

1) Adapting to a flipped classroom approach from traditional lecture is overwhelming.
2) Viewing long static videos can be boring.
3) A time-constrained setting to complete assignments can be intimidating in the early stages of using this approach.

IV. CONCLUSIONS & FUTURE WORK

In this study we report initial findings from a mixed-methods based experimental course design aimed at evaluating the flipped classroom model for teaching CS1. Our results show that the flipped approach has promise in improving student scores, but that students found this new approach to be overwhelming and intimidating at times. We aim to formalize our experimental method over the next two iterations of the course in subsequent years. We will be performing a longitudinal study during this period and collecting data from these iterations. Our intention of this study is to completely transform our CS1 courses to flipped classrooms.

The preliminary results presented were able to show that the flipped classroom model positively impacted student scores. Student computing self-efficacy also improved, but since the flipped approach was not used for the entire duration of the class, there is a chance for improper correlation between the approach and self-efficacy. We plan to address by further testing in the classroom.

We have early insights regarding the various approaches to flipping a classroom. It is not completely clear at this juncture whether all parts of the course need to be flipped. A change is definitely required in the way the videos are recorded. The approach of video taping long lectures taught by various instructors could be negatively impacting students value toward the flipped classroom model. Additionally, an important unknown to investigate is how best to increase students engagement levels with the videos.

ACKNOWLEDGMENT

The authors would like to thank the Arizona State University College of Technology and Innovation's Scholarship Support and Enhancement program for funding this research.

Improving Student Learning Using an In-Class Material Processing Design Project

Joseph P. Domblesky
James A. Rice
Jay R. Goldberg
Mark L. Nagurka
Marquette University
Milwaukee USA

Abstract— **At Marquette University, hybrid project-based learning has been implemented in an undergraduate mechanical engineering course on materials processing and forming using a team-based approach. The goals of the project are to 1) introduce more active and student-centered activities to improve student engagement and mastery of core concepts, 2) increase students' confidence in their ability to apply what they learned in the course to solving real-world problems, 3) enable students to gain experience using engineering software as part of the learning process and in applications contexts. While use of process modeling software in materials processing and manufacturing courses is not entirely new, the project has students actively developing a model around a realistic process, rather than passive users running "canned" models and reviewing the output. This paper presents details of the project and discusses preliminary results regarding its impact on student learning and confidence related to application of the course concepts. Recommendations for improving and expanding this in-class project are presented, along with a description of the assessment methods used to measure the impact on students.**

Keywords—project based learning; materials processing; finite element analysis; process modeling

I. Introduction

Recently there has been an increased level of interest in understanding how students learn in order to improve learning effectiveness and comprehension [1-5]. As a model is instructive for this purpose, it is useful to consider how engineering skills are acquired and to use this as a basis to implement practice-based learning activities and improve student skills. The process of formal skills acquisition, as opposed to skill gained through trial and error, can be modeled using the five stages of skill acquisition proposed by Dreyfus and Dreyfus [6-8]. This model (referred to in this paper as the Dreyfus model), which was originally based on a study of United States Air Force pilots, has also been applied to study skills development in the medical profession [9] and is also relevant to engineering. It should be noted that the Dreyfus model describes particular skill development traits rather than individual talent levels.

According to the model, a person acquiring a skill proceeds sequentially through several stages: a) novice, b) advanced beginner, c) competent, d) proficient, and e) expert stages. In applying this model to undergraduate engineering education, several implications can be discerned. A key idea is that student experiences in a traditional lecture-based engineering course are necessary to produce skills commensurate with the novice level. However, the expectation of most stakeholders is that by the time a student graduates, the engineering curriculum will enable students to develop skills that correspond to the level of an advanced beginner.

The issue of competency gaps raised by industry and the level of interest in project-based and problem-based learning provide some evidence that many graduates are not developing the expected skills [10,11]. Recognizing this, an increasing number of instructors are modifying courses in an effort to integrate more applied, hands-on content and improve student engagement. Many of these changes involve the inclusion of active, project-based, collaborative, and other forms of student-centered learning, which have been shown to improve student learning [11-13]. Active learning is an instructional method that engages students in the learning process. In active learning students conduct meaningful learning activities connected to what they are doing. While this definition could include traditional activities such as homework, in the education literature active learning most commonly refers to activities that are introduced in the classroom. The core elements of active learning are activities that engage students [14,15]. Active learning is often contrasted to the traditional lecture format where students passively receive information from an instructor.

Given the hierarchical nature of engineering education, the Dreyfus model suggests that rather than eliminating the novice steps, it is necessary to introduce experiences that allow for more open-ended learning and independence on the part of the students. In order to facilitate the transition from novice to advanced beginner stages, additional experiences such as hybrid project-based learning (PBL, a form of active learning) could be included in a way that allow for situational aspects to be introduced and tailored to the desired level within a project context. An additional consideration is that computer-based technology has transformed professional engineering practice, but this is not the case in education where it tends to be used

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

more as a means to automate the existing educational process rather than as an integral tool for learning and student inquiry [16]. Although computer and virtual based technologies are routinely used in industry for engineering and manufacturing work, many students are not conversant or being trained in virtual and digital technologies which are increasingly pervasive in professional practice. However, properly structured, such technologies can be effectively utilized for student learning and skills development in hybrid PBL.

II. Project Rationale

One of the key goals of an upper level engineering course is to enable students to achieve skill traits that are more similar to those of advanced beginners than novices. When the nature of skills development is considered, it can be argued that the exclusive use of traditional lectures and textbook problem solving activities is likely to improve knowledge but keep students at a novice skills level. We hypothesize that 1) the level of student competence in a course can be increased to that of an advanced beginner in part through the use of virtual/simulation tools, and 2) this effect is measurable.

Although engineering skills encompass a diverse range of activities, ABET learning outcomes c) an ability to design a system, component, or process to meet desired needs within realistic constraints, e) an ability to identify, formulate, and solve engineering problems, and k) an ability to use the techniques, skills, and modern engineering tools necessary for engineering practice [17] were most consistent with the intended project activities and scope. Thus, ABET outcomes c), e), and k) served as the framework for structuring the project activities and assessing its impact.

III. Background

Processing & Forming of Materials (MEEN 4440) is a fourth year elective offered at Marquette University in the Department of Mechanical Engineering and was used as a pilot course for the project. The emphasis in MEEN 4440 is on solidification and thermo-mechanical working and includes coverage of microstructural development in castings, melting processes, process-property relationships, and mechanics of metal forming processes. A first course in manufacturing processes is a pre-requisite for MEEN 4440 and develops skill traits that are consistent with a novice. In the past, MEEN 4440 has been offered as a lecture course. Although the course met student expectations, it was concluded that while they were able to perform analytical tasks, they struggled with using the concepts in an engineering context and demonstrated a low level of engagement/ownership in the learning process. PBL implementation in upper division courses necessitates that due to the greater technical depth that some degree of structured learning needs to be retained. Because of this, hybrid forms of PBL are well suited to engineering and were chosen for the project.

Given that a key requirement in a PBL environment is for students to produce a product/outcome, it follows that available resources at an institution will limit the type and scope of project work that students will be able to perform. In much the same way that simulation software provides practicing engineers with a powerful virtual tool that can be used for design and verification; the flexibility that such programs (particularly discrete simulation and manufacturing process modeling software) offers also make them highly effective as a learning tool in an academic environment. This is particularly true in manufacturing processes where computer-based visualization can convey concepts more effectively than text, equations, and two-dimensional images and promote student retention [18]. In comparison to a lecture-based course, PBL represents a natural environment where students can not only develop application skills using computer-based technology as part of the engineering process, but they can also use this technology as an *integral tool for self-directed learning* [19].

While materials processing provides a wide range of potential project topics, a project developed around forging process design was considered to be the most appropriate choice as it could be structured to be consistent with student skill levels and the course syllabus. Rather than using a contrived design problem, PBL philosophy indicates that an industry-based problem would provide more student motivation and connection between course content and real world problem solving. A Wisconsin company was contacted and agreed to furnish a forged gear blank geometry. Although impractical for students to actually demonstrate their process, finite element method (FEM) based process simulation enables them to build a realistic virtual model that includes the relevant materials processing physics. The ability to receive timely feedback is also an important element in PBL. By using an axisymmetric part geometry, simulation times are relatively short (on the order of 10 minutes using a laptop computer) and students are able to receive feedback regarding their design decisions and assess how well they meet the stated requirements.

To prevent skills development from being diluted and creating activities that were potentially confusing to students, it was decided that a unified, integrated approach using a single project was necessary. The project was structured so that students were provided with a set of specifications and a part print at the beginning of the semester. Students were then paired and tasked to develop a three-step prototype process that met multiple constraints. As students typically have little experience and familiarity with FEM and forging design principles, it was necessary to dedicate 2-3 class periods to cover basic concepts in these areas. Pre-project testing showed that in order to ensure that the project focused on engineering skills development rather than software usage, it was crucial to employ software that was user friendly and easy to navigate. A number of engineering software vendors have recognized that similar needs exist in industry and now offer easy to use interfaces and wizards to reduce the learning curve for beginning users. For the current project, the commercial code DEFORM (Scientific Forming Technologies Corporation, www.deform.com) was used.

In addition to using process modeling software, students also employed solid modeling to develop the necessary geometry files for the initial work piece and tool geometry. Using the post processor, students must verify that their process produces a sound forging and maintains conditions that are within workability limits for the alloy. Each team must also select an appropriate tool material and verify that stresses are within acceptable levels (i.e., below the 0.2% yield strength) based on a yield criterion. A further requirement was to demonstrate that the force profile was consistent with the kinetic envelope for a crank-slider press mechanism. To ensure that students and the instructor could monitor progress, a set of milestones and a timeline were developed with interim design documents being submitted by each team. This also provided an opportunity for the instructor to provide corrective feedback as needed and monitor the extent that key concepts were being explored by each group.

IV. Results and Discussion

The project was implemented in Fall Semester 2012 with an enrollment of 18 senior-level mechanical engineering students of which 51% had co-op experience and less than 20% had FEM experience in prior coursework or employment. Due to the low level of experience students had with FEM modeling at the start of the project, several activities were assigned as part of the interim reports that required students to investigate selected modeling concepts (e.g., mesh design) and consider the effect they had on the model performance. While there was initially some concern about students' ability to develop proficiency using the FEM software, 74% of the students were able to use the FEM software after initial training sessions with the remainder requiring minor technical advice. Most of the problems encountered were attributable to students being unsure how to approach an open-ended design problem. This was addressed through as-needed meetings between the instructor and groups to allow the instructor to provide suitable suggestions. It became apparent however, based on the interim documents submitted, that there was a need for students to improve their drawing and dimensioning abilities.

Although it is not a trivial task to assess engineering skills levels, the Dreyfus model does provide a description of attributes at each skill level that can be used to guide development of metrics. Applied to engineering practice, an advanced beginner is capable of situational discrimination and working with both context-free features and situational aspects to formulate a plan of action. This behavior is evidenced when students become less dependent on rote rule/procedure following, can independently discern which factors are important in solving the problem (i.e., situational discrimination), and are able to arrive and execute a workable solution albeit with some effort.

To determine the impact of the project on student design capability and ability to meet multiple design constraints, student success rates were determined with respect to whether or not their final design met each of the design specifications. The percentages of student teams meeting the project design criterion are shown in Table 1. While none of the teams were completely successful, 78% of the teams were able to meet 5 out of the 6 specified criteria though the low success rate in the blocker design task was unexpected. However, after using the software it was concluded that self-directed experiences alone were not sufficient to develop design skills. After reviewing the traits noted in the Dreyfus model, this suggests that it will be necessary to include additional design maxims and examples in future project assignments.

When considering how to assess the effectiveness of project oriented learning, it is necessary to consider attitudes and skills rather than simply comparing knowledge orientation as is done in traditional subject learning [18]. Students were asked a series of questions intended to conduct a self-assessment of their ability to design a process and use FEM as a modeling tool. A total of 17 students were assessed before (pre-test) and after (post-test) the project. These were intended to measure their abilities to perform a design and use a modern software tool as part of engineering practice. Pre (μ_1)/post (μ_2) evaluations were compared via a standard test of means (t-test) as well as a non-parametric test of means (Mann-Whitney U-test).

Based on their responses to questions regarding 1) understanding and confidence in designing a manufacturing process, 2) understanding thermal phenomenon in materials, and 3) understanding and applying effective stress in an applications, students were asked "How confident are you in your ability to design and model a manufacturing process?" Responses to this question were used to form a hypothesis for testing. Pre-test questions indicated that 64% of the students had low confidence in their ability to design a manufacturing process (question 1). Based on these results the hypothesis: "A student's ability to model a manufacturing process has improved" was proposed with the alternative hypothesis: "It is unknown if a student has improved his/her ability to model a manufacturing process". Results from the t-test and U-test are given in Table 2.

TABLE 1. Percentages of student groups meeting each of the six project design criteria.

Load Profile-Blocker	Load Profile-Finisher	Die Fill - Blocker	Die Fill-Finisher	Die Stress-Blocker	Die Stress-Finisher
89%	78%	11%	78%	89%	78%

TABLE 2. Assessment of student ability to design a prototype materials processing operation.

Test (μ_2>μ_1)	Calculated Probability (P-value)	Significance
t-test	$3.5x10^{-9}$	Yes
Mann-Whitney U-test	$2x10^{-8}$	Yes

Based on the results of both tests, it can be concluded that a statistically significant (small p-value) improvement was observed with respect to students' ability to design a prototype manufacturing process based on hot forging.

Responses to questions regarding 1) understanding how nodes function in FEM, 2) understanding of mesh design, 3) understanding of mesh density, and 4) understanding and ability to use information from the FEM model, resulted in students being asked "Do you understand Finite Element Analysis as it is applied to a manufacturing process?" This led to the hypothesis "A students' understanding of Finite Element Analysis as applied to a manufacturing process has improved," with the alternative hypothesis "It is unknown if students' understanding of Finite Element Analysis as applied to a manufacturing process has improved". Results from the t-test and U-test are given in Table 3.

Based on the results of both tests, it can be concluded that a statistically significant improvement was observed with respect to students' ability to understand the basics and use of FEM with respect to a manufacturing (forging) process.

An effort was also made to incorporate the modeling software as part of homework problems and exam questions in place of analytical calculations. This was done on a limited basis to ascertain if self-directed learning would increase understanding of the fundamental importance of effective stress and could be used to replace class discussions. One of the questions posed on a mid-term exam asked each student to define and discuss effective stress in his/her own words. Of the responses, 52% were deemed satisfactory and, while not conclusive, it is consistent with findings from other studies that PBL does not necessarily lead to an improved understanding of fundamental concepts.

TABLE 3. ASSESSMENT OF STUDENT ABILITY TO UNDERSTAND BASIC CONCEPTS AND USE OF A FINITE ELEMENT MODEL RELATED TO MANUFACTURING PROCESSES.

Test ($\mu_2>\mu_1$)	P-value	Significance
t-test	$4.7x10^{-10}$	Yes
Mann-Whitney U- test	$1.2x10^{-8}$	Yes

Student feedback regarding the value of the project and what was learned from it was solicited. The following is a sample of quotes from students who completed the course:

"I actually enjoyed working a lot with this software and it truly gave me a much better understanding of the whole forging process. I kind of wish we could have had more class time to fool around with the program. Other than that I think the use of this program for the mini-project was a great idea and very beneficial."

"I loved the project as it involved a real part made at a local company."

"I learned a lot about the different things that must be considered in the die forging design process including load requirements, die stress, temperature, fill, friction, etc. I have also gained a good understanding of the use of the DEFORM program and feel confident in my ability to simulate and assess forging operations."

"I learned many things such as how to use DEFORM, the relationships of temperature, stress, material flow, friction, contact time, etc. in a forging process, and I learned and understand more forging terms."

"Working with simulations allowed me to see how I could affect the outputs of a forging process by varying input parameters. Being able to see directly how I could affect results greatly facilitated my comprehension of course material."

"I gained a better overall understanding of processing as well as an appreciation for all of the time that goes into doing it correctly."

Student feedback indicated that students liked working on a real-world problem, learned about the forging process and other course material, and developed an appreciation for the many parameters involved in designing a forging process.

Due to the user friendliness of the software, minimal class time needed to be dedicated to the project from regular lecture discussions. Students were able to focus on self-directed learning using the software to study and visualize fundamental behavior while receiving more detailed feedback than would be possible in lecture, text reading, or visiting a website. While the project focused on materials processing, the experiences gained indicate that it not only provided suitable project/design experiences that can be used in a semester project, but that comparable efforts could also be applied to other courses. For example, a similar scaled-down project is being prepared for use in the pre-requisite junior-level manufacturing processes course for basic concepts related to materials forming. This would not only help to improve vertical linkage between the courses but also enable more time for coverage of necessary design maxims and examples without significantly reducing class time needed for coverage of other syllabus topics.

V. CONCLUSION

Hybrid PBL learning was implemented in an undergraduate mechanical engineering course on materials processing and forming through a team-based project. The goals of this project were to 1) introduce more active and student-centered activities to improve student engagement and mastery of core concepts, 2) increase students' confidence in their ability to apply what they learned in the course to solving real-world problems, and 3) enable students to gain experience using engineering software as part of the learning process and in applications contexts.

Based on the assessment results of the project completed in the MEEN 4440 course, we conclude that the goals of the project were met and the project experience improves students' ability to 1) design a prototype manufacturing process based on hot forging, and 2) understand the basics and use of finite element analysis with respect to a manufacturing (forging) process. While some refinement is needed, student response to the design experience and software usage was very positive and the project will become part of regular course activities.

ACKNOWLEDGMENTS

The authors would like to thank the Association of Iron and Steel Technology (AIST) for supporting this project through a Ferrous Curriculum Development Grant, and the Lafferty Family for their support of student-centered learning activities.

Abstract—**Given the demand in the area of Software Engineering for solutions that actually contribute to modern organizations, the search for qualified professionals who have considerable practical experience has been growing day-by-day. Set against this background is the learning process of traditional teaching, in which the Student is largely a mere recipient of information, including concepts and theoretical foundations, and is seldom given practice in problem solving. Therefore with a view to minimizing this problem, teaching and learning methods such as the Problem Based Learning (PBL) have emerged in higher education as an approach to foster changes in teaching and learning processes, which are aligned to the new requirements of the labor market and redefine the roles of those involved in educational processes. To evaluate these processes, a case study on skills training to teach Usability Testing is discussed, and important results presented that show the applicability of the proposed approach for teaching Software Engineering.**

PBL; Process Management; Software Engineering; Education.

I. Introduction

The continuous growing on the informatics market implicates in a bigger search for qualified professionals who are able to analyse and solve complex and various problems. Even though, it's easily noted how their education ends up being damaged by the use of traditional learning methods, in which the learning process enhances the theoretical learning in solving problems. It's also worth noticing that when trained in such a way, there is no relevant contribution to the development of skills to be considered in the professional condition. The lack of practical learning, where realistic practices are hold through simulated scenarios based on the current job market, hinders the Students from assuring an experience in dealing with complex situations associated to the interpersonal relationships required to this process.

Before this context, it comes to be relevant to consider the need for embracing training with different guideline approaches, intending to minimize the vantage in technology's market, as well as providing quality training to the professionals in the area. In order to attend to this need, new teaching methods, like the Problem-based learning have been introduced in higher education as an alternative in contrast with the traditional education.

Problem-based learning (PBL) [1] is compatible with the job market, once it promotes essentially a functional and practical learning by the use of problems which are similar to the ones found in the market. It's considered necessary to emphasize the alignment of the practices to the theoretical knowledge in an integrated way, what allows that non-technical abilities to be also developed.

Focusing on the Student, this concept has as inherent process the use of problems to initiate and motivate learning concepts and the promotion of necessary skills and decisions to come to a solution [2]. Even being best known in medicine, it has been applied in various areas, as in software engineering, where the results are considerably satisfying.

The benefits of the embracement and the changes in the learning process in PBL are evident. The redefinition of the roles in this process assigns Students, who are active agents, the responsibility of building their own knowledge through the collaborative learning, whereas the teacher takes the responsibility to guide the Student through the building process as a facilitator. However, many challenges have been faced in order to get effective results by its endorsement. In particular, the process management stands, because PBL is strongly directed to process [3], when considered that the term "process" is defined as being a "set of behaviours or activities performed by people or machines to achieve one or more objectives". Accordingly, the PBL process defines itself as a set of activities that aim its effectiveness by the preservation of the principles to achieve the requested objectives.

In this context, this paper proposes a PBL approach in education modeled on BPMN – Business Process Modeling Notation, but considering the method elements proposed in Santos [4] by the problems definition, practical learning environment, flexible content, human resources role, and the process of authentic evaluation.

II. The xPBL Methodology

The essence of PBL in being directed to process determines the need of a process that supports defined steps, as the planning, implementing, monitoring and continuous evaluation as a way to guarantee the theory's alignment (concepts) to the problem (practice) during the whole learning process. These steps refer to PDCA (Plan, Do, Check and Act) cycle, defined by Deming. As tool also applies to educational processes, the cycle promotes them through the management of the organization and proper execution of the activities of steps aimed at continuous improvement. The PDCA cycle was proposed as reference elements of the methodology xPBL.

In this article, emphasis will be given to the stages of planning and execution. The process, focused on the PBL approach to Software Engineering education, had as foundation the relation of the five principles of PBL elements proposed by Santos [4]:

1. *Real problems*: the problems must be real, asked by real clients, of reasonable complexity and relevant to the field and educational goals;
2. *Real environment*: the practical learning environment based on software industries promotes a better comprehension of the process by the Students, specially in its functions and responsibilities, activities and strategies to accomplish the clients satisfaction and the quality in the products;
3. *Human resources* involved: the value of each person involved contributes to the process growth in general, according to his or hers experience, education and formation, where the Students get supported by each other and also Tutors, Monitors and even the Client during the learning process;
4. *Content*: with the purpose of promoting a holistic view of the Software Engineering area, the resumes must be according to SWEBOK (Software Engineering Body of Knowledge);
5. *Assessment processes*: based on the authentic assessment strategy defined by Herrington and Herrington [5], the Students are involved in learning environments in which the activities are turned to the application of their knowledge, stimulating their ideas and critical vision and the implantation of different ways to solve them;

As a way to check these processes, the article presents the results of an experience in applying the elements of a case study proposed to Software Engineering studies, emphasizing Software tests accentuating usability.

III. Applying the xPBL Methodology in Real Cases

This section has as main objective to present some successful real cases, verifying the veracity of the PBL method. The Software Residency described in [4] was planned to form software engineers in the BADA platform for mobile devices, or by simplification "BADA Residence", used the Software Factories model as a practical learning environment, having the SIDI Samsung institute as real client of this project and CESAR as educational institution [6]. The Software Residency in Telecoms market – performed in a partnership between CESAR (www.cesar.org.br) the institution of technological innovation and Datacom Brazil (www.datacom.com.br) – had the objective of creating specialized professionals in a short period of time, so Datacom could hire, as it needed professionals with the required skills for new project [7].

In the Software Quality area, the Training in Software Tests (PCTS) was performed, aiming for offering the Students the proficiency and the dissemination of the technical knowledge on the Software tests area, using the PBL methodology [3]. It was implemented by the Software Productivity Lab (LabPS) of National Institute of Science and Technology (INES) in the Informatics Center of Federal University of Pernambuco (Cin-UFPE), with the collaboration of partners from the innovation institute C.E.S.A.R. (Recife Center of Studies and Advanced Systems) and of the software industry of Pernambuco, Brazil [8].

IV. PBL in Processes

In computer science there is a difficulty in having qualified professionals in Informational technology area, as, for example, software engineers. Some education methods try to solve this challenge, as PBL, that offers the Students a way to get the knowledge and developing skills and attitudes expected from a professional. The process based in xPBL methodology was created to assure the correct application of the PBL.

This section describes the formation structure of the Planning and execution processes based in xPBL methodology, referring to the five elements of the PBL approach in education: Real Problems, Real Environment, Human Resources, Content, and Evaluation Processes. Was seen the need to create one more element to join the elements of the methodology, the PBL Plan. The PBL Plan contains the steps of each activity, as a schedule, human resources involved and application place. It's clearly defined and aims at the entire process to be applied.

The process is composed by three splits that indicate the active people in the process, like the Client, the Coordinator and the Teacher/Tutor. In each split are the subdivisions.

A. Real Problem

The use of problems is a main tool on the PBL methodology, where it must be defined a specific problem based on real context and complexity. After defining the problem, the new learning activities start, that need to be connected to concrete facts, always searching for the reality in context. The definition process of the problem may begin from two situations, as shown in Fig. 1:

- Client defines the problem to be solved through a paper with its description and then pass it to the coordinator, when he or she will analyse the description and verify if the problem fits the PBL concepts so it can be passed to the teacher;
- The definition of the problem comes from the coordinator, so the same sends the actual problem to the Teacher through a paper with its description. The problem may have as objective to form test engineering, for example.

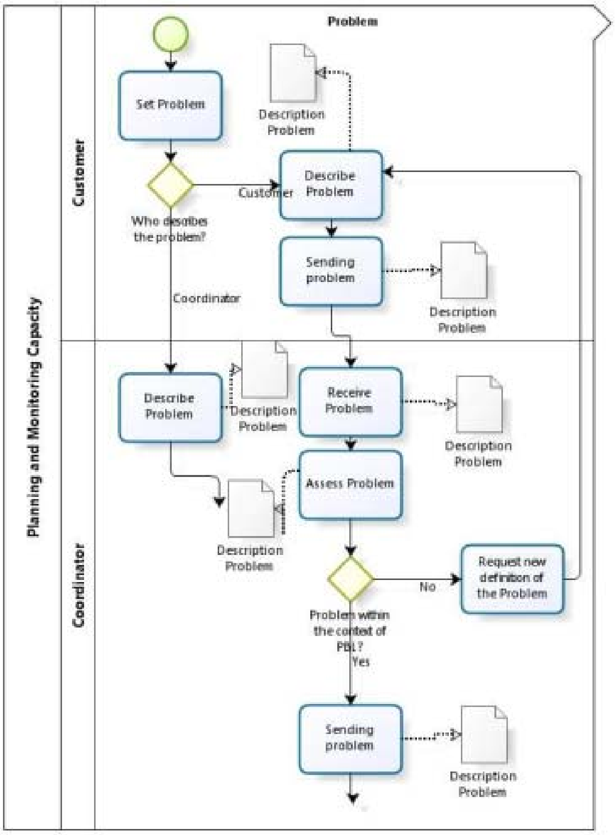

Figure 1. Processes on Real Problem perspective.

After defined the problem, the Teacher sets the educational goals, as shown in Fig. 2. Educational goals are defined objectives to determine in a most effective way which content level is wanted to achieve through a previously taught concept [7], are learning expectations over the Student.

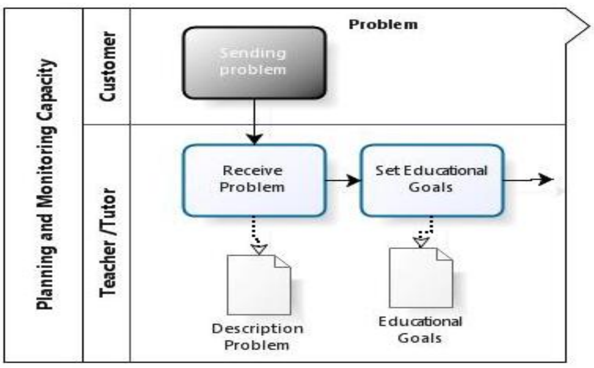

Figure 2. Setting Educational Goals.

B. Real Environment

In appropriate environment gives the Students a better structure to find the resolution of the problem (Fig. 3). This sub process is a coordinators responsibility since the definition of the local infrastructure and the necessary hardware, networks and softwares that the Students will use until the place and applications to be used are defined.

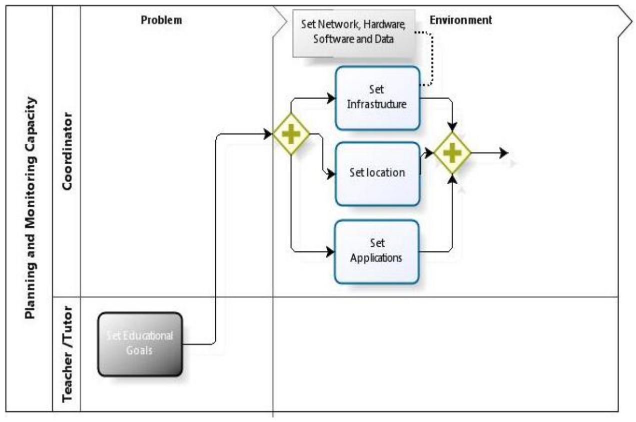

Figure 3. Processes on Environment perspective.

C. Human Resources

It's a key part of the planning process, because the value of each person involved contributes to the process growth as all, according to their experience, education and formation. The people involved are the Students, Teachers, Tutors and the Coordinator. Next, we will verify each one's role.

- *Student:* composes the team, and are responsible for performing the activities, having active role inside the PBL methodology;
- *Teacher:* responsible for teaching and preparing the subjects content, making the learning easier;
- *Tutor/Technician:* specialist on the PBL methodology and also responsible for supporting the Students, helping with the activities projections and assuring the application of the method;
- *Coordinator:* responsible for the demand of the problem, leading the methodology implementation, executing monitoring activities and validating results. and;
- *Client:* responsible for defining the actual problem.

According to the lack of professionals, Teacher and Tutor can be just one person (Teacher/Tutor) in this Process, provided they have the technical capability to both roles, as shown in Fig. 4.

Coordinator is the responsible for the definition of the teachers, tutors and the selective process itself, while the Teacher/Tutor is responsible for participating of the selection process and defining the teams, assigning roles and responsibilities for each one.

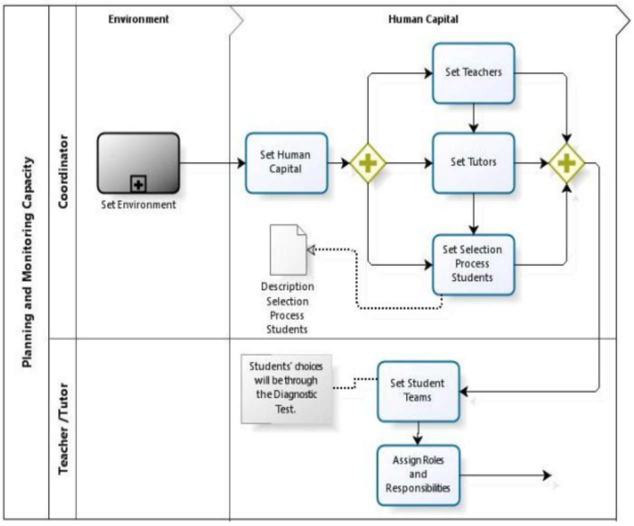

Figure 4. Processes on Human Resource perspective.

D. Content

It involves definitions of the subjects to be taught, defining their content related to the problems context and also defining the support material, like tests, exercises, etc. These definitions must be made by the responsible Teacher, according to the Students need for the problem resolution (Fig. 5).

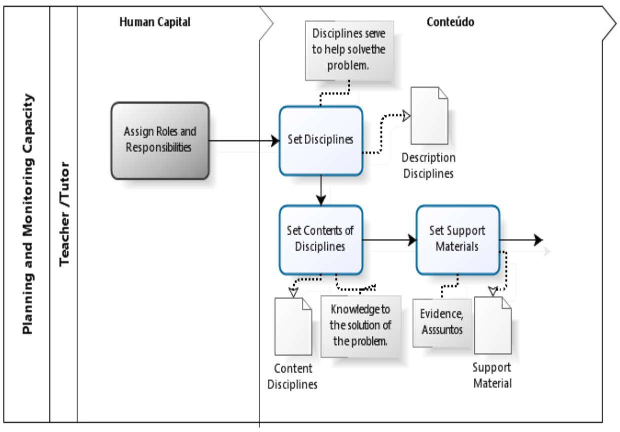

Figure 5. Processes on Real Problem perspective.

E. Assessment Processes

The evaluation must have a diagnostic function, checking the educational situation of the Students to propose improvements by the Teacher. In the proposed evaluation process, the Teacher/Tutor verifies if the educational goals were accomplished through mapping. The Coordinator defines the evaluation modalities, as well as its processes and the grading criteria (Fig. 6).

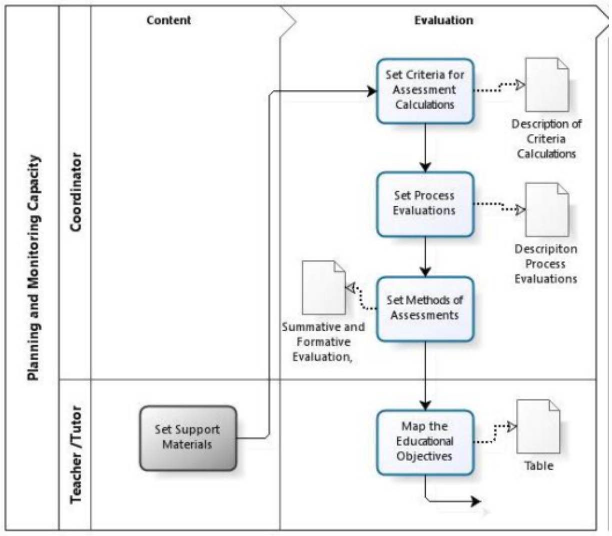

Figure 6. Processes on Assessment perspective.

F. PBL Plan

The actualization of the PBL plan is of a huge importance because a starting point is necessary so that the whole process may be applied in a clear and objective way (Fig. 7). Containing the step by step of each previously quoted element, as, for example, who will be involved inside the human resources and which are the defined contents.

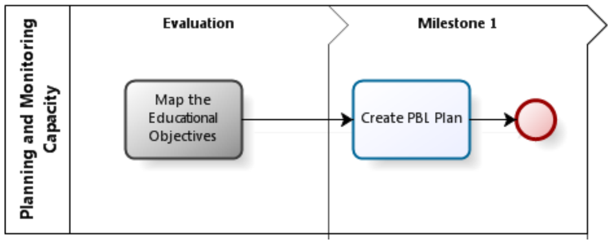

Figure 7. PBL Plan.

After accomplished the entire planning part, we move to the execution process, which is the second part of the process, where we apply what has been planned. After the Client describes the problem, the Coordinator receives the same and checks if it is necessary to divide the problem. If so, it divides and after, sent to the Teacher/Tutor.

The Teacher/Tutor is responsible for receiving the problem from the Coordinator and pass it to the Student, who analyses it and searches for solutions. If the Student finds troubles in the resolution, he or she may ask the Teacher/Tutor for help. After the questions are taken, the Student finishes the task by delivering the artefact to the Teacher/Tutor. When receiving the artefact made by the Student the Teacher/Tutor makes the following evaluations; process, performance, content and artefact. The Teacher/Tutor must also verify for fractionated problems and make the same evaluation to the remaining problems. For last but not least, the Teacher/Tutor checks if the problem which was described by the Client was solved and sends it to the Coordinator. If the problem was not solved, the Teacher/Tutor requests the Student to correct it.

When the artifact is delivered to the Coordinator, he or she passes it to the Client, who will evaluate the work. If the artifact is according to what was requested, the Client gives a positive feedback of the final product (artefact), which is passed back to the Coordinator, then Teacher/Tutor and finally, to the Student. If the artifact is not according to the requested, the Client asks the corrector for a check, who will sent it to the Teacher/Tutor, who will pass to the Student, starting a new cycle of execution until the problem is solved.

V. Applying the PBL Process

Savery & Duffy establishes eight basic PBL principles and emphasizes the need for supporting all learning activities and processes in a real problem inside a real context of an environment similar to the working place.

Before that, we chose to apply the process into a Software Test training emphasizing usability, in order to form qualified professionals inside the software quality field for the job market, in a similar environment to the working place, using the LMS Amadeus system to verify its usage, attached to the value to the system.

In many universities the term 'Software Test" is neglected, so the Students end their courses with little or none knowledge about this subject.

Software Test is the execution process of a product to determine if it has achieved its specifications and worked fine to the environment for which it was projected. The test does not depend on the development process for each stage (analysis / project / development). The objective is to expose flaws in a product, so that they can be fixed before the final delivery, achieving liability and making the software quality better [8].

The training was performed in CIN- Informatics Center in Federal University of Pernambuco in association with CiTi- Integrated Center of Informational Technology. Next, the description of the application of the process through the six elements:

A. *Real Problems*

The real Client defined the real problem "Our educational institution needs to adopt a management system of an easy use to support the learning processes of the technical courses offered. However, the communities Students rarely access the Internet, in addition to not having an ease in dealing with the computer itself. They told me about "Amadeus", but we really need to analyse this possibility! ".After validated the problem by the Coordinator, who verified that the problem was in the context and was consistent, it was sent to the Teacher, and he defined the educational goals. The educational goals were based by Blooms taxonomy, where know, understand, apply, analyse, synthesize and judge the following educational goals:

- Basic Concepts of PBL;
- TestLink tool;
- Amadeus tool;
- Basic Concepts of Usability;
- Basic Concepts of Software Test.

B. *Environment*

CIn- Informatics Center of UFPEs lab was selected, with one computer per Student with access to LMS Amadeus and TI TestLink (tool and management of test-cases simulating a software test industry.

C. *Human Resources*

The industry was structured with professionals with abilities compatible to the established objectives of the training, and interacted with the Students teams (Fig. 8). So, each Student got continuous support from the Teacher/tutor. The Client also frequently interacted with the teams, making the understanding of the problem easier to be solved. The teams division was performed in a homogeneous way, avoiding one to be weaker than other.

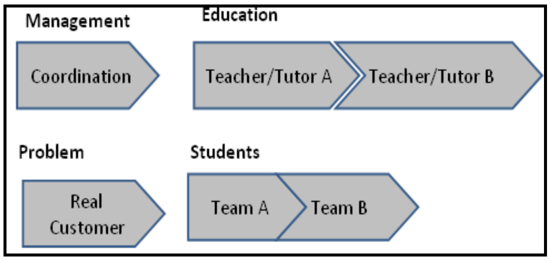

Figure 8. Human Resources in the Software Testing Training.

D. *Content:*

The following disciplines were selected according to the Students needs: Introduction to PBL, Amadeus tool presentation, Software test, TestLink tool and Usage Test.

E. *Evaluation Process*

The evaluation was based on the authentic evaluation by Herrington and Herrington [5], where the five elements the PBL approaches were evaluated based on the process xPBL.

1. *Content*: formative and summative evaluations were made to check the Students knowledge, evaluations those, made before and after each provided discipline. The table below shows the global evaluation of the Students referring to groups A and B. The result was announced at the end of the course, following the summative evaluation approach. The training used had three distinct activities of evaluation, such as:
   a. Exercise 1 was carried out for writing test cases as a whole;
   b. Exercise 2 was to write test cases for usability;
   c. The interaction was applied according to the students behaved performing the

above activities and were interacted with the rest of the group.

The criteria used for writing the test cases for both test cases in general and for the test cases for usability were the clarity, correctness and completeness. Was used at 5-point scale of values in the evaluation: "Excellent" (5) "Very good" (4) "Good" (3) "Satisfactory" (2) "Low" (1). The average content (Table I) was calculated by summing the values assigned to each question, and divided by the number of questions.

TABLE I. AVERAGE OF EVALUATIONS ON CONTENT ASSESSMENT

Team	Media
A	2,47
B	3,13

2. *Process:* The items to be analysed were projects presentation, deadlines and goals planned versus deadlines and goals accomplished, strong visions and improvement points. Due to the subjectivity of the analysis, a range of 0 to 10 points values were used, then the average taken. Notice that in the Table II, the grades were very tight, where the Students attended well in the process.

TABLE II. AVERAGE OF EVALUATIONS ON PROCESS ASSESSMENT

Team	Media
A	8,8
B	8,6

3. *Results:* The items to be analysed were understanding was applied that the teams had about Software tests, usability and PBL methodology, verification and validation of the artefacts, as well as the improvement in softwares usage. Due to the subjectivity of the analysis, a range of 0 to 10 points values were used, then the average taken. And about grades, we can see that team A was superior to team B (Table III), even though it must be considered that this group had lost two of its members.

TABLE III. AVERAGE OF EVALUATIONS ON RESULTS ASSESSMENT

Team	Media
A	9,7
B	9,2

4. *Performance:* A self-evaluation was held and also a constructive evaluation between the Students themselves [9]. It covered the self initiative, the capacity of learning, the collaboration, the communication and the focus on results. Was used at 5-point scale of values in the evaluation: "Excellent" (5) "Very good" (4) "Good" (3) "Satisfactory" (2) "Low" (1). The average content was calculated by summing the values assigned to each question, and divided by the number of questions. Notice that in the Table IV the team B has a good performance, even being in a number disadvantage.

TABLE IV. AVERAGE OF EVALUATIONS ON PERFORMANCE ASSESSMENT

Criteria	Team A	Team B
Self initiative	3,38	3,6
Learning capacity	3,62	3,49
Collaboration	3,5	3,7
Communication	3,9	3,67
Focus	3,56	3,55
Media	3,47	3,6

5. *Clients Satisfaction:* The real Client also evaluated the deadlines, the achievement of the goal, the quality of the work, if the team had a good communication during the process, the agility of the team and for last, the innovation. The average grades of both teams were very close. Team A had an average grade 7,91 and team B with 7,41.

TABLE V. AVERAGE OF EVALUATIONS ON CLIENTS SATISFACTION ASSESSMENT

Criteria	Team A	Team B
Time	10	10
Objectives	8	7,5
Quality	8,5	6,0
Communication / Transparency	4	5
Agility	9	7
Innovation	8	9
Media	7,91	7,41

F. PBL Plan

It contemplates all the training details, as local, date, hour, Teachers/Tutors, educational goals, subjects, giving a clear vision of the training performed.

Before the training we take some lessons as learned, which are:

- The lab environment was not agreeable so that the Students could reunite, when they got out of the lab to have meetings;
- The lack of time limited the interaction between them, because the training was applied in two consecutive days;

- Lack of Commitment of a Student made one of the teams unstable;
- Flexibility and unpredictability of approach favours the improvisation, and;
- The learning method motivates the Students to learn and also to contribute effectively in the learning process.

VI. Conclusions

The developed the process validated the application of PBL presented in this article, where it attempted to evaluate a training course in Software tests engineers, emphasizing the usage, based in used practices in the market, aiming at proving how effective a methodology that preserves principles, such as resolution of real problems inside real environments, with a minimum cost.

Before the authentic evaluation we had different evaluation points about the teams, providing a continuous feedback of improvement points for Students and tutors as well. It was shown that the individual and group work of the Students contributed to the development of specific improvements for each person, considering the evaluated criteria in the job market.

Finally, the case study presented successfully achieved its objectives: of the twenty subscribers, 70% of the Students attended and only 15% of those quit on the second day of training. Therewith, we formed an amount of twelve Students qualified in Software test with emphasis in usability.

Should the first course in computational problem solving and programming be Student-Centered or Teacher-Centered?

Cem Sahin* and Pramod Abichandani†
*Drexel Wireless Systems Lab, ECE Department, Drexel University
†Assistant Teaching Professor, College of Engineering, Drexel University
{cem.sahin, pramod}@drexel.edu

***Abstract*—Computational problem solving and programming are foundational skills for engineers. The first undergraduate level course that covers these topics is critical to laying these foundations. As instructors strive to incorporate the spirit of inquiry in their courses, an important question that comes forth is whether the teaching methodology should be student-centered or teacher-centered. This paper adds helpful information in the ongoing debate on this question. The paper reports on the student performance results obtained by teaching two sections (cohorts) of an introductory Computation Lab course sequence. This course sequence aims to teach new engineering students MATLAB scripting and programming in the context of technical problem-solving using mathematical models. Cohort A was taught using a traditional teacher-centered approach, while Cohort B employed an open-ended student-centered approach. Our results indicate that the teacher-centered approach has the potential of creating polarized grade distributions with relatively more A grades in the class compared to the student centered approach. On the other hand, the student-centered approach provided a smoother grade distribution, indicating that a higher number of students demonstrate noticeable progress as compared to the teacher-centered approach.**

Keywords*—*Student-Centered, Teacher-Centered, Computational Problem Solving, Programming, First Year Course

I. Introduction

Computational problem solving and programming are foundational skills for most engineers. The first undergraduate level course that covers these topics is critical to laying these foundations. As instructors strive to incorporate the spirit of inquiry in their courses, an important question that comes forth is whether the teaching methodology should be student-centered or teacher-centered.

In the past two decades, there has been an increasing interest in shifting the center of instruction from the teacher towards the students. There have been studies conducted using student-centered teaching methodologies, where the students were at the center of *learning*. Research shows that learning is triggered optimally if the course is set up correctly and is complemented with student-centered learning [1], [2]. It was also suggested that when student-centered learning technique is integrated with technologies, it provides students novel opportunities to try things and gain hands-on experience as they progress with the course [4]. On the other hand, research also shows that not every course can be taught using a student-centered approach. In [3], the authors provide insights into why students might need more than just the minimal guidance.

In this paper, we present the tradeoffs between student-centered learning and instructor-centered teaching techniques as applied to introductory computational problem solving and programming courses. We analyze two different sections (cohorts A and B) of a first-year (freshmen level) programming course, where each section was instructed using different teaching techniques. This paper is organized as follows: In Section II, we present the experimental methodology used in this research. Section III summarizes the results using numeric data collected and presents the statistics observed within the two cohorts. We then conclude this paper in Section IV.

II. Experimental Methodology

A. Course Sequence and Technical Topics

This first-year course sequence ran for 3 academic terms at Drexel University's College of Engineering. For the purpose of this study, we report on results from the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

first two terms. Technical topics that were covered in the class during the first term included MATLAB basics and plotting to illustrate fundamental software engineering and computational problem solving concepts, introductory data analytics: procuring, analyzing, and visualizing data, data visualizations - 2-D plots and animations, and string manipulation.

For the second term, technical topics that were covered in the class include MATLAB functions, mathematical modeling and simulation of physical processes (static and dynamic), 3-D visualizations, and numerical integration and differentiation.

B. Student Demographics

The two cohorts were run back-to-back and were taught by the same instructor (Abichandani) and teaching assistant (Sahin). Cohort A had 33 students and Cohort B had 34 students at the beginning of the year. The students were assigned into one of the two sections either by the college advising team or by online registration based on student schedule availability only. There were no intentional grouping of the majors of the students. Although the majority of the class (71%) was enrolled as freshmen, about 24% of the students were at sophomore level. The remaining 5% of the class population were pre-juniors (third-year students). There were no juniors or seniors enrolled in any of the sections. Out of the two sections, there was only one female student.

Both cohorts featured several engineering majors. Cohort A was dominated by Computer Science majors, where they occupied about 44% of the total enrollment. About 29% of Cohort B was comprised of Mechanical Engineering students, whereas the rest of the class was distributed relatively equally between the various engineering areas (Computer Engineering, Electrical Engineering, Civil and Architectural Engineering, Software Engineering, and Business and Engineering). Between the two sections, there were 5 *still deciding* students (who are enrolled in Engineering but did not declare a specific Engineering major yet). No race and country of origin data was collected for the purposes of this experiment.

C. Classroom and Computing Resources

The classes met for two hours every week in a computer laboratory, where the layout of the room encouraged collaboration and ideation. The students were given Macbook pro laptops at the beginning of the lab. They were asked to login with their own usernames and passwords, which enabled the students to save their work into their own workspace. All of the laptops had the exact same configuration (internet connectivity, installed programs etc.). The program used in this course was MATLAB, which is a scientific computation software. For both of the sections, the teaching materials were projected onto two different screens to ensure optimal visibility.

D. Pedagogy

In Cohort A, the problem solving techniques and programming exercises were demonstrated by the instructor in detail. The instructor introduced a problem and explained the logic behind solving the problem. Subsequent to this, the instructor demonstrated the complete solution process using MATLAB.

Cohort B was instructed using a student-centered approach that featured elements of guided discovery; specifically, the instructor introduced a technical topic very briefly, and then encouraged the students to explore the topic using problem-solving approaches and MATLAB programming with little guidance. Students were presented the basics of the topics and were asked to experiment and explore with their knowledge and to build up on them to self-learn some of the more advanced topics. Students were also shown external resources (e.g. the help file, useful websites) to encourage self-learning. Cohort B featured discussions among students, generation of ideas, and a convergence to a verifiable solution. This methodology allowed for students' independent and bold thought processes and decision-making to flourish while simultaneously honing their technical skills. The teaching assistant was asked to walk around the room throughout the whole lab session to monitor the progress of the students and to clarify any questions that might arise. The teaching assistant was directed to not give out any answers but, instead, to lead the students by asking them the right questions towards the correct answer. Students demonstrated their work and shared their solution approaches during lab sessions. No lecture notes given to the students in both cohorts.

E. Assignments

Each term consisted of 10 weeks of lectures and an additional week dedicated for final project submission. The two cohorts received the same assignments (5 in total), exams (2 in total), and project statements (1 at the end of the term) each term. Throughout the term,

TABLE I: Grading rubric for second term project

Item	Points
1. Idea and justification	Total: 15
1a. Submitted project idea	5
1b. Project idea has intellectual merit	5
1c. Project idea has broad impact	5
2. Creativity in implementing the idea	Total: 10
3. Functionality of implementation	Total: 30
3a. Submitted code works as promised	20
3b. Submitted code is efficient	10
4. Readability of the code	Total: 10
4a. Code comments explain the functionality clearly	5
4b. Code structure follows good programming practice	5
5. Design	Total: 10
5a. General GUI Appearance	5
5b. General flow of project	5
6. In-class demonstration	Total: 25
6a. Project Impact and Merit and Technical Challenges	10
6b. Solution Approaches and Overall presentation	10
6c. Q&A	5

the assignments were posted online (using the college's online course management system) within 24 hours after the lecture. They were due the morning of the next lecture. All work that needed to be graded was submitted by students using the online course management system. The instructor and the teaching assistant had full access to the course page.

The assignment questions were a mixture of closed-ended questions that were extensions of material that is covered in class and more open-ended questions. The exams were very similar to the assignments and contained two questions with extra credit opportunities. The final project statements were open ended and ranged from analyzing Twitter feed data of an account of students' choice to creating applications that featured rich physics based 3-D animations.

F. Student Work Evaluation Techniques

Grading for the course was done as fairly as possible. In order to remove any grader bias from the grades, the student work was evaluated by hiding the names. These assessment tools consisted of a combination of analytic and summative rubrics, where an example is shown in Table I. Although there were specific tasks that were being asked for, students were allowed to use their knowledge to analyze the data using any method they deemed appropriate. The grading rubrics were created in order to comprehensively cover all scenarios that a student might present during their work submission. All submitted materials were evaluated twice to ensure the order of grading didn't cause any bias.

The term projects were graded based on in-class student demonstrations and the final submission. It was noticed that there were students in both cohorts who came up with ideas worth mentioning. Some examples include train timetable lookup application, battleship game, 50 states game, and maze solver. A majority of students also included final projects with rich 2-D and 3-D visualizations.

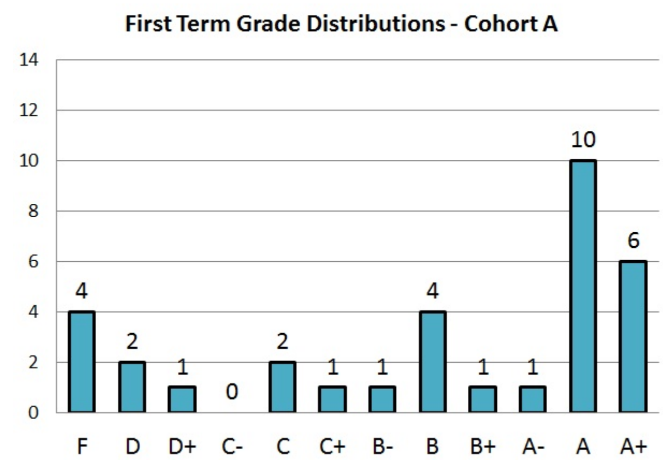
III. RESULTS

Assessment was performed using rubrics that focused on the following aspects (1) Problem-solving approach (2) Functionality and readability of the MATLAB code and (3) Final project reports. Both sections were graded using the same grading rubric for their assignments and exams.

In the following discussions, we present results for both cohorts for the first two terms of the this course sequence. Table II summarizes the average grades obtained from all grading categories from each cohort for the two terms. Table III displays the p-value of Kolmogorov-Smirnov (KS) tests run on the data across the cohorts. In the first term of the course, the teacher-centered approach yielded a final grade distribution that is fairly polarized, with approximately 45.5% of class scoring an A grade, and only 33.33% of the class scoring B and C grades. Approximately, 12% of the class failed. This polarization can be corroborated from the low average grade (79.89 points) and relatively high standard deviation (22.78 points). The student-centered approach, on the other hand, had a final grade distribution that is more spread out with only 32% of the class scoring an A grade, and 47% of the class scoring B and C grades. The failure rate was approximately 6%. The smoothness of the distribution can be corroborated from the high

TABLE II: Average grades and p-values for both cohorts for the first and second terms

	Cohort A		Cohort B	
	Term 1	Term 2	Term 1	Term 2
Assignments	86.8%	87.8%	83.1%	95.9%
Exams	78.6%	91.4%	86.4%	90.2%
Term Project	68.6%	89.5%	73.4%	93.3%
Avg. Final Grades	79.9%	90.4%	85.0%	93.4%



(a) First Term, Cohort A

Cohort A, Term 2 vs. Cohort B, Term 2	0.8332

average grade (84.95 points) and relatively low standard deviation (14.66 points). These results can be seen as summarized in Fig. 1a and Fig. 1b.

A similar analysis was also performed for the second term of the course, where Cohort A (teacher-centered) presented results with approximately 68% class receiving an A grade, an increase from the first term, and about 29% of the class receiving a B or a C. Only one student failed in Cohort A. Although a relatively high number of students received an A grade, the average grade point was 90.41, where the standard deviation was 15.53, which agrees with the grade distribution observed. For the Cohort B, a very high percentage, 81%, of the students received an A grade and only about 15% received a B or a C grade. There were no failing students. The lowest grade was a D+. These grades correspond to a Cohort-wide grade average of 93.44 points, and a tighter standard deviation of 9.90 points, which focused the majority of the students above a grade of 85 points. These results are also summarized in Fig. 1c and Fig. 1d.

In order to validate the results, a student-by-student comparison was also run. Each student's first term final grade was compared against their second term final grade. In Cohort A, 10 students received the same letter

TABLE IV: Grades change across the two terms

Cohort A	1.5% increase
Cohort B	6.1% increase

TABLE V: Number of respondents and response rate

	Cohort A	**Cohort B**
First Term	12 (36.4%)	13 (38.2%)
Second Term	9 (32.1%)	8 (29.6%)

grade in both terms, whereas, for Cohort B, this number was 7. As shown in Table IV and Fig. 2, overall trend for both cohorts was an increase in average final grades. Cohort B demonstrated a higher grade increase. 67% of the students received a higher letter grade, whereas only 7% received a lower letter grade. In Cohort A, the effect was less dramatic, with 39% of the students receiving a higher letter grade and 25% getting a lower letter grade.

A. *Student Course Evaluations*

At the end of each quarter, the university asked all students to fill out a course evaluation, which collected feedback from the students regarding the effectiveness of the teaching team in reaching the course goals along with their techniques and the materials used for the course. The students are also given the opportunity to add any comments regarding the teaching team. The students are given 2 weeks to complete the surveys. Participation was voluntary and students did not receive any extra credit if they decided to submit a course evaluation. In addition to the final grades of the students, the course evaluation results provided a more comprehensive picture for the effectiveness of the course. Table V shows the response rate of the course that is of interest.

The majority of the respondents indicated that the amount of knowledge they had at the end of the course

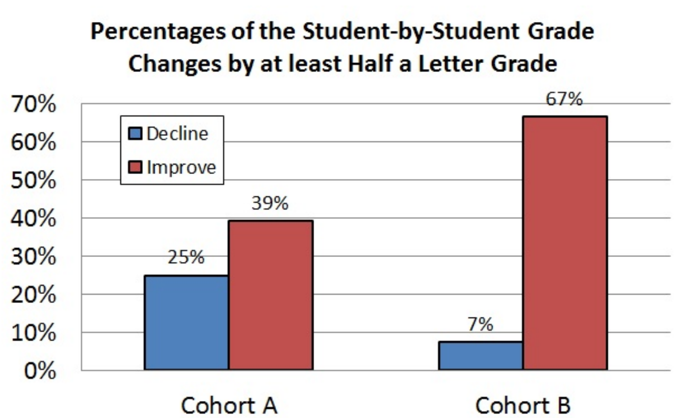

Fig. 2: Change in the final grades of individual students across the two terms

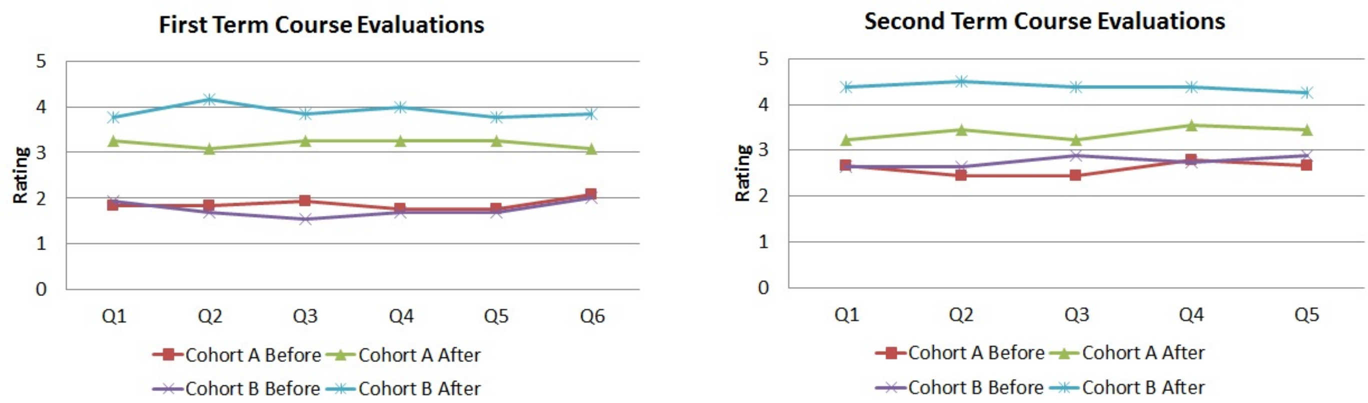
sequence is more compared to what they had before they were enrolled into the course sequence. Fig. 3a and 3b summarize the student responses. The numbers are based on the rating scale between 1 and 5, where 1 corresponds to ”do not agree at all” and 5 corresponds to ”agree completely”. In the first term, there were a total of 6 questions asked regarding the course, whereas, for the second term, the sixth question was dropped, yielding a total of five prompts. These questions below were asked in a ”before the term” and ”after the term” fashion.

The questions stemmed from the following learning objectives set for the class:
At the end of the class, students should...
- **Q1:** Be able to answer questions about practical technical situations using computation within the framework of mathematical modeling involving pre-calculus algebra.
- **Q2:** Be able to use programming constructs using numerical and symbolic computation, and scientific visualization, to automate sequences of computations of a few steps.
- **Q3:** Acquire a basic repertoire of computational actions and structures, and be able to use them to fashion solutions to simple technical problems.
- **Q4:** Acquire basic terminology of technical computation and be able to follow instructions that use it.
- **Q5:** Experience how numerical and symbolic computation, and scientific visualization, can help gain insight into problems within technical fields.
- **Q6:** Be able to utilize a technical computation tool to perform basic word processing and documentation tasks.

In addition to the numeric data collected, some of the written student feedback at the end of Term 2 included:

- *”It is a great course, but a basic understanding of programing is required”* - Cohort A
- *”we had freedom and the class involved real life scenarios”* - Cohort A
- *”I thought the creativity aspect introduced the semester was the extremely helpful in the learning process.”* - Cohort B
- *”Being taught Matlab helped me so much in*



(a) First Term

(b) Second Term

Fig. 3: First and second term student evaluation results

other classes" - Cohort B

- *"It was all good! every class i left wanting to do more programming!"* - Cohort B
- *"The course gave me knowledge of using a program completely knew to me and gave me the tools to work independently with it."* - Cohort B

As it can be seen, although the written feedback above are from within Cohort A and Cohort B, the majority of the students, who responded to the survey, thought the open-endedness/freedom, and the inter-disciplinary approach in the topics were suitable for their engineering needs. It can also be observed that Cohort B reported that they felt their knowledge at the end of the term was much more than what they started with at the beginning of the term. This observation is made by comparing the Cohort B (Fig. 3b) evaluation results to the Cohort A (Fig. 3a) evaluation results. The response rates shown in Table V should be kept in mind while analyzing the student feedback data. Although sample biasing is possible with lower response rates, studies show that surveys running for a long period of time but with low response rates provide more accurate measurements compared to those with higher participants [5].

IV. Conclusions and Take-Aways

In this paper, we presented the results of running an introductory computational problem solving and programming course using student-centered and teacher-centered methodology.

The results indicate the fact that for the class sequence discussed in this paper, the teacher-centered approach has the potential of creating polarized grade distributions, which is indicative of a pronounced divide between students whose problem-solving and programming skills improve substantially over the course of the class, and those whose skills do not improve as much. The analysis points to the fact that the teacher-centered education propels good students to better performance, but leaves the weaker students behind.

On the other hand, the student-centered approach provides a smoother grade distribution, indicating that while the relative number of students getting A grades, i.e., demonstrating superior computational problem-solving and programming skills may not be as high as compared to the teacher-centered approach, a relatively higher number of students demonstrate noticeable progress as compared to the teacher-centered approach. The better students achieve less than they would have achieved if educated in the alternative mode, but the weaker students end up with better performance. The average performance is higher but the better student paid a price for the better average. Furthermore, as students were exposed to continued student-centered pedagogy (in term 2), their individual performance increased substantially when compared to the teacher-centered approach.

As educators continue to push the boundaries of pedagogical methodologies for computational problem solving and programming courses, these results will help inform their decision making by demonstrating the tradeoffs between different methodologies.

Acknowledgments

The authors would like to thank Drexel University College of Engineering and Computer Science Departments for their support in organizing and running this course. The authors would also like to thank the anonymous reviewer whose suggestions helped improve this paper.

Developing Modules for an Inverted Classroom Project in Cost Estimating

Stuart Kellogg
Industrial Engineering
South Dakota School of Mines and Technology
Rapid City, SD

***Abstract*—** The need to serve increasingly diverse learning communities requires a curriculum that not only recognizes alternative modes of thinking but also helps students develop the complex thinking skills required by industry. Classroom inversion or "flipping" can provide a useful framework for this new paradigm by pre-engaging students with the material. The classroom lecture can then be replaced with collaborative problem solving exercises or model eliciting activities. While the most common methods used for pre-engagement include streamed lectures or podcasts, these techniques are subject to some of the same concerns associated with passive lectures or assigned readings. In this paper we present an approach for classroom inversion that is based on three premises: pre-engagement occurs through online interactive modules, classroom lectures are replaced with group problem solving activities, and homework assignments incorporate open ended problems or model eliciting activities. Examples of online interactive modules in accounting and cost estimating are presented. We follow with a discussion of the resultant transformation of the classroom learning environment along with some samples incorporating open-ended problem solving exercises. Preliminary assessments indicating gains in student learning along with future directions and implications for a broader approach to innovation and entrepreneurship is discussed.

Keywords-inversion; technology-enabled; problem solving skills

I. THE CHANGING PARADIGM

As a result of a global economy and the move to lean enterprises, industry has taken a stronger stance in asking for a different type of engineering graduate that has the leadership and complex thinking skills needed by today's industry. To maintain the nation's competitive advantage, the National Academy of Engineering issued a report on the changing business / industry paradigm for the 21st century. This report and a companion phase II report [2] identifies some of the ideal attributes of the engineer of 2020 as well as recommendations for curricular innovations that begin to address these attributes. The Accreditation Board for Engineering and Technology (ABET) implemented a revolutionary approach to accreditation by focusing on what is learned rather than what is taught, thereby fostering innovation [3]. Industry increasingly demands development of team skills, leadership skills, a better understanding of business processes, an ability to innovate and think outside of the box, and an ability to communicate effectively in a diverse environment (see, for example, [4]). In short, industry needs engineering graduates that can help solve and implement solutions to the complex problems industry is faced with today. Kellogg and Karlin [5] provide a holistic approach that includes technical skills, psycho-social development, cognitive development, and identity development. A conceptual framework for this approach and is reproduced in Figure 1 below.

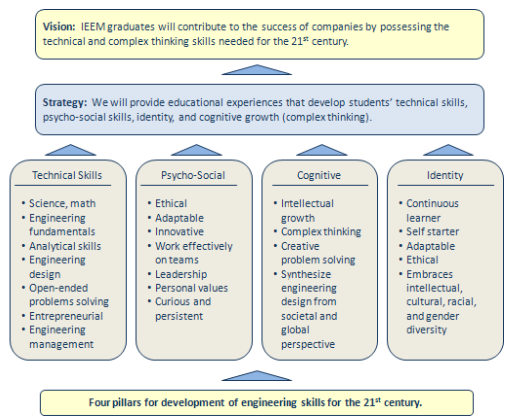

Figure 1. Four Pillars of Development of the Engineer of 2020

The Holistic Learner Development (HLD) model not only provides a useful conceptual framework, it incorporates many of the same strategies advocated by authors in the landmark 2005 edition of the Journal of Engineering Education [6-8].

The traditional engineering curriculum operates on a fundamental premise that technical skill development remains paramount and requires the bulk of instruction time. Psycho-social and identity development activities are generally relegated to minor roles and reside under the purview of student affairs and/or co-curricular activities. However, an increasing body of research indicates that this traditional approach limits student engagement and develops only a superficial understanding of engineering fundamentals. Indeed, regardless of discipline higher education seems to fall short of its promise to develop the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

complex thinking skills required for the leaders of tomorrow [9].

While Figure 1 provides a framework for the skills and attributes for the engineer of 2020, development of these skills remains a rich area of research for engineering educators. For our department, we have focused largely on activities that value intellectual diversity while simultaneously supporting improved complex thinking skills [9, 10] and promoting a better understanding of globalization and the business/management context of engineering.

II. Technology Enabled Support

According to a 2008 study, 52 percent of teenage boys and 26 percent of teenage girls spend over 42 hours per week watching TV, playing video games, computer, or internet time. Even the 73 percent of teenage girls and 48 percent of teenage boys that the researchers termed the "low screen time" group still spent 18 to 22 hours per week in front of a screen [11]. While this pre-disposition of the incoming (and already matriculated) STEM student body is generally considered detrimental to the completion of a student's homework, what if it were used instead to enhance learning and generate increased student buy-in to students' own education processes?

Over the past decade we have witnessed an enormous investment from many universities in distance education, classroom management software, technology enabled support from NSF, the National Engineering Education and Delivery and Delivery System (NEEDS), and Merlot online learning modules. Yet these efforts seem to have left a collective perception that, at least in terms of engineering and science education, these efforts fall woefully short of what is needed to dramatically improve learning gains. Faculty concerns seem pretty universal:

- Stand -alone interactive modules, either online or text based support, are seldom reviewed by students.
- Students most in need of additional support are also the students least likely to take advantage of support opportunities.
- Support modules do not adequately serve as a replacement for richer experiential learning activities.

The department has tracked student use, dwell time, and primary areas of interest for the past seven years. Data as well as faculty and student observations reflect many of the same concerns listed above. As an example, a critical area for industrial engineering graduates is statistical reasoning and the department has provided a number of online support modules in probability and statistics. Despite that effort, learning gains in that area remain elusive.

Despite these drawbacks, technology enabled support modules have a number of useful characteristics that, if incorporated well, can provide useful support for student learning. Specifically, well designed support modules can

- provide value added modules to enhance or expand learning opportunities,
- address alternative learning styles,
- aid understanding of complex ideas through a visual or animated framework.

More importantly, once developed, technology enabled support modules can ameliorate some of the instructional burden of the faculty member and allow her the opportunity to spend less time lecturing and more time engaging students in deeper learning activities. It remains our belief that technology enabled support remains a viable curricular element if it can be successfully integrated into the learning environment. The remainder of this paper is devoted to a discussion of a sample project in cost estimating which attempts to do just that.

III. The Inverted Classroom

In the traditional classroom, students are assigned a section of a textbook to read before class. Following this passive, if it occurs at all, students attend class where they are passive recipients of a lecture. For many students, the first real engagement with the course material occurs following the lecture when attempting homework.

In the *inverted* classroom, we attempt to pre-engage students with the material prior to class and move the active content engagement from post-class to in-class. The first systematic attempts at classroom inversion came from economic education [12]. These early attempts at inversion moved the passive student engagement with lecture to pre-class by using media, computers, and the internet to provide basic content information to students before class. By providing some content prior to class, the instructor is free to use appropriate active learning elements to draw the students deeper into the material.

There are a variety of techniques faculty members incorporate in an inverted class; they all share the same underlying imperative: students cannot passively receive material in class. Instead, they pre-engage with the material largely outside of class by reading, watching recorded lectures, or listening to podcasts. This pre-engagement is one of the reasons students often dislike inversion or flipping. When they are in class, students do what is typically thought to be homework, solving problems with their peers, and applying what they learn to new contexts. It seems clear that a well-designed inverted (or flipped) classroom can lead to better learning outcomes, better conceptual understanding, and increased student motivation [13]. However, inversion is not without its drawbacks [14]. Inversion is not the norm by which most students are taught. Consequently, the inverted or flipped classroom requires a paradigm shift on the part of the student and this is not always well received. A common concern of many students is why come to class if they must view the lecture, particularly a boring lecture, before coming to class. In this case, the primary focus rests with their perception of the teaching paradigm rather than on the learning that is actually accomplished. A second problem is that in the flipped classroom, students generally solve problems that are not template problems, or at least they should be. This is harder and is often met with reluctance on the part of the faculty member, the student, or both. Finally, the inverted classroom is almost always more labor intensive than the traditional lecture. It requires faculty to develop a well-organized set of materials, a cohesive set of learning objectives, and alternative learning strategies that focus on conceptual understanding rather than problem solving via the traditional pattern recognition paradigm.

IV. COST ESTIMATING PROJECT

In this project, we focus on inverting a basic skills course in Cost Estimating. We selected this course because the development time for a lower level skills class would be less and, once fully developed; the course could provide a value added component for non-majors. The course is modularized into three primary modules that consume roughly 1/3 of a semester each and are taught in sequence so that all three are covered over the span of a semester long course. The basic modules include

- Accounts, transactions, financial statements and analysis
- Business forecasting, budgets, overhead, and alternative costing methods
- Project estimating, product estimating, universal techniques, operation costs.

Modularization of the course allows us to do several things. It allows us to focus development efforts on an individual module while still allowing the course to be taught in a mixed mode that includes both inversion and traditional lecture. Because the topics are only loosely connected, modularization also seems to provide a better conceptual framework for the students. And finally, course modularization seems more palatable to non-majors who wish to complement their technical skills within a business or plant management context.

Prior experience with technology enabled support provided preliminary assessment information on different inversion techniques, different technology support designs, as well as some insight as to student perceptions regarding different support elements. Based on this preliminary data we concluded that we did not want to develop a course that relied heavily on online lectures or assigned readings in a standard text. Rather, we elected to incorporate a variety of medium intermixed with short lectures followed by group problem solving exercises. The following elements should be incorporated into the overall design.

- ***Online interactive text:*** When fully developed, each module will support an online interactive text. The text incorporates accounting and cost estimating basics but is supplemented by a wealth of reference materials for those students desiring traditional text. Interactive text incorporates reading coupled with student data entry and self-correcting exercises.
- ***Technology enabled support:*** a number of exercises similar to those covered in the text are included as stand-alone exercises on a department support web site. This allows students to review additional exercises or to review a simple method at any time during the studies. Most interactive exercises are developed in flash though a growing number are developed under alternative media. Tools include a plotter and numerical calculator.
- ***Podcasts:*** development of some materials is both labor intensive and complicated enough that students find it easier to visualize the material through a short podcast. All podcasts are accomplished via Camtasia which allows for integration of both PowerPoint and excel within one podcast. In addition, they reside on the instructor's computer so they can be easily edited for alternative applications. All podcasts are 5-10 minutes in length.
- ***Classroom Structure:*** the classroom typically involves a 10-15 minute lecture followed by a group problem solving exercise. We rarely accomplish more than two exercises in any given class period. Homework is assigned weekly with some graded in class and some open ended problems reserved for instructor grading.
- ***Model eliciting:*** we attempt to offer one model eliciting activity per module. Model eliciting activities attempt to engage students in open ended problem solving activities and understand fundamental concepts though model formulation.

Sample Online Text

The advantage of the online text is that student reading is supplemented by online data entry that is student controlled and self-correcting examples that essentially replace rudimentary homework assignments to reinforce fundamental concepts. This is accomplished by requiring students to complete online preliminary homework interactions prior to class instruction. A sample interaction is shown for financial analysis in Figure 2 below. The Try It button opens a new window and interactive exercise for students to complete before moving to the next section. In all cases, student interactions are automatically corrected after two miss-calculations.

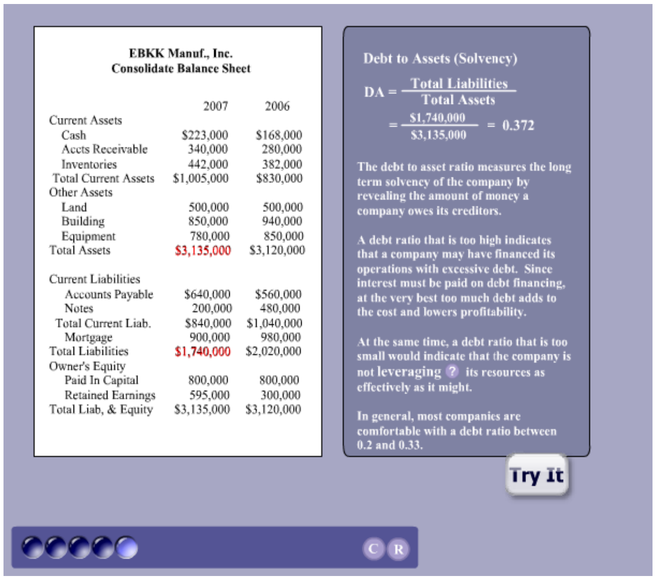

Figure 2. Sample Interactive Text with TryIt Button

For some sections a separate help dialog icon (similar to Microsoft's question mark help button) appears offering definitions of terminology or additional information. The help dialog box appears as a short window overlay on top of the main text. A sample help dialog box is shown in Figure 3 below.

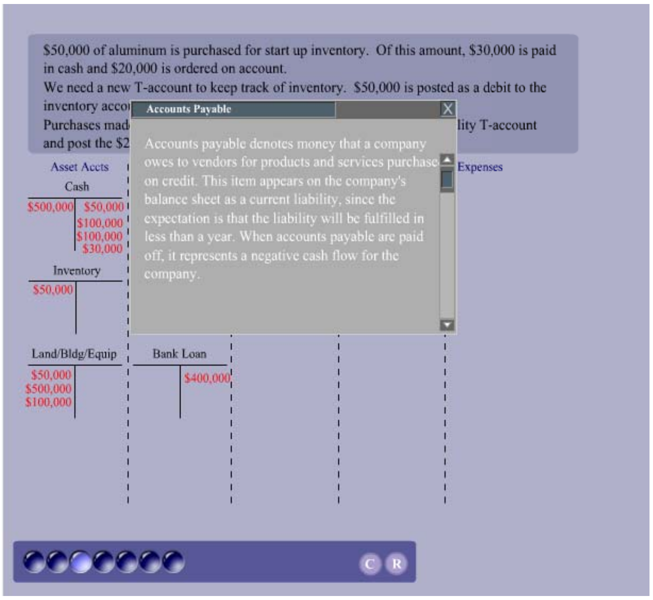

Figure 3. Sample Text with Open Help Dialog Box

A first step in the budgeting process requires a forecast typically through exponential smoothing. Figure 4 below shows a portion of the step-by-step solution for a simple exponential smoothing model. Supplemental tools include a functions page, an introduction to forecasting with moving averages, linear trends, and exponential smoothing. Short podcasts for each are provided on the course schedule page.

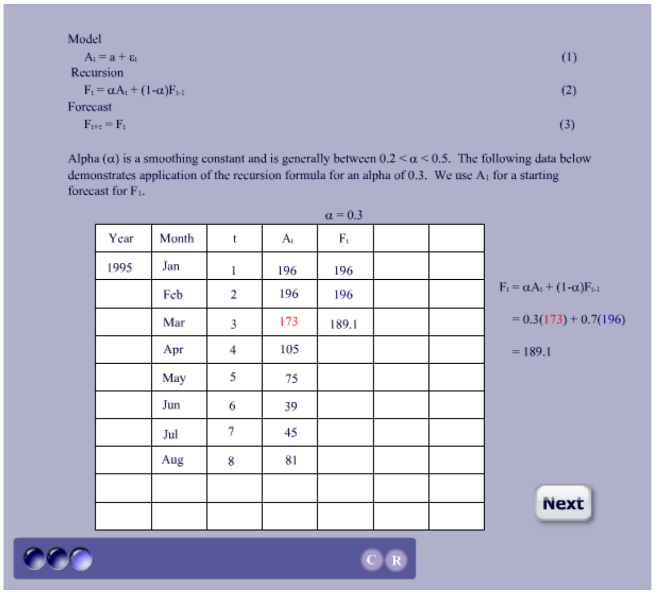

Figure 4. Online Support Module Demonstrating Exponential Smoothing

Along with the text, we provide a variety of supplemental exercises to allow students additional practice. These stand-alone interactions allow students to work through problems as they are reading through them. All interactions provide a self-correcting component which provides a hint and ultimately demonstrates how the calculation is to be made for more complex problems. A sample self-correcting exercise for a balance sheet problem is shown below in Figure 5.

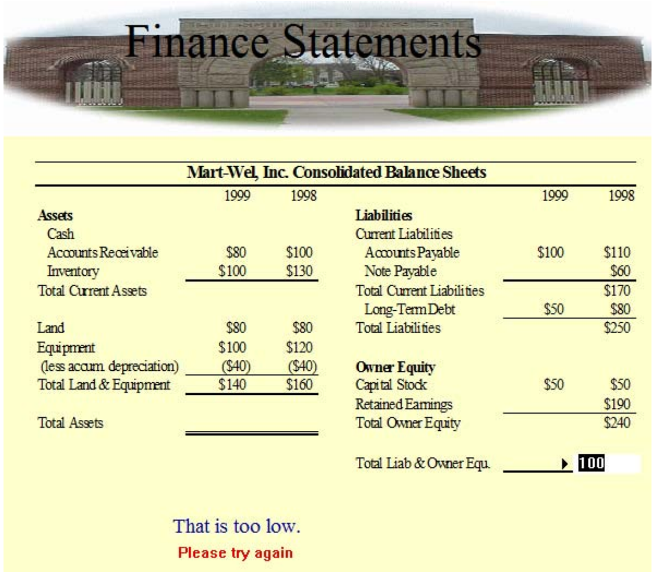

Figure 5. Self-Correcting Balance Sheet Problem

Along with sample exercises, the course includes supplementary materials that students may find useful or of interest but are not necessary for course understanding. Samples include a mortgage template, a retirement template, a loan calculator, and an interactive wealth accumulator which accounts for monthly investments, inflation, and growth rates. A sample interactive plot from the wealth accumulator program is shown below in Figure 6.

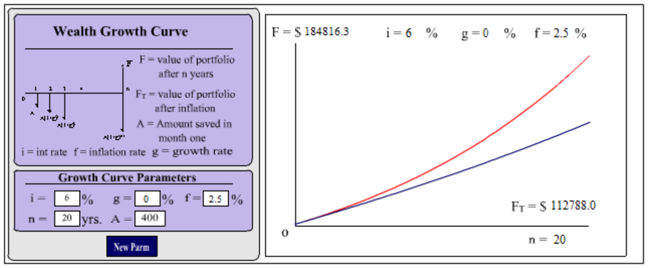

Figure 6. Sample Output from the Wealth Accumulator

V. PROJECT ASSESSMENT

While this project has required substantial development effort, ultimately less time is devoted to lecture and a greater portion of classroom time is spent on active collaborative in class problem solving. This allows for a greater variety and open ended homework assignments as well as incorporation of model eliciting activities. Assessment activities include statistical tracking of time modules used and time on task, a student satisfaction survey, and student performance on exams.

Figure 7 below shows page loads, unique visits, and returning visits for the last offering of the course. Not surprising, student usage for more developed sections. Page loads and dwell time are used as formative assessment to determine which modules are perceived to be more useful and which require additional development.

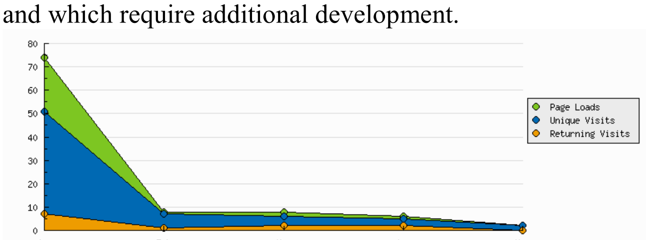

Figure 7. Student Use Tracking for Cost Estimating Modules

Student exam scores show a slight improvement from 2009 to 2012 (Figure 8 below) although it is not yet clear if real gains in conceptual understanding are realized. Department global measures include student typology using the Herrmann Brain Dominance Inventory and intellectual development through use of the Reflections of Current Issues instrument. These instruments show remarkable gains in both intellectual diversity and intellectual growth. While there is a belief that less reliance on lecture and greater reliance on active group problem solving is contributing to these gains, formal assessment correlating these gains to classroom inversion is currently under consideration. Finally, student self-reflection of learning gains indicates greater student satisfaction with the inversion approach.

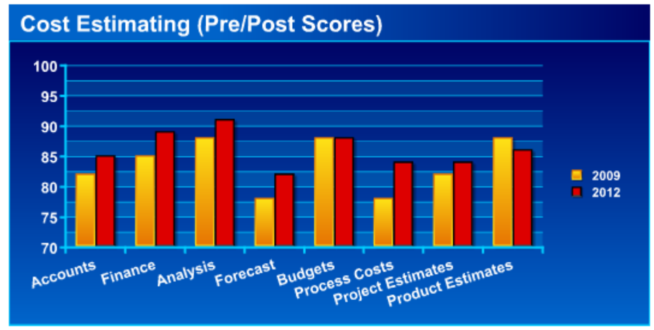

Figure 8. Pre and Post Exam Scores for Cost Estimating

VI. FUTURE DIRECTIONS

This project was established to ascertain the efficacy of classroom inversion through technology enabled support. While development efforts are significant and much still remains, it seems clear that textbooks of the future will require some incorporation of an integrated technology component. Department data, along with a substantive body of literature, indicates that students will not likely make voluntary use of supplementary materials. These materials must be integrated in the curriculum in some meaningful way. Given faculty constraints, higher learning gains are likely to be garnered at lower cost through other engaged pedagogies. Nevertheless, with the advent of new technologies, new strategies for inversion are likely to continue to be an important component of the classroom of the future.

***Abstract*— The introductory continuous-time signals and systems (CTSS) course is widely considered one of the most difficult courses in electrical and computer engineering (ECE) curricula. This workshop will be an interactive discussion about sources of difficulty and what can be done to help improve student learning and understanding. In the first part of the workshop, discussion will be sparked and encouraged through presentation of historical data and directed questions. The goal will be to advance a continually developing understanding of the problem. In the second part of the workshop, attendees will learn about hands-on activities that are being done at Bucknell and Rose-Hulman to help address what the authors think some of the issues are. Attendees will have an opportunity to attempt one of these activities and provide feedback based on the previous discussion about learning difficulties.**

Keywords—signals and systems; continuous-time; active learning; hands-on activities

GOALS OF THE WORKSHOP

The introductory CTSS course is one of the most difficult courses that students encounter in an electrical and computer engineering (ECE) curriculum. This is evidenced at Rose-Hulman over the last 10 years by drop/failure rates that are at least two times greater than any other course except electromagnetics. We have received NSF funding to explore why students find these courses so difficult and to determine effective methods for helping students grasp the concepts. This workshop offers engineering and science faculty an engaging opportunity to explore how to improve learning in introductory continuous-time signals and systems (CTSS) courses [1]. The two primary goals of the workshop are to provide:

- an interactive discussion that will try to provide as broad a perspective as possible to the question “Why is signals and systems difficult?” and,
- a hands-on experience with laboratories that developed and used at Rose-Hulman Institute of Technology and Bucknell University over the past 4 years to improve learning in CTSS courses

CONTENT OF THE WORKSHOP

While many people are developing supplemental materials for CTSS courses, very little exploration of the sources of difficulty from the student’s perspective has been done[2][3]. There are many opinions and ideas with regards to these sources, but we would like to take a scientific approach to arrive at more definitive answers. Once more of these sources are identified, we can tailor the supplemental materials to be more effective. This work is being done in collaboration with Dr. Ruth Streveler at the Purdue School for Engineering Education, who specializes in the learning of difficult concepts. We are analyzing historical data and developing new studies to try to identify more of these issues. In addition to those studies we want to gather input from the community at large to try to get as broad an understanding of the problem as possible. The first part of the workshop will be an interactive discussion with the purpose of gathering such input. Discussion will be sparked by presenting data, current ideas, and directed questions. The results of this discussion will be used to guide the remainder of the workshop.

We have been trying to address issues that are related to lack of motivation and learning by creating application-oriented hands-on active-learning opportunities for students [4][5]. There are many examples of such opportunities described in the literature, but most of these activities make use of MATLABP®, LabVIEWP®, or DSP hardware [6]. The exercises described in this workshop are based on analog circuits and real-world applications of continuous-time signal processing and system modeling. There are certainly advantages to using software simulation tools for laboratory exercises because they are relatively inexpensive and students can perform many “experiments” relatively quickly. In fact, many of the exercises described in this workshop could be simulated entirely using such software tools. We are not advocating the elimination of these simulators, and in many cases use them for both prelab exercises and/or analysis of results. However, there is one key advantage to using hardware-based hands-on activities and real-world applications that simply cannot be obtained with software-only based activities. Practicing engineers use the theoretical and mathematical concepts from CTSS courses to model real-world physical phenomena. The overwhelming majority of students have never had an opportunity to connect those theoretical concepts with the physical phenomena that they are trying to model[2]. So it’s possible that a lack of motivation could be due to a lack of understanding of what use the concepts have. While software tools can help students visualize the concepts,

This workshop is supported by NSF grant #1140995. The authors would also like to thank Ruth Streveler at Purdue Univeristy and Shannon Sexton at Rose-Hulman for their input on data analysis and learning theory.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

they are in-themselves also modeling tools. An important way for students to gain an experience of the phenomena that they are trying to model is to actually experiment with them[7]. Using a real system with real-world applications creates a degree of credibility and relevance that is not possible with software simulations. When students manipulate these systems, there is an understanding that they are changing something physical rather than simply adjusting a number.

In order to facilitate application-oriented hands-on activities, we have developed a number of laboratory lesson plans and an analog printed circuit board, the signals and systems exploration platform (SSEP)[8]. The SSEP can be configured easily to sum, multiply, filter, and sample continuous-time signals. With an onboard microphone, ECG/instrumentation amplifier, and generic signal input, a wide variety of signals can be studied and manipulated. During the workshop, several stations will be set up with portable electronic instrumentation and an SSEP.

The workshop will provide a brief introduction to the SSEP and some of the lesson plans that were developed both with and without the SSEP in mind. The attendees will then have an opportunity to run through one of the lesson plans. Finally, in order to close the loop, attendees will then be able to provide feedback relating the activities to the previous discussion about sources of difficulty in CTSS courses.

Intended Audience and Number of Attendees

We expect this workshop to be primarily of interest to undergraduate electrical engineering faculty who are involved in signal processing education. The examples and materials presented would also be of interest to those teaching Fourier theory in other disciplines such as physics, mathematics, and other types of engineering. We would expect to have approximately 10-15 attendees.

Workshop Agenda

I. Introduction to the workshop **(5 minutes)**
II. Discussion of the initial question: Why is CTSS such a difficult subject for students? **(30 minutes)**
III. Introduction to hands-on activities being done at Rose-Hulman and Bucknell **(10 minutes)**
IV. Brief Introduction to the SSEP **(5 minutes)**
V. Supervised hands-on activities with the SSEP (**25 minutes)**
VI. Reviewing activities with regard to the initial question. **(10 minutes)**
VII. Assessment of the workshop **(5 minutes)**

Take Away Skills

We are expecting attendees to leave the workshop with a greater appreciation for the sources of difficulty in CTSS courses and some ideas of simple hands-on activities that can be used to help make the material more approachable to the students. They will have some experience with these activities and knowledge about how to acquire the equipment and lesson plans so that they could begin using these activities at their own institution. They will also be invited to attend a more in-depth summer workshop at Rose-Hulman during the summer of 2014 and to participate in an ongoing discussion of the issues.

Qualifications of the Presenters

Mario Simoni is an Associate Professor of Electrical and Computer Engineering at Rose-Hulman Institute of Technology. He has been teaching for 12 years including the introductory CTSS course and analog circuits. He developed an analog circuit platform that facilitates hands-on activities in the CTSS course and the activities that go with it. He has been using these activities for the past three years.

Maurice Aburdene is a Professor of Electrical Engineering at Bucknell University. He has been teaching for over 30 years, including courses on linear systems and signal processing.

Farrah Fayyaz is a doctoral student in the School of Engineering Education at Purdue University. She holds Bachelors and Masters degrees in electrical engineering from the University of Engineering and Technology, Lahore, Pakistan and taught signals and systems, digital signal processing, analog circuits and microelectronics in Pakistan for more than eight years. Her Masters research focused on identifying student difficulties in learning signal analysis. She will continue investigating students' understanding of various concepts in signals and systems for her PhD dissertation.

True Grit: Toward a Culture of Psychological Preparedness in Engineering Education

Jesse Pappas, Olga Pierrakos, Eric Pappas, and Kurt Paterson
pappasjb@jmu.edu, pierraox@jmu.edu, pappasec@jmu.edu, paterskg@jmu.edu

Abstract: **The rigors of engineering education present each student with a unique set of academic and psychological challenges. Established interventional strategies are typically focused on enhancing academic - rather than psychological - preparedness, potentially leaving many students vulnerable to various demotivating factors. Participants in this special session will collaborate to develop a nucleus of ideas to inform the future development of psychological preparedness strategies - interventions specifically designed to facilitate productive processes such as self-efficacy, self-discipline, resilience, and motivation.**

Index terms – Student preparedness, psychology, motivation, resilience, self-efficacy, retention

INTRODUCTION

"All the Sputnik-like urgency has put classrooms…under a microscope. And there are encouraging signs, with surveys showing the number of college freshmen interested in majoring in a STEM field on the rise. But, it turns out, middle and high school students are having most of the fun, building their erector sets and dropping eggs into water to test the first law of motion. The excitement quickly fades as students brush up against the reality of what David E. Goldberg, an emeritus engineering professor, calls 'the math-science death march.' Freshmen in college wade through a blizzard of calculus, physics and chemistry in lecture halls with hundreds of other students. And then many wash out."

> - From *Why Science Majors Change Their Minds (It's Just So Darn Hard)*, The New York Times, 11/04/11

Being an engineering student can be tough. Pursuing an engineering degree typically involves facing greater academic challenges compared to those in many other disciplines [1,2]. But, as the passage above demonstrates, these challenges also have psychological components. The classes are often harder, the programs are often longer, the grades are often lower, and the commitment and self-discipline required are often greater. In the interest of student success, engineering educators have implemented a variety of preparedness activities in high schools, summer institutes, and their own programs [3,4]. While often successful, most of these interventional strategies focus on academic preparedness, while few seek to prepare students mentally or psychologically. Further, "in spite of considerable research about the poor retention rate of undergraduate engineering students, we still have an inadequate understanding of the factors that affect students' decisions to remain in engineering programs and their ability to perform well enough to be retained" [1]. Common sense and educational research [5-7] indicate that an inability to cope with the psychological demands of engineering education contributes significantly to student demotivation and attrition. This session will explore potential strategies for implementing a more holistic approach to student preparedness and success – one that acknowledges both academic and psychological needs.

The importance of mental preparation prior to a challenging task or journey, as well as staying attuned to one's own psychological state throughout such an experience, has been demonstrated in many contexts, perhaps most notably in competitive athletics [8] and the military [9,10]. Effective psychological preparedness activities often lead to greater resilience and the ability to maintain motivation in the face of uncertainty or self-doubt. In theory, instilling engineering students with such capabilities could lead to increased motivation, persistence, and retention.

The facilitators will begin this session by providing an overview of common psychological challenges faced by engineering students and orient participants with brief examples of psychological awareness strategies that have been effectively applied in non-educational contexts. Through semi-structured team brainstorming and discussion sessions, participants will generate ideas for developing and implementing psychological preparedness activities in various engineering education contexts. Next, we will

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

collaborate as a group to revise and synthesize our ideas into actionable concepts that can be administered independently or integrated into existing course material. Finally, the facilitators will outline plans for the development of a collaborative psychological preparedness program in the Department of Engineering at James Madison University (JMU).

SESSION GOALS

The four primary goals for this session are as follows:

1. Discuss the possibility that the following "preparation gap" exists in engineering education: *To be successful, students must be both academically and psychologically prepared for the rigors of a university engineering program, but most existing interventional efforts are focused specifically on academic preparedness, potentially leaving some students psychologically vulnerable and ultimately unable to maintain the motivation necessary to persist until graduation.*
2. Generate a nucleus of peer-developed ideas to inform the future development of psychological preparedness strategies, activities, and interventions designed to increase engineering students' self-awareness, self-efficacy, resilience, and motivation.
3. Describe the ongoing development of psychological preparedness initiatives in the Department of Engineering at James Madison University.
4. Provide session attendees and other interested individuals with resources to develop psychological awareness and preparedness activities in their own courses and programs.

SESSION AGENDA

The session will be highly interactive with much of the time spent in group work and discussion. Two short presentations will help guide the group discussions. The agenda is as follows:

1. Welcome, introductions, and a brief presentation on the "preparation gap" that may exist between efforts to improve the academic and psychological strength of engineering students, and how students might benefit from being better prepared to meet the characteristic psychological challenges of an engineering education. [10 min]
2. Brief introduction to literature supporting the value of psychological preparedness [5 min]
3. Focused, large group brainstorming session to generate a list of common psychological challenges and preparedness needs of engineering students. [15 min]
4. Brief presentation on psychological preparedness strategies/interventions that have been effectively applied in domains such as athletics, business, and the military to increase motivation, grit, and resilience. [10 min]
5. Team activity (5-8 people per team, including one session facilitator) during which groups generate potential psychological preparedness strategies/activities/interventions that address common challenges faced by engineering students. The spokesperson / note taker for each team will present team findings to the large group. [30 min]
6. Large group synthesis of implications and potential future directions in the study of psychological awareness and preparedness in STEM education. [10 min]
7. Short introduction to a collaborative psychological preparedness initiative in development at JMU. [5 min]
8. Wrap-up summary and Q&A. [5 min]

DESCRIPTION OF ANTICIPATED AUDIENCE

We expect this session to be attractive to a diverse group of engineering educators who are interested in student preparedness and well-being and/or in increasing retention rates across engineering disciplines. A major goal of this session is to provide participants with potential strategies to help their students sustain the psychological challenges of engineering education and become productive professionals.

EXPECTED OUTCOMES AND FUTURE WORK

The primary expected outcome of this session is a nucleus of innovative work on the emerging domain of psychological preparedness for engineering students, which will be disseminated to participants and other interested colleagues. In addition, participants are expected to gain insight into the psychological challenges faced by their students, potentially leading to more effective teaching and advising strategies. If this session does impact the future work of engineering educators, it may have transformative implications for students' well-being and perseverance. Further, this work will inform on-going research and publications emerging from James Madison University.

DISSEMINATION OF RESULTS

Since we do not anticipate having time to fully discuss and share the results of the group work during the special session, we plan to collect the results of the group work, organize them, and send them to session attendees and other interested colleagues after the conference. Please contact Jesse Pappas (pappasjb@jmu.edu) if you do not attend the session but would like to receive a written summary of our results.

Abstract - **The video consumption tends to grow in coming years and it will be increasingly imperative to know the validity and effectiveness of using this type of media especially in teach and learn activities. It is very important to be able to assess how much knowledge a particular didactic video content was effective in building students knowledge. In this paper we present a tool we developed and an experiment we realized with two classes of computer engineering course related to network computer subjects, totalizing 140 students. In our experiment we divided our students in two groups: half of them attended a video explanation and half of them had the same explanation but only in a traditional classroom format. Our experiments show that video can be a great ally in the teaching and learning processes. Nevertheless, our investigation must continue in order to understand all video potential in this purpose.**

Keywords - video, viewer engagement, learning processes.

I. INTRODUCTION

The video consumption tends to grow in coming years and it will be increasingly important for institutions that produce and use videos in their core activities, to have metrics and parameters with which to scale the physical infrastructure and human resources needed for such use. At the same time, it becomes increasingly imperative to know the validity and effectiveness of using this type of media. Especially in teaching and learning activities, it is very important to be able to assess how much knowledge a particular didactic content in video format was effective in building students knowledge, considering a student or group of students.

Many systems are designed to provide educational materials in video format for distance learning environments, as well as support learning material. The production of these videos requires a sophisticated infrastructure and a team to manage the entire process: the recording of videos, their edition, and the delivery process.

We wish to evaluate the degree of absorption of knowledge through this media consumption, as well as engagement with the subject. The concept of "viewer engagement" can be used in many ways, considering aspects such as usage scenario, age, or user´s cognitive characteristics, or by verifying the degree of involvement, using interactive tools and social networks to disseminate information or feelings about watching the video. In our case, we are more focused on education scenarios, with computer engineering students. Considering this, one possibility is to compare students' opinion about a video explanation, for instance, and their results in formal evaluation.

In this paper we present a tool we developed to monitor the video consumer behavior and, from polls, posting of opinion and multiple choice tests, infer about user interest about the video and the absorption of the content. We present also an experiment we have realized of video usage in learning processes with two classes of computer engineering course related to network computer subjects.

This paper is organized as follows. Section 2 presents related work. The monitor system is described in Section 3. Usage Scenario is showed in Section 4. Finally, results and analyses and conclusions and future work are presents in Sections 5 and 6, respectively.

II. RELATED WORK

Projections indicate that by 2012, video use will represent half the consumption of network in the world, already surpassing the P2P traffic, currently the most responsible for network traffic. By the end of the decade, projections indicate that this percentage will fit about 90% of the network bandwidth [1].

With this expectation is extremely important to monitor this consumption. Several monitoring tools have been released in recent years mainly for the purpose of checking the consumption of network resources.

For instance, Video Streaming Monitoring from Dotcom-monitor [2] that clam that the service monitor 3-5 seconds the media server, and in this period it verify the connection time, buffering time, received packages rate, frame rate and average bytes per second. Other example of commercial tool is Media Streaming Monitor by SciVisum [3]. Nevertheless, these kinds of tools focuses only in network consumption, and don´t make any monitoring related to video engagement.

2013 IEEE Frontiers in Education Conference
978-1-4673-5261-1/13/$31.00 ©2013 IEEE

So far, few academic papers in monitoring and evaluating video consumption field have been published. Studies found, which will be discussed below, can be classified into user engagement with the consumption of Web videos, and videos using the method of teaching / learning.

Dobrian [4] evaluated the impact of video quality on user engagement, concluding that live content is most impacted when there is quality lost. This study concludes also the context of the user is very important for the analyses. Milliken [5] studies the potential of UGOV (User-Generated Online Video) tool, which allows video generation. These videos are posted on YouTube to check the contribution of regional identity in their consumption, level of involvement and engagement of Internet users. Engagement, in this case, is measured using a questionnaire that includes, for example, questions about frequency of application use, how much a user learned, how a particular video changed user´s opinion on a particular subject, and how many comments posted on social networks were related to the concerned video.

In another study, conducted by Bardzell [6], physiological measures, such as heart rate and respiration per minute, were used to measure the emotions caused by the most popular videos. They also used strategies such as emotional **tag** (user indicates their emotional state by choosing emoticons), space for adding a text review and logging the user actions with respect to the video (pause, stop, browse the timeline of video (seek), etc.). The work uses triangulation to analyze results obtained, crossing information, relating them to perception and emotional experience, preferably video, as well as contextual factors.

Another work that deserves attention, as it deals with an educational context, is the article written by a group at Microsoft Research. The article´s aim is to test the effectiveness of a video annotation tool, which provides video and synchronized slides, and space to include participation textual support [7]. The tool was tested for learning purposes in-group work, and also with individuals, showing that there was excellent absorption of educational content with its use. Another study presents a tool that defines the best place to put ads in a video [8]. The evaluation was done subjectively; using as parameters the relevance of the site, comfort ability and user satisfaction.

III. SYSTEM ARCHITECTURE

Four modules compose the monitoring system we had designed, as showed in figure 1.

- Server module: monitors the metrics related to server;
- Application Module: responsible for metrics related to user interaction with application;
- QoE and Content Absorption Module: records the QoE and content absorption´s assessment score;
- Report Module: responsible for the use of the data obtained, crossing it to allow proper result analysis.

As the purpose of this system is to monitor the learning actions and check the student's engagement to consume video element, we chose to integrate the monitoring module to a system of teaching/learning, as LMS (Learning Manager System). Thus, we can join quickly and easily the video element to a course material, and monitor the student interactions.

Although monitoring modules are independent from any system, we choose Tidia-Ae LMS [9] to integrate QoE and Content Absorption Module, in order to build a learning context.

The diagram in figure 1 show the system overview and its modules, focusing on the communication flow, where solid lines indicate the request between user desktop/LMS and LMS/Video Server; the dashed line indicates the video streaming from video server to user desktop or device and the dotted line represents monitoring of data persistence in database.

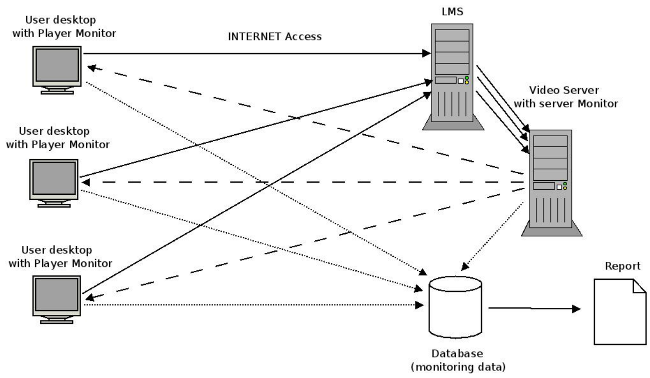

Figure 1: System overview with communication between modules indicated

Using the monitoring system it is possible to get many metrics of video consumption that can be classified by:

Video Player Parameters – monitored based on user interaction with video player:

- Mouse actions;
- Windows focus;
- Pause, fast forward, rewind
- Use of Comments tool;
- Interaction with social network tools (Facebook, twitter).

QoE – check the level of user satisfaction proposing a poll;

- Related to video content quality;
- Related to video quality;
- Related to transmission quality.

Content Absorption – check how much user has learned watching video content:

- Evaluation based on test learning validation;
- Other activities to check content absorption (debates, work groups, etc).

Figure 2 shows the interface of the LMS integrated with the monitoring modules. In this screen it is possible to see the video player, the text box for comments, social networks Facebook and Twitter icons, the stars that allow classification of video quality (and consequently transmission quality), and finally, next to the video player, the tests to assess content absorption.

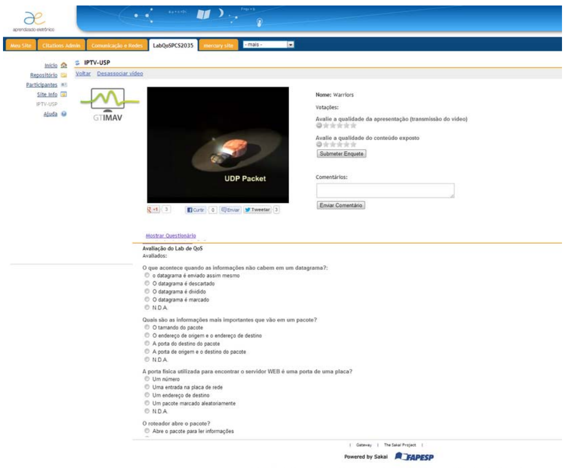

Figure 2: Shot screen video player in LMS integrated to monitoring modules

Please, refer to [10] for more information about system implementation.

IV. USAGE SCENARIO

When an user accesses a video, he/she can interact with it in different ways: evaluating it using tools provided in the application interface (chat, forum), commenting on it (by blogging, writing in a wiki or publishing comments in a public site), as well as sharing it in social networks. In addition, the user can be asked to answer several types of polls and tests about the watched video.

The use of video application to support the learning process is being considered as a baseline to guide the project development. We understand the potential of using video in this type of scenario and see that the goal is to design a monitoring service to assess the benefits of using video in this context.

Besides trying to measure how much the videos help in the learning process, we aim to enable the service to extract various other important informations, such as quality of content, level of effectiveness of a particular video on learning a specific concept, and the level of student interest in the subject.

In order to evaluate the service being developed, first we must create the following test scenario:

- Use of two groups of students. For the first group, class material will be available on video as supporting content. For the second group, this video material is not available, thus serving as a control group for testing.
- For the team using the video material, the assessment of student awareness and engagement with regard to the material will be made through a set of subjective questions, for example:
  - Evaluating the perception:
    -- Overall: excellent, good, indifferent, bad, very bad;
    -- Understanding of content: it helped a lot, helped, indifferent / did not help, made me confused.
  - Evaluating the engagement:
    -- Through comments made about the video;
    -- Through the sharing / recommendation of the video.

Figure 3 illustrates the usage scenario.

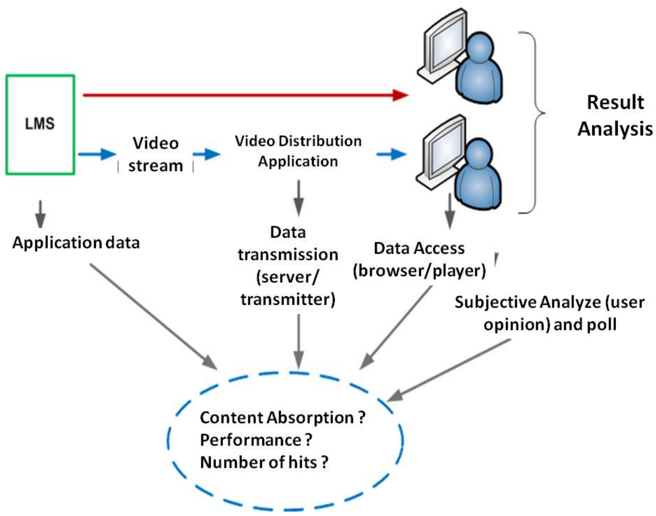

Figure 3: Learning scenario of system use

After the tests, based on the average score of each team and within the group that received the video as learning support, the variation of the grades will depend on the level of subjective evaluation, combined with evaluation of technical parameters collected (if the student had trouble watching the video due to a long buffering time or transmitter overload, for example, if he or she has watched all the content or not, interacted with the content by making a comment or engaging in video sharing/recommending)

Then, the final score of each group will be compared and analyzed, and within the group which received the video material, specific parameters will be created for the evaluations, such as the variation of grades depending on the subjective evaluation questionnaire that each student has answered. Adding to this, the technical data collected (directly related to the reception quality of the user), will also be considered. For example: difficulty in watching the video due to problems arising from the user's network infrastructure, the video application, network video transmitters, as well as analyzing whether the user has watched the video in its entirety or only partially, written comments or recommended the content in any way. Thus we have a complete analysis of the user experience quality and how these factors affect student performance.

From this scenario it will be possible not only to assess the potential of the service, but also to allow extraction of information that may be useful to improve the attractiveness of the videos and content, or make it possible to adapt the content (for example, videos should not last longer than a certain time, or the absorption level drops). These are just some examples of analysis that could be made from the data collected.

V. Results and Analyses

According to the procedures described in item VI we applied, during the last academic semester, an experiment as described above to a group of students at the beginning of the second year of engineer, and/or computer present courses. Actually these students are from any science or technology course offered by UFABC University, as it is an obligatory discipline. To this experiment we considered that it would be easier to accompanist students and listening to their opinions during present the classes so we took this experiment not in virtual classes but only in face-to-face classes. As the discipline was Communications and Networks we choose a movie with an explanation of how Internet works, focused on how packets move through the Net, and how routers and switches treat these packets. It is possible to see in Figure 2 a shot screen of the video we used in this experiment.

Our students were divided in two groups, one with 78 students and the other with 74 students. Each group belonged to a classroom and the professor, which was the same for the two groups, in both classes explained the same concepts but, in one of these classrooms, students were asked to watch a movie with the same explanation done in the classroom.

As students were not obliged to watch the video explanation only 41 from 78 students did this activity. To both groups were applied in their traditional evaluation two questions that were explained in classroom and that appeared also in the video explanation. We also did a Quiz questionnaire in the video page with the same two questions we did to both groups in their formal evaluation. In Figures 5 it is possible to observe the video quiz results.

Figure 4 shows the distribution of students that answered correctly equivalent question at video quiz for exam´s questions 2 (Q2) and 3 (Q3), and for that ones that answered wrongly equivalent question at video quiz for exam´s question 3 (Q3). The intervals considered are: Interval 1 is from 0,82 to 1, interval 2 is from 0,62 to 0,8, interval 3 is from 0,42 to 0,6, interval 4 is from 0,22 to 0,4 and Interval 5 is to 0 to 0,2. These show that, for instance for Q2, 88% of students got maximum score on this question at the final exam after doing video quiz; and considering Q3, 64% of students got maximum score at this question at the final exam after doing video quiz. In the other hand, 29% of students that answered wrongly Q3 at video quiz got worse score at this question at final exam.

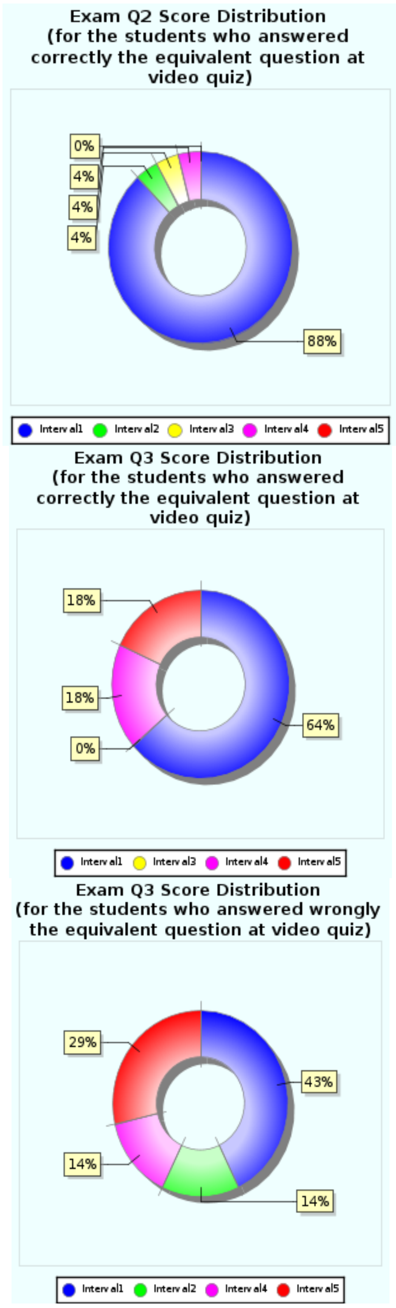

Figure 4: Video quizzes results*Normalized scores: interval5 = [0, 0.2], interval4 =]0.2,0.4], interval3 =]0.4,0.6], interval2 =]0.6,0.8], interval1 =]0.8,1]

We also applied to both groups the same questions in their formal evaluation, which means, both classes did an evaluation in a written format. We repeated the same questions to the group that watched and that had already done the same questions in the video quiz questionnaire and the results are shown in Figure 5.

From the results shown in Figure 5, one can observe that the students who watched the video performed better than students who did not watch the video. From these results, we conclude that the video content helped students better understand the educational content they were learning. In this case, the video content was used as a support material, since the same teacher in the subject that was requested during the evaluation taught both groups.

Comparison between classes

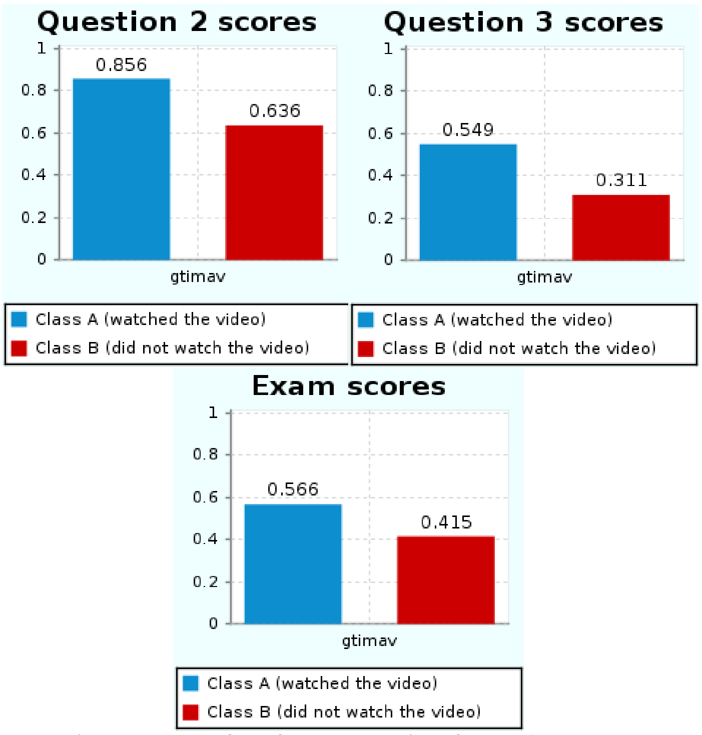

Figure 5: Results from formal evaluation of group A and B

Simultaneously we were observing how students were learning from the video contents; we observed how was their perception of video transmission quality and how was student's perception of video content, shown respectively in Figure 6 (a) and (b).

Another question we would like to answer in this project is: is there a relationship between student's learning profile and his/her behavior when exposed to a didactic content presented in a video format?

At the beginning of this experiment we imagined that it would be important to know our student's profiles to try to answer to question presented. It is not an easy task to determine and obtain this information but we applied a profile test based on Multiple Intelligences, proposed by Gardner [11] and tried to verify if there is any relationship between student's behavior in our video tests and their learning profiles. We can see some relations and some results in Figure 7.

Figures 6a and 6b: Students evaluating of video transmission quality and perception of video content

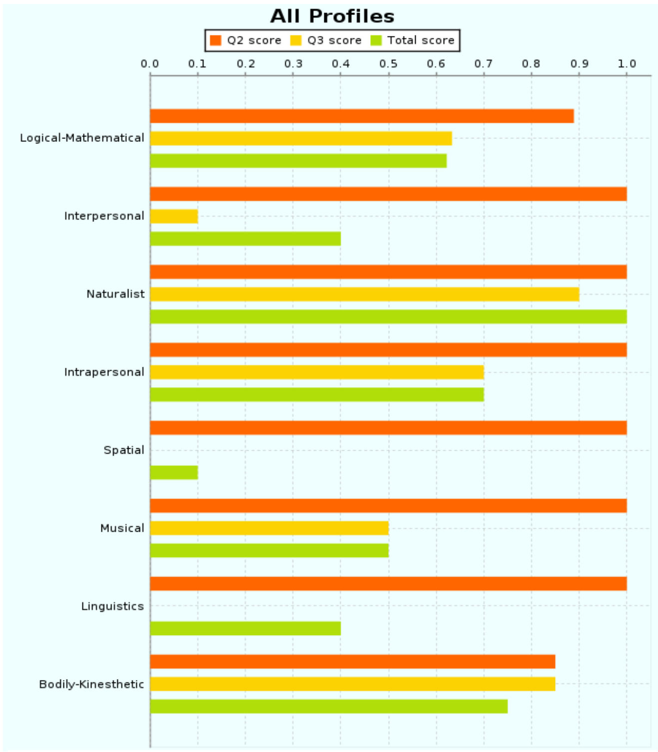

Figure 7: Relationship between student's profile and their performance in the test

VI. CONCLUSIONS AND FUTURE WORK

As presented in this paper, video consumption tends to grow in coming years and it will be increasingly important for institutions that produce and use videos in their core activities, to have metrics and parameters with which to scale the physical infrastructure and human resources needed for such use. At the same time, it becomes increasingly imperative to know the validity and effectiveness of using this type of media. Especially in teaching and learning activities, it is very important to be able to assess how much knowledge a particular material in video format was effective in building, considering a student or group of students. The results that we see from this experience seem to be like that the offer of educational content in video formats tend to achieve better results in our intent to teach a specified content.

But, although we developed our experience with groups formed by a significant number of students, it is not easy to observe the relationships between the data collected. So these data are not yet sufficient to say that actually students learned more based on didactic content offered in video format. So to be able to say with certainty that a didactic content in video format is effective in the learning process we need to develop more experiments like this so that we can cattegorically state that it worth it produce educational video content once this format not only entails a higher cost of production but also distribution, since resource-intensive network infrastructure are needed.

Another important conclusion we obtained is that to prepare an experiment like this it is necessary to produce in advance all videos will be used, to define in what moment during the discipline period they will be offered and what questions will be done to be possible to infer what and how much students have learned. To do this it is important to have a group to setup the experiment because it demands a lot of work to a teacher develop alone.

Finally, as nowadays there are a lot equipments to produce 3D video, we want to produce some didactic material in this new format, to try to understand if the conclusions we obtained by observing the 2D didactic content can be applied to 3D format as well.

Acknowledgment

This project and research has been supported by the RNP - Rede Nacional de Ensino e Pesquisa (Brazil) in the context of the work group GT-IMAV, which we would like to thank. We would also like to thank the research team: Lucas Chigami, Renata Takehara and Adriano Adoryan.

***Abstract*— A study was conducted to find out who needed online problem-solving tutors and who benefited from using them. In particular, the study focused on whether there were any significant differences between male and female students and between traditionally represented and under-represented racial groups. Data collected by two Computer Science tutors over multiple semesters was analyzed. The only significant differences found between sexes and racial groups were when female students practiced significantly more concepts because they had solved significantly fewer problems during pre-test, or when they demonstrated greater pre-post increase in score because they had scored significantly less on the pre-test. In both the cases, the tutors helped female students overcome differences in prior preparation vis-a-vis male students. No difference was found between the sexes or racial groups on the number of practice problems solved per practiced concept. Finally, students needed and benefited from the tutors in the same proportion, regardless of sex or racial group.**

Keywords- problem-solving; online learning; demographics; software tutor; computer programming

I. INTRODUCTION

Solving problems is an integral part of learning STEM (Science, Technology, Engineering and Mathematics). Traditionally, problems have been included at the end of each chapter in STEM text books. Instructors have given out problem-solving assignments, and used problems for assessment during tests.

Problem-solving activity is increasingly going online. The benefits of online problem-solving are several: students get their answers graded instantly; they can receive feedback on how to solve problems correctly; and they can solve problems as often as they please, at their own pace, and on their own time.

Some online problem-solving systems that are available for computer programming include CodeLab (turingscraft.com), myprogramminglab (myprogramminglab.com), codingbat (codingbat.com), CodeMate (pearsonhighered.com/mycodemate/), and CloudCoder (cloudcoder.org) - they provide practice writing code snippets focused on specific programming constructs. In contrast, we have been developing software tutors to help students learn programming concepts by solving code-tracing problems, called problets (problets.org)

Most of the studies of the effectiveness of learning Computer Science concepts from online tutors originate from research on Intelligent Tutoring Systems (ITS). For example, in one of the early studies, ITS researchers documented one standard deviation improvement in learning LISP using a problem-solving tutor [1]. However, many of the studies in Intelligent Tutoring Systems have been conducted *in-vitro* rather than *in-vivo*. More *in-vivo* evaluations of online tutors in Computer Science would better justify the wide-spread use of such tutors in Computer Science and the concomitant costs associated with developing the tutors. In one of our early *in-vivo* studies, we found that online tutors indeed helped students learn [2] and students who used the tutor for practice learned better than those who used a printed workbook [3].

Women and minorities are significantly under-represented in Computer Science, e.g., in 2011-2012, the latest year for which Taulbee survey figures are available (cra.org), women represented only 12.9% of Bachelor's degree graduates; Caucasians represented 64%, Asians 16.3%, and non-Asian minorities accounted for less than 20% of the graduates. Given the rising popularity of online tutors in Computer Science, it is appropriate and timely to study the differential effects, if any, of using online Computer Science tutors on women and minorities. In one of our earlier studies, we found that female students did learn using problets, and that there was no statistically significant difference between the improvement in the learning of female and male students using problets [4]. In another study, we found that using problets improved the self-confidence of female students to be on par with that of male students when female students started with lower prior self-confidence than male students [5]. We also found that female students assessed problets more positively than male students [6], and whenever there was a statistically significant difference between racial groups, under-represented racial groups assessed problets more favorably than positively stereotyped racial groups [7].

Two interesting questions about the differential effects of using online problem-solving tutors in Computer Science are: who *needs* to use them, and who *benefits* from using them. In particular, whether there is any significant difference between male and female students, and between traditionally

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

represented and under-represented racial groups. In order to answer these questions, we conducted a study using problets, spanning multiple semesters. In this paper, we will present our findings, after first discussing the research methodology, and data analysis.

In the study, participants were asked to identify their sex (biological notion of male/female) rather than their gender (social/cultural notion of man/woman) [8]. Therefore, the analysis will be presented in terms of sex rather than gender. When comparing racial groups, two groups were considered: traditionally represented racial groups versus under-represented racial groups. Asians are positively stereotyped in quantitative domains such as Computer Science (e.g., [9]). Therefore, Asians were combined with Caucasians to form the traditionally represented racial group (referred to as "majority" in another study [10]). The other racial groups, viz., Black/African American, Hispanic/Latino, Native American, Native Hawaiian/Pacific Islander and Other designations were combined to form the under-represented racial group.

Given the significant under-representation of women and minorities in Computer Science, the results of this study will be of interest to educators who use problem-solving software tutors in their Computer Science courses. If women and/or minorities are found to need and/or benefit from using problem-solving tutors, the results would provide justification for greater development and use of such tutors in Computer Science.

The online problem-solving software used for this study, called problets, deals with introductory computer programming concepts. Each problet presents problems on a specific programming construct and has the student solve them. When the student submits the answer, the problet grades it, and provides feedback, including step-by-step explanation of the correct answer, which has been shown to help students learn [2].

Each problet is configured to administer pre-test-practice-post-test protocol as follows:

- **Pretest** – During the pretest, the problet presents one problem per concept. If a student solves a problem correctly, the student is given credit for the corresponding concept. No feedback is provided to the student, and no more problems on the concept are presented to the student. On the other hand, if the student solves a problem incorrectly, feedback is presented to the student immediately after the student submits his/her solution to the problem. Additional problems are presented on the concept during the subsequent stages.
- **Adaptive practice** – During this stage, additional problems are presented to the student on only the concepts on which the student made mistakes when solving problems during the pre-test. For each such concept, the student is presented multiple problems until the student masters the concept, i.e., solves at least 60% of the problems correctly. On each problem, the student receives feedback explaining the correct answer step by step.
- **Post-test** - During this stage, the student is presented test problems on the concepts that the student mastered during adaptive practice.
- **Demographics** - Students are provided the option to identify their demographic information, including sex and race. Demographic information is solicited after the pre-test-practice-post-test protocol to avoid the effects of stereotype threat [11,12,13].

The pre-test-practice-post-test protocol was limited to 30 minutes and was administered back-to-back, entirely over the web.

Given this set up, the following were the types of experiences students had using the problet:

- The student solved all the pre-test problems correctly. So, the student was presented no practice or post-test problems.
- The student solved at least one of the pre-test problems incorrectly. However, the student ran out of time solving practice problems and never solved any post-test problems.
- The student solved at least one pre-test problem incorrectly, solved sufficient practice problems to demonstrate mastery of at least one concept and solved a post-test problem on each such concept. For these students, **the number of practiced concepts** was the number of concepts on which the student solved pre-test problems incorrectly, solved sufficient practice problems to demonstrate mastery and solved the post-test problem.

For analysis purposes, we grouped students into four categories, and used the following measures to compare them:

- **Students who did not need to use the tutor** – these were the students who scored 100% on the pre-test. So, the tutors did not present any practice or post-test problems to these students. For these students, the time spent per pre-test problem was compared - those who solved problems faster had greater self-efficacy [14] when they started using the tutor.
- **Students who needed the tutor, but did not get to practice with it** – these students scored less than 100% on the pre-test. But, they spent all 30 minutes solving pre-test problems. So, they ran out of time and did not get to solve any practice or post-test problems. For these students, the score per pre-test problem was compared - those who scored more per problem were better prepared when they started using the tutor.
- **Students who solved practice problems, but not enough to practice any concept** – these students scored less than 100% on the pre-test, so they needed to use the tutor. They solved practice problems, but not in sufficient numbers to demonstrate mastery, i.e., score 60% or more on any one concept. So, the tutor did not present any post-test problems to these students. For these students, the number of practice problems was compared - the more practice problems a student solved without mastering any concept, the less the tutor helped the student learn.

- **Students who practiced one or more concepts** – these students solved less than 100% on the pre-test, solved sufficient number of problems during practice to score at least 60% on one or more concepts, and went on to solve post-test problems on those concepts. For these students, the number of concepts practiced and the pre-post change in score on the practiced concepts were compared – the more the number of practiced concepts and the more the increase in score from pre-test to post-test, the greater the learning. The number of practice problems solved per practiced concept was also compared – the more the problems solved, the more the effort needed by the student to learn with the tutor.

For this study, two tutors were used, both on introductory concepts:

- Arithmetic expressions tutor, designed to help students learn to evaluate arithmetic expressions as used in computer programming. Each problem contains an arithmetic expression that includes one or more operators. The student is asked to evaluate the expression one operator at a time, according to the rules of precedence and associativity.
- Selection tutor, designed to help students learn to trace programs containing if and if-else statements. Each problem contains a computer program that includes selection statements. The student is asked to predict all the outputs of the program, one output at a time, along with the line number of the code that generates the output.
