The goal of strengthening moral reasoning is enhanced when we situate engineering ethics within a reflexive process involving the analysis of the relationships and conflicts between value claims. Reflexivity analysis is guided by a set of questions developed to encourage analysis of applicability, relevance, and repercussions within each SIRA module. For instance, students are asked how they specify and prioritize principles in the context of each case, as a means of encouraging reflection on the principles of the particular case. This iterative analysis parallels an engineering design process and can be readily adopted by engineers. Reflexive analysis deepens the disciplinary discourse but also facilitates the applicability of ethics and moral reasoning into emerging fields of engineering. It helps engineering ethics fulfill a role as a proactive or "preventative" ethic [8] guiding the profession, while helping developing engineers gain deeper insights into the practice of moral reasoning.

III. Cyber-Enabled Learning Modules

The pilot course was developed and delivered in a hybrid format integrating live classroom interactions with a set of online learning modules delivered on a sophisticated cyber-infrastructure for global engineering education, GlobalHUB (globalhub.org). We piloted four SIRA modules and a meta-module on reflexive principlism, in a graduate engineering ethics course with in-class and online students (N=20) which fulfilled a mandatory ethics requirement. Four cases were tested from several engineering contexts. Two were previously published, including a disaster (*Hyatt Regency Skywalk Collapse*) [9] and a design case (*Engineering Pediatric Heart Valves*) [10]. The other two were developed for the course and included developing technology (*Diagnostic Device Development*) and a recent environmental disaster (*BP Deepwater Horizon Oil Spill*).

Each SIRA module was designed to be completed in a two-week timeframe, progressing students through a series of six structured learning stages including: (a) establishing knowledge; (b) perspective taking; (c) compare and contrast; (d) inducing conflict; (e) decision-making and justification; and (f) reflection and reflexivity (see Table 1). In each stage we specified the type and form of content to be delivered, and the form of learning activities required to facilitate educational goals. The degree of scaffolding provided was gradually reduced, progressing from high in the first two stages to low in the final two stages. For example, early in the module students were specifically instructed to make decisions using the four principles; in later modules, these prompts were faded.

IV. The Learning Testbed and Research Methods

To assess the efficacy of this framework, we examined the relationship between students' participation in and experience of the online learning module and their development of moral reasoning and satisfaction with ethics education. The fundamental questions addressed by this research are:

(1) What is the impact of a SIRA approach on the development of students' moral reasoning, and their satisfaction and engagement with engineering ethics education?

(2) What characteristics of the SIRA approach contribute to change in moral reasoning ability, and to student satisfaction and engagement?

We take a mixed-methods approach [11], and gather both quantitative and qualitative data. In this first year, we analyzed the efficacy of the course modules, and the change in two primary measures: moral reasoning and student satisfaction and engagement. In a process of concurrent triangulation [11], surveys, observation of class sessions, focus groups, and semi-structured structured interviews were used to evaluate moral reasoning development, student satisfaction and engagement, the use and success of scaffolding/resources, and the efficacy of the course module structure. In the following we discuss the instruments and measures.

A. *Moral Reasoning Development*

To evaluate the impact of the learning module on the development of moral reasoning two assessment tools were administered using a pre- and post-test strategy at the beginning and end of the course: the well-validated Defining Issues Test (DIT2) [12], and the novel Ethical Reasoning Instrument (ERI). The latter was developed to measure moral reasoning in the context of engineering [13]. Both instruments provide quantitative measures of change in students' moral reasoning as a result of participation in the SIRA modules. We also assessed a variety of artifacts submitted by students during the course, and used reflective analysis to assess changes in students' moral reasoning abilities.

B. *Satisfaction and Engagement*

To assess the impact of the SIRA modules on student satisfaction and engagement with ethics education, an additional survey was administered at the beginning and end of the course. The survey was derived from published scales from the SEED survey [14], which has been validated with over 3000 engineering students at 18 institutions nationwide.

C. *Course Efficacy*

Student views regarding the efficacy of specific elements of the course modules were captured from (a) written responses to meta-reflection questions at the conclusion of each module, (b) a survey administered midpoint and at the end of the course, and (c) from semi-structured interviews at the conclusion of the course. Questions in these assessment instruments included ones such as: "*Which elements of the*

TABLE I. STRUCTURE OF SIRA MODULES

Learning Type: *(time allotted)*	**Establishing Knowledge** *(1 day)*	**Perspective Taking** *(2 days)*	**Compare and Contrast** *(3 days)*	**Inducing Conflict** *(1 day)*	**Decision-making and Justification** *(2 days)*	**Reflection and Reflexivity** *(3 days)*
Type of Content:	Scenario, facts, and expert info about emerging technology	Stakeholder perspectives	Comparing perspectives	Common ethical principles	Debate with justification; Opinion by technical ethicist	Meta-reflection on ethics and process
Form of Content:	Multimedia -video and text (multiple perspectives)	Responsive writing / Journaling	Multimedia responses in text, voice, video	Expert ethicist's presentation (video, slides, or text)	Live web-video conferences & Recorded statement	Multimedia responses in text, voice, video
Learning Activity:	Narrative	Reflection	Moderated Discussion	Listening / Reading	Facilitated Debate	Meta-reflection
Scaffolding	High / *hard*	High / *hard*	Medium / *soft*	Medium / *hard*	Low / *soft*	Low / *soft*

module were most important to your development of moral reasoning?" and "*How and where did your thinking about ethics change in this process*?" The midpoint survey data were used to adjust the scaffolding, content, and staging of the modules to optimize student access and comprehension. At the conclusion of the course, we conducted semi-structured interviews to probe additional aspects of student participation, and elicit dimensions of the modules that were significant to the learning process or to engagement. The interview data also assisted in interpretation of quantitative data, and provided contextual seeds to revise questions in subsequent instruments.

V. FUTURE RESEARCH AND DEVELOPMENT

Building upon theory and research in ethics, engineering education, and communication, these highly interactive and modularized learning modules for engineering ethics have broad implication for being embedded into a wide variety of courses and curricula across disciplines, and at undergraduate, graduate, and post-graduate levels. Through our use and development of measures to assess the efficacy of ethics education, we are building evidence of effectiveness of the principlist approach in engineering ethics education contexts. In addition, we provide resources for engineering educators including materials, case studies, research instruments, and a research-tested framework for cyber-enabled learning that has applicability to graduate, undergraduate, and professional ethics education needs around the world.

In the next phase of the project, we will embed the SIRA modules in an online ethics course for students around the globe through Purdue's NeXT and GlobalHUB environments. Sixty first-year graduate students will be recruited and offered 1-credit of graduate level coursework in Ethics for completing a four-module series. Their progress will be measured against a comparison group of students enrolled in a graduate ethics course that does not employ the SIRA framework. Four additional modules will be developed and tested to bring the total number of deliverable SIRA modules to eight, covering a broad range of cases related to emerging technologies in multiple disciplines including Biomedical, Materials Science, and Mechanical Engineering. Concurrent to this continuing development of course modules and cyber infrastructure, we will continue assessing the efficacy of the SIRA learning environment for developing moral reasoning skills, to iteratively test and refine our framework.

ACKNOWLEDGMENT

We are grateful for the administrative and technical support received from HUBZero, GlobalHUB, and Eckard Groll.

Development of a Classification Scheme for "Introduction to Engineering" Courses

Kenneth J. Reid, David Reeping, Tyler Hertenstein, Graham Fennel, Elizabeth Spingola
Engineering Education
Ohio Northern University
Ada, OH
k-reid@onu.edu

***Abstract* — "Introduction to Engineering" courses are often designed from scratch and can become a grab-bag of unrelated topics. They are often designed by instructors to cover what they feel is important. Therefore, while they may be *prerequisites* to second-year courses, first-year engineering programs are not necessarily *integrated* into the curriculum. Further, since they are often designed with little consideration for existing models, overall outcomes and content may vary widely. The results include an issue of course developers "reinventing the wheel" as successful models are not adequately disseminated.**

Results of multiple methods of investigation are presented. An analysis of syllabi for Introduction to Engineering courses identified course learning objectives, and these objectives were grouped to establish an initial classification scheme. A workshop in which objectives were discussed was held at a national conference and a separate draft classification scheme was proposed. A concurrent effort uses a Delphi procedure to define and categorize expected outcomes in first-year courses. Survey data from the Delphi study has been collected toward a single, final classification scheme.

This paper will present results of the first two components of the study and the initial high level classification scheme identified as the Delphi analysis begins.

Keywords—classification scheme; first-year; introduction to engineering

I. Methodology

This project involves a study and the development of a classification scheme for courses meant to introduce engineering to first-year engineering students. Such courses are typically entitled "Introduction to Engineering" or similar; yet, this course title can describe fundamentally different courses. For instance, an introduction course with weekly presentations from different departments is fundamentally different than one with an outcome to cover programming fundamentals. With the various nuances and contrasts in the content of "Introduction to Engineering" courses between universities, these classes should be classified differently. The problem is exacerbated by a lack of definition of first year models. For example, a developer may know what they want in a course, but how do they find a course with similar outcomes with nothing more than "first-year engineering" as a description?

Prior research in the first year of engineering has focused on an understanding of student success directly related to coursework [1], innovative curriculum design [2,3,4,5], and specific necessary components of the first year including a solid foundation in math [6]. Brannan and Wankat [7] looked at different components in the first year, including introductory courses. Little research to classify various first year engineering courses is available, although establishing a common framework seems to be a necessary step toward informing curricular reform and program development.

Three separate methodologies were used to develop the classification scheme.

A. Analysis of syllabi

In an effort to identify common concepts and student learning objectives, an Internet search of web sites from universities, colleges and programs was conducted for courses entitled "Introduction to Engineering", "Engineering 1", or courses with similar titles. A team of undergraduate research assistants was tasked with executing this Internet search and summarizing results in cooperation with the principal investigator during the 2012 spring semester. Researchers used common search engines to search for "introduction to engineering" and similar terms. When such a course was identified, an additional search for the course syllabus was completed. Each syllabus found was reviewed to ensure that the course was meant to apply as a common engineering course rather than a technically oriented, discipline specific course: for example, delineating between "Introduction to Engineering" and "Introduction to Electrical Engineering." The Introduction courses may contain significant technical content (such as MATLAB programming), but must be either intended for students in multiple disciplines or have an interdisciplinary focus to be included in the analysis. Further, courses were not to be general orientation courses geared strictly toward understanding the culture of a university or a general introduction to university life – although again, these topics may appear in a course meant to introduce engineering. Finally, courses were not to be those that might introduce engineering to non-engineering majors, such as a "How Things Work" survey course. To be considered, a course must be presented to an interdisciplinary population of first-year engineering students and not meant as only an orientation course.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The team identified 28 syllabi that met the criteria. Each team member was assigned to review 14 (half of the syllabi), thereby reviewing each syllabus twice. As the intent was to develop an exhaustive list of all course outcomes, each specified course outcome along with other course outcomes that could be gleaned from the course description were listed. For example, one syllabus described a significant project to design a robot, yet no course outcome similar to "discover robots" was specified. This was considered as a (potential) course outcome from this course.

Team members listed each outcome from each syllabus. The team developed a mind-map or concept map by grouping similar outcomes using post-it notes on a whiteboard. In the event of similar outcomes (for example, Programming in C++ and Computer Programming), group consensus was reached to determine whether the outcomes were identical. If judged to be identical, or for cases of absolutely identical outcomes, a count was maintained. The final scheme evolved from this concept map.

The intent of this initial search was to develop a framework to guide formation of initial questions for and analysis of results for the upcoming Delphi study.

B. Analysis of results of workshop discussion

A workshop for informal discussion of establishing the classification scheme took place at the Frontiers in Education conference in Seattle, WA in October 2012. A Catalyzing Collaborative Conversations (CCC) session was designed and organized jointly by Directors of First Year Engineering programs at Ohio Northern University and Virginia Tech. The session offered an opportunity to convene a community with a common interest in first-year engineering education, and establish a set of existing and desired course outcomes for Introduction courses as a group. The guided, informal discussion offers the opportunity for participants to submit their ideas; the collective ideas of the group then guided conversation toward the development or discovery of other ideas generated through the group discussion.

Approximately 24 attendees were seated in groups of 6; each group was tasked with having a discussion around a set of guiding questions distributed at the beginning of the workshop. Each group had a designated recorder to capture results. While the initial intent was to allow a fixed time for small group discussion, then to bring the groups together and have a culminating discussion among the full group, the leaders opted to allow the conversations to conclude naturally, or to continue to (and past) the scheduled end of the session.

The set of guiding questions for each group included:

- What are the objectives of the first-year engineering programs?
- Why isn't there a common set of objectives for the first year engineering courses?
- What would we consider to be the best practices for first year engineering program?
  For example, should we teach Matlab/Excel rather that introducing students to the disciplines?
- If students were so successful in High School, why is there so much emphasis on success?
  What do we mean by success?
- Are there any of these objectives that are hard to assess? How might we assess them?
  Is there anything that we think should be a best practice that isn't because it is too difficult to assess?

Results were collected from the recorder of each group. These results were analyzed by the team of researchers, then a similar mind-mapping process was employed to develop a concept map from the written comments of the reporters from each group. Again, the research team came to consensus on any outcomes judged to be similar or identical.

As in the case of the scheme from the search of online syllabi, results of this analysis were used as the framework toward the development of the initial round of questions for the Delphi study.

C. Delphi study

The Delphi procedure was employed to engage a group of participants with a common interest to develop shared images based on three rounds of question development and information, with iterative feedback [9,10,11,12].

The initial invitations to participate came from a list generated by a steering committee of faculty in first-year engineering programs, e-mail invitations to the listserve of the First-Year Program Division of ASEE, email invitations to all participants in the 2012 First-Year Engineering Experiences conference, and targeted e-mail requests sent to a variety of universities with first-year engineering programs identified through ASEE and through recent literature. Given a potentially large quantity of information from each round of surveys and the eventual expected duplication of responses, a target of approximately 35 participants was selected [11,12]. Thirty seven participants submitted their interest in participating and 31 participants completed the initial round of data collection.

The Delphi procedure is administered online. Questions for the initial round consist of those initially developed by the steering committee and refined from results of the first two phases of the project. The goal of the first round is a collection of all possible outcomes found in an Introduction to Engineering course.

The second round includes asking participants to examine a draft of a scheme developed from responses to the first round and the first two preliminary schemes to ensure that all outcomes were captured. Participants were directed to a website with the scheme available for review, then to a survey site to record answers. Feedback from round two served to develop a final proposed classification scheme. The advantage of the Delphi method for these first rounds is the elimination of 'groupthink', where participants fail to fully participate or modify their responses based on the perceived majority opinions found in a group.

In the third round, participants received final proposed classification scheme generated by all prior work and asked to use the scheme to analyze their courses, and asked to comment.

As round three was completed, it appeared that consensus had been reached and only minor modification to the proposed scheme was necessary.

Results of all three methods are used to define the final classification scheme which is planned for final testing and discussion at a culminating workshop during the 2013 First-Year Engineering Experience conference.

II. RESULTS

A. Analysis of Syllabi

A total of 28 syllabi were found online that fully met the specific criteria. A diverse set of institutions were represented: community colleges, private and public universities, and large research-based institutions. Each individual syllabus was inspected to cull student learning objectives and/or course objectives, whether expressly listed or found in a descriptive summary of the course objectives. Course objectives were listed and categorized.

A complete concept map was generated by grouping related outcomes, eliminating exact duplicated (judged by a consensus among the research team), and specifying the relationship among the outcomes. As a concept map was developed, main factors (i.e., Professional Skills) and subfactors (i.e., Tech Comm) emerged from the cloud of individual course objectives. The classification of the course objectives found in the examined syllabi is shown in figure 1. Figure 1 shows the scheme to a subfactor level; in other words, "Tech Comm" includes individual objectives such as effective public speaking, effective report writing, poster and/or web page design, etc. that are not shown in this figure.

Objectives were found to group into four main categories:

- engineering skills,
- professional skills,
- orientation to the university / course / program, and
- orientation to the profession.

It is important to note that there is often not a clear delineation of objectives: for example, one objective specifically mentioned in a syllabus "prepare the student as a person including preparation toward their chosen field" may best represent an objective under orientation to the programs of the university or toward the profession. The analysis of the syllabi is intended to support the Delphi study, so further, specific classification of objectives where a subcategory was not immediately evident was not overly analyzed in this part of the project.

It should also be noted that the order in which the subcategories appear is significant: outcomes appearing most often in syllabi appear first (leftmost) and toward the right in descending order. For example, most if not all of the syllabi expressly listed teaming or teamwork among the course objectives; those that didn't expressly list them had group projects described in the syllabus. Fewest (but at least two) syllabi mentioned "global responsibility" (or similar). Since the goal was to collect as many outcomes as could appear in an introduction class, it is not important to what extent these courses instruct students in effective teamwork; rather, the appearance of group projects in a course description indicates that the potential for instruction on effective teaming exists.

B. Analysis of results of workshop discussion

Similar analysis was done based on the answers to the initial question in the Catalyzing Collaborative Conversations workshop: "What are the objectives of the first-year engineering programs?" This question generated most of the conversation, and most comments were listed under this item in the notes from each recorder. Discussion on the other questions typically drifted back to addressing this first question, or became a discussion of objectives that should ideally be (but may not currently be) included, all of which contribute to the goal of the data collection in this case.

Other discussion during the workshop critiqued the set of questions themselves. For example, "Are there any of these objectives that are hard to assess? How might we assess them?" was discussed for its merit as a valid question rather than discussing answers. The consensus was objectives that *should* be included but were *not* were such because of a lack of time or a lack of defining how to include those objectives rather than their ability to be assessed.

A similar mind mapping process was used to generate a concept map from data from reporter notes from each group. Individual team members reviewed the entire set of 18 pages of notes from the reporters from each small group. Individual outcomes were grouped to form main factors and subfactors. Again, specific objectives that may be most appropriate to more than one subcategory were assigned to one of the appropriate subcategories rather than an extended analysis of which would be best, since the goal is to capture all of the objectives mentioned within the group.

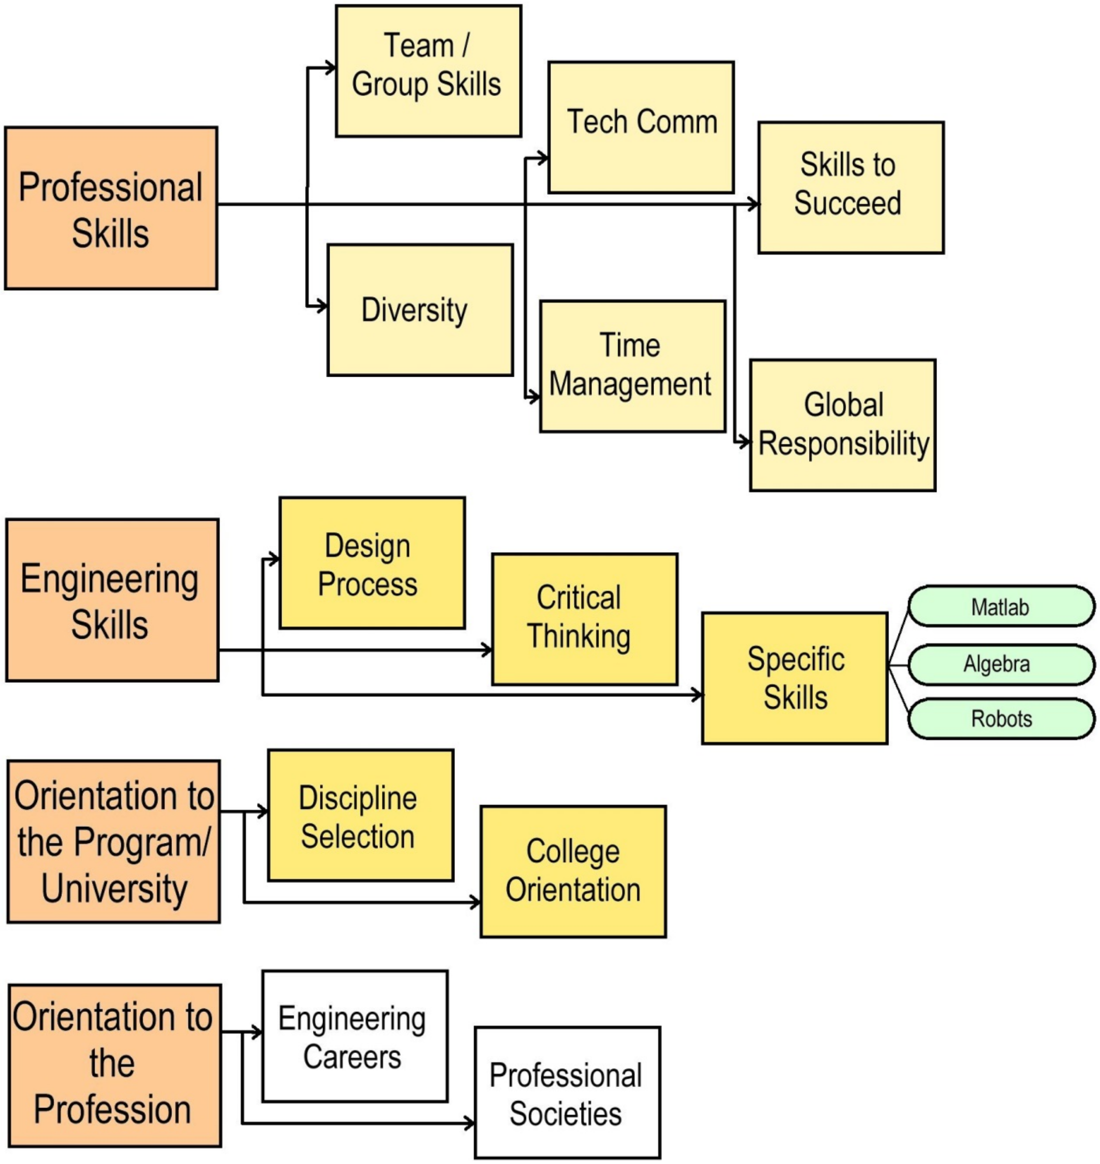

Figure 1: Draft of classification based on examined syllabi at the main factor and subfactor level

Figure 2 shows the concept map of objectives mentioned in the group discussions. Objectives were classified into similar themes as the analysis of syllabi. All subfactors included more than one objective, or objectives mentioned more than once in group discussions (according to reporters' paperwork).

Items are categorized from most often to least often mentioned, but always mentioned more than once. The exception is when any specific technical or discipline specific engineering skills were mentioned; these were included for the sake of comparison.

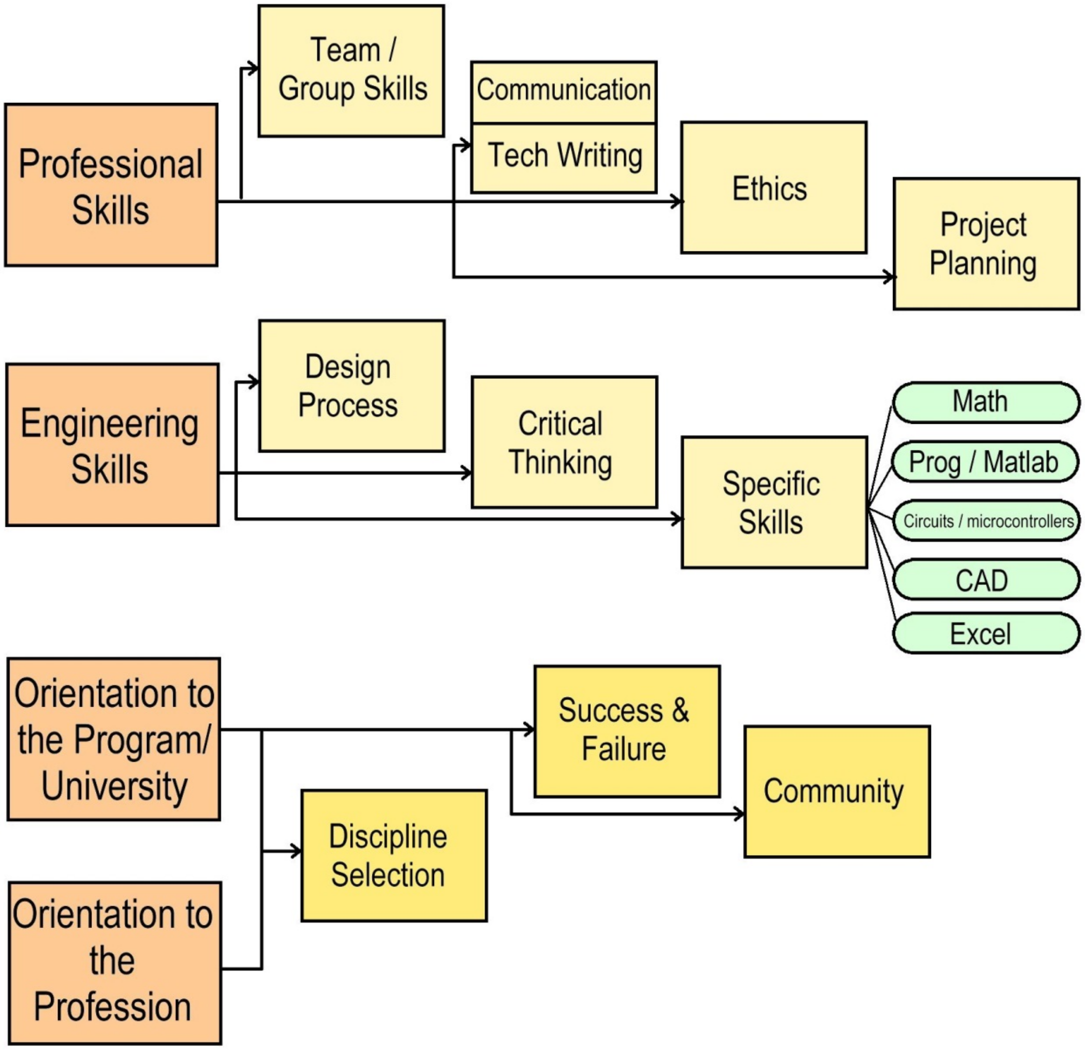

Figure 2: Draft of classification from CCC workshop at the main factor and subfactor level

III. Discussion

The same main categories emerged from both analyses. However, interesting and key differences emerge from objectives classified beneath each of these categories.

A. Engineering Skills

The specific objectives under the engineering skills heading showed the least difference between the two activities. The only difference was in specific engineering technical skills listed where the group discussion generated more examples of specific skills within a course. This is easily attributable to the dynamics of the group discussion and the occasional lack of specifying specific technical skills on course syllabi.

B. Professional Skills

Teaming skills and communication were mentioned in most if not all syllabi and group discussion. Given that these are often the most cited characteristics from employers and specifically cited in ABET criteria, this is to be expected.

From here, the most often cited objectives from participants in the CCC workshop were a consideration of engineering ethics and project planning, neither of which appeared in the analysis of syllabi. The lack of 'ethics' appearance in course syllabi is somewhat surprising. It is possible – and remains to be investigated – whether, for example, "project planning" and "time management" are meant to be included in the same category.

With more specific objectives mentioned and a more rich and thorough description of these objectives in the CCC discussion, a separation between technical writing and verbal (or other non-verbal) communication rather than a more generic "Communication" objective found in syllabi was introduced. Rather than focus on the validity of delineating different types of technical communication, further analysis was left for the Delphi study.

C. Orientation

The discussion seemed to go in two distinct directions: orientation to the university's engineering program and orientation to the disciplines to the profession in general. There is an inherent difficulty in defining the intended meaning of "orientation" objectives from course syllabi.

A discussion of including failure and success from both an engineering and orientation / integration context also emerged from the CCC discussion. Indeed, while research and discussion of the importance of incorporating "failure" into engineering plans of study, this only appeared specifically as a course objective in one syllabus.

This is an excellent example of a topic that is often discussed as one that "should be included" but often does not appear as a specified objective.

IV. Delphi Study

The initial round of the Delphi study featured the following question set based on input from both rounds of data collection thus far:

> When answering the following questions, please answer them within the framework of Introduction to Engineering / First-Year Engineering course(s). Do not consider other required courses within the first year. For example, please do not consider math, science or general education courses.
>
> - What topics are included (please list) in first-year engineering courses at your institution?
> - Are there topics that are not, but should be included in first-year engineering courses at your institution? Please list:
>   - (please do not duplicate answers from the previous question)
> - What are (please list) the expected student outcomes in first-year engineering courses at your institution?
> - What other student outcomes should be included in first-year engineering courses? Please list:
>   - (please do not duplicate answers from the previous question)

Of the 37 participants who originally indicated interest, 31 completed round 1. Results of this round were used in combination with the results of the analysis of syllabi and workshop to establish a proposed list of all objectives that currently exist or should exist within the Introduction courses. This list was published on a website, and participants were asked to review and comment on the list. The second round asked:

> After reviewing the proposed classification scheme / concept map, are all course outcomes in your existing course AND all outcomes that should be in an Introduction to Engineering course included in the diagram? If not, please list any that are missing.

Of the 31 who completed the initial Delphi round, 24 completed rounds 1 and 2.

A. Preliminary Delphi results

As anticipated, the open ended nature of the initial round of Delphi questions along with the inclusion of outcomes that "should be, but are not included" led to a more varied and complete picture of all possible outcomes included in Introduction to Engineering courses.

The highest level of the classification scheme is shown in figure 3. Eight of the nine highest level categories map directly to the four main categories from the prior two analyses. Pedagogy became the subject of conversation in the second round of the Delphi process.

Initial discussion pointed out that "pedagogy" drifted away from the intent classifying outcomes, as pedagogical methods implemented in the course are certainly not the same as student outcomes; therefore, "pedagogy" was removed entirely from the scheme.

B. Completion of the Delphi processand final classification scheme

The final round of the Delphi process will result in a complete classification scheme that is tested on each "Introduction to Engineering" course coordinated and/or taught by each participant. Once tested, the classification scheme will be presented at a culminating workshop in conjunction with the 2013 First Year Engineering Experience (FYEE) workshop. This workshop will involve discussion and additional testing (in which participants will use the scheme to classify their courses).

V. Future Work

The classification scheme gives a means to definitively classify an Introduction to Engineering course. While this is inherently useful for transfer credit and defining outcomes which can be expected in future classes, it also can indicate where gaps in assessment exist. Defining a student outcome that may be an integral part of a course implies that the outcome should be assessable. In cases where there is no assessment mechanism, one or more may need to be developed. This is expected to provide opportunities for further research, and is on the agenda for the FYEE workshop.

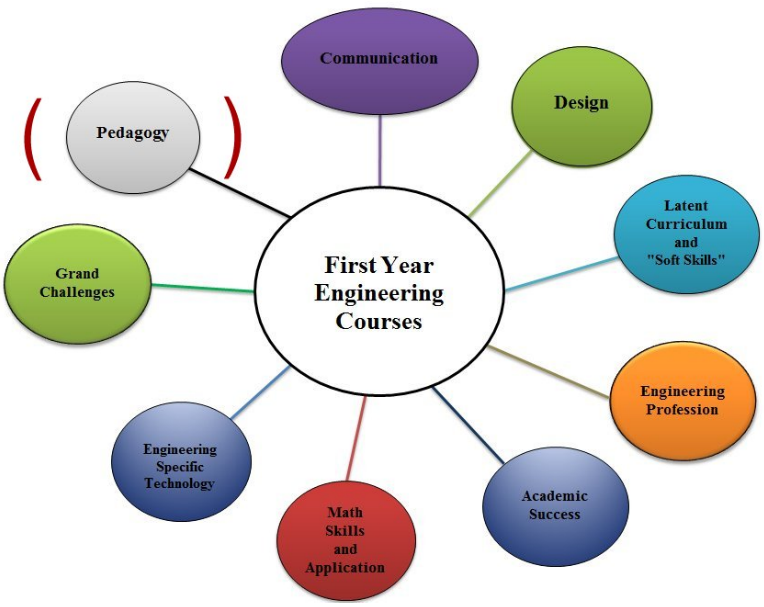

Figure 3: Top level of Classification Scheme from Delphi Method (Pedagogy was originally included but has been removed)

VI. CONCLUSION

A classification scheme is emerging from a study in which three different methods were used to collect course objectives from "Introduction to Engineering" courses. The final classification scheme will be useful to definitively define these courses within programs, especially as programs evolve. Further, the scheme will be useful when evaluating transfer credit and may have value in evaluating proposals for funding for research involving the first year of study in engineering.

Results thus far seem to indicate that course objectives can be grouped into eight major categories: Design, Latent Curriculum (soft skills), Engineering Professionalism, Academic Success, Math Skills, Engineering Specific Technology, Communication, and Grand Challenges, with any related outcomes or objectives defined as subcategories.

The final development of the classification scheme is expected to lead to future research into defining a naming convention (for example, "design focused") that could allow developers and researchers to use a common set of terms to describe different courses. Further research into using the scheme to define gaps in assessment of course outcomes is also expected.

***Abstract*—A recurring question raised by professors and undergraduate students involves the distribution of basic and practical — or professional — courses. Some authors defend a curriculum with more basic courses, such as mathematics, physics and chemistry, in order to create a solid foundation. Moreover, there is a growth of academic exchange programs all around the world, which require a common learning core.**

Since 1960, the importance of mathematics in Computer Science (CS) undergraduate curricula has been decreasing, particularly, because new fields in CS have risen and they were assimilated in the curricula. Despite its of reduction, mathematics still has its role in CS's curricula.

The goal of this paper is to analyze the amount of the courses related to mathematics in different CS undergraduate curricula. In this work is analyzed the lecture hour load dedicated to mathematics courses on eleven Brazilian CS undergraduate programs: The Federal Universities of Ceará, Minas Gerais, Campina Grande, Pernambuco, Rio de Janeiro, Rio Grande do Sul and Santa Catarina, State Universities of São Paulo (two programs) and Campinas and the Pontifical Catholic University of Rio Grande do Sul. These programs were selected among others due their 5-stars rating in the Guia do Estudante 2012 Ranking, published by Editora Abril.

To allow this comparison, a definition was established of what was considered to be a lecture hour of mathematics. For a reference point, such programs were compared with two reference curricula in the area: The Brazilian Computer Society curriculum (SBC) and the Computer Science Curriculum 2008 made by the IEEE Computer Society and Association for Computing Machinery (ACM) joint task force.

The curricula presented in the official websites of the selected universities in 2012 were analyzed and it was possible to conclude that more than half of the programs don't achieve the minimum amount of mathematics study hours necessary during undergraduate studies according to IEEE/ACM's or SBC's reference curricula.

I. Introduction

The recent growth of different higher education courses have resulted in a worsening of the identity crisis inside the university. Since its creation in the late thirteenth century [1], its function varied with the political context of the local society, basically presenting values related to national issues. Still, persisted the existence of two orthogonal trends, the one which states that the university mission should be to fix the current problems of society, and the one which states that its main task is to be a beacon, glimpsing the future. The present difficulty is that there are some undergraduate programs that follow the first trend and consequently aim immediate employability by focusing on technical knowledge and others that follow the second trend, valuing the academic knowledge and being more interested in graduating professionals able to deal with problems that still don't exist.

According to Renato Janine, Brazilian philosopher, there is a certain knowledge which is volatile, usually the technical one, which should be taught by companies. Furthermore, it's better that, in their educational period, the young deal with what's perennial, by giving them a solid foundation, than with details in constant change [2].

Universities should provide the necessary cultural and professional foundations so that, after graduating, a person may be able to adapt to different standards used by companies in the practice of the profession whose qualification was obtained. Therefore, the university should not bother to teach different types of procedures established in the labor market or teach techniques to deal only with some particular problems of the profession. In face of a rapidly changing world, where new challenges appear in an ever increasing rate, it should rather prepare students to learn by themselves how to deal with any problem or types of procedures at any time, whether present or future.

After all, procedures may vary not only across companies, but also change over time. Thus, the trained professional would not be prepared for the future and could only adapt to companies that could handle certain problems and only dominate some specific techniques. One can easily notice this fact through the rapid evolution of software, which requires a constant learning of their manipulation, generating in some cases a disposal of knowledge previously used.

Therefore, it is evident that theory and fundamentals are essential for this type of education and can not be *replaced* by just technical or practical knowledge. After all, foundations give the ability to tackle a given problem and use different approaches or reasoning to solve it. This issue has greater impact on technology-intensive undergraduate programs, such as engineering, a field where professional associations govern

The authors would like to thank the financial support from the University of São Paulo via the Ensinar com Pesquisa grant.

the exercise of the profession.

On the other side, practice has also an important role in the learning process. It allows students to apply concepts in real problems and thus reach conclusions which strengthen and sediment their knowledge of the area. This is particularly true for areas like Computer Science, which need to balance theory derived from algorithms and graph theory with programming, for example. As [3] states, one desirable characteristic of graduates is the appreciation of the interplay between theory and practice. "A fundamental aspect of computer science is the balance between theory and practice and the essential link between them. Graduates of a computer science program must understand not only the theoretical underpinnings of the discipline but also how that theory influences practice."

One of the common points, located in virtually every course curriculum that deal with technology are the contents of mathematics. Those, which in most cases have only a basic level of depth, precisely fit the definition that Renato Janine presented for tasks to be developed within the university. According to Anthony Ralston, mathematics develops the mind and "improves students' learning skills." [4]

Moreover, both Ralston, Kelemen et al [5], are emphatic in noting that the way mathematics is offered in undergraduate programs in American universities, more specifically the Bachelor in Computer Science (BSc CS), influences on student learning.

An important fact detected by several of the studied previous works ([4], [6]) is that an analysis of the reference curriculum provided by the IEEE and Association for Computing Machinery (ACM) joint task-force [7] [3] indicates that the role of mathematics has been decreasing gradually since at least the 1960s, although at a lower rate today.

This scenario is considered bad, because for Computer Science / Software Engineering students, in particular, mathematics is important because the logical reasoning inherent in any mathematical thinking is very similar to logical thinking necessary in software development [4]. In developing and implementing software projects, the graduate needs to develop effective ways to solve computational problems and the amount of mathematics used in daily life of a programmer usually increases when the structures are built using a more formal language. [4]

According to [5], "Computer Science students should be able to model 'real world' problems precisely using mathematics and using structures like arrays, linked lists, trees, finite graphs and matrices. They should be able to design and analyze algorithms that transform such structures [...], understand the nature of a mathematical model and relate mathematical models to areas of real problems [...]. Strategies for solving problems such as divide-and-conquer and backtracking are also essential."

This paper aims to fill a need from university faculty who want, for example, to reform their curriculum. By presenting an updated overview of how much math is studied in various well ranked Brazilian curricula it is possible to make better decisions. The consolidated information is then compared with standards in the academia, allowing a broad and weighted view of the current math education reality in Brazilian CS undergraduate programs.

II. Methodology

This paper makes a comparative study of different Brazilian Computer Science programs through a quantitative comparison of the number of lecture hours in the area of mathematics both in absolute and in relative values to the total hours required for graduation. The main goal is to identify whether the selected programs have more or less emphasis on mathematics compared with two reference curricula in the area, the Brazilian Computer Society Reference Curriculum (SBC) [8] and the Computer Science Curriculum 2008 (CS2008) made by the IEEE Computer Society and ACM joint task force [3].

It is important to point out that a quantitative assessment of the hour load allows an objective classification of studided programs; on the other hand, may be less effective in analyzing the different facets that mathematics is presented in CS programs, such as the emphasis of a particular program in the area of continuous (Calculus) or discrete mathematics (Algebra, set theory etc).

The task of isolating covered topics or areas in different curricula — such as mathematics in this paper —, for comparison purposes is, on one hand, very important as it enables objective analysis; on the other hand, is difficult to be done as different curricula have their own peculiarities. This is one of the challenges faced by accreditation organizations such as the European Network for Accreditation of Engineering Education (ENAEE), Accreditation Board for Engineering and Technology, Inc. (ABET) and the Asociación Iberoamericana de Instituciones de Enseñanza de la Ingeniería (ASIBEI). All of them are responsible for certifying that different Engineering curricula satisfy a common body of knowledge in order to facilitate students exchanges.

For this paper, are considered math disciplines those that address the areas of Calculus, Linear Algebra, Vectors, Geometry, Algebra, Proof Techniques, Counting, Probability, Statistics and Set Theory. These subjects are usually taught by the universities mathematics departments. A difficulty is that in some cases the names of the courses, or their syllabi, do not represent what is actually taught. All curricular material was read and classifications were created to select what in fact can be identified as mathematics.

The eleven Brazilian CS undergraduate programs studied were selected among others due to their 5-stars rating according to the 'Guia do Estudante 2012' Ranking, published by 'Editora Abril'. [9] The list comprehends the Federal Universities of Ceará (UFC), Minas Gerais (UFMG), Campina Grande (UFCG), Pernambuco (UFPE), Rio de Janeiro (UFRJ), Rio Grande do Sul (UFRGS) and Santa Catarina (UFSC), State Universities of São Paulo (USP) and Campinas (UNICAMP) and the Pontifical Catholic University of Rio Grande do Sul (PUC-RS). USP is further sub-divided in two distinct CS programs, the one held at the Institute of Mathematics and Statistics (IME/USP) and the other held at the Institute of Mathematical Sciences and Computing (ICMC/USP).

The methodology for this ranking is described in [10] and has the following process: The 'Guia do Estudante' office contacts yearly all universities in Brazil to catalog all undergraduate programs that will be accepting new students for the next year. Are considered for ranking programs that grant a bachelor's degree, are at least two years old and are in-class. After this step, the office contacts the courses coordinators in order to ask them to fulfill an online questionnaire containing 15 specific questions about the program. Among the topics covered are themes relative to the faculty, scientific production and physical installations. The questionnaires are not graded, only are made available to a group of peer reviewers to help in their grading process. Even if a program does not fulfill the questionnaire it will be graded.

The survey has a group of peer reviewers composed of course coordinators, directors of departments and teachers. They are responsible for evaluating the programs on a scale ranging from 5 (excellent) to 1 (poor) and "prefer not to opine". Each peer reviewer assesses a maximum of 30 randomly chosen programs, preferably in the region where he teaches and excluded those programs from his institution. Each program receives grades from six consultants, the best and worst being excluded. The final score is the average of the four intermediate ones. The process has technical consultancy from Ibope Inteligência and is audited by PricewaterhouseCoopers.

It is noteworthy that, since this is an opinion poll, the results reflect mainly the image that the course has before the academic community. A side effect of this choice is that most of the programs studied are held by public universities, which must be taken into account in the data analysis since they may have different emphases in the quantity and approach in fundamentals disciplines (especially mathematics) in comparison to private universities.

In 2011 the Brazilian Ministry of Education applied the latest National Test of Student Performance (ENADE) on CS programs. While some universities, like USP, chose to not participate, it presents a fairly accurate estimate on how many CS programs are in Brazil. According to it, there are at least 354 programs, 258 private and 96 public. [11]

III. Reference Curricula

As pointed out previously, Brazilian CS programs have their curricular contents mainly guided by two reference curricula. In an international level by the ACM/IEEE Computer Science Curriculum which current revision is from 2008 (CS2008) [3] and in a country level by the Brazilian Computer Society Curricular Reference from 2005 (CR2005) [8].

CS2008 is internally subdivided in three granularities, from bigger to smaller: knowledge areas, knowledge units and learning objectives. The Discrete Structures (DS) knowledge area is the only one that fits (partially) in the definition of mathematics used in this paper. More specifically, DS has the following knowledge units: Functions Relations and Sets, Basic Logic, Proof Techniques, Basics of Counting, Discrete Probability, Graphs and Trees. From these, all but Graphs and Trees were accounted as math.

In accordance with CS2008, 280 lecture hours are necessary to comprise the whole obligatory curriculum, with the math area representing 39 lecture hours. [3] Note that CS2008 only addresses contents closely linked to Computer Science. There are no mentions on the requirements for Calculus, Linear Algebra or Differential Equations, necessary for advanced disciplines.

TABLE II. MATH COVERAGE IN BRAZILIAN CS CURRICULA

University	Total math hours	Total curricular hours	Percentage of math in curriculum
ACM/IEEE [3]	39	280	13.93%
SBC (4 years) [8]	30	160	18.75%
ICMC/USP [22]	540	4395	12.29%
IME/USP [23]	750	2985	25.13%
PUC-RS [24]	300	3045	9.85%
UFC [25]	400	3280	12.20%
UFCG [26]	420	3120	13.46%
UFMG [27]	540	2625	20.57%
UFPE [28]	285	3495	8.15%
UFRGS [29]	360	3240	11.11%
UFRJ [30]	480	3075	15.61%
UFSC [31]	486	3528	13.78%
UNICAMP [32]	510	3000	17.00%

On the other side, CR2005 has a broader definition of mathematics than the one used in this paper. It states that the following topics fall in the area: Linear Algebra, Combinatorial Analysis, Differential and Integral Calculus, Differential Equations, Analytical Geometry, Mathematical Logic, Discrete Mathematics, Probability and Statistics and Complex Variables. CR2005 doesn't detail how much time each of these topics should receive, it only affirms that it's necessary 30 "credits", didactic activity units, for the whole mathematics area. The full CR2005 curriculum requires at least 160 "credits" for 4-year programs or 200 "credits" for 5-year programs.

IV. Data

Table I presents the general panorama of the eleven chosen CS programs indicating their size, location inside the university and course characteristics. While most programs are diurnals (Full-time), with the majority lasting four years, it's possible to perceive two different sources of influence on the undergraduate program based on the location of the department responsible for it: in one side there are the ones that are closer to the mathematics departments in the university, IME/USP, ICMC/USP and UFRJ and the more technological ones, closer to engineering departments.

Table II deals with the total time necessary to achieve graduation and the portion of this time that is dedicated to mathematics as defined previously. It is important to notice that the totals shown include elective disciplines or mandatory internships when they exist.

Analyzing the amount of hours column we can see that there is a great variability in the hour load required by the curricula of different universities and the reserved portion to math. On average $3097h$ are required ($\sigma = 302h$) for 4 years programs, $3270h$ ($\sigma = 212h$) for 4.5 years programs and $3698h$ ($\sigma = 986h$) for 5 years programs. Studied universities have an average of 14.47% ($\sigma = 4.92\%$) of disciplines exclusively in this area.

The most important fact derived from data is that few CS programs achieve the minimum hour load for math according to CS2008 or CR2005. This can be better visualized in Figure 1. Only IME/USP and UFMG fully meet the standards presented, while UFRJ and UNICAMP meet only CS2008.

TABLE I. STUDIED CS PROGRAMS PANORAMA

University	Period	Organization	Foundation	Years to graduate	Students per year	Where is located
ICMC/USP [12]	Diurnal	Public	1979	5	100	Institute of Mathematical Sciences and CS
IME/USP [12]	Diurnal	Public	1970	4	50	Institute of Mathematics and Statistics
PUC-RS[13]	Nocturnal	Private	1983	4	60	Faculty of Informatics
UFC [14]	Diurnal	Public	1975	4	60	Center of Sciences
UFCG [15]	Diurnal	Public	1977	4	90	Center of Eletrical Engineering and Informatics
UFMG [16]	Diurnal	Public	1978	4	80	Institute of Exact Sciences
UFPE [17]	Diurnal	Public	1974	4.5	100	Center of Informatics
UFRGS [18]	Diurnal	Public	1983	4.5	100	Institute of Informatics
UFRJ [19]	Diurnal	Public	1974	4.5	50	Institute of Mathematics
UFSC [20]	Diurnal	Public	1976	4	100	Institute of Informatics and Statistics
UNICAMP[21]	Nocturnal	Public	1969	5	50	Institute of Computing

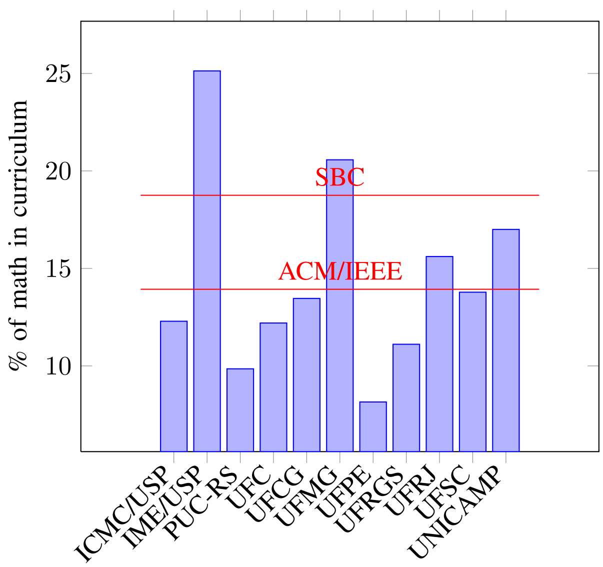

Fig. 1. The proportion of mathematics in each curriculum compared with the reference curricula

This implies that there is no evident correlation between the location of a CS program and its mathematical bias. Despite the fact that the ICMC/USP program is located near the math and statistics departments, it didn't achieve the minimum in both standards.

V. CONCLUSIONS

In Brazil there are many undergraduate rankings available. Beyond Guia do Estudante, the ENADE ranking, for example, could be used to analyze a different set of universities. Just like Guia do Estudante, ENADE analyzes the infrastructure of the university and the level of professors' graduation, but also applies a test on a subset of the freshmen and senior students in order to evaluate the knowledge acquired in the graduation years. [33] Using the Preliminary Concept of Course (CPC) available at [11] the 10 best ranked universities are: Federal Universities of Rio Grande do Sul (UFRGS), Goiás (UFG), Campina Grande (UFCG), the city of Rio de Janeiro (Fluminense - UFF), Minas Gerais (UFMG), Pelotas (UFPel), Viçosa (UFV) and the Pampa (UNIPAMPA) and the private Universities of the West of São Paulo (UNOESTE) and of the North (UNINORTE).

With both comparisons another possibility is to analyze if there is a positive correlation between a highly ranked program in different rankings and the amount of mathematics studied during undergraduation. If so, further investigation may be necessary in order to find if there is a correlation of cause and effect between the math study and the quality of an undergraduate program.

Finally, different studies are possible to measure the actual utility of a more theoretical topic in the professional life of a graduate. One possibility is to apply questionnaires to former students with the goal of identifying strengths and weaknesses of a curriculum.

In this paper it was possible to note that mathematics, although considered an area important for the basic formation of a student in Computer Science, is experiencing a decline in its relevance, in part by the emergence of several new trends in the market that are absorbed in undergraduate curricula.

An analysis of the current emphasis on mathematics in eleven Brazilian CS curricula from ten different universities was conducted through the study of absolute and relative workload in the area. It was found that only two programs fully and two other partially meet the minimum hour load for mathematics in an undergraduate CS curriculum according to two different academic standards, one national and the other international.

***Abstract*—Effective teaching assistants (TAs) are crucial for effective student learning. This is especially true in science, technology, engineering, and mathematics (STEM) programs, where TAs are enabling large programs to transition to more student-centered learning environments. To ensure that TAs are able to support these types of learning environments, their perspectives of training, their abilities, and other work related aspects must be understood. In this paper a survey that was created based on interviews conducted with eight TAs is discussed. The survey has four primary categories of content that are critical for understanding TAs' perspectives: (1) background, (2) motivation, (3) training, and (4) grading and feedback. This research team is first utilizing this survey at Purdue University to test for validity and reliability of the instrument, as well as identifying ways to improve the experiences and effectiveness of the First-Year Engineering Program's TAs' support system, training, hiring process, and any other relevant components of the infrastructure. The more generalizable goal of this research is to further develop this survey to be used by any STEM program as a diagnostic tool for identifying opportunities to enhance the TA support systems and therefore improve student learning.**

Keywords—first-year engineering; undergraduate and graduate teaching assistants; training; motivation; feedback

I. Introduction

Teaching assistants (TAs) have come to play a prominent role in undergraduate instruction. They are fundamental to the success of large introductory science, technology, engineering, and mathematics (STEM) courses. At large universities, graduate teaching assistants (GTAs) teach the majority of the science laboratory and discussion sections [1]. There is also a growing movement towards using undergraduate teaching assistants (UTAs) in introductory courses with large numbers of students [2-4].

As more undergraduate students work as teaching assistants, their unique position as both student and instructor introduces the challenge of balancing student and teaching responsibilities. Another problem is that many teaching assistants reported being assigned to undergraduate courses with no prior training [5]. In the case of GTAs, they are assumed to have the content knowledge, while pedagogical knowledge is not emphasized [5].

Since TAs are crucial to the success of large courses with a student-centered pedagogy, this research was conducted to create a survey to act as a diagnostic tool for STEM program utilizing TAs. Similar surveys have been created to understand TAs' perspectives of the benefits of training, effectiveness of course materials, helpful experiences, and many other aspects of programs [6-9]. This survey was created based on an analysis of existent, relevant surveys and previous research on interviews conducted with TAs in the First-Year Engineering Program at Purdue University. This survey tool targets TA responsibilities, training techniques, and other identified factors to answer the research question. This study is driven by the following research question: How so TAs perceive the affect of their previous experiences, motivations, and training on their ability to enact their responsibilities (e.g., grading, giving feedback, and helping students)?

In our previous study to investigate how TAs perceive their responsibilities and to identify factors that influence their ability to execute their responsibilities, eight TAs (i.e., 4 UTAs and 4 GTAs) from a large introductory engineering course sequence (enrolling about 1700 students) were interviewed in Fall 2012 [10]. This course sequence has introduced the use of authentic, team-based, iteratively-solved open-ended problems, in the form of mathematical modeling activities [11] and design projects. Some of the TAs' common responsibilities include: (1) attending TA training, (2) preparing for class, (3) helping with in-class activities, (4) supporting the course instructor and other TAs, (5) grading and giving feedback on students' solutions, and (6) helping students by answering questions in and out of class. From 18 different responsibilities within these six categories, TAs most frequently discussed five responsibilities from the three categories of training, grading, and helping students [10]. Prior knowledge and experience, training, and intrinsic motivation were among the most helpful factors; time commitment and the open-ended nature of problems were among the most frequent hindering factors. The helpful factors were aspects of TAs' positions that they identified as better enabling them to execute their given responsibilities. The hindering factors refer to difficulties that the TAs expressed.

II. Literature Review

Fuller (1969) identified three concerns that teachers have: concern about self, task, and impact. He considered these concerns linearly in that teachers progressed through them with experience [12]. Choo et al. (2011) built upon these concerns and proposed the following specifically for graduate teaching assistants: class control, external evaluation, task, impact, and role/time/communication. These concerns highlight teachers' worry about being deficient or incapable [13]. However, the impact concern represents a GTA's hopefulness and desire for growth. In terms of professional development, the aim is for teachers to view these other concerns in terms of growth and improvement, rather than deficiency.

These concerns served as a framework for this study. This study aimed to identify the presence and form of these concerns for both graduate and undergraduate teaching assistants in an introductory engineering course sequence. The three categories that emerged from the qualitative piece of the study were training, motivation, and grading. Training is a crucial piece in TAs development and understanding of both their role and their tasks. Motivation, both external and internal, relates to concerns with external evaluation, role, and impact. Grading and feedback relate specifically to the unique task required in teaching these courses.

A. Training

Training is considered crucial for the success of TAs to fulfill their job requirements [7,14-16], especially grading and giving feedback [10]. There have been various forms of surveys that have analyzed different important aspects of training and identified some fundamental knowledge that should be understood about TAs' perspectives on training, its benefits, and its affects. Some of these include their perspectives of the value of various content within training [7], their understandings of pedagogical approaches and how they feel training affected their knowledge [8], and their understanding of their role as TAs to ensure all aspects align with the programs' intended role for the TAs [9].

B. Motivation

Motivation was identified as one of the helpful factors for TAs in helping students and teams [10]. Motivation and its effects have been a subject of many studies (e.g. [17-19]). Both intrinsic and extrinsic motivations have been discussed in different studies as influential factors in choosing to teach. Some of the intrinsic motivation factors are personal satisfaction with career, working with children, and contributions to society. Extrinsic motivational factors include salary, job status, and job security.

C. Grading – Feedback

Effective instructor feedback is vital for student success; it is also acknowledged to be a challenging responsibility [20]. Many studies have identified attributes of effective feedback [20-23]. Feedback should be timely and constructive, and it should scaffold students' learning [21,22]. Feedback given in open-ended problem solving settings should be responsive to students' solutions [23], while not pushing a single "correct answer" [24]. The amount of progress towards a high quality solution that students make in open-ended problem solving settings depends heavily on the feedback they receive from the instructor, which in many courses are the TAs [23].

III. Method

This study has a qualitatively driven design [25]. In the qualitative component of this study, interviews were conducted with TAs to explore their perspective of their TA position. From this data, a quantitative instrument was developed.

A. Setting and Participants

About eight graduate and eighty undergraduate teaching assistants for two sequential first-year engineering courses enrolling about 1700 students were asked to participate in this study in Spring 2013. The two courses are required for all FYE students and each is a 2-credit hour course (with 4 hours of face-to-face class time per week). The UTAs range from sophomores that just completed the FYE courses to second-year seniors completing their fifth year of college. All UTAs are required to take the courses (or the honors sequence) and pass them with a B or better to be a TA in these courses. Prior to administering the survey, the team piloted the survey with a GTA from the FYE Honors Program at Purdue; the GTA gave feedback which led to some minor modifications. Then the survey was distributed. There was a 25% response rate for GTAs (i.e., 2 GTAs responded) and a 54% response rate for UTAs (i.e., 43 UTAs responded).

B. Instrument

The survey instrument was created based on the prior interview findings to further investigate TAs' perceptions of their responsibilities and the factors that help or hinder their abilities to execute their responsibilities; the survey focuses on prior experiences, training, grading/feedback, and motivation. The survey facilitates understanding of a greater number of TAs' perceptions regarding their responsibilities. This survey contains four sections: (1) background information, (2) motivation, (3) training, and (4) grading and feedback. The motivation, training, and grading/feedback sections consist of 6-point Likert scaled items, with a scale of importance that ranges from not at all important to extremely important, a scale of agreement that ranges from strongly disagree to strongly agree, a scale of beliefs that ranges from very untrue of what I believe to very true of what I believe, and a scale of frequency that ranges from never use to always [26].

The background information section focuses on understanding potentially relevant prior knowledge and experiences that the TA may have (e.g., took the course as a student, level of education, field of study, tutoring experience, and other TA positions).

The motivation section aims to understand TAs' intrinsic and extrinsic motivation regarding their TA position. A motivation category was included to identify intrinsic or extrinsic motivational drive for being a teaching assistant. The questions were adapted from Factors Influencing Teaching (FIT) choice questionnaire by Richardson and Watt (2006) [18].

The training section includes questions about the types of training the TAs received and questions about time spent and effectiveness of the various aspects of training they received. The TAs are queried about three types of training (i.e., university level, departmental level, and course-specific level) and three modes of training (i.e. online, face-to-face, and apprenticeship). These modes of training are also further defined by how they are taught (e.g., lecture, discussion, practice grading, and role playing). There are "other" options wherever applicable to allow a TA to indicate any additional training formats.

The interviews revealed that a primary concern for TAs was providing feedback to their students. In this course, the process of providing feedback is critical to the implementation of the open-ended problems. The feedback and grading portion of the survey asks about the types of work the TAs graded and/or gave feedback on (i.e.. close-ended problems and open-ended problems). The TAs are prompted to rate how prepared they feel to do various grading and/or feedback tasks. The last portion of the grading/feedback section focuses on the types of feedback TAs give. They are prompted to rate how often they feel they use various types of affective feedback (i.e., praise, neutral, and negative) and cognitive feedback (e.g., summarize student work, state correct answer, ask thought-provoking questions, and copy content from training materials). The last portion of the survey prompts the TAs to rank their training and prior experiences from most to least helpful in developing their grading and feedback skills.

IV. Future Work

TA interviews [10] were used to inform the development of a survey. The survey has been administered to the participants within the setting described in the method section. Preliminary results will be presented at the time of the conference. After the data from the surveys are quantitatively analyzed, the research team will utilize this data and the qualitative analysis of the interviews to conduct a final mixed methods analysis.

***Abstract*— Myopia on foundations early in undergraduate work is pandemic throughout STEM undergraduate training. This "sink or swim" foundational approach begets attrition and reduced motivation, engagement, and performance for those rugged students who stay in the major. Current approaches to alleviating this myopia, including integrative curricula and extracurricula, provide some context and community, but require great faculty and staff effort, and often requires onerous changes to the base curriculum, while leaving students stranded segueing into the sophomore year. Here we introduce and report on an initial pilot of an online alternative. Our one-credit, pass/fail course, Engineering Virtual Studio (EVS), provides explicit connections between foundational courses and real-world products and problems. The course also fosters both scholarly and pre-professional identity building as constant processes. We report on the course design, work in progress in our pilot year, and opportunity for improvement.**

Keywords—integrative thought; identity; cyberlearning; underclassmen

I. Introduction

Our nation needs engineers that will drive innovation and leadership. Colleges and universities have outstanding undergraduate programs to train these rising engineers. Students receive critical elements of this training, however, only late in their undergraduate education. All engineering programs necessarily begin with foundational study, in mathematics, basic sciences, and underlying engineering principles. Explicit integration over this material and student presentation of ideas happens most often in upper-level or capstone courses. This structure of curricula is sensible given the goal of proper foundation preceding higher difficulty challenges. The big ideas and big challenges, however, are the elements that attract many students to engineering in the first place. Departments of engineering should meet this interest directly, as early in undergraduate education as possible. As programs meet this goal, students become engaged in larger ideas more quickly and become facile in connecting between materials, thinking broadly. With early engagement in big ideas, our students will be more adept at tackling our nation's problems and leading scientific progress.

Currently, however, a vast majority of STEM majors (including our own) are devoted to foundations throughout the first two years. On one hand this foundation is critical to base upper level work; on the other hand a preponderance of the first two years is spent in serial isolation. A typical semester would have each BME student study in courses beside majors in other departments, focusing on material and examples outside their home discipline. Students easily develop disconnect from their primary motivation for the overall enterprise. Disconnect often segues into dispirit, which for many students leads to decreased performance or transfer to another major.

The disincentives built into STEM foundational curricula are entrenched by departments and professors who have built educational programs based on a four-year perspective, not based on retaining students and students' interest as underclassmen. The rigid structure of courses is even more onerous in engineering, within which departments need to deliver engineering foundations, content, and substance as mandated by ABET.

II. Methods – Structure of Online Course

Our Engineering Virtual Studio (EVS) program aims to build support, community, and novel opportunity for our undergraduates (Figure 1). Here is our vision of how undergraduate engineering life will improve with EVS.

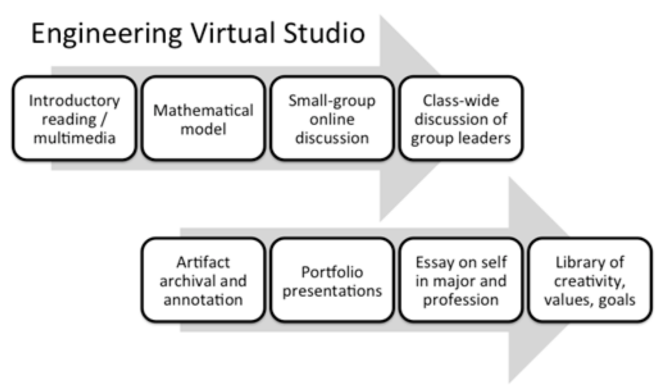

Figure 1
Two streams within EVS: one that introduces and reinforces connection and consideration between foundational material and real-world products and research, and one that fosters investment into scholarly and pre-professional identity.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Underclassman students register for a one-credit, pass/fail course. Students are assigned a discussion group of six peers and an upperclassman who serves as a mentor / moderator. The work required for the one-credit pass is twofold: online discussion among peers, and an essay at the end of the semester reflecting on how the student is building integrative wherewithal and building his/her own focus within the major.

EVS provides one "bulletin" for each course students take outside the major. Each bulletin links a core concept within that course to a real-world, current topic in BME. Each bulletin includes paragraphs introducing the connection between the core concept and real-world products and research; a review paper or multimedia that illustrates that connection; a computational model simulating that connection; and a set of questions to initiate online, integrative discussion. Each group dissects the published material, explores the computational model, and examines the discussion questions. This group work builds a local community of scholars, both pushed and supported to complement their deep foundational study with broader, more integrative consideration.

In our pilot year, we complemented the bulletins on particular foundational material with articles on broader engineering topics and on integrative thought within engineering education. In subsequent years we will continue to build these broader opportunities, including bulletins that explicitly foster creativity and early entrepreneurial mindset.

Students also build their own scholarly and pre-professional identity through EVS. During the semester students store and annotate artifacts that document their interests, talents, and aspirations. Students build portfolios of these artifacts to provide evidence of consideration of self. Content may come from the bulletins and discussion, course readings, online resources, and most importantly from their own product. EVS will therefore serve as a natural home to accumulate a student's own interest, with a backbone of their own readings and writings.

At each semester's end students write an essay reflecting on successes and works-in-progress toward finding their undergraduate and post-graduate goals, with identification of subsequent steps toward concretizing and substantiating those goals with evidence. Within this essay students address how they have integrated and considered material across the semester. Some of this thought may address the bulletins, but the broader goal is a self-evaluation of how the totality of the student's training has built their identities, both scholarly and pre-professional. These essays are kept in a student's library so each student can track their own progress throughout their undergraduate training.

III. THEORETICAL AND PRACTICAL BASIS FOR EVS

Pedagogical literature across academe and particular to engineering has recently recognized the advantage of introducing integration and innovation throughout a curriculum, rather than delaying bigger approaches and questions. In the National Academy of Engineering report "Educating the Engineer of 2020," a central recommendation to schools was that "the essence of engineering – the iterative process of designing, predicting performance, building, and testing – should be taught from the earliest stages of the curriculum, including the first year." These experiences "connect engineering design and solutions to real-world problems so that the social relevance of engineering is apparent(.)"

The next passage, however, recognizes that while these early experiences seem to aid in retention, there is little "rigorous investigation" of "how to evaluate individual student performances" and that presents the real need for investment and study into the impact of these experiences. EVS project will address this exact need, through constant recording and analysis of online student responses. Bulletins in the pilot year offered some room for creativity, but admittedly this was limited to broader discussion rather than explicit design consideration. We will keep the student experience online and virtual, but with subsequent years and the advent of the sophomore version integrate virtual creativity through mathematical models.

An essay by Dr. Gretchen Kalonji in the same volume calls for engineering programs to "boldly reformulate engineering education" to move away from "the tyranny of the assumption that 'courses' are the primary (and in many cases almost the sole) mechanisms for student intellectual development." Dr. Kalonji calls for establishment of formalisms that recognize, reward, and prioritize a broader view of the big questions in engineering, societal impacts of those questions, and each student's personal investment into their role in those questions and impacts. EVS will build content, environment, and community to value exactly these goals. Students will invest in their own learning and their own identities across the curriculum, which will prime each student's passion for their interests and direct application of those interests to society.

One basis for the EVS approach lies in constructivism. According to a recent review by McDaniel and Wooldridge, "Constructivist teaching methods therefore differ from traditional education in that students are expected to take responsibility for their own learning in order to actively create knowledge structures." The structured elements within EVS all support this approach: the examination of core concepts, integrative models, and open-ended questions with peers and a mentor; the reflection on their own skills and worldviews in the semester-ending essay; and the fostering of a community that places explicit value on the development of the person as a thinker, explorer, and inventor ready for real-world engagement, rather than solely as a student. With this "construction," students will be more flexible in applying foundations to different, new, and open questions (von Glasersfeld, 2005; Kuhn, 2007). The rigorous foundations our students learn in their coursework will remain 100% as rigorous and complete. EVS adds a light exoskeleton to these foundations within which students will build their own constructivist wherewithal. We directly and explicitly address observed gaps in integrative learning, reflective learning, and writing in engineers compared with their undergraduate peers (Lichenstein et al 2000).

IV. Report on Initial Pilot

In 2012-13, 120 freshman biomedical engineering majors participated in a pilot of EVS. We built two types of bulletins: general exploration of connections between first-year material and real-world BME, and specific ties between topics in first-year physics and precise problems or products in BME. In subsequent years we will expand the freshman bulletins to tie between foundational math, chemistry, and biology as well. Sophomore EVS will provide ties to biology, math, and foundational engineering, while providing more opportunity for students to research their own specific interests with broader opportunity for creative exploration and simulated design.

Overall participation and quality of writing indicate that the one-credit, pass-fail, online model successfully engaged students and provided connections across the curriculum. Students posted within each discussion at least once over 95% of the time. Each group then needed to post to a course-wide board; these postings occurred 93% of the time without reminder from course staff. We did note, in the two-week window during which students could discuss, the vast majority of activity transpired late into the period.

In responses, students demonstrated deep consideration of the readings and suggested discussion topics. For example, in consideration of replacement tissue and organs, one group summarized:

> "Our group discussed the articles and reached the consensus that although they had great potential, the only plausible technique, given today's technology, was the regrowing of more structural tissues such as windpipes, as opposed to a complex functional part i.e. the heart. Consequently, trying to predict which technology would be the most successful in the long term would be difficult, because the technologies with the greatest potential are in the earliest phases of development.
>
> Next we discussed technology, such as skin sprays, which allows victims of severe burns to quickly regrow their own skin by stimulating the cell tissue in the inflicted area. The healing time could be reduced from several weeks down to a few days. This technology is in place and has proven to be very beneficial. We believe that it has the potential to be extended towards other issues and could potentially be very beneficial in other areas. Although this technology was not specifically addressed in the article, the ability of the skin spray to drastically reduce healing time, makes it a very important technology moving forward…"

Our initial pilot in student self-growth, through artifact annotation, portfolio build, and reflective essay, has also proven effective as a proof-of-principle that freshman can substantively integrate and grow from these investments into identity. Of the 118 essays analyzed from the first semester, 68% showed insights into connections across their curricula, 71% showed the beginnings of a scholarly identity, and 54% displayed some form of pre-professional identity. The 96 essays analyzed in the second semester showed similar results. Of these, 45% showed standard insights into curriculum connections, and 11% showed growth in this area. Standard expressions of scholarly identity were found in 30% of essays, and 23% of essays showed growth in scholarly identity. Finally, 38% of essays exhibited standard expressions of pre-professional identity, and 8% showed growth.

Two passages from student essays exemplify the growth in the areas described:

> "…Classes at first appear to have no rhyme or reason, but as the semester goes on, and we learn more and more with the guest lecturers in BME 140, everything seems to fall into place. All of my classes have fed into the other, from calculus and learning about cross and dot products, to physics and stresses and strains. All which appears to be disorderly has order."

> "Although initially I thought that biology was too difficult and possibly some of the concepts were unnecessary, over time I began to see how the things we learned fit together and how they fit with the things I learned in my previous semester. For example the lectures over cell systems, signal transduction, and repression helped me understand how the drugs would interact in the body and the lectures on sequencing, transcription, and translation helped me understand how the next generation sequencing we learned about in BME 140 truly work..."

V. Conclusion

The quantitative and qualitative data presented here reveal that students engage in both threads, connecting foundational ideas to real-world engineering and building their own identities. Our analysis of the semester-ending essays provides a baseline of evidence for student summative consideration across the semester, but room for improvement. We have, however, shown a proof of concept, that a lightweight, online intervention can provide context and community for engineering underclassmen who otherwise would be predominantly or wholly disconnected from the major during foundational coursework. We aim to further build and improve this concept, toward broad diffusion across US undergraduate engineering education.

Abstract—

A major challenge in engineering design graphics classes has been the development of semester-long projects, which supports curricular goals while maintaining student interest. In this paper, we will describe a project to develop flash drive casings. The project scenario was structured as a request by a client to design a themed set of flash drive casings and a presentation case suitable for use as a gift to outstanding employees and high value clients. Each student rapid prototyped one flash drive casing of his or her own design. The project was implemented as a series of team and individual assignments spread over the semester, with the product of those assignments returned to the instructors in memo format.

This project was implemented in three phases, over several semesters, with the number of students increasing at each stage to ensure that its full scale adoption was successful. The initial test of the curricular elements was made in two, approximately 20 student summer classes. At that time, several challenges were identified. Reflection on this phase revealed a need for additional written documentation containing "project hints" to help students provide designs that meet the rapid prototyper's production constraints. It was also determined that a number of intermediate assignments were needed to motivate students to remain on schedule for project completion.

The project is currently nearing the end of development phase 2 and most design issues have been resolved. However, curriculum changes are warranted in response to student conceptual difficulties. As in many graphics design projects, a major challenge has been the development of three-dimensional spatial skills. Students have had difficulty creating designs containing layered structures, particularly those needed to secure the electronics within the casing. As expected in a first semester, first year course, some students have shown an inability to follow detailed instructions. While this weakness is normally only a grading issue, the flash drive covers are prototyped directly from their CAD files, making type of error particularly problematic. One major success of the project has been student excitement in the project and the improvement of their graphics skills from re-creation of existing designs to the development of novel designs.

Keywords—Graphics Project Development; Flash Drive

I. Introduction

The Engineering Design Graphics Program's Industrial Advisory Board recently recommended modification of current curriculum to emphasize original design and the introduction of "real world" issues, such as budgeting and non-graphics-based communications. In addition, the program purchased a state-of-the-art rapid prototyper with improved output quality and increased production rate.

These recommendations were implemented through a major revision of the course project. The authors chose to apply the "independent project method" described by Lee [1]. As noted by Bell et al. [2], a well-designed scenario has the potential to: (1) "provide opportunities for students to integrate the learning outcomes from the lecture and laboratory-based teaching sessions," (2) "enhance generic skills such as teamwork, problem solving and communication," and (3) "extend their knowledge using some of the principles of PBL." Further, their results "demonstrate the value of a hybrid approach to an engineering curriculum, which embeds elements of problem- and project-based learning alongside traditional lecture and laboratory teaching." [2].

The availability of rapid prototypers allows an engineer (or engineering student) to move through the entire design process from idea to part creation [3]. Additionally, the prototypers assess no penalty for the creation of a wide variety of complex objects with a high degree of manufacturing precision [4], and are emerging as an industrial process [5-7]. This capacity makes it an effective adjunct to computer aided design by allowing students to realize their designs. Until recently, the cost of rapid prototypers has been prohibitively expensive, but they have decreased in cost over the last few years, with low-end model prices ranging from $400 to $4,400 [8].

II. Project Development

A. Student Population Description.

Students in this course were drawn from a variety of disciplines, ranging from engineering transfer students to industrial distribution majors. General studies students also enroll in this course, as they attempt to enter engineering after failing to meet the College of Engineering's entrance requirements. The majority of students were in their first year of college and therefore had minimal ability to perform the analysis required by an intensive design project.

B. Project Development Phases

The ultimate goal of this revision was to introduce a project suitable for introduction into the graphics component of the Freshman Engineering Program and into the first year engineering design graphics course. The combined course sections serve several thousand students per year, in sections approaching 100 students. On this scale, even minor issues in the modified curriculum had the potential to cause significant disruption in the course. Therefore, the authors chose to introduce curriculum modifications in three phases, with revisions occurring at the end of each phase. The phases and their scheduled semesters were:

Phase 1: The creation and testing of the design project and the development of a project manual – summer sessions I and II of 2012

Phase 2: Intermediate scale-up of curriculum to increasing numbers of student and revision of the project manual – Fall Semester 2012 and Spring Semester 2013

Phase 3: Full scale introduction of the project into courses – Fall Semester 2013

C. *Additional Curricular Goals*

As previously noted, the project was used as a vehicle to introduce non-CAD curricular content to the students. The authors chose to insert the following goals into the course: (1) the introduction of an engineering design paradigm, with an emphasis on satisfying design constraints, (2) increasing the variety of communication methods applied by the students, (3) the basic elements of project planning, particularly the use of Gantt and PERT (Project Evaluation and Review Technique) charts, and (4) the development of basic budgets.

D. *Course Project Description*

The project required students to design a series of custom flash drive casings and a presentation case. The students were required to identify a common theme for the presentation set. The theme (e.g. biomimetics of ocean creatures, important engineering structures, or military weapons engineering) tying the drives together needed to be suitable for use a gift from an engineering consulting firm. The exact areas of expertise of the firm were left undefined to allow the students maximum flexibility in their choice of theme. Examples of student designs are shown at right in Figures 1 and 2.

E. *Course Assignments*

As the project was developed, an effort was made to create a project structure that could be reused in future semesters (1) a sequence of design memos, (2) a final design portfolio, (3) a project presentation, and (4) rapid prototyping each student's design.with minimal adaptation. Thus, an effort was made to isolate the item designed, so that other items could easily be inserted/exchanged. The authors chose to implement these goals through the following major project assignments:

The first two assignments for the project were designed to move the students through an iterative design process, with the last two assignments capping the project. Throughout the semester, a number of smaller homework assignments were given to keep the students on track for the major project completion.

E. *Course Assignment Schedule*

The following timeline was followed during the semester:

Week 1: Project Assignment and Design Brainstorming Exercise – The project was assigned in the form of a memo to the project teams. The brainstorming exercise required pairs of students to generate 50 ideas for flash drive casings in 10 minutes. The rapid pace of idea generation was deliberately chosen to reduce the level of intragroup criticism.

Week 2: Project Teams Assigned – The project was assigned to teams of 4 members. Team membership was chosen by the instructor. Additional descriptive information regarding project was provided to the student teams and they were asked to begin researching possible designs for their drive casings.

Week 3: Full Project Manual Handed Out – The project structure was provided to the students and a detailed description of the project's deliverables was supplied.

Week 4: Concept Memo and Associated Sketches Due – The memo required each group member to submit sketches of potential flash drive casing designs and themes for consideration. The memos were returned with critique of the sketches and comments on potential problems with specific designs.

Week 6: Flash Drive Electronics CAD Drawing Due, Detailed Discussion of the Project Portfolio, and a Project Planning Lecture and Assignment – The students were assigned the creation of a dimensioned CAD drawing, based on measurements of the flash drive electronics performed by the students using a digital micrometer. The lecture described project planning processes. Students were required to generate PERT and Gantt charts for the project using the software package *GanttProject* [9] and to assign responsibilities for the project.

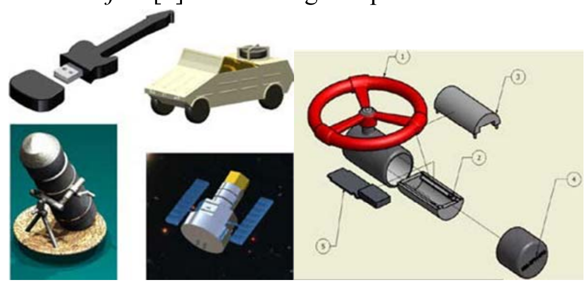

Figure. 1. Examples of designs for flash drive casings.

Figure. 2. Example flash drive cases printed on an Objet rapid prototyper (left and middle). Example set of flash drives and a case based on the space program (right). The case was designed to mimic a segment of the international space station.

Week 8: Final Design Choice Memo Due – This memo contained the final flash drive design and a theme that bound the flash drives into a cohesive set. The students were required to attach updated isometric drawings of the flash drives.

Week 11: Parametric Model of Flash Drive Electronics

Due – These models were used in flash drive assembly drawings and provided a mechanism to allow students to examine issues such as part fits and physical assembly problems.

Week 12: Files for Each Individual's Flash Drive Casing Design for Rapid Prototyping Due – CAD files used by the rapid prototyper were reviewed prior to printing. Subject to available printer time, the rejected designs could be revised and resubmitted for printing.

Week 13: Working Drawings of Individual's Proto- typed Flash Drive Casing Due – This assignment was aimed at keeping students progressing towards project completion.

Week 15: Project Portfolios Due and Presentations Given – The project presentations were structured to resemble intra-company sales pitches with the projects "competing" for the right to be produced.

F. Phase Assessments

1) Phase 1:

We introduced the curriculum into two small classes with less than 20 students in each section. The smaller classes allowed intensive instructor/student interaction as challenges in the curriculum schedule and project developed. The issues that arose during this phase were (1) a need for additional documentation to clarify the assignments, (2) The need for tolerance values for the *Objet* rapid prototyper, and (3) the need for design recommendations for use with the rapid prototyper.

2) Phase 2:

In phase 2, we scaled the project up to 5 class sections of 50 to 55 students each and entailed printing of over 1,400 separate parts. At the end of the semester, meetings were held students and with the design laboratory manager. The discussions with the students yielded only minor recommendations including rescheduling some of the assignments and earlier creation of the STL files used by the rapid prototyper. Discussions with the design laboratory manager indicated that the parts were printed over a 4 week period at the end of the semester, with the rapid prototyper operating continually during that period. This level of output requires consideration of several factors, including:

Material Cost: The most obvious factor was the cost of the material (~$300/kg). A decision was made to limit each student to 30,000 mm (~31g) of printed material, based on available funds from course fees.

Design Laboratory Time: Time required for printing using a rapid prototyper falls into two categories; student technician time and printing time. Technician time typically occurred during the setup of the print jobs and post-printing part cleaning. Depending on the equipment used, these times can vary greatly. In addition, the printing load end of each semester, occasionally resulted in mechanical problems with the prototypers.

Printing Time: Rapid prototypes require only minimal oversight during the printing process, permitting overnight and weekend print jobs, and making it most efficient to print large numbers of parts in each manufacturing run. Most rapid prototypers have constrained print volumes. However, because the flash drive casings are small; the constraining factor is their cross-sectional area, since this limits the number of parts that can be printed in any batch. Therefore, the authors have added a maximum cross-sectional area restriction to the project's design constraints.

Submission Management: Each student was allowed to print one flash drive casing. A file and parts management scheme was required in order to ensure that printed parts were credited and returned to the individual. The expansion to the larger number of students quickly revealed that the system needed to be revised to provide additional information on the submitted parts and in the submission file names. As a consequence, students were required to emboss their team number and name to more easily facilitate return of student casings.

A post semester review halfway through phase 2 indicated that students were experiencing problems with the design process, rather than the project itself. Therefore, materials were added to support the students' design skills. The materials included: addition of a design paradigm to the course materials [11, 12] and addition of material to help students build teaming skills and to understand the issues that occur during team formation based on Tuckman's stages of group development [10].

III. Conclusions

The authors' experience in this curriculum revision has confirmed the benefits of a multi-stage review process. This development, currently in the second "scale-up" phase of the planned curriculum improvement, has benefitted from the re- vision cycle. We are nearing the end of the second semester of phase two and now have reasonable confidence in the project's ability to survive contact with the larger number of students. In addition, the program's faculty has adopted the project for other engineering classes and the authors are working to adapt the project to those needs.

Enhanced STEM Learning with Online Labs:

Empirical study comparing physical labs, tablets and desktops

Prema Nedungadi, Raghu Raman, Mark McGregor
CREATE @ Amrita, Amrita University, India

***Abstract*- India's educational challenge includes a large school going population, shortage of science teachers and lack of science labs in many schools. To counter this challenge, the Online Labs (OLabs) pedagogy is designed as a complete learning environment with tutorials, theory, procedure, animations, videos and simulations while the assessment includes conceptual, experimental, procedural and reporting skills.**

We discuss two separate empirical studies using OLabs to study the performance gains, student attitudes and preferences while using physical labs, desktops and tablets. The first study was at a school that compared students who learnt individually with OLabs on desktops, to students who learnt with the traditional teacher led physical labs. The second study was at a science camp and compared OLabs on desktops to OLabs that were context adapted for android tablets. There were significant differences between the physical labs and the self study mode using OLabs on desktops, but no significant differences between OLabs on desktops compared to OLabs on tablets.

Keywords—Olabs; traditional labs; animation; simulation; online labs; virtual labs; elearning; cognitive learning; conceptual skills; experimental skills; procedural skills; reporting skills; assessment

I. INTRODUCTION

The National Focus Group on "Teaching of Science" suggests prevention of marginalization of experiments in the school science curriculum. In this regard, investment is required for improving school labs to promote an experimental culture. Majority of the schools in developing countries, lack both minimum infrastructure and trained teachers. Often assessment of practical skills for a large class size is difficult and may comprise of well written assignments or objective assessments alone.

OLabs science simulations are based on sophisticated mathematical models that offer a complete learning environment of science practical labs with interactive tutorial animations, video demonstrations and assessments. OLabs was recommended by the Central Board of Secondary Education (CBSE) as a teaching and learning aid to the 15000 schools that follow the CBSE curriculum.

We discuss two separate empirical studies using OLabs to study its effectiveness, performance gains and student attitudes and preferences using different modalities and compare it to traditional labs. The first study was at a school that compared students who learnt individually using OLabs to perform the experiments on the computer lab, to students we did the experiments at the teacher led traditional labs.

The second study was at a science camp and compared students learning with OLabs on desktop computers v.s. OLabs that were context adapted for low cost android tablets. There were significant differences in learning and performance between the teacher led traditional labs and the self study mode using OLabs on desktops, but no significant differences between OLabs on desktop computers compared to OLabs on tablets.

II. SIMULATION FOR PRACTICAL SCIENCE EXPERIMENTS - A SURVEY

Many educators suggest that computer simulations offer considerable potential for the enhancement of the teaching of science concepts. Simulations enable students to have direct control by modifying variables and being able to visualize the effects of their changes [1]. While both traditional laboratory activities and simulation are forms of inquiry which engage the learner in the process of observing, hypothesizing, experimenting and forming conclusions, computer-simulated experiments, as inquiry tools, are considered by some authors to be superior to conventional laboratories [2]. A model-based learning using simulations within a complete learning environment instead of stand-alone simulations was discussed in [3] Some authors have proposed a framework for combining traditional and virtual labs based on specific learning outcomes such as cognitive, affective and psychomotor related objectives and concluded that student's conceptual understanding was enhanced by the combined learning approach [4], [5].

As students can immediately see the output to simulations based on the input they provide, they can make connections between the hypothesis and the results [2]. A framework for learning-enabled online assessment of practical skills, which gives due consideration to both the structure of the practical assignments and immediate feedback promotes learning[6]. Simulations teach both real and theoretical behavior to the learner [7]. Reference [8] through their interactive science simulations allowed students to explore science topics and concluded that with minimal explicit guidance students were able to perform in ways similar to how scientists explore phenomena. Immediate responses may encourage students to examine various system states without fear of making mistakes or being criticized. Control of variables enable students to assess the effect of each individual variable as well as their combined effects, promoting clearer understanding of this key aspect of inquiry work. OLabs provides a flexible simulation environment, which maps to the school curriculum while allowing additional variables that can be controlled by the student to enable a richer learning experience.

Simulations engage the learner, provide visualization and show the effects and consequences [9]. Some studies suggests that simulations used in science education can be classified along four dimensions: the amount of user control, the extent and nature of the guiding framework of how information is represented, and the nature of what is being modeled [10]. OLabs consists of rich interactive simulations based on accurate mathematical models, tutorial animations and video demonstrations, feedback and scaffolds, and the assessment of various skills. Simulations offers a learner direct experience of a system, even though it is simulated [11].

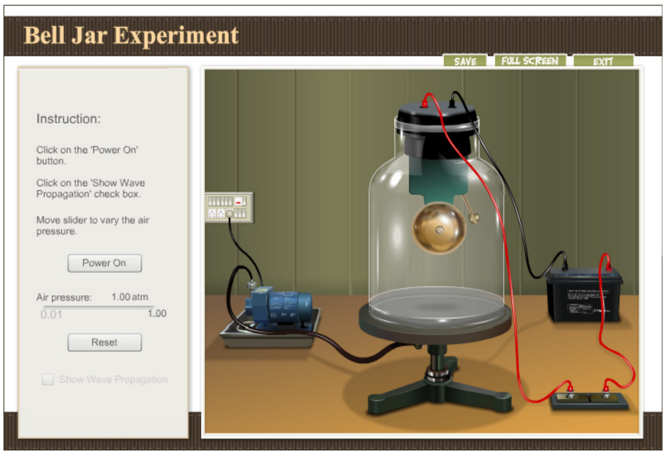

Fig. 1. Simulation of the Bell Jar experiment.

The OLabs simulation labs allow a student to experiment with dimensions that are impractical or impossible in a lab, e.g. performing experiments in a zero gravity environment. It eliminates time-consuming setup and allows learning of experiments that require equipment that is too expensive to purchase. The complete set of supporting materials such as the theory, lecture notes, animation and video tutorials are in an organized form as related to the experiments being performed and has supplementary reading on the related material. The simulations and assessments have automated feedback and scaffolds to aid in better learning outcomes. Assessment of lab skills includes conceptual knowledge, procedural and manipulative skills, understanding the experiment and the equipment including manipulating them and reporting and interpreting skills.

III. THE OLABS DIFFERENCE - MULTI-PRONGED LEARNING ENVIRONMENT AND ASSESSMENT

There is universal acceptance of the importance of performing experiments in the school physical lab to enhance students' conceptual understanding in science. When there is limited time to access physical science labs, the learning cycle is limited as learners cannot try out different scenarios [12]. In addition, a formal assessment of science lab skills is lacking, with most schools employing the traditional theory based or multiple choice questions (MCQs) to evaluate students.

Simulations are not a total learning package but provide only a part of the learning experience but must be integrated into a curriculum, which provides support for the simulation and in which the simulation supports other learning activities [13]. OLabs is built not just as stand-alone simulations but as a complete learning environment with supporting theory, animations, videos tutorials, interactive simulations, assessments and reference material.

Simulation based labs for science experiments have been an increasingly growing trend to alleviate this problem but they provide only a part of the lab experience. What is needed is an integrated approach for assessment-for-learning of simulation based lab skills. Such an approach will have the following four quadrants –a) simulation based labs (Fig. 1) b) feedback and scaffolding c) assessment of lab skills (Fig. 2) d) animations (Fig. 3) and video tutorials in an organized form as it relates to the experiments being performed and supplementary reading on the related material.

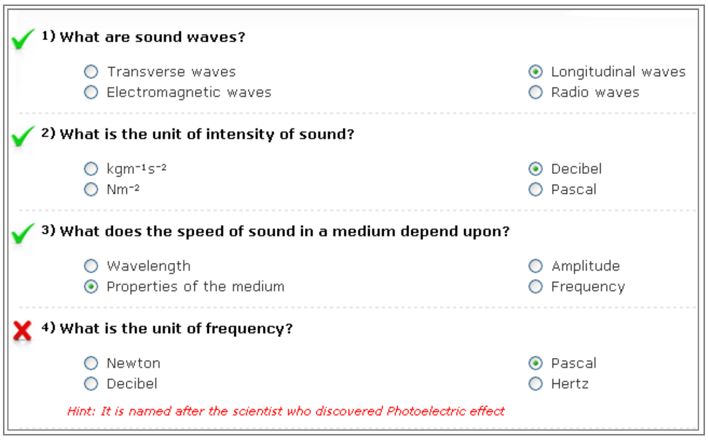

Fig. 2. Assessment – Mutliple Choice Type.

Assessment of practical skills in science in an objective manner is a difficult task with the difficulty increasing manifold if the assessment is to be carried out when a class size is large. The Central Board of Secondary Education (CBSE), India mandates that conceptual skills, procedural skills, experimental skills and reporting skills are improved and assessed as part of science labs and hence our study incorporates all four skills.

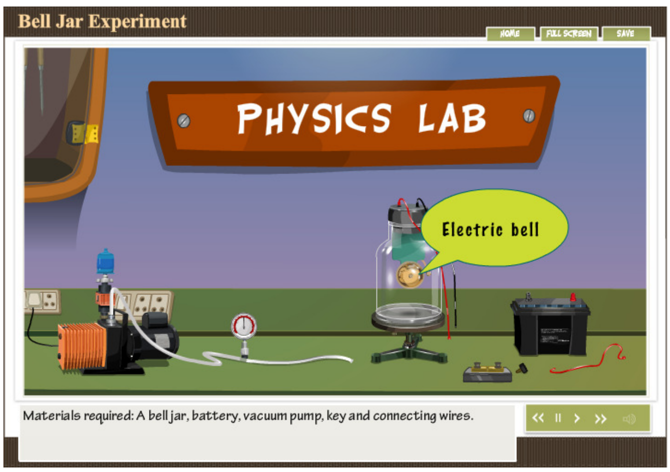

Fig. 3. Animation of the Bell Jar experiment.

IV. Collaborative Accessibility Platform for Practical Skills

OLabs are hosted on a distributed Collaborative Assessment Platform for Practical Skills (CAPPS) [14]. CAPPS reduces the cost of deployment of labs by scheduling and allowing secure access of online labs. In addition to this, CAPPS has a collaborative authoring module to create new labs and a built-in learning management system. The iLabs developed at the Massachusetts Institute of Technology [15] that provides this kind of architecture for developing and deploying labs built by multiple institutions. CAAPS provides a single user interface to labs developed by multiple institutions, thus allowing the student to access any available lab that are built by different authors and geographically distributed at different institutions.

V. Research Study

A. Research Questions

1. How do traditional lab learning with teacher instruction and OLabs without teacher intervention but tutorial e-learning material compare when evaluated by the four types of assessments such as conceptual, procedural, reporting and experimental skills?
2. On evaluating the four assessment types, are OLabs with content and context adapted for tablets comparable to OLabs on desktops?

B. Participants and Materials

There were two separate studies conducted using OLabs. The first study comparing traditional labs with OLabs at the computer lab was conducted in a school in Kerala, India in with (n=59) eleventh grade students. The second study comparing OLabs on tablets with OLabs on desktop was done during the DST Inspire Science Camp in May 2012 with (n=62) eleventh grade students.

Android tablets and Desktops were connected to the OLabs server. Traditional Labs had the physical equipment to perform the experiments.

C. Measures

A 5 point Likert-scaled questionnaire to gauge student perceptions of the ease-of-use and preferences for OLabs and for device types was conducted after the post-assessment.

The CAPPS tracks every input of the student, including the current state of the experiment, variables changed by the student, pages visited and time spent on each page, thus providing a complete history of all student activity. The number of questions attempted and the answer choices selected are logged. These have been used in the analysis.

D. Case 1 Traditional Labs v.s. OLabs

The students were randomly divided into two groups using the cluster sampling method of numbers for the experimental groups, one using OLabs and the other control group using the traditional labs. The students were given a brief introduction about the study and then given the pre lab assessment to check their knowledge level of the given experiment at that stage. In the computer lab: they were instructed to go through the theory first, followed by the procedure, tutorial video/animation, the simulation and then the viva questions. The traditional lab was conducted exactly as it is typically done in the school, with a subject matter expert from our team explained and demonstrated how to perform the complete experiment after which the students performed the experiment.

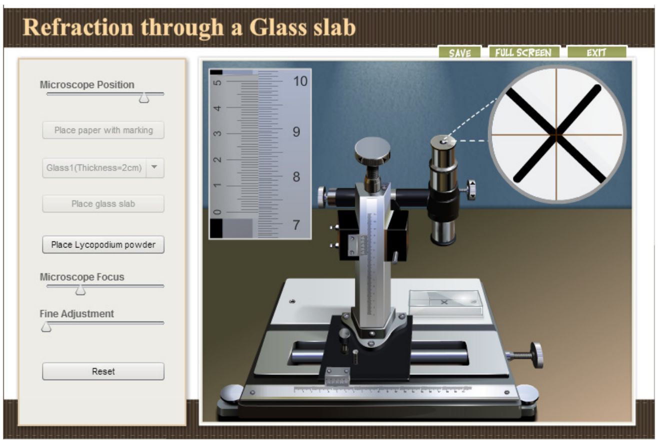

Fig. 4. Simulation of experiment 'Refractive Index of a Glass Slab'.

The students from both the groups performed the experiments and then completed the lab records using the template provided. Then the students were given the post lab questionnaire. Finally they answered a post lab survey. The experiment selected for this study was, "Refractive Index of a Glass Slab" and the objective of the lab is to determine the refractive index of a glass slab (Fig. 4).

E. Case 2 OLabs on Desktops v.s.Tablets

The experiment selected for this study was the 'Verification of Archimedes' Principle' (Fig. 5) and the objective of the lab is to establish the relationship between the loss in weight of a solid and weight of water displaced when the solid is fully immersed in various solutions.

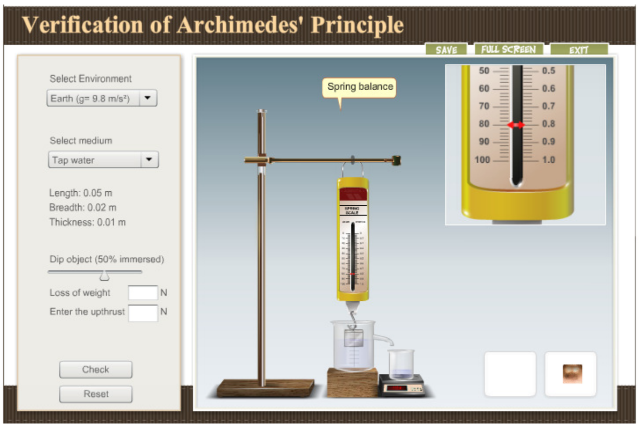

Fig. 5. Simulation of experiment 'Verification of Archimedes Principle'.

Students were randomly divided into two groups for the tablet and the desktop studies and were assessed using the same pre-test and post-test. They were asked to go through the learning materials such as the theory, procedure, video, animation tutorials and then perform the experiment after which they needed to answer a Likert scale questionnaire. The learning material was similar for the tablets and desktop though it was context and content adapted for tablets.

VI. Discussion

This study suggests that an integrated OLabs environment which included learning tutorials relevant to the simulation has the potential to increase STEM learning. When compared to traditional labs with teacher demonstration, OLabs had an advantage in conceptual skills, while traditional labs had an advantage in procedural and reporting skills.

OLabs was equally effective on both desktop computers and on android tablets though the context and content of OLabs was adapted to fit the smaller screen sized lower powered android tablets.

A. Case 1 Traditional Labs v.s. OLabs

In both groups, the performance improvement between the pre-test and post-test scores could be significantly noticed using paired t-test. After adjusting for pre-test scores, there were significant effects of the two between-subjects-factors: Instruction type, F (1, 48) = 4.51, $p < .05$, partial $\eta^2 = .086$; and Gender, F (1, 48) = 14.87, $p < .005$, partial $\eta^2 = .237$. Adjusted mean post-test scores suggest an advantage to traditional laboratory instruction (M=13.28, SE=0.34) over OLabs, (M=12.4, SE=0.33); as well as an advantage to Males (M=13.76, SE=0.31) over Females (M=11.91, SE=0.37). The interaction between instruction type and gender were insignificant.

Fig. 6. Mean Improvement in Score (posttest-pretest) based on type of Lab and on Gender.

As all the students in the OLabs group worked with the simulation, the advantage seen in OLabs group over Traditional Labs in conceptual skills may be a direct result of performing the simulation.

Interestingly, analysis based on the four assessment types suggest an advantage to Traditional Laboratory for the Procedural and Reporting skills (p<.05), with no significant difference seen in Experimental skills (p >.05), and an advantage to OLabs in the Conceptual skills (p <.05).

A possible reason for the lower performance in the procedural skills of the OLabs group may be that the traditional group had the advantage of instruction and demonstration by the subject expert. Though the OLabs group was instructed to watch the tutorial video and animation, we noticed that many of the students skipped this and went on directly to perform the online simulations.

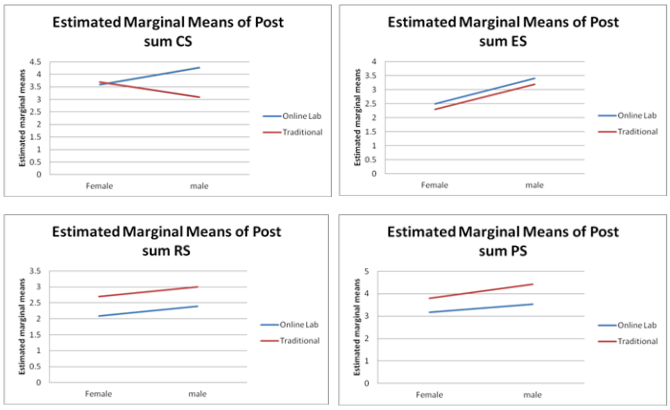

Fig. 7. Estimated Marginal Means of Post Sum Conceptual Skills (CS) Experimental Skills (ES), Reporting Skills (RS) and Procedurral Skills (PS).

As all the students in the OLabs group worked with the simulation, the advantage seen in OLabs group over Traditional Labs in better conceptual skills could be a direct result of the learning environment integrated with the simulation.

TABLE I. Summary table for each category based on Instruction Type and Gender

Skill Type	Instruction Type Traditional v.s. Online Labs	Gender
PS	T>O	M>F
CS	T<O	M=F
ES	=	M>F
RS	T>O	M=F

There also seem to be an advantage to males over females in the overall performance for PS and ES skills.

Most studies of simulations have focused on conceptual under-standing, providing promising evidence that simulations can advance this science learning goal. We have included four types of assessments required by the Central Board of Secondary Education, India and a complete learning environment that attempts to replicate teacher instruction.

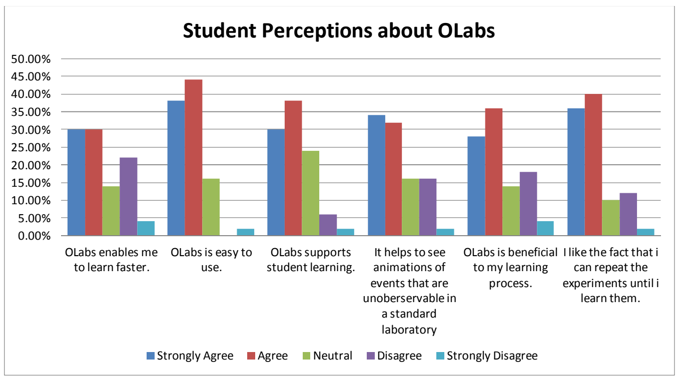

Fig. 8. Student Perceptions about OLabs.

It would be interesting to replicate this study so that students are mandated to go through the theory sections, the tutorial videos and animations before attempting the simulation.

B. Case 2 OLabs on Desktops v.s.Tablets

As the research study was held as a competition at a Science camp held at Amrita University and the students were motivated to perform well. Unlike in CASE 1, which was a mixed ability class from one school, the students selected to attend the camp were all high performers from different schools.

The students were randomly divided into two groups. Both groups were given the same instruction and performed the same experiment, the only difference being that the group with the tablets had content that was context and content adapted for the smaller screen.

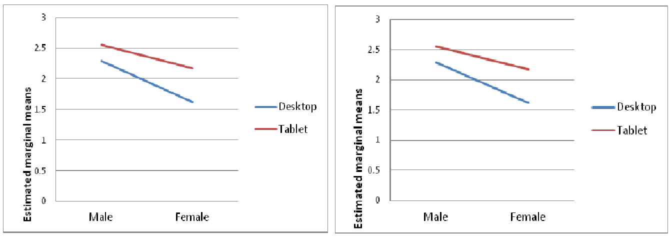

Fig. 9. Estimated Marginal Means of Post Sum Reporting Skills(RS) and Experimental Skills (ES).

A paired t-test showed that the total mean post_test (11.1167) score for both is significantly higher than mean pre_test(9.2333) score. The mean post_test (11.4) score is significantly higher than the mean pre_test(9.5) score for device tablet and the mean post_test (10.8333) score is significantly higher than the mean pre_test(8.966) score for device desktop ($p < .05$ in both cases). Hence both groups improved their performance after using OLabs.

For this OLabs experiment, there seems to be an advantage to males over females in the overall performance for ES and RS skills ($p < .05$ in both cases).

TABLE II. SUMMARY TABLE FOR EACH CATEGORY BASED ON INSTRUCTION DEVICE AND GENDER

Skill Type	Instruction Type (desktop or tablet)	Gender
PS	=	=
CS	=	=
ES	=	M>F
RS	=	M>F

However, there is no difference in test scores between Desktop and Tablet in post_test ($p > .05$) showing that in spite of context and content adaptation for the smaller screen size and the capacity of the android tablets, the learning outcomes are similar.

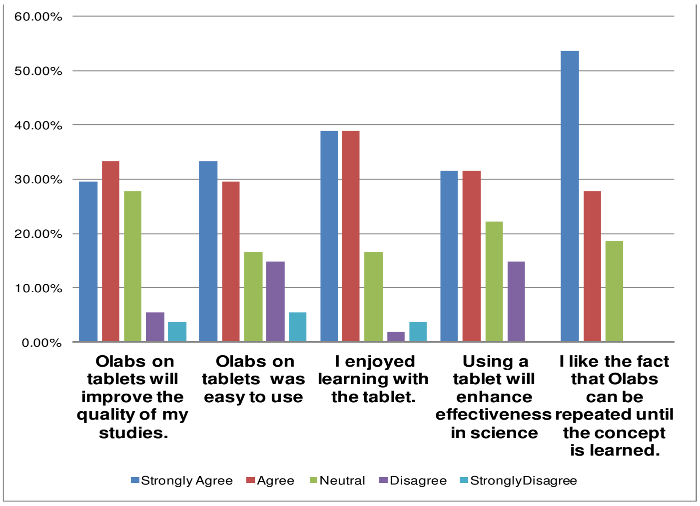

Fig. 10. Student Perceptions about OLabs on tablets.

VII. CONCLUSION AND NEXT STEPS

Science learning is a complex process and simulations built with supporting learning material have the potential to advance multiple science learning goals, including motivation to learn science, conceptual skills, procedural skills, experimental skills and reporting skills.

This study comparing pre and post test scores showed that that the integrated OLabs environment significantly increased STEM learning using both desktop and mobile devices in all skills.

When compared to traditional labs, students using OLabs had a significant performance improvement in conceptual skills than in traditional labs. While the simulation itself was developed to be similar to the traditional lab, OLabs had an integrated learning environment that includes video demonstration, animation, references and the conceptual theory behind the experiment was more useful than just performing the experiment after a tutor lead demonstration. OLabs could be repeated many times and 81.4% of the students liked the fact that they could repeat the experiments until they learnt the concept.

Overall the traditional lab students performed better in the reporting and experimental skills and a possible explanation could be that the traditional group had the advantage of a demonstration of the entire procedure of the experiment by the subject expert before performing the traditional lab. This was to done to maintain the current traditional labs in India, where the teacher demonstrated the experiment before the students attempt to work on it.

OLabs was equally effective using either desktop computers or android tablets even though OLabs was context and content adapted to fit the smaller screen size and lower processing power of the android tablets.

The assessment in the school showed an advantage over males to females in science practical skills for procedural and experimental skills whereas the assessment at the Inspire Science Camp showed an advantage to males over females for experimental and reporting skills. An interesting area of study in the future would be to understand the cause of the lower performance in girl students and perhaps find ways to modify OLabs and traditional labs to overcome the gender differences in STEM learning.

VIII. ACKNOWLEDGEMENT

This work derives direction and inspiration from the Chancellor of Amrita University, Sri Mata Amritanandamayi Devi. OLabs is developed by Amrita University and CDAC. OLabs supported by the Department of Electronics and Technology (DeitY), Government of India. The Collaborative Accessibility Platform for Practical Skills (CAPPS) project was partly supported by the HP Catalyst Leadership Award. We also thank the faculty at Amrita University for their valuable feedback.

***Abstract*— We have developed and implemented a comprehensive, three-year professional development program for in-service secondary teachers to prepare them to teach engineering design and problem solving, and to use design-based teaching approaches in their science curriculum. The program used a constructionist, immersion pedagogy and a three-phase learning cycle. The program consisted of intensive summer workshops followed by monthly one-day workshops, school visits, and support activities during the academic year. This paper describes the program philosophy and activities, and presents outcome results using both qualitative and quantitative data. Pre- and post-test results indicate the workshop pedagogy and program structure were successful in meeting the goals and desired outcomes of the program.**

Keywords*— *Teacher Professional Development, Teacher Training, Engineering Design

I. INTRODUCTION

According to the National Academy of Engineering and the National Research Council (NAE–NRC) Report, *Engineering in K-12 Education*, introducing engineering concepts into K–12 education has the potential to increase student engagement, improve learning in science and mathematics, increase technological literacy, provide a better understanding of what engineers do, and increase the number of students who pursue STEM careers [1]. However, the Report also notes that there is limited data to support these claims, in part because there are still few programs to study, and in part because of the variety of program types and their emphasis on different outcomes.

School administrators considering adding engineering to the curriculum face three questions: What engineering material or concepts should be included; what is the most effective way of introducing this material into the school curriculum; and who is qualified to teach them? Our program, the Rice Engineering Design Experience (REDE), like most others, bases its content on the NAE–NRC Report principles that K–12 engineering education should emphasize "the design process, the engineering approach to identifying and solving problems," along with engineering habits of mind including systems thinking, creativity, collaboration, communication, and attention to social and ethical considerations in choosing technological solutions. Many believe these are the essence of technological literacy and essential skills for citizens in the 21st century [2]. Focusing on engineering design, problem solving, and habits of mind represents a useful pedagogical strategy in the absence of national learning standards for K–12 engineering.

The REDE program began in 2009 with a two-year grant from the Texas Teacher Quality Grant Program* for professional development of high school science teachers. This focus was motivated by the recent addition of a Texas high school graduation requirement for a fourth year of science (and mathematics). One of the handful of fourth year science courses approved was a new course on Engineering Design and Problem Solving, which had explicit learning standards. Few teachers were prepared to approach such a course. We proposed an experimental, prototype training program based on techniques we had used to introduce university undergraduates, both aspiring engineers and other majors, to the same subjects.

During the course of our program, Texas modified the fourth-year science requirement and added additional courses. It became clear that almost no Houston, Texas high schools were going to offer the Engineering Design course, and we changed our focus from preparing teachers for that specific course to giving them the skills to **infuse** team-based design projects and engineering-oriented material into existing core science classes. Our hope was that this approach could achieve the potential benefits of incorporating engineering in secondary school with the advantage of reaching every child.

During the second year of our program the granting agency awarded us a third year of funding and allowed us to enroll some middle school teachers. This program was never structured or viewed as a research program, but we did use a mixed-method evaluation to give us an indication of how well we met our general goals. This paper describes the program and results over its 2009-2012 period.

II. THE RICE ENGINEERING DESIGN EXPERIENCE

The specific objectives of the REDE program can be grouped into three general goals:

- Give teachers the content and implementation skills to develop and integrate project-based learning lessons, open-ended activities, and design challenges into science courses to enhance student motivation and learning.

* This work was supported by the Texas Higher Education Coordinating Board through the Teacher Quality Grants Program, with additional support from the Rice University George R. Brown School of Engineering.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

- Provide teachers with the experience, knowledge, and skills necessary to guide student teams through engineering design problems that integrate science and mathematics concepts aligned with state standards.
- Familiarize teachers with engineering professional practice, the content of the different engineering areas, and the nature of various engineering degrees and their requirements, so that they can advise students.

It is a rare secondary school teacher that has such a knowledge and skill set, necessitating a comprehensive professional development (PD) program. In addition to the training, the program provided teachers with instructional materials, online resources, and continuing support to implement effective teaching strategies and to develop a community of practice.

A. Tne Professional Development Challenge

Designing a PD program to meet the goals above is a challenge. Most teacher PD programs focus on improving or updating knowledge and skills in an area that teachers have already studied. Unlike for core subjects, there are no teacher credentialing standards for engineering, virtually no pre-service training programs [3], and in-service PD is rare and variable in content [4]. It is not surprising that there is a wide variation in what takes place in classrooms in the name of engineering education. For our program we could not assume any prior knowledge of engineering on the part of participants.

We believe that only a deep understanding of engineering design and problem solving by teachers can lead to transformational change in the classroom and the benefits claimed for incorporating engineering in secondary school. Open-ended design problems have multiple "correct" solutions that represent different choices of how to meet the design goals within the problem constraints; guiding students through them and assessing the results from student teams requires a new set of skills for science teachers. The only way to understand and learn to apply the design process is to do it. Like learning to swim, one can read books, listen to lectures, and watch demonstrations, but eventually, one has to jump into the pool and actively struggle to master the skill. And as Kolb notes, "It is difficult, if not impossible, to teach in ways that one has not learned" [5].

The REDE program began in 2009 as a two-year program with a single cohort of participants taking part in extended summer workshops and academic year meetings, with over 100 contact hours per year. Ten high school teachers enrolled in 2009; two more, plus one middle school teacher joined the next year in 2010. Later the program was extended for a third year; Five teachers joined in 2011, all but one middle school teachers. Thus, the program enrolled a total of 18 teachers, although during the course of the program a few participants became inactive because they left teaching or changed subjects. In addition to an immersion in engineering design, the program incorporated characteristics that have proven to promote teacher learning [6]: a focus on engineering content and a pedagogy that builds on the teachers' existing subject skills; a well-defined image of effective classroom learning and teaching; in-depth, active learning experiences; opportunities for reflection and collaboration that engage teachers as adult learners, and an extended duration of formal training followed by ongoing support and continuing education.

B. Program Activities

Each year of the REDE program consisted of an extensive summer workshop, 5–10 full-time days, plus academic year meetings for about one full day per month. The initial 2009 summer workshop provided a ten-day immersion in the design process for the beginning participants. Teams of teachers were asked to design, build, and demonstrate a prosthetic hand using rapid-prototyping materials (LEGOS NXT systems). The workshop led the teams through the ten steps of the design process using an innovative three-phase learning cycle, illustrated in Fig. 1.

First, Building the Knowledge Base, (BKB) developed *content knowledge* through reading, lectures, and activities. For example, for design Step 5: Develop Multiple Concepts and Solutions, the BKB material covered brainstorming, conceptual blocks to innovative solutions, and how to break those blocks. During the second phase, the Challenge, the teacher-teams implemented that content knowledge to devise multiple solutions for their design problem. During their active experimental work they were supported and mentored by course staff and instructors to build confidence, keep forward momentum, and insure success. In this stage teachers developed their experiential, *intrinsic knowledge* of design.

The third phase was Advancing Classroom Technique (ACT). Teachers came together to reflect on and share their experiences in working on the project. Guided by master teachers and the instructors, they discussed how to implement this step of the design process in their classroom, how to integrate design into the STEM subjects they teach, how to guide students through it, and how to deal with anticipated problems. This stage provided *pedagogy skills* and knowledge. The class then moved on to the next step in the design process, repeating the BKB, Challenge, and ACT cycle.

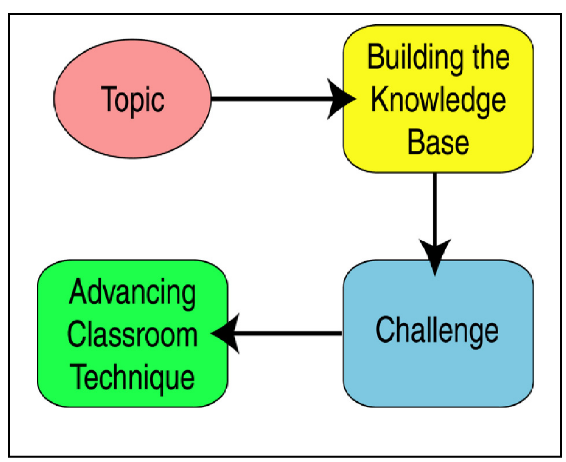

Fig. 1. The three-phase learning cycle used in the workshop.

All through the steps, the teams wrote reports documenting their progress. Such reports were an essential component of the design process, but they also served as formative assessment tools for the instructors to modify the pace or content of the workshop as necessary. At the end of the workshop, the teams presented and demonstrated their solutions to the Challenge, and together the teachers had a final ACT phase to discuss the entire design process, and its curricular implications.

The 2010 summer workshop challenged the participants to test and develop several Design Teaching Kits (DTK). A DTK is a set of hands-on activities, plus a design contest, to supplement the teaching of a specific set of science topics. It does not replace curriculum but enhances it. It also provides information for students on the engineering design process, the difference between science and engineering, and engineering disciplines and practice. The REDE DTKs were based on activities developed at the University of Virginia as senior engineering design projects [7-9]. For example, the *Save the Penguins* DTK supplements lessons on the nature of heat, radiation, convection, and conduction, and insulating materials. Teams of students make observations about heat flow, measure the insulating properties of different materials, and then design an enclosure, an "igloo," to minimize the melting of a penguin-shaped ice cube in a heated environment. Teachers in the workshop tested and modified the activities, aligned them with state science standards, and wrote scaffolding information for teachers. These kits were subsequently supplied to the teachers. Another kit focused on solar energy, solar cells, electric measurements, and motors, torque and gears.

The final 2011 summer workshop included a review of the design process with a short team design project, as several new participants had joined the program. A particular focus of the workshop was how to tailor projects to the ethnic, gender, and cultural diversity of the student body, and to incorporating English language proficiency activities into design projects. A key point is that technical communication and the vocabulary of engineering and design is a "foreign language" to virtually all students, not just English language learners, and activities and techniques were shared that help all students develop good oral and written communication skills.

All during the program, the monthly academic year meetings provided review of the summer workshop material, and support for the teachers using design projects in class. These meetings also covered the majority of material on engineering professional practice, the content of the different engineering areas, and the nature of various engineering degrees and their requirements. Most meetings included a talk and laboratory tour by an engineering faculty member, to help put an engineering discipline in concrete terms. All the material from the workshops and meetings is archived in an online collaboration site available to the participants and other interested teachers. The site also provides tools for communication between participants, forums, blogs, and a wiki. This resource will remain in place after the end of the project to facilitate ongoing work and community building.

III. Results

The effectiveness of our program was assessed using both quantitative and qualitative measures. Pre- and post-tests were written and graded by the project directors. These were used as formative assessment during the program to guide meeting activities, and as a final summative assessment of the program. Independent external evaluators surveyed participants after workshops and meetings, held focus groups, and visited classrooms to observe classroom activity, and to interview students.

A. *Pre- and Post-Tests*

The pre-and post-tests consisted of a combination of 16–17 open-ended questions and multiple choice items. Pre-and post-test items differed by changes in the ordering of the items, wording changes, and different questions. We identified eight specific outcomes or objectives of interest for our program, as shown in Table I. Each objective was associated with one or more questions on the pre- and post-tests. Over the three year program, participants took both tests a variable number of times, depending on when they were active in the program. For our summative evaluation we compared the first pre-test score of a participant with their last post-test score, and computed a participant average (arithmetic mean) for each objective, and for the entire test. The pre-test data represents results from all 18 enrolled participants; the post-test data represents results from 17 participants.

As shown in Table I and Fig. 2, post-test scores were higher for all objectives, and increased over pre-test scores an average of 23 percentage points.

TABLE I. PROGRAM OBJECTIVES AND TEST SCORE RESULTS

	Objective Description	**Pre-Test**	**Post-Test**
A	Develop, integrate, & implement design-based, open-ended activities for science classes.	44%	70%
B	Explain the engineering design process, & compare it to the scientific inquiry process.	61%	77%
C	Organize, develop, & guide student design teams.	70%	85%
D	Apply appropriate formative & summative assessment to team project outcomes.	48%	85%
E	Be able to describe engineering practice & discipline areas.	50%	93%
F	Be able to advise students about educational paths into STEM careers.	64%	71%
G	Explain engineering ethics, responsibility to the public, & consideration of social values in design choices.	58%	81%
H	Develop student communication skills through documenting team design projects.	38%	52%
	Average for all objectives:	54%	77%

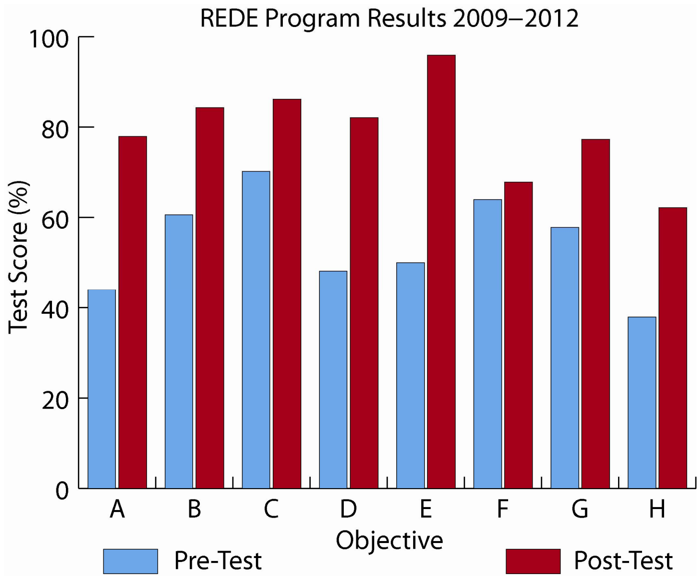

Fig. 2. Pre- and Post-Test Scores by Program Objective. The pre-test data represents results from all 18 enrolled participants; the post-test data represents results from 17 participants.

B. Observations

Over the course of the grant participants were observed and interviewed by external evaluators to determine their expertise and comfort in teaching the design model to their students. To triangulate the visit, a student survey was developed and administered to students in the observed class. The observations, based on program goals, evaluated participants' use of the design process with their classes, the formation of effective teams to solve the problems and the integration of design-based exercises into science classes where applicable.

Secondarily the observations were designed to record the dissemination of information on careers in the STEM fields and the preparation required for pursuing a career in the field. The observation/interview/student survey also encouraged the participants to address issues such as intellectual property and ways to protect it. An Observation Protocol initially developed for observing science and math teachers was modified and used as the guiding instrument. One-time direct observations were conducted to document changes in teacher practice. All the participants seemed committed to using the design model in their classrooms. Their responses on questions relating to the use of the model (100% response) indicated they were using it with their students. Over the three years the observers witnessed students engaged, working in groups and using the design process. What changed was the level of teacher comfort with the process and therefore implementation of effective challenges within expected frames of time.

Participants were rated on a 5-point system: 1 Not Evident, 2 Not Observed, 3 Needs Improvement, 4 Satisfactory, and 5 Excellent, on teacher and student behaviors. Four teachers were observed in both 2010 and 2011. Their total scores declined from 169 in 2010 to 151 in 2011; however, three teachers were observed in both 2011 and 2012. Their total scores increased from 114 to 190.

Respondents were asked what was most beneficial about the training. Some responses related directly to the structure of the workshop and the learning cycle used, such as, "Getting the student perspective on working as a member of a team on a design project…," "The connections to the real world. The structure was modeled in the way we should do it in class," and "The most beneficial part was designing the prosthetic hand."

Students had a positive attitude toward doing design-based projects based on survey results, with 98.7% saying they liked doing the design contests. "It was really fun coming up with different ideas …that would help mankind." "I found …hands on projects is the way I learn best." "Usually students do not get the chance to build creations at this level." "We learn new skills from these projects." The percentage of students indicating they received information about engineering careers increased from 58.1% in 2010 to 80.0% in 2012. The source of this information primarily came from teachers (40.2% in 2010 to 68% in 2012). Most students, 87%, also said they planned on taking STEM classes in college, and 75% said they were planning a STEM major in college and a STEM career, with 24% mentioning engineering as a possible career choice.

C. Student Achievement

A matched comparison groups design was used to evaluate whether there were differences in student achievement for teachers that participated in REDE training compared to student achievement for a similar group of students attending schools that were demographically comparable to the REDE schools. A criterion-referenced state assessment was used as the outcome measure for both mathematics and science. Students were matched on race/ethnicity, gender, gifted and talented, and socioeconomic status. If all variables did not match, decisions were made to find the best match based on the strength of the relationship between the variable and the Texas Assessment of Knowledge and Skills (TAKS) scale score.

Three years of student-level TAKS data were available for 7 of the participating schools.

Over the three year period, students of teachers that participated in REDE outperformed the comparison group for both percent passing and commended performance on the mathematics and science TAKS. Science passing rates for REDE students increased from 74.5% in 2010 to 84.3% in 2012, although there was a slight decline of 1.5 percentage points from 2011. Science passing rates for the comparison group were 70.4% in 2010 to 73.0% in 2012, with a slight decline of 1.4 percentage points from 2011. Commended rates for REDE students increased from 8.5% in 2010 to 19.7% in 2012. For the comparison group, commended rates increased from 6.5% in 2010 to 14.6% in 2011, but declined by 2.5 percentage points for 2012.

An independent-samples t-test was conducted to compare student achievement scores in science and mathematics for students in the treatment (REDE) group and students in the comparison group for 2010, 2011, and 2012. For 2010, there was a significant difference in the science mean scale score for the REDE students in grade 10 compared to the students in the comparison group; however, for grade 11, there was no significant difference in science scores. For 2011 and 2012, the mean mathematics and science scale scores of REDE students exceeded the comparison group for all grade levels. These differences were statistically significant.

IV. Conclusions

This was a pilot program with a modest number of self-selected participants from the Houston, Texas area. While the three-year duration of the program had many advantages, it also meant that some teachers left and entered the program at various points. We also ended up with a mixture of high and middle school teachers, some from science faculty and some from technical and career training faculty. The results and conclusions should be viewed in light of this small and diverse data set.

The workshop pedagogy and program structure were successful in meeting the goals of the program in regard to giving teachers the experience, knowledge, and pedagogical skills to integrate engineering design and habits of mind into their science classrooms. The survey data indicates that their students obtained a better understanding of what engineers do, engineering disciplines, careers, and STEM educational paths. It is much harder to assess whether this program led to increased student learning in science and mathematics, or an increase in technological literacy. The results of standard tests in science and mathematics are influenced by many factors, and technical literacy and problem solving are rarely a part of such exams. Still, the limited data we have are encouraging. It would take a detailed longitudinal study to determine if the students of our teacher participants actually pursued STEM careers at rates that exceeded their peers.

Other approaches have been used to introduce engineering into secondary schools. A series of studies shows that replacing conventional science curriculum with design-based teaching of science concepts resulted in superior student knowledge gain, engagement, and retention compared to scripted-inquiry teaching [10-12]. The engineering design pedagogy was most helpful to low-achieving, traditionally underserved students. Stand-alone engineering courses are another approach. Project Lead the Way, for example, claims significant gains with its sequence of engineering courses for middle and high school [13]. However, these courses require an expensive contract, are rigidly structured, and are usually offered as electives. The infusion approach we used avoids difficult curriculum restructuring and reaches every child by using some science laboratory time for open-ended, design-based activities. This requires considerable teacher training, as do all the other approaches. This program was a learning experience for the authors as well as the participants, and based on our experience, we believe equivalent results could be achieved with a one-year intensive professional development program, or with a one-semester course for pre-service teachers. We are currently applying what we have learned to a program for teams of middle school teachers from four schools in Spring, Texas.

Acknowledgments

We would like to acknowledge the contributions of our other instructors, Mr. Maikel Garcia, high school physics teacher in Spring Independent School District, Texas (and an electrical engineer with industrial design experience), and Dr. Terry Talley, specialist in techniques for English language learners, Southeast Regional Texas STEM Center. An early version of this paper with intermediate results was discussed at the 2nd P-12 Engineering and Design Education Research Summit, Washington, DC, April 2012.

Young People's Perceptions of Computing Careers

Tom McEwan
Institute for Informatics and Digital Innovation
Edinburgh Napier University
Edinburgh, UK
t.mcewan@napier.ac.uk

***Abstract*— Recruitment into computing-related undergraduate degree courses is challenging in several countries. This is despite employers reporting skills shortages, and the sector generally offering better salaries than for graduates of more popular courses. This paper describes a study (n=111) of the interest of 16 and 17 year olds in taking Computing-related degrees, particularly those that lead to user experience (UX) careers, where there is both a local and global skills shortage. The picture that emerges is of surprisingly pronounced and entrenched attitudes, which are worthy of a more detailed study. Only one of eight typical computing job roles (Tester) was familiar while the term UX was almost unknown. The females in this study expressed antipathy even towards finding out about computing careers. An unexpected additional finding is the commonplace, and apparently inappropriate, use of Myers-Briggs-style questionnaires in offering careers advice on computing to local school children. This paper will be of interest to those who seek to progress professionalism in the field of computing and to recruit (particularly female) school leavers into computing degrees.**

Keywords— Computing and Gender, Computing Careers

I. Introduction

Recruitment into computing-related undergraduate degree courses is challenging in several countries. This is despite employers reporting skills shortages, and the sector generally offering better salaries than for graduates of more popular courses. This paper describes a study of the interest of teenagers in taking computing-related degrees, particularly those that lead to user experience (UX) careers, where there is both a local and global skills shortage. The project grew out of a group discussion at a national event involving 16-year olds, colleges and universities, employers and public policy bodies. The other stakeholders realized that they could not respond adequately to a teenager's request that, unlike the situation for medicine, law or plumbing, the computing profession could not describe a student's progression over the next ten years before demanding their commitment.

After a review of the situation in other countries, we focus on a single local high school, one with a high university participation rate, and investigate the views of 16 and 17-year olds (n=111) through an intermediary. Ethical constraints limit both the access to the subjects, and the generalizability of the data, yet the picture that emerges is of surprisingly pronounced and entrenched attitudes, which are worthy of a more detailed study.

A. Evolving Professions in Computing

The recent rapid growth in career opportunities in User Experience (UX) offers new opportunities for human-centred careers in computing. Such roles help to counter the geeky/nerdy image of workers in computing, while the high salaries and rapid career advancement add to the lustre. Universities have added degrees in UX to those in Human Computer Interaction (HCI) or Interaction Design. Thus one might expect strong demand from school leavers, especially since they have lived their entire lives with access to the Web. Yet these "Millennials" appear to lack desire to study and work in the field of computing.

There is an alarming downwards trend in the number of young people, particularly females, choosing to study computing (this definition is broad and includes IT, IS, Networks, HCI, Digital Media, Interaction Design) as a subject at secondary school or as a career path. This is despite technological advancements, faster and cheaper access to the Internet, the popularity of social networking sites, the increasing numbers of online transactions and the widespread use of devices such as smart phones, laptops, iPhones or the eReaders. Several UK organisations, such as NAACE, BCS, The Chartered Institute for IT, and the Royal Society have expressed their concerns over this issue. The latter's call for evidence attracted 120 responses, highlighting the complex nature of the issue.

This has implications for HCI, as the stereotypical view of computing people as "lacking in empathy" both becomes a self-fulfilling prophecy and marginalises those who do care about the user. HCI job roles, on the other hand, have become better defined in recent years, with a range of roles defined in competency frameworks such as the UK's Skills Framework for the Information Age (SFIA) [1], following many years of engagement by the community with those who define professionalism and job roles in computing.

II. The Evidence Of Decline

The literature reviewed for this study demonstrates that the issue of engaging young people, especially of female students in computing classes or undergraduate programmes and careers is a global consideration. A study [2] of school leavers in

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Germany found only 7.6% chose to major in Computer Science (CS) despite a dropout rate of 38%. A report by the Victorian Government in Australia [3] finds a worrying low regard for computing amongst school leavers, though other research [4] suggests there is no such issue for India. The OECD data for Europe [5] in Table 1 indicates a steady downward trend although some smaller or lower-salary countries stabilise or even slightly increase.

Table 1: OECD data for Undergraduate Computing students 2005-7 [5]

Country	2005	2006	2007
Denmark	1259	1143	1212
Finland	1843	1785	1819
Iceland	94	91	71
Norway	1770	1666	1537
Poland	19133	19931	20119
Sweden	1742	1787	1463
UK	29191	27617	24875
Estonia	364	350	431
Slovenia	128	144	164
total	***57529***	***56520***	***53698***

In the UK, The Royal Society [6] highlights the decrease in the numbers of students across the UK "with a fall of 33% in just three years in Computing GCSE students, a fall of 33% in six years in A level Computing and 57% in eight years in A Level Computing students in England" and find a similar trend in Wales, Northern Ireland and Scotland. Scotland has a different educational system to the rest of the UK, and needs [7] 10,400 new computing employees a year. Current participation in computing qualifications falls well short of this. The Scottish Qualifications Authority (SQA) 2006-2009 data shows a 3% decline in university entrance exam (Higher/Advanced Higher (AH)) passes in computing-related subjects, and 17% in the more junior Standard Grade Level.

Authoritative voices in the UK [6] suggests this decline is due to "poor quality of computing curriculum limiting the students' understanding and enjoyment" and that the Computing education in schools does not inform young people about the relevance of a career in IT. BCS cites a TV sitcom [9] as contributing to the poor media image of computing scientists and ICT specialists, presenting ICT jobs as "low status, routine, badly paid, held by anti-social geeks and likely to be offshore or evil hackers" [10]. Additionally only a small number of teachers in England have a degree in the subject [11]. Google CEO Eric Schmidt gained widespread press coverage by criticising the British computing curriculum and teaching approaches [12]. More recently BCS and others have worked together to respond [13] to these challenges and in England the new Computer Science curriculum, and, based on recent UK government announcements [14], have influenced policy.

The situation in Scotland is seen [8] as a little better to the rest of the UK: primary school students learn Scratch programming and in secondary schools, computing is integrated into almost every subject on the curriculum. Nevertheless, Scotland shares the very low female representation in computing courses. In 2011, only 26% of those achieving A-C results (ie "good" passes) in Highers were females, and this worsens to 17% (80 female, 381 male) for the AH (the equivalent of first year at a Scottish University). Students take a practice "Prelim" exam before sitting these examinations, and, in 2011, only 20% of those taking the AH Computing Prelim were female.

A. Comparisons with other countries

Over the last ten years similar situations appear to have emerged in other countries and been addressed at different speeds and in different ways. Californian computing education was considered [15] a "land of missed opportunities" where connections are not made between computing and learners' interests. Just as in the UK, high school students were seen as learning how to *use*, rather than *create*, software; teachers lacked computing qualification; counsellors advise college-bound students away from computer science. High school students' perceptions of computing professionals are people who sit "in front of computers and programming all day" [16]. Students at Carnegie Mellon University analysed academic papers, popular media and interviews to establish that "the images of computing were for the most part either absent or negative" [17]. Most were aware that the public had a narrow perception of CS and identified a gender gap in the enrolment data of their own department, which they attributed to cultural issues.

In their attempt to understand stereotypes in CS, German and American university students were asked to write computer autobiographies [18], (a method also used [19] for the purposes of understanding the reasons why undergraduate students are dropping out of CS courses). They identified negative stereotypes even in the biographies of CS students. While non-CS students used stereotypes to "differentiate themselves from nerdy computer experts, even some CS students distanced themselves from CS with comments such as "normal Computer Scientists", because of "the implicit low status of the prevalent stereotype about computer scientists" [18].

However, computing is not negatively portrayed in all countries. An analysis of South Indian cinema draws attention to the reversal of this image in India, in contrast to the western culture. Though there is still a distorted understanding of computing, a positive image of programmers and computers in Indian films transcends cultural, class and gender barriers. For example: fathers in rural parts of India, who once would refuse their daughters' requests to move away from home to pursue a career, now think "if they work for computers, it is good" [4]. This positive portrayal of computers and their users in Indian media is claimed to make India a "leader in the Information and Communications Technology for Development (ICTD) movement…" and why India has no problems in convincing its youth in pursuing computing careers.

Different terms may be significant here – CS has a more technical focus in some cultures than using the terms computing, IT or ICT.

B. Awareness of computing careers

"Loss of interest in the field and its potential careers" is cited as the most important reason why students leave computing courses [19]. Typical statements highlight the narrow understanding of the field, viewing careers as purely programming. Another study [20] summarises the findings of Eccles et al. (1999): "values attached to relevant job characteristics were significant predictors of teenage career aspirations". An analysis [21] of career expectations formed at age 16, concludes that, while a teacher's description of an occupation is influential, school resources devoted to careers advice "have limited influence on children's career expectations". That some of this data comes from the 1970s suggests a longstanding tradition of teachers being influential in their students' career choices.

In attempting to stem the decline, most initiatives target underrepresented groups – females, ethnic minorities and the underprivileged. The results show a common style that seems to work, but most of these studies require longitudinal methods to gauge effectiveness in changing perceptions and ultimately convincing these groups to take up a career in computing.

C. Summary

The declining interest in computing subjects appears to be global and confirmed by studies from the USA [22], Australia [3] and Germany [2]. This causes great concern to industries, governments and educational institutions. An exacerbating factor (for the computing community) is that female participation in higher education is now notably higher than male in many industrialised countries. The consistent factors that emerge are the:

- Computing curriculum lacks relevance and context that is interesting to young people
- Quality of learning and teaching experience
- Impact of negative first experiences with computers
- Personal attributes
- Lack of qualified teachers
- Lack of career guidance and career options in computing
- Negative images of computing

The literature shows that a partnership of governments, educational institutions and industry are working hard to design more engaging, relevant and pedagogically-effective computing curricula. These partnerships are also providing better infrastructures and national learning resources and mediums such as intranets for learning tools and best practice to be shared. If successful, these should gradually increase interest and participation in computing as a subject or as a career, however there seems very little to be done in order to achieve a more direct shift in the attitudes of young people. Retention studies at universities [19], [20] show that these negative views even influence those students who have chosen to do a degree in the field. There is a large amount of literature relating to intervention programmes that have been implemented to change the declining interest in computing. Much of this literature, eg [23], [24] shows that for any intervention programme to be successful, raising awareness of computing and related careers is crucial.

III. Research Objectives

The scope of this investigation is in the context of identifying the requirements for a website for High School students and is limited to discovering young people's awareness and perception of computing careers, and the way in which these might have an impact on their career choices. The objective of this research is to answer the following questions:

- Which factors shape young people's career choices?
- How much do young people know about computing jobs and to what extent does this impact on their career decisions?
- Are there negative perceptions of computing careers and computing professionals that might affect young people's career decisions?
- Are there gender differences in young people's interest in, awareness of and pursuing of the computing career path?
- Are there negative perceptions of computing careers and computing professionals that might affect young people's career decisions?

There are complex ethical issues to consider in a study involving people aged under 18, and the timescale for this was such that a prolonged ethics approval process was not feasible. Thus we sought an ethically-valid compromise. The involvement of these young people is certainly justified to ensure that they can contribute, as stakeholders, towards the design of a system, such as a website, intended for their use. Beyond the scope of this paper is a review of how to carry out academic research with children and young adults – a highly specialised area which requires considerable training. After discussion with the faculty's ethics advisor, it was agreed that

- no one aged under 16 would be involved in the study,
- the researcher would have no direct contact with the 16 and 17 year olds being surveyed, but rather would ask their teacher or career advisor to administer the questionnaire survey in the context of their general teaching and support roles.

Thus students could input as stakeholders as part of a website design process, but there are limitations on the validity of applying inferential analysis to the resulting data. This was not the only ethical constraint in the overall project - for the design of the website we would have preferred qualitative input from our stakeholders, but accepted evaluation by a domain expert instead.

A. Questionnaire

A structured questionnaire was designed based on an existing attitudinal survey [3] of young people's awareness of computing careers. The questionnaire consisted of four pages with 12 questions that aimed to gather data on the following six sub-titles: demographics, familiarity with computing job titles, knowledge of and interest in computing careers, factors affecting career choices, source of career choices and young people's perception of computing jobs. All the items, except for age, were closed items (four point Likert scale plus "Don't Know") for ease of analysis and to enable generalisations. The questionnaire was piloted on 7 people between the ages of 19 to 55 before the edited version was administered to the target group.

Table 2- Demographic Information

	Frequency	Percent
Female	43	38.7
Male	68	61.3
Age 16	53	47.7
Age 17	58	52.3
Studying computing	31	27.9
Not studying computing	80	72.1

One of the considerations for this study was to find samples to represent young people at the career decision stage of their lives. The survey was administered by a qualified teacher, a Head of Year with responsibilities for career advice under exam conditions during the timetabled "study skills" classes. The teacher agreed to give the following verbal explanation to the students:

- This survey will take no longer than ten minutes.
- You do not have to complete the questionnaire if you do not want to.
- If you feel uncomfortable with any of the questions, you do not need to finish it.
- The results will be used to help identify how best to advise school leavers about career opportunities.

Additionally a short explanation was printed on the survey sheet. Only age and gender was captured as personal data. 126 students from the final two years (S5 and S6) of a secondary school in Edinburgh took part in the study at the beginning of school year 2011/12, and 111 completed responses were received. Unexpectedly, another 11 were returned from those listing their age as 15 (at that time of year, some children had not reached their 16th birthday) and, after taking ethical advice, these were excluded from further study and destroyed. At the time of the study, the total number of S5/S6 students in the school was 341 (178 male, 163 female). The selection of participants was arbitrary based on the classes of the teacher who agreed to administer the questionnaire, 43 females and 68 males completed the survey, thus females were underrepresented in the sample. Due to the number of 15 year olds, we cannot be precise, but approximately 40% of eligible boys and 30% of eligible girls participated.

For the purposes of this study cluster sampling [25] was used, as a secondary school already consists of a natural selection of the age group required for the survey; however it should be noted that the secondary school where the survey was administered is in an affluent part of Edinburgh and does not represent the entire population of young people in Scotland or in the United Kingdom (UK). The school also has an unusually high proportion of students who progress to university.

IV. RESULTS

A. *Students who have already chosen a career*

The majority (72 or 64.9%) of these students have already decided on their future jobs. 22 (30.6% of the above subset) first heard about this job from family, 19 from media and 17 from someone who does the job. Unexpectedly, Teachers (6) and career advisers (4) were cited by few. In terms of a computing career, 31 said they will "definitely not" and 27 said they are "not likely to" pursue a computing career. Only 7 students said they will "definitely pursue" a computing career and the same number said they "might". These seemingly low figures are consistent with overall percentages of the population in professional computing careers, but one might expect a higher proportion from those likely most to progress to higher education.

B. *All students*

49.5% of the full sample stated that they know "very little" (41) or "nothing" (14) about ICT careers, and, when asked if they would like to learn more about ICT careers, 40.5% (45) were "not sure" and 27% (30) said "definitely not".

We used modes to analyse the response to questions about perceptions of computing jobs (1=Strongly agree (SA); 2=Agree (A); 3=Don't know (DK); 4=Disagree (D); 5=Strongly disagree (SD))

Table 3: Modal responses to perceptions of computing jobs

	Mode
12a. Computing careers lack human interaction.	2
12b. There are not enough jobs in the computing industry.	3
12c. People who work in the computing industry are mostly socially awkward.	4
12d. A career in computing would be very boring.	2
12e. Computing is a male dominated field.	2
12f. A computing career involves sitting in front of a computer all day.	2

C. *Applying statistical tests*

Despite the stated limits to the validity of inferential analysis, some standard statistical tests were run on the data to see if it suggests any particularly strong relationships, ie those for which $p<0.001$, or a 0.1% chance of error, compared to the more typical 1% or 5% tests.

A Mann-Whitney U test comparing those who would "definitely pursue" (7) with "definitely not pursue" (47) suggest a strongly significant difference between those participants for the following perceptions of computing jobs:

- "Involves human interaction" ($U=36$, $z=-3.3$, $p< 0.001$).
- "Computing is fun" ($U=27$, $z=-3.9$, $p<0.001$).
- "Computing is prestigious" ($U=27.5$, $z=-3.8$, $p<0.001$).

A Pearson's correlation was used to analyse the relation between *knowledge of computing* and enthusiasm for *pursuing a computing career* finding significance level less than 0.001 and $r=0.652$ (Table 4).

Table 4 Knowledge of Computing * Pursue Computing

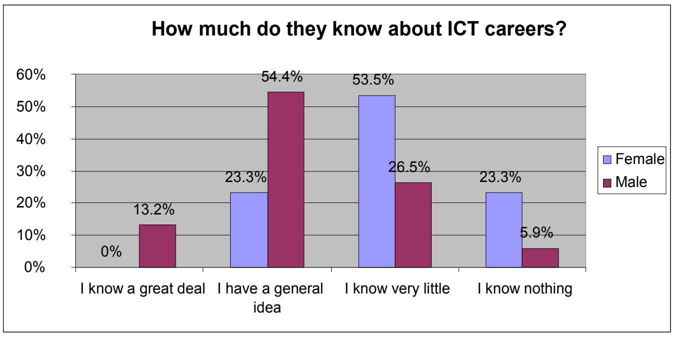
		Pursue Computing Career	Knowledge of Computing Careers
Pursue Computing career	*Pearson Correlation*	1	.652**
	Sig. (2-tailed)		.000
	N	111	111
Knowledge of Computing Careers	*Pearson Correlation*	.652**	1
	Sig. (2-tailed)	.000	
	N	111	111

**. Correlation is significant at the 0.01 level (2-tailed).

Similar Pearson's analyses suggest that young people's *positive perception of computing careers* is correlated with *intent to pursue a computing career* ($p<0.001$, $r = 0.630$) and *knowledge of computing* ($p<0.001$, $r = 0.383$).

D. Gender

The differences between male and female respondents is quite pronounced – compared to the males in this study, the females are much less likely to be studying computing, even less likely to study it in future. They say they know little about computing careers and have no interest in finding out.



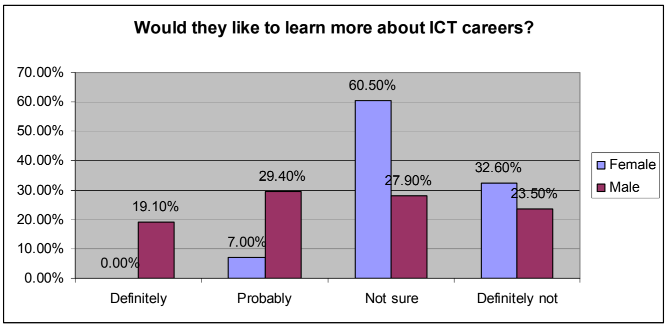


Figure 1 Awareness of, and interest in, ICT careers (MvF)

This may be due to the sample – only 11% (F) v 38.2% (M) were studying an ICT-related subject, 95.4% (F) v 67.6% (M) were *unlikely to*, or *would definitely not*, pursue an ICT career. However these gender differences reflect typical gender splits in university computing departments and in ICT-related graduate recruitment in the UK.

E. Awareness of Typical Roles

We listed eight typical computing roles (drawn from local job adverts to represent a cross section of computing specialisms) and asked familiarity with these. The range of responses was unexpected. The majority said they know exactly what a *Tester* does while a majority claimed they know a "little bit" about what a *Games Developer*, *Software Engineer* and *Programmer* do. For *Systems Analyst*, *Database Developer* and *Security Engineer*, most knew *little* or *nothing*, *while User Experience Developer* is the only computing job in the list which the majority of all the students had "*never heard of it"*. This is particularly surprising, given high salaries and local skills shortage in this field, and that these jobs provide the high levels of human interaction desired by participants. On reflection, alternative terms such as UX Design, Interaction Designer, or Usability Professional, though less prevalent at the time, might have elicited a different response. An analysis (March 2013) in Google Trends of these terms suggests that a more prevalent term now would be UX Design Jobs, or UX Designer Jobs. In the UX industry, globally, there is both a lack of formal definition of UX Designer v UX Developer, but also a degree of consensus about what each does. Local recruiters tend to use the terms more interchangeably.

The gender divide on this question – only a single female knew what was involved in this job, and a proportionately more females than males had "never heard of it" – is particularly interesting, as the local UX industry has a roughly even gender split. A similar set of results was found for the term Systems Analyst.

Table 5. Awareness of User Experience Developer role

No Answer	2	1.8%
Never Heard Of It	65	58.6%
Heard Of It, But Don't Know What It Involves	26	23.4%
I Know A Little Bit Of What This Person Does	12	10.8%
I Know Exactly What Is Involved	6	5.4%
Total	111	100%

V. Discussion

The results indicate that the majority of these young people have already decided on their future jobs by the ages of 16/17. Family, media and "people who are already doing the job" seem to have most impact on students' career decisions. This contradicts a study [21] of past cohort data which suggested the teacher was the greatest influence on their students' career decisions. This could indicate that any intervention programme to reverse the current trends in computing should involve families and media, while any product to challenge misperceptions should present people from the computing industry as role-models.

Our study is consistent with previous research (for example, [19] [22] [26]) which highlights the lack of popularity of computing subjects and careers among young people in the western world. While not every young person is suited to computing, from this sample a surprisingly high proportion "definitely do not want" a computing career. Lack of knowledge, or negative images, of computing people and careers is correlated with this lack of interest. Conversely, the more these young people know about computing and computing careers, the more they are likely to have positive perception of the field. While we might expect interest in, and knowledge of, to be related, the majority (typically estimated at 60-65%) who work in the UK computing industry do not have a computing qualification and tend to join the profession after converting from an earlier degree. An early intervention programme to inform young people of computing careers and the opportunities available in the field appears likely to increase interest and lead to an earlier choice of a computing career.

Answers to other questions in our survey suggested that career decision factors of location, commuting, ease of promotion, or salary appeared not to differ between those who do, and do not, want to pursue computing careers, while studying computing at school does unsurprisingly correlate ($p<0.001$) with *positive perception*, *knowledge of computing*, *interest in learning more about computing*, and *intent to pursue computing career*. This suggests that the computing profession needs to influence subject choice that students and parents make from age 13 onwards.

This study is consistent with literature on gender difference: the proportion of girls who study computing and who want to pursue computing as a career, is significantly lower than that of boys. A far lower proportion of girls, than boys, in our survey state they know anything about computing careers, that they would like to learn more about computing careers, or hold positive perceptions of the field. Again, earlier intervention is needed to attract more girls to the computing field.

VI. Future Work

Our data gathering was to establish requirements for a website, which was developed and prototyped with teachers to a positive response. Subsequent initiatives (such as http://www.bigambitionscotland.com/) have already addressed issues that we planned to address, but a further, much more detailed study appears to be justified into teenage attitudes to the range of computing careers. Such a study should ensure equal participation by males and females, cover a socio-economic range of schools, and go through the ethical processes to allow a wider range of younger children to participate. This could be triangulated with investigations into the views of parents, employers, teachers and careers advisors.

One aspect, that space does not permit us to cover here, is the apparently widespread use of Myers-Briggs (MBTI) [27] (or MBTI-style) tests in existing websites to advise students on careers, particularly in those websites promoting computing careers. Discussions with specialists in human resources suggests this is, at the least, an abuse of the MBTI licensing requirements, while an international recruitment consultant has provided us with rich reasons why he considers such tests are ineffectual for most, if not all, aspects of recruitment into graduate computing roles. It may even be that the mechanistic nature of these tests only serves to confirm antipathy towards computing. For example one study [28] suggests "ESTJs, ESTPs, ENTJs and ENTPs make good systems analysts" and "ISTPs, INTPs, INTJs make good programmers" It's not hard to imagine that a 16 year old might intuitively reject such a reductionist view.

In subsequent work, we would like to document the development and expert evaluation of the web-site, and place this in the context of other recent "Computing in Schools" initiatives in the UK.

VII. Conclusion

Despite the acknowledged limitations of this study, this school is typical of Scotland in terms of the gender split of students studying computing. Thus specific intervention programmes, such as Google's two-month-old F scheme [29] or Scottish Resource Centre's "work with women entering further and higher education, those in education and women working in SET" [30] are steps in the right direction. While both initiatives appear to be effective in supporting females who have already chosen the field, there seems to be a dearth of initiatives to recruit more young girls into the field in the first place. Our female participants say they don't know whether working in the computing field is prestigious or if there is a high job demand in computing. Young people need this data in an understandable form.

This study confirms other work [31] which found that, by the ages of 16/17, the majority of the young people already have an idea about their future careers. Therefore, any intervention programme that aims to promote computing careers should do so earlier. The expert evaluators involved in the website evaluation stage of the project told us that, while young people may say they have made their career decisions, they tend to change their opinions while studying for a degree, or realise that they cannot gain the qualifications required for their choice and end up having to change their plans for future. Thus there is a subsequent window of opportunity to inform about careers in computing.

An unexpected finding of this study is that Careers Advisers or Teachers seem only to play a very small role in the career decisions these young people make. The major influences on these young people's career decisions are, respectively, their parents, the media, and someone who already works in the field. Furthermore, when asked who they think should inform them of computing careers, most believe that it should be someone who does the job. If this is consistent in other schools, then any intervention programme to change perceptions of young people should focus more on parents and role-models, and on careful media campaigns. Although inconsistent with the findings in Australia [3] that rated people from the industry and work experience more highly than the family; this may be due to differences between careers advice practices in Australian and Scottish schools.

In line with works of [16], [19] and [26] the findings of this study also suggest students have an "incorrect perception of the computing field or none at all" or the images of computing are "either absent or negative" [17]. If generalizable, the attitude of Scottish youngsters is similar to that of 14 to 19 year olds in Victoria, Australia and the following negative images of computing careers are still waiting to be challenged in Scotland:

- Computing careers lack human interaction.
- A career in computing would be very boring.
- Computing is a male dominated field.

- A computing career involves sitting in front of a computer all day.

Encouragingly, in contrast to previous studies [18], the majority of the participants disagree that the people who work in the computing industry as ‘socially awkward’.

ACKNOWLEDGMENTS

This paper is mainly based on research carried out, under my supervision, by Aysu McConnell MSc as part of her dissertation "An Exploratory Study: Young People’s Perception and Awareness of Computing Careers" for Edinburgh Napier University. Aysu has requested neither to be involved in subsequent papers, nor named as co-author, but I am very grateful to her for both the quality and quantity of her research, and for allowing this selection to be written up and published. Her dissertation is available by request to the email address at the start of this paper.

***Abstract*— The courses in computing, especially those focused on software development, require many skills of novice students of computer programming. Due to the fact that computer science is a new area for most of novice students, they demonstrate great difficulty in initial courses in this area. They do not have specific skills in computer programming. This work presents the results obtained from the application of a teaching method, for computer programming students of the integrated high school mode, that combines patterns-based programming and games. The games uses concrete materials and collaborative activities based on sports in non-formal spaces. The results show improvements in students' motivation and in programming abilities. The method proposed in this work takes advantage of analogies between programming logic and games using concrete materials in order to develop programming skills.**

Keywords— teaching programming; patterns; games; collaborative activities

I. INTRODUCTION

Concern over the lack of manpower in technology, especially in the area of Informatics, has been drawing a lot of attention these days, both by the government, and by private enterprise. The Federal Brazilian Government will invest R$ 1.2 billion in Federal Education, Science and Technology from 2012 to 2014 [9]. Part of these funds will be allocated to the creation of computer professionals and mid-level technician, with priority to integrated school. An integrated school in Brazil offers traditional high school learning together with a technical learning. The great majority of the Federal Institutes in Brazil offers a course that combines a technical course in computer science and traditional high school. Today, for instance, the Federal Institute of Mato Grosso (IFMT), an institution that hosts this study, offers this course in three of the ten campuses.

With respect to courses where the base of technical training in programming, the initial goal should be the mastery of the basic concepts of algorithms and computer programming. Most students encounter great difficulties, whether resulting from a deficient training in Elementary Education or the total lack of focus of the course in which they are entering. This is due to the fact that most of them are motivated users of computer technology and choose the course based on this fact.

In order to meet the demand for Information Technology professionals is essential to enhance the quality of teaching and learning in courses in computing. One of the bottlenecks of these courses is the high failure rate and evasion at the beginning of the course in the disciplines of programming and algorithms [12]. In general, students who enroll in integrated courses are teenagers, aged from 13 to 15 years. In the case of IFMT, half the vacancies of the courses is designed for students who attended all nine years of primary education in public schools and the other half, called for universal access [7], which are the vacancies for the students that had not completed all primary education in public educational institutions or came from of private institutions.

Thus, given the particularities of the students in question, it is necessary to search for new approaches and teaching methods, as opposed to the traditional teaching of algorithms and computer programming. In the traditional teaching of programming, the content is presented orally by the teacher and after the students go to the informatics laboratory to solve computational problems using a programming language. As shown in [2], in the traditional way, the teacher presents content and some examples by means of a pseudo code and asks the students to make some exercises. The traditional way cannot easily motivate students to become interested in discipline; it is not clear to students the importance of certain content for their training [3].

In this paper, we present and discuss results obtained by combining the teaching pattern-oriented instruction [6], and games to high school students in the integrated mode. The games use concrete materials and are based on sports and collaborative activities in non formal spaces, making analogies with computer programming.

In Section II, we discuss advantages of teaching

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

programming based on patterns and the necessity to propose new methods to approach it. In Section III, we describe and analyze the proposed method by means of a pre-post case study involving collaborative games using concrete materials and programming patterns. In section IV we analyze the interaction and participation in the games created by students. In Section V, we present the results of the study and future work.

II. PATTERNS OF PROGRAMMING IN LEARNING

Novices students in programming present many difficulties, such as problems related to the lack of ability of abstraction and lack of skills to deal with problems. In the case of students fresh out of the ninth year of elementary school there are other learning problems, especially in mathematics, physics and chemistry.

The two major challenges for the students are learning a new programming language and learning how to create a solution that solves a given computational problem [16]. Regarding the first problem, learning the rules of syntax and semantics of a programming language is relatively complex. However, the biggest challenge for the novice programmer, is really interpret the problem, solve it algorithmically and code the algorithm into a programming language.

Experienced programmers can easily solve a problem, identifying which statements to use, what data types involved, as well as distinct ways to solve the same problem using different strategies. Based works with previous programming experiences of students for teaching programming language Pascal, Johnson and Soloway [8] discuss that experienced programmers are able to solve new problems using previous experience, adapting previous solutions to solve them. These previous experiments provide the basis for the programming patterns, which are solutions that recurrently appear in computational problem solving. Programming patterns reflect programming strategies designed by experts. Thus, students take advantage of good programming practices.

These basic patterns also called educational programming patterns [14] contains the skeleton in which the problem will be solved by then beginner in computer programming. Programming patterns form a basis for initial micro solutions that can be adapted and combined by the students during the development of their programs.

A programming pattern describes a solution to a problem and provides information about the context in which it should be applied [2]. Thus, students starting their studies in programming, when faced with a particular kind of problem, can direct their resolution from the known patterns. The teacher has a key role in this process, which will be discussed later. Clancy and Linn [5] described how patterns can be used in the teaching of programming, concluding that students need to make the process of learning, creating and reshaping programming patterns, making it a regular practice in their learning programming process. Thus, the teacher should create the exercises in order to stimulate the use of simple patterns, combinations of different patterns, and stimulation of the creation of new programming patterns by the student.

Programming patterns are solutions to computational problems. They are basic blocks for the development of programs. Programming patterns refer to the classification of computational problems according to your goal [10]. Thus, the student may, by identifying a classification from the problem to be solved, which programming pattern can be used for preparation of a program. Another problem for the beginner in programming is the lack of abstraction ability. In the study made by Haberman and Muller [6], they propose a teaching method of abstraction, combined with problem solving and the use of programming patterns. In this study, the authors investigated the influence of the combination of patterns-based instruction with abstract data types. Thus, the study showed that it is possible to combine teaching with other pattern-based teaching methods.

Considering teaching programming, other issues are discussed by Muller [10]. One issue is the student's ability to recognize similarities between problems, particularly between the problem at hand and problems encountered and solved previously. Due to this fact, there is a need to develop new teaching methods to approach patterns in programming learning.

In the next section, we describe and investigate the teaching method proposed in this work.

III. CASE STUDY

The experiment was conducted in two stages, during the year 2012, in the course Algorithms and Logic Programming, offered in Technical Computing, Integrated mode in high school. 30 students in the first year of high school participated in the experiment, 18 boys (60%) and 12 girls (40%) aged between 13 and 15 years.

For this work, we explore the patterns for selection available by Bergin [4]. As a reference to loop patterns, we explore the patterns available in Astrachan and Wallingford [1].

We categorize the programming patterns into three types: selection patterns, loop patterns and combination patterns. The table below shows the patterns used in this work, types and an example code in the programming language C++.

TABLE I. SUMMARY OF THE PATTERNS USED IN THE EXPERIMENT

Pattern Name	**Patterns presented in the classroom**	
	Type	***Code***

Simple choice	Selection	if (a > 0)
		{
		b = 10;
		}

Pattern Name	Patterns presented in the classroom	
	Type	***Code***

Alternative choice	Selection	if (a > 0)
		{
		b = 10;
		} else {
		b = 20;
		}

Sequential choice	Selection	if (a > 0)
		{
		b = 10;
		} else if (a == 0)
		{
		b = 20;
		} else {
		b = 30;
		}

Serie of possibilities	Selection	switch (a) {
		case 1:
		b = 10;
		break;
		case 2:
		b = 20;
		break;
		default:
		b = 30;
		}

Loop and a half	Loop	cin>>a;
		while (a > 0) {
		b = b + a;
		cin>>a;
		}

Process All Items	Loop	for (i=0;i<10;i++){
		cout << i;
		}

Counter	Combination	if (average >= 6.0) {
		approve = approve+1;
		}

Accumulator	Combination	if (num % 2 == 0){
		pairs = pairs + num;
		}

The implementation of lists, as well as the presentation of programming patterns was made using the programming language C + +. Used for encoding programs to IDE Dev C + + version 4.9.9.2, using the objects input and output data (cin and cout). Despite the use of C + +, we do not use object orientation in this study. The description of each step is given below.

A. First step: approach using Pattern Oriented Instruction (POI)

In this step, which occurred in the first half of 2012, we worked the introductory part of building programs, as well as patterns of selection and repetition. Content such as data types, declaration of variables, assigning values to variables and mathematical operations using variables related to programming patterns.

The POI approach, described in [6] was used in this step. The instructional materials used by the teacher and students have been adapted for POI. The patterns were presented and discussed in the classroom and computer lab with students. Sometimes, given the difficulties of abstraction presented by most of the students are examples relating to issues of everyday patterns familiar to the student, such as the usage patterns of the school uniform.

Also in this stage, students have two classes, just to reinforce the concepts of programming patterns in the school gymnasium. In these classes the teacher was only reinforced what worked in the classroom, without going into any game. This activity also served to prepare students for the second stage of the study.

After the presentation and discussion of programming patterns, we ask students to solve exercises lists containing programming problems, relating the solution to the programming patterns discussed above. In the final step, we applied a questionnaire to evaluate how students used programming patterns in the encoding of programs as well as the difficulties faced by them and also on motivation to program.

The first question sought to know whether the process of solving the proposed exercises, what is the student's behavior with respect to programming patterns. The results were that 73.3% searched patterns to be used when solving exercises, 20% started to encode the problem in the programming language before searching the pattern to be used, and 6.7% waited a feedback from the teacher to copy the response.

About the greatest difficulty in the use of patterns in coding programs, subject of the second question, the result was that 33.3% could not relate the problem to be solved to a certain pattern; 43.4% failed to match patterns creating a new pattern programming, 13.3% did not understand what it does and what good programming patterns, 10.0% have no difficulties in the use of programming patterns.

The third issue related to motivation to program, the results showed that: 60% of students relate that motivation depends on the problem you are trying to solve, 20% responded that they are often motivated to program; 16.7% responded that the motivation for program is related to points (reward) to solve a problem or list of exercises, 3.7% answered that they are often unmotivated to program.

The last question sought to identify the expectations about students' motivation before a working methodology using games outside the computer lab. The question was about changing the space of classes, classroom and computer lab for the school's sports court and using other materials unrelated to teaching computer programming. All students responded that a change in this direction could be a differentiator for learning patterns-based programming.

School year in IFMT is divided in four quarters. In each quarter, we made a final evaluation. The passing grade for the IFMT is 7.0.

In the first quarter, the simple average of the notes in a scale between 0 and 10 was 6.22 and 6.42 in the second quarter. Therefore, at this stage, the overall mean of the experimental group was below the average minimum passing in the school year.

B. Second step: using patterns approach with collaborative games and activities using concrete materials

This step happened in the second half of 2012, and was divided into two sub-steps that are described below.

1) Work using games offered by teacher

Classes took place at this stage merging activities in the computer lab and school sports court. In the computer lab, students solved the lists of proposed exercises and sports court, at first, took part in activities involving sports games suggested by the teacher. Classes were interspersed so that every two classes, one was held in the gymnasium.

The games chosen for the experiment explored all the patterns that were worked in the computer lab. In these games, we use concrete materials related to sports games popular in Brazil, such as football, volleyball and handball.

The suggestion was made by the game played by teacher and some students. Then the teacher presented and discussed programming patterns related to the game, with examples relating to lists of exercises, linking the concepts of programming patterns in the game that was running. For example, in a volleyball match, the pattern **counter** is used to mark the score of the match, as well as the pattern **loop and a half** is used to limit each set of the match, since while the number of points scored by one team is less than 15, the game continues.

Because it is a new environment for teaching and learning programming, different from what they were accustomed in the first half, we made some guidance to students about work in the sports field. These guidelines were intended not to scatter the students' progress in school, establishing the boundaries in which they could move. With these guidelines, this step of the experiment was successful.

2) Work using games created by students

In this activity games using programming patterns analogies were created by students. The class was divided into 5 groups with 6 students each. Each group had the task of creating or adapting a known game, which should be built in order to demonstrate the programming patterns, both for those who were playing, and for those who were watching the game. For the creation of the games were made available to students balls of volleyballs and soccer, masking tape for marking sports court and plastic bottles. This task constitutes the following steps:

a) **Description of the game**: each group described the game created, taking into account the materials used in the game, the programming patterns identified and the rules of the game, which are also described as the interaction happens between players;

b) **Presentation of games for other groups**: after the description, each group demonstrated, playing for the other groups, the operation of the game according to the rules defined by the group;

c) **Games between groups**: after the presentation of the games for the other groups, the students of the group that created the game, invited students from other groups to participate in the game created.

We recorded on video throughout the implementation process of the games created by students. Each group submitted via social networking site Facebook, a document containing a detailed description of the game created. The table below shows a summary of the games created by students, the materials used, the goal of every game, the patterns used in the creation and execution of the game and the number of players participating in each round of the game.

TABLE II. DESCRIPTION OF GAMES CREATED BY STUDENTS IN GROUP

Group	Games created by students			
	Materials	***Goal***	***Patterns***	***Players***
Group 1	Ball of soccer, beams and masking tape	Achieve five points with the fewest errors out of 10 trials	Loop and a half, process all items, alternative choice and counter	03
Group 2	Tree branches and masking tape	Getting the other team's tree branch and return to his field without getting caught	Loop and a half, simple choice and alternative choice	14
Group 3	PET bottles, soccer ball and bleachers of the gymnasium	Hit the bottles with the ball using only the feet, each bottle has a score. The player with the highest score after 5 attempts, wins the game.	Loop and a half, serie of possibilities, counter and accumulator	02
Group 4	Ball of volley	Eliminate all opponents until one person remains	Loop and a half, simple choice and counter	06
Group 5	Four dice, chairs to be used as obstacles and masking tape	Be the first player to reach the center of the sports court	Alternative choice and process all items	04

At the time of the game, the teacher was asking students to interventions that would tie the game with part of the programming patterns. For example, in the game of group 1, with each round the students stopped the game and together with the teacher, explained the combination of patterns used in the game, in which case the loop process were all items and counters. Another example is the group 4 where the goal was to kick a ball in pet bottles arranged in the bleachers of the gymnasium. With each move, the students organized themselves and took the roles of varying patterns of counters and accumulators.

We note that in the description of the games, all groups were able to include and adapt programming patterns in the activities created. In presentation of the games to the other groups, we found that all groups were able to describe the patterns and combinations of patterns used to create game schedules, according to the rules of the game. Finally, in games between the groups, all students understood the use and combination of programming patterns in the game that was running. Thus, we consider that the experience using collaborative games with concrete materials has been successful in teaching and learning computer programming based on patterns.

In the process of creation, all groups created effective activities for work and gaming programming patterns, proposing activities relevant. Regarding originality in the creation of games, groups 3 and 5 activities created fully original. The games created by groups 1, 2 and 4 were adaptations of games already known by the students.

It is worth noting that adjustments were made in the games through a combination of a game already known by the students, with the increase of tasks or steps to highlight the connection between the game and programming patterns. In the games created by groups 3 and 5, the activities and proposed solutions were beyond what was requested, with a higher degree of innovation compared to other groups.

As the first step of the study, we did two evaluations at the end of the third and fourth quarter 2012. The simple average of the third quarter, on a scale between 0 and 10 was 7.31 and the fourth quarter, 7.52. The results were greater than in the first quarter.

IV. ANALYSIS OF THE INTERACTION AND PARTICIPATION IN THE GAMES CREATED BY STUDENTS

For the analysis of the interaction and participation in games created, we have adapted four categories among the 10 based on Newman, Webb and Cochrane`s model [15]. Following we describe the four categories.

Category 1. Relevance: Relevant states or diversions.

Category 2. Novelty, new info, ideas and solutions: New problem related information or repeating what has been said.

Category 3. Ambiguities; clarified or confused: Clear statements or confused statements;

Category 4. Practical utility (grounding): Relate possible solutions to familiar situation or discuss in a vacuum.

Considering the category 1, the relevance was strongly identified in groups 1, 2, 3 and 5. In group 4, some diversions were identified. We believe this occurred because the characteristic of the game created utilized an strategy for elimination of opponents and some degree of brute force boys to play the game. Even at any given time, some female students refused to participate in the activity.

With respect to category 2, all games were created, both in its creation and in its implementation, innovations, new ideas and solutions. Highlighting the activities present in games created by groups 2, 3 and 5. In these games, besides taking into account the patterns of programming, students were led to think about how to solve the problems encountered in game shape, trying new strategies and interacting with them in search of the best group performance.

In category 3, ambiguities were detected mainly in game created by group 1. Although ease in execution of the game, by using combinations of patterns more complex schedules, for example, the pattern loop and a half inside another loop and a half, leading to ambiguous interpretations, where students on some occasions could not identify which the bonds were being executed in this game, teacher intervention was necessary at various times due to these factors. Ambiguities were also identified in game created by group 2. We believe that these ambiguities arose during the game due to activity count with 14 players in each match, which also made necessary the intervention of the teacher to clarify that the pattern used at any given moment of the game was different from that identified by the student. In the games in groups 3, 4 and 5 we did not detect problems with ambiguity, perhaps because these games use less complex combinations of patterns than in groups 1 and 2.

In category 4, the practical usefulness with respect to programming patterns was identified in all groups. As in all games the teacher related patterns with lists of programming exercises to be solved in the computer lab, students and even commented related relationships between certain stages of the game with certain exercises.

V. CONCLUSIONS AND FUTURE WORK

In this paper we present and compare two approaches for teaching computer programming based on patterns for high school students in integrated mode. The first approach used only the POI approach. The second approach was made using the POI approach together with collaborative games using concrete materials in a non-formal environment for teaching computer programming. Considering the motivation to learn programming, the second approach proved to be very promising with respect to the first, considering the age and socio economic cultural level of the students involved in the study.

We could observe that the work done outside the classroom and computer lab, contributed greatly both to stimulate the creative process and the students' motivation to learn computer programming. We also had an increase considering the notes of the first half of the semester. In the first half of the semester the average was 6.32 and the standard deviation was 1.986. In the second half of the semester the students obtained an average 7.41 and the standard deviation was 1.394. There was a significant increase of 17.42% on average between the two semesters.

The profitable interactions and participations were identified in all the games created by the groups. However, the level of interaction and participation depended on several factors. The first was that, regardless of the materials used, the more students involved in the games, the greater the participation of the whole class. In games such as Group 1, which had only three players per round, attention, both with regard to the game as with respect to programming patterns were lower. Already in the second group match, who counted in each round, with 14 players, so the attention of the students who participated in the game, as the students who were outside, was superior.

In future work, for achieving stronger results, we will perform other pre-post case studies, using the same test in both stages. We will also study the use of concrete materials and collaborative games in teaching of object-oriented programming to high school students in integrated mode.

***Abstract*— This paper describes the Digital Culture BA degree: an engineering-arts undergraduate curriculum that combines competency-based education (CBE) and knowledge-oriented education (KOE) structures and related Pull-Push approaches. The degree has been offered for three years at Arizona State University, has 200 enrolled students and is continuing to grow. The degree embeds nine knowledge-oriented concentrations, each offered by a relevant participating department, within an interdisciplinary CBE context. The CBE part of the degree provides customized access to 40 interdisciplinary digital culture courses from 12 different academic units by connecting these courses through a set of core competencies. Access to courses is not determined by fixed prerequisites but rather by having one of several possible combinations of lower level competencies. This flexible curriculum is attractive to students, promotes integrative collaborative learning that inspires innovation, and prepares the type of engineering-arts experts and complex problem solvers that are currently needed in creative industries. This type of degree also presents several important challenges for educators and administrators. To address these challenges we developed project based assessment approaches, custom web-based software for advising a very diverse student body, as well as online tools for facilitating peer critique and feedback in large creative classrooms.**

Keywords*— *interdisciplinary; engineering; arts; media; competency-based education

I. Introduction And prior work

In a recent interview for the Sunday New York Times [1], Tony Wagner of the Harvard Graduate School of Education, identified three "reinvented" colleges where students are trained to innovate: The Olin College of Engineering, The MIT Media Lab and the D School at Stanford. One similar characteristic of these three programs is that all three combine training in engineering and arts. (Engineering in this paper will be used broadly to connote both engineering and computing. Similarly Arts will be used to connote design, architecture, media arts and visual and performing arts). Research and education that bridges arts and engineering has long been associated with innovation. Industry examples of engineering-arts induced innovation include Apple Computer [2], Bell Labs [3], and Pixar [4]. The Beyond Productivity Report of the National Academies [5] identified education and research activities that bridge arts and engineering as a catalyst for innovation and creativity in the 21st century. The report predicted the continuous growth of creative industries that rely on the merging of arts and engineering expertise [social media, interactive computing, games, mobile design etc.]. The increased merging of engineering and the arts is part of a bigger trend. There is growing evidence [6,7,8] that the complex problems of the 21st century can not be solved through exclusive reliance on STEM approaches. The technological and scientific dimensions of complex problems have to be addressed in tandem with the many human-centric dimensions of these problems. Such holistic and innovative solutions require diverse teams that combine humanist and scientific skills and perspectives [9, 10] and can address in an integrative manner quantitative and qualitative issues [11].

Accordingly, in the past 15 years we have witnessed a rapid increase in the number of undergraduate [12] and graduate programs [13] that merge engineering and arts perspectives, with the goal of preparing students to collaborate in diverse teams, produce innovations with direct real world impact, contribute to the growth of creative industries and solve high dimensional problems. We see a growing support for liberal education [12] and the emergence of federal (Creative IT), industry (Intel, EA) and private (Mellon, MacArhur) funding streams dedicated to education efforts that bridge the arts and engineering. The proliferation of studio pedagogy in engineering [14, 15] is one of the most obvious educational benefits of the increasing connections between arts and engineering. The use of studio pedagogy as meeting ground for arts and engineering practices is also benefiting arts education. It is promoting evidence-based, quantitative analysis and assessment of studio training [16] and of arts-based training overall [17]. However, the complex cultural differences between the arts and engineering fields have also produced challenges both in industry [18] and academia [12]. Engineering and arts differ in key parameters. The fundamental knowledge basis for engineers and artists are fairly distinct as engineering starts from science principles and arts from aesthetic and form construction principles. The trees and branches of knowledge, or tool boxes [9], of engineering and arts, do not have significant overlap and thus require sequences of learning that are fairly independent. The "traditional axiom in engineering education is learn the basic sciences, then learn the applied sciences and then reduce this knowledge to practice" [14]. Where as arts training does all three concurrently, with practice starting even before basic theory is well understood. Engineering training focuses on "derivative innovation" (derived by applying knowledge of existing scientific principles) [14] whereas arts training focuses on originality (where creative outcomes start from blank pages). Much of engineering education and research focuses on increased efficiency and productivity, whereas arts training focuses on contemplation and meaning [19, 20]. Although engineering and arts use some similar terminology (especially in media arts contexts), in many cases these terms arise from different ontologies and thus their usage leads as often to misunderstandings as to connections [21]. For example, in collaborative development of interactive systems for neurorehabilitation, a bioengineering student uses the term "effective feedback" to denote an accurate and simple (easy to comprehend) mapping between a body movement parameter and a constructed information stream that may promote self-assessment by the user. For the arts student "effective feedback" is an information stream with formal and aesthetic characteristics that engage the user in a purposeful meaning-extraction interaction [22]. All these differences, make the combination of engineering and arts within a traditional curriculum challenging.

II. Key design concepts of the Digital Culture Curriculum

Most traditional curricula are examples of knowledge oriented education (KOE). Such curricula focus on the principles and concepts that need to be learned in each discipline [23, 24]. KOE curricula often follow a "push" model where the student follows a constrained pre-structured path that covers all key concepts of the discipline [25]. A KOE-Push approach may serve well the transmission of established knowledge in a discipline (it can produce engineers that know all the basics) and the combinatorial transmission of established knowledge in closely interrelated areas (it can produce bioengineers that know the basics across biology and engineering). However, KOE approaches can not produce combinatorial curricula across arts and engineering since the areas are distinct in purpose and knowledge structure. To train good artist-engineers through a KOE approach requires two parallel majors [26]. Although this approach can cover the basics in both areas it does not address comprehensively the issue of integrative engineering-arts education.

Integrative curricula across engineering and arts, especially when related to evolving application areas (like new media), require a combination of competency-based education (CBE) and knowledge-oriented education (KOE) and a related combination of Pull-Push approaches. CBE focuses on "why something has to be learned and how it can be used in solving a complex problem" [23, 24]. CBE focuses on allowing students to "pull" the knowledge they need on demand to solve "authentic" complex problems relating to their future work [27]. In the 21st century, CBE is evolving to allow this "pull" to occur through many new channels (like online learning or peer to peer learning) rather than through only traditional lectures in classes [28].

Because CBE focuses on complex problem solving, and complex problems are better solved through diverse teams, many contemporary CBE curricula include significant collaborative projects components. Collaborative teams that include many differing perspectives can better avoid getting stuck in local minima [9]. In such teams, a collective expertise for solving the problem tends to emerge from the interactions of team members [29]. CBE is thus well fitted for structuring effective integrative engineering-arts curricula. The diversity of purpose and concepts of these two areas becomes an advantage within the context of authentic problem solving [4] rather than a friction point within KOE which focuses on learning of fundamental disciplinary concepts. However, teams can only solve problems effectively if each member possesses adequate individual expertise in their area of knowledge [9, 30].

We therefore structured an engineering-arts curriculum, the Digital Culture BA, that embeds different KOE concentrations within a CBE context. Students bring the expertise gained through their disciplinary concentration into a network of interdisciplinary courses and projects that are connected through a common list of competencies. In the next section we present three key components of the implemented Digital Culture curriculum: the structure of the degree and its enrollment data, the online tool that helps students customise their paths through the degree, and Critviz - an online tool that helps expand the concept and capacity of the studio based classes of the Digital Culture curriculum so that the studios can bring large numbers of diverse students together to perform authentic tasks. We conclude with a section on lessons learned.

III. Results

A. The structure of the degree and enrollment data

The digital culture degree provides interdisciplinary engineering-arts training for students interested in careers in 21st century creative industries: social media, media arts, interactive computing, multimodal digital communication, responsive environments, games, mediated learning, theme parks, and more. 120 total credit hours are required for completion of the Digital Culture degree. They are allotted as follows: 49 hours of Digital Culture core credits, 30 hours of concentration credits and 41 hours general studies credits. There are nine available concentrations (see Table 1).

Concentration credit hours are earned through a sequence of 10 three credit courses aimed to give the student fundamental expertise in a contributing disciplinary area of digital culture. For example students in the Media Processing concentration can complete a path of EE courses focused on signals and systems, or a CS path focused on data structures and algorithms. The student can select their 13 Digital Culture core courses from a menu of 40 courses provided by 12 different academic units spanning the Schools of Engineering, Design, Arts, and Social and Cognitive Sciences. Twenty of these courses were newly developed to address key digital culture topics (e.g. Animating Virtual Worlds, Physical

Computing, Motion Capture for Interaction) in an interdisciplianry manner. The remaning 20 digital culture courses were exsiting courses that were adapted to fit the digital culture rubric. All 40 digital culture courses are connected by a set of 27 core competencies (proficiencies) developed by faculty of the participating units with input from industry partners (see Table II).

Table II Competencies

These 27 competencies are diverse and represent key knowledge components of 21st century creative industries. Individual courses provide competencies at various levels (a 300 level course produces 300 level competencies). Access to each course is not determined by fixed prerequisites but rather by having one of several possible combinations of lower level competencies. Completion of each course provides a student up to four new competencies, which further "unlock" access to more advanced courses. The same proficiency can be gained through courses in different disciplines. For example, the "modeling and inference" 300 proficiency can be gained through a 300 level computer science, industrial design, digital music, or anthropology course, meaning students can gain entry to courses via radically different paths. Therefore, the same upper level course can be reached through multiple paths. (See Table II for a list of competencies and their freqeuncy of use in connecting coures).

The Digital Culture degree acknowledges that the same competency can have multiple instantiations generated by different ontologies or related trees of knowledge. Instead of trying to resolve these differences in favor of one generating ontology, the degree (and its constituent collaborative courses and projects) leverages this diversity of perspectives for exploring the multidimensionality of complex problems, generating innovative insights, and preparing students to work in diverse creative teams. This of course generates a challenge for the instructors. In a traditional disciplinary learning hierarchy [23], the instructor can expect a relatively uniform cohort of students who have acquired a particular competency through the practical application of a constrained set of skills, and knowledge acquired through a predefined learning sequence. In the case of Digital Culture courses, the student cohort is very diverse in terms of skills and knowledge (and interpretation of competencies) since students come from different disciplinary concentrations of the degree and have followed different paths to the courses. Thus Digital Culture core courses can not focus on teaching of specific basic skills. Basic skills a student needs are covered by the disciplinary courses provided by the concentrations (and in the case of cross training skills by remedial courses - see lessons learned), or by a student initiated knowledge "pull". The Digital culture courses focus on meta skills: how different competencies (and generating ontologies) can be combined to solve complex problems - with special focus on 21st century creative industry contexts. As students advance through the degree their understanding and application of competencies improves which is why a competency is offered at different levels (200, 300 etc).

Let us look at an example that illustrates the relation of skills to competencies in the Digital Culture degree. Table III shows three competency combinations that open access to the 300 level course on Compositional and Computational Principles for Media Arts. The instructor can expect that all students will be able to apply computational tools to media authoring and have some 200 level experience with computing but can not expect specific programming skills from all students. The instructor can expect that all students have composed a visual and/or sonic and/or text based work but can not expect that all students have specific composition skills in one of these areas (i.e. 3D computer animation). The instructor can also expect that all students have experience either in improvisatory performance or rapid prototyping. The outgoing competencies are Communication and Networks 300, Computational Media Analysis 300, Embodiment and Kinesthetics 300, Performance and Interaction 300. This denotes that the instructor will focus on combining the existing skills of the students toward developing interactive embodied media systems, as well as placing these systems in a historical context. The instructor will not be directly teaching computer coding or formal principles for narrative tension and release. It is assumed the students already have these skills and if not they will "pull" them by their own initiative through an online resource or peer to peer approach. Furthermore, the course will help students contextualize some of their required disciplinary training achieved through their chosen concentration and inform their remaining selections of Digital Culture core courses.

Path 2	Path 2	Path 3
200 Computational Tools	200 Computational Tools	200 Computational Tools
100 Narrative Construction	200 Form and Composition	200 Form and Composition
200 Performance + Interaction	200 Improv and Iterative Design	200 Performance + Interaction

Table III: Competencies for 300 level media computing course

Each student over time accumulates a proficiency collection representing a unique pathway which can be analyzed and used as a customized guide, pointing the student to specific types of research opportunities (junior year) and capstone projects (senior year) eventually leading to employment opportunities best fitted to their particular set of interests. The key mechanism used by faculty to assess performance and progress is the inclusion of collaborative projects in each core course [28]. A senior year capstone project is the overarching mechanism used to demonstrate the training provided by the Digital Culture degree. Creative industries place significant weight on what future employees can actually produce and on their ability to collaborate in diverse teams for catalyzing innovation [5]. In course evaluations, students rate each course not only for its content but also on how the course engaged the expected incoming and outgoing competencies. This data, in combination with data from the paths students have chosen, allow instructors to assess the status of the digital culture network in terms of overall course and competency usage and in terms of efficient generation of listed proficiencies (edges) by each course (node).

The digital culture degree was launched two and half years ago. There are currently 165 students enrolled in the digital culture BA and based on current admissions data that number will grow to 220 by next Fall (see Table II). It has been challenging to advise so many students, each with a different concentration, a different custom path and a different background. In response we have developed the online digital culture visual planner (presented below) to assist students with exploring future alternative paths and to encourage them to participate in their advising. The significant weight placed on collaborative projects throughout the digital culture degrees creates a significant review and assessment challenge. As discussed earlier, studio based pedagogy is a very effective way to to bring engineering and arts students together but it is a hard model to scale as it requires continuous hands on mentoring and review of process and product [14]. We have developed a online studio/peer critique tool (also presented below) to assist us with scaling the studio model to large number of students.

B. The Digital Culture Visual Planner

The Digital Culture Visual Planner is an interactive web based interface for students to visually explore possible pathways through the DC curriculum. The system is personalized, it knows which classes each student has already taken and thus which competencies each student has obtained. The system also knows which classes are being offered in future semesters several years in advance and the associated competencies those courses require. Using this information, the tool visualizes for each individual student the landscape of future pathways he or she might take towards graduation. The student can make hypothetical decisions about which courses to take next, and see various subsequent pathways open or close. The student can explore the long range implications of taking one class versus another, safely trying out various pathways through the curriculum. Finally, as the student actually sets out following a path, leading to internships, capstone projects, and onward to a job and a career, they leave a trail of "breadcrumbs" so that newer students can see where these paths may extend to beyond the courses themselves.

The interface for this tool is quite simple. The screen has two main panels. The first panel shows a list of all the possible competencies in Digital Culture, with highlights over the competencies already obtained by the student. A second panel shows a semester by semester list of course offerings. These two panels are interactively linked to each other. Rolling the mouse over elements in one panel will highlight related elements in the other. For instance, rollover a specific course and the competencies related to this course will highlight. Or, rollover a specific competency and all the courses that provide this competency will highlight in the other panel. This dual action "brushing" allows for an interactive exploration of the web of interrelationships between courses and competencies.

In order for a student to truly explore various pathways through the curriculum, the tool needs a mechanism by which the user can simulate, or create a hypothetical scenario. For this the tool allows the user to "pin" a future course, or simulate the completion of this course. A pinned course will cause a cascade of effects, adding to the students collection of competencies, and opening up all those future courses that these new competencies would unlock. As this cascade of effects unfolds, these newly opened courses look and act as though they are now available to take, but visually they retain a different look and feel to indicate to the user that these effects are due to the provisional or hypothetical "pinning" of a class. In addition, as the pinned courses open up access to new courses, these courses too can be pinned, creating a further cascade of options.

C. *The online studio crit/peer critique tool*

Our Digital Culture degree emphasizes collaborative projects and is growing fast. This leads to large classes of up to 100 students where multiple teams with diverse membership work in parallel on collaborative making. To serve this need our physical spaces are reconfigurable "maker lab" classrooms, where the boundary between the lecture hall and the fabrication shop is not clear. As instructors, we want students to acquire and hone both technical and creative skills, and although students do receive traditional letter grades, individual assignments rarely have clearly "right" or "wrong" answers. We focus on experimentation, discussion, critical thinking, invention and creative risk-taking. In this setting, making mistakes is often the very best way to learn.

The prevailing studio pedagogy model consists of few students receiving feedback and evaluation from a single [or few] expert instructor [14, 15]. This model can be ideal at a certain small scale, but as the classroom grows, the amount of attention the instructors can provide declines linearly with the numbers of students in the classroom. More students simply mean less time to spend evaluating each individual. Additional teachers or assistants can be added, but the problem of scale persists. Shifting larger classrooms to use peer critiques can alleviate this problem by increasing the amount of feedback each student receives. "Because teachers do not have time to provide extensive feedback, peer conferences are a way to engage students in meaningful formative assessment dialogues with each other" [31]. This shift however only changes the nature of the problem from that of "instructor overload" to "critique management." The bottleneck is no longer the instructor's time and attention, but how to effectively manage a large, cohesive critical discussion. These discussions can of course be distributed over multiple groups or multiple class sessions, but this fragments the class and/or leaves little time for anything but critique.

Organizing our classes around peer critique is ideal for the kinds of material we teach, but the scale of our classes presents a logistical problem. Running fully inclusive in-class critiques with 50 - 150 students is difficult in face-to-face settings. Using online tools to help facilitate large critiques is an obvious direction, so we sought a method for conducting peer critiques for our classes via the participatory web. We found existing technology for sharing and turning in student's digital projects (e.g. uploading files to BlackBoard, blogs, message boards, email attachments) less than optimal for both instructor and peer evaluation. Often these tools caused more cognitive overhead, complexity, message overload, and confusion than they were worth. It quickly became clear that there are no existing online tools designed to facilitate a large classroom critique session. We decided to develop CritViz: a system specifically intended for the purpose of facilitating high quality, real-time critique sessions for large classes.

In CritViz the instructor creates assignments which consist of descriptions of the work to be done, supporting documents, screencasts, code examples and relevant readings. Importantly, each assignment has two deadlines. One for when the work is due, and the other for when the critique is due. Students log on and see a list of assignments with large countdown timers. When the timer reaches zero (usually a week or so) students can no longer submit work. Next the critique period begins. Each student who successfully submitted work is assigned to review the work of five other students (at random), give them critical written feedback on their work, and importantly rank order the works.

We currently have 19 classes that have used CritViz, with 10 currently running it this semester, including one high school class. There are currently 618 users in the system. Since starting CritViz a year ago, 172 assignments have been created by faculty for students, and students have responded to these assignments with 6451 responses, leading to 11,010 peer critiques. We have had a total of 288,647 unique page views on the system, and are averaging over 60,000 page views per month. Through CritViz's countdown timers, assignment uploading, and randomized peer feedback, we can now run effective critiques in much larger classes. But we have also seen some unintended positive changes in overall classroom "motivational structure." Students who have used CritViz report that an audience of peers—as opposed to just a teacher—elevates their work quality and effort.

IV. LESSONS LEARNED

Student centric education works but needs to be used with care. The Digital Culture degree had 100% retention last semester. That is a very high number for any degree but particularly impressive for a large scale degree at a large scale public university where a number of students are also holding down jobs to finance their education. The degree is actually the fastest growing undergraduate major at ASU. Discussions with students have shown that the main attraction of the degree is its flexibility that allows students to custom build their paths. Other key attractive elements include the applied nature of the degree (its focus on preparing students for future jobs in creative industries) and the interdisciplinary collaboration emphasis. However, it is also becoming clear that not all 18 year-old students are ready to self-advise their career. Many students enroll in the degree (and choose a concentration) based on what they like to do rather than because of careful exploration and career planning. For example, the most popular concentration is that of Music because students enjoy listening to and making music using new media. However, for most of them making music will be an avocation not a vocation. Much of our early advising effort for these students is to emphasize the need for them to use the degree to gain strong technical skills in new media development (thus making them employable in multiple industries) rather than making music. We therefeore expect more technical concentrations (i.e. media processing), or concentrations with broader applications (desing, technology enterepreneurship) to grow in enrollment.

Interdisciplinary education needs to address basic cross-training skills. Working successfully in interdisciplinary teams requires each member to have expertise in one area [9, 30] but also many times requires members to have basic working knowledge of skills outside their expertise. For example, a specialized artist working in an interdisciplinary digital culture team requires basic programming skills to prototype their work and be able to participate actively in implementation discussions. Their preparation/concentration in the arts does not provide them with that skill. Therefore, the digital culture degree now integrates introductory courses and one credit deficiencies modules that cover basic cross-training skills (programming, rapid prototyping, 3D fabrication, principles of form, calculus).

Assessment of training through projects needs to be introduced gradually. Collaborative projects are a key training assessment mechanism in the Digital Culture degree. For students used to Knowledge Oriented Education models from high school, this can be a hard transition. The Digital Culture degree now requires that all freshman and sophomores attend a weekly presentation forum where juniors and seniors present their projects and receive critiques from interdisciplinary groups of faculty and visiting experts from industry. This introduces underclassmen to project based assessment and offers a good opportunity to upperclassmen to present their work in a friendly environment. These forums also help build community.

V. CONCLUSION AND FUTURE WORK

Interdisciplinary education that bridges engineering and the arts can prepare students who can work proficiently in diverse teams to solve complex problems in an innovative, human centric manner. The demand for such students in creative industries is increasing. Curricula that combine KOE and CBE approaches, like the digital culture degree of Arizona State University, can help bridge the differences between engineering and the arts. Such curricula are highly customizable and thus are attractive to students. Tracking of placement and career evolution of students who graduate from such degrees is necessary in order to fully assess and evolve these types of innovative degrees. Sharing of outcomes (including innovative tools like the visual planner and Critviz) may help increase the impact of efforts like the Digital Culture degree but require a forum of institutons that are willing to support the generalizaiton of tools and approaches.

***Abstract*—Health informatics is one of the nation's largest growing industries. To protect health information systems, it is extremely important for health informatics professionals to be well educated and trained in information assurance, and to understand the many concerns of security, privacy, integrity and reliability. To meet this demand, we are creating a new, interdisciplinary curriculum model of Bachelor of Science in Computer Science (BSCS) concentration in Health Informatics Security and Privacy (HISP) at North Carolina Agriculture and Technical State University (NC A&T). To establish this BSCS concentration in HISP, we developed a new course on health information systems in the Department of Computer Science, a new course on Mathematics for Health Informatics in the Department of Mathematics, and modified an existing course in the Department of Management to include topics on business practices relating to health information technology. We also developed three course modules on health informatics security and privacy and are integrating these course modules into the existing information assurance courses in the Department of Computer Science. This paper describes the new curriculum, the new courses, and the three course modules we have developed.**

Keywords—health informatics, health information systems, security and privacy, HIPPA curriculum.

I. INTRODUCTION

Health informatics is one of the nation's largest growing industries. Compared to other data intensive industries, the health care industry is underinvested in information technologies. Recently, President Obama has made the use of information technology and electronic health records a top goal to cut down costs in the US healthcare system, offering up to $27 billion in government funds aimed at speeding the switch from paper to electronic medical records [1].

Together with many other factors, mandated electronic recordkeeping and tightened patient privacy regulations are making health informatics a sought-after skill. US News & World Report named Healthcare Informatics as one of the top careers. According to Don Detmer, CEO of the American Medical Informatics Association (AMIA), the main professional body relating to health informatics in the U.S., approximately 70,000 health informatics specialists are needed [2]. According to the US Bureau of Labor Statistics, employment of medical records and health information technicians is expected to grow by more than 20% through 2018, resulting in over 207,000 jobs creation by 2018 [3].

With the government's increasing interest in electronic health records and growing investment by healthcare organizations in technology, a degree in health informatics or health information systems will give graduates some of the strongest career opportunities in today's economy. To protect health information systems, it is highly important for health informatics professionals to be well educated and trained in information assurance, and to understand the many concerns of security, privacy, integrity and reliability. To meet this demand, we are creating a new, interdisciplinary curriculum model of Bachelor of Science in Computer Science (BSCS) concentration in Health Informatics Security and Privacy (HISP) at North Carolina Agriculture and Technical State University (NC A&T).

This project is the joint effort of the Department of Computer Science, the Department of Mathematics and the Department of Management at NC A&T. To establish this BSCS concentration in HISP, we developed a new course on health information systems in the Department of Computer Science, a new course on Mathematics for Health Informatics in the Department of Mathematics, and modified an existing course in the Department of Management to include topics on business practices relating to health information technology. We also developed three course modules on health informatics security and privacy and are integrating these course modules in the existing computer security and information assurance courses in the Department of Computer Science. Such a curriculum will produce computer science graduates who have skills in health informatics, as well as skills in security and privacy in health information systems. It will also allow students in the field of nursing or health care to learn about health informatics and health information systems, allow students in mathematics to apply mathematics to health informatics, and allow students in management to learn about the business aspects of health informatics. This project leverages the strength of the existing information assurance program at the Department of Computer Science, and the existing collaboration among Department of Computer Science, Department of Management, and Department of Mathematics. The three departments collaboratively established the University's Center for Cyber Defense, a national Center of Academic Excellence in Information Assurance Education (CAE/IAE) designated by the Department of Homeland Security and the National Security Agency.

This paper describes the three new courses we developed, the three new course modules, and the new

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

curriculum of Bachelor of Science in Computer Science concentration in Health Informatics Security and Privacy at NC A&T. The curriculum model and instructional materials produced through this project can be adopted by educators in multiple disciplines such as computer science, information assurance, health informatics, information technology, mathematics, and business.

Some institutions such as Walden University [2], DeVry University [3], and University of Illinois at Chicago [5] offer bachelor's programs in health informatics. However, most of them are based either on information systems or information technology with only a few core health informatics related courses. There is not enough emphasis on security and privacy issues in health information systems. Topics like security policies, architectures, risk management, disaster recovery and business continuity, network security, and cryptography are not commonly covered by these degree programs. Knowledge of security is a key requirement for graduates to function effectively in mid- to high-level specialist positions in a health care organization. Our program is unique in that it is interdisciplinary, and it emphasizes health informatics security and privacy.

The remainder of this paper is organized as follows: Section II describes our BSCS Concentration in Health Informatics Security and Privacy. The new courses and course modules developed for the BSCS concentration in HISP are described in Section III and IV. Section V concludes the paper.

II. The BSCS Concentration In Health Informatics Security And Privacy

The BSCS concentration in Health Informatics Security and Privacy requires the following core courses:

- COMP323: Introduction to Healthcare Information Systems
- MATH 410: Mathematics for Health Informatics
- MIS640: MIS Topics
- An Information Assurance elective (choose from: COMP320: Fundamentals of Information Assurance *or* COMP321: Computer Systems Security *or* COMP420: Applied Network Security *or* COMP421: Security Management for Information Assurance)

In the regular BSCS program at NC A&T, a student normally needs four years and with 124 total credit hours to graduate [6]. The course requirements are listed by category in Table I. The proposed BSCS concentration in HISP requires the same number of total credit hours as the regular BSCS program, and the same number of credit hours in each subject category as shown in Table I.

In the 59 computer science credit hours, 9 credit hours are computer science electives. For the BSCS concentration in HISP, the 9 credit hours will be used for taking the following courses: COMP323: Introduction to Healthcare Information Systems, MATH 410: Mathematics for Health Informatics and an Information Assurance elective course. In the 27 General Education credit hours, 3 credit hours are required for approved Business Electives. For the BSCS concentration in HISP, the course MIS 485: MIS Topics will be used to satisfy the Business Electives requirement.

TABLE I. BSCS Program Requirements

Subject Category	**Credit Hours**
Computer Science	59
Mathematics	20
Science	12
General Education	27
Free Elective	6
Total	124

Currently the three new courses have been developed, and have been approved by the University. The course "COMP323: Introduction to Healthcare Information Systems" was offered in the Fall 2012 semester. The courses "MIS 48:5 MIS Topics" and "MATH 410: Mathematics for Health Informatics" are being offered in Spring 2013 semester. The BSCS concentration in HISP is in the final stage of being approved by the University Curriculum Committee. The following sections will describe the three new courses and course modules for the concentration.

III. The New Courses For The BSCS Concentration In Health Informatics Security And Privacy

This section describes the new courses we developed for the BSCS concentration in Health Informatics Security and Privacy.

A. Course 1: COMP323 Introduction to Health Information Systems

This course introduces broad aspects of health care information systems. The goal is to prepare students with knowledge for effectively managing health care information systems. The main topics of this class include: types of health care information and data, regulations, standards, and laws of health care information, history of health care information systems, main features of EHR systems, information technologies in health care information systems, health care information systems certifications, security in health care information systems, and management of health care information systems.

This course was offered in the Fall 2012 semester for the first time. The textbook is Healthcare Information Systems by Karen A. Wagner [7]. Four projects were given to the students. These projects are described below.

Project 1

Research available job openings in Healthcare Information Systems (Informatics) or closely related areas. Find one or two job types that most interest you. Find out what the education requirements and skills needed for the job(s) are. State why you are interested in this/these particular job(s).

Project 2

Search the Internet and find five healthcare information system vendors that offer EMR products. Compare and contrast the functions and features of each product. Submit at least a three- page report explaining your findings. Also submit a presentation slide for your homework.

Project 3

Search the Internet for health organizations and find out which ones are using Web 2.0 technologies to establish connections with patients or other consumers. Describe how they are using Web 2.0 technologies.

Project 4

This is a hands-on project on using an open source health information system (OpenEMR [8]) to create a health care practice and keep track of patients' medical records. The detailed description of the project is as follows.

In this project, you are given the following scenario:

For the past two weeks, Travis has been having severe headaches. He decides to schedule an appointment with Dr. Gregory Wallace at McLeod Health Center for the 25th of November. On the day of his appointment, Travis arrives and checks in with the front desk clerk, Ms. Susan Jones. Because this is his first visit, Travis must be added into the system. After giving all of his information to Ms. Jones, Nurse Wise calls him to the back and begins filling out a new patient encounter form for him. She checks his vitals, family history, and enters a brief consultation description. She then walks Travis into exam room 4, where he waits for Dr. Wallace. Dr. Wallace enters the exam room after about twenty minutes and begins the examination. He asks Travis about his migraines, and asks many other questions. Dr. Wallace concludes that Travis needs a prescription for apaprox. He is given a prescription for 30 pills of 200 mg that he is to take in the morning orally. Travis then walks to the front desk to pay for his visit and to get a receipt. Ms. Jones informs Travis that because of his insurance he only has to pay a co-pay of $25.00. Travis pays his co-pay and takes his receipt and leaves to go pick up his prescription.

You are to create Travis's visit from beginning to end using OpenEMR. You must accomplish the following tasks:

- Create a practice
- Create a pharmacy
- Create three users: Dr. Gregory Wallace, Nurse Patricia Wise, and Ms. Susan Jones
- Create patients demographics
- Enter patient vitals
- Enter patient history
- Enter prescription
- Enter Patients receipt

B. Course 2: MIS485 MIS Topics

This course is a capstone course for undergraduate MIS majors and for other students who are interested in MIS topics. It focuses on emerging information systems (IS) and information technology (IT) topics. The topics covered in this course may vary from business data communications, the business practices relating to health information technology, health informatics, Internet security and privacy, electronic business and electronic commerce, data mining and data warehousing, strategic information systems, IS/IT project management, to IT infrastructure.

This course is being offered in Spring 2013. The textbook for this course is "Handbook of Informatics for Nurses & Healthcare Professionals" (5th edition), by Toni Lee Hebda and Patricia Czar [9]. This course covers the following main topics:

- Informatics in Healthcare Professions
- Ensuring Quality and Best Use of Information
- Professional Use of Electronic Resources
- Healthcare Information Systems
- Selecting a Healthcare Information System
- Information Security and Confidentiality
- System Integration and Interoperability
- The Role of Standardized Terminology and Languages in Informatics
- Telehealth
- Evidence Based Practice and Research

In this course, each student is assigned with a group of articles that focus on one area in Health Informatics. For each article, he/she is required to cite one paragraph that best represents the spirit of the article, and then write a 1-2 page proposal for corporate use of Health Informatics using the concepts/techniques/models provided in these articles and relating them to the lectures. Based on the given articles each student will prepare a presentation that summarizes those articles in 15-20 minutes.

This course was taught in the Spring 2013 semester. The instructor's observation of this course is that, Health Informatics topics were well received by the students. Students are aware of the demands of IS/IT in health industry, the importance of health informatics, as well as the shortage of healthcare IS/IT professionals.

C. Course 3:MATH410 Mathematics for Health Informatics

This course examines the mathematics of health informatics. It covers mathematical core competencies that are needed for advanced research in health informatics. Topics include cryptography, biostatistics and linear programming. In addition the course covers new developments in the application of mathematics to health informatics privacy and security.

This course was offered in the Spring 2013 semester. It covers the following topics:

- Descriptive biostatistics and sample distribution
- Probability distributions and Estimation
- Testing hypothesis, regression analysis, nonparametric and distribution-free statistics
- Heath information privacy and security

Four projects are assigned to the students. They are described below:

- *Project 1*: This project involves writing R programs to compute basic statistic such as mean, variance and percentiles, and plotting statistical graphs. R is a free programming language used for statistic computing and graphics.
- *Project 2*: This project involves using R packages abd, asbio and tsmodel, and analyzing breast tissue data.
- *Project 3*: In this project, students use R for Poisson distribution, Estimation and Hypothesis testing.
- *Project 4*: In this project, students select a topic on their own in health information security and write a paper on that.

The instructor found it challenging to teach and design suitable projects for students. Students seem engaged and excited about the topics covered and the projects given in the class.

IV. The Course Modules

A. Course Module 1: Health Information Assurance and Security

This course module introduces information assurance as it relates to health information systems. It discusses laws including Pre-HIPAA (Health Insurance Portability and Accountability Act) legislation, HIPPA, Gramm Leach Bliley Act, Sarbanes-Oxley Act of 2002, Patient Safety and Quality Improvement Act of 2005, and Health Information Technology for Economic and Clinical Health (HITECH). It also investigates strategies and process models for securing information and discusses information assurance and security industry standards such as ISO 17799, Control Objective for Information and Related Technology (COBIT), the Health Information Trust Alliance (HITRUST) Control Security Framework (CSF), ISO/IEC 27002:2005, ISO/IEC 27001:2005, ISO 27799:2000, NIST (National Institute of Standards and Technology) Special Publication 800-53, ISO 27799:2008, ISO 17090:2008, and ISO/TS 25237: 2008 [10, 11]. A number of scenarios or mini-case studies are designed to help students have deep understanding of HIPPA. An example scenario is listed in Table II.

This course module was integrated into the existing Computer Science course "COMP320 Fundamentals of Information Assurance," in the Spring 2013 semester.

B. Course Module 2: Access Control in Healthcare Information Systems

This course module introduces Role-Based Access Control (RBAC) based on the NIST model [12], and exposes students to current open source health information systems OpenMRS [13]. The NIST RBAC model is organized into four step sequences of increasing functional capabilities, which are Flat RBAC, Hierarchical RBAC, Constrained RBAC, and Symmetric RBAC [12]. A series of scenarios are developed to assist students to understand the above four types of RBAC models. Some scenarios are used for in-class discussion, and others are used as homework. An exemplified scenario and discussion questions are listed in Table III [14].

TABLE II. AN EXEMPLIFIED SCENARIO FOR TEACHING HIPPA

Scenario: *Joe applies for a job in a robot factory and must take a pre-hire drug test. Before taking the test, he signs a HIPAA authorization allowing the drug test results to be given to the factory. While taking the test, one of the lab technicians notices that Joe is exhibiting symptoms of another medical problem. When she tells Joe about her observations, Joe decides to take another test. Unfortunately, this second test reveals that Joe has a serious illness.*
Question: *Under HIPAA, should the technician disclose this information to the factory?*

TABLE III. AN EXEMPLIFIED SCENARIO FOR TEACHING HIERARCHAL RBAC

Hierarchical RBAC Scenario: *Because a Doctor role can create a Secretary role, Doctor Kelly makes a Secretary role for John a new hire brought in to update patient information. Often, Larry logs in as an LT (Lab Technician) and performs his assigned lab procedures. Doctor Hart is a Doctor. However, Doctor Hart's thirty years of experience has allowed him to be selected as the hospital administrator and is thereby responsible for all hospital staff. He now logs in as a HA (hospital administrator) role.*
Questions: *1) Map out the roles connecting them with lines in either a tree or inverted tree structure. Next, map the users to the corresponding roles.* *2) Can a Doctor share resources with an LT? Explain why or why not.* *3) Could Doctor Hart, while in the HA role, create a Secretary role like Doctor Kelly did?*

Student will be asked to create roles and permissions on the OpenMRS system given a scenario. The students will also learn how RBAC is implemented using J2EE architecture in OpenMRS.

This course module was also integrated into the existing Computer Science course "COMP320 Fundamentals of Information Assurance" in the Spring 2013 semester.

C. Course Module 3: XML Security in Health Information Systems

This course module provides a basic introduction to XML (Extensible Markup Language) which is widely used in representing health information. Health Level 7 (HL7) versions 3, whose specifications are completely based upon XML is introduced. HL7 is a non-profit organization that provides standards for the exchange, integration, sharing, and retrieval of electronic health information that support clinical practice and the management, delivery and evaluation of health services. Techniques used to secure the data being transmitted in XML format, such as XML signature, and XML encryption are discussed [15].

As a case study, the students are also introduced to Microsoft HealthVault [16] – a cloud based system that helps people collect, store, and share health information with family members and participating healthcare providers. It connects with a variety of third-party applications and devices to help people manage their fitness, diet, and health data. The students will learn how health information is represented in XML format in Microsoft HealthVault. This course module will be integrated into the Computer Science existing course "COMP621 Web Security."

V. Conclusion

This paper describes the new curriculum of Bachelor of Science in Computer Science (BSCS) concentration in Health Informatics Security and Privacy (HISP) we are developing at NC A&T. This is through the joint effort of three departments: the Department of Computer Science, the Department of Mathematics, and the Department of Management. For this interdisciplinary program, three new courses and three course modules have been developed. These new courses and new course modules are described in this paper. One course was taught for the first time in the Fall 2012 semester, and the other two new courses are being taught in the Spring 2013 semester. One course module has been taught, and two course modules will be taught in the near future. The BSCS concentration in HISP is being approved by the university. Our future work will include advertising this program to computer science students, as well as advertising the new courses to students in related disciplines such as mathematics, management, information systems, nursing, biology, etc.

Abstract—*AIRSPACES (Air-propelled Instrumented Robotic Sensory Platform(s) for Assateague Coastline Environmental Studies) project funded by the Maryland Space Grant Consortium (MDSGC) provides a model platform to involve a multidisciplinary team of Science, Technology, Engineering, Agriculture, and Mathematics (STEAM) students in a challenging experiential learning and research endeavor that promotes active learning in field and laboratory settings. The overarching goal of the project is to develop an autonomous surface vessel to collect and map selected water quality variables, geo-located with GPS sensors in lakes and ponds on campus, as well as Assateague and other nearby coastal bays for further scientific analysis. The project has been adapted for undergraduate students; however, outreach efforts by engineers and scientists at NASA Wallops Flight Facility have provided an overview of expanded scope of the goals and objectives that may be addressed in a professional setting.*

Keywords—STEAM; Multidisciplinary; Robotics; Active and Experiential Learning; Environmental Studies

I. INTRODUCTION

During a NASA-ASEE Summer Faculty Fellowship at NASA Goddard Space Flight Center's (GSFC) Wallops Flight Facility (WFF), the primary author had been involved with a preliminary feasibility study and simulations for an under-actuated Surface Autonomous Vehicle (SAV) under the auspices of the OASIS (Ocean Atmosphere Sensor Integration System) project [1]. The OASIS project goals are aimed at gathering oceanographic data. It has been adapted and modified to form the basis of the AIRSPACES project with the overarching goal of involving a multidisciplinary team of undergraduate STEAM majors to design and develop smaller SAV platforms instrumented with GPS, compass, and several water quality monitoring sensors that may be deployed in lakes, rivers, and bays in low to moderate wind and current. While design efforts of the project are led by engineering, engineering technology, and computer science students, the scientific objectives of the project are delineated by involved faculty in the School of Agricultural and Natural Sciences (SANS). Undergraduate and graduate students from SANS biology and food sciences program at UMES are also encouraged to participate in the project and deploy the designed platforms to collect and map water quality data in locations of interest. Besides STEAM students at UMES, an exchange student from the University of Maryland College Park (UMCP) also worked on the project in the summer of 2012 and made significant contributions. Johns Hopkins, the lead institution of MDSGC coordinates a summer exchange program for engineering students enrolled at minority serving institutions (MSI) in Maryland that includes Morgan State, UMES, and UMCP. In 2012 summer, the exchange program supported two students from each campus to work on existing NASA related project at one of the other campuses.

NASA engineers and staff have also revived a dormant internal project at WFF titled, ROVER (Remotely Operated Vehicle for Environmental Research) and have integrated experiential learning of undergraduate students in cross-disciplinary teams as a predominant emphasis in the endeavor. To this end, the lead NASA engineer of the ROVER project and supporting staff developed a kit for a remote-controlled SAV platform and provided the kit to the project team at UMES in 2012 summer. The UMCP exchange student worked with UMES students to assemble the mechanical and electrical components (Figure 1) to construct the remote- controlled *ROVER X-2* platform. The ROVER baseline design uses electric ducted fan propulsion to maximize safety and minimize corrosion and *fouling* (Figures 2a and 2b). Remote control is accomplished using a

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

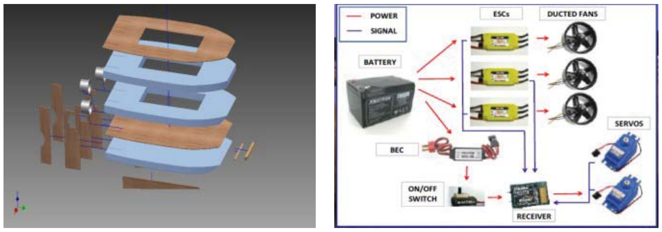

Figure 1 : Rover Kit (Mechanical and Electrical)

75 MHz radio control system, with two receivers onboard for redundancy and increased reliability. Steering is provided by a pair of rudders that deflect water and air in

Figure 2a: CAD solid model Figure 2b: R/C ROVER X-2

forward operation, and deflect water in reverse mode. For the initial phase, a LABQUEST 2 interface [2] was utilized to collect geo-located water quality data such as salinity, pH, dissolved oxygen (DO) and temperature with Vernier sensors [3] on the boat (Figures 3a and 3b). Subsequently,

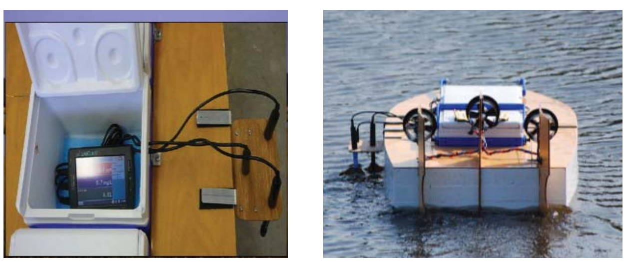

Figure 3: LABQUEST 2 interface with Vernier Sensors on ROVER X2

efforts were also devoted in 2012 summer to replace the LABQUEST 2 platform with GPS integrated ARDUINO microprocessor board [4]. The Vernier sensors were interfaced with the ARDUINO board and the readings were appropriately calibrated. Utilization of the ARDUINO board will lend itself favorably to evolving the ROVER X-2 to a fully autonomous surface vessel for gathering water quality data. Besides lakes and ponds, the ROVER X-2 can be deployed in rivers and coastal bays for long duration (2-hours) in low to moderate wind and current, and could potentially be utilized for ground-truthing satellite data.

II. STUDENT LEARNING, CROSS-DISCIPLINARY COLLABORATION AND TEAMWORK

UMES students have also independently designed and developed a smaller autonomous surface vessel which they call, “Shrimp” (Figures 4a & 4b) under the auspices of the AIRSPACES project. Shrimp has a single propeller and a rudder system for navigation and can be deployed in the autonomous or remote controlled navigation mode in lakes and ponds in low wind and current.

Figure 4a: UMES Shrimp

Figure 4b: Shrimp deployed

A LEGO-NXT brick is utilized for logging GPS and Vernier sensor data in both modes of operation. In the autonomous mode, the GPS and compass units specifically developed for NXT bricks by Dexter Industries [5] are used. NXT code is developed using NXT-G graphical programming as well as ROBOT-C. A multiplexer has been acquired and is being interfaced to a sensor port of the NXT to allow incorporation of additional water quality sensors on the “Shrimp” platform.

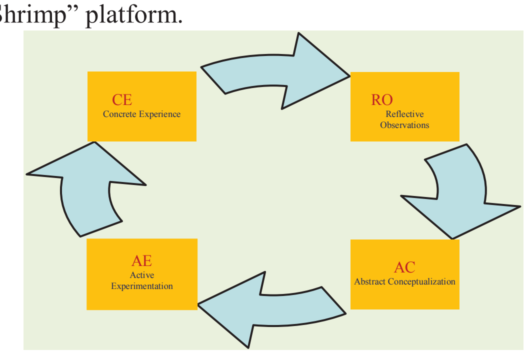

Figure 5: Kolb’s Experiential Learning Cycle

Although the “Shrimp Boat” designed by the students can only be deployed in lakes and ponds under low to moderate wind, it encompasses a rich set of learning outcomes that may be desired by future employers, including NASA. While no formal framework is used to structure the project activities, project leaders have made efforts to integrate all aspects of the Kolb’s experiential learning cycle (Figure 5) [6] to move the project goals forward. From the inception of the project, the student participants hold weekly meetings and discuss success and pitfalls with the action items from the previous week and set goals for the following week. The faculty supervisors are present at these meetings for advice and to ensure the project remains on track, but senior students are encouraged to take leadership roles and to keep a vibrant vertically integrated group together. Interested engineers, scientists, and staff from NASA Wallops Island facility which is about 70 miles from UMES campus are invited to attend these meetings.

III. ONGOING EFFORTS AND RESULTS

The data collected using LABQUEST 2 on the ROVER X2 needed significant post processing to retrieve data related to

Figure 7a & 7b: Desired and actual path followed by boat

specific points of interest. This was one of the reasons why efforts were devoted in the latter half of summer of 2012, to use ARDUINO UNO with an independent GPS shield and input pin interfaces to read Vernier sensor data. In all circumstances appropriate measures were taken to calibrate the sensor data. Use of the ARDUINO microprocessor to collect geo-located sensor data also provided the basic foundation for making the ROVER X2 fully autonomous. Student transitions have slowed these enhancement efforts that are currently ongoing.

Figure 7 c: Temperature data recorded at desired locations

Similar data collection efforts were undertaken with the "Shrimp" running on remote control in water bodies within the UMES campus. However, from the very inception efforts were undertaken to make the Shrimp platform autonomous. To this end, a compass sensor was used in conjunction with the GPS sensor for autonomous navigation. NXT brick used with this configuration was utilized for the trial run in one of the ponds in Ocean City, Maryland, close to campus in the late summer of 2012 as illustrated in Figures 7a, 7b, and 7c. Five GPS points were selected in the pond. The points were connected by straight lines as shown in Figure 7a to describe the desired path. In this trial run, a proportional control was used to turn the rudder depending on the heading error. Figure 7b shows the GPS track actually followed by the Shrimp to get to the desired locations as it fights wind, current, and other disturbances. Although path followed is not accurate, the desired locations are reached, and temperature data are collected at appropriate locations as shown in Figure 7c.

Geo-located sensor data could be conveniently displayed using the cloud based GPS Visualizer software which is available online free of charge [7]. Participating students could easily use the tool with minimal instructions.

The ROVER X2 successfully negotiated the coastal waters in the Assateague Bay under remote control. Interested readers can watch the video footage at the URL: http://www.youtube.com/watch?v=9yUGZkYGhQ&feature=youtu.be.

Complete autonomous operation of the ROVER X2 using ARDUINO board is one of the key aspects of future plans. Due to limitations in the NXT sensor ports it was not possible to log more than one water quality variable using the only available sensor port during the initial autonomous runs of the Shrimp. Efforts are now underway to appropriately interface a suitable multiplexer to the available port attach upto four Vernier water quality related sensors to the Shrimp platform. Efforts are also underway to improve the control algorithm for the autonomous navigation of the Shrimp.

IV. CONCLUSION

Intense STEAM courses particularly in engineering, mathematics and, the sciences fail to inspire students. The informal out-of-classroom setting of projects such as AIRSPACES allows students to see how various components of the curriculum fit into real world problem solving endeavors. Enforcement of turf lines in academia, are often promoted by school and departmental administrators from motivations that are not necessarily "student-centered" or "learning-oriented" but rather driven by ease of "bean-counting" and limits confined by perceived/imposed "reach of authority". NASA personnel routinely perform "science driven" missions that integrate intense mathematical analysis, safety considerations, and, engineering design and problem solving that help diffuse traditional disciplinary lines that can form artificial boundaries in academia. Involvement of NASA and other federal agencies in cross-disciplinary projects such as AIRSPACES, involving undergraduate students promote dimensions of learning through co-curricular activities that cannot be addressed in a typical formal curriculum. Annual surveys developed in consultation with collaborators assess academic and life-skill outcomes and document student feedback and comments.

ACKNOWLEDGMENT

Several others students (besides co-authors) have participated in various aspects of the project, their contributions are acknowledged with gratitude. Student support from MDSGC/NASA for AIRSPACES and other synergistic projects have been largely responsible for the success of the project.

Integrating design and bridging activities of the engineering and the design college:

Merging language cultures, creativities, and perspectives

Mani Mina and David Ringholz
Iowa State University, mmina@iastate.edu, ringholz@iastate.edu

Abstract – **This paper describes a unique and an innovative pedagogical experiment conducted between engineering and design faculty. The goal of the experiment is to create innovative bridges between student design and creative activities and projects that would converge and unify two different approaches: Engineering and Industrial Design. In this class, third and fourth year students from Material Engineering and Electrical and Computer engineering are teamed up with the students from the graduate level Industrial design studio. Together the teams are assigned to a major industry sponsored design project. This paper discusses the class concept, execution, outcomes, reflections, surprises, and will provide discussions on designing, implementing, and modifying such classes. This work mixes students with different academic levels from three departments of the engineering college together with the first year graduate students in the college of Design. They are all working on a semester long industry sponsored design activity. The paper describes the goal of the experiment, the implementation, and the unique findings of the experiment. In particular, this paper focuses on early results of this pedagogical experiment. Discussions are provided about the issues of implementation, identification of the hurdles, difficulties, and the commonalities. Possible approaches and paths to make such classes possible in diverse environments and cultures are provided. Faculty, students, and industrial client reflections and observations are included. Finally attempts to bring about some guidelines for initiating, conducting daily activities, project planning, and ways for bridging the cultural gaps between the seemingly separated fields are described.**

Keywords – Engineering design, multidisciplinary work, studio

I. INTRODUCTION

One of the most important characteristics of engineering and industrial design education programs is the systematic approach to design. The role of design and design experience is of essential importance in both of the programs. Both of the programs emphasize problem solving, system level thinking, and practical components (studios, labs, and design elements) of the curricula. Students are ideally taking many classes that would build the foundations of their thinking, problem solving, methods, tools, and analysis. Then in addition in the design labs, studios, and similar platforms students are supposed to learn the practical knowledge integration. The design elements will help synthesize their learning. Working on projects helps achieve that with many interacting elements such as teamwork, collaborate learning, research, planning, implementation, testing, documentation, and presentation.

The faculties involved in the programs have always realized that each approach (the engineering and the design approaches) is valid. The two seem to have constructive overlaps, and huge complementary relationship. At our school this has been testing in more than a few cases. We have tried invited lectures from design program in engineering classes (especially capstone) and have engineering faculty lecture for the design classes. In all of the trials the interaction helped to excite the students and enhance their perspectives. Consequently, the natural step would be trying to see how both approaches could coexist in the same class. That is how this experimental class was initiated. The question was how to create overlapping classes that would meet and interact, play, learn, and create in the same environment. Our main focus was to empower the student. The students, their experience and their growth have always been the focal point for curricular development in our perspectives.

The main purpose of this experiment has been to enrich the experience of the engineering and industrial design students, as well as the faculty involved. Each program has unique capabilities and approaches focusing on slightly different points of the design process. By combining the engineering and the industrial design approaches and sharing the process, we would enrich the students' experience of the overall design process.

II. THE MAIN PERSPECTIVE

The process of design is a multistep synthetic process that starts from an idea (from thought) and ends up with an implemented design (to a thing). In this creative, convoluted, and multifaceted approach students will learn different aspects of the journey from thoughts to things that encapsulated multiple aspects of what design really encompasses [1-4].

Students from different programs were brought together into this shared studio environment. Each group maintained their own assignments, reporting, and developments, as well as their respective design classes. However, they were required to work together in the studio, interact, and share their experiences. The students also were encouraged to attend the lectures of the different groups. For the common shared studio experience, the three leading faculty were actively engaged in presentations, discussion, and consultations.

The shared experience of the class was set up as a studio. There were three groups of students who participated in the experiment.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The first was a group of graduate students taking a six credit studio in the Industrial Design Department at the design college. By training, the graduate group had the most intensive study and depth in defining products and functionalities. So, naturally they would be the engine that would lead and derive this experiment. There were two international visiting students (from Denmark and Sweden) from design schools in Europe who were in the graduate class. Their perspectives and approaches also helped all of us see even another side of the culture of design and synthesis.

The second group was Electrical Engineering students taking a 2 credit junior level engineering studio class (the first studio in college of engineering at our school). These students were working on practical data collection methods based on LABVIEW environment and sensor integration for their studio class. They were also required to do a major design experience. This group was strongly advised to attend all of the lectures that were presented in the graduate class for the Industrial Design experience. The students were strongly encouraged to do that at the beginning. After few weeks, they would look forward to the lectures and presentation and would invite other student friends from other classes to also attend and participate in the lectures and presentations. They truly believe the perspective for the industrial design enhanced their maturity of understanding of the process of analysis.

Finally we had another group of engineering students who were taking multidisciplinary senior design (capstone class) for 3 credits. These students were senior in Material Engineering program. Their project for the class was the one that was the main project for this experiment. This group of students was also encouraged to attend as many studio activities. At the beginning they were very reluctant but later in the term they were spending more time in the common activities. They also believe the activities presentations and interactions enriches their experience, but they also had many demanding classes during the term, which would naturally reduce their available time. However, during the last part of the term they became active participant in the synthesis and analysis process.

The class was set up with the main lecturer from the industrial design program. In addition two collaborator faculties from Electrical Engineering and Mechanical Engineering were also involved.

A. Defining a Unifying Project

In order to make a valuable shared platform experience, a focused and central collaboration platform was needed. We decided to have a common final design requirement. A project with practical and challenging requirements with meaningful purpose and deadline was needed. Consequently, the team decided to work on an industry-defined project that was provided by one of the nationally known collaborators.

The idea was developing clearly. While going through this experience by mixing the lectures, applications, discussions, and collaborations, we would also work with a major industrial partner that would require realistic outcomes. In this case the partner was a major culinary kitchenware company that has very close and good working relationship with the Industrial Design program. Their product managers suggested the project. They created the project definition and were excited to see our team with mixed, multidisciplinary, multilevel, and multitalented group. In particular the managers were excited to see the collaboration between the design and engineering students.

The project was to evaluate some of the existing products and identify changes, modification, and future designs for the company's major electrical line of products. The company's specific requirement was to have a solid product definition, with valid market study, gap analysis, and engineering inputs for the product ideas and modifications. In addition the teams had to identify a design for a whole new product for them. To help, the company shared many of their documentations to our team. The managers were also available for questions, suggestions and idea evaluation at all times. We also decided to have periodical evaluation and discussion sessions with the company. For the final presentation the company would bring few of their managers and visit us on campus.

B. First stage: products and definition

The industrial design students had more experience in product definition and market analysis, they led the project by setting up task analysis, user feedback system, and product definition. At this early stage the engineering teams would work as observers and collaborators. They would attend discussions, lectures, and work sessions that were led by the industrial design team to do market research, define product evaluation rubrics, conduct some consumer surveys and test the products. The engineering team would help the design team to understand the engineering specifications, major electrical, material, and mechanical definitions, questions and possibilities and would also take part in the testing of the product as users. At the end of this stage a meeting was set with the industrial/commercial partner. Ideas were shared and thoughts were presented. Good feedback was generated to help the team focus on to the company's needs and possibilities.

C. Second stage: Systematic product analysis

After the students used the product and understood how the product and 2 to 3 of the competitor products were used, they had to look deeper in the product. The products engineering specifications, power, heat, efficiencies, materials, manufacturing issues and all the details were carefully analyzed. The engineering student led this and the industrial design students would be helping, observing, and asking very well thought and specific questions. During this stage the heating surfaces were analyzed for temperature distribution, infrared imaging of all products were obtained. The basic electrical components were examined and motors and displays were opened up and carefully characterized by the engineering students.

This process helped all students. In particular, the industrial design students used this opportunity to identify the needs and market gaps and started their ideas of future needs, developments and future modifications for a better product definition by the company.

D. Third Stage: Idea generation, specifications and definitions

In this stage all teams, led by the industrial design students, worked together to identify the requirements, engineering possibilities, and modifications that would help the company with their current products as well as future product lines. The Industrial designer team would generate functionality charts and product definitions. They would provide ideas, requirements, and product sketches. The engineering team would help identify what is possible as well as what are efficient and good engineering decisions. Based on the discussion, presentation, ideas generations, and product definition, a possible set of specifications were created by the whole group.

E. Fourth Stage: Finalizing concept creation, suggested modification, documentation, presentation

In this stage the team worked together to document their findings and ideas. Product sketches, possible specifications, possible current and future engineering developments and modification were identified. The industrial design team led the documentation and sketch generation as well as the presentation. The engineering teams provided the support of the ideas, specifications, and engineering considerations.

This synthesis was the most amazing process for all of us to observe. At the end when the teams would suggest a modification for the current products, they would provide reasons and possibilities from a broad aspect of the product perspective. This included, usage, user perspective, engineering possibilities, material and manufacturing possibilities, future product sketches, and specifications.

III. The Challenges and Observations

One of the most important parts of this experience has been observing how the different engineering groups and the industrial designers interact and convey information.

Generally speaking, a typical engineering design in an undergraduate program starts with specifications and teams need to deliver a system that would satisfy the specifications. This project was different, since the final deliverable item was product definitions and ideas. The main activity in this detailed and time consuming collaboration was a process of identification, examination, and characterization of products, specifications, and functionalities. This posed many challenges for all engineering students. The experience helped all of the teams profoundly understand and appreciate the design aspect and importance of this type of synthesis.

The electrical and computer engineering team understood the importance of the lectures and discussions led by industrial design team very early on and tried to be present in all of them to get to know the right perspectives and approaches used. Consequently, the electrical and computer team became a useful resource from early on. The material engineering team eventually became used to the process. They were great resource and provided valuable detail material analysis and suggestions. By the end of the term, the final report and presentation included a comprehensive array of elements that spanned all aspects of design, aesthetic, functionality, and specifications that is required by a good product design process. The team that was the main communicator and managed the process the most effective was naturally the graduate design students.

IV. Some Reflections

Based on the feedback from faculty reviewers, industrial partners, and students' reflections, our experiment was very useful for all patrons. Engineering students realized a better process of careful and creative definition of a product and coming up with specifications and industrial designers understood the engineering detail, rigor, and implementation. Consequently, this experience was of great value.

However, it did not have much of detailed traditional engineering design elements. We spent most of our time in the left side of the product development continuum. The Electrical and Computer Engineering team recognized the lack of traditional design, however, they valued the experience and their contribution as essential part of the design process.

The Material Engineering students were more comfortable with their role in this project. We believe it is due to the fact that their area is much more closely associated with the material science where the development process is of great value and the detail product specification and delivery is not the only guiding light. Consequently, this did become a more valid design experience for that material engineering team.

Though there were still some technical questions unaddressed, the overall quality, fidelity and detail of the resulting work was a notable improvement over studio design projects that do not include interdisciplinary involvement. The engineering teams introduced new resources and insights that allowed the design students to advance the quality of their thinking and execution. The resulting documentation (technical drawings, animations and computer models) was very high caliber.

V. The Final Remark

Students of all teams did believe that they had a great and rich experience working with many different perspectives and associating with an active and creative industrial partner. The client was very happy and indicated that they were pleased with the major contributions of each group. They would like to continue these types of projects and idea and product definitions with the team at our program. The client also clearly identified the value of these types of projects for the engineering students.

In conclusion, this experiment has enhanced our experience regarding broad possibilities of integrating students from different backgrounds to focus on a systematic collaboration in a synthesis/design project. Having the different perspectives and celebrating and enhancing them, together with team teaching and coaching by various instructors have a great potential to be a versatile and effective platform for a true inquiry based collaborative learning and critical thinking as well as knowledge integration.

It is important during this process to have very effective and frequent feedback process and make sure that each group of students have faculty coaching and guidance as a group as well as within the whole class settings.

As usual the challenge of any diverse design team would be to make the deliverables in small pieces with frequent deadlines in the early stages, and more challenging and integrated pieces at the later stages.

During such efforts, the leadership of the project is of utmost importance. Our experience shows that on the left side of the cycle the leadership needs to reside with the Industrial design and on the right side of the cycle with the engineering team.

This work was partially supported by the National Science Foundation under awards: DUE 0837314 and DUE-0920164. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation

Integrating International Students' Contests with Software Engineering Courses

Lessons Learned and Best Practices

Amir Zeid
Department of Computer Science and Information Systems
American University of Kuwait
Kuwait
azeid@auk.edu.kw

***Abstract*— There are many general computer contests targeting undergraduate and graduate students. The prizes vary from cash, trip, fame, conference participation and others. Contests can be class, school, national, regional or global.**

This workshop aims to share the knowledge and experience of different educational institutes of integrating students' contests with academic software engineering courses. The main goal is to identify, discuss and promote best practices to properly benefit from such integration.

Keywords*— *Teaching Software Engineering.

I. Background

There are many computer contests that can be integrated with software engineering courses [3]. Such integration leads to solving some of the typical problems in courses that include software development projects like capstone and software engineering courses [3]. It can be argued that this integration results in raising the quality of the projects developed in such courses (when properly aligned with the time-line and learning outcomes of the courses). Contests that can be integrated with software engineering classes include Microsoft Imagine Cup, Google Apps Developer, IBM/IEEE Smarter Planet and Score [3].

II. The Goal of the Workshop

The main goal of the mini workshop is to identify, share and discuss possible contests that can be integrated with software engineering course.

The following are some of the possible topics:

- Evaluation of available software engineering related contests.
- Best practices for integrating contests with software engineering courses.
- Teaching software engineering using contests.

III. Anticipated Audience

The workshop is intended for faculty members who desire to gain experience in integrating contests with software engineering courses. The model can be applied to other science and engineering courses as well. The workshop is open to all researchers and industrial practitioners interested in teaching software engineering. The attendees have to be registered in the conference. The expected number of participants is 10-15.

IV. Learning Outcomes of the Workshop

Attendees of the workshop will gain an insight about different computer related contests and how they are integrated with software engineering courses. They will share experiences with educators from different countries and cultures about the benefits, challenges and logistics of such integration.

V. Workshop Activies and Agenda

The following is the initial agenda of the workshop:

- Goals, background and workshop framework (15 minutes). The organizer will briefly present different samples of computer contests that can be integrated to software engineering courses. He will also present his experience in integrating one of the contests with academic programs [2]. A suggested framework to evaluate contests will also be presented [3].
- Attendees will be divided into groups. Each group will consider one contest and how it can be integrated (30 minutes).
- Important findings by attendees will be shared by short presentations. Duration per group will depend on number of participants (40 minutes).
- Wrapping up session (5 minutes)

VI. Post Workshop Activities

Interested attendees will be invited to co-author a paper about the findings of the workshop. The findings can lead to

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

suggest changes and modifications to existing contests. The suggestions will be delivered to contests organizers as recommendations. This can lead to improve the quality of related contests and eventually will encourage more participants to join.

VII. BIOGRAPHY OF ORGANIZER

Dr. Amir Zeid is an associate professor of computer science at the American University of Kuwait (AUK). He has above 60 publications in international conferences and journals. Dr. Zeid's research interests include: global software engineering, cloud computing, gender-issues in computing and using technology to promote environmental sustainability. In addition, Dr. Zeid is interested in research about creative methods in computer education. He received numerous research funding grants and international awards. Throughout his career at AUK, Dr. Zeid has been working on encouraging student innovation. He led three teams of AUK students to win the prestigious Microsoft Imagine Cup Competition for the Gulf region in two different categories. He is a member of ACM and IEEE.

Individual Sustainability: Preliminary Research

Eric C. Pappas
Department of Integrated Science and Technology
James Madison University
Harrisonburg, Virginia
PappasEC@jmu.edu

***Abstract*—All societal change begins with the individual. One cannot do for a community what one cannot do for one's self. The topic of Individual Sustainability is a controversial one, as students often appear to be unable to align their demonstrated behaviors with their admirable values related to sustainability. Individual behavior creates the foundation for action in social, economic, and environmental sustainability, and potentially guides our ability to work with one another to make life-affirming decisions. In short, it is a matter of aligning our day-to-day behaviors with our well-stated values that will result in greater sustainable community action.**

The general objective of this research is to help students align their behaviors with their values. This change is a necessary precursor to demonstrating sustainable community behavior. We believe that creating a "cognitive dissonance" between an individual's values and behaviors tends to encourage individuals to balance more effectively the self-knowledge that motivates intentional personal development towards more sustainable behavior. While most students indicated they believed their behaviors consistently reflected their values, the students' broad range of responses and survey responses revealed behaviors quite in conflict with their values.

Keywords—sustainability, individual sustainability, systems theory, cognitive dissonance

I. Introduction

All societal change begins with individual change. One cannot do for a community what one cannot do for one's self. The topic of Individual Sustainability is a controversial one, as students often appear to be unable to align their demonstrated behaviors with their admirable values related to sustainability. Individual behavior creates the foundation for action in social, economic, and environmental sustainability and potentially guides our ability to work with one another to make life-affirming decisions. In short, it is a matter of aligning our day-to-day behaviors with our well-stated values that will result in greater sustainable community action.

This research, funded by two National Science Foundation grants (IEECI Grant #0933948 and EEC Grant #1158728, E. Pappas, P.I.), is one of more than a dozen projects we are conducting on Individual Sustainability (also referred to as Sustainable Personality), which we define as follows:

Sustainable individuals are characterized by creating harmony, interconnection, and relatively high levels of self-awareness in their values, thoughts, behaviors, and actions as well as cultivating continued individual growth in their physical (health), emotional, social, philosophical, and intellectual abilities.

Individual sustainability includes possessing a well-developed and demonstrated value system that acknowledges the importance and interconnectedness of all global biological and social systems, and our appropriate place within them.

Nearly 250 students in an undergraduate science and technology course were given a 50-item multi-source feedback online survey (on PersonalityPad.org) that assessed individual sustainability in the following contexts: emotional, social, health, economic, and intellectual. Following a post-test, reflective essays, and a later follow-up survey, results revealed that most students found their behaviors related to individual sustainability did not always align well with their well-stated values.

II. Objectives

We believe that creating a "cognitive dissonance" between an individual's stated values and demonstrated behaviors tends to encourage these individuals to balance more effectively the self-knowledge that motivates intentional personal development towards more sustainable behavior. In other words, students experience a cognitive dissonance when they realize their behaviors related to sustainability do not reflect their values. We expected students would work to align their behaviors with their values.

This research had the following three primary objectives meant to encourage students to change their everyday behaviors:

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

1) to facilitate individual sustainability awareness;

2) to study the cognitive dissonance that occurs when students realize that their behaviors related to physical, emotional, social, economic, and intellectual sustainability do not align with their stated values; and

3) to determine, when faced with this inconsistency, if and how students' behaviors motivated individual change.

III. LITERATURE REVIEW: INDIVIDUAL SUSTAINABILITY

An important context missing from most discussions of sustainability, especially within academia (or society in general), is individual sustainability. Living a sustainable lifestyle includes creating harmony, interconnection, and relatively high levels of awareness in one's values, thoughts, and behaviors, as well as maintaining an increasing control over one's physical, emotional, social, philosophical, environmental, and intellectual life. The general dispositions that support individual sustainability are awareness, motivation, and the ability to engage in intentional self-development. As well, individual sustainability includes possessing a well-developed and demonstrated value system that acknowledges the interconnectedness of all global biological systems and our appropriate place in the Natural World.

A considerable number of psychologists, educators, philosophers, and engineers have noted the complex nature of what constitutes personality and how it manifests itself, and some have indicated that these characteristics (or skills) are dependent upon each other in order to produce a highly functioning individual. What these writers have in common is the understanding that personality is related to a variety of factors, and that these factors comprise a complex system.

If one understands the complexities and interconnectedness of one's own individual sustainability contexts, then he or she might well transfer this systems understanding to address community environmental, social, and economic problems[1,2,3]. Such growth may be difficult for some, and the challenges to individual development may be hindered by personal, career, family, and psychological issues, as well as a dysfunctional relationship with time or technology [4].

The are countless historical roots here. Bertrand Russell [5], in his lecture on *Belief*, outlines the mutually dependent components of a holistic intellectual life which consists of "beliefs, reasoning, theories of knowledge, and metaphysics...out of which our philosophical outlook evolves" (p.139). Hegel [6] views the "whole" of existence as a non-self-contradictory complex system. His philosophy always considers Reality as a whole. James [7] delineates the constituents of the self as "the material self, the social self, the spiritual self, and the pure ego" (p.292). These factors, he says, provide the human foundation for self-seeking and self-preservation, an understanding of one's self in the broadest sense.

Dewey [8] refers to consciousness as composed of "natural and social operations" (p.244) and is a "connected course of experience" (249). Further, he proposes the synthesis of human processes "in which elements combine into complex wholes and series" (p.245). He notes "knowing, willing, feeling [are the] name states of consciousness" (p.252), and acts and attitudes all found in experience. He later refers to consciousness as a "system of truth" (p.257). A few years later, Dewey outlines a similar system guiding successful education: "Education, we received from three sources—Nature, men, and things"…that the "concurrence of three kinds of education is necessary to their completeness (p.108). Each kind of education, he stresses, determines the success of the other two.

Maslow [9] describes the 13 characteristics of a self-actualized individual as follows:

1) Superior perception of reality
2) Increased acceptance of self, others, and of nature
3) Increased spontaneity
4) Increase in problem-centering
5) Increased detachment and desire for privacy
6) Increased autonomy, and resistance to enculturation
7) Greater freshness of appreciation, and richness of emotional reaction
8) Higher frequency of peak experiences
9) Increased identification with the human species
10) Changed (the clinician would say improved) interpersonal relations
11) More democratic character structure
12) Greatly improved creativeness
13) Certain changes in the value system

He notes these characteristics as a path to "a fuller knowledge of, and acceptance of, the person's own intrinsic nature, as an unceasing trend toward unity, integration, or synergy within the person" (p.25).

Rogers [10], a decade of so later, notes the "Qualities of a Person of Tomorrow," twelve characteristics of a highly functioning and balanced individual, a list clearly reminiscent of Maslow's and characterized by "a world in which the mind, in its larger sense, is both aware of, and creates, the new reality" (p.352). They are as follows:

1. Openness
2. Desire for authenticity
3. Skepticism regarding science and technology

4. Desire for wholeness
5. The wish for intimacy
6. Process persona
7. Caring
8. Attitude toward Nature
9. Anti-institutional
10. The authority within
11. The unimportance of material things
12. A yearning for the spiritual

Capra [11] offers his systems view of personality "based on awareness of the essential interrelatedness and interdependence of all phenomena—physical, biological, psychological, social, and cultural" (p.265). He notes that there is no established framework for such an approach, either conceptual or institutional, that would accommodate paradigm change, but that individuals, communities, and networks develop their own approaches to such growth. In addition, Capra notes that "systems thinking is process thinking, form becomes associated with interaction, interrelation with interaction…" (p.267). Csikszentmihalyi [12] takes a similar interactive approach and reflects on the complexity of consciousness, stating that knowledge or intelligence need be in harmony with feelings and actions—"to create harmony between goals and desires, sensations and experiences" (p.207).

Some writers, like Thoresen [13] delineate a sustainable personality, what she considers responsible citizenship, from the perspective of "empathy, relationships, critical skills, co-operation, self-awareness, equality, feeling concerned" (p.8)—individual attributes that would increase our chances of survival. She groups over two dozen human behaviors and values into three general areas: "Biological determinants, Social expectations, and Moral imperatives." While Thoresen's approach is not quite as expansive and inclusive as Maslow, Rogers, or Capra, her approach does cover an extensive variety of intellectual, affective, and ethical skills and dispositions as well as provide a foundation for instruction in higher education.

Encouraging curriculum change in higher education to foster individual sustainability, Kagawa [14] suggests problem solving skills, creative and critical thinking, and self-reflection as necessary components to encourage sustainable development and points out "And what kind of development do we want to sustain: social, cultural, political, spiritual and/or economic? (And are these separable?)" (p.325).

Education for sustainably should foster learning new attitudes, perspectives, and values that guide and impel people to live their lives in a more sustainable way" (p.63), according to Gadotti [15]. Feeling, simplicity and quietness, identity, justice, and a culture of peace characterize sustainable societies, notes the author, who further encourages political and social revolution based on an "anthropocentric and individualistic view of humanity's well-being" (p.96). Stone's [16] approach to curricular change includes instruction in "cognitive, emotional, active, and connectional" (p.44) topics, similar to integrating approaches to personality in Goleman, Barlow, & Bennett [17]. Employing a similar structural format, Lowenstein, Martusewicz, and Voelker [18] focus on a social approach related to the discourses that shape our modern industrial cultures.

Three methodologies inform this work. First, this research employs a *systems theory* methodology (which stresses that the interrelationship of factors in a unified system depend upon the unpredictable nature of the relationship of these individual factors). Second, we consider *values*, whether they be corporate, government, community, or individual, as the principle guiding force for defining and solving sustainability problems [19]. Third, following years of researching and teaching sustainability, we understand it is an individual's demonstrated *behaviors and skills*, not simply his or her *knowledge* of, or *attitudes* toward, sustainability that support and promote sustainability. It appears that offering the opportunity to learn about sustainability does not necessarily lead to more sustainable behaviors [20]. We recognize that developing an individual's values may provide motivation to behave in a manner more congruent with sustainability principles [21]. This transformative process employs instructional theory and methodologies that offer students greater insight into, and understanding of, sustainability problems...far greater than traditional instruction that focuses on increasing "student knowledge" or learning basic laboratory skills.

Creating a "cognitive dissonance" between an individual's values and behaviors tends to encourage individuals to balance more effectively the self-knowledge that informs decision making and problem solving [22].

A topic we find missing in many of these works is significant discussion of reciprocal influences among the factors noted by authors, that each factor influences the others in unpredictable ways (See Discussion).

IV. METHODOLOGY

This study utilized a unique multi-source feedback platform developed by three James Madison University faculty members: Morgan Benton, Jesse Pappas, and Eric Pappas. Personality Pad (www.PersonalityPad.org) is a fully automated on-line experience in which participants generate and interpret individual sustainability feedback based on their values, as well as several friends' and/or family members' external perspectives on their (the participants') values and behaviors, in order to engage in intentional self-development in the direction of sustainable thought and action [23]. The site offers five sources of multi-source feedback based on methods commonly used in organizational settings for professional development. Research has consistently shown that, when conducted effectively, the multi-source feedback process can lead to greater evaluative accuracy and higher levels of participant acceptance compared to single source evaluation alone [24]. It is also more likely to increase motivation and lead to specific developmental actions [25].

In a critical thinking General Education class, nearly 250 undergraduate students in a wide variety of majors participated in the study; 80% were first-year students. These students were given a 50-item survey that assessed individual sustainability in the following contexts: emotional, social, health, economic, and intellectual using a seven-point Likert scale (strongly agree—strongly disagree).

Sample questions:

I am a person who

...feels the need to have a lot of material possessions (Economic context)

… demonstrates openness, acceptance, and respect in my relationships (Social context)

…actively seeks new knowledge (Intellectual context)

…frequently experiences significant stress in my life (Emotional context)

…actively pursues good physical health habits and activities (Health context)

"Friends and Family" responses were phrased in this manner:

(*Student's name*)…actively pursues good physical health habits and activities.

Following the survey, students were directed to reflect upon their responses and write short reflective essays to the following questions: 1) Do you think the values expressed in the survey are relevant to your personal life? and 2) Do you demonstrate these values in your daily life? Five weeks later, a ten-question follow-up survey and narrative required students to assess whether the previous surveys and reflections resulted in any changes that helped them align their behaviors and their values related to individual sustainability. Each student was asked to list up to five behavioral changes she experienced due to participating in this study (if, indeed, she had experienced any changes).

Study students were awarded a small amount of course credit (equal to two homework assignments) for simply completing the study, regardless of their investment in the study or quality of their participation. In general, students seemed interested in the study since the focus was on personal development. For this reason, we consider students' responses and narrative essays mostly authentic. The study was conducted with no class discussion, apart from clarifying the instructions.

While most students initially indicated they believed their behaviors consistently reflected their values, the students' broad range of responses on the seven-point Likert scale and reflective responses revealed behaviors quite in conflict with their values (and sometimes disruptive to personal lives). Most students in this study noted at least three areas (three of the questions for which they received feedback) in which the imbalance was substantial or disturbing.

Summarizing the 50 responses, the post-test, and follow-up survey here for 250 students will be limited to the most salient trends related to the objectives of this research. The cognitive dissonance and behavioral changes reported by students were greatest when their individual perceptions of themselves were compared to the perceptions of five of their "Friends and Family" (in which friends and family responded to the same 50 questions— evaluating *the student's* individual sustainability). This multi-source feedback was especially valuable, considering the friends and family feedback was anonymous, offering these friends and family members the opportunity to honestly evaluate the participant.

V. RESULTS

In general, 97% of students agreed that "this survey addresses skills and habits you generally consider to be valuable," while 89% believed that they "demonstrated (in your daily life) the skills and habits noted in the survey that you consider valuable."

On the follow-up survey, 75 percent of students agreed to the following statement: "Based on the personality feedback I received during this study, I have some personal changes in mind that I would like to pursue."

Similarly, Table 1 and Table 2 show the follow-up survey responses related to individual development and students' intention to make personal changes.

TABLE 1: On a scale of 1-10, how much did you learn about yourself (overall) by participating in this study?

I didn't learn anything about myself.	0%
2	2%
3	6%
4	6%
5	12%
6	24%
7	27%
8	15%
9	6%
I learned a whole lot about myself.	3%

TABLE 2: On a scale of 1-10, how likely are you to pursue a personal change based on what you learned about yourself?

Not at all likely	1%
2	1%
3	7%
4	5%
5	15%
6	18%
7	29%
8	15%
9	5%
Extremely likely	5%

Overall, 81% of students reported actively working on behavioral changes due to their participation in the study. Of this group, the average number of changes reported was 2.4 per student. Common changes reported included emotional changes (reducing stress, improving relationships, worrying less); academic changes (organizing more effectively, improving time and study efficiency, being more open); and self-image changes (being more confident and outgoing, being more empathetic, eating better, working out).

Surprisingly, when asked (on the follow-up survey) about who had a more accurate perception of their (students') overall individual sustainability, 66% reported that their friends and family did, while only 34% of students indicated that they, themselves had a more accurate perception. Almost 89% of students agreed that "periodically reviewing external feedback about myself (e.g. from friends and family) could help me make productive personal decisions."

VI. DISCUSSION

It is clear from this research that, before participating in the study, students generally did not consider whether their behaviors reflected their values, or if they did recognize this, they refrained from intentionally attempting to align these factors. As well, only after the study do students report considering aligning behaviors and values an issue related to personal integrity or authenticity.

Our results in this study are encouraging, and we continue to research these effects. If students' self-reports are to be believed, this study has yielded significant personal behavioral change in students. Many students reported that their relationships, study behaviors, time use, and relationship with technology have improved. As well, because they experienced some success in these improved behaviors (that is, behaviors aligned with their values), students' narratives reflected an improved sense of personal integrity and self-esteem. In particular, many students reported a decrease in stress and anxiety, as they tended to improve their behaviors in family and friends' relationships. It is true here, perhaps, that if a change in one's behaviors improves daily life, then those behaviors tend to be repeated and perhaps become a personality characteristic [26].

Short educational interventions, such as the one described in this paper, may be of particular value to educators. The current study required no more than two hours of a student's time (at home), very little or no classroom time, and yielded what we consider significant educational results. More research, of course, is needed. In the two next years, we will conduct longitudinal studies involving the now 1200 students who have already participated in Personality Pad research.

One of the major challenges to this systems approach is that the five sustainability contexts influence each other in complex ways, and understanding these interactions requires increased awareness. It appears that determining individual sustainability depends upon the careful and complete *assessment and evaluation* of a range of human factors. As noted earlier, because sustainability factors comprise a *complex system*, a change in one sustainability factor is likely to result in an unpredictable change in the others. It is quite possible that one context in sustainability will be quite in conflict with another—that is, that making a positive change in one factor may produce some unwanted effects in another. Too little work has been done to understand and assess the reciprocal influences this complex system creates.

VII. CONCLUSION

Measuring educational outcomes using behaviors is the central objective of our efforts. We believe that student behaviors, more than content knowledge or attitudes, measure learning more thoroughly and effectively (especially long-term). The fact that successful behaviors may tend to become personality characteristics drives our research and experimentation. Our research indicates that students' desire for integrity and individual value consistency tend to move them to align their values and behaviors.

We fully recognize the limits of self-report, especially when a study is conducted in an academic class, but the overwhelming positive responses related to improved behavioral change are encouraging and support our ever-evolving work in this area. We recognize, as well, that these changes may be temporary, hence we will conduct longitudinal research in the semesters to come.

We further recognize that the Sustainable Personality Survey is in a developmental stage; hence, the results could be questioned. But, as we have developed the survey (this is the second iteration of published results), our results are remarkable consistent. Our next version of the survey will be considerably improved.

VIII. FUTURE WORK

Two substantial National Science Foundation grants have afforded us the means for conducting nearly a dozen studies related to individual sustainability, and values and behaviors, over the past two years. Our work developing the multi-source feedback platform, Personality Pad, and the *Sustainable Personality* survey (here referred to as Individual Sustainability), continues, and following further reliability and validity tests, we plan to have a version suitable for wide distribution in 2015. The Personality Pad platform will be ready for more widespread use in 2014 and will provide multi-source feedback in a wide variety of applications, both in academia and, as well, for government organizations, non-profits, and other organizations that measure growth and success in terms of human productivity rather than profit.

This material is based upon work supported by the National Science Foundation under Grants IEECI #0933948 and EEC #1158728. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

***Abstract*—The need for more post-secondary students to major and graduate in STEM fields is widely recognized. Students' motivation and strategic self-regulation have been identified as playing crucial roles in their success in STEM classes. But, how students' strategy use, self-regulation, knowledge building, and engagement impact different learning outcomes is not well understood. Our goal in this study was to investigate how motivation, strategic self-regulation, and creative competency were associated with course achievement and long-term learning of computational thinking knowledge and skills in introductory computer science courses. Student grades and long-term retention were positively associated with self-regulated strategy use and knowledge building, and negatively associated with lack of regulation. Grades were associated with higher study effort and knowledge retention was associated with higher study time. For motivation, higher learning- and task-approach goal orientations, endogenous instrumentality, and positive affect and lower learning-, task-, and performance-avoid goal orientations, exogenous instrumentality and negative affect were associated with higher grades and knowledge retention and also with strategic self-regulation and engagement. Implicit intelligence beliefs were associated with strategic self-regulation, but not grades or knowledge retention. Creative competency was associated with knowledge retention, but not grades, and with higher strategic self-regulation. Implications for STEM education are discussed.**

Keywords—motivation; self-regulation; engagement; STEM learning; goal orientation; emotion; perceived instrumentality

I. INTRODUCTION

The need for more post-secondary students to major and graduate in STEM fields is widely recognized as in the National Academies report "Rising above the gathering storm: Energizing and employing America for a brighter economic future" [1]. Substantial funding is provided for enhancing instruction in STEM fields [2]. A relatively low percentage of students major in STEM fields, and despite attracting students with generally better academic preparation and aptitude, students in STEM fields experience higher attrition than those in other post-secondary majors [2].

Students' strategic self-regulation has been identified as playing a critical role in their success in STEM learning [3,4], but how students' use of strategy, metacognitive self-regulation, and engagement impact different types of learning outcomes is not fully understood. Also, despite considerable past research, including recent work reported in prior Frontiers in Education conference proceedings [5, 6, 7], theory and research have not completely described the dynamics of student motivation for pursuing productive strategic self-regulation and engagement. Our goal in this study was to investigate how motivation and strategic self-regulation, together with creative competency, were associated with course achievement and long-term learning of computational thinking knowledge and skills in introductory computer science (CS1) courses.

II. THEORETICAL FRAMEWORK

A. Motivation and Affect

Motivational variables in this study were drawn from goal orientation [8, 9, 10], future time perspective (FTP) [11], implicit belief theory [12, 13], and emotion/affect [14, 15, 16]. These aspects of motivation have been shown to be associated with higher academic achievement, greater engagement, and more strategic self-regulation [17].

Goal orientation concerns the types of goals students set. Goals exist at different levels of specificity. Consistent with Elliot *et al*. [9], there are goals for specific tasks and assignments anchored in the context of doing or evaluating the task and, at a more general level, students set goals for their courses [9, 10]. In this study, we used a framework proposed by Shell *et al*. [18] and Shell and Soh [4] that examines course goals in three dimensions (learning, performance, and task) with each dimension having an approach and avoid component. Learning-approach goals are goals directed at learning new knowledge or gaining competence consistent with most past formulations of learning or mastery goals [8, 10]. Learning-avoid goals are deliberate goals to avoid learning of course material. Think about the old saying *you can lead a horse to water, but you can't make it drink*. This reflects the Shell *et al*. [18] notion of learning avoidance. A student might complete all assignments and do enough to get a score on a test or a grade in a class, but not put forth the additional effort to really learn the material.

This study was funded by a TUES Grant (DUE-1122956) from NSF and a Pathways to Interdisciplinary Research Centers-Phase II Grant from the UNL Office of Research and Economic Development.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Performance-approach goals reflect a desire to obtain favorable judgments of one's abilities by others or perform better than others in the class and performance-avoid goals reflect the desire to avoid negative judgments of one's ability or do worse relative to others in the class [10]. Performance-approach and avoid goals have been found to motivate very different behaviors. Approach seems to be positive for increasing effort and positive self-regulation; avoid seems to be detrimental, decreasing effort and self-regulation [4, 10].

Task- or work-avoid goals reflect a desire to get through the class with as little time and effort as possible [20, 21, 22]. Task-approach goals reflect wanting to perform well on course assignments and tests [4]. They differ from performance goals because they are about doing well without reference to normative performance or gaining positive or avoiding negative evaluations evaluation of competence. They also differ from learning goals in that students can have a goal to "do my work to the best of my ability" without any expectation that they will learn anything.

Perceived Instrumentality (PI), is defined as a person's perception of how useful a present task is for a future goal [4, 24, 25]. Endogenous instrumentality reflects instrumentality for personally meaningful future goals and outcomes. Exogenous instrumentality reflects a utilitarian connection between task results and future outcomes. Past literature indicates that an individual's perception of instrumentality positively affects learning in the classroom [4, 7, 24, 25]. Students with high perceived instrumentality can see the connection between their current class activities and their more distant future academic, career, and life goals leading to increased motivation for their present learning in school [4, 7, 11].

Implicit beliefs about intelligence have been shown to impact students' goals, motivation, and achievement [12, 13]. Students who believe that intelligence is malleable and changeable through effort, learning, and practice set learning goals, achieve better, and engage in better strategic self-regulation. Students who believe that intelligence is fixed and unchangeable are more likely to set performance-avoid goals and be at risk for learned helplessness [12, 18]. Research has found that 50% of engineering students held an entity view of fixed intelligence [26].

Affect/emotion involves students' general feelings and reactions to the class [15, 16]. Positive emotions have been shown to increase students' engagement in academic work and support more adaptive self-regulation [4, 16, 21]. Negative emotions have been found to decrease motivation and lead to maladaptive self-regulation [4, 21].

B. Strategic Self-Regulation and Engagement

Four aspects of student strategic self-regulation in classes have a long history of research. The first is general metacognitive self-regulation. Students who are self-regulating engage in active planning, monitoring, and evaluation of their learning and apply general learning strategies to accomplish their goals. [27, 28]. They are what Pressley *et al*. [29] called good strategy users. The second aspect comes from the knowledge building approach to learning proposed by Bereiter, Scardamalia, and their colleagues [30, 31]. Central to the knowledge building approach is the idea that meaningful learning involves the production of knowledge rather than the reproduction of knowledge. This knowledge building is accomplished by an in-depth study of a topic that goes beyond simple factual or recall learning. Learning is tied to personally meaningful goals and includes examination and connection of new knowledge to existing knowledge and coursework in other classes.

The third aspect of strategic self-regulation concerns more dysfunctional self-regulatory strategies [8, 22, 32, 33]. Lack of regulation [4, 21, 32] describes students who are confused, have difficulty studying effectively and self-regulating, and also need support from others. Lack of regulation has been shown to be negatively associated with grades [4, 32] and is a key component of learned helplessness in classes [4, 21].

The final aspect is student engagement with the class as reflected in active participation and effort. Engagement concerns student study time and effort for the class [4, 21, 34]. Engagement also considers the extent of student active course involvement as indicated by question asking [4, 21, 35]. Students who are more engaged tend to have more positive experiences in the class and higher achievement [14, 16].

C. Creative Competency

Epstein's Generativity Theory defines creativity as a process integral to human intelligence, which can be exercised within any context and can be practiced, encouraged and developed [36, 37]. Epstein [36, 37] has identified four core cognitive competencies involved in creative thinking: (1) *broadening* by acquiring information and skills outside one's current domains of study and expertise; (2) *challenging* established thinking by engaging in difficult, ill-defined problems and tasks where new behaviors and approaches must be tried; (3) *surrounding* oneself with new people and environments that require one to look at things in new ways, and (4) *capturing* by recording novelty as it occurs. Epstein has substantiated the validity of his core competencies in numerous laboratory and applied studies [36, 37]. His core competencies have a solid anchoring in contemporary cognitive and neuroscience research on learning and cognition [18].

III. The Present Study

The goal of this study was to investigate how students' motivation, strategic self-regulation, and creative competency, were associated with course achievement and long-term learning of computational thinking in introductory computer science (CS-1) courses. This study was part of a larger NSF-funded effort to improve learning of computational thinking and better incorporate computational thinking principles into the disciplines through integration of computational and creative thinking [38, 39]. Courses included one for CS majors, one for a combined business/computer science honors program major, one for engineers with content tailored for engineering, one for a mix of CS, engineering, and general science majors, and one for humanities and journalism majors. The courses are all required within the students' major field of study (e.g., engineering, physics, computer science, etc.).

IV. METHODS

A. Participants and Proceedures

Participants were 175 students who consented to participation (151 men; 24 women; 78 freshman, 49 sophomores, 32 juniors, 13 seniors, 3 other/unknown) from five courses in a suite of required introductory computer science course (CS-1) at a large Midwestern state university. Core content was the same for all courses, but courses were tailored for different majors with different programming languages and lab exercises. Participants completed all survey questionnaires on Survey Monkey in approximately 30 minutes during a single proctored course laboratory period in the final week of classes.

B. Strategic Self-Regulation Measures

Strategic self-regulation was assessed with three scales from the Student Perceptions of Classroom Knowledge Building instrument (SPOCK) [4, 21, 32]. All questions were answered on a five-point Likert scale from 1 (*almost never*) to 5 (*almost always*). Scores were computed as the mean score of the scale items. Coefficient alpha reliability estimates for the self-regulated strategy use, knowledge building, and lack of initiative scales were respectively .82, .86, and .69.

Self-regulated strategy use (5 items) assesses the extent of participant planning, goal setting, monitoring, and evaluation of studying and learning (e.g., "In this class, I tried to monitor my progress when I studied"). *Knowledge building* (5 items) assesses the extent of student exploration and interconnection of knowledge from the class [30, 31] (e.g., "As I studied the topics in this class, I tried to think about how they related to the topics I have studied in other classes"). *Lack of regulation* (4 items) assesses participants' lack of understanding of how to study and need for assistance and guidance in studying (e.g., "In this class, when I got stuck or confused about my work, I needed someone else to figure out what I needed to do").

C. Engagement Measures

Engagement was assessed with four measures. Two scales from the SPOCK assess the extent of question asking in class. *High-level question asking* (3 items) assesses the extent to which students ask questions that extend or expand on the basic information being provided in the class (e.g., "In this class, I asked questions to more fully understand the topics we were learning"). *Low-level question asking* (3 items) assesses the extent to which students ask questions to obtain or clarify basic course information ("In this class, I asked questions to be clear about what the instructor wanted me to learn"). Scores are computed as the mean of the items in each scale. Coefficient alpha reliability estimates for high-level and low-level question asking were respectively .87 and .86.

Two scales assessed self-reported studying [4, 21, 32]. Study time was assessed by asking participants to indicate the average number of hours per week they spent studying for the class on a 1–7 scale from 1 (<5 h per week) to 7 (over 30 h per week). Perceived study effort was assessed by asking participants to indicate their perception of the effort they put forth studying relative to most students on a 5-point Likert scale from 1 (*much less effort*) to 5 (*much more effort*).

D. Goal Orientation

Participants' goal orientation was measured with an instrument adapted from that used by Shell and Soh [4]. Scales were shortened to two items due to administrative time constraints. Participants rated goals on a 5-point Likert scale from 1 (*very unimportant*) to 5 (*very important*). Scores were computed as the mean score of the items in each scale. Reliability cannot be statistically estimated accurately for 2-item scales, however, coefficient alpha estimates for the parent scales [4] were .89, .88, .78, .87, .91, and .82 for the learning approach, learning avoid, performance approach, performance avoid, task approach, and task/work avoid scales respectively.

Learning-approach goals (2 items) assess goals for developing long-term, deep understanding of information and skills learned in the course (e.g., "Learning new knowledge or skills during the class just for the sake of learning them"). *Learning-avoid goals* (2 items) assess deliberate avoidance of long-term learning or retention of course information ("Getting a grade whether you remember anything beyond that or not"). *Performance-approach goals* (2 items) assess normative performance relative to other students and favorable assessments of ability by the instructor for ego protection (e.g., "Doing better than the other students"). *Performance-avoid goals* (2 items) assess avoiding negative performance evaluations and unfavorable assessments of ability by others (e.g., "Keeping others from thinking I am dumb"). *Task-approach goals* (2 items) assess efforts to achieve highly and do well on class assignments and activities without reference to normative comparisons (e.g., "Doing my best on course assignments and tests"). *Task-or work-avoid goals* (2 items) assess deliberate intention to put forth minimal effort in the course (e.g., "Getting through this course with the least amount of time and effort").

E. Perceived Instrumentality

Students' perceived instrumentality was measured with the Perceptions of Instrumentality Scale [4, 25]. The scale measures both endogenous instrumentality (4 items. e.g., "What I learn in this CS1 will be important for my future occupational success") and exogenous instrumentality (4 items. e.g., "The only aspect of this class that will matter after graduation is my grade"). Participants indicated their agreement with each question using a 5-point Likert scale from 1 (*strongly disagree*) to 5 (*strongly agree*). Scores are computed as the mean of the items in each scale. Coefficient alpha estimates for the endogenous and exogenous scales were respectively .94 and .92.

F. Implicit Intelligence Beliefs

Students' beliefs about intelligence were measured with the Implicit Theories of Intelligence Scale [12, 13]. The scale measures incremental beliefs (4-items) that intelligence is changeable (e.g., "No matter how much intelligence you have, you can always change it quite a bit") and entity beliefs (4-items) that intelligence is fixed (e.g., "You can learn new things, but you can't really change your basic intelligence"). Participants indicate their agreement with each question on a 6-point Likert scale from 1 (*strongly disagree*) to 6 (*strongly agree*). Scores are computed as the mean of the items in each scale. Coefficient alpha reliability estimates for the incremental and entity scales were respectively .95 and .94.

G. Course Affect

Participants' course affect was measured by a modified version [4, 21] of the Positive and Negative Affect Scale (PANAS) [40]. Participants rated the frequency with which they experienced 10 positive (e.g., excited, inspired, determined) and 10 negative (e.g., nervous, distressed, upset) emotions on a 5-point scale from 1 (*a few times or none*) to 5 (*most of the time, 80%-100% of the time*). Scores were computed as the mean of the items in each scale. Coefficient alpha reliability estimates for the positive and negative scales were respectively .92 and .90.

H. Creative Competency

Creative competency was measured with the Epstein Creative Competencies Inventory [37] administered at the Web site "mycreativityskills.com." The percentage score (0-100) for total creativity was used.

I. Computational Thinking Knowledge Test

Students' retention of computational thinking knowledge and skills from the course was measured with a computational thinking knowledge test developed by CSCE faculty [4]. The test contained 13 conceptual and problem-solving questions for the core computational thinking content common to all CS-1 classes. The coefficient alpha reliability estimate was .76.

V. RESULTS

A. Associations of Strategic Self-Regulation, Motivation, and Creative Competency to Grades and Retention

We used Pearson correlations (*r*) to examine how students' strategic self-regulation, motivation, and creative competency were associated with course grades and retention of core course content as indicated by the computational thinking knowledge test. These are shown in Table 1. Course grades and retention of course content were only moderately associated ($r = .350$), suggesting that students can achieve high grades without necessarily retaining much of the information from the course.

Student grades and knowledge retention were associated with similar but not identical patterns of strategic self-regulation, engagement, motivation, and creative competency. Both were positively associated with self-regulated strategy use and knowledge building, and negatively associated with lack of regulation. Engagement measures had considerably smaller correlations with grades and retention than strategic self-regulation measures with only study time associated with higher knowledge test scores and only study effort associated with higher grades. These findings suggest that the quality of strategies and self-regulation employed makes more difference in student achievement than general levels of active engagement.

Learning-approach goal orientation was positively associated with both grades and retention; conversely, learning-avoid goal orientation was negatively associated with both. Task-approach goal orientation also was associated with higher

TABLE I. ASSOCIATIONS OF STRATEGIC SELF-REGULATION, MOTIVATION AND CREATIVE COMPETENCY WITH GRADES AND KNOWLEDGE

Variable			***Course Grade***	***Knowledge Test***
	M	***SD***	***r***	***r***
Course Grade	2.72	1.35	--	.350**

Creative Competency	56.80	15.02	.055	.139*

*$p <= .05$, **$p < .01$

grades and knowledge retention. Consistent with prior research [4,10], performance-avoid goals were negatively associated with course grades confirming that focusing on goals to avoid low achievement and negative judgments of ability is detrimental to achievement.

Perceived instrumentality was associated with grades and knowledge retention. Endogenous instrumentality was associated with higher grades and knowledge retention; conversely, exogenous instrumentality was associated with lower grades and knowledge retention. It appears that students who focus on only the utilitarian value of grades do not achieve or learn as well as students who focus on more personally meaningful instrumentality.

Positive emotional/affective reactions to the class were associated with higher grades and knowledge retention, and negative emotions/affect in the class was associated with lower grades and retention. Unlike prior studies [12, 13], implicit beliefs about intelligence were not associated with either grades or retention. Dweck [12] and Shell *et al.* [18] have argued that implicit intelligence beliefs operate by influencing goals. To test this, correlations between implicit beliefs were examined. Consistent with theory [12, 18], incremental intelligence beliefs were associated with higher learning-approach ($r = .24$) and task-approach ($r = .17$) goal orientations and lower performance-avoid ($r = -.17$) and task-avoid ($r = -.20$) goal orientations. Entity intelligence beliefs were associated with higher performance-avoid ($r = .25$) and task-avoid ($r = .22$) goal orientations and lower learning-approach ($r = -.16$) goal orientation, suggesting that impacts of implicit intelligence beliefs on achievement and learning are likely indirect.

Studies have not examined how Epstein's creative competency [37] might be related to STEM course achievement and learning. Overall creative competency was significantly associated with knowledge retention but not grades, suggesting that creativity may be associated with deeper learning and building of expertise, but may not be related to course achievement.

B. *Strategic Motivation, Self-Regulation, and Engagement*

Because students' strategic self-regulation and engagement were associated with their course grades and retention, we were interested in what motivated students to engage in these behaviors. We again used Pearson correlations (r) to examine how students' strategic self-regulation and engagement were associated with their motivation, affect, and creative competency (Table 2).

Students' self-regulated strategy use and knowledge building strategies were associated with similar patterns of motivation, affect, and creative competency. Both were associated with higher performance-approach, learning-approach, and task-approach goal orientations and lower learning-avoid and task-avoid goal orientations. These associations are consistent with prior research on goals [4, 9, 10]. Self-regulated strategy use and knowledge building were associated with higher endogenous instrumentality and lower exogenous instrumentality similar to findings in prior studies [4, 7, 24, 25]. As in prior research [4, 21], positive course affect had a large correlation increasing self-regulated strategy use and knowledge building; and negative affect was associated with lower levels of these. Implicit intelligence beliefs were not associated with self-regulated strategy use, but incremental beliefs were positively associated and entity beliefs were negatively associated with knowledge building. Interestingly, creative competency was positively associated with both self-regulated strategy use and knowledge building, suggesting that creative competency can enhance positive strategic self-regulation.

TABLE II. ASSOCIATIONS OF STRATEGIC SELF-REGULATION, MOTIVATION AND CREATIVE COMPETENCY WITH GRADES AND KNOWLEDGE

Variable	*Self-Reg. Strategy*	*Know. Building*	*Lack of Reg.*	*Study Time*	*Study Effort*
	r	*r*	*r*	*r*	*r*
GO Performance Approach	.19**	.20**	-.21**	.07	.13*
GO Performance Avoid	-.11	-.08	.12	.05	-.07
GO Learning Approach	.31**	.44**	-.20**	-.04	.05
GO Learning Avoid	-.27**	-.36**	.21**	.03	.06
GO Task Approach	.21**	.17*	-.19**	.16*	.19*

Creative Competency	.32**	.29**	-.07	.08	.01

*$p <= .05$, **$p < .01$

Lack of regulation was associated with almost the reverse pattern of motivation and affect. Learning-avoid goals were associated with increased lack of regulation. Performance-approach, learning-approach, and task-approach goals were all associated with lower lack of regulation. Exogenous instrumentality and negative affect were associated with higher lack of regulation, and endogenous instrumentality and positive affect were associated with lower lack of regulation. These associations are consistent with prior research [4, 21, 33] suggesting that lack of regulation is a function of negative emotional/affective reactions to the class coupled with a utility-based instrumentality for the course and learning-avoid goals.

Study time and perceived study effort both were associated with higher task-approach and lower task-avoid goal orientation and with positive affect. Additionally, study time was associated with higher performance-approach goal orientation and endogenous instrumentality. Higher study time also was associated with negative affect, suggesting that engagement may possibly be motivated by both positive and negative reactions to the class. Perhaps those experiencing negative emotions make themselves study and persist more to compensate. This aspect of motivation for studying needs more study.

VI. DISCUSSIONS AND CONCLUSIONS

Recent theorizing in the fields of motivation and self-regulation [4, 16-18, 21, 27] has emphasized the complex links among motivation, affect, and students' strategic and self-regulated behavior in classrooms. The need to consider how multiple aspects of motivation influence a broad constellation of strategies, engagement, and self-regulation to advance course achievement and learning is increasingly recognized. Because motivational and self-regulatory constructs have emerged within different theoretical and research traditions [17, 27], research and discussion have tended to focus on only one (or a few) constructs and strategic behaviors at a time. Our findings show the need to consider how multiple aspects of strategic self-regulation and engagement produce higher grades and retention and how achievement and effective strategic self-regulation are motivated by different facets of students' goals, beliefs, and emotional reactions.

We found that course grades and retention of course content were associated with classic cognitive and metacognitive self-regulation [27, 28, 29] and active engagement [4, 16, 21, 34]. But, achievement and knowledge retention also were associated with a knowledge building approach [30, 31]. These findings suggest that high achievement and long-term retention require both effective studying and self-regulation and in-depth examination of course content through personally meaningful knowledge building. Findings also suggest that STEM educators need to pay attention to students who are not being effective in their studying and self-regulatory efforts, as we found that lack of regulation was associated with lower grades and knowledge retention. Prior research [4, 21] has implicated lack of regulation as a key component in learned helplessness [8] that can potentially lead to disengagement and failure.

Effective interventions to enhance student strategic self-regulation have been reported [28]. These typically involve special courses in study skills [28] or other outside-of-class interventions. Referral to these resources may help alleviate lack of regulation difficulties. Instructors themselves can help students manage time and prioritize by being clear about assignment time demands. They can encourage students to ask questions when they do not understand course material or assignments. Interventions in classrooms to foster knowledge building have been described [18, 30, 31]. Collaborative activities, especially those involving Computer Supported Collaborative Learning (CSCL), have been shown to increase knowledge building [30, 31, 32].

We found that similar patterns of motivation and emotion/affect were associated both with grades and knowledge retention and with higher strategic self-regulation and engagement. These findings support theoretical views that motivation and emotion work through their impact on strategic self-regulation and engagement [14, 15, 17, 18]. Learning-approach goal orientation has been singled out as critical to effective learning and building of expertise [18]. Our findings supported the association of learning-approach goal orientation with increased achievement, knowledge retention, and strategic self-regulation. Our findings also suggest the potential for learning-avoidance goal orientation to undermine these, as they were negatively associated with grades, knowledge retention, and strategic self-regulation and were positively associated with lack of regulation. Shell *et al.* [18] discuss a number of strategies for helping students adopt learning-approach goals. Instructional strategies such as worked examples and models that focus on learning as opposed to solving problems or producing products have been found to be especially effective by directing students to attend to learning rather than outputs [41].

Task-approach goal orientation also is necessary to motivate the self-regulation and engagement needed to study and practice enough to build knowledge and skill [18]. Our findings supported this linkage, as task-approach goal orientation was associated with achievement, knowledge retention, self-regulated strategy use, knowledge building, and engagement while task-avoid goal orientation was associated with decreased self-regulated strategy use, knowledge building, and engagement. But, task-approach goals need to be balanced by learning-approach goals. As noted by Bereiter and Scardamalia [19], students often approach school as a series of tasks to complete rather than as an opportunity to learn. Instructors need to be sure that students are focused on learning the content and not just focused on getting the assignments completed.

Perceived instrumentality has been identified as crucial to student motivation in STEM [4, 7, 18, 25]. Our findings supported this connection as endogenous instrumentality was positively associated with achievement, knowledge retention, self-regulated strategy use, and knowledge building and negatively associated with lack of regulation. Utility-based exogenous instrumentality, on the other hand, was negatively associated with these. These associations suggest that seeing "getting a grade" as the only important outcome of the class does not necessarily lead to effective strategic self-regulation and learning. Students need to see the endogenous instrumental connections between the course and personally meaningful future goals [11, 18]. Research suggests that students do not necessarily see these connections [4, 39], so STEM educators may need to be very explicit about how course material links to the students' major and career aspirations. Endogenous instrumentality can be impacted by classroom intervention, such as providing videos of past students talking about how they used the course content in their other courses [7].

Having incremental intelligence beliefs has been shown to be important for setting learning-approach goals and for fostering knowledge building strategies. Our results supported this prior work as we found a positive association between incremental intelligence beliefs and knowledge building and a negative association between entity beliefs and knowledge building. Numerous studies at all educational levels have shown that incremental intelligence beliefs can be fostered by instructor feedback focusing on how ability and skill can be improved through study and practice and by specific interventions such as having students read a passage about brain plasticity [13].

Our findings that positive emotions were associated with higher levels of achievement, knowledge retention, strategic self-regulation, and engagement and negative emotions were associated with lower levels of these were consistent with much prior research [4, 14, 15, 16, 21]. Research [4, 39] suggests that students in STEM courses that are required but not specifically in their major often have very negative emotional reactions to the course as a whole and to specific assignments designed to enhance deep learning. Establishing a learning-approach climate in the class and fostering higher perceived instrumentality are thought to increase positive affect [15], but there is limited research on how to overcome strong negative emotions in the class [15].

This study is one of the first to look at the role of creative thinking in STEM course achievement and student strategic self-regulation. The Center for Computational Creativity research team has proposed that that using Epstein's [36, 37] model, creative competency can improve learning of computational thinking [39]. The findings provide support for this contention. *Creative competency was not associated with grades, but was associated with higher retention of course material.* Also, *creative competency was associated with higher self-regulated strategy use and knowledge building*. These results suggest that creative competency may enhance the strategic learning strategies associated with building new knowledge and understanding that lead to greater long-term retention and development of expertise. This suggests that enhancements to creative competency may be a valuable instructional tool [39].

***Abstract*— As we engage in an increasingly complex and quickly progressing world, the development of science, technology, engineering, and mathematics (STEM) students will be increasingly important to the continuation of the United States' competitiveness. However, the overall number of STEM students earning a degree will not be able to meet the increasing demand for practicing professionals especially within historically underrepresented groups such as women and minorities. One way to tackle this problem is to increase the retention of STEM students by studying the processes that influence persistence to completion of a STEM degree. Retention is critically important to the field of engineering as over 10% of all engineering majors will switch to other STEM degrees and even more will not persist within STEM fields at all.**

The focus of this paper is to utilize Expectancy-Value Theory to determine how freshman engineering students (both those who persisted within the major and those who switched out of the major) perceive engineering. Research was conducted at a predominately undergraduate liberal arts institution with a medium sized engineering program. Interview data was examined for 11 entering freshman who stayed with the engineering program (persisters) and 10 entering freshman who switched to different majors (switchers).

Keywords—EVT; Engineering; STEM; Persistence; Expectancy-Value Theory; Attitudes; Beliefs

I. Introduction

With innovation accounting for over half of the documented economic growth within the United States over the last 50 years, the ability to provide students with the opportunity to succeed in science, technology, engineering, and math (STEM) fields is increasingly important [1]. STEM occupations are expanding at a faster rate than their non-STEM counterparts, but even with this increase in demand, many STEM fields are barely keeping pace with the rate of degrees awarded in other fields. STEM bachelor degrees have dropped from a high of 24% in 1985 to 18% by 2009, while masters have declined from 18% to 14% during the same period [1]. This phenomenon is especially troubling in the field of engineering, where the National Science Foundation's (NSF) Science and Engineering Indicators for 2012 show that 10% of all declared engineering majors will switch to earning a mathematics, physical science, or computer science degree [2].

Another concern is that many of the STEM degrees being awarded within the U.S. are going to foreign students, who might take their skills back to their home country, leaving positions still unfilled domestically. The U.S. Congress Joint Economic Committee indicates that the share of degrees going to domestic students has dropped from 74% to 54% and the NSF's Science and Engineering Indicators for 2012 indicate that foreign students have continued to increase at the graduate level particularly within engineering and computer science [1].

It is also troubling to note that many traditionally underrepresented groups still struggle to break into certain STEM fields. The NSF indicators for 2012 show that while women make up approximately 57% of bachelor degree earning students, they are still a minority of the students who are awarded degrees in engineering, computer science, and physics. These statistics also indicate that the proportion of women within these fields has not changed significantly in the last 10 years [2]. Racial and ethnic groups have witnessed a small increase in the number of STEM degrees awarded but no more so than the overall increase in total degrees awarded. These increases have also failed to close the gap concerning employment within STEM fields as Hispanic and African American workers only account for 6% of all STEM positions, which is disproportional to their overall percentage of the population (Hispanics make up 14% of the overall population while African Americans make up 11%). These trends have left us trailing behind some of our global international competitors in both diversity and competitiveness and have led some to call into question the ability of the United States to maintain its economic leadership [1, 2].

These worrying trends have led to a new emphasis on research which focuses on factors that affect recruitment and retention. Educators have begun to focus their efforts on identifying what factors influence students to choose STEM majors and what factors influence their decision to persist with a STEM degree, with the hope that once these factors are identified tools can be developed to capitalize on them in order to increase the total number of students graduating with STEM degrees. Within this paper, we will focus on how Expectancy-Value Theory (EVT) influences engineering student's motivation to persist or switch out of an engineering degree. By analyzing how students' motivation is influenced by a variety of factors, major motivational markers can be identified

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

which will serve as the foundation for further exploration of a predictive tool to increase overall retention within engineering, and other STEM majors, to provide the opportunity for targeted analysis to solve for underrepresentation of specific groups within STEM fields.

II. Literature Review

Over the past decade researchers have begun to question the effectiveness of traditional lecture-based methods for teaching students which has led to the development of alternative student-centered learning environments. This push for novel pedagogical practices has led to the study of both external and internal factors and how they influence retention within the classroom.

Researchers have studied how external factors influence students' retention and motivation within classrooms through experimenting with alternative teaching styles. Prince reviewed 168 studies on retention and found that collaborative learning, which relied on group work, was able to increase student performance and decrease minority attrition by 22% [3]. Yusof, Hassim and NMA have demonstrated that Problem-Based Learning (PBL) which promotes smaller group based project work is also able to influence retention through external factors. They found that PBL was able to increase student problem-solving, directed learning, motivation, confidence, and team cohesion within a Process Dynamics and Control Course for chemical engineers [4]. Bernold, Spurlin, and Anson found that engineering students could be categorized into four main learning styles (WHY, WHAT, HOW, and WHAT-IF), which corresponded to specific desires for external classroom environments. They found that traditional lecture-based courses only catered towards WHAT and HOW learning styles which desired verifiable data, individual assignments, straightforward tasks, and measurable products. Without relying on alternative teaching styles WHY and WHAT-IF groups demonstrated lower performance and retention rates due to their desire for an environment that fostered creativity, innovation, abstract application, and cooperation with other students [5].

Other researchers have focused on how internal factors have influenced student retention. Attitudinal research is one such area of study which seeks to examine the intersection of attitudes and beliefs. An attitude is commonly defined as a learned consistent response to an action or object [6]. This is different from a belief, in that a belief is an individual's pre-existing knowledge [7]. Self-Determination theory (SDT), a subset of attitudinal research, seeks to determine how the strength of certain motivations (deemed autonomous or controlled) influence a person's decision making processes [8]. Amelink and Meszaros used SDT to show how different internal and external frames of reference influenced male and female students' evaluations of situations and affected their decision to remain within engineering [9]. Beam et al. demonstrated that a student's self-conceptualization of identity and its alignment with their conception of being an engineer could also be a factor that influences the likelihood of a student persisting within the major [10].

Expectancy-Value Theory (EVT) builds off the foundation set by previous works in attitudinal research and seeks to explain how attitudes and beliefs influence expectancies and values. It seeks to measure how external stimuli and factors are internalized into internal reactions to explain retention. Lawler defines EVT as "the strength of a tendency to act in a certain way depends on the strength of an expectancy that the act will be followed by a given consequence (or outcome) and on the value or attractiveness of that consequence (or outcome) to the actor" [11].

EVT originated in the work of John Atkinson in his 1957 publication, "Motivational Determinants of Risk-Taking Behavior." His laboratory studies focused on how expectancies and values influenced an individual's performance, motivation, determination, and objectives [12]. Expectancies are defined as preconceived ideas concerning the likelihood of an outcome to occur and can be divided into ability beliefs (broad beliefs about competency in a domain) and expectancies of success (beliefs about competency at a specific task) [7, 13]. However as research has expanded beyond laboratory environments where variables can be isolated and manipulated, researchers have found that in real-world situations both types of expectancies are highly interrelated and thus not statistically different. This has led many researchers to referring to expectancy as a singular unit [12].

Value is defined as the amount of worth a person assigns to a task and has been categorized into four main components by Eccles and colleagues: intrinsic value (enjoyment gained by finishing the task), utility value (usefulness of completing the task), cost (things given up in exchange for doing the task), and attainment value (importance of success) [13-14]. Trautwein et al. later confirmed this division of value in a study of 2,508 upper secondary students. In this study researchers found that, while there was a high correlation between many of the value dimensions, any model which did not combine the value dimensions was able to account of more variance than those that did combine one or more of them. [12].

Eccles and colleagues developed a framework which combined the internal factors of expectancies and value with research into attitudes and beliefs, serving to interrogate how internal and external factors interact [14]. Their studies on domain specificity of knowledge and the development of expectancies and values as children age have demonstrated that beliefs about a task, a person's perception of their past performance, beliefs about other people's attitudes, cultural influences, and personal history all effect both expectancies and values, which in turn influence their performance, persistence, and choices [13].

Jones, Paretti, Hein, and Knott in 2010 and Matusovich, Streveler, and Miller in 2010 both applied EVT research to the field of engineering education and retention studies [15-16]. Jones, Paretti, Hein and Knott found that value dimensions were better predictors of career choice than expectancies when analyzing data collected from freshman students [15]. Matusovich, Streveler, and Miller found that high attainment value (i.e. identity correlates strongly with being an engineer) was highly correlated with persistence, and indicated that students demonstrating low attainment values offer an opportunity for educators to influence the persistence process. They also found that low/moderate attainment or interest when combined with high utility can produce persistence when costs remain low and that low attainment, interest, and utility with high costs produced situations where students were less likely to persist [16]

This paper seeks to expand upon previous research into EVT and engineering retention by focusing on how costs influence other value dimensions specifically as it applies to persisters and switchers in order to understand how different students can view the same event from different value frames. By understanding how these events are internalized through motivational structures, alternative pedagogical practices can be adjusted to accommodate student learning and increase the likelihood that students will persist within the major. The ultimate goal of this research is to build the foundation for the development of a predictive tool that can serve as an aid to both high school and college counselors to assist them in identifying motivational strategies to inspire students to become engineers and remain within engineering programs.

III. Methodology

All data used within this study was part of an ongoing research project aimed at understanding engineering retention produced by Beam et al. and Pierrakos et al. [10, 17]. Data was originally collected from 45 interviews and focus groups conducted with freshman students (STEM and non-STEM) at a large predominately undergraduate liberal arts institution during the Fall of 2008 and Spring of 2009 [17]. Because of the scope of this research, information was limited to the 21 students who entered the university's medium sized engineering program as freshman [10]. Eleven of the interviewees planned on staying in the engineering program at the post-interviews conducted at the end of their freshman year (labeled as persisters) and ten of the interviewees switched out of the program (labeled switchers). Students were recruited through e-mail requests and those who consented were interviewed orally by proctors using a semi-structured format for 30-50 minutes. Each interview was recorded for transcription and analysis [17]. The overall goals of the interviews were to evaluate: influences that led students to choose engineering, students' knowledge of what an engineer is, a students' sense of being prepared, a students' sense of community within engineering, and influences to a students' professional identity [17]. Because these goals align closely with factors that influence expectancies and values, the data when analyzed by EVT provided relevant results.

Based on the research done into the multi-disciplinary application of EVT and specifically EVT's effect on retention in engineering education, three categories were developed to analyze: expectancies, beliefs, and values. After these categories were identified, several of the interviews were analyzed to identify common themes deemed relevant given previously evaluated literature and their relation to the predetermined categories.

From this analysis, thirteen themes were identified as common to many of the interviews and were incorporated into the coding process. The division of these themes has been represented graphically below in Figure 1. The expectancy themes identified included: expectancies of success (degree that a student feels they will do well on a particular subject matter related to engineering), evaluation of prior knowledge of engineering (degree of certainty that a student feels about whether their evaluation of what engineering is, was accurate), ability beliefs (degree that a student feels they will do well in the discipline of engineering), perception of inclusion in the community (degree of belonging to the engineering community and sense of acceptance by faculty and peers), and perception as an engineer (degree of identification with being an engineer). The belief themes included: prior knowledge of engineering (level of correct perceptions about engineering), beliefs about how others perceive engineering (degree of perceived positive reactions by others to the engineering discipline), and previous engineering experience (level of involvement with activities that relate to engineering prior to survey as evaluated by experts opinion of field). Finally the value dimension included: intrinsic value (degree of value based on enjoyment of activities related to engineering), utility value (degree of value based on perceived usefulness of activities related to engineering), cost (degree of value based on perceived opportunity costs or negative consequences of activities related to engineering), and attainment value (degree of value based on perceived importance of succeeding at engineering).

A team of three researchers was assembled to code the data for presence of each theme. Each interview was assigned to two researchers who coded the analysis independently on a scale of zero to three. A score of zero represented that the researcher did not think that the theme was present at all within the interview. One indicated a presence at low value, and three represented a theme was present at high levels.

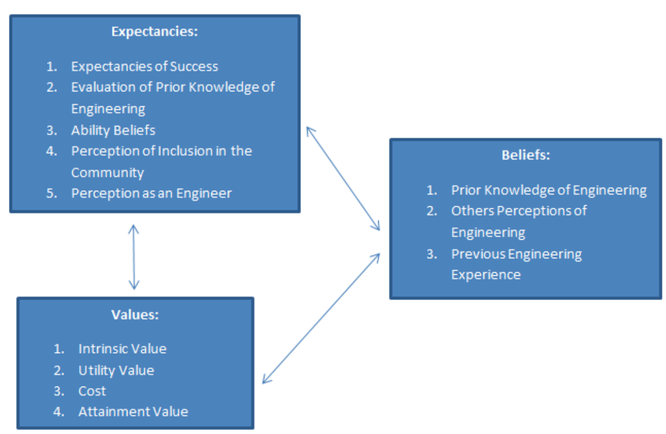

Figure 1: Breakdown of Themes by Category

For example, a three in the category of costs represented that the interviewee clearly and strongly indicated that engineering caused them to miss out on opportunities or provided them with opportunity costs that outweighed the values of engaging in engineering.

Some limitations exist with the application of EVT to the data analyzed within this paper. EVT is generally applied to situations in which people are asked to predict their responses or beliefs about certain situations; whereas the data collected for this research utilized interviews which expressed passed feelings and recollections. While this does introduce some error in the application of EVT, the data still provides valuable insights into motivations of STEM students. Future research into the development of an assessment tool to aid in counseling for retention can increase their applicability of EVT by gathering data explicitly for the purpose of EVT analysis and phrasing questions to capitalize on the predictive nature of EVT variables.

Finally, the inter-rater reliability and generalizability of our coding method was tested by using two raters with high levels of familiarity with EVT literature and one rater who did not have previous experiences with EVT. Rater 1 and 2 were both involved in the developent of the EVT coding framework and both possessed previous experience with EVT literature, while rater 3 was not involved with the process until the coding began. When the raters average scores and the standard deviations for their averages were compared, no significant differences could be discerned between the different raters as shown in figure 2 below. This indicates that the coding rubric developed for describing and ranking themes provided an adequate introduction to the topic of EVT and the specific themes being examined. As the goal is to eventually develop a tool to help counselors identify areas to address retention in engineering, this finding was encouraging.

Figure 2: Reliability Between Raters

IV. Results

This paper began by examining the differences between persisters and switchers to determine which themes would prove the best indicators for differentiating between the two groups. Our initial hypothesis was that people who switch out of engineering would show significantly higher scores in the area of cost, while persisters would demonstrate higher scores in all other themes analyzed. We further hypothesized that value themes would prove better indicators for persistence then either expectancies or beliefs. This hypothesis was corroborated by the data collected.

The average of the two coders' scores for each theme from all of the persister and switcher interviews has been depicted below in figure 3. Using this data, a Cohen's D analysis was performed to directly compare the significance of the differentiation between persisters and switchers. Through this analysis it became evident that students who persisted past the first year in general showed large effect sizes in all themes except for "others perception of engineering" and "utility".

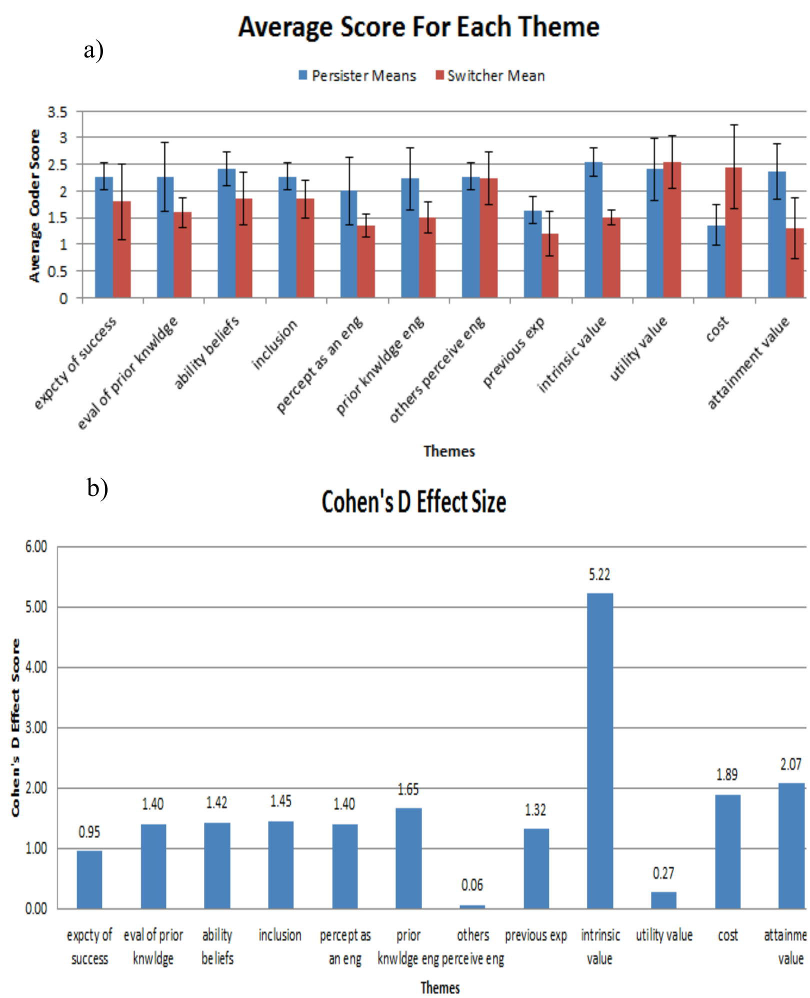

Figure 3: Thematic Analysis. a) is the average of the two raters scoring for all of the persisters and switcher presented for each theme b) is the Cohen's D effect size calculated for each theme.

A. Expectancies

As highlighted in Figure 3, students who demonstrated higher levels of expectancy were more likely to persist within engineering then those who did not. One explanation for this trend is that people who expect to do better will view problems as a challenge to overcome and will put in more time and effort to succeed in the task at hand. If students doubt their ability to succeed it can lead to a self-fulfilling prophecy where students do not work as hard as they otherwise might. One switcher described this feeling as, "I was really like pumped about the engineering program like, I loved all of the professors, ... I feel like I have that much more of a disadvantage with this calc[ulus] because everyone else is like on the track… I just don't like going into something, not being sure that I can do it." When this view is contrasted with a persiter who in Table III indictates that the math requirement was a necessary challenge to overcome and not a disadvantage, the data shows that differing expectancies can lead two different students to view the same task from different viewpoints such as one viewing it as a cost while the other views it as a benefit. In this case, a low expectancy score led the switcher to view math as an insurmountable obstacle to continuing engineering even though they also indicated that another math teachers might have been able to relay the necessary information if they took the course again.

The students who were interviewed came from a broad background with different skill levels and even switchers who indicated that they were not struggling with the skills portion of the classes demonstrated these overarching principles. Table I illustrated that students isolated issues ranging from not fitting in, to fear of being stuck at a desk, and even the idea that engineering is too individual oriented as opposed to group oriented, as reasons why they felt their personal background and identity did not set them up to succeed within the environment that they perceived engineering to be. This also shows that expectancies, beliefs, and values are interrelated. The switcher in this case encountered a situation that influenced his/her expectancies which influenced his/her values of engineering, which will over time influenced his/her belief structure.

TABLE I.

	Examples of Responses		
	Themes:	Definitions:	Examples:
Expectancies	**Expectancies of Success**	Degree that a student feels they will do well on a particular subject matter related to engineering	• "I've always been good at math and physics" • "Yeah, I'm confident that I've been well prepared"
			• "My physics class from high school wasn't very good and everyone dropped out of my calculus class so it was kind of tough going into here when I didn't really know any calculus because they dropped the program at my high school" • "poorly on math placement"
	Evaluation of Prior Knowledge of Engineering	Degree of certainty that a student feels about whether their evaluation of what engineering is, was accurate	• "I used to work for an actual firm…it was for civil engineering, we helped design a project for a new stadium" • "I took engineering in high school"
			• "I just really didn't have any clue how you know difficult it would be once I got here" • "I don't want a job where you know working by myself…maybe engineers interact more than I perceive them to but as far as the studying and work you do in class, that's certainly all individual work"
	Ability Beliefs	Degree that a student feels they will do well in the discipline of engineering	• "I knew being an engineer would be tough, but I'm not really worried" • "Do you think you're background has prepared you….? Yes"
			• "I just wasn't that interested and then the difficulty of the courses themselves, I just couldn't, couldn't do it" • "Really unprepared when it comes to science"
	Perception of Inclusion in the Community	Degree of belonging to the engineering community and sense of acceptance by faculty and peers	• "pretty accepted in the science classes" • "I feel like I belong because all of our personalities are similar"
			• "my lab partner, was actually my roommate so like, I got along with him, but the other people were just there" • "I never felt like I really like fit in with everybody else who was doing it"
	Perception as an Engineer	Degree of identification with being an engineer	• "I don't feel like an engineer as in like that's my job; I feel like an engineer as like being a student with the classes and everything" • "I like telling people I'm an engineering major and people are like WHOA"
			• "Do you feel like an engineer? Not really yet in many ways, might be because I have so many different areas of interest" • "I haven't really felt like an engineer yet"

[a.] Higher scored responses denoted in grey and lower scores denoted in white

B. Beliefs

The data highlighted in figure 3 also indicates that prior beliefs followed similar trends to that of expectancies, in that persisters consistently scored higher in each belief theme then switchers. The largest Cohen's D effect size was prior knowledge of engineering, which indicated that students who knew more about what they were getting themselves into were less likely to be surprised by the course load and work involved with the program. As Table II demonstrates a number of students came into the engineering program with little knowledge of what an engineer does or the requirements that they had to meet. This lack of knowledge left some students shocked or distressed by the amount of and type of work that they were expected to do which contributed to their decision to leave. One switcher when asked if they felt prepared coming from high school said, "I thought I was prepared. I took physics, I didn't take AP because I figured it was the same thing, and I found out it wasn't." In general students indicated that they expected to take hard math and science courses but beyond that had difficulty describing what is involved within an engineering curriculum.

Students who had participated in activities like those listed on Table II such as engineering summer camps, engineering school courses, or who had expereience with engineers through their family or work were more likely to persist then students who scored lower in this category. Interestingly, figure 3 indicates that others' perception of engineering represented the lowest Cohen D's effect size. A majority of students thought the community views engineers positively whether they persisted or switched. This theme proved the least beneficial indicator of intent to switch or persist.

C. Values

Finally, values proved to be the best indicator of persistance, a finding consistent with previous work by Jones, Paretti, Hein, and Knott [15]. Within the themes for value, intrinsic value, followed by attainment and costs were the best indicator which differs slightly from Matusovich, Streveler, and Miller's findings that attainment value is the best predictor of persistance [16]. As figure 3 demonstrates, all three themes produced large Cohen's D effect sizes, while utility produced only a small effect size.

The high significance of intrinsic value, is indicative of the need to enjoy a subject to be able to persist through the challenges that a student faces. Students who found enjoyment in the classes they were taking were much more likely to persist in engineering then those who viewed engineering

TABLE II.

	Themes:	Definitions:	Examples:
Beliefs	**Prior Knowledge of Engineering**	Level of correct perceptions about engineering	• "I knew being an engineer would be tough" • "engineering is in my family (dad works with missiles"
			• "Hands on (there is behinds the scenes deskwork?) ….stereotypical "ocean miners" and whatever they do"
	Beliefs about how Others Perceive Engineering	Degree of perceived positive reactions by others to the engineering discipline	• "overall quite supportive, everybody needs engineers" • "parents/grandparents/family have always been supportive"
			• "the people in the engineering program, or course there's like nerdy kids, like ok, stereotypical" • "the actual workers who have to put together, they think that engineers are idiots, I kid you not they always talk about how they hate engineers and how they screw up things because they never make anything practical"
	Previous Experiences	Level of involvement with activities that relate to engineering prior to survey as evaluated by experts opinion of field	• "IB program" • "governors school in field ecology"
			• "Any experiences…that led you into engineering?...Not really because I didn't really enjoy physics and stuff" • "did a summer camp thing"

[a.] Higher scored responses denoted in grey and lower scores denoted in white

TABLE II.

	Examples of Responses		
	Themes:	Definitions:	Examples:
Values	**Intrinsic Value**	Degree of value based on enjoyment of activities related to engineering	• "like building/designing things" • "they put a high emphasis on sustainability, environmental aspect, and that's, that was a big like role play in what I wanted to do"
			• "I didn't want to go into business" • "I didn't really want to be stuck in an office"
	Utility Value	Degree of value based on perceived usefulness of activities related to engineering	• "yeah it's a very prestigious job" • "I chose it because like it would be financially stable"
			• "I haven't really thought that far"
	Cost	Degree of value based on perceived opportunity costs or negative consequences of activities related to engineering	• "considered music (violist), also considered physics" • "I guess just the amount of time you have to put into it, and that fact that you know it's not really creative in any way"
			• "Math is necessary in engineering but I like a challenge"" • "You could major in bio, but then you'd just do bio and have to specialize, etc. If you get an engineering degree there's a lot you can do with just that"
	Attainment Value	Degree of value based on perceived importance of succeeding at engineering	• "I like the saying that engineers "make things better," they don't invent, they improve upon things and I would like to be a part of that improving upon" • "I have pretty high expectations for being able to solve really hard problems when I'm like out of school, senior year, being able to come up with creative solutions"
			• "I've never really thought about what kind of ideal job I wanted" • "I wasn't that dedicated to engineering, but…you need to be, they've told me and I've understood that like you need to be determined to do that"

[a.] Higher scored responses denoted in grey and lower scores denoted in white

solely based on its utility. In fact students who presented high utility without moderate to high intrinsic or attainment value were more likely to switch to a major they "enjoyed" more. One switchers response to the question why are you leaving engineering was, "I was an exchange student in Germany last summer, and that's where I really, really developed an interest for it and when I came here I found out that I couldn't continue studying it…I knew then, if I'm sacrificing something that I really love for something that I don't love as much, there's something wrong." Students who changed majors based on enjoyment often indicated that no change to the program or counseling structure could deter them from leaving.

The second best indicator was attainment value, which represents how important success is to the student. The data suggested that students who wanted to succeed independent of skill level were more likely to persist. In general, it appeared that these students were more likely to view obstacles as a challenge as opposed to a cost. Usually students who ended up switching out of the major indicated that the opportunity cost was too high for them to be able to continue. As Table III indicates students often indicated they would prefer to take other classes, be able to join a club, or wanted to expand their social life. What was concluded from this information was that the difference between a student who switched and a student who persisted was not a result of a physical time difference (i.e. that these students took longer to complete the tasks assigned to them) but was often a result of the perception of the student with regards to the task.

V. Conclusion

While expectancies, beliefs, and values all provided evidence of their ability to serve as indicators for persisting or switching, values were by far the best indicators with intrinsic value serving as the most indicative of a persons intention to switch or persist. The large Cohen's D effect size for intrinsic value indicates that those who enjoy what they are doing are more likely to persist and view tasks as an opportunity for betterment rather than a cost. This correlation also makes sense with respect to the results for attainment. Many people who scored high in the attainment value category viewed situations that arose as part of the process for attaining their goals as opposed to costs. Finally, utility value showed a slight negative correlation with persistence, as money or prestige was often not able to overcome a lack of intrinsic value.

Expectancies followed by beliefs were the next best indicators, and illustrated consistent properties between both categories due to their interrelatedness. Our pre-existing beliefs influence our predictions on whether we think we will succeed just as our predictions for success may color our memories about beliefs. The significant anomaly was the category of others perception of engineering. This category represented a small difference between persisters and switchers, as most people believe the community views engineers with respect. This serves to limit this theme's ability to serve as an indicator for future development of aids in predicting persisters or switchers.

VI. Future Research

While most research on EVT focuses on intrinsic value, attainment value, and utility, this study has indicated that in fact cost can often play a role in students' intention to persist in engineering or switch out of the field. The way that students view a situation and the frame of mind that they use to evaluate consequences significantly influences how they approach different tasks. It is possible that if counselors or teachers were able to identify students who had a negative frame of mind then it would also be possible to build learning opportunities to change these students' perceptions about engineering and the process of becoming an engineer. EVT through its analysis of attitudes, beliefs, and motivations, provides a unique tool capable of examining previously unexplored motivations behind retention of students within STEM fields, and if a framework for development of evaluation tools can be developed, it provides the opportunity to train individual instructors to identify and react to different motivational and learning structures to produce targeted advancement for recruitment and retention.

Research still needs to be expanded in the development of evaluation tools for identifying these themes within students. Research will need to focus on incorporating processes that allow for a predictive identification of the themes as opposed to past recollection and should be expanded to understand the differences between motivational patterns for underrepresented groups. Research should also be expanded to include how EVT intersects with other types of attitudinal research. Vansteenkiste, Lens, De Witte, & Feather have produced studies which indicate that applying both Self-Determination Theory and EVT at the same time is able to account for more variance within the data then either alone [8]. Looking at the intersection of multiple attitudinal research types could provide a more nuanced evaluation of the data collected within future EVT research. Finally in relation to retention, EVT should be used to inform practices involed with the applicaiotn of alternative pedagogies such as PBL and cooperative learning. Motivational sturctures can inform classroom pedagogies to increase the effectiveness of both as we move towards a more inclusive learning environment.

First-Generation Engineering Transfer Students:

A Qualitative Study of Social and Cultural Capital

Abstract—**We present the preliminary results of interviews with 18 first-generation engineering transfer students at two institutions. We employ a unique method for categorizing students according to generation status and then examine whether their experiences differ from one another. We then describe the different experiences of transfer students based on parental education status, with a focus on negotiating the transfer process, involvement in extra-curricular activities, the use of study strategies, and assistance received from families. Our early results suggest that it is useful to make finer distinctions between the various levels of parental education (i.e., use three rather than two categories).**

Keywords-transfer student; first-generation student; social capital; cultural capital; persistence; STEM

I. Introduction

There has been much discussion about the needs, expectations and experiences of first-generation college students. Some studies focus on operationalizing the definition of "first-generation," while others look at the differences in the social and cultural capital of first-generation versus non-first-generation college students (students for whom one or both parents attended college and/or earned a college degree). [1]

This paper is the second in a series investigating the influence of various forms of social capital on transfer student outcomes and thus attempts to fill a gap identified in research on transfer students (those who attend more than one institution during their academic careers).[2] An earlier paper reported preliminary findings on how social, cultural, and transfer student capital interacted with institutional student orientation and advising efforts.[3]

II. Literature Review

In this paper, we seek to better understand whether the parental education status of transfer students is related to transition experiences. First-generation students are a growing segment of the college student population and the transfer pathway holds promise for expanding the diversity of higher education in general and engineering in particular. Given that parental education is related to both socioeconomic status (SES)[4] and race/ethnicity,[5] it is important to better understand how parental education influences student educational pathways.

From a theoretical perspective, parents can be an important source of various forms of student capital, including social capital,[6] cultural capital,[7] and transfer student capital.[8]Taken together, these forms of capital refer to the knowledge, skills, networks, and access necessary to successfully negotiate and ultimately graduate college .[9] Since first-generation students' parents did not attend college, those students may have low amounts of capital (e.g., information, access to social networks, etc.), potentially hindering their ultimate success in college. We contend that first-generation transfer students may experience "dual culture shock" resulting from being the first in the family to attend college and from the transfer process itself.

Methodologically, we respond to a call to go beyond the traditional approach of using only two categories of parental education (first-generation vs. non-first generation) to examine the influence of social capital on student retention and outcomes.[2] Since a large proportion of transfer students begin at 2-year colleges, we wanted to learn whether using a three-category definition that includes 2-year institutions would result in a more nuanced understanding of the role of parental education PE on student outcomes. Previous research suggests that such distinctions are important for learning about the "conditional impacts" of different levels of parental education.[10] We posit that including a mid-level of parental education, which includes earning a 2-year degree as the highest level of education, will allow us to capture the unique experiences of transfer students, many of whom transfer from 2-year institutions to 4-year institutions.

III. Research Questions

Theoretically, we investigated: (1) How the experiences of engineering transfer students vary, depending on their parental education (PE); and (2) When adjusting to the new institution, whether students enacted social and cultural capital in different ways, based on their parents' education. In particular, we examine the following dimensions of the transfer student experience: negotiating the transfer process, the use of advising and study strategies, and involvement in extracurricular activities. We also summarize the level and character of support from family members. As described above, methodologically, we expand previous research by including an additional PE level to understand student experiences.

IV. RESEARCH METHODS

We recruited our students from two large public research institutions, located in the Southeastern United States, that graduate a significant proportion of engineering students. Representatives at the two institutions emailed an invitation to engineering transfer students who had matriculated into the institution in the two years preceding the semester of the interview. Interested students provided demographic and interview scheduling information through an online survey. Participants were selected from six engineering majors (civil, chemical, computer, electrical, industrial, and mechanical). To meet our research objectives, we limited our study to those students who were seeking their first bachelor's degree (unless they were in a 3+2 program through which students attend one four-year institution for approximately 3 years before transferring to another institution, ultimately receiving degrees from both institutions). Students were diverse in terms of gender, ethnicity and PE. Selected students were interviewed in Spring and Fall of 2012. Interviews ranged from 19 to 65 minutes; the average length was about 37 minutes. Participants were paid $20 after the interview. Interviews were audio-taped and then transcribed verbatim and verified. We used a constant comparative coding method to elicit major themes related to our research questions concerning the influence of PE on transfer experiences.

Based on previous research [10], we categorized students based on whether: (1) both parents' highest level of education was graduating high school or lower ("low parental education" - LPE); (2) both parents graduated high school and one or both parents attended college and/or earned an associate's degree ("mid-level parental education" - MPE); or (3) both parents' highest level of education was a bachelor's degree or higher ("high parental education" - HPE).

For the current analysis, due to time constraints and the exploratory nature of this paper, we randomly selected six interviews in each category from among a total of 39 interviews at the two institutions.

V. INITIAL FINDINGS

A. Negotiating the Transfer Process

LPE students were more likely to describe their strategy for applying to the receiving institution as self-initiated. They had to "take the bull by the horns" to figure out the logistics of applying and determining which courses would transfer. They reported disappointment in the lack of support at both the sending and receiving institutions; they expected help but did not get it. The one LPE student who reported a more positive experience with the transfer process was part of a 3+2 program.

MPE students were more likely than LPE students to report meeting with counselors to learn more about the transfer requirements. They consulted individuals at both the sending and receiving institution. HPE students were most likely of the three groups of students to describe the transfer process in positive terms as "not so bad" and "smooth." One student said she felt confident about applying to the receiving institution "after taking courses [at the sending institution] and knowing what college is like." Another HPE student, who had attended two prior institutions, described using a variety of strategies to ensure her credits would transfer, including visiting the MIDFIELD institution, calling her major department, and utilizing the transfer credit equivalency website.

B. Advising and Study Strategies

There were distinct differences in student descriptions of their advising experiences. LPE students were most likely to describe their advising as "self-initiated" or as inadequate, especially at the sending institutions. The one exception was for a student who was a part of a 3+2 program; she reported that her advisor (at the sending institution) was quite helpful. MPE and HPE students were both more likely than LPE students to report using personal networks to obtain advice about coursework and succeeding at school. For example, an MPE student reported that the dean at his sending institution provided in-depth assistance in obtaining a scholarship. All HPE students reported receiving in-depth support from their advisors. For example, a student described receiving specific suggestions from his advisor for succeeding at the receiving institution: "My advisors told me to take easier classes and take a lighter load…he told me that most transfer students don't do well their first semester. So I should take a lighter load."

Respondents used a variety of survival strategies to ensure a smoother academic transition. LPE students were more likely to describe themselves as independent enough to "figure it all out"; others indicated they were still trying to navigate the system. MPE students also participated in a variety of study strategies, with one saying that he sought help "every day, every night" and another who attended all the tutoring hours, similar to an LPE student who said he went to supplemental instruction "as much as humanly possible." While HPE students also engaged in a variety of study strategies, they were more likely to indicate that they sought help from professors than did the other students.

C. Involvement in Extracurricular Activities

Extracurricular activities can be an important source of social and cultural capital for first-generation students who are negotiating a new academic environment.[10] All LPE students said they were very involved with extracurricular academic and social groups, with one saying she got involved "right off the bat." They did so for a variety of reasons: to reinforce classroom learning, network with others, and to ease the transition to the new schools. MPE students were also involved with student groups, with one indicating it was important for "engineering students to stick together" to get through the major. While HPE students were more likely to indicate they joined a variety of groups, they did not describe taking an active role in these organizations to the extent that MPE and LPE students did. For example, one HPE student said he really didn't see a need to join a group for transfer students; rather, he relied on friends that he knew from high school to learn how to succeed at the receiving institution.

D. Assistance from Families

Students from all three groups described receiving moral, emotional, and financial support from their families; however, LPE and MPE students used stronger adjectives to describe such support (e.g., "My parents are extremely proud of me";

and “They don’t want me to quit.”). An LPE student reported feeling immense pressure being the first in his family to attend college; he said he was “heartbroken” after receiving a failing grade on an engineering test, knowing this would disappoint his parents. An HPE student reported receiving practical and logistical support from parents in applying to school and negotiating the transfer process; for example, one student indicated relying on his parents to complete financial aid forms. In direct contrast, an LPE student indicated that, “you have to have the initiative… Because nobody…you don’t have your mom fill out those applications. My mom didn’t do that…frankly, she’s lucky I did it on my own.” Another LPE student commented that he sought academic advice from other adults who had earned a 4-year degree. MPE and LPE students often contrasted their own educational experiences with their parents’ educational experiences, which is not surprising. However, these comments allude to some potential challenges posed by the “cultural divide” with their parents. For example, one MPE student described himself as being the “black sheep” in his family for attending college, saying “I’m the smart one.” His family often teases him by calling him “Professor.” This same student reported “starting my own family tradition” by being the first in his family to go to college. Several LPE and MPE students said their parents could not at all relate to the logistical and practical challenges posed by both the transfer process and majoring in engineering.

VI. Future Research

Our research expands knowledge about the differential experiences of engineering transfer students based on parental education level. Early results suggest that LPE students were more likely to feel isolated upon arrival. They were more likely to report getting moral support from their families for attending college and for their choice of engineering major. However, of the three PE levels, LPE students described receiving less support from the institution for navigating the complex transfer and higher education pathways. This finding supports previous research on the relationship between parental involvement and parental education.[4] MPE students had similar experiences and were more likely to identify as “first-generation” even if one or both parents had college experience (attended college or earned an associate’s degree). HPE students relied on parents for practical assistance, but were equally as likely as LPE and MPE students to utilize a variety of study strategies.

Overall, our results support using a more nuanced definition of PE that includes a mid-level of parental education. This is especially important given that this level incorporates the distinct experience of attending a 2-year college. It should be noted that our research is based on student reports of their parents’ educational status; we did not ask the students about the experience of their siblings. That is, a respondent may have had an older sibling or other close relative who had attended college and given them advice about how to succeed.

In future papers we will analyze 86 interviews conducted at five large research institutions to learn more about the influence of PE on engineering transfer student experiences. These data will allow us to compare across the five institutions to learn how institutional context and individual characteristics mediate the influence PE on transfer experiences. We will investigate to what extent other sociodemographic characteristics, such as gender and race, may shape student experiences.[11] Our previous research suggests that distinguishing between sending institutions (2-year vs. 4-year) merits further investigation as well.[12] Finally, we will ascertain the influence of locus of control, motivation and other psychological factors that are important to consider, especially in the context of understanding how student experiences may vary based on parental education status.[4]

A New Vision: Changed Engineering Outcome Expectations through EWB-USA

Kaitlin Litchfield, Amy Javernick-Will
Department of Civil, Environmental and Architectural Engineering, University of Colorado at Boulder
Kaitlin.Litchfield@colorado.edu, Amy.Javernick@colorado.edu

***Abstract*—With the growing demands for additional and diverse engineers, the atypical gender balance experienced by Engineers Without Borders-USA (EWB-USA) is a unique engineering education research setting. Exploring the gender balance of this organization could assist the field's efforts in better recruiting and retaining female engineers. In this work-in-progress study, a social cognitive career theory framework is used to explore the engineering outcome expectations of engineers both involved and not involved with the organization. Qualitative methods were used to gather outcome expectations of male, female, professional, and student engineers, and initial case-based and thematic coding was performed. Preliminary results suggest that EWB-USA members have unique engineering outcome expectations that are often influenced by their organizational involvement. This study may identify ways in which the larger engineering field can replicate similar alternative expectations, particularly to aid the recruitment and retention of a more gender balanced engineering population.**

Keywords—outcome expectations; EWB-USA; retention

I. Introduction

Shortages of skilled engineers present concerns for future global economic competition [1]. These shortages have caused researchers to search for solutions in creative methods and settings including K-12 initiatives, work-life balances, pedagogical alternatives, mentorship programs, etc. [2], [3]. One unique context to study how to aid the engineering population is the non-profit, engineering organization Engineers Without Borders-USA (EWB-USA), which provides engineering solutions to developing communities around the globe. In its eleven years of existence, this organization has rapidly grown to 12,000 members in both student and professional chapters, and it reports roughly 40% female involvement [4]. Because this organization experiences such a contrasting demographic from traditional engineering settings, which average between 11% and 20% female involvement, this setting provides a unique context for research [3]. The large goal of this study is to explore EWB-USA's gender-balanced membership in order to better understand what can be done to recruit and retain more women in the engineering profession.

The framework for this study departs from social cognitive career theory which has been well studied in the context of math and science fields [5], [6]. This theory describes career choice motivations as based heavily upon both self-efficacy expectations (asking, can I do this?) and outcome expectations (asking, if I do this, what will happen?) [5]. These two factors are the primary drivers for this model of career choice and action. Several researchers have studied the impact of self-efficacy on engineering motivations (e.g. [7]), but very few studies have focused on outcome expectations, which some researchers claim should receive more attention [8]. Therefore, this paper fills the gap to explore the engineering outcome expectations of EWB-USA members.

Because social cognitive career theory proposes that career related interests and choices are dynamic and continuously adapting, this theoretical model offers a framework to show that engaging in EWB-USA can alter the outcome expectations and career goals and actions of an individual. Using this underlying framework, this study addresses the following research questions:

1. What are the engineering outcome expectations of EWB-USA members?
2. Do engineering outcome expectations differ between EWB-USA members and engineers not involved in the organization?
3. How does EWB-USA influence engineering outcome expectations of its members?

II. Methods

Due to the exploratory nature of this research, qualitative methods were used for their strength in rich descriptions. Semi-structured ethnographic-style questions were used to conduct both interviews and focus groups covering topics including motivations, career goals, and expectations of an engineering career. In total 165 engineers participated—105 EWB-USA members and 60 engineers not involved with the organization. Participants were primarily recruited through engineering organizations such as EWB-USA, ASCE, ASME, etc. and were selected purposively for a mix of males, females, students, and professionals. Recordings were transcribed and uploaded into qualitative coding software for inductive case-based and thematic coding.

Analysis is still underway, and thus far two thirds of the transcriptions have been coded using QSR NVivo 10 software. Data has been coded at the macro level for engineering outcome expectations which were recognized in the transcriptions through Bandura's three main types of outcome expectations: social, material, and self-evaluative [9].

This material is based in part upon work supported by the National Science Foundation Research in Engineering Education program under Grant No. 1129178. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

Distinctions between these three types have not yet been analyzed; however, all three were used to operationalize the framework in the coding process. Once transcriptions were coded at this macro level, the resulting coded segments were carefully read by the research team to look for themes and comparisons.

III. Preliminary Results

The results presented here are based on trends from initial coding and are preliminary. Further micro-level coding is continuing to distinguish the types of expected outcomes, to determine the relative frequencies of the response themes, and to explore differences between demographic groups such as students and professionals.

A. Engineering outcome expectations

Initial coding highlights that the engineering outcome expectations of EWB-USA members show hesitancy about the profession. In order to illustrate these hesitancies, some representative quotes from the data are shared. When asked about their expectations of an engineering career, most EWB-USA members expected a disconnect between the workplace and school ("*from the work that I've done in the private sector, I don't think that much of anything will look like going to school here*"); they expected to be bored or feel stuck ("*I don't want to be the type of engineer that is stuck in the office looking at technical sketches all day*"); they expected that it would not be social or impactful ("*the reason that [a lot of my friends] didn't go into [engineering] is because… they wanted to be out in the community and be active and help and do all these things and I don't think it was clear that you could do that in engineering*"); and they expected that they would not be happy and would eventually want to leave ("*I can't see myself being happy actually doing that for the rest of my life*"). While there were some more positive exceptions to these outcome expectations (such as one male's comment, "*so hopefully engineering will help me out somewhere*"), the majority of the engineering outcome expectations from this group were more hesitant than positive.

In comparison, the engineers not involved with the organization had more positive engineering outcome expectations. Some engineers were excited about the money or job security that they expected in engineering, ("*the reasons for [me] being an engineer is job security because that's obviously important right now*"); and they expected to be able to pursue their interests ("*I prefer the hands-on practicality, so that's why I'm an engineer").* In some ways their responses were similar to the EWB-USA members in that they were unsure how much their engineering curriculum would align with important on-the-job skills ("*[at work] you are not doing the problem just to solve a problem, you are not doing it just to get a grade, you are doing it to make money*"). While some engineers in this group showed hesitancies about their engineering outcome expectations, many more engineers in this group seem to be positive about the outcomes they expected from their engineering career.

B. EWB-USA influencing engineering outcome expectations

These contrasting engineering outcome expectations suggest that those engineers in EWB-USA are less likely to pursue engineering than engineers not in the organization. Yet in taking a case-based approach at answering the third research question, how EWB-USA influences its members' engineering outcome expectations, we start to see four pathways emerge, each of which will be described briefly here with a case. For each of these pathways, the research team used a low level of inference in order to identify influence based on participants' direct language.

1. Some members "see the light" in a traditional engineering career through EWB-USA as it helps them expect to be able to balance their multiple interests. For example, one female student said that "*I think the interpersonal aspect of EWB and working with the communities solidified the fact that you don't just need math and science to be good in engineering. … It made me think that I'd made the right decision… that I could survive engineering*."

2. Other members show that they have "found their niche" in engineering through EWB-USA by seeing a unique type of engineering that they can expect. As another female student said, "*I really want to do engineering but not like smartphone engineering, I wanted to do a different kind of engineering… I don't want to work in a process plant, that is not why I am studying engineering… and I get comfort from being in EWB because I have kind of stopped doubting that engineering was the right thing*."

3. A third pathway shows other members who, through EWB, have seen that they do not like the outcomes that they expect in their careers and plan to "readjust". One female professional member claimed, after witnessing the careers of people in EWB-USA, "*I am probably going to go back to school for a master's degree and probably just refocus my engineering career because… I had been able to see that what I am doing now isn't what I want to be doing long term*."

4. A fourth pathway comes from those members who have come to expect, through EWB, a mismatch between their interests and their careers. Those on this pathway plan to stay in the engineering profession for a limited time in order to "use the profession" for some valued outcome such as technical skills or salary. As one woman said, "*[EWB] sort of kept me in engineering… I don't find joy in designing a tank… I'm staying to make sure I can truly be the best engineer… I sort of go through every spring wanting to leave*." Members on this path are considering leaving engineering for a better match elsewhere, but are persisting for a certain gained value from the profession.

While each of the examples in the four pathways above quotes a woman involved with EWB-USA, some men show similar responses, such as one male who "found his niche" in unique engineering positions. He said of EWB-USA engineers, "*we're going to be pretty hard to impress with business as usual, status quo engineering*." Similarly, a woman not involved with EWB-USA talked about changed engineering outcome expectations through research she did as an undergraduate, "*it was all about helping kids in India… and for me that was just the kind of boost that I needed in the midst of the misery of engineering school, knowing that what we do is great*." This woman showed how her research experience changed her outcome expectations to help her "see the light" in engineering.

These examples highlight that there may be other men in EWB-USA who follow these pathways, or that there may be other engineers not in the organization with changed engineering outcome expectations through alternative activities; however, the majority of cases where engineering outcome expectations changed came from the EWB-USA members, particularly the female members. These pathways suggest that EWB-USA influences the engineering outcome expectations of its members in varying, yet significant ways.

IV. CONCLUSIONS

So far, the results from coding suggest that EWB-USA members have different engineering outcome expectations than engineers not involved with the organization. As their stories show, these differences can arise from the influence of the organization; EWB-USA influences what these engineers expect from an engineering career by altering their perceptions of its related outcomes. Based on a preliminary, case-level of analysis, four general pathways of these outcome expectations have emerged—some keeping EWB-USA members in engineering and some encouraging their exploration of alternatives. Theoretically, these results add to the application of social cognitive career theory, particularly in the call for extended understanding of outcome expectations and their link to choices and actions. Practically, these findings suggest that EWB-USA could act as an important link to engineering for those with traditionally less presence in the engineering field by giving them an opportunity to pursue their diverse interests (e.g. "*a different kind of engineering*") and explore their fit in engineering, even if for a short time. These practical results suggest that universities and workplaces should encourage the creation of this link between engineering and diverse interests through organizations like EWB-USA; however, they should also be aware of the potential struggles when enthusiasm is unmatched by a supportive culture [10].

Continued analysis for this project will solidify these pathways and quantify the results. The results presented are limited to a first, macro-level coding scheme based on emerging trends. Because this study is not longitudinal, results are also limited to participants' retrospective interviews where outcome expectations are interpreted through participants' use of direct language. Final results could impact the ways that the engineering profession addresses recruitment and retention of engineers, particularly females, by altering engineering outcome expectations.

ACKNOWLEDGMENT

We gratefully acknowledge EWB-USA Executive Director, Cathy Leslie, for her input and assistance with data collection. Additionally, we extend our gratitude to Jessica Byrne for her data analysis assistance.

***Abstract*—Students begin each new course with a set of expectations. These expectations are formed from their experiences in their major, class level, culture, skills, etc. However, faculty and the students are often not on the same page with respect to expectations even though faculty provide students with course syllabi. It is crucial for faculty to understand students' expectations to maximize students' learning, satisfaction, and success. Furthermore, it would promote classroom transparency. There would be no hidden unstated expectations; disappointments during the course can potentially be minimized. We present the results of a survey focused on understanding student expectations. Specifically, we focus on examining the differences in expectations of the students of Computer Science and Engineering (CSE) courses and non-computing STEM courses. We present our analysis and observations of the results using aggregate data for all students at all class levels. We observe various differences and similarities among the STEM fields. Identifying differences is crucial since many non-computing STEM majors are enrolled in computing courses, especially in the lower level courses. We provide a detailed comparison among sophomore and senior level courses in computing, biology and chemistry courses. We also compare sophomore and senior CSE courses. Finally, we discuss the importance of paying attention to all students' needs and expectations. Armed with this knowledge, faculty members can increase transparency in the classroom, student satisfaction, and possibly student retention.**

I. Introduction

Education is a national interest and President Obama has said "If we want America to lead in the 21^{st} century, nothing is more important than giving everyone the best education possible from the day they start preschool to the day they start their career" [16]. The President's Council of Advisors on Science and Technology (PCAST) in its 2012 report to the president put forth an ambitious goal of producing one million additional college graduates with degrees in the different Science, Technology, Engineering, and Mathematical (STEM) fields [17]. Computer and Computational Sciences and Engineering have a significant impact on almost all other STEM fields. It is a vital and crucial foundation to be built upon in other STEM fields [27]. This translates to a desire to push for multi-disciplinary connections between computing fields and other STEM fields. Projects such as *Engaging Computer Science in Traditional Education* (ECSITE) [8], [9], which developed curricular units that are embedded into non-computing $K-12$ classes to introduce computing to $K-12$ students, and the special session chaired by U. Wolz and L. Cassel to promote and discuss interdisciplinary computing [4] are two efforts that show the existence of initiatives in improving and introducing computing to curricula at different levels and stages. These initiatives originate from the reality that, all over the world, computational technologies have become an integral part of our daily lives. Other efforts that aim at improving science education such as Anderson *et al.* [2] have made recommendations for general science education, including adopting techniques already proven to increase learning.

The two thrusts above, namely, the need and importance of integrating computing into current and future curricula in the $K-12$ realm and at colleges and universities as well as the goal of producing more STEM graduates, mean that there are a larger number of students who are expected to be enrolled in colleges in STEM fields and that they will have more exposure to computing. If these efforts succeed, Computer Science & Engineering faculty should expect more students from other fields, specifically other STEM students, in their classes. It is important to understand and address the needs and expectations of this new category of students not only for their own growth, but also for the future of computing in general. Understanding, contemplating, and acting upon students' expectations will ultimately maximize the efficiency of the time that students are in the classroom and will increase the likelihood that learning goals are achieved. We may even entice a good portion of students to transition to a computing degree or to add computing as a second major. Without spending time in understanding our students and their expectations, it will be very difficult to move forward or to achieve these goals.

In this paper, we introduce a survey conducted with 816 students in 25 different STEM courses that addresses the need for examining the students' expectations at the beginning of any individual course. Results are presented alongside data from two specific computing courses. The rest of the paper is organized as follows: Section 2 discusses the related work and provides an overview of literature on student expectations. Section 3 describes the development and content of the survey tool we piloted (the survey can be found at [10]). Section 4 presents the results from the pilot with a variety of breakdowns. Section 5 is a discussion of the impact such a tool can make. Section 6 describes future directions of research.

II. Related Work

Understanding students and their expectations is not a new idea; a large volume of work exists in the literature that

TABLE I. A SUMMARY OF THE SURVEY CATEGORIES, QUESTIONS AND SELECTIONS

Categories	Questions	Available Choices	
	Which of the following do you expect in this course?	Learning Management Systems	PowerPoint
(1) Technology	Rank the three most important components in	E-Textbooks	Social Media

(5) Timeliness	Respond to email and phone calls, post grades,	Within 2 days	Within a week
of actions	return assignments, be available to meet	[Longer than a week] Never	N/A

investigates this ideas. For example, Tricker [24] looks for the reasons behind changes happening in student expectations over a period of three decades. The most relevant, closest, and most prominent work is the National Survey of Student Engagement (NSSE) [12]. NSSE assesses how students are engaged in learning, what practices affect this, and several other measures. With a focus on institutional-based measures, it collects data only from freshmen and graduating students. Likewise, Sander *et al.* [19] introduces a survey called University Students' Expectations of Teaching (USET), measuring incoming students' hopes, dislikes, and expectations for teaching and learning methods. These learning methods are general pedagogical choices such as regular formal lectures, group work, and private study. The limitation of Sander's work is shared with NSSE's. Both aim for comprehensive curriculum design but are cumbersome and lacking the detail necessary for an instructor who wants to address a specific class. Another limitation with Sander's work, compared to our work, is that courses surveyed are only in business, psychology, and medicine.

Trudeau and Barnes [25] focus on identifying and ranking the 'teaching dimensions' that students value the most and the least. These dimensions, taken from regular course evaluations, again address ideas like "Knows Material" or "Instructor Availability", without giving concrete knowledge about what students expect exactly to happen in a course. Furthermore, it does not give the students a space where they can freely express their views, limiting response choices to content in course evaluations. Several studies aim to determine the effects from cultural differences in international [22], first-generation and traditional students [5], or working-class students [14]. Additional studies focus on the expectations that surround technology [7], [15].

Reflecting a general concern over graduating students computing capabilities, numerous recent research and teaching initiatives have been devoted to increasing enrollment in CSE courses. Adams and Pruim [1] recognize the lack of supply of graduates with advanced computing skills and suggest ways to encourage non-CS majors to take CSE courses. They present strategies to attract science students to take additional CSE courses.

Our work is complementary since we are trying to provide and illustrate the differences and similarities between the expectations of computing majors and non-computing STEM majors which can be used to adapt computing courses to non-computing STEM students. In other publications, [20], [21] we consider different aspects of our expectations study, which we conducted at UMD as part of a year-long fellowship. In [21], we discuss the survey and its class-specific use in biology courses. In [20], we tangentially address some of the issues pertaining to computer science versus STEM in terms of expectations.

All in all, there is a significant volume of work on expectations. However, we did not find work that is focused enough to clarify why something is not perceived well or to be used in redesigning courses.

III. DEVELOPING THE SURVEY (METHODS)

A. Motivation

To guarantee both success and satisfaction for students in a course, we have to understand expectations of our students. A mismatch between student expectations and what happens in the classroom can have serious negative consequences [11]. Lang in "The Chronicle of Higher Education" [13] discusses classroom transparency, where openness is a key factor in mutual understanding and success between faculty and their students. The University of Illinois, Urbana-Champaign has developed an initiative [26] to increase transparency in the classroom. The initiative provides a platform for collecting results from testing different course changes, but only analyzes the effect at the end of a semester. It is important to increase transparency and close the gap of mismatched expectations between faculty and the students.

Our goal in this work is to create a resource for faculty that could inform them of what students were expecting in a course and to open a dialogue with our students about what faculty themselves expected and planned to utilize in a course. The survey was created as an adaptable, customizable, portable, and generic tool that can be used in any course on any university campus. In addition, we believe that excessive length can adversely impact survey participation and completion. We decided to make the survey as short as possible while still determining course expectations. The design goal was to create something that would take only a few (5 – 10) minutes to finish. In summary our design goals were: 1. Collect information directly related to a specific course; 2. Examine course components that were applicable to any course; 3. Focus

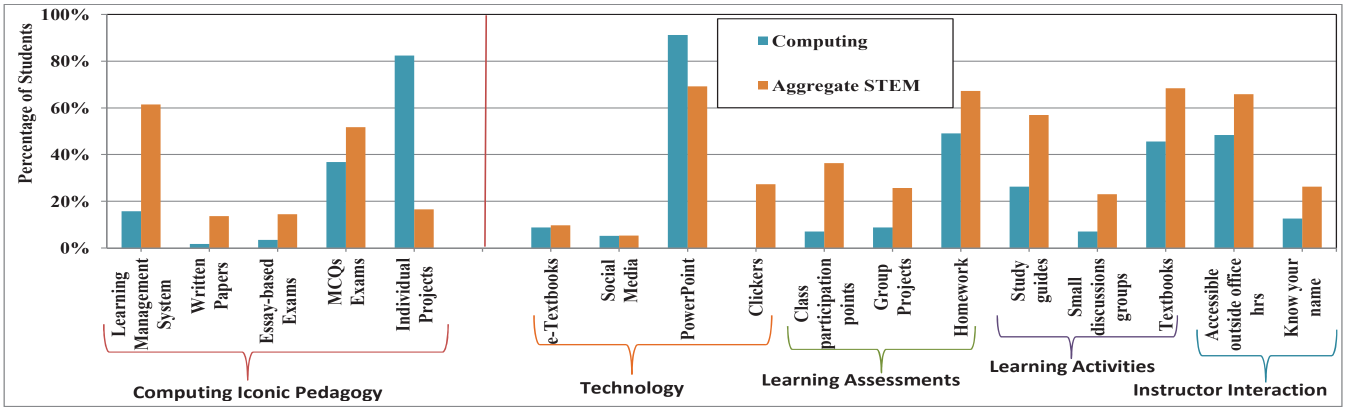

Fig. 1. A selected subset of the aggregate data for students' expectations in courses

survey content to be easily and quickly completed, yet still relevant for instructors.

B. Survey Structure

To satisfy our above stated design goals for the survey, we divided the survey questions into two groups. The first was a set of five demographic questions to provide context and classification for the results and to help us understand the make-up of the student population. The second was designed to gauge the expectations of the students to help faculty in planning, classroom management, assignments, and interactions with and among students. This second set of questions fell into five pedagogical and learning categories: 1. Technology and its Use; 2. Learning Activities; 3. Learning Assessments; 4. Faculty-Student Interactions; 5. Timeliness of instructor's actions.

Table I (adapted from [20] with some modifications) has a concise summary of the second group of our survey. The table outlines each of the five subcategories with the questions being asked and the choices the students can make for each question. The actual complete survey can be found here [10]. The last question we asked (not included in Table I) was an open-ended question which gave the students the opportunity to elaborate on their previous responses – "What misconceptions do you believe faculty have about students?"

C. Deployment & Updates

We deployed the survey in the early Spring 2012 at the University of Maryland, College Park, an R-1 state university. After the deployment, feedback was solicited from instructors whose students participated in the study. We received many useful suggestions and were able to modify our survey based on these insights. Notably, because of feedback from the instructors, in the "timeliness of action" category we added a new choice, namely "longer than a week" to address a gap between "within a week" and "never" in the options originally provided (Table I). We also added "lecture" as a selection option for the first three categories 1–3. Table I includes the suggested changes indicated by square brackets around them. We also clarified some of the questions. We do not believe these missing items jeopardize the validity of our results nor weaken our conclusions, especially in the case of the missed "lecture" option. As for the timeliness, we do not report any of this category's data in this paper. The edited and updated survey consisted of the three relevant demographic questions and six learning related questions. The survey is freely available via a creative commons license through the Center for Teaching Excellence [10]. The Department of Family Science is adopting this idea and thus, the department will deploy the tool in all of its undergraduate curriculum starting Fall 2013.

IV. Results

A. Participation

Instructors from across a wide range of departments were solicited for the study with 27 instructors opting to participate. This provided data from 25 different courses in 8 different departments across campus. Students from all 13 undergraduate colleges and schools at the university are represented in this sample. The final sample included 816 undergraduate students enrolled in STEM courses. Within this comprehensive data-set, there were two Computing courses surveyed, which we will discuss in greater detail: Introduction to Computer Systems (CMSC 216) and Programming Language Technologies and Paradigms (CMSC 433). The responses included 42 from CMSC 216 and 15 from CMSC 433.

The remainder of this section will present selected highlights of the aggregate data including a comparison to computing courses, a breakdown by class status, a breakdown by course level, and a STEM vs. Non-STEM comparison. We present two detailed case study comparisons of four 200-level courses from three STEM departments: Computer Science, Biology, and Chemistry, and three 400-level courses from Computer Science, Biology, and Bio-Chemistry. The complete results are available upon request.

B. Aggregate vs. Computing

Figure 1 presents a large series of comparisons between the aggregate data from all STEM courses including Computing courses and the average result of the two Computing courses surveyed. A few categories with minimal differences have been omitted for brevity. However, the majority of component categories ($\sim$ 75%) did have differences. Several of these results can be expected from iconic pedagogies historically used by computing courses, like programming projects. They are shown in the first section of Figure 1, and are presented to remind instructors that Non-Majors may not be expecting the level and volume of individual projects in a computing course.

The difference in Learning Management Systems points out another trend that is challenging to address. Students from other majors frequently expect professors to utilize university-wide course management systems. However, instructors that are accustomed to an in-house, department-specific, or non-standard learning management system often struggle or refuse to do so. This can create dissatisfaction in students as the information and interactions they have come to take as standard are not available to them.

Within the technology components, several unexpected results appeared. First, while many educators are exploring how to utilize e-Textbooks and social media, students themselves seem to expect very little use of them with only 10% and 5%, respectively, supporting the claims of low technology expectations by Lohnes & Kinzer [15]. This suggests that either the instructors are not using these techniques since they are relatively new in the classrooms or students did not see them in their past experiences and thus are not expecting them. Even though students are not expecting such technologies, there is work in some classrooms and some fields to develop such techniques to improve the learning process [23]. The question will be whether the students will see enhanced learning using these techniques. Instructors will need to take a step-by-step approach when introducing such technology. If instead these technologies are proving even marginally beneficial, it would make sense to spend time experimenting with them to find their rightful place in the classroom alongside other well-documented and researched pedagogies such as active learning [18].

Meanwhile, PowerPoint is highly expected, more so than in other STEM courses. The need to present pre-written code might explain this, however caution should be used since Craig and Amernic [6] have evaluated a significant body of literature related to PowerPoint usage and come to a very 'clear' ambivalence about the success of PowerPoint in enhancing learning. Alternatively, clickers, which several studies have shown to be effective for enhancing learning, are not being used or expected within Computing, even in the larger CMSC 216 course, simply because the instructors in the courses surveyed did not use that technology whereas in lower level CMSC courses clickers are used heavily. In other STEM courses, clickers are clearly expected.

The differences shown in Learning Assessments for Homework and Group Projects reflect a significantly higher expectation of Individual projects in Computing in general. However, the very low expectation of Group Projects is not unexpected since most instructors in lower level undergraduate computing courses opt to use individual projects and not group projects. This probably should be balanced, given the prevalence of team projects in industry, and raises the question of whether we are realistically preparing our students for their future jobs. Finally, class participation points are shown as something instructors should be aware of, and make explicit for students who might have other expectations as it can create an immediate mismatch between reality and expectations (as explained in [11]) for interdisciplinary courses.

The three Learning Activities components with significant differences perhaps harken again to the different pedagogical style inherent in Computing, though these are certainly less prevalent than the components already identified as inherent. Both study guides and small discussion groups highlight areas where instructors might easily introduce important learning activities that will increase student engagement with materials. While study guides are frequently a source of contention, discussion groups are a successful and proven method to help students process materials in class.

The final category of instructor interaction highlights two areas for focus, especially in higher-level interdisciplinary courses. Students from other STEM disciplines fully expect instructors to be accessible (66%), while Computing students have a noticeably decreased expectation (48%). They also have more than twice the expectancy for an instructor to know their name. Both these aspects reflect that a more personalized approach and availability are expected from non-Computing students. This might suggest that we have to build a better rapport with non-Computing students, which might make them more interested in computing and more willing to seek our help.

C. Breakdown by Class Status

Within the comprehensive 816 responses, we had a nearly equal distribution among class status, 29% freshmen, 20% sophomores, 28% juniors and 23% seniors. This provided the opportunity to identify trends in expectations as a student progresses in his or her collegiate career, such as an increase in expectations of discussion, essay-based exams, and group projects (not shown). Nearly all of these match trends are identified in other literature or are generally expected. We do, however, want to highlight one surprising result, which is of particular interest to computing: the overall expectation of technology usage, shown in Figure 2. A mean technology expectation was found by averaging the number of components each student expected in the category of "Technology". The mean technology component expectation for all students was 1.73 with the specific value for each class status shown in Figure 2. This indicates that most students only expected one or two technology components in a course and freshmen expected even less ($p < 0.001$). This data is in-line with the results of Lohnes and Kinzer [15] but challenges initial intuitions.

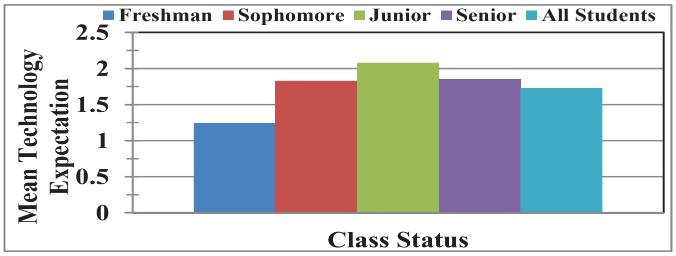

Fig. 2. Mean technology expectation by class status

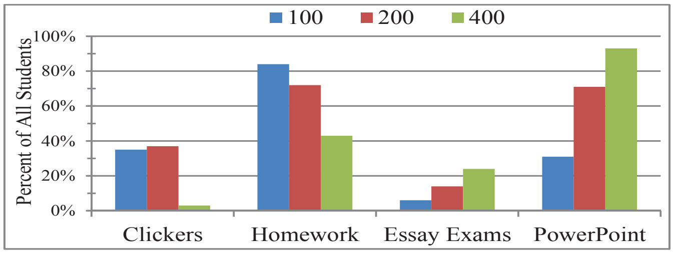

Fig. 3. Expectations in 100, 200, and 400 level courses in selected categories

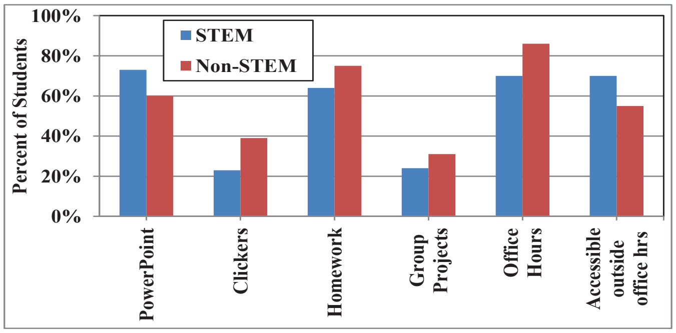

Fig. 4. Selected expectations of STEM/Non-STEM students

D. Breakdown by Course Level

When we break the results by course level, we found that only a small portion of the data came from 300-level courses, mainly from one course. Specifically, the breakdown distribution was 20% from 100-level, 53% from 200-level, 4% from 300-level, and 23% from 400-level courses. Therefore, Figure 3 contains only results for 100-, 200-, and 400-level courses from which meaningful statistical comparisons can be made. While many of the trends present in the breakdown by class existed in the course-level breakdown (essay exams and PowerPoint are shown), the results in clickers and homework expectancy bear particular attention. There is a clear break between larger, introductory courses and their expected use of clickers (used heavily in one of the biology classes surveyed) and smaller more individualized senior-level courses. The expectation for homework also fell, even though other individualized work increased.

E. Breakdown by STEM vs. Non-STEM

Our final breakdown is the expectations of STEM and Non-STEM students. In our data set, 73% of the students belonged to STEM colleges and 27% to Non-STEM colleges. All of the data comes from STEM courses, however, since many of the courses surveyed satisfy general education requirements, a significant portion of the students belonged to Non-STEM colleges and programs.

In Figure 4, there are three pairs of comparisons: technology, assessments, and instructor interactions. Within technology, the difference in PowerPoint is certainly worth noting. Students coming from non-STEM majors expect it noticeably less and may find classes frequently utilizing PowerPoint less interactive. The increased expectation of clickers is clear, but may be an artifact of a larger portion of Non-STEM students in large biology and chemistry general education courses where clickers are heavily used.

Within assessments (category 3 of Table I), we found an overall trend of Non-STEM students having higher expectations than STEM students, of which the most pronounced were group projects ($p < 0.05$) and homework ($p < 0.01$) as shown in Fig 4. The only choice from the assessments category in which they expected less was essay-based exams (not shown). This trend may indicate that Non-STEM students are generally used to and more comfortable with a wider range of assessments. Alternatively, it might suggest that Non-STEM students are less sure about which types of assessments will be utilized in a STEM course.

Finally, there are statistically significant differences between STEM and Non-STEM students in two categories of interaction with the instructors. First, STEM students show a higher expectation of accessibility outside office hours. This may reflect a better understanding of how STEM instructors spend their time or their responsiveness to emails. Contrary to that, Non-STEM students have higher expectations that instructors will hold regular office hours. This discrepancy is worthwhile to consider when scheduling and publicizing availability for students early in the semester. One way of explaining this gap is that non-STEM students are used to getting individualized help because they are coming from writing and art, where such instructor-student interaction is the norm.

F. Breakdown of Computing by Course Level (200 vs. 400)

Presented for completeness, we compare the two Computing courses in Figure 5. Most categories did not show a significant difference. In the five categories that did, most are exactly what we might have expected, representing a shift to more individualistic and interactive learning, which is a global conclusion we saw in the previous breakdowns. Specifically this can be seen in the increase in discussion groups and non-textbook readings, with the corresponding decrease in whiteboard usage. The other two categories most likely reflect individual course decisions made by the instructors and explained in their syllabus. Future studies with a broader sampling of Computing courses will illuminate these trends more clearly.

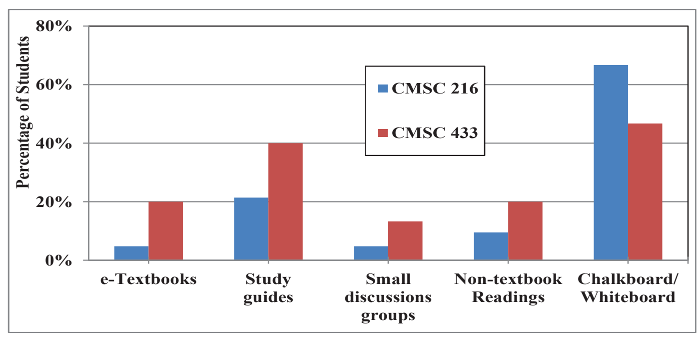

Fig. 5. Comparison of the 200 and 400 CS courses

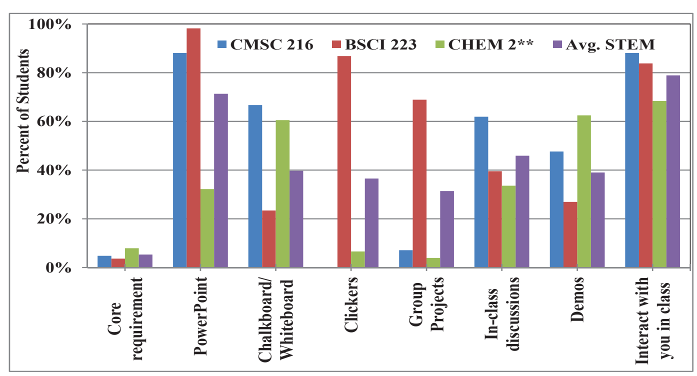

Fig. 6. Comparison of 200-level courses in Computing, Biology and Chemistry

G. Comparing Computing, Biology, & Chemistry Courses

1) Case Study 1: 200 Level: As our first case study, we consider four different 200 level STEM courses: General

Microbiology (*BSCI 223*), General Chemistry (*CHEM 232*), and Organic Chemistry (*CHEM 271* and *CHEM 272*)), and Introduction to Computer Systems (*CMSC 216*). As can be seen in Figure 6, only about 5% of the students were taking the course to fulfill a core requirement, with the Chemistry courses being slightly higher. This low percentage indicates that the expectations in the course are not obscured by students taking the course from a widely varied background (of colleges at the university). The results presented can give us a closer view of how different majors think, remembering that *CMSC 216* is taken by CSE majors only.

While students in chemistry courses did not expect projects, both *CMSC 216* and *BSCI 223* students did, but of very different types. Furthermore, the greater than 20% differences in expectations of homework (Figure 1) need careful consideration. Are the expectations we have for Computing students sufficiently high? When we offer courses to Non-majors are we challenging them to perform at their best?

Differences existed in nearly every category we examined, many of which were similar to the comparison of Computing to the aggregate data. Several unique differences, however, also existed between the courses with the most pronounced shown in Figure 6. There is evidence of different teaching methods with higher expectations of PowerPoint from CMSC and BSCI students and higher Whiteboard usage in CMSC and CHEM students. We see a higher clicker expectation in *BSCI*'s $> 85\%$, since the course requires clickers. We also see a dramatic difference in group projects for BSCI, similar to CMSC's high individual projects in Figure 1, demonstrating two different realms. Our final observation is that CMSC had the highest in-class discussion and interaction (the course has a discussion section in addition to regular lecture), suggesting that, even though all the courses are large, the CMSC course by design pushed for active participation and engagement with the students.

2) Case Study 2: 400 Level: Our second case study, shown in Figure 7, compares three senior level courses in Computer Science (*CMSC 433*), Biology (*BSCI 440*), and Bio-Chemistry (*BCHM 463* and *BCHM 464*). With the higher expectations of study guides and textbook usage, students from Biology or Bio-Chemistry may be unprepared for the learning styles of interdisciplinary courses such as Bio-Informatics. This is further exacerbated for the biology students by an expectation for a very different classroom style involving participation points and various forms of discussion. The Bio-Chemistry students, on the other hand, had very similar expectations of classroom learning activities to computing courses. Also, it seems that both Bio-Chemistry and Biology students expect to have a more personal interaction with their instructors. They expect the instructors to know their names and be accessible outside of office hours. Finally, students outside of Computing have a significantly higher expectation of accessibility outside of office hours as seen in Figure 7, but did not differ significantly in any of the timeliness categories (not shown).

V. Discussion

A. Impact on Curricula

The survey was originally designed to help instructors improve their courses by beginning discussions to increase

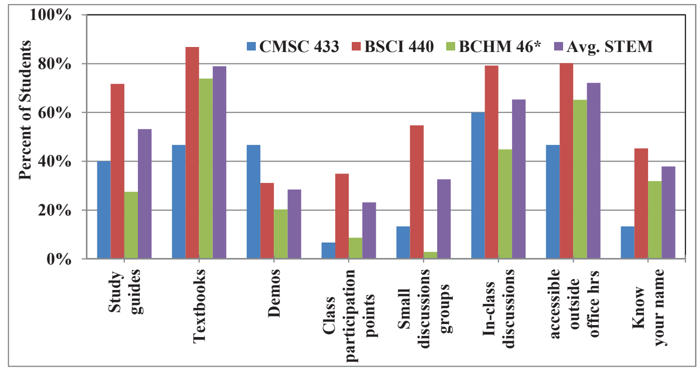

Fig. 7. Comparison of 400-level courses in Computing, Biology and Chemistry

classroom transparency (as discussed in Sect. 3a). While the results in Section 4 point out several interesting trends, we are looking for a greater impact. We started by examining the increasing necessity of computing in all STEM courses as well as beyond STEM disciplines. As more students take introductory courses, these courses can be designed to capitalize on the different expectations that Non-STEM students have, for example by incorporating more group projects or homework. Further, if departments choose to offer courses specifically designed to interest non-majors, as suggested by Adams and Pruim [1], or to offer higher level interdisciplinary courses as suggested by Anthony [3], the courses can be tailored in such a way that the students will leave with a higher satisfaction and thereby increase learning according to James [11] and Lang [13]. Beyond simple adaption, understanding expectations lets instructors address why specific technologies and techniques are used in-class and how they can help students better learn required skills and knowledge. It is vital to remember that while the students might be novices in Computing, they are not novices in the classroom. As one student responded to the open-ended question: "[Faculty believe] [t]hat we don't want to learn – if we show up to class, we are there to learn – it is not hard to "skip" a class. In that vein, if we are in class, please do not baby us, do not mock us for asking questions, and do not waste your time or ours going into information that is irrelevant…" Other important impact areas are retention rates, increased satisfactions, and, if we pay more attention to the expectations of women and minorities, increased diversity.

B. Study Limitations

While the reported results produced several interesting insights and conclusions, there are some issues to address. The instructors administered the survey after the first week of classes and the syllabi had been distributed and presumably discussed. Thus, we would expect students to have a decent idea of what to expect in the course. However, in many courses, categories were often not "expected" 100% or 0% by students. This suggests that even though students had jointly experienced a course there was no unanimous expectations for or against some common things. This may be a self-reporting problem, or perhaps confusion on the students' part. Another limitation is that the data was only collected at a large R-1 school. It would be very exciting and interesting to analyze the expectations at smaller colleges and universities. Another limitation is that a large sector of STEM is missing from our results. Not many Engineering courses were included in the survey, although we did have some Engineering students participating.

VI. Future Work

We are convinced that we have touched the surface of a large area of research that we hope to further work on in the short-term. One faculty member even responded on their feedback form saying: "I thought this survey was great at getting a cross-section of what my students expected from a class…I was surprised at some of the expectations…" To capitalize on this work, we must first understand how data from the survey will influence courses. This is particularly important since we do not anticipate faculty simply meeting students' expectations, but rather discussing survey results to help students better understand the learning process they are involved in (meta-thinking).

However, since this study was the first, faculty members were not able to get the results quickly enough to implement changes to their courses. With the survey now publicly available and ready for use (see [10]), turn-around time in future deployments will not be an issue.

The data we collected dealt only with STEM courses. We would want to do a similar study for Non-STEM courses. It would be interesting to see how the expectations of STEM students would be in non-STEM courses and how they differ from their expectations in STEM courses. Intuition suggests that the expectations in Humanities courses will differ. Another aspect that would be intriguing to add is a longitudinal study – similar to the medical and pharmaceutical studies – tracking the change of student expectations from the day they step into college until the day they graduate to observe the evolution of their expectations, similar to the NSSE tracking.

Conducting a direct extension of this work would be administering this survey across multiple colleges and universities, and comparing both CSE and other STEM students across liberal arts colleges, small or large, teaching and research institutions. A nation-wide study is our more ambitious goal. We would expect such future research to have a large impact on policies and on our understanding of the different institutions and their students.

Acknowledgment

The research was conducted at UMD with support of the Graduate School and CTE. Thanks goes to Ms. Grossnickle, Mrs. Shaw and CTE staff and our deepest gratitude goes to the instructors and students who participated.

Teaching Software Maintenance with Open Source Software: Experiences and Lessons

Swapna Gokhale, Thérèse Smith and Robert McCartney

University of Connecticut
Storrs, Connecticut 06269–4155
Email: [ssg, therese.smith, robert]@engr.uconn.edu

***Abstract*—Software Engineering (SE) careers are overwhelmingly devoted to the maintenance and evolution of existing, large software systems, where the key challenge is code comprehension especially in the face of inadequate documentation and support. SE courses must thus prepare students to meet this challenge. Open Source Software (OSS) furnishes a valuable source of realistic, sizeable projects for inculcating the appreciation and skills involved in code comprehension and evolution. This paper describes experiences and lessons learnt in using OSS projects to teach an introductory, sophomore/junior-level SE course with an emphasis on comprehension, maintenance, and evolution. Students' reactions and undertakings, acquired through participant observation and homework assignments, suggest that OSS can meaningfully illustrate comprehension and evolution difficulties. Finally, it describes the characteristics of OSS projects that are conducive to highlighting maintenance challenges.**

I. Introduction and Motivation

The dramatic growth of the software industry has intensified the need for skilled and talented software engineers. To respond to this need, most institutions now incorporate a mandatory Software Engineering (SE) course in their curriculum. This SE course must prepare students to handle industrial challenges, which arise from an imminent and pervasive need to comprehend, maintain, and evolve legacy systems [1]. Comprehension and evolution of legacy systems, however, is difficult and cumbersome because these systems may be: (i) subject to many fixes and modifications; (ii) poorly written; and (iii) sparsely documented. It is thus imperative to train students in the skills necessary for efficiently and effectively maintaining software systems. It is also critical to cultivate students' attitudes towards rigorous and systematic system construction to ease subsequent maintenance and evolution.

SE projects with a "maintenance-centric" focus can illustrate these industrial challenges. Maintenance-oriented SE projects, however, require an easily accessible code base of reasonable volume, complexity, and quality. Without this, laboratory projects involve building a system from the ground up and incorporate very small maintenance and evolution tasks where the students modify their own recently written code. A semester's worth of self code can hardly impart comprehension and maintenance skills appropriate to large bodies of code written by multiple others, nor does it necessarily emphasize the importance of systematic system construction. Therefore, these present projects are inadequate at offering realistic, industry-relevant experience and training.

Open Source Software (OSS) projects can offer a diverse, rich, and extensive code base which could be used as a starting point for designing maintenance-centric SE projects. In this paper, we report on our experiences and lessons in integrating OSS into an introductory sophomore/junior SE course, where through a series of laboratory assignments the students were required to understand, analyze, and extend existing OSS systems. Our objectives were for the students to become acquainted with software maintenance: to comprehend another's software, to modify it for the better, and to appreciate a systematic approach. Without being hindered by sparse documentation and with minimal support, the students enhanced their chosen OSS projects with a range of features, suggesting that OSS can offer extensive opportunities for deep involvement with the code. They also cultivated the ability to exploit and reuse the existing code and learnt to appreciate the overreaching impact of project architecture on the ease of implementing enhancements. Finally, we discuss how architecture, state of implementation, and subject matter of a project can influence its suitability for highlighting maintenance difficulties.

The rest of the paper is organized as follows: Section II lays out the case for using OSS. Section III describes teaching maintenance with OSS projects. Section IV discusses characteristics of OSS projects. Section V compares related work. Section VI offers conclusions and future directions.

II. Promise of OSS

The OSS revolution is having a lasting impact on the way software is developed, disseminated, and adapted. This is evident from the myriad of OSS projects already available, and the pace at which they continue to grow. The revolution has thus created easily accessible and exponentially growing [2] volume of code. Popular OSS repositories such as Sourceforge [3], Freecode [4], CodePlex [5], and W3C [6] host more than 200,000 projects. We use these simply as code sources; students do not contribute back to them.

OSS projects span a variety of domains such as tools for software development, financial analysis, security and networking, data manipulation and visualization, audio and video engineering and text editing, operating and database systems, and games and entertainment [3]. These projects

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

target common platforms including Windows and Linux and are written in languages such as C, C++, Perl, Fortran, Python, Java, Tcl, Objective-C, Ada, and Php. Although the OSS development process appears *ad hoc*, many projects are completed successfully with rich functionality and high reliability because their latent social structure allows the projects to grow in an organized manner [7], [8]. Moreover, because most participants of OSS do so to build reputation, or for self-development [9] and altruistic reasons, they may be inherently committed to applying SE principles, which may lead to projects that are carefully designed, engineered, and maintained. The quality of open source code may span a range wider than that of industrial systems; because some code is not good enough to be industrial, while some code having had the benefit of a fresh start, is refined compared to industrial code. Therefore by selection with filtering, we hope to find OSS projects that exhibit characteristics and quality similar to industrial systems, and hence, provide a valuable resource of example code for teaching SE.

III. Teaching Maintenance with OSS

Our objective was to integrate OSS into an early, introductory SE course for sophomore and juniors. Our students had limited experience in Java programming and could write, test, and debug only small volumes of code after having taken a data structures course. Our SE course was designed to be "maintenance-centric," and the laboratory exercises, performed in teams of two on OSS projects challenged students to practice code comprehension, use appropriate tools (source code control systems, reverse engineering) [10], and implement an enhancement of their choice. We manually searched and evaluated about 1000 projects from several OSS repositories to find a collection of 17 projects from Sourceforge [11] that were commensurate with our students' preparation.

These 17 Java projects spanned the application domains of Games, Art, Skills, Indexing, Searching and Client/Server applications [12]. Project sizes ranged from 5,500 to 10,500 lines of code; we believe that smaller projects may not adequately provide comprehension and enhancement difficulties, while substantially larger ones may be beyond our students' capabilities. The projects were reasonably modular to demonstrate best practices that aid maintenance. Modularity was assessed by examining the depth, number and naming conventions of directory hierarchies, number of files, and packages, and average and variances of the number of files within a directory and lines of code in a file. Projects were lightly documented, in case outstanding documentation might not adequately represent comprehension and evolution challenges.

A. Sample OSS Projects

In this section, for each project, we describe the intended functions and attempted enhancement, scoped within the range of feasible extensions.

1) **CarDriving:** This arcade car game had a primitive user interface with no user instructions. A range of enhancements, from advancing the capabilities of the car and the environment through which it is navigated, were possible. Students upgraded the GUI to include a driver's wheel that could be turned. They also improved collision detection and wrote a tutorial.
2) **Coppit:** A board game with a computer player, this project also did not have a very imaginative GUI. The range of enhancements stretched from improving appearance to artificially intelligent players. The students overhauled the interface resulting in a significantly improved interaction experience. They fixed some bugs, and also delved into the selection of players and legal progress of pieces in the game.
3) **Domination:** This project, a "single-shooter" game was quite simple. The students implemented a sophisticated GUI, including a menu of choices.
4) **FourRowSolitaire:** A GUI simulation of a "card game" had a moderately detailed display. A spectrum of enhancements were possible; from user interface to artificial intelligence. The students' enhancement allowed a pleasing display of predictable sequences.
5) **ChessBoard:** This polished game already included an automated opponent, and ambitious enhancements such as advancing the level of play with artificial techniques were possible. The students attempted a cautious one though, customizing the appearance of the game.
6) **JigsawPuzzle:** This game broke a user-selected image into a specified number of pieces and then provided a GUI to assemble these pieces. The enhancement chose to provide a puzzle solving hint upon request, highlighting a piece adjacent to the selected piece.
7) **JugglePat:** This animation project clarified patterns. Advanced modifications such as judging whether a given string represents a legal juggling pattern or inventing new patterns with concatenation could be imagined. The students improved the GUI significantly with coordinated music, making it appealing to an audience beyond the juggling aficionados.
8) **Melosion:** This game accompanied the practice of musical skills with animation. It separated the concerns of interfacing with peripherals such as MIDI and WII over several packages. Students chose a minimal enhancement, being the entry of a new song.
9) **Monopoli:** This project offered very little scope for enhancement while remaining within the rules. The students improved the GUI for rolling the dice.
10) **MusicSkillsCoach:** The implementation of song and activity selection in this project was at an early stage. It allowed for adding the planned functionality such as microphone input and testing pitch for *solfeggio* practice. Enhancements included the ability to play a whole song, to pause and continue to rewind, and an improved GUI.
11) **NocNorade:** This project included an attractive board, but very little implementation of a client/server game of increasingly complex levels. The students implemented one game, devising their own rules and moves.

12) **Picofarm:** This client/server application allowed users to remotely select animals and place them on a farm. The students extended this project to include additional farm animals and placement options such as close to a barn and a pond. Architecturally, they increased the prominence of the local mode over the client/server one.
13) **Puggle:** This project provided indexing directories for search. Although highly polished, it was easily extensible. The students chose to add two document types to the indexed list, which widened the domain instead of increasing its complexity.
14) **SlimeWarrior:** This was a 2D role-playing arcade game with scrolling images and ability to score points. It used sound and simple animations. Possible, open-ended changes included additional characters, scenery and story line. The students enhanced it to allow a user to direct the actions of the warrior, controlling the speed, direction, and height of jumping and scaling obstacles.
15) **vgt-battleships:** This complete but unpolished game offered opportunities for enhancement ranging from user interface, artificial intelligence for the computer player and including more vessels. The students updated the GUI to provide instructions and sound effects. They also put a lot of productive effort into the documentation.
16) **Sudoku:** The students added first level of artificial intelligence to this polished project. Complicated enhancements would include advanced reasoning and hints.
17) **Simulum/Mulumis:** This complete project produced a lovely star field display. The students enhanced it to incorporate star generation, zoom and pan, and associated music as a sound track, whose volume could be modified in accordance with the speed of the display. Many other extensions would have required solving equations governing the motion of celestial bodies.

B. Engagement with Maintenance

We comment on how the projects and their extensions engaged students with maintenance aspects.

1) Enhancement Difficulty: Table I ranks the difficulty of attempted feature enhancements as “Small (S)”, “Medium (M)” and “Large (L)”. We judged difficulty based on our estimate of the extent of impact on the existing code, and the existence of industry standard approaches for the functionality, using our combined programming experience, which exceeded forty years. We also included conversations with students as they were working on their projects. Only two teams chose easy, superficial enhancements, while other extensions were of at least medium difficulty. Updates and improvements to GUIs were most popular, which could be due to the visual feedback and satisfaction that a functional GUI provides. These were followed by incorporating varying degrees of artificial intelligence into the games. A few projects also introduced and coordinated displays with music.

2) Degree of Comprehension: The table also categorizes the degree or the extent to which the students had to comprehend their code in order to implement their enhancements as “Superficial”, “Isolated Modules” and “Thoroughgoing”. This comprehension was focused on two aspects of the code, namely, architecture and data representation. Understanding the architecture involved figuring which classes invoked which others and with what information; in other words, how information was moved and transformed in the system. Understanding the data representation involved checking for validity of input and how data was stored and used in advancing the logic. Examples for each degree are provided below:

- **Thoroughgoing:** Coppit represented an example of thorough understanding; because in order to change the appearance the students had to know its method of presentation. They also had to know how and what data was brought into the system, to change how the GUI asked about the players. In order to repair incorrect enforcement, they had to know how the program represented and used the rules. They added some capabilities for players, so they had to know where and how the program accomplished the different choices about pieces and moves of the players. They left no stone unturned in implementing these enhancements.
- **Superficial:** ChessBoard represented an example of superficial understanding, where the students modified the appearance of the pieces. They discovered that the appearance of displayed objects was provided through style sheets or skins [13], which they added. They also allowed chess pieces to take a set of monster/ogre appearances [13]. Melosion also allowed superficial understanding; the data representation made adding a song so simple, it almost evaded the goals of the course.
- **Isolated:** Puggle was an example of isolated understanding, its layered architecture allowed the students to implement an interface for another file type, with some sense of assurance that the impact of their code change would remain confined; and they need not concern about specifics of modules outside their own.

GUI updates were most popular because students may have expected, albeit incorrectly, that such enhancements could be implemented with superficial understanding. Evidence in the table, however, contradicts any such latent or unspoken expectations as most GUI enhancements needed a comprehensive understanding of both the architecture and data representation. The positive interplay between the difficulty of enhancement and the depth of involvement is also seen. Small enhancements (ChessBoard, Melosion, and Monopoli) could be implemented with either a superficial or an isolated understanding. By contrast, all large enhancements (CarDriving, Coppit, Domination, NocNorade, vgt-battleships, and Simulum) required a thorough understanding of the architecture and data representation. Some medium-difficulty enhancements (FourRowSolitaire, JigsawPuzzle, JugglePat, Picofarm) necessitated detailed understanding, whereas others used only isolated comprehension.

3) Impact of Architecture: We learnt about the students' conceptions of architecture by listening to their discussions in

TABLE I
SUMMARY OF ENHANCEMENTS

Project	Enhancement	Difficulty	Aspects	Degree
1. CarDriving	GUI Tutorial	L	Architecture Data Representation	thoroughgoing
2. Coppit	GUI Game rules Bug fixes	L	Architecture Data Representation	thoroughgoing
3. Domination	GUI	L	Architecture Data Representation	thoroughgoing
4. FourRowSolitaire	GUI Game Rules	M	Architecture Data Representation	thoroughgoing
5. ChessBoard	GUI	S	skins	superficial
6. JigsawPuzzle	GUI	M	Architecture Data representation	thoroughgoing
7. JugglePat	GUI Coordinate Music	M	Architecture Data Representation	thoroughgoing
8. Melosion	Entry of a new song	S	partial data representation	superficial
9. Monopoli	GUI	S	Architecture	isolated modules
10. MusicSkillsCoach	Play, pause, rewind GUI	M	Architecture Data Representation	isolated modules
11. NocNorade	Game rules	L	Architecture Data Representation	thoroughgoing
12. Picofarm	GUI	M	Architecture Data Representation	thoroughgoing
13. Puggle	Add document types	M	Architecture some Data Representation	isolated modules
14. SlimeWarrior	GUI	M	Architecture Some Data Representation	isolated modules
15. vgt-battleships	GUI Documentation	M/L	Architecture Data Representation	thoroughgoing
16. Sudoku	Rules	M	Data representation	isolated modules
17. Simulum	GUI Coordinate music	L	Architecture Data Representation	thoroughgoing

the laboratory. Many students learnt to appreciate the impact of architecture in facilitating the implementation of their enhancements. The Puggle team consulted with us on whether it was really permissible to "just add new document types" given that this addition did not require knowledge of all the other aspects of the implementation. The JigsawPuzzle team realized that the project's architecture was brittle, compelling them to change its underlying structure to complete their extension. The Picofarm team checked whether it was enough to change the architecture to handle local representations of animals, without also exercising the remote server portion. JugglePat's modular architecture followed the Model, View, Controller (MVC) pattern [14], which eased its modification. The Melosion team agreed that separating peripheral types into packages helped them narrow their attention. Finally, the NocNorade team stated that having documentation of the planned architecture helped them orient their thoughts.

4) Code Reuse: The students were specifically asked to explore code reuse, and to connect new code for their enhancement to the original code. Coppit and Domination teams reused the overall structure of their respective games, yet renovated almost all of the parts. A developer familiar with the original project would recognize the activities, control flow, events, and objectives, but would find richer, more correct implementation with more options. Earlier designers of CarDriving, by contrast, would notice the addition of new modules and an improvement of previous ones. The original designers of Picofarm would see that what they had imagined had been greatly extended. The emphasis on client/server interactions had been reduced, and GUI interaction that had been minimal had been made more feature rich. Original designers of Monopoli would see that a change of limited impact made use of all of their work. This limitation of impact was even more pronounced in the case of ChessBoard, where the architecture of cascading style sheets made it possible to change dramatically the appearance of the game without modifying the code very much at all. The Puggle team reused code by implementing an already existing interface.

5) Availability of Documentation: Most projects offered very minimal documentation; CarDriving, Coppit, Domination and NocNorade included web sites with ancillary information, but nothing directly about the code. JugglePat, ChessBoard, Puggle, and Simulum included some documentation via HTML and Readme files. vgt-battleships included comments and variable names in Polish. SlimeWarrior included rare remarks in Dutch, however, these did not hinder the students.

6) Additional Skills: Students needed to acquire many additional skills to implement their enhancements. GUI enhancements required AWT and Swing, menus and event handling, bounding boxes, 2D and 3D graphics, buffered I/O streams, file I/O, obtaining resource location via URLs. Specific enhancements called for additional skills: geometry, trigonometry (CarDriving, JugglePat, Simulum), random number generation (Coppit), sockets, TCP/UDP/IP, servers, IP addresses and ports, multithreading (Domination, Puggle, SlimeWarrior), affine transformation (JigsawPuzzle), XML and DOM (JigsawPuzzle, JugglePat, Puggle, Coppit), GIF animations (JugglePat), Newtonian physics for position, velocity, acceleration (JugglePat), permutations and symmetry (JugglePat), linear algebra for matrix transformations (JugglePat, Simulum), grammars and parsers (JugglePat, NocNarcade, Puggle), encryption, password protection (Puggle), MP3 handling (Puggle), archive extraction (Puggle), Rich Text Format (Puggle). The students as a whole learnt a broad range of skills; each team learnt at least what was called for by their own project, in a small amount of time, closely mimicing how software engineers need to make up for deficiencies in skill and knowledge under severe time constraints.

Overall, the students' initial frustration was replaced with a healthy sense of pride, accomplishment, and self-achievement, as they navigated through the code and completed their chosen extensions with a new set of skills under their belts. Survey results [15], [16] showed students' appreciation that software maintenance and evolution was: (i) challenging, resource intensive, and time consuming; (ii) significantly aided by documentation and comments; and (iii) greatly eased by good architecture, but dramatically hindered by a brittle one.

IV. Suitability of OSS Projects

We observed that OSS projects could meaningfully engage students with various aspects of maintenance. However, not all projects could offer these opportunities equally. Therefore, we noted three characteristics of a OSS project that makes it particularly conducive for teaching maintenance.

1) Project Architecture: We wished students to approach the code in a top down manner, rather than habitually seeking lines of code using a debugger with a step capability. Therefore, we chose modular projects and exploited evidence of architecture. Architectures with horizontal infrastructure layers with a top layer of variations upon a type of object were readily extended, because students could build new variations, using the one or more top layer objects as examples and points of departure. Once the students discovered these layers after examining the code, they did not have to comprehend all of the code at the granularity of lines. They could implement the extension by expanding the domain of objects over which the code operated, without changing the architecture. Students working on these projects also benefited from exposure to a good design. For example, Puggle followed a layered architecture and the students easily added indexing for two more types of documents. Although layered projects may be low risk from the perspective of permitting extensions, because the students only need a local understanding and they do not have to struggle with an architecture that is resistant to change or with damaged modularity, these projects may not adequately represent maintenance difficulties.

2) Project State: The project state should provide a set of possible enhancements of varying difficulty. Students can then begin with enhancements that are not overly difficult, and progress throughout the semester, as noted by Rajlich *et al.* [17]. A state of polished completion seems less helpful. Projects were classified as incomplete (works in progress) and complete based on the extent to which planned features were already implemented. Thus, projects that rendered a game board but did not provide a game, or projects whose menus included options that, when chosen, did not result in any usable situation were regarded as incomplete. It was useful to differentiate between projects that were incomplete because of a lack of intended functionality and those where the extension capacity of the implementation was exhausted or was no longer adequate. For example, extending a fixed size data structure with no unused bits (capacity exhausted) was very different than extending it by converting unused bits into used bits. Similarly, in an architecture where peripherals were separated by types, whether a new peripheral was a small variation of an existing one, or a new kind of peripheral was a judgement call. Deciding that a peripheral was new would have had more resource impact than deciding that it was a small variation, because the latter might not warrant a whole new package, but the former would, to be consistent with the architecture. For example, JigsawPuzzle used a two-dimensional array to store information on puzzle pieces. It was an integer field. When additional information was desired, such as the current location of "my neighbor" pieces, the students were initially at a loss for how to extend or expand this data representation to hold this information. Similarly, Picofarm required some changes to move the animals around; and though originally they could be one place or another, our students allowed for rotation and scaling by expanding the animal data structure to incorporate these attributes.

The students were most gratified with projects that were incomplete or works in progress, yet showed enough organization of functionality into packages with documented intent. For such projects, being able to discern the architecture from the code or documentation was important as it provided the students with a good example and a starting point. Although incomplete projects offered much liberty for extension and completion, students working on these might deserve a lot of support to make up for the absence of exemplar modules as in the layered architecture. In our collection, NocNorade, MusicSkillsCoach, and Picofarm were incomplete and followed different architectural styles. Picofarm was implemented with interfaces supporting extensions to additional animals. In this project, the code was significantly extended because the architecture was not limiting. However, incomplete projects providing many avenues of improvement might also allow students to opt for only easy modifications and some method of counteracting timidity or at least ensuring that timidity did not inhibit progress might be warranted. In NocNorade, students showed initial timidity but followed it with a substantial change resulting in a game. The initial timidity in Melosion, on the other hand, was followed by procrastination resulting in a very minimal enhancement.

Thoroughly polished projects that also did not suggest obvious functionality improvements might be less satisfactory. Chess and Monopoli belonged to this category and the depth of involvement was not very high. To implement medium or large enhancements in these projects, the students would not only have to learn the software organization but also how to include new modules, incurring significant effort. For complete projects, it also mattered whether the students examined the architecture before or after choosing the enhancement. Students chose appreciable enhancements when they considered a use case perspective without first examining the architecture, which sometimes led to an in-depth investigation of and struggle with the architecture. Melosion was examined late but because its architecture was organized with each peripheral in its own package the students did not have to struggle as much. JigsawPuzzle was also examined late, which caused a review of options. JigsawPuzzle team knew that they could make a destructuring but relatively easy change, or they could revise the structure. Ultimately, its brittle architecture inhibited deep involvement. On the other hand, when the students investigated the architecture early as in Chess and Monopoli and restricted their choice of enhancement to match what the architecture facilitated, they chose superficial enhancements and did not have to struggle as much implementing their change.

3) Subject Matter: Students cared about the value of the program and the undertaken enhancements from the perspective of users, consistent with the appropriateness of authenticity mentioned by Clear [1]. They derived a measure of enjoyment or other meaning from the domain of the projects be it games, music, general productivity or humanitarian. The subject matter also seemed to have a curious effect on the students' creativity. For example, students did not turn Chess, Monopoly and Coppit into some other game, such as Chinese Chess, or a Monopoly with different cards to be drawn, or other improvements on property. Thus, invisible boundaries restricted students' creativity, and hence, less well-known games and activities might not be as inhibiting. Finally, projects with trustworthy representation of industry practice, such as inclusion of test modules, were appealing.

A summary of these characteristics is as follows:

- Projects with layered architectures can be extended easily, but may not adequately illustrate maintenance difficulties.
- Projects that are incomplete or works in progress but well planned, although initially daunting, offer greater flexibility for creative extensions and prove gratifying compared to the polished projects.
- Students prefer projects with enhancements ranging in difficulty. Also, extensions chosen without examining the project architecture tend to be meaningful and beneficial.
- Projects with useful domains, clear purpose and perhaps an industrial tilt may have higher appeal.

V. Related Research

OSS has been used to teach SE activities such as design, testing, quality assurance, maintenance, and usability [18]–[26]. It has also been used to teach basic and advanced programming and software development concepts [27]–[31]. Some of these works allowed students to choose their own projects [18], [27], [31], while in some courses faculty chose from a few familiar [22], [23], [30], [32], or popular ones such as Apache and Mozilla [21], drawing, editing and file management programs [17], JUnit [19], software studio [32], or pertaining to specific domains such as Web and Web 2.0 [25] or tools [20]. Some used software written by their students [26], [28], [33], while some solicited projects from academia and industry [24].

We easily found works evaluating OSS projects before choosing them for a specific purpose; however, works evaluating the suitability of projects after use for achieving the course objectives are limited. Ghapanchi *et al.* [34] noted a lack of literature exploring the software development process considerations to predict OSS project success. Fox *et al.* [35] chose software as a service cloud-based applications to increase student productivity and their appeal to the employers. Papadopoulos *et al.* [36] considered the maturity of OSS projects to allow students to act in specific roles such as requirements analyst and tester. Purcel *et al.* [37] evaluated OSS projects for student participation based on maturity, stability, potential growth and support for learning objectives. MacKellar *et al.* [38] selected projects by interacting with real-world users, which highlighted requirements analysis and acceptance testing. MacDonnell [39] selected a humanitarian project to alleviate the criticism that the school is disconnected from software development in the real world. Damian *et al.* [30] selected their project based on the learning objectives of global collaboration, and working with a real client. Barr [40] chose projects specifically to illustrate well-designed structure to the students. Zhang *et al.* [41] used business applications for a contest in which they chose to compete using a "small scale time intensive web" project and exposed a Scrum/Agile process to the students. Stamelos [42] reported that Tigris.org focused specially on projects suitable for students.

In summary, our literature search has yet to find reports on an experience using quite a few open source projects at once, that have been chosen and groomed for the students' use by the course staff. What literature review has shown, for courses starting with existing code, is: (i) courses using one carefully selected project; or (ii) a project that agreed with a real customer; or (iii) using many open source projects at once, but selected by the students from the forges. The present paper, in reporting the experiences and lessons from a specific collection of OSS projects, while abstracting generic insights that can guide future project selection fills this void.

VI. Conclusions and Future Research

This paper reports on integrating OSS into an introductory SE course to emphasize software maintenance and evolution. Our experiences suggest that OSS projects can allow a range of enhancements of varying level of difficulty, and hence, can offer meaningful opportunities for deep involvement with the code. They can readily illustrate several facets of comprehension and maintenance, namely, difficulties arising from sparse documentation, importance of the role of architecture, exploring and exploiting code reuse, and learning and acquiring new skills under time constraints. However, not all OSS projects are equally capable of illustrating these challenges, and project suitability hinges on its architecture, state and subject matter.

Our future research is involved with developing a systematic approach for efficient selection of projects from OSS repositories subject to the above three characteristics.

***Abstract*—Theory of Computation provides students of the computing disciplines with understanding that some problems are not solvable, and that there is a range of complexities of problems, in terms of significant resources, including but not limited to time and memory. Theory of Computation acquaints students with reasoning processes by which they can know (for some cases) the complexity class of a given problem, and by which they can, for some problems they might find in the future, determine the complexity. People formulate these reasoning processes in symbols, and use logic with quantifiers; an example of this is the application of the pumping lemma for regular languages.**

We categorized the errors students made in applying the pumping lemma for regular languages, to develop an understanding of the possible misconceptions, in turn, to improve teaching.

I. Introduction

Problem solving by computer is core to the computer science curriculum. A subset of problems, decision problems, e.g., “Should I apply the brakes now?”, but not ”When should I apply the brakes?”, can be represented by set membership. For infinite sets, the expressiveness required by the description of the set membership function is unsurprisingly mirrored by the discriminatory power required of the process which decides whether an object is or is not a member of the set. This range of expressiveness, equivalently particularity, is subdivided into classes, e.g., regular, context free, etc. Theory of Computation includes the idea of classification of how difficult problems are. Computer scientists need to be aware of these classes.

One such class is the set of regular languages. Due to the simplicity of this class, i.e., its lack of power to discriminate between certain strings, the membership of a string s in a regular language, when the length of s exceeds a certain length p, implies membership of a countably infinite number of strings related to s. Stated formally, we have the pumping lemma for regular languages, which we take from Sipser’s text [1](p. 78):

> **Pumping lemma for regular languages** If A is a regular language, then there is a number p (the pumping length) where if s is any string in A of length at least p, then s may be divided into three pieces, $s = xyz$, satisfying the following conditions:
> 1) for each $i \geq 0, xy^iz \in A$,
> 2) $|y| > 0$, and
> 3) $|xy| \leq p$

For an aid to intuition, see Figure 1. We recall that there is an alphabet from which letters in the string are taken, and that a string is processed one letter at a time in sequence, and that, prior to any letter having been processed, the machine corresponding to the language is in its (single) start state. The processing of each letter executes a transition from a state to a state, therefore, by Dirichlet’s pigeonhole principle, when the number of letters in the string equals or exceeds the number of states, a state must be revisited during string processing.

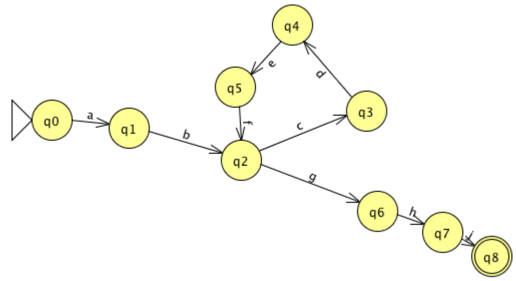

Fig. 1. Example deterministic finite automaton, a machine corresponding to a regular language. Segment x (in this example, ab) is a substring whose processing involves following transitions from the start state to a reused state. For a string with as many, or more, letters (transitions) than there are states in the machine, a cycle must have been followed. This example cycle contains four transitions; one or more transitions returning to a state constitute a cycle. A substring z (in this example, ghj) takes the machine from the last reused state to an accept state. A substring processed by a cycle is denoted y (in this example, cdef). The machine cannot keep count of the number of times the cycle is traversed. From 0 to as many times around the cycle as you please, to the machine, it is all the same.

The pumping lemmas are applied in proofs that a given problem is more difficult than a class (regular and context free, respectively), thus we wish students to understand the pumping lemmas well enough to apply them.

The research question that guided this study is: **Which proof skills, needed in applying the lemma, do students still lack at the end of the course?**

Section II-A describes the background of the study. Section II-B describes the course. Section III describes the methodology. Section IV describes the data obtained. Section V describes the analysis. Section VI discusses the results. Section VIII gives our conclusions. Section VII relates this to some prior work. Section IX describes extensions we would like to carry out.

II. Background

A. Theoretical Framework

Proofs, according to many sources, e.g., [2]–[4] are arguments that are convincing to the mathematical community, but there are other views, e.g., see Reid and Knipping [4].

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Consistent with social-constructivism applied to learning, we believe that discussion, including formulating questions and expressing opinions, helps students learn [5]. Though interested in Moore's method [3] of teaching students about proof, we did not use it during lectures. We applied example and discussion for helping students advance through Bloom's taxonomy [6] towards comprehension of proofs and perhaps further, to application of proofs.

B. Course Description

1) Scope: We taught the course from Sipser's third edition [1], using chapters 1 through 5 and 7. The pumping lemmas were given emphasis in class, help sessions and tutoring, in homework, exams, and in review. We treated the pumping lemma in the context of logic, emphasizing the inversion of quantifiers. We discovered that some students seem to tire of attending to statements with more than one quantifier, consistent with Devlin [3]. We also treated the pumping lemma with diagrams of machines from Sipser's book [1].

2) Policy: We encouraged student collaboration on all learning activities, including homework. We used only known individual work (exams) for their grade. To encourage active learning [7] beyond using the classroom response system, we assigned participation in a discussion of a specified question, weekly. We discovered that students preferred to have their contributions to these discussions be anonymous to other students.

3) Website: To supplement the text and overheads, we offered additional sources on a class website. A mid-semester survey revealed that the 20 students (approximately half the class) who responded to the survey did not avail themselves of the supplementary material. A question area on the website was much used; several different questions might appear on any given day. The assigned problem discussion area was supported on this website.

4) Lectures: From Peer Instruction to Lecture Pacing: To maintain awareness of the level of understanding of the students as each lecture was conducted, and, on an individual student basis, over the course of many lectures, we used a classroom response system ("clickers").

Lectures were prepared in advance of the class and posted on the website, as teaching this course in a previous offering had shown that students greatly appreciated being able to print the lectures for class, and take notes on them, as well as developing questions to be asked during class time.

Mainly to aid the lecturer, indications when clicker questions were to be asked were placed in the lecture notes. Thus students could predict when questions would be asked, but not know the questions, as these were kept in a separate file, published only after class. Students requested that these be published, with explanations for the correct answers.

Though we used clickers for classroom response, and we started with a peer-instruction style of question, discussion, question [9]–[11] students requested that we deemphasize their discussion and offer more questions, and that we explain after each poll, what the answers were and why. We found it valuable to note the votes as they arrived, and we saw a population that voted early and mostly correctly, followed by a population that was less sure. We adjusted the amount of time spent on topics in lecture according to the fraction of students less sure. Based upon a survey taken halfway through the course, the students were grateful that their understanding influenced the pacing of the lectures.

Students requested instruction on inverting logical statements including multiple quantifiers. This topic was addressed, not only with overheads, but, in two separate lectures, interactively, at the board. (Regular: $\exists$ at least one segmentation, $s = xy^iz, |y| > 0, |xy| \leq p$, s.t. $\forall$ values of $i \geq 0, xy^iz \in \mathcal{L}$, so, not regular: $\forall$ segmentations $s = xy^iz, |y| > 0, |xy| \leq p$, $\exists$ at least 1 value of $i \geq 0$, s.t., $xy^iz \notin \mathcal{L}$.)

5) Differences from Other Offerings: We examined three sets of overheads, those from the MIT course 6.045J [12], associated with Professors Lynch and Aronson, those from the peer instruction class at University of California, San Diego (UCSD), by Dr. Bailey-Lee, available at peerinstruction4cs.org, (where some of our overheads can also be seen), and our own. The MIT overheads delivered the material thoroughly and comprehensively, our class emphasized more how to see the language specification in what might be called feature space (as used in machine learning [13]), to provide guidance in the choice of string to pump out of a language, and the UCSD overheads showed a storyboard-like decomposition approach to the reasoning process during application of the pumping lemma.

6) Help Sessions: A modified version of Moore's method [3] of asking a student to volunteer to prove a theorem (in this case, that a given language was not regular) was used in help sessions: A student volunteer would try a proof, but would receive helpful hints when not progressing.

Some students were stuck at the notion that a pumping length was an attribute of a machine. When challenged to draw a (small) machine and then show how a machine could process a string whose length equalled or exceeded the number of states without revisiting a state, students made sense of this attribute. They learned the abstraction using the diagram. The distinction between comprehension and application, excerpted from Bloom by Anderson and Sosniak [14], was exhibited in this learning experience. Students attending the session could easily have answered "What is the pigeonhole principle?", and could probably have applied it to the diagrammatic representation of the DFA, had they been prompted to, but on their own, they did not observe that p, the string length that implied reuse of a state, was equal to the number of states. Thus we located the students' advancement on the pigeonhole principle as comprehending but not applying, on the Bloom's taxonomy. A distinction can be drawn between, on the one hand, abstracting the idea of machine states encountered while processing a string, to the notation, and manipulating the symbols, while remembering what they symbols denote, and on the other hand manipulating some statements composed of letters. The rules about which manipulations are valid, when the letters have no meaning, must be remembered; when the symbols have meaning the rules make sense and understanding can aid memory.

7) Tutoring: Tutoring sessions provided additional awareness of the students' thinking and their capabilities. They also furnished numerous occasions where it appeared that students grasped concepts benefiting from seeing and working with diagrams.

8) Assessments: The class had many formative assessments on which collaboration was encouraged, including weekly homework and discussion postings, and two summative assessments, namely the exams. We knew, from the research of Mazur and Fagan [15], that students can adopt a "plug and chug" approach to dealing with problems, without necessarily developing an understanding of the process.

One method of assessing whether students understood the ease of application of the pumping lemma to a language to be proved not regular was offering a choice between using the Myhill-Nerode theorem with a strong hint or using the pumping lemma. The pumping lemma problem, which could very easily have been solved by application of the Myhill-Nerode theorem, especially with the supplied hint, was designed, when tackled with the pumping lemma, to require, for each possible segmentation, a different value of i (the number of repetitions) that would create a string outside of the language. The intent was to separate students who understood the meaning of the equation's symbols, and the equation itself, from those students engaged in s manipulation with at most superficial understanding.

III. Methodology

A. Design of the Study

The study was carried out on the exam documents. The interpretation was informed by remembering events that occurred in the natural conduct of lectures, help sessions and tutoring.

B. Sample Selection

In a recent course offering to 42 students, of whom 34 were men and 8 women, 41 traditional aged, one former Marine somewhat older, one collegiate athlete (a woman), there were three students having Latin-heritage surnames, 1/4 of the students had Asian heritage, 2 had African heritage, and 8 were international students. Each student individually took the final exam. A choice among five questions was part of the final exam; one required applying the pumping lemma. Half the students (21/42) selected this problem. These were 17 men and 4 women. Three quarters of those (15/42) selecting the pumping lemma got it wrong. These students, who chose the pumping lemma problem and subsequently erred on it, form the population of our study.

C. Data Analysis

We used the final exam as our data source.

We looked at all of the solutions to the pumping lemma problem. We selected from these, the ones with errors.

We wrote a description for each error. The erroneous solutions were categorized, to discover what improvements could be made in teaching.

With the categories, we looked for support for inference.

We used homework, classroom responses, extra credit assignments, participation in office hours, help sessions, and tutoring, for insight into the development of the students' understanding.

TABLE I. Some example errors

Let x be empty
$\|xy\| \leq p$, so $xy = 0^p$
$\|xy\| \leq p$; let $x = 0^{p+r}, y = 0^{p-r}, 0 < r < p$
Let's choose $\|xy\| = p$
$0^{p+1}0^b1^p \neq 0^{p+1}1^p \therefore xy^2z \notin \mathcal{L}$ where $\mathcal{L} = \{0^i1^j, i \neq j\}$
we choose $s = 0^{p+1}1^p$ within $\|xy\|$
thus $\neq 0^p1^{p+1}$
Let $x = 0^a, y = 0^b1^a$
$x = 0^{p-h}, y = 0^h$
$x = 0^i, y = 0^i, z = 0^i1^j$

We carried out some inferences, which are our findings. Compliant with the guidance of our Institutional Review Board, we report only anonymous, aggregate data. We compared these with findings from the literature.

D. Validity and Reliability

Some support for the validity of the results comes from seeing several variations of each proposed error type. We found in our data multiple versions of unwarranted restrictions: choosing x to be empty or choosing the length of xy to be p, and others. We found in literature warnings against attempts to prove statements with universal qualifiers true by means of showing the existence of examples [2], [16]. These warnings suggest these errors have occurred before. In textbooks [17], [18] we find single counterexamples for showing such a statement false, and the method of exhaustion for showing a finite universal statement to be true. Proof by contradiction for the purpose of showing such a statement true, i.e., that any particular tentative counterexample contained an inherent contradiction, is not itself universally accepted, due to not necessarily being constructive [19] (page 2). We also found in our data, several versions of misunderstanding inequalities. We found support in literature for errors of misunderstanding how to work with inequalities, by students of this level [20].

E. Researcher Bias and Assumptions

The authors find diagrams useful; one (TMS) believes diagrams aid the abstraction process. The researchers tend to believe that students want to learn, and will try to comprehend and to become able to apply the material, and that the limitations temporarily present in the student can be overcome by explanation and practice.

IV. Results

The most common error was not understanding that the segment xy, the part of the automaton from the starting state and including the number of traversals of the cycle in the sample string, can be of length less than the pumping length, denoted p. Other errors suggested lack of understanding of the individual symbols, x, y, z, p, i.

An excerpt of the errors is shown in Table I.

One error was stating the rule that $|xy| \leq p$, and then immediately afterwards equating $|xy|$ to p. One error was stating the rule that $|xy| \leq p$, and then immediately afterwards

TABLE II. EXAMPLE ERROR DESCRIPTIONS

TABLE III. CATEGORIES

understand inequality
formulate correctly
distinguish between particular and generic particular
correctly apply universal quantifier
recognize string as member of language set

giving a segmentation in which $|xy|$ was $2p$. One error was stating the rule that $|xy| \leq p$, and then immediately afterwards giving a string $0^{p+1}1^p$ which, it was claimed, was necessarily segmented with $|z| = 0$. One error was restricting to the case $|x| \neq 0$. One error was stating the rule that $|y| > 0$, and then immediately afterwards equating $|y|$ to 1. One error was stating that y^0 corresponded to one instance of the substring y occurring. One error was stating that pumping would change the content of the segment x. One error was exhibiting one segmentation that could not be pumped, without addressing all possible segmentations. One error was claiming the rule $|xy| \leq p$ could be violated by some specific content in z. One error was not being able to show that, for any given segmentation, pumping would produce a string, for some i, that was outside the language. One error was confusing a string as a member of a language with a description of a language.

V. ANALYSIS

We wrote descriptions for each error. Some example descriptions are in Table II.

A handful of students did exhibit their reasoning that for all segmentations there would exist at least one value of i that would generate a string outside the language.

We categorized the errors as misunderstandings of one or more of:

1) $|xy| \leq p$ permits $|xy| < p$
2) x is the part of the string prior to the cycle
3) y is the part of the string which returns the state of the automaton to a previously visited state
4) z is the part of the string after the (last) cycle up to acceptance
5) $p - 1$ characters is the maximum size of a string that need not contain a cycle, (strings of length p or greater must reuse a state)
6) i is the number of executions of y
7) There must be no segmentation for which pumping is possible, if pumping cannot occur.
8) A language is a set of strings.
9) A language class is a set of languages.

Categories are shown in Table III.

Some examples of inferences are shown in Table IV.

Some errors. e.g., $|xy| \leq p$, Let $x = 0^{p+r}, 0 < r < p$ illustrate students are not recognizing the symbolic formulation, entirely apart from the pumping lemma's segmentation of

TABLE IV. EXAMPLE INFERENCES

$x \leq p$ then $x = 2p$ is formulation
Inequality $x \leq a$ restricted to $x = a$ could be inequality or quantifier.
Inequality $x \leq a$ restricted to $x = a + 1$ is both inequality and quantifier.

strings, and apart from choosing a merely particular example when a generic particular is required. The presence of this, accompanied by others slightly less clear, show that some students need remediation at the level of formulating mathematical relations.

There are many examples of unwarranted restrictions, such as $|x| = 0$, $|x| \geq 1$, $|z| = 0$, and they occur in the context of inequalities. Concerning these errors involving inequalities we wish to see whether we can draw a distinction between two particular misconceptions.

One misconception is that restrictions can be chosen by the student without invalidating the work, and the other is that inequalities of the form $\leq$ and $\geq$ do not mean the disjunction of the equality relation and the less-than relation. One error begins with $|y| > 0$ and then restricts to $|y| = 1$. Because this is not a case of restricting $\leq$ or $\geq$ to being equality, we see that instead it is misconstruing that restriction (to a "mere" particular, rather than a generic particular) is valid.

Errors such as $|xy| \leq p$, so $xy = 0^p$ seem to be restrictions to merely particular cases, as opposed to generic particular cases, as are needed to prove a statement with a universal quantifier true.

This observation is of more general applicability than that of the pumping lemma. Perhaps more time could be beneficially spent observing what is required for a generic particular to be generic.

Errors suggesting a lack of understanding of the context of the pumping lemma, attaching meaning to the individual symbols, x, y, z, p, i include that pumping would change the content of the segment x, that a case of $i = 0$ corresponded to one copy of the segment y, and that the content of z could violate the rule $|xy| \leq p$.

Concerning the errors that inability to pump a single segmentation constitutes a sufficient argument that a string cannot be pumped, we observe these errors are, with the errors above, related to applying reasoning with quantifiers. We believe that these students could state the definition of for all ($\forall$), and of there exists ($\exists$), but we see empirically that when called upon to exercise these concepts as tools, they do not always succeed.

The pumping lemma is one example of a statement with multiple quantifiers, but such statements are used more generally [2], [18].

Some inferences specifically related to the pumping lemma are: Had the students understood that $|xy|$ denoted the part of the string that moved the state of the automaton from its initial state to the completion of one iteration of the cycle, and that any finite length could occur prior to the cycle, and that p was the number of states, they would not have restricted their considerations to $|xy| = p$, or, for that matter, $2p$. Had the students understood that x denoted the initial transitions prior to the state reused in the cycle, they would not have excluded the start state from being susceptible to reuse. Likewise, had the students understood that z denotes the part of the string occurring after the last cycle, they would not have restricted its length to 0, nor claimed that a setting for z would change the content of xy.

VI. Discussion

Students seemed to have trouble with applying reasoning involving quantifiers, understanding symbolic formulations and forming abstractions. These skills are relevant for proofs in general, not only those specific to pumping lemmas. While the pumping lemma for regular languages furnished a test case, other problems surely also serve to illuminate students' abilities to deal correctly with quantifiers and inequalities.

A. Quantifiers

Perhaps the most interesting result was that students applied unwarranted restrictions to their considerations, when they needed to show something held for all cases.

That is, students showed existence of one case (for example, one segmentation), when what was needed for a sufficient argument was to handle all cases.

We know these students have seen proofs using a generic particular, and we wonder whether they grasp what is needed for a particular case to be generic.

We had students who found statements with more than one quantifier difficult to comprehend. We found students who comprehended, but did not freely apply, the pigeonhole principle.

Devlin [2] reports logical statements containing more than one quantifier as a source of difficulty for beginning students. Velleman [21] observes that students find logical statements containing more than one quantifier confusing. He recommends an approach to understanding these [21].

So it appears that the topic of how many is enough, whether it be the quantity to satisfy a proof or quantities in the pigeonhole principle is one that permits Bloom's [6] level of comprehension without necessarily requiring the ability to perform Bloom's [6] level of application.

B. Symbolic Formulations

A second result was that students would carry out operations using symbols, exhibiting inconsistencies in the use of the symbols, such as the case where the very thing that was $\leq p$ was also $= 2p$, for $p > 0$.

The possibility of students attempting what Fagan [15] calls a plug-and-chug approach appears to be worthy of some effort to counteract it. We want to draw a distinction between performing then using a formulation (a kind of abstraction), and making use of a formulation, without having understood it. In the former case, efficiency is gained. Rules for manipulation make sense in terms of the original situation. In the latter case, the reasons for the rules are not appreciated, and the rules might be more easily forgotten. One example of a correct formulation, seen and learned, used a variable a to take on any of the values $0 \leq a \leq p$; the variable was not understood to represent the range, instead was thought to be as a single value, somewhere in the range $[0, p]$. This error might be related to the misunderstanding seen about merely particular vs. generic particular, because the generic particular, of course, represents the whole range. It seems an important kind of error for computer scientists, because variables play an important role in programs. The difference between "holding a single value" and "representing an ensemble of values" should be useful in situations were characterizations of accuracy apply, for example.

As Devlin [22] says "Our goal here is to develop mathematical thinking skills. The symbolic (expressions) are ...a way of achieving that ...strongly recommend ...approach every problem in terms of what it means, using its own language."(p. 44).

From the perspective of the mathematical symbol representation, we have seen evidence that inequality might be difficult to handle, as Mattuck has observed in Introduction to Analysis [20].

C. Abstraction

Representing the machine (which the students see as a graph of states and some memory) in a symbolic formulation is an act of abstraction. Looking at a symbolic formulation is not necessarily an act of abstraction.

We want the students to master the symbolic formulation so that they can use the power it brings, through abstraction, to the reasoning process. If the students are not reasoning about the underlying system that is represented symbolically, rather only hoping that the manipulation steps they perform are valid, they do not gain the benefit of the abstraction.

We agree with Weidmann [23] that students might need practice thinking abstractly. Papert and Harel [24] have shown that when students are tasked to write a program to teach an abstract concept, such as fractions, the programmers learn the abstraction well. Because Sipser's [1] diagrams aid understanding and Papert and Harel's [24] students, who were shown to learn abstraction successfully depicted fractions, and as Reid and Knipping [25] cite Martzloff [26] observing the use by Euclid of "$\delta\epsilon\iota\kappa\nu\upsilon\mu\iota$", which meant "to make visible", perhaps there is a role for pictures in enhancing the ability of student to learn abstraction.

D. General Significance

Students of computer science need the ability to comprehend and apply inequalities, symbolic formulations, quantifiers and abstraction. They need the ability to comprehend simple proofs involving these concepts. Do we wish students to think of program variables as profoundly different from defined constants, e.g., as able to take on a range of values, for an ensemble of program executions, perhaps even having probability density functions for those values? If the value taken by a program variable depends upon input data and the data are stochastic, it can be useful in sensitivity analysis to think of the variable as taking on a range of values, and focus on that range. The results of this study suggest that juniors in computer science might not be prepared for this.

Supplementary course resources could be provided, that help the students master these generally useful concepts. Incoming assessment addressing these specific needs, and provided materials and learning environments, we can guide and support the students in mastering this material. This is merely an application of a recommendation of Simon et al. [27] to the Theory of Computation course. Additional emphasis on the difference between the universal quantifier and the existential quantifier seems warranted, as well as practice with statements containing multiple quantifiers.

Because the underpinnings of these ideas for which we found misconceptions are treated in a course on Discrete Systems, discussion fora and tests for mastery of these concepts might be particularly useful in that subject.

VII. Related Work

Mattuck [20] states “analysis replaces the equalities of calculus with inequalities: certainty with uncertainty. This represents for students a step up in maturity.”[page xiii] and “these are things which I find that many of my students don’t seem to know, or don’t know explicitly. They subtract inequalities . . . ”

In 2010 Pillay [28] asserted that “there has been no research into the actual learning difficulties experienced by students with the different topics” in formal languages and automata theory. Of the pumping lemmas, Pillay states “A majority of the students made logical errors when proving that a language is regular and using the Pumping Lemma to show that a language is non-regular. These could be attributed to a lack of problem-solving skills and an understanding of the Pumping Lemma.” Devlin [2] observes that quantifiers can appear daunting to the uninitiated, and that statements containing multiple quantifiers can be difficult to understand. Hüttel and Nørmark [29] described a successful method for improving both student activity level in the course and final grades, which combines peer assessment with creation of notes that can be used during the exam. (“The incentive was that their answers to text questions would be available for them to use at the written exam. No other textual aids would be allowed at the exam.”[p. 4]) The better performance on the exam is welcome; whether it is due to having notes compared to closed book, or having performed the review might not be certain.

According to Arnoux and Finkel [30], it is not unusual for students to acquire mathematical knowledge without attaching meaning to it, and leaving them unable to solve some problems. They go on to report that Paivio proved that “double coding (verbal and visual)” facilitated remembering. They also report that different parts of the brain are used to process verbal and visual information, and therefore more of the brain is involved when both verbal and pictorial communication is used. They prefer multi-modal representations.

Xing [31] writes about aiding students comprehension of proofs being aided by graphs. She reports “students feel that Pumping Lemma(PL) is so abstract to grasp that using it to prove that a language is non-regular is a daunting task.” She shows a graphically laid out proof that a given language is not regular. This graph has the advantage over a traditional proof, i.e., a sequence of statements, that the dependencies of states on axioms or intermediate results are plainly shown by graph edges.

Simon et al. [27] ask “Is it possible that students plug and chug in computing, not really understanding the concepts as we would like them to?” and go on to say “We posit that the need exists for computing instructors to design assessments more directly targeting understanding, not just doing, computing. And, of course, to adopt teaching approaches that support student development of these skills.”

Mazur [9] developed peer instruction to address students’ propensity to practice a plug-and-chug approach to problems. This approach has been applied to computer science teaching, including theory of computation, by several researchers including Simon, Zingaro, Porter, Bailey-Lee and others [11], [32]–[35].

In 2003 Weidmann [23] wrote a dissertation on teaching Automata Theory to students at the college level. She found that past performance in prerequisite theory courses was a statistically significant indicator for success in their college level course. She described a theoretical framework called “pedagogical positivism” a stance between logical positivism and constructivism, allowing the notion of a teaching method best suited to a group of students to learn Automata Theory. She interviewed a teacher with “several” years of experience teaching this course (p. 5), who “admitted that she did not have a better way to teach abstract thinking other than repeated exposure” (p. 98).

In chapter 5, Discussion, Conclusions and Implications, of this dissertation [23], the suggestion “Instead of simply providing the solution to a problem in class, or stating the intuitive leap that makes the problem easy to solve, the students should be exposed to the iterative thought process that lead to the intuition that created the solution.”(p. 201) appears. One suggestion is “Learning objectives should be set to focus on familiarity with formalisms and rigorous mathematical notations” (p. 224) and another suggestion is “Include programming projects as part of the required coursework”(p. 224). The combination of these brings to mind the suggestion of Harel and Papert [24]: “constructing personally designed pieces of instructional software”, and the thought that the students might dwell more effectively on the notion of abstraction as they tried to teach someone else about it.

VIII. Conclusions

Students are not necessarily well enough prepared when they arrive at the Theory of Computation class, to understand the logic used in the pumping lemmas, which deters them from applying the pumping lemmas correctly. As the purposes of the class include practicing abstraction, and noticing the increase in power from stack memory and subsequently random access memory, and as this increase in power manifests itself in the increased complexity of the languages, if students’ preparedness is weak such that they cannot use the tools for discriminating among these languages, such as applying the pumping lemmas, then they are not equipped to be properly convinced of the differences in these complexities.

Incremental approaches to learning the logical components underpinning the pumping lemma, to exercising synthesis of these components, and to learning abstraction using constructionist techniques exist.

It remains to be seen whether application of these approaches can be carried out in a semester leaving enough time for the student to apply these improved capabilities to Turing machines, reductions and complexity classes beyond regular languages and languages with context-free grammars.

IX. Future Work

We plan to emphasize reasoning with inequalities, symbolic formulations, multiple quantifiers and abstraction in student discussion, such as in Piazza [36], and provide anonymous (to students) discussion fora. We would like to qualify each concept, on the list of concepts needed to understand the pumping lemmas, with the level of advancement along Bloom's taxonomy needed for that concept. For example, we found some students' state of advancement, according to Bloom's (cognitive) taxonomy [14], on the pigeonhole principle to be comprehension without application and we know we need application for understanding how to apply the pumping lemmas. We would like to assess the students' advancement according to Bloom's taxonomy, as they start and continue with Introduction to Theory of Computation, on these several concepts. The ability to invert logical statements containing multiple quantifiers is one such concept that we found the students not yet masters of comprehension, and we would like to study how to encourage the students, adapting pedagogy from mathematics to computer science. We would like to compare various discussion questions for their ability to clarify to students when it is a statement with the universal quantifier that they must prove, and how to distinguish a generic particular from a merely particular example. We would like to test the hypothesis that comprehension for inversion of logical statements containing multiple quantifiers is enough for the purpose of mastering the ability to apply the pumping lemmas. Alternatively, application might be needed. We would like to determine the scope of support, such as preliminary reading, but also formative assessment, for achieving the hypothesized necessary level of advancement. We might want to find out whether, having achieved these levels, students subsequently learned from lectures, to apply them successfully. We could use the pumping lemmas as test cases.

***Abstract*—The Agile Software Development (ASD) process is at the forefront of rapid product development driven by changing customer requirements and a trusted, self-organizing development team. Scrum has become a viable model of ASD focusing on determining immediate deliverables and structuring short timelines, called Sprints, for designing, implementing, and providing them for testing by the customer. While these practices are being adopted by organizations, there is significant difficulty in scaling them to the classroom. Once in place, it is a complex task to evaluate individual student performance based solely on the product outcome and Sprint grade. Thus, there is limited opportunity to catch performance problems that may lead to missing deliverable deadlines or decreasing team trust. In this paper, we impose ASD using Scrum on a senior software projects course in Computer Science. Using a collaborative environment that embeds a social network, project management modules, and event capture system, we perform broad data and event capture and analysis to investigate metrics that are relevant to assessing individual performance aspects related to functioning on an Agile team for software development. Our results suggest that predictive data is available after each Sprint to ascertain individual performance attributes and their relationship to product outcomes.**

Keywords—Agile Software Development; performance assessment; Scrum; undergraduate software engineering

I. Introduction

Many organizations have moved toward Agile Software Development (ASD) [1] for rapid deployment of software products, especially for web applications, web services, and cloud computing. A research survey conducted at Microsoft [2] found that around one-third of the respondents use ASD, with Scrum being the most used practice. Only recently has ASD and Scrum, specifically, been studied and reported on within a software engineering course setting. Many studies have analyzed the design of the curriculum covering the benefits and drawbacks of ASD and Scrum [3, 4]. For example, meeting frequency can be burdensome if it is required to be face-to-face every time. This observation parallels industry surveys where meeting frequency is viewed as a necessary drawback of Scrum [2]. Despite the drawbacks, the benefit of rapid delivery of product functionality from using ASD translates into student teams realizing non-trivial software products using three Scrum Sprints over a 16-week semester; something that is enormously advantageous to the graduating computer scientist.

When deploying Scrum in a course setting, product requirements and user stories are placed in an adaptive *Product Backlog*. Teams construct incremental, functional deliverables in the short timelines of the Sprints. A *Sprint Backlog* houses the tasks required to develop each deliverable designated for that Sprint. *Sprint Meetings* require team members to individually discuss their current progress on assigned tasks, their next task, and any problems they encountered or impediments they see in deliverable given their results and those of other team members.

While methods for integrating ASD into software engineering courses have solidified, assessing individual performance can be difficult because the Agile team's productivity and outcomes can mask individual contributions. Such assessment is needed to identify how an individual participated and to what extent. The assessment requires metrics that separate the individual's participation from the team results. Though research has been performed on individual assessment in a variety group projects, it often relies only on self-reporting by individuals on their efforts and their team members' efforts to produce a grading scheme. Virtual teams have been studied to determine if leadership or influence attributes can be assigned by studying social network interactions. Because we are studying ASD teams that are pre-formed in a pedagogical setting, we need specific metrics that track the Scrum process and its use by team members to deploy Sprint deliverables. The goal is to determine if predictive data exists after a Sprint that indicates individual performance so that individuals can be better trained to reach team goals. The study requires online tool support for capturing the discussion and logging product-related activities as they occur.

There is wide recognition in the tool support community [4-6] that specific tools must be made available, such as wikis or Google collaboration tools, forums or email, version control, and shared calendar applications to support project management, product development and interaction. However, substantial effort is needed to consolidate information captured from diverse tools into a single time series necessary for team or individual assessments.

In this paper, we define four performance metrics. These metrics are designed to characterize the depth and quality of individual performance as it relates to ASD team functions. *Contribution* measures the direct participation and quality of involvement of the student during Sprint Meetings. *Influence*

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

measures if and how an individual directs the team's progress by being an engaged and active member of the team. *Impact* documents the causal relationships between what students say they will do, the actions the actually take, and the artifacts that result from their actions and, ideally, improve the Sprint deliverable's quality. Finally, *Impression* measures how well team members acknowledge the effort and performance that fellow team members make toward the successful completion of project deliverables.

We outline a methodology to assign values to each metric. The values form a numeric *assessment profile* of an individual student within an ASD team using Scrum in a university capstone software engineering course (see Table 1 for example). We rely on our open source courseware, called SEREBRO, to capture and consolidate team event data. Subject matter experts (SMEs) perform content inspection to calculate the metric values. We state research questions relevant to the study that direct how the assessment profile can be used to understand individual performance on an ASD team.

In the next section, we discuss various studies on ASD. Section III outlines the capabilities of SEREBRO and prior studies conducted with using its data capture functions. Section IV details the methods for measuring Contribution, Influence, Impact, and Impression, states the research questions, examines the data collected, and discusses the implications of the results. Section V concludes the paper.

II. Related Work

Pushing ASD into an undergraduate or graduate software engineering class requires careful set up and management so that the students are not overwhelmed by the pace and activity of the process, given what is involved in a Scrum Sprint. Researchers have drafted such courses and reported, often anecdotally, on the findings [7]. Studies conducted in undergraduate classes have examined the social interaction with respect to ASD for the purpose of determining if students have more effective learning opportunities. One study [8] points to pair programming in ASD as a potential learning opportunity for software development. A Social Interaction Model of Pair Programming resulted from data collected in two forms for assessment: interviews to gauge participation and satisfaction, and self-reported documentation by the students about their perspective on project outcomes. These results indicated not only a feeling of more productivity, but also an increased skillset confidence and interest in IT.

In contrast to focusing on process, studies examined human behavior based on automatically data collected by IBM's collaboration tool JAZZ [9]. A social network was constructed by finding indirect interactions through developer build commits and artifact versioning as entered in a time-stamped software repository. The resulting *socio-technical network* was used to predict software quality based on whether or not successful incremental builds showed a high degree of connectivity, and hence, collaboration among developers [10]. These results emphasize the importance of collaboration in software engineering teams, further substantiating the use of collaboration metrics as performance measures [11].

Other studies examine the perception of productivity and satisfaction of using ASD [2, 4, 12]. Assessment is generally performed via surveys and personal interviews. Many claim a positive response to the practice, including a perception of increased productivity and product quality [13]. Others found that the main values attributed to ASD relate to communication and collaboration [14]. Studies of using ASD in graduate software engineering courses concur; also citing increased student team productivity and product quality [7].

A review of literature on assessing individuals in group projects does not provide adequate, reusable metrics for ASD teams. Existing measures heavily rely on self-reporting activity, detailed project evaluation rubrics, surveys and grades based on individual submissions related to the project [15-17]. This lack of metrics is especially an issue for classroom settings where feedback and individual grades should be provided after each Sprint to improve student activity quality and accountability on the project, in general, and within the development process and on a team, more specifically.

III. SEREBRO

SEREBRO 3.0 is used as courseware for three classes at the University of Tulsa: Software Engineering Projects I and II and Introduction to Psychology. SEREBRO features an *idea network*, which combines aspects of issue management and social networking, a set of *project management modules*, and an *event capture system* that logs all activities within the idea network and modules.

Fig. 1 is a screen shot of a SEREBRO idea network as a graphical forum for asynchronous postings of brainstorms (blue circles), agree and disagree nodes (green and orange triangles), and comments (bubbles). Multiple brainstorms may be used within a single topic thread and may be started by any team member. SEREBRO provides optional directed email alerts for posting and project activities to ensure team visibility. The idea network is implemented in jQuery and displays post content when a user hovers over a node icon. Clicking an icon in the network marks it on the left and brings up the corresponding post to the right of the tree for user response.

SEREBRO's project management modules include a Gantt chart, calendar, wiki, document upload area, Subversion (SVN) software repository, activity feed, and a spreadsheet. The wiki is most often used to build and structure project documentation. SEREBRO *uploads* typically consist of images, presentations, and other non-textual files relating to the project. The *SVN module* provides source and version control repositories for each team as well as a WebSVN UI, which allows team members to make manual changes from a web browser, and a commit feed that displays commit messages and allows SVN commits to be tagged using the tagging system. The SEREBRO *spreadsheet system* provides Excel-like functionality in a web-browser to allow students to store and process numerical or textual data. The Gantt Chart is used to assign and track tasks throughout development milestones.

Previous studies have been performed using SEREBRO data captured in the CS and Psychology courses. These studies examined motivational techniques to increase creativity [18], including features to support teams [6],

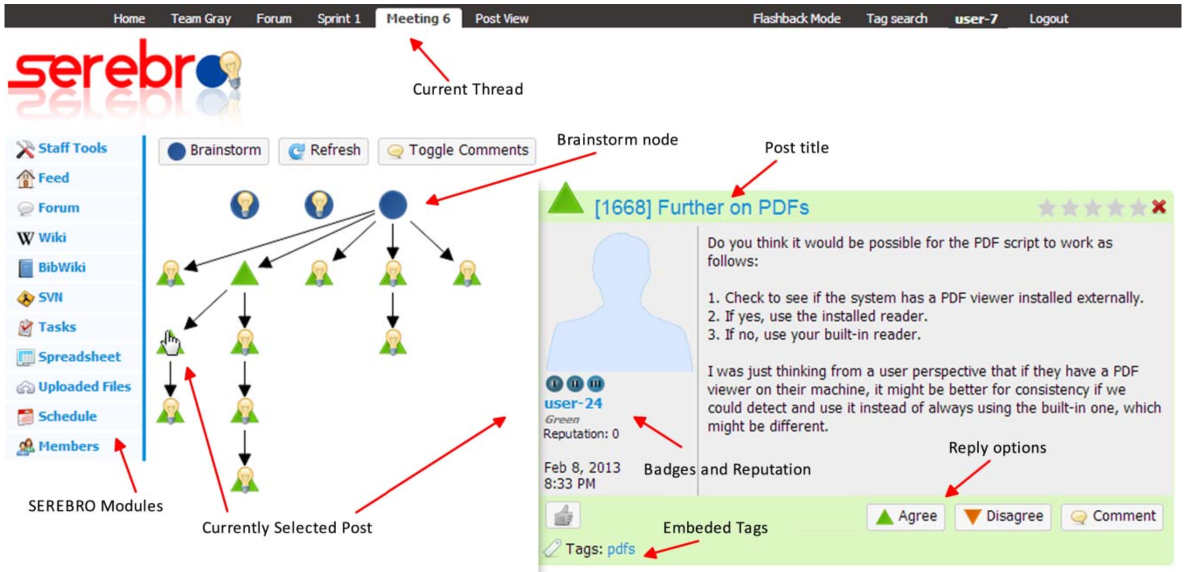

Fig 1. Sample SEREBRO Idea Network and Interface

developed event logging and automated scoring techniques for analyzing milestone performance within the Rational Unified Process [11], provided a tagging system for traceabilty across the artifacts [19], and proposed potential learning indicators evident in web-based collaboration [20]. Prior to Fall 2013, all Software Engineering Projects classes used a cross between the Waterfall development process and the Rational Unified Process to drive milestone formation and completion, which formed the basis for the prior studies. SEREBRO was tailored by class rubrics designed for each process milestone. Thus, posting in previous studies was very unstructured and conversational, informal, and sometimes completely off-topic. In addition, there was more freedom in how the various SEREBRO support modules were employed. The introduction of ASD, as discussed in this paper, required the teams to use the idea networks and project management modules in a much more structured way to facilitate Scrum practices such as attending Sprint Meetings, and maintaining the Product Backlog and the Sprint Backlog.

IV. Methodology and Assessment

In this study, we work within the ASD process using Scrum to the extent possible where there are frequent meetings with specified individual input requirements. The full set of SEREBRO modules is used to produce the various Scrum Sprint artifacts. The goal of the effort is twofold. First, we need to understand what is required to successfully scale Scrum to a class setting with one instructor and external customers, when students have additional classes and are preparing for graduation. Second, we want to get a clearer and more readily available picture of individual performance on an Agile team by obtaining predictive assessment metrics that identify how individuals perform during a Scrum Sprint.

Our study follows 16 students, across 4 teams in Software Engineering Projects II, working on non-trivial software products. The students were prepped on the use of SEREBRO, ASD, and Scrum as part of the previous fall semester software engineering immersion class (Software Engineering Projects I). During the fall course, students used SEREBRO for short project challenges to practice Sprints. For the Spring Sprints, the instructor serves as the Scrum Master and external customers serve as the product owners. Because pair programming in ASD has mixed reviews in both industry and academics [21], it was discussed as a potential strategy, but not required of the teams. We use the following artifacts generated within SEREBRO as part of a Scrum Sprint.

Meeting Check-ins: These are specific posts required in the idea network that are structured to simulate Sprint Meetings, though check-in times are generally 48-72 hours apart. In the studied Sprint, we analyze 10 meeting check ins that occurred over a 3 week period.

General Posts: These posts reside within the idea network and include face-to-face meeting minutes during customer meetings, general discussions on research, server configuration, technical problems, and conversations with the instructor. These posts have value as part of the general student engagement in the project.

Wiki: Generally, the wiki holds all documentation related work products. For the examined Sprint, the Wiki was required to hold an executive summary of the product, use cases, research on technology and competition, execution instructions, and a Sprint review or post mortem.

Subversion Repository (SVN): The shared repository contains code commits and associated commit messages for version control during product development.

Gantt chart: A project management and task assignment tool houses the Sprint Backlog that is updated as tasks are assigned and completed during the Sprint or issues and impediments identified by the team are added and assigned to responsible parties.

Spreadsheet: The spreadsheet module in SEREBRO contains the Product Backlog that includes the product requirements and user stories.

Uploaded documents: SEREBRO provides a shared space for storing non-textual documents such as images and presentation files that supplement other module content.

Team Evaluations: After each Sprint, team members submit a confidential evaluation sheet on perceptions of their performance and their team members' performances during the Sprint. The evaluation consists of two parts. The first part is a questionnaire with 10 general evaluation questions in which every person evaluates his or her personal performance and the performance of each team member using a range of 0-10, with 10 being the highest. The second part of the form denotes a variety of roles and responsibilities, such as general manager and organizer, leader and inspirer, programmer, designer, analyst, and tester. In this part, each person denotes a percentage weight for a role or responsibility for each team member and then scores that performance from 0-10 at that role or responsibility.

Team Rankings: Each student ranks the amount of perceived engagement in intellectual input (product vision, understanding, and interpreting customer requirements), creative input (elegance in design, coding, aesthetics), and results achieved (tangible evidence of work and experience) for each team member. These rankings supplement the more detailed Team Evaluations with direct comparison.

Sprint Deliverable Grade: The deliverable for the Sprint includes a stand-alone functional component within a web application or integrated components that meet one or more essential requirements and encompass at least one user story. The deliverable is accompanied by project management artifacts that include the Product Backlog of requirements and user stories, the Sprint Backlog of tasks, impediments, and issues related to the Sprint, wiki documentation associated with the deliverable, the SVN repository, and the Sprint presentation and demonstration. A project grade is given to the team according to the quality of the deliverable overall. The Sprint Deliverable was worth a total of 800 points for which a complete set of rubrics was provided to the class.

A. Contribution Scores

Contribution assesses the direct participation and quality of involvement of the student in required Sprint Meetings, in the form of Meeting Check-ins. There were four separate check-in requirements: (a) being on time, (b) stating what was done since the last meeting, even if it was little to no activity, (c) stating what will be done for the next meeting, and (d) discussing a project issue, impediment, or activity found by the individual or a team member. Each requirement was worth 3 points with the Subject Matter Expert (SME) scoring as follows: 0 = not met, 1 = almost met, 2 = met, and 3 = exceeded requirement. The Total Meeting Points is the sum of the requirement points from 0-12 per individual for each meeting across all 10 meetings. The data in Table 1 consists of the users (column 1), the Sprint Deliverable Grade (column 2), the Total Meeting Points (column 3), and the final Contribution score (column 4) which is defined as the Total Meeting Points divided by the 120 maximum possible points. Contribution scores ranged from 31% to 90%, with a 54% average. Values for Impact, Impression, and Influence (columns 5, 6, and 7, respectively) in Table 1 and discussed in subsequent sections, comprise the numeric *assessment profile* for each student.

The first research question accounts for ASD and Scrum expectations, that short, frequent meetings where individuals are self-directed, accountable, and trusted produce better product outcomes. It assesses whether the amount and quality of meeting participation leads to a better deliverable.

RQ1: Does a team with high overall Contribution have better product outcomes?

To answer this question, we examine the linear dependence between the Contribution score and Sprint Deliverable Grade in Table 1 using the Pearson correlation coefficient (Pearson's r) [22] to determine if higher individual Contribution scores correlate with higher Sprint Deliverable Grade. Correlation values for this and subsequent research questions are calculated using sum of squares, as part of linear regressions between series of data for two metrics. All r values are calculated with 14 degrees of freedom (df) corresponding to the 16 users present on the 4 examined teams, i.e. df = 16-2 for two-tailed test. In this and the following sections, we use the standard critical values for r as follows:

- $|r| > 0.426$ corresponds to a significance level, denoted by a p value, of $p = 0.10$ (shown in correlation tables as purple),
- $|r| > 0.497$ represents $p = 0.05$ (red),
- $|r| > 0.574$ represents a high significance of $p = 0.02$ (yellow), and
- $|r| > 0.623$ is indicative of a very strong significance $p = 0.01$ (green).
- Any r values such that $|r| < 0.426$ are considered to be not indicative of a correlation (white).

TABLE 1. GRADE AND ASSESSMENT PROFILE

Student	Sprint Deliverable Grade	Total Meeting Points	Contribution	Impact	Impression	Influence
user-6	0.88	49	0.41	0.76	8.81	0.19
user-9	0.88	59	0.49	1.35	8.60	0.18
user-11	0.88	53	0.44	1.47	9.27	0.23
user-23	0.88	64	0.53	3.12	9.25	0.39
user-13	0.86	69	0.58	2.47	9.54	0.29
user-18	0.86	64	0.53	1.53	9.27	0.21
user-19	0.86	74	0.62	2.47	9.19	0.21
user-22	0.86	70	0.58	1.18	9.21	0.23
user-2	0.98	49	0.41	1.41	8.82	0.06
user-17	0.98	95	0.79	4.71	9.56	0.29
user-21	0.98	108	0.9	5.00	9.28	0.49
user-24	0.98	61	0.51	0.53	7.74	0.14
user-7	0.82	37	0.31	0.24	7.46	0.09
user-8	0.82	71	0.59	1.59	9.43	0.37
user-10	0.82	64	0.53	0.35	9.24	0.23
user-16	0.82	44	0.37	0.35	8.48	0.15

The p value is formally described as the probability of obtaining the observed result given that the null hypothesis is true. Our work uses a null hypothesis which can be stated as *there is no relation between metric X and metric Y*. Thus, a p-value of 0.01 would mean there is a 1% probability that one could observe a correlation given there is actually no linear dependence between the two metrics. In other words, the lower the p-value, the higher the likelihood that the correlation result is significant of an actual dependency relationship between X and Y.

For RQ1, we found that higher Contribution scores correlated with higher Sprint Deliverable Grades (r=0.47, p=0.10). This suggests that, with 90% confidence, we can say that better individual contributions across the team lead to better final products. All correlations discussed henceforth will report the r and p values.

B. *Influence Scores*

Influence measures if and how an individual directs the team's progress by being an engaged and active member of the team. This activity may be in the form of intellectual and creative input or vision, results production, general project communication, and managing the team. We measure influence using the SEREBRO event system to obtain a raw count of the total number of posts, activities affecting artifacts, and the average events per day for an individual. Since each team has unique project requirements, energy, commitment, and skill sets, we weight the Influence score against the events of the team as a whole (see below). Given an individual's calculated Influence score, the second research question examines if an engaged and active team member, i.e. one with a high Influence score, drives the product progression. The third research question determines if an engaged and active team member is recognized as such by the team. The importance of these questions to the study is to understand how engagement and activity can and should be manifested so that an individual's participation is recognized as valuable.

$$\textbf{Influence score} = \frac{average(individual\ events\ per\ day)}{average(total\ team\ events\ per\ day)}$$

RQ2: Does an individual's Influence determine how much that person impacts the overall product?

For this question, we return to the students' numeric assessment profiles in Table 1. Influence and Impact (defined next) are highly correlated, (r=0.74, p=0.01) indicating there is a very strong relationship between the number of events an individual performs relative to the team and his/her impact on the final product.

RQ3: Does an individual's Influence score match the team's overall perception of the person's activities?

To answer RQ3, we use the Team Rankings to determine if a seemingly engaged and active person is ranked highly in intellectual input, creative input, and results achieved as perceived by their peers. Table 2 shows the results. Note that the negative numbers are inversely correlated because the higher the influence (i.e. the more events) the lower the rank should be, since students are ranked from best (1) to worst (4). For intellectual input, (Intellect with r=-0.58, p=0.02), the strength of the correlation indicates that highly influential people are recognized as providing vision and quality ideas to the development process and resulting product. This result implies that individuals who communicate more frequently in the idea network or create more artifacts (i.e, code, wiki documentation, spreadsheets, or uploads), are perceived to have provided intellect through that effort. Similarly, the results achieved (Results) strongly correlates to Influence (r= -0.65, p=0.02), indicating that the team acknowledges that engaged and active people produce actual work products. This correlation is expected because high result achievers will likely perform more artifact manipulation, increasing their Influence score. Creative input did not correlate with Influence. We infer from this result that either creativity is not well understood by the team members, or there is no perceived association between a person's creative input into a project and the activities performed. Though not shown, creative input also did not correlate with intellectual input (r = 0.42) indicating that individuals did not rank their teams using the same criteria for intellectual and creative rankings.

TABLE 2. INFLUENCE CORRELATED WITH INTELLECTUAL, CREATIVE, AND RESULT RANKINGS

	Intellect	Creative	Results
Influence	-0.58	-0.01	-0.65

C. *Impact Scores*

Impact documents the causal relationships between posts and activities that subsequently alter artifacts. Impact scores are based on three forms of self-regulated learning strategies [23]. An individual posting that he or she will perform a task is a form of planning. Following that statement with an action constitutes a preplanned activity. If a user performs an action and then posts, any request for evaluation is a third form of self-regulated learning.

To measure an individual's project Impact, we link communication posts with artifact creation activities. We automatically filter posts according to phrases and words indicative of the self-regulated learning strategies, such as "will," "done," "I'll," "I can," "I have," "doing," "I did," and "I've." A manual review of the filtered posts is performed to remove any spurious posts. The remaining posts contain one or more *goal statements* that relate to the creation or advancement of the Sprint Deliverable. The SME compares the posts against the set of product deliverables to determine if the goal statements relate to actionable events in SEREBRO. An actionable event is defined as the creation or modification of an artifact within a SEREBRO module. Actionable events include SVN code commits, file uploads, updating the Product or Sprint Backlogs, and documentation wiki edits. The SME records the number of *links* that a goal statement post has to an actionable event and assigns a quality value to the event's effect on the deliverable. These values are

- 0 = Poor quality work – event had minimal effect on deliverable completion.
- 1 = Low quality work – event had little effect on deliverable completion.
- 2 = Good quality work – event had direct effect on deliverable completion.
- 3 = High quality work – event had significant effect on deliverable completion.

Some example quality assessments include:

- poor quality code commit (uncommented, no commit messages, few lines or single characters)

- high quality code commit (well commented, commit messages, significant number of lines added or changed)
- poor quality use case diagram uploaded file (lots of errors, carelessness is evident)
- high quality use case diagram (no or low errors, thoughtful, complete)
- poor quality wiki change (spelling errors, broken links, incomplete, and non-descriptive, with no change messages provided)
- high quality wiki change (no errors, no broken links, complete and descriptive, change messages provided)

We calculate a single Impact score using the formula:

Impact score =

$$\frac{\text{Scored Posts}}{\text{Total Scored Posts for Team}} * \text{Average\#Links} * \text{Average Quality Assigned}$$

where Average#Links is the average number of links the individual has across all filtered and scored posts, Average Quality Assigned is the average assessment value of all of the links found, and (Scored Posts / Total Scored Posts for Team) normalizes the Impact score given a particular team.

RQ2 shows that an individual's Impact is related to his or her engagement and activity (i.e., Influence). We introduce a fourth research question to determine if an individual's Impact is indicative of overall product outcome. This question studies whether an individual's planning of an activity, followed by its performance leads to a better overall deliverable.

RQ4: Do individuals with high Impact Scores have better product outcomes?

We answer this by determining if Impact scores correlate with higher grades given the student assessment profile in Table 1, which shows a strong relationship ($r=0.54$, $p=0.05$).

D. Impression Scores

Impression examines how a team member acknowledges the effort and performance that another team member has made toward completing a successful Sprint Deliverable. A poor evaluation by the whole team can cost a member a letter grade for the Sprint Deliverable, so they are taken very seriously. How individuals view and value their team members should qualify the extent of the high trust environment on an ASD team. If an individual is a 'social loafer', then the team may continue the project without input from him or her, and provide low evaluation scores. In contrast, if everyone's impression of a person's role and responsibilities and the effort put into them is similar, then it can be assumed that the person can be trusted at some level of proficiency, competency, and work ethic. Thus, individuals that are actively involved with the team with tangible effort toward a successful Sprint Deliverable, as measured by Contribution, Impact, and Influence scores, should be highly valued.

Using the Team Evaluations, we form Impression score as:

Impression score =

$$\frac{\text{Avg(G.Q1...G.Q10)} + \text{Avg(R.Q1...R.Q10)}}{20} = \frac{\text{G.Avg} + \text{R.Avg}}{2}$$

where G.Q1…G.Q10 are the 10 general survey questions taken from the Team Evaluations and R.Q1…R.Q10 are the 10 weighted role-based survey questions. The metric G.Avg is the average across the 10 general questions, while R.Avg is the average across the 10 role-based questions. The next research question (RQ5) asks if team member impressions are indicative of overall performance.

RQ5: Do group impressions of team members accurately reflect the team member's performance towards completion of a Sprint Deliverable?

To answer this question, we examined group impressions at the aggregate level using G.Avg, R.Avg, and the combined Impression score, and also at a finer granularity by examining individual question responses of the Team Evaluations. These values are correlated against Impact, Contribution, and Influence. We correlated these values with measures of specific activities. We compare the Team Rankings on intellectual input, creative input, and results achieved and Impression against the other metrics to determine if ranking mirrors the Impression score.

TABLE 3. CORRELATIONS BETWEEN IMPRESSION METRICS AND IMPACT, CONTRIBUTION, INFLUENCE, AND PERFORMANCE METRICS

	Impact	Contrib.	Influence	Wiki	Upload	SB	Commit	Artifacts	Thread	Ideas
G.Q5	0.16	0.25	0.54	0.67	0.72	0.62	0.10	0.59	0.32	0.44
G.Q9	0.48	0.35	0.23	-0.13	0.06	-0.12	0.28	0.29	0.03	0.16
G.Avg	0.54	0.60	0.67	0.14	0.29	0.17	0.57	0.63	0.61	0.57
R.Q1	-0.14	0.04	0.31	0.57	0.66	0.70	-0.31	0.29	0.17	0.27
R.Q7	-0.25	-0.17	0.01	-0.09	-0.04	-0.02	0.03	0.14	-0.16	-0.10
R.Q8	0.54	0.46	0.45	-0.20	-0.09	-0.28	0.69	0.32	0.49	0.50
R.Avg	0.59	0.54	0.51	0.20	0.33	0.22	0.40	0.60	0.27	0.36
Impress.	0.59	0.60	0.64	0.17	0.32	0.19	0.53	0.65	0.50	0.51
Intellect	-0.50	-0.46	-0.58	0.17	-0.07	0.13	-0.67	-0.48	-0.60	-0.55
Creative	-0.10	0.01	-0.01	0.34	0.14	0.05	-0.08	-0.08	0.02	0.06
Results	-0.52	-0.61	-0.65	0.05	-0.08	0.00	-0.70	-0.61	-0.56	-0.57

Table 3 shows these correlations along with a sampling of five individual questions (G.Q5, G.Q9, R.Q1, R.Q7, and R.Q8) taken from the Team Evaluations. In G.Q5, individuals are asked to score how well a team member "Contributed to document artifact creation and/or review." We found that individuals with high G.Q5 evaluation scores had higher percentages of Wiki changes, Uploads, and Sprint Backlog (SB) updates relative to their peers as well as higher overall numbers of ideas, artifacts and thus higher Influence scores. R.Q1 asks team members to weight the specific responsibility of "Organizing the requirements, user stories, and Sprint Backlog" and score that effort. In SEREBRO, these activities are recorded in the wiki, the Sprint Backlog, and uploaded document files, so it is not surprising that there are correlations to each fine-grained activity. Another question R.Q8 grades team members responsible for "Demonstrating exceptional programming ability." Table 3 shows that highly rated R.Q8 individuals also had higher Impact, Contribution, Influence and Code Commits relative to lower rated peers. On the other hand G.Q9 asked if, in general, a user "Completed all tasks assigned at agreed upon timeline" and R.Q7 which grades those users responsible for "Delegating tasks appropriately" both correlated very weakly across the board suggesting that either the team members did not have significant information to form accurate impressions about these topics or that the performance metrics in the table were not representative of the team evaluation questions.

Overall, the correlations shown in Table 3 suggest that team member impressions reflect performance reality during the use of ASD and Scrum within a class setting. The communication structure and notification system provided by SEREBRO appears to aid the ability of team members to accurately assess their teammates by providing better visibility and transparency across the board. That is to say, such a tool makes it easier for team members to detect the extent to which their teammates are performing their assigned tasks.

V. Discussion and Conclusion

In this paper, we define and study four metrics to quantify and qualify various individual attributes with an ASD team. The metrics, Contribution, Influence, Impact, and Impression, provide broad characteristics of the level of engagement, activity, and product related results of an individual on a team. We find that teams with higher individual levels of contribution and impact had better final product outcomes. In addition, team members are able to form accurate appraisals of each other's contributions, influence, and impact on the project given high visibility of the development process. The study provides a foundation for direct and objective feedback to individuals regarding more detailed qualities regarding performance after each Sprint.

Our results suggest that using collaborative environments to obtain performance and collaboration metrics allows for extensive individual evaluation and assessment. They also suggest that that high levels of transparency, as expected within the ASD process, contributes to a high trust environment, since individual efforts are visible to the team in tangible ways. This visibility relates directly to project outcome. The challenge is to craft a supportive environment for ASD process facilitation and collaboration for a class. While these environments are becoming more readily available, such as IBM's Jazz, automated methods for detecting impact links, analyzing conversations and code commits, and assessing collaborative activity are lacking. Without environmental support, it is difficult to attach an objective value to an individual's detailed project performance. This dilemma is more notable at the university level when training in software engineering should result in a grade that shows where improvements can be made. Unless event and activity tracking can be translated into the performance metrics discussed, Impression must be heavily relied on for performance evaluation.

Exploring Student Representational Approaches in Solving Rechargable Battery Design Problems

Oluwatosin O. Alabi[1], Alejandra J. Magana[1], and R. Edwin Garcia[2]
Purdue University: Computer and Information Technology[1] and Materials Science Engineering[2]
West Lafayette, IN., U.S.A.

Abstract—**The focus of this study is to characterize the representational practices of engineering graduate students who were involved in using computational and analytical mathematical models to solve a complex battery system design problem. The research question of this study is: How do students develop and use representational artifacts, while using mathematical or computer simulation models, for articulating their solutions to a complex battery system design problem? Results of this study provide descriptions of students representational artifacts produced in each of the stages of the problem solving process. The outcome of the study provides a framework for future studies using a larger sample size for investigating the role of mathematical and computational models in supporting students' problem solving processes in engineering education.** ***Keywords— representational media, computational tools, modeling and simulation.***

I. Introduction

Engineering disciplines have historically relied on computer simulations as a tool for solving problems and describing physical phenomena using mathematical models [1]. In particular, mathematical and computational models assist engineers and scientist in making central features of a phenomenon explicit and in generating representational artifacts required to inform scientific predictions and explanations within a particular domain [2, 3].

Educational researchers have maintained that the use of representational tools and artifacts can have a significant role in guiding students' conceptual understanding and problem solving processes [4, 5]. In particular, literature in math education suggests that the ability to implement and translate meaning among different representational forms results in higher forms of conceptual understanding and learning transfer [4, 6]. Although researchers have observed a positive correlation in students' cognitive development and their use of modeling and simulations tools, there is evidence that students face challenges when learning using modeling tools [7]. For example, computer simulations tools used in engineering educational settings are often developed by domain experts [8], have steep learning curves [9], and require some programming and computational thinking skills [9].

Current literature highlights a critical gap in understanding how to best integrate computer simulations tools in a way that constructively develop novices' conceptual understanding and problem solving skills. The purpose of this study is to address the current gap by investigating the role of mathematical and computational models in supporting students' problem solving process in engineering education. Specifically this study explores the representational practices of engineering graduate students who were involved in using computational and analytical mathematical models to solve a complex design problem in the Material Science Engineering domain. The research question of this study is: *How do students develop and use representational artifacts, while using mathematical or computer simulation models, for articulating their solutions to a complex battery system design problem?*

II. Theoretical Framework

Engineers use computational models as tools to critically analyze current real-world systems in order to construct predictions, formulate new ideas, and design new materials and devices [10]. Hamilton et al. [5], described models as conceptual structures that an individual employs to solve real-world problems. Having students involved in the process of construction of models helps them to articulate and build their own understanding of a system or physical phenomenon. Computational tools are becoming more useful pedagogical tools because of their ability to create and display representational models, often interactively and as a function of time [9]. Specifically, representational artifacts such as graphs, visual models, and simulations of physical or non-physical phenomena can serve as mediation tools to construct solutions in engineering design [2].

III. Conceptual Framework

The conceptual framework for this study integrates a conceptual system model from Lesh and Doerr [2] and Polya's model of the problem solving process [11]. The Lesh and Doerr representation media model, adapted for this study, is depicted in Figure 1. Lesh and Doerr's model defines conceptual understanding as a function of representational fluency, i.e., the ability to represent ideas in multiple forms and make connections among different representational media [2].

In addition, Polya's work describes the process of problem solving as a four step model that includes: (1) Representation of the problem, (2) Goal setting and planning, (3) Execution of the plan and (4) Evaluation of the solution. These two models can be applied in conjunction to provide insight of the interplay between the students' representational artifacts and the students' solution processes in solving problems using computation tools and written analytical solutions. Specifically, we implemented these two frameworks to examine and explore the participants' use of conceptual systems and artifacts to solve problems related to the design of rechargeable batteries.

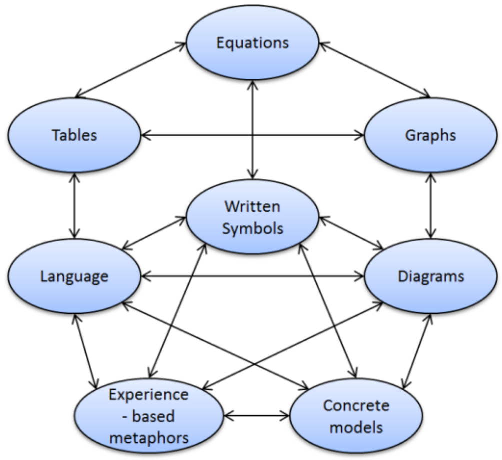

Fig. 1. Diagram of conceptual systems implemented to support and communicate understanding [2].

IV. Methods

Participants of this study were drawn from a population of twenty-four graduate students from a materials engineering course titled Introduction to Rechargeable Batteries. Using the homework assignments outlined in Table 1, the selected population included a total of six students, three in each group (Group 1: analytical tools; Group 2: computational tools). Students self-selected the assignment they wanted solve (i.e., analytical or computational), which determined the analysis group they were assigned to. The general population under study consisted of students in their first two years of graduate study with majors in engineering. Information on gender and ethnicity was not provided for this investigation. The sample population include students that scored 80% or higher for their particular homework assignment.

The assignments for Group 1 focused on mathematical analytical modeling and students' were asked to develop an expression for the reaction zone. Secondly, Group 2 students utilized the Virtual Kinetics of Materials Laboratory (VKML) [12], simulation tool and were asked to develop a computer model to design a graded porous electrode. The VKML tool was designed to be an open source online computing tool that (a) performs mulitiphysical equilibrium and kinetic calculations of material properties and (b) enables the novice user to focus on rapid model development and results visualization, not programming [13]. Both groups were then asked to respond to questions related to battery performance, such as discharge time, total charge, power density, porosity gradients, electrical conductivity, and additional parameters related to the design of a $LiMn_2O_4$ based battery system. Qualitative analysis was conducted using Lesh and Doerr's model [2] in order to describe the elements of the conceptual systems students employed for each stage of the problem solving process. The frequencies were summarized and compared between groups.

TABLE I. Mapping of Polya's problem solving process for each groups' design problem

Polya's model	Group One HW Questions	Group Two HW Questions
Represent the problem	Develop a model to design a graded porous electrode. 1. For the porous graded electrode with given gradient develop a an expression for the reaction zone. 3 & 4. Find an expression for the discharge time given the conditions of the porosity gradient, a. where Q3 α > 0, positive and Q4 α<0, negative.	Develop a computational model to design a graded porous electrode. 1. Extend the proved script to describe the porous graded electrode with given gradient. Make the appropriate substitutions for the reaction zone and baseline porosity.
Goal setting and Planning	2. Find conditions for which the reaction zone will be positive and real. How will this result impose a constraint on the porosity gradient? 5. For both types of porosity gradient electrodes, α is positive or negative, will allow for longer discharge time on the electrode?	3 &4. Using the developed model find the porosity gradient the minimizes/ maximizes the discharge time given the conditions of the porosity gradient, a. where Q3 α > 0, positive/Q4 α<0, negative.
Execute the Plan	6. For the $LiMn_2O_4$-based system propose: a porosity gradient (α), baseline porosity (ε_o), and electrode thickness (h_c) that optimizes the battery microstructure for a $LinMn_2O_4$ based system.	2. Given your developed model propose a battery microstructure: porosity gradient (α), baseline porosity (ε_o), electrode thickness (h_c) that optimizes the battery microstructure for a $LinMn_2O_4$ based system.
Evaluate the solution	7. How would your results change if you instead use a battery with constant porosity, ε_o? 8. Considering the results obtained in questions 6 & 7, comment on the advantages and disadvantages of a graded porous electrode battery.	5. For both types of porosity gradient electrodes, a positive or negative, will allow for longer discharge time on the electrode? 6. How would your results change if you instead use a battery with constant porosity, ε_o? 7. Considering the results obtained in questions 2 & 6, comment on the advantages and disadvantages of a graded porous electrode battery.

V. Results and Summary

Table 2 presents a summary of the conceptual systems students used to approach the solution to the design problem. Preliminary results describe students' use of representational media and how it is related to conceptual models they used to guide the problem process. These findings also suggest that students conceptual understanding are distributed across a variety of representations [2].

TABLE II. Summary of Represnational Media Usage

Polya's model	Representational media	Group 1			Group 2		
		S1	S2	S3	S1	S2	S3

1. Represent the problem	Written	6	0	2	0	0	0

	Written with Symbols/Equations	3	7	5	1	1	0
	Computational	0	0	0	0	0	0
4. Evaluate the solution	Written	6	2	2	1	3	0
	Pictures	0	0	0	0	0	1
	Equation	3	3	3	2	0	0
	Graphic	0	0	0	0	0	1
	Written with Symbols/Equations	4	0	2	2	0	2
	Computational	0	0	0	0	0	0

The results of this study are supported by Lesh's and Doerr's theory for conceptual systems in problem solving, in that students conceptual understandings are distributed across a variety of representational media [2]. The participants' performance in the first group varied from the second group in terms of their use of representational media. The data suggests, students not using computer simulations relied more on analytical equations and related symbols to help investigate and infer the behavior of variables related to the physical battery system they were designing. These results highlight the relationship between the problem representation and the cognitive process students used to approach problem solving. In addition, results highlight the nature of computing tools in supporting students conceptual system to reason with more graphical and pictorial artifacts.

Table 2 does provide a means to identify the differences for the individual mappings among conceptual structures students followed throughout the problem solving process. Potential explanations for these differences can be hypothesized, from the data summarized in Table 2. In particular, students using a computer system, relay on more on the process of abstraction when using the computer program to generate additional representations of the design problem and the instructions to complete the computer program [1]. Furthermore, student's inquiry process can be supported using computer tools, without the need to explicitly reproduce the computational abstractions in written or graphical form. In contrast, the traditional methods of using mathematical analytical models, directs students to rely more on the use of explicit representations such as equation and symbolic forms.

This exploratory case study provides a framework for future studies using a larger sample size for investigating the role of mathematical and computational models in supporting students' problem solving processes in engineering education. Results also help to gain meaningful insight for future exploration in the way representations are used in each of the stages of the problem solving process using a verbal protocol analysis or interviews with student participants in engineering education.

Health Clinic Infrastructure Design across Cultures in a High School Biology Course

Camilla Nix, Jared Coyle and Adam K. Fontecchio
Drexel University
Philadelphia, PA

Dr. Stuart Surrey,
Philadelphia High School For Girls
Philadelphia, PA

***Abstract*—A design project is a great way to engage and interest students about engineering subjects. This paper describes an engineering design project intended for use within the high school classroom that transcends global boundaries. The main goal of the project is to give students a better understanding of engineering, and introduce students to the concept of engineering design. Students assume the roles of engineers, first designing, and then building a small model of a health center. This paper describes the design project, as conducted in East Africa, which has a similar component implemented within the United States. Project implementation in East Africa occurred over a two-week period, while the project is designed to last for a longer period in the United States. Survey results and classroom observation from the East African component reveal project efficacy in the areas of student engineering awareness, engineering interest, engineering efficacy, and cross-cultural sharing.**

Keywords— engineering design; international collaboration; high school design project

I. Introduction

Engineers are essential in society and economy. The technological innovations that engineers create can range from processes and systems, to medicines and devices, which are all designed to make improvements in how people live everyday [1]. These achievements have helped to shape our way of living, allowing for safe drinking water, access to large databases of information, power and electricity in areas and medical innovations that cure and treat the most deadly of diseases. These achievements represent what engineers have been able to accomplish in the past, but as the future approaches, engineers have increasingly more challenges to face. The National Academy of Engineering's (NAE) 14 Grand Challenges for Engineering seek to describe those future challenges that engineers will continue to work on. They include the need for advancing healthcare informatics, making solar energy economical, and managing the nitrogen cycle [2]. Most K-12 students understand that engineers are proficient in math and science [3]. However many still fail to realize the impact that engineers have on the community and their contribution to everyday life.

To increase student interest in engineering fields, a project was created using the NAE grand challenge "Restoring and improving urban infrastructure" as a point of motivation. Infrastructure refers to the systems (both physical and organizational) that make up society and engineers help design and maintain the systems that govern infrastructure, playing roles in water management, facility development and energy resource design. To implement an infrastructure project within a high school biology course, healthcare was selected as a topic of interest. Health centers are a major point of service for the prevention and treatment of disease within a particular community. It is normally the first place, residents turn for preventative and long term care [4]. The combination of these topics into a fun and entertaining design project allow students to get a better understanding of engineering principles, while allowing students to refine skills necessary for success in their science classes. By allowing students to work on this as a design project, it will inspire a greater number of students to begin thinking about engineering careers.

The use of project based learning with hands-on activities provides a great way to introduce students to introductory concepts and increase awareness in a particular area [5]. This has been shown to be an important approach when teaching engineering concepts to students at many educational levels [3, 6, 7]. In this project, students learn about the engineering design process. The engineering design process is used by engineering teams to come up with a solution to a design challenge [7]. The project takes students through a modified version of this process, in which students take on the role of an engineer and design a health facility for a community within either Philadelphia or Kenya. By allowing students to take on these roles and go through the process for themselves, they can learn how engineers create technological designs, and get a better understanding of what engineers do [5]. This project was presented by an NSF GK12 Fellow in Biomedical Engineering who spent instructional time both in East Africa and in Philadelphia. The clinic design project was implemented over a two-week period in East Africa and is currently being introduced to students in Philadelphia.

In this work, two classrooms in rural East Africa and two classrooms in a large urban school district in the United States (a total of 93 students) participate in a health clinic engineering design project. Students work in groups with classes divided into teams of 3-7 students. Students first conduct research about the design and construction of health centers, then use that information to help in designing a three dimensional model of the clinic. After initial research on the design and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

construction of health centers, students were tasked with first designing the blueprints and schematic for a health center. They were asked to create the drawings to a set scale in order to be able to translate those designs into a three dimensional representation. The primary desired outcomes of the project are to:

- Introduce students to the National Academy of Engineering's Grand Challenges
- Demonstrate how the engineering design process works and how engineers are fundamental in society and the economy
- Encourage students towards careers in engineering
- Foster an international collaboration between two schools

In this paper, the project as presented in East Africa and designed for the United States is described. While carried out as part of an NSF GK12 program, this work can be a sustainable model for teachers to use in any cross-cultural collaboration or individual classroom design project. Student work is shown and survey results that measured student interest and opinions are presented.

II. Project Implementation in East Africa

The design project was implemented over a two week period for the students in Kenya. Over the course of that time, the students were introduced to engineering through a series of lectures and activities. Students were presented introductory modules on engineering through lectures and activities; while project work consisted of the research on the construction of health clinics, the design blueprint and schematic, and a presentation of the model to their peers. In the first week, students were given lectures and activities that would introduce students to engineering careers such as biomedical, electrical, and chemical and computer as well as to engineering challenges such as information transfer, medical research, and energy storage. During the second week, students became junior engineers to design and construct a physical model of an ideal health clinic.

A. Engineering Introduction

"What is engineering?" "What do engineers do?" These were the questions initially posed to the students. To introduce them to engineering careers, challenges and achievements, students were presented lessons about engineering technology in medicine, energy storage, and infrastructure management. These technologies were shown to address NAE grand challenges such as Advancing healthcare informatics, and restoring and improving urban infrastructure. Additionally, small activities were incorporated to help students in understanding these engineering challenges.

B. Identify the problem and do background research

Student research on the design and construction of clinics within Kenya was conducted prior to fellow arrival. Students were presented with the challenge to design a health clinic for the opposite location. In order to better prepare students for the design project, several students visited a health clinic and came up with the materials used in the construction, departments located within, and how illnesses were being treated in a health clinic. The students used this background information in the schematic design of their ideal clinic and also translated this information into the development of the physical model of their schematic design.

C. Specify the requirements: The internal and external layout of a health clinic

Students were shown pictures and given information about health clinics located within Philadelphia. This information coupled with their own pre-existing knowledge about the structure and layout of health clinics (from clinic visit and research), served as the background research for students to come up with a list of specifications for their clinic design. This list helped to guide students in the schematic design and subsequent physical model building activity that followed. Students completed the design and build phase of the clinic project over the course of the second week.

D. Create solution: Schematic design and model building

After a lecture and activity on schematic design and model creation, students were asked to create the schematic design and blueprints necessary to create their model clinic. In order to demonstrate the necessary components of the drawing, students were asked what information was needed and how they would recreate a desk located at the front of the room. Using this information, students came with their own specifications for their schematic drawing and used those dimensions when creating the scale model of their clinic design. After building the model, students presented to their peers. In the presentation, they were asked to not only present the design, but also to present any challenges they faced during building and also how they managed to overcome those challenges.

III. Pre-project Preparation-United States

Project implementation within East Africa and the United States were meant to be similar (the task, and deliverables), however the project was run separately in both countries. The main difference between project implementation within the United States versus East Africa is the time the fellow spent with each group of students. While the East African component was meant to be a short term experience, the fellow had an entire school year (~ 9 month period) to work with students within the United States. Therefore, project work was prolonged over the course of the year, and small sections about engineering and other aspects were introduced on a weekly basis.

Before beginning the design project, students were introduced to engineering ideas, achievements and concepts in a few short presentations and activities by the NSF GK12 Fellow. Each of these short presentations and activities were meant to introduce the students to engineering ideas, by relating the presentation or activity to one of the National Academy of Engineering's Grand Challenges for Engineering [2]. This set of 12 challenges served as a guide to create introductory material that related to the areas the students were already studying as a part of the state prescribed curriculum.

A. Introduction to Engineering Jeopardy Game

As an introductory module to engineering, students were divided into teams to play in a competitive Jeopardy style game. Students were positioned in groups of 4 and took turns selecting a category for questioning. The categories held questions that related to topics that were meant to introduce students engineering achievements in the past and present, the National Academy of Engineering's Grand Challenges, and what type of jobs engineers hold.

B. Engineering News Report

During the course of the school year, bi-weekly presentations were prepared to introduce the students to many current engineering achievements, as well as discuss the jobs of the engineers who created those achievements. After the presentation, students were invited to ask any questions and discuss the significance that achievement may have. The topic for presentation was chosen based on the relation of the National Academy of Engineering Grand Challenges to the current topic students were covering in class. Using this format, the students were able to cover challenges such as providing access to clean water and engineering the tools of scientific discovery, while learning about achievements that were related to each challenge, such as advancements in water filtration technology, and molecular imaging modalities.

C. Design Process Module

Students are first introduced to engineering design by presenting the engineering design process in an analogous manner to the scientific method. To reinforce the concepts presented, students were given the challenge to design and create a tall tower using very limited resources. Groups were asked to use the design process to address that challenge. The primary restriction was that the tower had to be comprised of a single A4 sheet of paper. The goal was to redesign the paper to make the tower as tall as possible. Following activity completion, to assess student understanding, students are asked to describe the steps of obtaining their solution, using the process as a guide, as well as outlining the main issues involved with addressing that challenge.

IV. Project Implementation in the United States

The design project was implemented over a four month period for the students in Philadelphia. This work was completed after the fellow spent time in East Africa. Over the course of that time, they were given four main tasks to complete. These tasks were meant to mirror different steps of the engineering design process to allow students to get a better idea of how engineers perform their jobs.

A. Identify the Problem and do background Research

The first project deliverable will be a research summary that will describe the basic elements of a clinic and also a disease that affects the population of Kenya/Philadelphia. The students are asked to design a clinic that will be able to treat that particular disease. In the summary, students are asked to describe the disease in detail (based on a list of questions), as well as summarize the difference between a hospital and clinic, and what services are offered. The main purpose of this segment of the project is to introduce students to the needs of the population and for students to identify the services within a clinic that are needed to treat that particular disease. Students were able to use web, text or any other resources available to find the information needed to complete the summary.

B. Specify the Requirements

The students are asked to design a clinic that will be able to treat the disease chosen during their research summary segment. As a second deliverable, students were asked to create a report describing the clinic design. A list of the requirements for the report is included in Table I.

TABLE I. Tasks for Design Report

Blueprint	*Research Summary*
Schematic	*Material Choice*

C. Create solution: Schematic Design and Model Building

Students were also asked to create a small scale model of their clinic, based on the design report given. The students are given several different material choices and then time building that model. They can create the model using foam, cardboard, wood, plastic, or any other type of material available. The main purpose of this portion is to illustrate how engineers translate drawings into models that can be used to test the performance of that object. Students then present their designs to their peers.

V. Assessment

A survey comprised of Likert-based and free response questions was developed in partnership with a third party evaluator to assess the outcome of the project. The students were given a pre-project survey before any of the introductory modules or project classes. A similar survey was then administered after completion of the project. In addition to the surveys, classroom observations and interviews with participating students were also used. The purpose of the assessment tools was to address program efficacy in achieving the primary desired outcomes:

- To introduce students to the National Academy of Engineering’s Grand Challenges
- To demonstrate how the engineering design process works and how engineers are fundamental in society and the economy
- To encourage students towards careers in engineering
- To foster an international collaboration between two schools

VI. RESULTS

Reception to the two-week program in East Africa was overwhelmingly positive. In examining the efficacy of lecture-based classes versus hands-on problem based lessons, the classroom observations revealed that the classes which contained hands on instruction were more enjoyable. In-class informal examinations also revealed better retention of content beyond the duration of the program. The observations also revealed increased student engagement in the project during hands-on lessons. These observations are also in agreement with the results from the survey question: "What was your favorite part of the NSF visiting Scholar programme?" In response to this question a majority of the students (66.7%) explicitly mentioned that the hands-on project experience was their favorite part of the program. An example of the hands-on experience is demonstrated in Figures 1, 2 and 3. These figures show the progression of students' participation in an introductory module (Figure 1), then building the clinic (Figure 2) and finally the completed clinics (Figure 3).

Figure 1 shows students working during one of the hands-on modules about Engineering. The theme for the day was Energy. After a brief discussion about various energy sources, students were given the task to create a battery using pennies and nickels. Students were engaged in the task and were able to make conclusions in their work. Students were initially more fascinated by the American currency, but after realizing that the batteries were in fact creating voltage, they became more engaged in the activity at hand. When asked the following week what they learned from the previous week about engineering, several of the students began discussing the principles and energy resources learned in this lesson.

When examining the overall goals of the project, the survey results are in agreement with the notion that the project was successful in its intended outcomes. The answers to both the free responses and Likert survey questions (Figures 4 and 5) show an overall increase in student understanding of engineering and the job that engineers do. They also show an increase in the percent of students that were considering pursuing engineering academically and professionally.

A. *Introduce students to the National Academy of Engineering's Grand Challenges*

Classroom observation revealed a dramatic increase in student ability to recount the various NAE Grand Challenges, which is in agreement with the results shown in Figure 4, demonstrating that nearly all students experience an increased knowledge of global engineering challenges.

To further assess this matter, a look at the students' understanding of engineering is helpful. This was assessed in the survey questions: "In your own words, what is engineering?" and "What does an engineer do?". The student responses to this question are presented in Table II. Prior to administering the project, 50.0% of the students had some understanding of what was engineering was. It can also be seen that few students (16.7%) had a solid grasp of engineering, while there was a number of students (33.3%) who had little to no understanding as well. After project implementation, there is a substantial increase in student engineering awareness. This increase can be seen by looking at the dramatic increase in students with some understanding or a solid grasp of engineering.

Fig. 1. Students working during introductory Module.

TABLE II. STUDENT UNDERSTANDING OF ENGINEERING

In your own words, what is engineering? What does an engineer do?		
Level of Engineering Comprehension	***Before Project***	***After Project***
Solid Grasp	16.7%	40.7%
Some Understanding	50.0%	44.4%
Little or No Understanding	33.3%	14.8%

B. *Demonstrating the engineering design process and how engineers are fundamental in society and economy*

During the second week of the scholar program, students designed and built a model clinic. This portion of the project served to demonstrate how engineers create designs that can be constructed. Figure 2 shows students building their clinic design model. The students were engaged and participating throughout the entire activity. They required little encouragement to remain on task during the building activities. Students took the initiative to organize themselves during the activity, with each group defining its own specific roles in the building process. Students were enthusiastic when translating their designs into three-dimensional structures, and even spent hours outside of the scheduled classroom time working to complete the models. A completed design is shown in Figure 3.

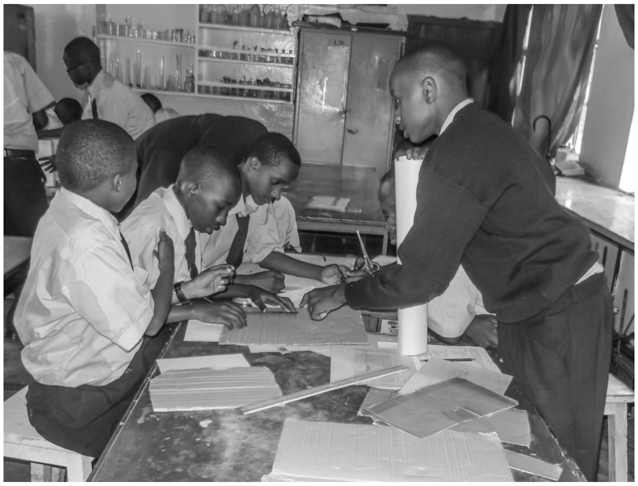

Fig. 2. Student collaboration during desing project building

Fig. 3. Completed student clinic models

Responses to the Likert-based survey shown in Figure 5 reveal that students demonstrated marked growth in awareness of the engineering design process and in their confidence to perform independent research. The free responses to the questions: What did you learn about engineering in the visiting scholar programme?" and "how has the health clinic design project helped you to see engineering differently?" also indicate that students felt as though the project allowed them to think positively about their own skills, to enhance creativity, and to think critically about executing tasks. Of particular importance to students was the introduction of the creative design process in solving problems. Despite increased awareness of the engineering design process, students showed insignificant increase in understanding the fundamental role that engineers play in society.

C. Encourage students towards careers in engineering

To assess whether the project was successful in encouraging student interest in engineering fields, the results to the survey question: "Select two career fields you are most interested in pursuing academically and professionally" are examined (shown in Table 3). In this question, students were asked to choose the two career fields they were most interested in pursuing academically and professionally. The pre-survey responses reveal that students indicated having some interest in engineering prior to introduction to the project. Despite having a large percentage (43%) of students who were interested in pursuing engineering, the post –survey showed a large increase in the number of students who self-selected engineering (63%). These results were also supported by the likert based survey questions shown in Figures 4 and 5. A majority of students agree or strongly agree that the clinic design project increased their interest in engineering (Figure 4). Additionally, the longitudinal results in Figure 5 demonstrate increases in selecting engineering careers. The results to the free response question "How has the health clinic design project helped you to see engineering differently?" show positive ideas about engineering and pursuing engineering after high school. Several students noted that they are very proud of the work they have completed, and that the project had given them hope of becoming an engineer one day. In the words of one student, "The design has made me feel like a real engineer and the design has made me see the difference between construction and the design of different things." Another student stated, "the health clinic design project has increased my interest in engineering and the health clinic design project gave me an idea of an engineer's role and responsibilities."

TABLE III. STUDENT CAREER FIELD INTEREST

Select two career fields you are most interested in pursuing academically & professionally		
	Before Project (%)	***After Project (%)***
Engineering	43	63
Law	5	15
Finance	5	0
Information Technology	14	7
Architecture	0	15
Healthcare	19	11
Art or Music	19	15
Public Safety	10	11
Business	10	7
Scientific Research	10	19
Other	19	11

VII. CONCLUSIONS AND FUTURE CONSIDERATIONS

In this paper, the implementation of a clinic design project in Africa and the proposed plan of execution for the same project within the United States were described. The results showed several trends. Students demonstrated an overall increase in engineering understanding and desire to pursue

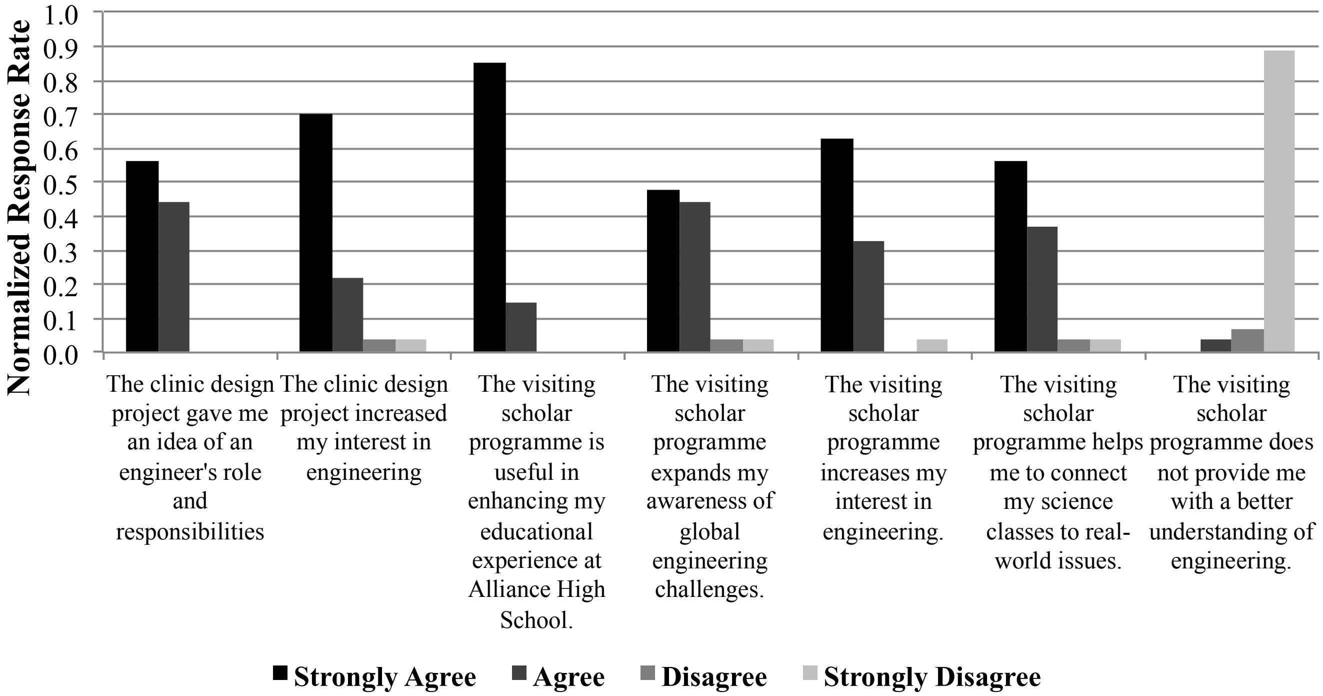

Fig. 4. Student responses to Likert-based questions after participating in the health clinic design project.

engineering career paths. In addition to giving students a better understanding of engineering concepts, students also came away with new ideas about engineers and working within the engineering field. The project was therefore successful in its engineering-related outcomes. Due to technological limitations, however, the ability to support cross-cultural interaction was limited. This was the primary idea for improvement that both evaluators and participantes mentioned. Methods for enhancing cross-culural sharing are currently being implemented, as the project is a part of a long-term commitment by all participating schools. The most important element is the ability to find low-bandwidth, engaging and secure ways to facilitate direct

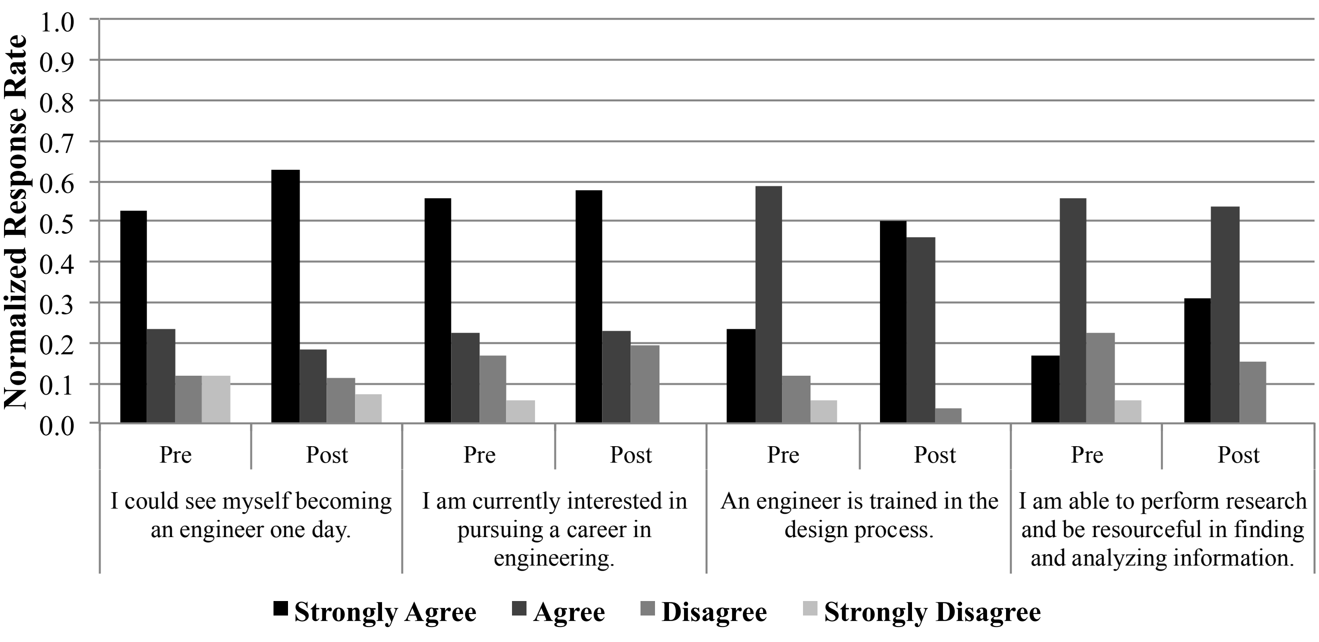

Fig. 5. Longitudinal student responses demonstrating the progress of student interest and awareness of engineering, engineering design and research skills

student interaction. Differing outcomes between the United States and Africa, including both cultural elements and the effects short-term versus long-term implementation of the design project are also under way.

ACKNOWLEDGMENT

This work was supported by a fellowship from the National Science Foundation STEM GK-12 program “Catalyzing STEM Education via the NAE Engineering Grand Challenges”, grant #DGE-0947936 through Drexel University.” We would also like to thank the School District of Philadelphia and Munoru Highlands School for Boys. Thanks to all Drexel GK-12 partnership schools, Teachers, Fellows and project co-investigators for your support and feedback.

Establishing a Global Software Development Course: A Cultural Perspective

Amir Zeid, Rehab El-Bahey
American University of Kuwait,
azeid@auk.edu.kw, relbahey@auk.edu.kw

***Abstract*— Global software development (GSD) is one of the main practices in software industry. The ability to outsource and manage software development at remote sites allows organizations to benefit from GSD since they get access to a wider and more economically feasible pool of developers. Recently, global software engineering courses are being introduced at academic institutes as part of computer science and software engineering degree requirements. There are many challenges associated with managing and executing globally distributed software projects in academic settings. In this paper, we will attempt to analyze the framework and components of a collaborative global software engineering course from a cultural perspective. We examine the different challenges related to team-setting, grading, communication tools, gender issues and associated risks. A discussion of how cultural differences may affect setting up the course is included. The uniqueness of the proposed research lies in two main areas: it examines collaboration between Kuwait, USA and Poland; and it investigates the proposed topics from a cultural perspective.**

Keywords—Global software engineering, computer education.

I. Introduction

Kuwait is a small country situated in the Persian Gulf region (GCC). With a 40% expat population, the government of Kuwait is working hard to encourage local employment and to generate qualified local caliber. Within this context, the Kuwaiti government is reinforcing educational reform at all levels [1].

Software and IT industries are truly global today - and so is software engineering. Global software development is increasingly becoming a common practice in the software industry. The ability to develop software at remote sites in projects allows organizations to overcome the geographic distances and benefit from access to a rich resource pool and reduced development costs. The rapid globalization of the software industry creates software engineering challenges due to the impact of temporal, geographical, and cultural differences [2].

In this paper, we will investigate the cultural factors that may affect initiating a global software development (GSD) course at the American University of Kuwait (AUK). Cultural dimensions suggested by Hofstede [3] will be considered as guidelines for recommendations. The following sections will be structured as follows:

- Section 2 outlines relevant background.
- Section 3 discusses similar projects.
- Section 4 summarizes the methodology and the research plan.
- Section 5 investigates relevant cultural dimensions.
- Section 6 includes a discussion of the relation between cultural dimensions and suggested course activities.
- Finally, directions for next steps are discussed.

II. Background

The American University of Kuwait (AUK) is an independent, private, equal opportunity, and co-educational liberal arts institution of higher education. The educational, cultural, and administrative structure, methods and standards of AUK are based on the American model of higher learning. The language of instruction is English. AUK was established as a Kuwaiti University but with an American name. This necessarily makes it bi-cultural. So while the educational system is American, it exists in a very different cultural environment which offers both challenges and opportunities.

The main aim of this paper is to investigate the challenges in setting up a new global software development course. The course is part of a project to establish a global software development lab in Kuwait. The goal of the project is to create an innovative, highly challenging learning environment for educating the next generations of software engineers. The environment allows students to envision new systems, understand user needs, and develop new concepts. It offers students opportunities to conduct their experiments and projects, and simulate operations of real systems in a scientific setting.

The main idea of this research is to have at least three teams in different sites (one at AUK, one in USA and one in Poland) collaborate in developing software projects. The three sites belong to different cultures which may result in challenges. The model simulates outsourcing in software development context. Many issues will be studied while the project is progressing. Typically, the teams are enrolled in a special topics course. Courses that involve such activity are 300-400 level courses with software engineering as prerequisite. The associated tools, risks and best practices will be investigated.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

III. Literature Review

A. Cultural Dimensions

Geert Hofstede conducted one of the well-known and most widely used studies about defining cultural dimensions. According to Hofstede, culture can be measured by six dimensions [3]. The following three dimensions are the most relevant measures to global software engineering [11]:

- Power Distance (PDI): This dimension expresses the degree to which people and society accept that power is not equally distributed. In societies with low power distance, people strive to equalize the distribution of power and demand justification for inequalities of power [3].
- Individualism versus collectivism (IDV): the degree to which people are attached to the group/tribe/family [3]. A society's position on this dimension is reflected in whether people's self-image is defined in terms of "I" or "we."
- Uncertainty avoidance (UAI): The degree to which people accept ambiguous and unknown future [3]. The fundamental issue here is how a society deals with the fact that the future can never be known: should we try to control the future or just let it happen? Weak UAI societies maintain a more relaxed attitude in which practice counts more than principles.

There are other cultural dimensions that will not be considered in our initial study. The remaining dimensions are[3]:

- Masculinity versus femininity (MAS): The masculinity side of this dimension represents a preference in society for achievement, heroism, assertiveness and material reward for success.
- Long-term versus short-term orientation (LTO): The long-term orientation dimension can be interpreted as dealing with society's search for virtue.
- Indulgence versus Restraint (IVR): Indulgence stands for a society that allows relatively free gratification of basic and natural human drives related to enjoying life and having fun.

Other efforts to define culture were reported. Examples include: Trompenaar's dimensions and Hall's dimensions [4]. The decision to base this discussion on Hofstede's dimensions is due to the fact that it is the most widely used cultural benchmark in the context of software industry since it was originally conducted at IBM. In next phases of research, other models and dimensions will be considered.

B. Global Software Engineering

Collaborative GSD is mainly concerned with studying methodologies, tools, infrastructures, and other factors that influence distributed software development by culturally diverse teams. The main classifications of collaborative software development are: context, support, tasks interaction, teams, individuals and overreaching factors [5]. Many empirical studies and literature reviews focus on the identification of challenges in collaborative work [6]. In the context of GSD in academia, there were similar projects that investigated possible challenges through experiments. The first project had two sites of software development (in multiple countries): one in Turkey and one in USA, while another experiment was done between USA and Sweden [7]. The clients in both experiments were from industry. During the first study, students from the US visited Turkey twice during the semester, once at the beginning of the project and once at the end. It was reported that time difference and language were among the major obstacles in performing the experiments [7]. The research group of Global Software Engineering at University of Victoria, Canada carried out several related research projects. One of the projects investigated whether geographical distance continues to affect developers' collaboration in large teams that use development environments specifically designed to support collaborative distributed teams. Communication and response time were analyzed [8]. Another project at the same university developed an improvement to the original socio-technical congruence calculation in the literature. A metric that measures the strength of relationships between people and tasks, interdependent tasks and between project members was used [9].

A model GSD academic center should have the following components [10]:

- Research and Development activities
- Educational activities: courses, seminars, lectures
- Members: faculty and students
- Credible affiliates/sponsors : academic, industry, and government

Many efforts aimed at applying Hofstede cultural dimensions on global software engineering. The same approach of Borchers[11] was followed in this research. Other research efforts argue that applying Hofstede's dimensions is not sufficient to study cultural factors in GSD [4]. Shah et all proposed using different cultural models instead of the dimensions of Hofstede [4].

IV. Methodology and Plan

The main plan for the research includes three main phases: initiation, implementation and analysis.

A. Phase I Initiation Phase (Initiation visits and meetings)

In this phase, the framework of the project will be established. The framework will include overall planning and time alignment. In addition, the type of courses to be integrated will be determined. Learning outcomes of the courses must be coordinated (there should be some sort of overlap of learning outcomes at least). Time alignment is a crucial factor because some universities adopt semesters while others adopt quarters, so university calendars have to be taken in consideration.

In this phase, professors and supervisors from the participating institutes should meet to decide on type of projects, possible communication models and tools. Possible tools include Skype and videoconferencing.

B. *Phase II Implementation*

In this phase, the experiments will commence at different sites. Data collection in this study will be based on the results of assignments and surveys. The following activities will be carried out:

- Courses will be offered in different locations.
- Meeting of participating students and mentors at to launch the experiment.
- Development projects will start.
- Surveys will be conducted at the end of the experiment.

C. *Phase III Analysis*

In this phase, analysis of the outcomes and documenting the findings will be carried out. The findings will be compiled in the form of a two dimensional matrix:

- Cultural dimensions proposed by Hofstede[3] will represent the vertical dimension
- Collaboration dimensions will represent the horizontal dimension. Collaboration dimensions include: Communication, Leadership, Coordination and Dependency.

V. Relevant Cultural Measures and Activities

Figure-1 illustrates the three chosen dimensions (PDI, IDV UAI) for the three proposed sites. The dimensions were extracted from the Hofstede center web-site based on Hofstede's surveys [12].

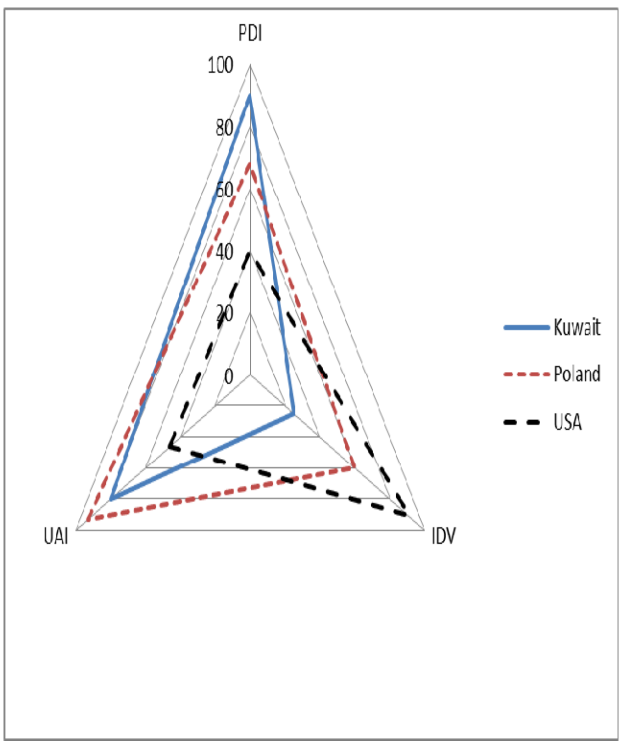

Figure-1 Cultural dimensions in Kuwait, Poland and USA

TABLE-1 CULTURAL DIMENSIONS IN KUWAIT, POLAND AND USA

	PDI	IDV	UAI
Kuwait	90	25	80
Poland	68	60	93
USA	40	91	46

It can be noticed from Table-1 that:

- Kuwait has the highest PDI, followed by Poland then USA.
- Poland has the highest UAI, followed by Kuwait then USA.
- USA had the highest IDV, followed by Poland then Kuwait.

A. *PDI*

- Kuwait has the highest PDI (90) which means that people accept an extreme hierarchical order which needs no further justification. Hierarchy in an organization is seen as reflecting inherent inequalities, centralization is popular, subordinates expect to be told what to do and the ideal boss is a generous autocrat.
- Poland (PDI 68) is a hierarchical society. This means that people accept a hierarchical order which needs minor justification.
- The United States score low on PDI (40) which is evidenced by the focus on equal rights in all aspects of American society and government. Within American organizations, hierarchy is established for convenience, superiors are always accessible and managers rely on individual employees and teams for their expertise [12].

B. *IDV*

- USA has the highest IDV which means that it is a very highly individualistic culture. This translates into a loosely-knit society in which the expectation is that people look after themselves and their immediate families. There is also a high degree of geographical mobility in the United States and most Americans are accustomed to doing business with, or interacting, with strangers. Consequently, Americans are not shy about approaching their prospective counterparts in order to obtain or seek information. In the business world, employees are expected to be self-reliant and display initiative. Also, within the exchange-based world of work, hiring and promotion decisions are based on merit or evidence of what one has done or can do.
- Poland, with a score of IDV 60 is an Individualistic society. This means there is a high preference for a loosely-knit social framework in which individuals are expected to take care of themselves and their immediate families only.
- Kuwait, with a score of 25 in IDV is considered a collectivistic society. This results in a close long-term commitment to the 'group', be that a family, extended

family, or extended relationships. Loyalty to the group in a collectivist culture is essential [12].

C. UAI

- Poland and Kuwait have high UAI thus they have a very high preference for avoiding uncertainty. Countries exhibiting high uncertainty avoidance maintain rigid codes of belief and behavior and are intolerant of unorthodox behavior and ideas. In these cultures, there is an emotional need for rules (even if the rules never seem to work). Time is money, people have an inner urge to be busy and work hard. Precision and punctuality are the norm, innovation may be resisted. Security is an important element in individual motivation.
- USA scores 46 on this dimension and therefore, the American society is what one would describe as "uncertainty accepting." Consequently, there is a larger degree of acceptance for new ideas, innovative products and a willingness to try something new or different, whether it pertains to technology or business practices [12].

VI. Discussion and Recommendations

In this section, a discussion about some of the major issues in establishing a global software development course is included. The issues are related to the cultural dimensions previously discussed in section V.

A. Team Structure

Research question: What is the optimum team formation to minimize risks and optimize the quality of the outcome? To be able to answer this research question, three different settings for the teams will be investigated and the outcomes will be compared. Figure-2 depicts a typical team structure with team leader in each participating academic site. Each team has three different types of roles: analyst, designer and developer. In this setup, each team will implement a subsystem of the project then integration will take place.

Discussion: Sites with low IDV (Kuwait) are more likely to collaborate locally due to their collectivist nature. Sites with high PDI (Kuwait) is expected to assume that the team leader has upper hand in decision making, while the case may be different in sites with low PDI like USA. Integration is expected to be challenging [11].

Figure-3 depicts an alternative approach. In this approach, each site is specialized in a certain activity (requirements, design and development) that better suits the culture and nature of participants in that site. Culture dimensions can be used as guidelines to assign roles.

Discussion: In this setting, courses at different locations may have different nature. One site can have systems analysis course to work with the requirements, another site can have an object-oriented design course to handle the design, while the third site can have a pure software development course. So the main advantage of this approach is that it minimizes the need to initiate new courses as most of these courses already exist in computer science curricula. However, timing and coordination will be a challenge.

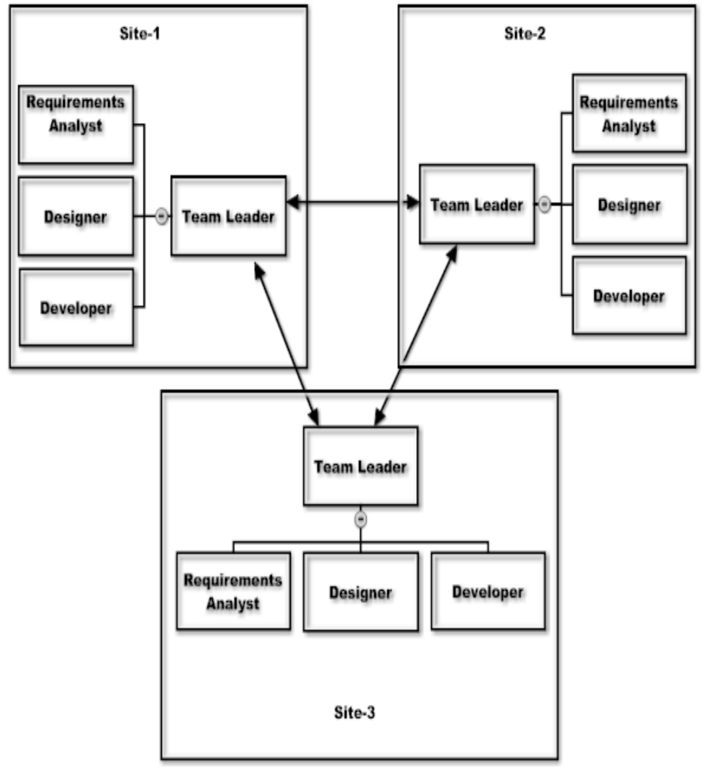

Figure-2 Setting-1 for team formation

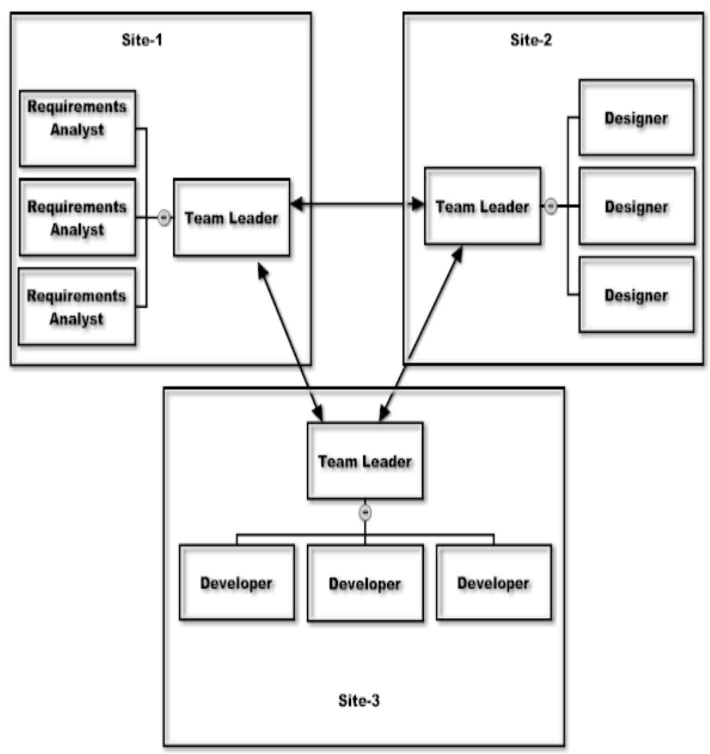

Figure-3 Setting-2 for team formation

Figure-4 depicts a more complex model. In this model, each team leader leads a team of a mix of cultures. In this setting, the members of each team are distributed. The role of each member is based on his/her qualifications.

Discussion: Leaders have to be aware of different cultures, otherwise delays and misunderstandings are probable. In addition, there is an overhead of communication among team members since they are in different sites and from different cultures and time-zones. The question to investigate is whether the qualifications of each member will make up for the overhead of communication or not. Problems may happen due to high expectations from the leader in groups where team members are from high PDI culture.

B. Communication Methods

Research question: What are the best communication methods? Difference in time zones is a factor that will affect comunication methods. Kuwait is UTC+3:00, Poland is UTC+01:00 (one hour behind Kuwait during daylight saving, two hours otherwise) while the American site follows EST (7 hours behind Kuwait during dalight saving, 8 hours otherwise). It is also worth mentioning that both Poland and USA follow daylight saving while Kuwait does not. Due to the time-zone factor, the following two methods of communications can be considered: synchronous and asynchronous methods. Synchonous methods include video conferencing and chatting, while assynchronous methods include email and document sharing.

Discussion: A combination of both methods will be investigated. Clear meeting agendas and minutes have to be written and disseminated early enough to give people with high UAI chance to read and prepare for meetings. Local meetings will provide an opportunity for low IDV teams to prepare and discuss in a more relaxed way before the actual formal meetings. A superior moderator for the meetings will be needed to accommodate teams with high PDI (Kuwait), while the moderator role could rotate in groups with low PDI (USA).

C. Collaboration Model

Research question: What is the best collaboration model? To be able to answer this research question, two different collaboration models will be considered and investigated. Possible models include client/developer model and development together model. In Client/developer model, one team will act as a client while the other will act as a software developer. Each team will be located in a different site (country). In development together model, both teams (in two different sites) will develop the same software together (using the same client).Yu proposed different models for collaboration to minimize risks [13].

Discussion: Choosing an industry client may lead to some cultural problems [7]. The availability of such client to the co-located team/members can be beneficial in settings 2 and 3 where all the requirements team/members are co-located. The language of the client can be a factor in proper understanding of the requirements [7].

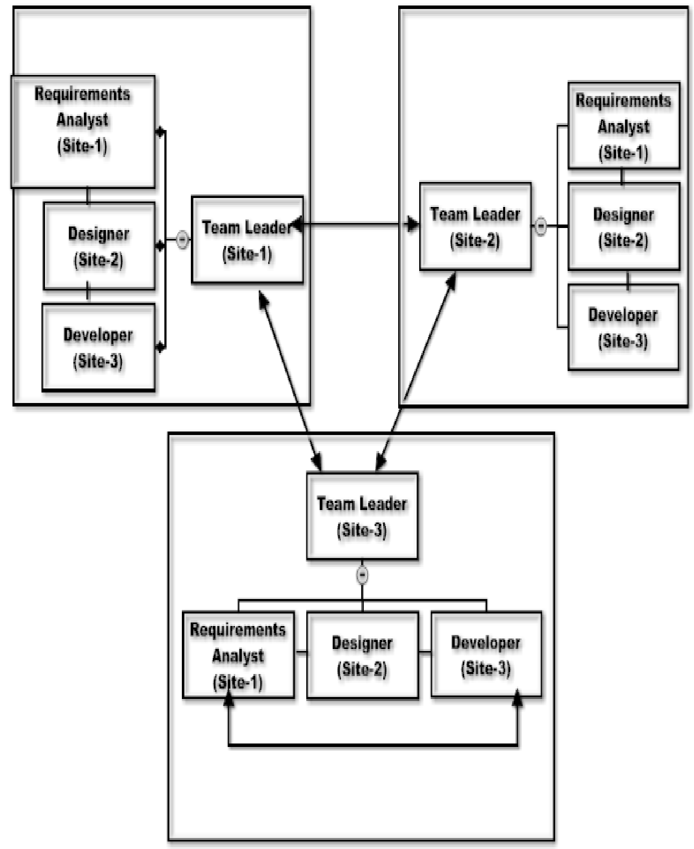

Figure-4 Setting-3 for team formation

D. Learning New Technologies

Research question: Can teams learn and apply new technologies in such setting? Which teams may have more flexibility to adopt and investigate new technologies?

Discussion: From the cultural interpretation in section 5, cultures with low UAI have larger degree of acceptance for new ideas, innovations and willingness to try something different. Depending on the team structure and culture mix, we will investigate which teams are faster in grasping and learning new technologies in such setting. This can be done by introducing a new programming environment and assigning the same assignment to all groups, then comparing the quality of the outcomes.

E. Documentation and Risk Management

Research questions: What are the best techniques to manage and avoid risks? Various risks related to GSD were reported in literature. Lack of understanding of requirements, selecting a wrong project, product quality and poor documentation are among the anticipated risks [13][14]. Risks in academic environment may vary from the ones related to industry.

Discussion: Using UAI as a guiding measure, it can be predicted that teams/members with high UAI can be more suitable for carrying out risk analysis and taking care of documentation along the way. The produced risk analysis documents will be compared and analyzed to verify this hypothesis.

F. Grading and learning outcomes

How to grade team members? Will the course be pass-fail or will it have scale with rubrics? Individual grading is expected to be more challenging where IDV is low. Low IDV indicates more loyalty to the collectivist culture. Cultures were IDV is high will have a more straightforward individual grading. The other anticipated problem is the difference in university calendars, national holidays and grading scheme. Due to difference in educational systems, courses may be offered as (pass-fail) in one site, while the matching course is graded (A to F) on the other sites. It was reported that difference in grading scheme may lead to lack of trust among different teams [7].

Discussion and Recommendations: It is better to have the courses following with the same grading scheme (if possible) to avoid such problems. The assessment criteria should be based on the experience gained out of the experiment rather than the completion of the software project itself. This will provide a way to evaluate each team member individually. The assignments can focus on student perceptions of cultural differences within the group [7]. Learning outcomes of the courses must be aligned properly before the courses are offered.

G. Gender-Issues

Percentage of females studying computer science and engineering in Kuwait is high compared to USA and most of Europe [15]. Teams will definitely have unbalanced gender distribution. While gender-segregation is a dimension of culture in Kuwait [15], it is not applicable in the other two sites. In previous research in Kuwait, it was found that gender-segregated students perform better than mixed-gender students [15]. It will be an interesting issue to research and investigate in setting up the teams.

Discussion: It is worth investigating with teams with high PDI, if gender will be an issue in choosing the team leader. This will be investigated by the survey that will be conducted at the end of the experiment.

VII. Conclusion and Future Work

In this paper, we presented the initiation phase of developing a GSD course at AUK. Hofstede's cultural dimensions were used to analyze and provide a framework for initiating the course. In the coming phases, other models will be investigated and integrated. In the next phase, more hypotheses of the research will be formulated and finalized. One of the possible outcomes in the next phases is to develop cultural-aware software development tools with features that support collaboration. Trust issues among distributed team members can be investigated. It is also worth investigating different process models to identify which ones can be properly used in such courses.

***Abstract*—This paper presents the results of a comparative study of motivation and learning strategies between American and Chinese undergraduate engineering students. A total of 109 sophomore engineering students from two American and Chinese universities responded to a Motivated Strategies for Learning Questionnaire (MSLQ) survey. The survey includes six motivation scales (totaling 31 items) and nine learning strategy scales (totaling 50 items). Descriptive statistics and independent sample t-tests are performed to analyze students' responses to each MSLQ scale. The results show that statistically significant differences exist in three motivation scales and six learning strategy scales between American and Chinese students surveyed. Overall, American students exceed Chinese students in motivation, but fall behind in learning strategies.**

Keywords: Comparative study; motivation; learning strategies; American undergraduate engineering students; Chinese undergraduate engineering students

I. INTRODUCTION

Extensive research evidence has shown that motivation and learning strategies significantly affect student learning outcomes [1, 2]. A comparative study of motivation and learning strategies among different countries helps develop a better understanding of how diverse cultural backgrounds and experiences shape student learning, and thus helps develop appropriate pedagogy and course curriculum to maximize student learning outcomes [2]. Such a comparative study is important now as online and distance education expands rapidly across national borders to reach a global audience.

This work-in-progress study is the first comparative study of motivation and learning strategies between American and Chinese undergraduate engineering students. The research question is: Are there statistically significant differences in motivation and learning strategies between American and Chinese undergraduate engineering students?

A total of 109 sophomore (second-year) engineering students from Utah State University (USU) in the United States and from Beijing Forestry University (BFU) in China participated in this study. The two institutions share many common features: Both are comprehensive, public, research-intensive, and PhD-granting institutions. At the end of a recent semester, all student participants from the two countries responded to a well-adopted Motivated Strategies for Learning Questionnaire (MSLQ) survey [3]. This survey is an 81-item self-reporting instrument for students to assess their motivational orientations and their use of different learning strategies in a college course. The 81-item MSLQ survey includes six motivation scales (totaling 31 items) and nine learning strategy scales (totaling 50 items). Pintrich et al. [3] have provided a detailed description of each scale and each item. Each item can be rated from 1 to 7.

In this work-in-progress study, descriptive statistics and independent sample t-tests are performed to analyze students' responses to each MSLQ scale. The motivation and learning strategy scales in which statistically significant differences exist between American and Chinese undergraduate engineering students are identified. Beyond this WIP study, future research will be focused on studying how students' motivation and learning strategies affect their academic performances in the United States and China. The future research will also help understand diverse cultural backgrounds and experiences of engineering students in both countries.

II. STUDENT PARTICIPANTS

A total of 109 sophomore engineering students participated in this study: 71 from Utah State University (USU) in the United States and 38 from Beijing Forestry University (BFU) in China. USU students were primarily from mechanical and aerospace engineering majors (52.1%) as well as from civil and environmental engineering majors (26.8%). BFU student participants were all from civil engineering majors.

III. STATISTICAL ANALYSIS

Tables I and II show the results of descriptive statistics and independent sample t-tests for each MSLQ scale. The scales in which statistically significant differences ($p < 0.05$) exist between American and Chinese undergraduate engineering students are highlighted in Table II. Effect size (ES) is also listed in the last column in Table II. ES is calculated as:

$$\text{Effec size} = \sqrt{t^2/(t^2 + df)} \quad (1)$$

Based on the probability (p) values listed in Table II, statistically significant differences exist between American and

TABLE I. DESCRIPTIVE STATISTICS

MSLQ scales	American students (n=71)		Chinese students (n=38)	
	Mean	SD	Mean	SD
Intrinsic goal orientation	4.59	1.06	4.83	1.10
Extrinsic goal orientation	5.22	1.21	4.61	1.25
Task value	5.52	1.28	4.75	0.91
Control of learning beliefs	5.77	1.13	4.60	0.98
Self-efficacy for learning & performance	5.17	1.24	4.95	0.96
Test anxiety	3.77	1.66	3.96	1.42
Rehearsal	3.81	1.13	4.38	1.14
Elaboration	4.35	1.04	4.43	0.91
Organization	3.87	1.39	4.81	1.23
Critical thinking	3.54	1.33	4.59	1.50
Metacognitive self-regulation	4.14	0.73	4.50	0.83
Time/study environmental management	4.78	0.93	4.32	0.51
Effort regulation	4.73	0.65	4.61	0.67
Peer learning	3.23	1.68	4.25	1.21

TABLE II. INDEPENDENT SAMPLE T-TESTS

MSLQ scales	t	df	p	ES
Intrinsic goal orientation	-1.10	107	0.275	0.11
Extrinsic goal orientation	2.51	107	**0.014**	0.24
Task value	3.67	98.8	**0.000**	0.35
Control of learning beliefs	5.38	107	**0.000**	0.46
Self-efficacy for learning & performance	0.97	107	0.333	0.09
Test anxiety	-0.58	107	0.564	0.06
Rehearsal	-2.52	107	**0.013**	0.24
Elaboration	-0.40	107	0.691	0.04
Organization	-3.52	107	**0.001**	0.32
Critical thinking	-4.21	107	**0.000**	0.38
Metacognitive self-regulation	-2.35	107	**0.021**	0.22
Time/study environmental management	3.29	106.9	**0.001**	0.30
Effort regulation	0.93	73.7	0.354	0.11
Peer learning	-3.68	97.9	**0.000**	0.35

Chinese students in the following three motivation scales and six learning strategy scales:

Motivation scales:

- Extrinsic goal orientation (t = 2.51, p = 0.014)
- Task value (t = 3.67, p = 0.000)
- Control of learning beliefs (t = 5.38, p = 0.000)

Learning strategy scales:

- Rehearsal (t =-2.518 , p = 0.013)
- Organization (t = -3.52, p = 0.001)
- Critical thinking (t = -4.21, p = 0.000)
- Metacognitive self-regulation (t = -2.345, p = 0.021)
- Time/study environmental management (t = 3.292, p = 0.001)
- Peer learning (t = -3.68, p = 0.000).

Positive t-scores mean that the mean score of American students is higher than that of Chinese students (refer to Table I). Negative t-scores mean that the mean score of American students is lower than that of Chinese students. The differences of American and Chinese students in these nine MSLQ scales represent medium-sized effects varying between 0.22 and 0.46. Overall, American students exceed Chinese students in motivation, but fall behind in learning strategies.

As a representative example, Figure 1 shows the comparison of histograms for critical thinking between American and Chinese students. As seen clearly from Figure 1, a higher percentage of American students provided lower ratings (less than 4) for their critical thinking skills than did Chinese students.

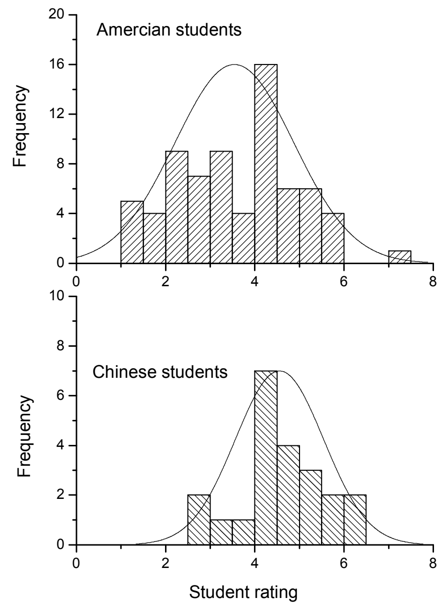

Figure 1. Comparison of histograms for critical thinking.

IV. CONCLUSIONS

Based on data collected from 109 engineering undergraduates from two comparable American and Chinese universities, the answer to the research question is: Statistically significant differences between American and Chinese students exist in three motivation scales (extrinsic goal orientation, task value, and control of learning beliefs) and six learning strategy scales (rehearsal, organization, critical thinking, metacognitive self-regulation, time/study environmental management, and peer learning). Overall, American students exceed Chinese students in motivation, but fall behind in learning strategies.

ACKNOWLEDGEMENT

Graduate student Mr. O. Ha is acknowledged for help posting the MSQL questionnaire survey online.

***Abstract*—This paper presents the results of a comparative study of learning style preferences between American and Chinese undergraduate engineering students. A total of 132 sophomore engineering students from two American and Chinese universities responded to an Index of Learning Styles (ILS) survey. The survey is a 44-item, self-scoring questionnaire that assesses learning style preferences on four pairs of dimensions of the Felder-Silverman model: active/reflective, sensing/intuitive, visual/verbal, and sequential/global. Descriptive statistics and independent sample t-tests are performed to analyze students' responses to the survey. The results show that statistically significant differences exist in four dimensions (reflective, sensing, visual, and verbal) between American and Chinese students. Overall, American students show higher preferences in all four of these dimensions than do Chinese students.**

Keywords: Comparative study; learning styles; American undergraduate engineering students; Chinese undergraduate engineering students

I. INTRODUCTION

Students' learning style preferences are an important factor to consider in designing appropriate pedagogy and course curriculum [1, 2]. A comparative study of learning style preferences among different countries helps provide insights into how diverse cultural backgrounds and experiences affect student learning styles [3]. As online and distance education expands rapidly across national borders to reach a global audience, such a comparative study is particularly meaningful and important [4].

This work-in-progress study is a comparative study of learning style preferences between American and Chinese undergraduate engineering students. The research question is: Are there statistically significant differences in learning style preferences between American and Chinese undergraduate engineering students?

A total of 132 sophomore (second-year) engineering students from two universities in the United States and China participated in this comparative study. The two universities are: Utah State University (USU) in the United States and Beijing Forestry University (BFU) in China. The two institutions share many common features: Both are comprehensive, public, research-intensive, and PhD-granting institutions.

All student participants from the two countries responded to an online, well-adopted Index of Learning Styles (ILS) survey [5]. The survey was particularly developed for engineering students and has a high degree of reliability and validity. The survey is a 44-item, self-scoring questionnaire that assesses learning style preferences on four pairs of dimensions of the Felder-Silverman model. The four pairs of dimensions are: active/reflective, sensing/intuitive, visual/verbal, and sequential /global. Felder and his colleagues [2, 5] have provided a detailed description of each dimension. For example, "active" means that the student retains and understands information best by doing something actively with it: discussing, applying, or explaining it to others. "Reflective" means that the student first thinks about information quietly [2, 5].

In the present study, descriptive statistics and independent sample t-tests are performed to analyze students' responses to each dimension. The dimensions in which statistically significant differences exist between American and Chinese students are identified. Beyond this work-in-progress study, future research will be focused on studying whether or not students' learning style preferences are correlated to their academic performances in the United States and China.

II. STUDENT PARTICIPANTS

The USU student participants (n = 61) were primarily from mechanical and aerospace engineering majors (50.8%) as well as from civil and environmental engineering majors (26.2%). The BFU student participants (n = 71) were all from civil engineering majors.

III. DESCRIPTIVE STATISTICS AND INDEPENDENT SAMPLE T-TESTS

Tables I and II show the results of descriptive statistics and independent sample t-tests for each ILS dimension. Note that the eight dimensions listed in Table I and II are grouped into four pairs (as stated before). If a student shows preference for one dimension in a pair, he or she is excluded from the other dimension in the same pair. For example, in the active/reflective pair, if a student prefers "active" learning, then he or she will not be categorized as a "reflective" learner. Thus, the number of students is different in each dimension, as is shown in Table I.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

TABLE I. DESCRIPTIVE STATISTICS

Learning style dimensions	American students (totally 61)			Chinese students (totally 71)		
	n (%)	Mean	SD	n (%)	Mean	SD
Active	26 (42.6%)	4.46	2.92	39 (54.9%)	3.31	2.66
Reflective	35 (57.4%)	3.80	2.75	32 (45.1%)	1.81	1.89
Sensing	54 (88.5%)	5.63	3.15	57 (80.3%)	3.77	2.85
Intuitive	7 (11.5%)	3.00	2.00	14 (19.7%)	1.71	0.99
Visual	54 (88.5%)	6.37	2.85	54 (76.1%)	4.41	2.65
Verbal	7 (11.5%)	3.57	1.90	17 (23.9%)	1.94	1.43
Sequential	42 (68.9%)	3.85	2.34	39 (54.9%)	3.97	3.21
Global	19 (31.1%)	2.47	1.47	32 (45.1%)	3.38	2.12

TABLE II. INDEPENDENT SAMPLE T-TESTS

Learning style dimensions	t	df	p	ES
Active	1.650	63	0.104	0.20
Reflective	3.469	60.5	**0.001**	0.41
Sensing	3.261	109	**0.001**	0.30
Intuitive	1.605	7.5	0.150	0.51
Visual	3.704	106	**0.000**	0.34
Verbal	2.303	22	**0.031**	0.44
Sequential	-0.189	79	0.851	0.02
Global	-1.632	49	0.109	0.23

The effect size (ES) listed in Table II is calculated as:

$$\text{Effect size} = \sqrt{\frac{t^2}{t^2 + df}} \quad (1)$$

Table II highlights the dimensions in which statistically significant differences ($p < 0.05$) exist between American and Chinese students. These dimensions are:

- Reflective ($t = 3.47$, $p = 0.001$)
- Sensing ($t = 3.26$, $p = 0.001$)
- Visual ($t = 3.70$, $p = 0.000$)
- Verbal ($t = 2.30$, $p = 0.031$)

Positive t-scores mean that the mean score of American students is higher than that of Chinese students. The effect sizes (ES) of these four dimensions are medium:

- Reflective: ES = 0.41
- Sensing: ES = 0.30
- Visual: ES = 0.34
- Verbal: ES = 0.44

Overall, American students show higher preferences in all the above four dimensions than do Chinese students. Take the "visual" learning style preference as a representative example. Figure 1 shows the comparison of histograms for the "visual" learning style preference between American and Chinese students.

In Figure 1, a score of 1-3 indicates well-balanced preference, 5-7 moderate preference, and 9-11 very strong preference. Coincidentally, the same number ($n = 54$) of American and Chinese students preferred "visual" learning. However, as seen clearly in Figure 1, more American students chose higher scores (i.e., stronger preference) for "visual" learning than did Chinese students. The mean score for "visual" learning style preference is 6.37 for American students and 4.41 (i.e., two points lower) for Chinese students.

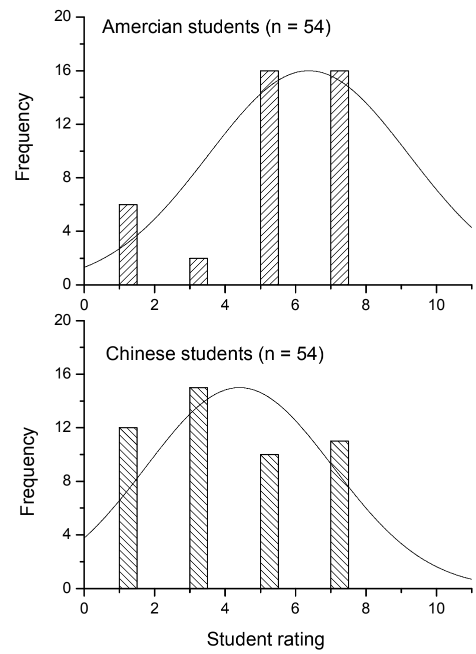

Figure 1. Comparison of histograms for the "visual" learning style preference.

IV. CONCLUSIONS

A total of 132 engineering undergraduates from two comparable American and Chinese universities participated in this work-in-progress study. The students responded to the Index of Learning Styles (ILS) questionnaire. Based on the results of descriptive statistics and independent sample t-tests for each ILS dimension, the answer to the research question is: Statistically significant differences between American and Chinese undergraduate engineering students exist in four learning style preferences. These four styles are: reflective, sensing, visual, and verbal. Medium-sized effects are found in all these four dimensions. Overall, American students show higher preferences in these four dimensions than do Chinese students.

The Institute of Technology at the University of Washington Tacoma - UWT is expanding its international cooperation by hosting Brazilian undergraduate and graduate students in the Computer Engineering and Systems program. In the first research project originated from this cooperation we propose a generic and scalable system, based on Wireless Sensor Networks (WSN). Using the data acquired from the sensor nodes this system will be able to take simple decisions, such as turn on/off heater and lights and help in other more complex decisions, such as rearranging rooms based on the occupancy. These actions aim to save resources and make buildings more comfortable and efficient. In this paper we describe how this research project is being structured and conducted in order to maximize the cooperation between Brazilian and UWT researchers. Also, we show which strategies are being adopted to make the project scalable and generic. This will allow us to aggregate multi-disciplinary people and make the knowledge and technology produced to be reusable by future project members.

Keywords—International Cooperation; Wireless Network; Sensors; ZigBee.

I. Introduction

In the academic year 2012-2013 the Institute of Technology[1] at the University of Washington Tacoma - UWT[2] expanded its international cooperation by hosting Brazilian undergraduate and graduate students in the Computer Engineering and Systems program. It was the first collaborative, multi-disciplinary, sustainable research effort in this program.

In the Fall Quarter 2012 the first four undergraduate students in Computer Engineering arrived at UWT. They are sponsored by the Brazilian exchange student program "Science Without Borders"[3] and are expected to stay for one year at UWT. These students have gone through a rigid selection process that considers among other things knowledge in English language, prior to participation in research projects and good grades. This way, the selected students have high academic performance and are experienced with research projects. Furthermore, the UWT chose students who share common interests with its expertise areas. In this specific case, the area of interest is Wireless Sensors Networks (WSN) due to research interests, previous experience and previous achievements of the Computer Engineering faculty and their Brazilian academic partners.

In the first research project originated from this cooperation, called "Development of a Smart Building Using Wireless Sensors Networks", we propose a generic and scalable system, based on WSN, capable to acquire and analyze data originated from wireless sensor nodes deployed throughout UWT buildings. Brazilian universities are cooperating with the project with professors that work conjointly with UWT team.

The set of variables measured by the sensors include temperature, humidity, luminosity, power consumption, water consumption and occupancy. The acquired information, provided by the sensors, will be useful to help saving resources and make buildings more comfortable and efficient. Furthermore, in the future, the system will be able to take simple decisions, such as turn on/off heater and lights and help in other more complex decisions, such as rearranging rooms

based on the occupancy on each season or other specific period of the year.

The motivation to develop this system is the fact that the UWT buildings are not equipped with any intelligent or software-based tool to manage or control energy resources. In addition, accordingly to the U.S. Department of Energy, the buildings sector consumes 41% of the U.S. primary energy and around 73% of the electricity [1]. These numbers have been motivating many research efforts in order to make buildings more energy efficient. Some of them aim reduce heating, ventilation, and air-conditioning (HVAC) loads [2],[3]. Others, aim to optimize computer's [4],[5] and lightning [6] energy consumption, which are also responsible for a significant amount of energy utilization.

This project involves students and faculty with different skills and from different countries (Brazil and India). Also some members, especially the Brazilian students, usually have limited time staying in United States. So, the turnover of project members is the first challenge. Other challenge is develop a system that allows the addition of new sensors nodes in the future, which requires a generic and therefore scalable WSN platform.

In this paper we describe how this research project is being structured and conducted in order to maximize the cooperation between Brazilian and UWT researchers. Also, we show which strategies are being adopted to make the project scalable and generic. This will allow us to aggregate multi-disciplinary people, add new sensors and make the knowledge and technology produced to be reusable by future project members.

II. System Architecture

The system architecture is critical to the project development. A clear definition of all modules of the system is useful to organize the development team and assign tasks for each project member. Also, to preserve the scalability, this modular architecture is being planned in a way that allows new sensors and functionalities to be added without major changes in the core system. Figure 1 presents an overview of the architecture of the system.

So far, the system has three kinds of sensor boards: Power Meter Sensor Board (PMSB), Generic Wireless Sensor Board (GWSB) and Occupancy Sensor Board (OSB). All these boards will be deployed in rooms at UWT buildings and send data continuously to the Intermediary Station (IS) using ZigBee protocol[4]. The "IS" is responsible for aggregating the data received from all sensor boards installed in the rooms on each floor of a building, store this data temporarily and then send to a server using WiFi protocol.

The server is the base station of the system. It will store all data acquired in the sensor boards, provide a Graphic User Interface (GUI) with web real time access to the data being collected and other functionalities, such as, analysis of the data stored in the database, control of the room's lights and heater/air conditioner, etc.

[4] http://www.zigbee.org

The PMSB and OSB are sensor boards built specifically to measure only one variable each, respectively, power consumption and occupancy in a room. We chose to build them separately as a dedicated board because they are digital sensors and require a lot of specific signal processing techniques.

On the other hand, the GWSB is a sensor board with ten analog channels available. So, it is able to read samples from up to ten different analog sensors simultaneously with customizable sample rates.

In the preliminary tests being conducted, we plugged in the system five different sensors to measure the following variables: temperature, humidity, luminosity, room occupancy and power consumption. The first three variables are measured using three analog sensors plugged in the GWSB. The other two have their own specific sensor board as mentioned before. In the future, many other sensors can be added to the GWSB, such as water flow sensors.

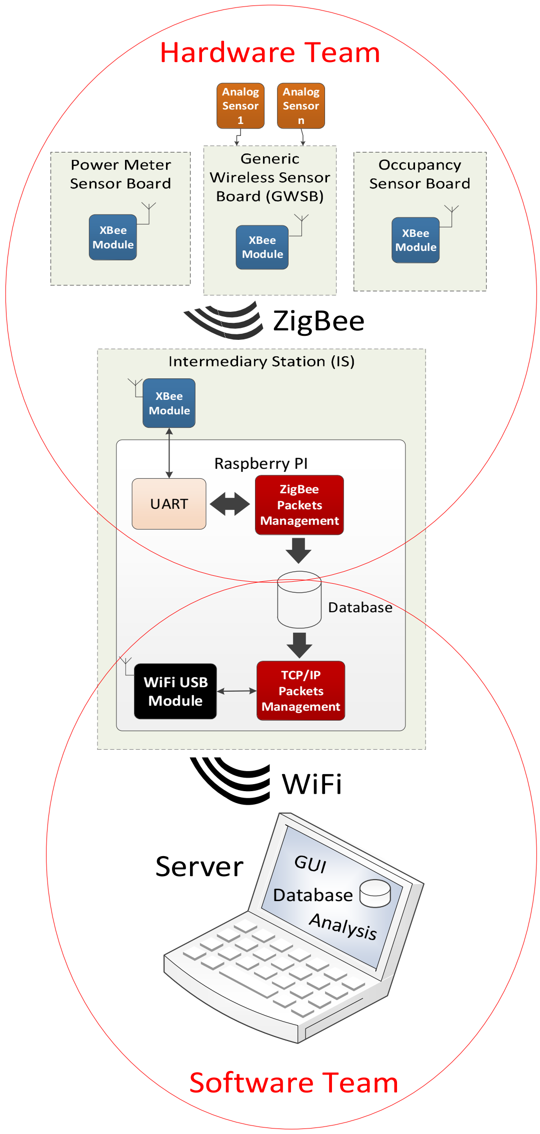

Figure 1 - System's Architecture Overview

III. TEAM ORGANIZATION

The work group currently has 4 professors and more than 12 undergraduate and graduate students. To make easier the project management of all the staff and divide tasks between the members, two main strategies are being used: the division of the team into smaller groups that meet weekly and the participation of the entire group in meetings that happen twice a month.

As highlighted in Figure 1, by the red ellipses, the development team was divided in two groups, the "Hardware Team" and "Software Team". The Hardware team is responsible for developing the embedded systems side of the system while the Software Team is in charge of the web server that will provide a user interface and the system intelligence. Each team works independently; only the system architecture and the interface between the server and the embedded systems are discussed together. Although there isn't a strict hierarchy between the members in each team, members naturally assign the status of leader to a person, usually the most technically experienced and with better communication skills. This makes easier and faster to take decisions when group members have different opinions.

There is one student responsible for supporting both groups, secure the resources (software, hardware parts, services, room reservations, meetings appointments among others project management issues) necessary for a proper project development.

Twice monthly there is a meeting with all members of the WSN Group. In this meeting critical technical aspects of the system are discussed. Also, the work carried out since the last meeting is presented to all the team. We also use these meetings to present short workshops about the technical concepts and technologies employed in the project. Such periodic meetings force the students to be more organized and active, since they should present its technical and practical advances regularly to its advisors.

Some members of the WSN Group are students from other countries, primarily Brazilians (that usually do not work more than a year on the project). So, the turnover of team members is a challenge. To minimize this problem, new students, both from UWT as from Brazilian universities, are continually invited to join the group. Workshops are organized by the most experienced members to perpetuate the knowledge and progress done in the past for the new members.

IV. COOPERATION WITH BRAZILIAN UNIVERSITIES AND FUTURE PROSPECTS

Through this project the Institute of Technology at UWT is expanding its partnerships with Brazilian Universities. It is the first collaborative, multi-disciplinary, sustainable research effort in the Computer Engineering and Systems program at the Institute of Technology, University of Washington Tacoma [7]. The goal of the UWT team is to extend the project described in this paper to all UWT installations in the next years.

Brazilian students were recruited through established, strong faculty connections and Memoranda of Understanding for long-term collaboration between UWT and some renowned institutions as the Institute for Advanced Studies in Communications (IECOM) [5], the Federal University of Campina Grande (UFCG) [6], the Department of Computer Engineering of the Federal University of the Vale do São Francisco (UNIVASF) [7] and the Department of Electrical Engineering of the Federal University of Paraíba (UFPB) [8]. When returning to Brazil after the academic year at UWT, Brazilian students should replicate the project with its faculty and try to deploy it in its native universities.

UWT is currently signing cooperation agreements with more Brazilian institutions, in order to promote the exchange of students and faculty with and other engineering schools.

In early 2013 the UWT hosted a master's student in Electrical Engineering from the University of Campinas – UNICAMP[9] (one of the most important universities in Brazil). This student, founded by a private bank, worked within the WSN Group developing the power meter used in the system. The expertise of this student in the embedded systems development was crucial for the team. It is expected the arrival of a PhD student from UNICAMP in the second half of 2013 to collaborate with the WSN research group at UWT.

In summary, we have described the partnership between UWT and Brazilian universities. Wireless Network and Energy Efficiency were identified as common interest areas between the institutions currently involved, so future projects in these areas should be expected in a near future.

***Abstract*— We have been exploring a variety of computerized techniques for analyzing student writing in introductory biology. We achieve computer-to-expert inter-rater reliability (IRR) on par with expert-to-expert IRR (> .8). In Fall, 2012, we piloted the use of automated text analysis to facilitate the use of written formative assessment for Just-in-Time Teaching (JiTT) in a large-enrollment introductory biology course at a large public Midwestern university. A total of 12,677 student responses to 15 online homework questions were collected in three 300+ student course sections with four instructors. We used automated analysis to create feedback for instructors before the next class period (less than one working day), so that instructions could use this feedback to inform their instruction. Instructors used many of the questions pre- and post-instruction and the reports we provided to them allowed them to see how their students' answers changed as a result of their instruction. Focus groups with the instructors revealed that they already knew some of the topics that challenged students, as revealed in previous semesters with multiple-choice examinations. However, the instructors pointed out that the written assessments were particularly important for gaining insight as to <u>why</u> students have struggled continuously with these ideas.**

Keywords—large-enrollment introductory courses; constructed responses; lexical analysis; Just-in-Time Teaching (JiTT)

I. Introduction

Developing rich, reliable, and robust measures of the composition, structure, and stability of student thinking about core scientific ideas (such as natural selection, conservation of mass and energy, and genetics) is a challenge that may be too complex to accomplish via multiple-choice assessments such as concept inventories (CIs). For example, as Nehm & Schonfeld demonstrate, the multiple-choice Concept Inventory of Natural Selection measures whether students understand "pieces" or elements of the theory of natural selection, but does not provide any measure of students' abilities to assemble the pieces into a coherent and functional explanatory structure [1; 2]. Moreover, multiple-choice CIs introduce significant validity threats as they are constrained to "either-or" forced-choice ("misconception" vs. scientific key concept) item preference and do not typically allow the detection of students who harbor "mixed models" of correct and incorrect conceptions [1; 3; 4; 5; 6; 7; 8].

Multiple-choice assessments also require different cognitive processes (recognition, selection) than constructed response (CR) assessments in which students must represent their ideas in writing or by creating other models. CR assessments are widely viewed as providing greater insight into student thinking than closed form (e.g., multiple-choice) assessments [9] which encourage students to study by memorizing, rather than learning critical thinking and analytic skills that are crucial for success in all STEM disciplines [10].

Thus, CR assessments that capture students' explanatory models are needed to mitigate these constraints and reveal students' mixed models. In the past, financial and time constraints made CR assessments significantly more challenging to execute in large-enrollment courses than multiple-choice assessments. But today, advances in both technology and measurement research make it feasible to apply these techniques in instructional settings with the potential to have substantial educational impact [11].

In the Automated Analysis of Constructed Response (AACR) research group (www.msu.edu/~aacr) we employ cutting-edge, lexical and computer analysis technology to analyze student writing in biology and chemistry. We have been able to create statistical models of student writing that predict expert human raters' scoring with computer-to-expert inter-rater reliability (IRR) that is similar to expert-to-expert IRR (generally, > .8) [8; 12; 13; 14; 15].

In this paper, we report on our initial efforts to move these techniques from research-to-practice in a pilot study in which we investigate applying our models to support Just-in-Time Teaching (JiTT) [(JiTT) 16] by providing instructors formative feedback about students' writing through an automated

This material is based upon work supported by the National Science Foundation under award 1022653 (DUE). analysis and reporting system which allows faculty to receive rapid feedback on students' writing to use in class the next day. We also describe some of the lessons learned and future directions for building on this model.

II. Methodological Details of the AACR Approach

In this section, we provide an overview of our approach to developing, validating and implementing AACR assessments as background for the work we will do in the proposed project. The entire process is captured by the Question Development Cycle (QDC) shown in Figure 1. In general, we use linguistic feature-based methods [17] to extract linguistic features from students' writing [e.g., WordNet, see 18; 19] and then use those linguistic features as variables in statistical models that predict human raters' scores of the student's writing.

A. Developing AACR Questions to Assess Core Disciplinary Concepts

In the first stage of the QDC, we *Design New Questions* to measure student thinking about important disciplinary constructs. Generally, we use concept inventories as the basis for the questions because they represent the topics that disciplinary researchers have identified as being particularly challenging for students. *Data Collection* is typically done by administering the questions via on-line course management systems into which students can enter their responses. *Lexical Resource Development* is done using lexical analysis software to extract key terms and scientific concepts from the students' writing. These terms and concepts are used as variables for *Exploratory Analysis* which aid in *Rubric Development*. We use the rubrics, both analytic and holistic, for *Human Coding* of student responses. During *Confirmatory Analysis* the *Lexical Resources* are used as dependent variables in statistical classification techniques to predict expert human coding of student responses. The entire process is iterative with feedback from the various stages informing the refinement of other components. The final product of the QDC is a *Predictive Model* that can be used to completely automate the scoring of a new set of student responses, predicting how experts would score the responses.

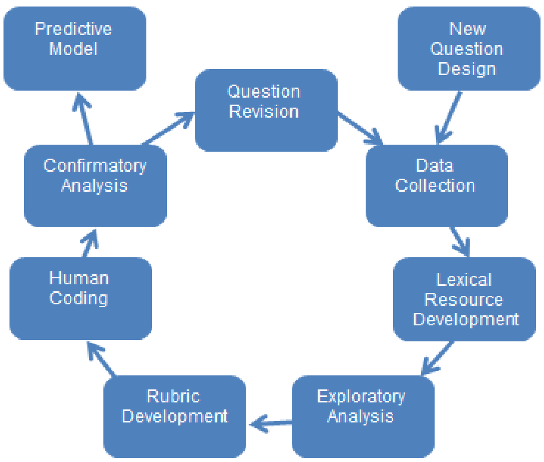

Figure 1: Question Development Cycle (QDC)

An example of an introductory biology question for which we have completed the QDC is: **Jared, the "Subway" guy, lost over 200 pounds on his diet. Where did his mass go?** This question is designed to reveal students' ability to reason about pathways and transformations of energy and matter, one of five core biology concepts [20] for which we are developing AACR assessments [21; 22]. In the following sections we elaborate on the lexical resource development and exploratory analysis phases of the QDC for the Jared problem. We first outline the process for validating the assessment and then we show how instructors can implement the AACR questions in the classroom.

B. Validating AACR Assessments through Lexical and Confirmatory Analysis

We use IBM SPSS Modeler [23] to perform the lexical and statistical analyses. Modeler provides data mining tools that can be used to build Modeler streams (Figure 2a) to automate analyses by assembling nodes that perform various tasks, such as accessing and merging data files, data conversions, lexical analysis, statistical analysis, machine learning, and reporting. Following the order of the nodes in Figure 2a, for example, we collect student responses (from on-line homework) to the AACR question to be analyzed, in this case the question about Jared's weight-loss. The responses are processed by the text analysis node.

Figure 2b shows some details of the text analysis node. The software extracts terms -- words and phrases in the students' responses that are relevant to the question (colored text Figure 2b, middle panel). These terms are stored in libraries (similar to dictionaries) that come with the software or were created by the researchers. Extracted terms that represent homogeneous disciplinary concepts are grouped into categories (Figure 2b, left panel), using both automated procedures and refinement by content experts. For example, the category glucose/glycogen in Figure 2b includes a number of terms (e.g., glucose, glycogen, sugar, and sugar molecules) that represent molecules that are metabolized to release carbon dioxide. Each student response is classified into one or more categories based on the terms used in that response (Figure 2b, right panel).

Continuing along the stream (Figure 2a), the text analysis categories are used as independent variables in statistical analysis or machine learning nodes. In the exploratory phase, as demonstrated in this example, we use cluster analyses to group responses that have the most similar sets of categories (Figure 3 shows example cluster results). These clusters help researchers refine the rubrics that are used for human scoring to build confirmatory models (e.g., discriminant analysis and machine learning techniques) that predict human scoring with computer-to-expert inter-rater reliability (IRR) as good as expert-to-expert IRR [8; 12; 15]. The final nodes of the stream select examples of student work most representative of the cluster, (i.e. closest to the cluster centroid). This information was used to build Just-in-Time-Teaching reports.

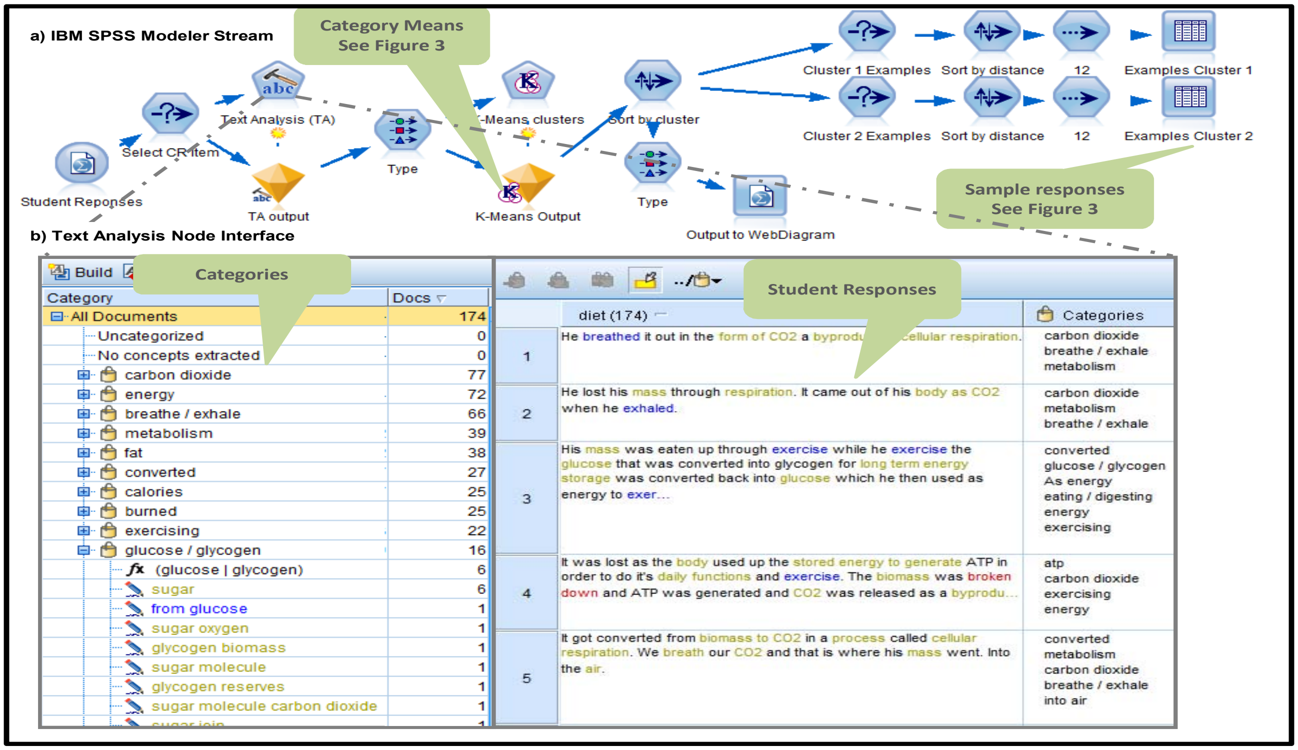

Figure 2: IBM-SPSS Modeler showing a Report Analysis Stream (a) and Text Analysis Node (b) for the assessment question: *Jared, the "Subway" guy, lost over 200 pounds on his diet. Where did his mass go?*

III. Implementing AACR Questions for Just-in-Time Teaching

To test the feasibility of accelerating the QDC (Figure 1) and rapidly making the research results available to faculty in near real time, we conducted a JiTT pilot study during fall, 2012, in three sections (N=309; N=302; N=455) of an introductory cells and molecules biology course for science majors at MSU [24]. We administered 15 different homework questions in four subject areas: biomolecules, genetics, metabolism, and thermodynamics using the university's Learning Management System (LMS). Questions were asked pre-instruction, so that the responses could be analyzed and a report returned to the instructors to allow them to address misconceptions during the next class period. Some questions were also asked post-instruction, which allowed instructors to see how students' explanations had changed. We collected 12,677 student responses and used previously created SPSS Modeler streams (Figure 2) to generate the JiTT reports. For each question we closed data collection at midnight. We began analysis and report preparation the following morning and completed and emailed reports to instructors in the afternoon for use during the next class period.

Some features from a report for the Jared question are presented in Figure 3. Reports included the question asked, the category means within each cluster (the percentage of responses classified in this category within a given cluster), cluster descriptions, example student responses that were most representative (defined by the statistical distance from their cluster centroids) and a web diagram showing the relationships

QUESTION: Jared, the "Subway" guy, lost over 200 pounds on his diet. Where did his mass go?			
Cluster 1		Cluster 2	
Mean	Category	Mean	Category
0.65	carbon dioxide	0.98	energy
0.61	breathe/exhale	0.40	converted
0.23	metabolism	0.35	fat
0.05	converted	0.13	calories
0.04	energy	0.13	glucose/glycogen
0.04	fat	0.06	sweat
0.02	glucose/glycogen	0.04	metabolism
0.01	sweat	0.00	breathe/exhale
Cluster Descriptions			
Cluster 1 responses state the mass was lost as carbon dioxide and expelled through exhalation, breathing or respiration.		Cluster 2 responses describe the fat as being converted into energy and possibly being used or released.	
Cluster 1 Examples		Cluster 2 Examples	
His mass was lost through breathing out carbon dioxide.		His mass was lost as energy exerted.	
He breathed it out in the form of carbon dioxide.		It was let out into the atmosphere as energy.	

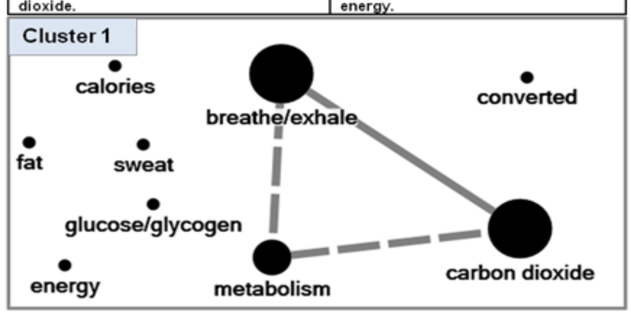

Figure 3: Subset of Pilot Study JiTT Faculty Feedback Report Features **Legend**: Circle size corresponds to the frequency of responses containing a category. Lines indicate the percentage of shared responses. Solid lines indicate >50% shared responses.Dashed lines indicate 25-50% shared responses. Nodes < 25% shared responses were not linked.

among categories in students' answers. For most questions, responses were classified into 3-5 distinct clusters. The most important categories in the predictive model (as indicated by cluster analysis results) were included in the report, along with the frequencies distributions of categories in each cluster.

For the analysis of the Jared question (Figure 3), we see that students in Cluster 1 write about Jared's mass being converted to carbon dioxide and expelled from the body. Student answers in this cluster had high means (frequencies) for carbon dioxide (65% of the responses in Cluster 1) and breathe/exhale (61% of the responses in Cluster 1) categories. The web diagram shows that responses in Cluster 1 have strong associations (solid line) between these two categories, as shown in the Cluster 1 example student responses, meaning that students in Cluster 1 tend to write about these ideas together. Cluster 2, however, had high means for the categories energy, converted, and fat. These students wrote that Jared's mass was converted into energy, revealing a common misconception for introductory biology students [21] as shown in the Cluster 2 example student answers.

IV. Pilot Study: Instructor Use of the Reports

We used the results of lexical and cluster analyses to generate rapid feedback reports for faculty to use for JiTT. Typically, data collection on the online management system closed at midnight. Analysis and report preparation began the following morning and were completed and emailed to faculty that afternoon for use during the next class period (usually one to three days away). Instructors then used these reports in a variety of ways in their instruction.

A. Faculty focus groups

We held four 1- 2 hour focus groups with the four participating faculty during which we discussed their participation in this pilot study. The early-semester focus group introduced faculty to the constructed response assessments, text analysis and the utility of the report. We also interviewed faculty about what aspects of the report they would find useful in their classrooms. We met with faculty mid-semester to identify difficulties that they had encountered using the report, allowing us to address those issues. During both the mid-semester and end-of-semester focus groups, faculty described how the report informed their awareness of students' thinking, including prior knowledge, misconceptions, and gaps in their knowledge. Faculty also discussed how they had used the information provided in the feedback report to modify their instruction. Based on these focus group discussions, we describe faculty instruction based on the analysis and report of student writing in the following section.

B. Faculty interventions and instruction in response to JiTT feedback

Faculty instructors were interested in determining students' prior knowledge about several topics prior to instruction, and identifying student misconceptions or ideas that were challenging to students. After reading the report, the instructors provided students feedback in several different ways. Some instructors created instructional materials, such as a sequence of clicker questions to address these challenges. For example, one instructor created clicker questions to use over multiple class sessions to emphasize the concept that energy is required to break bonds, and how reactions are coupled within biological systems to create a favorable reaction. This coupling is often implicit or overlooked in biology instruction at the introductory level, leaving students with the idea that breaking phosphate bonds in ATP is solely responsible for the energy released during metabolic processes. This faculty member used student sample responses from, or responses similar to those in, the feedback reports as multiple-choice options for the clicker questions. This exercise was designed to help student identify responses options that expressed ideas similar to their own homework responses. Students had the opportunity to discuss their options in groups with their classmates and then groups shared their response with the entire class, which allows them to express their ideas and get feedback from both the instructor and their peers.

Before assigning CR questions, instructors were already familiar with some of the ideas that challenged students as they had encountered these problems in previous semesters with multiple-choice examinations. However, the instructors pointed out that the written assessments were particularly important for gaining insight as to why students have struggled continuously with these ideas. One instructor was aware of students' confusion about central dogma of molecular biology concepts ("DNA makes RNA makes protein"), but was finally able to identify that students had not grasped that transcription and translation were different processes using the responses to the CR questions.

Faculty also used materials that were already prepared to address misconceptions such as the conversion of matter to energy in metabolic reactions. Our questions on metabolism were developed from multiple choice items from a diagnostic question cluster (DQC) 8, 9. Pre-existing clicker questions, created in response to the DQC project, were used by some instructors to revisit misconceptions about photosynthesis and conservation of matter during respiration.

Often with pre-instruction administration of the CR questions, a large fraction of the class was unable to give a correct or relevant response. In some instances the items reviewed material covered in the prerequisite chemistry course (e.g. exergonic reactions). Few introductory science courses have writing practice, and this may be the first attempt for many students to construct a representation of their understanding. Therefore, more opportunities to practice writing may be needed, which could be facilitated by automated analysis. Faculty also proposed future in-class activities to improve student writing skills, including critiques of poorly- and well-written responses gathered from CR questions and opportunities to write in class and turn in work for credit (e.g. minute papers).

C. Encouraging student participation

Each of the three course sections used a different type of incentive to encourage participation. We found that the two sections which gave regular homework credit had better participation (53-83%) than the section which gave extra-credit points (22-46% participation). Additionally, in the section with low participation, there were significant differences in the GPA and course grade of students who participated in homework assignments for extra credit and those who did not (Mann Whitney U –test; $p< 0.005$). In the low-participation section, students who answered CR questions on average entered the course with a higher GPA (2.56±1.37) and obtained a higher grade at the end of the course (2.62±1.06) compared to students who did not participate in the CR online homework (average GPA at start 2.49±1.15; average grade in course 2.00±1.31). This suggests that students who perform more poorly do not often take the opportunity to complete extra credit work and do not get the benefit of the additional practice. Therefore, we suggest instructors using these homework assignments should make them a required part of the regular coursework.

D. Scheduling

Automated analysis and the generation of reports within a few hours allows faculty to have data about their students' learning immediately available to them. Generally the online homework assignments were due around midnight, analysis began at 9am and reports were ready for faculty before the end of the work day for use in class the next day. The faculty reported that they needed more time than the overnight period to digest the contents of the report and modify their lesson plan. Often this was because faculty had prepared their instructional material days or weeks in advance.

We can address this in three ways

1) The homework assignments could be given earlier: one week or more in advance, especially in the case of pre-instruction assessments. This would give the faculty sufficient time to modify their lesson plans. This approach is less efficient for post-instruction assessments where immediate feedback to students during the next class meeting would be ideal.

2) During the pilot, we usually gave sets of two to six questions for each online homework assignment. Alternatively, faculty could assign just one question that targets a particular misconception. Faculty could modify their lesson plan to address this one misconception, and have material prepared beforehand in the event that there is a considerable fraction of students whose responses suggest that they hold this misconception.

3) A third option would be to design instructional material and provide support to inform faculty instruction based on the results of the constructed response assessments in their classroom. Plans for faculty professional development are discussed in more detail in the following section.

V. Professional Development for faculty using CR questions and JiTT reports

Faculty were very enthusiastic about using the CR online homework assessments to get students writing and the JiTT reports as a means of evaluating student writing. Because of the quick turnaround time between administering questions, generating the report and having the next class meeting the following day, faculty requested assistance in modifying their instruction to address areas of difficulty for students as identified in the report. Having a suite of materials that would address misconceptions identified by each question would reduce the prep-time required, which is especially important for faculty to make use of the JiTT feedback.

Therefore we are developing materials to accompany questions, so that faculty will have those available when planning their instruction. We are building a community of science education researchers and instructors who will design and test these materials, and make them available for widespread use. These faculty will be part of an online community interested in using constructed response assessments in their classrooms. Faculty will also be able to share resources they have created for their own classroom, such as those developed by faculty who participated in our pilot study. The web portal that will host these online activities is described in the Future Directions section below.

Additionally, we held two meetings with faculty early in the semester to get them familiar with the reports. We will continue to provide this support to faculty, especially as they first begin to use the assessments and instructional material. Faculty who receive support are more likely to continue with the use of innovative research-based instructional materials [25]. Support in implementing a new practice also helps faculty adopt the practice as intended [26].

VI. Future Directions

We are currently investigating the feasibility of developing an automated web-portal, where faculty could upload their own students' responses and receive a feedback report similar to what we have described in this paper. We envision this portal as place where CR questions with developed analytic resources are available for faculty to download and use in their own courses or learning-management systems. An faculty instructor could upload student responses in electronic form and, in a matter of moments, be presented with a feedback report. These reports could contain various levels of detail about the entire class performance or individual students based on the interest of the faculty. Critical to this web-portal idea is the development of a completely automated analysis procedure, which is hidden behind the user interface. A key step in moving in this direction is the validation of clusters/models by both additional student responses, as well as discipline experts. In addition to the CR questions and generated reports, we envision faculty contributing their own experiences or classroom materials in order to address the student difficulties highlighted via the feedback reports. In this way, the portal will facilitate the building of a community of practice: faculty interested in improving their own teaching along with researchers investigating students' learning of science.

Another feature we are considering for the future is how to best return direct feedback to students. Students have expressed interest in learning whether their submitted response was "correct" or "incorrect", in order to gauge their own learning. Although we do not advocate using automated analysis to assign points or "correctness" to individual responses, we may be able to provide students with formative feedback in one of two forms. We may provide a direct report to students that include which concepts they used in their explanation, which cluster their response was placed in or which other responses were most similar to their own, along with information about an "expert" or target answer. Alternatively, each response is assigned a probability of being grouped into a particular cluster, and we can use this information to guide student feedback. In the case of responses with high probabilities of being grouped into a cluster, we may report directly to students the clusters into which their responses fell. In the case of responses with low probabilities, we can recommend that an instructor review these responses before the results are reported to students. This will greatly reduce the number of responses that an instructor will have to read while still providing direct feedback to students. Providing feedback to students may be a key factor in keeping participation rates for the online homework high throughout the semester.

In addition to building an automated analysis web-portal, we want to continue to explore research questions that deal with teaching and learning. We have an assessment structure in place to capture student ideas both before and after instruction. In this way, we can measure change in student ideas and ask questions about whether completing the homework or a particular classroom intervention had an effect on student knowledge. We are also interested in exploring which student difficulties are the most resistant to change. Can we identify common "conceptual-paths" students take as they develop from naive ideas or misconceptions to more sophisticated ideas or scientific ideas? In addition to the change in student thinking, we would like to continue studying what faculty are doing in the classroom. Specifically, what exactly are faculty changing in their instruction, if anything, due to information about their students' responses contained in the feedback report? Does addressing these problems in class or via additional assignments make a difference in student learning? What methods are most effective for addressing these problems? What parts of the feedback report are most meaningful in determining whether to and how to change instruction? We see these as important questions in making progress towards rigorous, reformed science teaching that promote the best outcome for students.

VII. CONCLUSION

Writing is both an important form of communication and a critical part of the thinking process. Through writing learners organize and refine their ideas. Therefore, instructors can use writing as a tool to encourage students to think deeply about engineering [27]. Brent and Felder described how engineering writing assignments can be used to help students develop skills such as critical thinking and creativity, which are desired outcomes for all engineering students [28]. Written assessment also to allow instructors to observe how students work through the assignment [9; 29]. Despite all these affordances, writing assignments are often restricted to upper-level and graduate courses [30; 31; 32; 33]. Automated analysis can facilitate the use of writing in larger first-year courses and allow engineering students to practice writing at an early stage

If we are to heed the call for promoting higher order student thinking and providing more opportunities for students to write, while at the same time containing costs, we must find ways to leverage technology in the service of supporting and evaluating constructed response assessments. The approaches outlined in this paper demonstrate the feasibility of using off-the-shelf analytic software to allow instructors to include written assessments as a regular form of assessment, even in 400 person classrooms, and students can get practice representing their thinking in their own words. Furthermore, this innovation is highly applicable to other large-scale teaching environments such as the rapidly developing massive open online courses (MOOCs).

The text analysis resources (libraries and categories) used to conduct this study and other analyses of student writing in science can be freely downloaded (with a registered account) on our AACR group website (www.msu.edu/~aacr).

ACKNOWLEDGMENT

We would like to thank the four instructors who participated in the study and the students in their classes who completed these assignments.

A Comprehensive ABET-focused Assessment Plan Designed to Involve All Program Faculty

Olga Pierrakos and Heather Watson
Department of Engineering and Center for Innovation in Engineering Education
James Madison University
Harrisonburg, VA, USA

Abstract — **In this paper, we present a comprehensive and innovative assessment plan and continuous improvement process used by one of the newest engineering programs in the United States. The program was developed from the ground up to have a strong culture of assessment in preparation for ABET. In developing the assessment plan and continuous improvement process, one design requirement was that the assessment plan involve all faculty in the program in order to establish a strong assessment culture. The assessment plan includes both direct and indirect assessment measures, as well as quantitative and qualitative evaluations of student outcome attainments. The assessment plan targets not only program-level continuous improvement, but also course-level continuous improvement. Course-level continuous improvement involves *Course Evaluations* and *Course Assessment and Continuous Improvement (CACI) Reports*, which are prepared by the faculty and serve to document direct assessments of course outcomes and student outcomes. Program-level continuous improvement involves evaluation of the collection of CACI Reports that feed into the *Student Outcome Summary Reports (SOSR)*, which are annually prepared by the Assessment Committee members. Methods developed as part of our assessment plan are generalizable and included in the paper.**

Keywords- ABET; Assessment; Continuous Improvement; Student Outcomes, Program Educational Objectives, Engineering

I. INTRODUCTION

"Accreditation may be defined as a process, based on professional judgment, for evaluating whether or not an educational institution or program meets specified standards of educational quality" [1]. Continuous improvement is an important concept in education because it defines the framework for assessment and evaluation, which is required by accrediting agencies. There is one fundamental question driving the continuous improvement process. Can the program demonstrate the degree to which students have attained the anticipated student outcomes or program outcomes? The assessment evidence of student learning is used to identify student strengths and weaknesses related to each of the student outcomes for the purpose of making decisions about how to improve the program teaching/learning processes. Assessment processes that focus on the continuous improvement of the program produce results that can be systematically used by faculty and administration in meaningful ways. Although there are several challenges to developing an assessment plan and a continuous improvement process, one major challenge is for the assessment plan and continuous improvement process to be owned by the entire faculty body and not just a select few faculty who lead the assessment efforts [2]. Certain engineering programs and departments have implemented approaches to streamline the assessment process so that faculty are involved without a burdensome effect on their time [3-5]. One of the underlying factors in the development of a sustainable assessment plan is active engagement of faculty in the steps of the process so that this sense of ownership is fostered. Faculty engagement often occurs at the course-level using course assessment reports [5-7]. Some programs have also developed online tools and automated processes to carry out this reporting [8-10]. Another important aspect of a sustainable assessment plan is the establishment of a reasonable data collection and analysis schedule. The assessment plan and continuous improvement process developed in the new Department of Engineering at James Madison University (JMU) reflects best practices and is created to promote a culture of assessment.

II. JAMES MADISON UNIVERSITY ASSESSMENT CULTURE

James Madison University is an institution with a strong assessment culture, and the Engineering program was founded with clear goals and objectives and a commitment to ongoing assessment. The University's Center for Assessment and Research Studies (CARS), a nationally renowned program that offers the only Ph.D. in assessment and measurement, supports the design, administration, and analysis of assessment instruments administered at each stage. CARS staff members work with each program to design and develop assessment processes and instruments in every academic major. JMU uses many diverse strategies and assessment prompts including locally developed, regional, and national comprehensive exams; on-line information-literacy/library skills assessments; portfolio assessment; performance assessments; essay/term paper review; oral comprehensive exams; external on-site supervisor ratings; exit interviews, surveys and focus groups. Annually scheduled Assessment Days (one preceding the fall semester and one during the spring semester) at JMU establish the importance of assessment as central to academic and student development. On the annual Spring Assessment Day each February, the University (through CARS) collects general educational and developmental information from sophomores and juniors who have completed 45 to 70 credit

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

hours. This day also provides an opportunity for programs to assess their students. Some academic programs use the February Assessment Day to administer assessment tests or surveys; others embed assessment activities within department courses. The Engineering Program uses both approaches. On an annual basis, the Engineering Assessment Committee prepares an Assessment Progress Template (APT) report that is submitted to CARS for rigorous evaluation and feedback. Further, the University conducts reviews of all academic programs on a five-year cycle, and evaluating progress in assessment is a key part of these comprehensive reviews.

III. CONSTITUENTS & THE CONTINUOUS IMPROVEMENT PROCESS IN THE JMU ENGINEERING PROGRAM

From day one of the Engineering program, which welcome the inaugural class of students in August 2008, assessment was integral to the program development and a key facet to curriculum and programmatic development and continuous improvement efforts. We started by identifying all the constituencies of the JMU Engineering program:

- *Industry and Employers of Program Graduates* – Our graduates must be able to make significant and sustained contributions to the success of their employers.
- *Advisory Council* – The JMU STEM Executive Advisory Council (EAC) serves as an external constituency of the Engineering program. The members of the EAC are representatives from industry and academia, and are leaders in their respective fields.
- *Alumni of the Engineering Program* – Our graduates must be prepared with the knowledge and skills for successful engineering careers or advanced studies.
- *Current Students of the Engineering Program* – Our program must provide an environment which fosters the success and accomplishment of our current students.
- *Program Faculty* - Our faculty play a critical role in identifying the needs of students as well as employers and building those capabilities into the program. The department faculty bridge and integrate all constituencies to assure the program accomplishes results.

Per the program assessment and evaluation plan, Table 1 summarizes how input is gathered from each of these constituencies. In its assessment activities, Figure 1 represents the Engineering program's continuous improvement loop, which is a six-step iterative process involving both internal constituents (i.e. faculty and current students) and external constituents (i.e. alumni, employers, industry, and ABET). The first three steps of the process involve defining and refining the Program Educational Objectives (PEOs), Student Outcomes (SOs), and Performance Indicators (PIs). Performance Indicators are measurable learning outcomes and concrete actions students should be able to perform as a result of participation in the program. These three steps are the foundation of the assessment process and ever since the establishment of the Engineering Program we have iterated and refined the PEOs, SOs, and PIs. The ABET and Assessment Committees are the two faculty groups that oversee these initial steps of the continuous improvement process, but all constituents have a role in these three steps. The fourth step in the process is defining and refining the assessment metrics for the PEOs, SOs, and PIs and as a program we have focused on both direct and indirect assessment methods to evaluate attainment of PEOs, SOs, and PIs. The Assessment Committee is the faculty group that oversees this fourth step of the continuous improvement loop, but all constituents also have a role in this step. The fifth step in the process is collecting, analyzing, and assessing data to evaluate attainment of PEOs, SOs, and PIs. Once again, the Assessment Committee is the faculty group that oversees this step of the continuous improvement loop, but all constituents have a role. The last step in the continuous improvement loop is deciding on actions, implementing the actions, and reassessing. All the engineering faculty are integral to this step given that at all levels (project, course, and program), the faculty are the ones driving the continuous improvement efforts, deciding on the actions.

TABLE I. MAPPING OF CONSTITUENTS WITH ASSESSMENT METHODS

Constituents	Assessment Methods for PEOs	Assessment Methods for SOs
Industry and Employers of Program Graduates	• Employer Survey (every two years) • Employer Interviews (as needed)	• Employer Survey (every two years, indirect)
Advisory Council	• Periodic review of PEOs • Review of placement data and overarching assessment results (annually)	• Review of overarching assessment results (annually)
Alumni	• Placement Data (annually) • Alumni Survey (every two years)	• Alumni Survey (every two years, indirect)
Current Students	• Senior Exit Survey (annually, indirect)	• Course Evaluations (every semester, indirect) • FE Exam Results (annually) • Engineering Science Concept Inventories (annually) • Capstone Project Assessment Survey (annually, indirect) • Senior Exit Surveys and Interviews/Focus Groups (annually)
Program Faculty	• Periodic review of PEOs • Review of placement data and overarching assessment results (annually)	• Student Work Assessment via Course Assessment and Continuous Improvement (CACI) Reports (every semester) • Capstone Design Project Rubrics on Design Process, Writing, and Presentation (annually) • Capstone Project Assessment Survey (annually, indirect) • Review of overarching assessment results (annually)

In assuring a quality assessment process and metrics, the Assessment Committee maintains an ongoing program that obtains multiple measures of student attainability for PEOs and SOs. The assessment methods are a mix of *direct measures*, which are defined as quantified observations and ratings of student performance/attainment, and *indirect measures*, which are both qualitative and quantitative evaluations of student achievements/attainments, such as survey data.

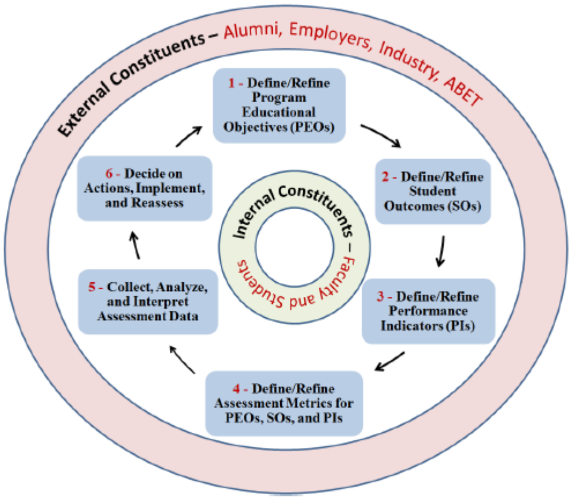

Figure 1: JMU Engineering Continuous Improvement Loop.

The assessment of SOs is performed as much as possible with direct measures, including evaluations of specific samples of student work, targeted exam questions, and evaluation of capstone projects. These direct measures are supplemented by indirect measures, such as student surveys. For the assessment of PEOs, indirect measures are more prominent, as the graduates and their employers are the best sources of information about post-graduation success. Several quantitative measures, such as number of promotions/salary increases, number of professional development activities, and membership in professional organizations also are used to measure achievement of PEOs. The following list delimits the direct and indirect measures for assessing PEOs and SOs.

Direct Measures of Program Educational Objectives:

- Alumni Survey (Specific questions)
- Senior Exit Survey (Placement Questions)
- Employer Survey

Indirect Measures of Program Educational Objectives:

- Alumni survey (Objective-focused questions)
- Admissions / Enrollment data

Direct Measures of Student Outcomes:

- Faculty Assessment of Student Work Samples via Course Assessment & Continuous Improvement Reports
- Faculty Evaluation of Capstone Projects via Capstone Design Process Rubric, Capstone Report Rubric, and Capstone Presentation Rubric
- Fundamentals of Engineering Exam Results
- Engineering Concept Inventories

Indirect Measures of Student Outcomes:

- Senior Exit Survey (Outcome-specific questions)
- Course Evaluation Surveys (Outcome-specific questions)
- Faculty Survey on Capstone Project Assessment
- Student Survey on Capstone Project Assessment
- Alumni Survey (Outcome-specific questions)

Other Assessment for Continuous Improvement:

- Freshman Entrance Survey
- Senior Exit Survey (General questions)
- Senior Exit Interviews/Focus Groups

The JMU Assessment Plan demonstrates our overarching goal of establishing connections between course-level assessment (where the key internal constituents are the program faculty and the students) and program-level assessment of the SOs (where the key internal constituents are the program faculty, the Assessment Committee, and students) and the PEOs (where the key internal constituents are the program faculty, the ABET Committee, the Assessment Committee, and students). External constituents (alumni, employers, industry, and the advisory council), described previously, are also integral to the assessment efforts of the program. In this assessment plan, course-level assessment from the students is attained via the Course Evaluations and from the faculty via Course Assessment and Continuous Improvement (CACI) Reports, which serve to document direct assessments of course outcomes and also Performance Indicators using student work, examinations, projects, etc. On the other hand, program-level assessment is evaluated also from the collection of CACI Reports that feed into the Student Outcome Summary Reports (SOSR), which are annually prepared by the Assessment Committee members. Each of these constituents has a role in this plan and these responsibilities are described below. The Assessment Committee is the principal faculty group responsible for coordination of assessment activities. The Assessment Committee reviews assessment instruments appropriate to specific PEOs and SOs, reviews the assessment process to identify areas for improvement, and provides recommendations to the Academic Unit Head and program faculty. The Assessment Committee also organizes assessment-focused faculty meetings every semester.

The assessment process is designed to inform the faculty on the strengths and weaknesses of the program in a way to bring about continuous improvements in curriculum, teaching pedagogy, advising, student services, and all other facets of the program. Annually, the Assessment Committee prepares an Assessment Progress Template (APT) report that is submitted to CARS for rigorous evaluation and feedback. The APT, which summarizes all assessment work that has been conducted during the academic year, is also sent to all engineering faculty for solicited feedback. Any recommendations or issues identified in the report are carefully considered and a course of action is developed. The assessment reports often serve as triggers for requests for additional specific assessment data and analyses to be used for specific studies or improvement projects by faculty/sub-groups within Engineering.

IV. Assessment and Evaluation Plan for ABET Student Outcomes A to K

The JMU Engineering program has developed an assessment and evaluation plan employing the best practices we have identified from several peer institutions, input from assessment advisors, CARS, and ABET resources [11]. In general, the assessment and evaluation plan ensures that the engineering faculty create, maintain, and monitor performance related to the SOs with advice and input from constituent representatives. An essential element of assessment and evaluation processes involves broad faculty involvement coupled with identification of specific responsibilities. This section presents the duties of various committees and individuals.

Assessment Committee

The Assessment Committee is the foundation for our assessment and evaluation processes and is the faculty team ultimately responsible for organizing and executing key assessment activities:

- Update assessment and evaluation plan as needed and distribute to faculty.
- Plan and conduct assessment-focused faculty meetings.
- Administer engineering science concept inventories in coordination with instructors.
- Administer the Senior Exit Survey, Alumni Survey, Employer Survey, and Capstone Project Assessment Surveys (to both capstone advisors and senior students).
- Plan and conduct Senior Exit Interviews/Focus Groups with graduating students.

Course Coordinators

Each course is assigned a course coordinator by the Assessment Committee and this faculty member plays a critical role in assessment. For all program faculty to be involved in these assessment processes, each program faculty members serves as course coordinator for at least one course per year. The course coordinator duties are described below.

- Review syllabi from all sections and instructors to ensure that these syllabi are compatible with the master syllabus.
- Oversee the coordination of assessment activities across all sections of a course.
- Prepare the course-specific questions on the Course Evaluation Survey at the end of each semester and provide these to the instructors in all sections of the course.
- Assemble and evaluate the collected assessment data.
- Prepare Course Assessment & Continuous Improvement (CACI) Reports each semester a course is taught.
- Assemble/update the course binder.
- Prepare reports at assessment-focused faculty meetings.

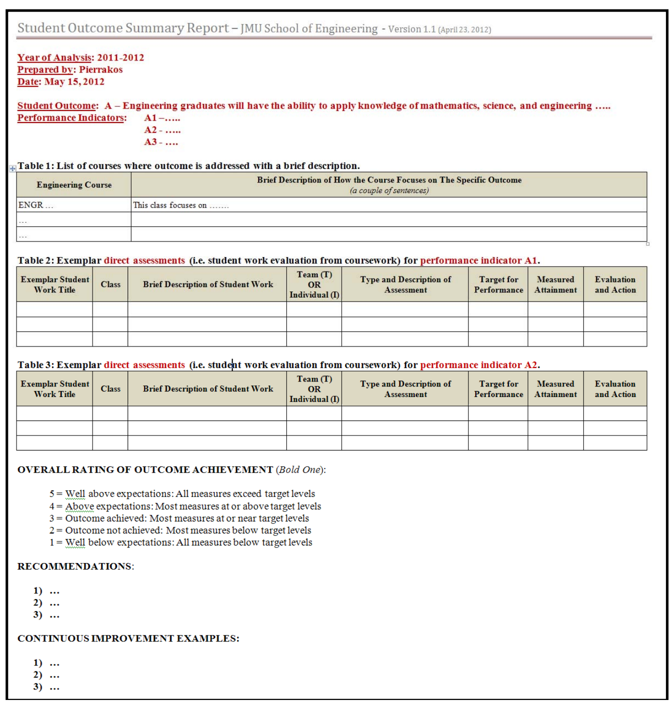
Outcome Coordinators

Each member of the Assessment Committee serves as an outcome coordinator, which requires the integration and analysis of the individual course assessment materials related to a specific Student Outcome. The responsibilities of the outcome coordinators include:

- Reviewing relevant CACI reports and prepare the Student Outcome Summary Report (SOSR) at the end of each academic year and submit to the Assessment Committee.
- Evaluating the overall degree of outcome attainment and whether the information provided supports the outcome accomplishment using the rubric in the Student Outcome Summary Report (SOSR), shown in Figure 2.
- Preparing an oral presentation for an assessment-focused faculty meeting and lead discussion related to the Student Outcome.

Assessment Committee Chair

The Assessment Committee Chair also has the additional responsibilities of preparing that annual assessment report, also known as the Assessment Progress Template (APT) which was briefly described previously. The APT is a summary of all program assessment activities and program assessment results for the academic year. The APT is submitted to the staff of the JMU Center for Assessment and Research Studies (CARS) for feedback annually. To prepare the APT, the Assessment Committee Chair reviews all CACI and SOSR reports to select exemplar assessments of student work (as the direct metrics) and indirect assessment results to provide an overarching story of program assessment and attainment of Student Outcomes. The APT is disseminated to program faculty for feedback and discussion, which often leads to the identification and actions for program continuous improvements.



Student Outcome Summary Report – JMU School of Engineering - Version 1.1 (April 23, 2012)

Year of Analysis: 2011-2012
Prepared by: Pierrakos
Date: May 15, 2012

Student Outcome: A – Engineering graduates will have the ability to apply knowledge of mathematics, science, and engineering .....
Performance Indicators: A1 –.....
A2 - .....
A3 - ....

Table 1: List of courses where outcome is addressed with a brief description.

Engineering Course	Brief Description of How the Course Focuses on The Specific Outcome (a couple of sentences)
ENGR ...	This class focuses on ....
...	
...	

Table 2: Exemplar direct assessments (i.e. student work evaluation from coursework) for performance indicator A1.

Exemplar Student Work Title	Class	Brief Description of Student Work	Team (T) OR Individual (I)	Type and Description of Assessment	Target for Performance	Measured Attainment	Evaluation and Action

Table 3: Exemplar direct assessments (i.e. student work evaluation from coursework) for performance indicator A2.

3) ...

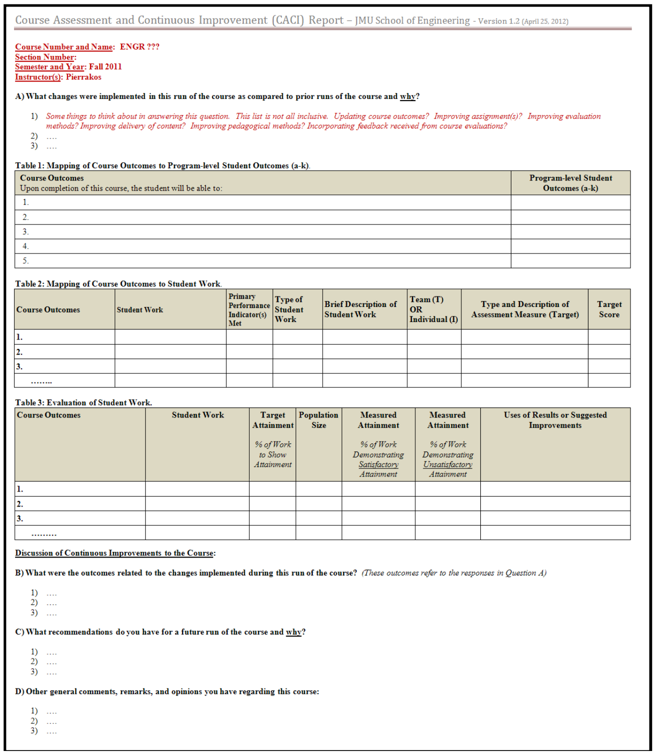
Figure 2: Student Outcome Summary Report (SOSR) template.

Our Student Outcome assessment and evaluation plan stipulates the use of both direct and indirect methods to evaluate attainment of each SO and these metrics are described below. The following list describes the direct assessment methods for SOs used in the JMU engineering program:

Faculty Assessment of Student Work – All Student Outcomes and Performance Indicators are directly measured by faculty assessing student work in specified courses. In some cases, there are specific scoring or rating rubrics used, in other cases there are specific assignments evaluated based on grades received, and yet in other cases there is an overall faculty evaluation on course work based on a variety of sources (e.g. case studies, observations, assignments, course evaluations, etc.). Targeted exam questions are also utilized and these are selected by the instructors. Faculty capture results of these direct measures using the Course Assessment and Continuous Improvement (CACI) template in Figure 3. In these CACI reports, which are submitted by the course coordinators to the Assessment Committee at the end of each semester, the following items are captured: mapping of course outcomes to Student Outcomes, mapping of student work to Performance Indicators, description and characteristics (e.g. team-based or individual) of student work, description of assessment method, metric for assessment, target attainment, measured attainment, evaluation and uses of results, etc.



Course Assessment and Continuous Improvement (CACI) Report – JMU School of Engineering - Version 1.2 (April 25, 2012)

Seven Engineering Science Concept Inventories–National engineering science concept inventories (CIs) evaluate students' understanding of fundamental engineering knowledge, so inclusion of such direct measures enables us to assess program goals A and E, given that these goals pertain to graduates having the ability to apply mathematics, science, and engineering knowledge to solve problems. The seven engineering concept inventory with the corresponding course in parentheses in which they are administered are: (1) Statics Concept Inventory, (2) Dynamics Concept Inventory, (3) Materials Concept Inventory, (4) Fluid Mechanics via the Thermal Transport Concept Inventory, (5) Thermodynamics via the Thermal Transport Concept Inventory, (6) Heat Transfer via the Thermal Transport Concept Inventory, and (7) Circuits Concept Inventory. Instructors in each of the courses where the inventories are administered select a target set of concept inventory questions to use for assessment purposes. This is done to assure that concepts covered in class are the ones that are indeed measured. For motivation purposes, students receive some type of course credit (e.g. final exam points, homework credit, or extra credit points) as decided by the course instructor.

Fundamentals of Engineering (FE) Exam – Scores from the national FE exam taken by senior engineering students prior to beginning the practice of engineering work enable us to assess Student Outcomes A, E, F given that these goals pertain to graduates having the ability to apply mathematics, science, and engineering knowledge to solve problems. A pass rate of 70% is our target performance on the FE Exam.

Faculty Evaluations of Capstone Project Reports and Presentations – Capstone projects by definition represent the culmination of students' educational experiences in the program. As such, they are an outstanding opportunity to observe student achievement of many SOs. A previous publication details the JMU two-year capstone model [12]. Using the Capstone Design Process Rubric, Capstone Report Writing Rubric, and Capstone Presentation Rubric developed by the engineering design instructors with feedback from the Assessment Committee, faculty evaluate the design process and quality of the senior capstone projects. The Capstone Design Process Rubric is used to evaluate the final capstone reports on twelve design process dimensions under four overarching categories: (1) Planning and Information Gathering, (2) Concept Generation, Evaluation, and Selection, (3) Design Embodiment, and (4) Testing and Refinement [13]. Further, the Writing Rubric evaluates the quality of the capstone reports on six writing-related dimensions and the Presentation Rubric on three delivery-related dimensions as well as the design process. The design instructors oversee the evaluation of all the senior capstone reports and all program faculty (with some external engineer practitioners as external evaluators) are involved in the evaluation of the senior capstone presentations.

The following list describes the indirect assessment methods for SOs used in the JMU engineering program:

Senior Exit Survey – The Senior Exit Survey administered as an online survey is given to the seniors in April. This survey is focused on indirectly assessing attainment of the SOs, Performance Indicators, and PEOs, as well as collecting placement information of our graduates. The placement questions in the survey pertain to career plans after graduation including employer information, position titles, starting salary information, graduate school plans, etc. The survey also includes a couple open-ended questions to collect more in-depth feedback on program and curriculum.

Faculty and Student Survey on Capstone Project Assessment – Assessing student learning as a result of participating on a two-year capstone project [12] is a critical piece to indirectly showing attainment of SOs. It is important to capture the perspective of the capstone faculty advisors as well as the student. These two sets of surveys (capstone advisor version and student version) are administered at the end of the capstone experience as online surveys. Capstone faculty advisors assess their capstone students' degree of learning outcome attainment at the end of the two-year capstone design experience. Similarly, students self-assess the degree of learning outcome attainment at the end of the two-year capstone design experience. Capstone faculty advisors' responses are compared to student responses and the results enable us to assess the extent to which the capstone design experience has enabled students to meet Student Outcomes. This survey, National Engineering Students' Learning Outcomes Survey (NESLOS) [14-15], includes 55 ABET-derived learning outcomes that map to the eleven SOs and some of the forty Performance Indicators. In this survey, we also assess the degree to which the capstone project enabled students to apply knowledge and skills from all required science, math, and engineering courses in the curriculum. Such information enables us to better understand how effectively students are applying and integrating knowledge from coursework and also helping us set some standards during project solicitation and project selection.

Alumni Survey – The Alumni Survey seeks for demographic background of alumni, appropriateness and attainment ratings of the PEOs, appropriateness and attainment ratings of the SOs, the ability of the SOs to support the PEOs, importance of PEOs and SOs to the workplace, employment details, employer contact information, and several open-ended questions. The Alumni Survey is administered to alumni as an online survey. Contact information of our graduates is collected during the Senior Exit Survey and this contact information is used in administering the Alumni Survey.

Course Evaluation Surveys – At the end of every course, instructors administer an online survey to students. The Course Evaluation Surveys include standard questions devised by the faculty as well as custom-designed questions by the course instructor(s) for the purpose of continuous improvement. The Course Evaluation Surveys include students' ratings of textbook usefulness, amount of work required in the course in comparison to other similar level courses, degree of challenge in the course, appropriateness of examinations, ratings of the value as well as the difficulty of specified course projects or assignments, ratings of students' achievement of the course outcomes, and open-ended questions. The survey employs a 5-pt Likert scale for most questions. Our goal is to achieve 70% of survey responses at the 4 or 5 level. Faculty are encouraged to include course evaluation findings in CACI reports.

Senior Exit Interviews/Focus Groups – To accompany the more quantitative and structured Senior Exit Survey, all of our seniors are also offered the opportunity to participate in a Senior Exit Interview or Focus Group to provide more general feedback and satisfaction with the program at all levels – curricular, extra-curricular, professional, etc. The questions are open-ended and semi-structured. Seniors are offered opportunities to participate in focus groups which are conducted by the Academic Unit Head and a member of the Assessment Committee who is not an instructional faculty member but rather the Student Coordinator in the program. Data from the interviews/focus groups indirectly map to SOs and PEOs.

Having described the metrics for assessing SOs, it is also important to describe the timeline and frequency of these metrics. A three-year cycle is used for assessing SOs, corresponding to 3 to 4 each year. The annual groupings of SOs for each year (i.e. Student Outcomes A, C, E, and H during year 1, Student Outcomes B, D, J, K during year 2, and Student Outcomes F, G, and I during year 3) are based on the fact that we recognize critical connections between SOs.

V. Assessment Results and Attainment of Student Outcomes

In this section, we present a sample of assessment results corresponding to Student Outcome C. More specifically, Figures 4 and 5 correspond to the summary of direct and indirect assessment results for Student Outcome C. The tables include details about the assessment methods, the target or expected student attainment results, the measured student attainment results, as well as an evaluation of the results and actions to be taken. Direct assessments of Student Outcomes (i.e. Figure 4) are primarily focused on showing attainment of the Performance Indicators by targeting exemplar student work across the curriculum. This mapping is based on the CACI reports, the SOSR, and the Assessment Committee working closely with the program faculty. The target attainment for all direct assessments was set at 70%. For program-level target attainment, all direct assessments were set at 70%, but course coordinators could set their own target attainments for courses.

For indirect assessments of Student Outcomes (i.e. Figure 5), assessment results focused on data from the Senior Exit Survey, the Faculty Capstone Project Assessment Survey, the Student Capstone Project Assessment Survey, and the Alumni Survey. The target attainment for all indirect assessments was set at 80%. Figures 4 and 5 are from the JMU Engineering ABET Self-Study.

Performance Indicators	DIRECT Method(s) of Assessment	Brief Description of Assessment Method	Course	Attainment		Evaluation and Action
				Target	Measured	
c1. Analyze and evaluate products and processes based upon economic, environmental, societal, and technical characteristics.	Reactor Design Assignment	Evaluation of adequacy of a conceptual reactor design in which students were required to determine the size and efficiency of constantly mixed flow reactors as well as batch reactors for effectively removing pollutants and minimizing the environmental impacts of anthropogenic wastes in lakes and rivers. Student attainment based on percentage of students achieving a score of 70% or higher.	ENGR 411	70%	83%	**Performance Indicators Adequately Met.** **Evaluation** – There is a focus on engineering design throughout the curriculum which is evident not only in the six design courses that serve as the spine of the design instruction but also in other courses in this table. Students are learning fundamental and advanced knowledge and skills related to design. The recent inclusion of the design challenges in the design courses has helped with better illustrating to the students the integration between engineering science and design knowledge, two domains that students initially see as independent but quickly see as interdependent. **Action** - (1) Continue to integrate design thinking and knowledge in the engineering science, engineering management, sustainability, and systems courses. (2) Continue to improve assessment methods.
	Holistic Product Design Project	Evaluation of thoroughness of a product critique using holistic design and sustainability principles. Student attainment based on percentage of students achieving a score of 70% or higher.	ENGR 431	70%	75%	
	Analysis of JMU Bus System	Evaluation of report designed to assess students' ability to apply systems concepts related to the JMU bus system. The analysis was based on qualitative assessment of economic, environmental, societal, and technical characteristics and impacts. Student attainment was based on a report rubric (4-pt scale) and the percentage of students scoring a "3" or "4."	ENGR 413	70%	62%	
c2. Identify qualitative and quantitative needs and constraints associated with a design project.	Identification of Customer Needs for Sophomore Design Project	Evaluation of thoroughness of customer needs identified and categorization of customer needs. Student attainment was based on the percentage of students achieving a score of 75% or higher.	ENGR 231	70%	91%	
	System Level Analysis Project	Evaluation of project presentation and report focused on the assumptions identified by students during their system analysis. Student attainment was based on presentation rubric (4-pt scale) and the percentage of students scoring a "3" or "4."	ENGR 413	70%	100%	
c3. Apply an engineering design process to design a system, component, or process.	Design Challenge: Infant Monitor	Evaluation of thoroughness and justification of the design process report relevant to the design challenge focused on an infant respiratory rate monitor. Student attainment was based on the percentage of students achieving a score of 70% or higher.	ENGR 431	70%	70%	
	Design Challenge: Kitchen Cabinet Accessibility	Evaluation of thoroughness and justification of the design process report relevant to the design challenge focused on kitchen cabinet accessibility for a wheelchair bound client. Student attainment was based on the percentage of students achieving a score of 70% or higher.	ENGR 432	70%	87%	
	Circuit Design Project	Evaluation of a team-based project demonstration, oral examination, and written summaries to design, build (on breadboards), test, and refine a complex circuit for an electronic system of students' choosing. Student attainment was based on the percentage of students achieving a score of 70% or higher.	ENGR 313	70%	100%	
	Capstone Project Design Process	Evaluation of the adequacy of the capstone design process, which was based on the twelve dimensions (4-pt scales) of the capstone design process rubric. Student attainment was based on the percentage of teams adequately addressing (with a "3" or "4) seven of the twelve dimensions. See Appendix 4-8 for the capstone design process rubric.	ENGR 432	70%	80%	

Figure 4: Summary for direct assessments of Student Outcome C.

Student Outcome	INDIRECT Method(s) of Assessment	Brief Description of Assessment Method	Attainment		Evaluation and Action
			Target	Measured	
C. Design a system, component, or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability.	Senior Exit Survey	Evaluation was based on an online survey where each student self-rated the extent to which she/he agreed (5-pt scale) that the JMU engineering curriculum enhanced their abilities to achieve the three performance indicators aligning with Student Outcome C. Student attainment was based on the percentage of seniors agreeing or strongly agreeing.	80%	99%	**Student Outcome Adequately Met.** **Evaluation**– Students perceive that they are adequately meeting the performance indicators aligning with Student Outcome C. **Action** – Not applicable.
	Capstone Project Survey - Faculty Assessment	Evaluation was based on an online survey where faculty rated the extent to which her/his capstone design students demonstrated an ability to achieve the learning outcomes aligning with Student Outcome C. Faculty submitted a response (5-pt scale) for each senior capstone team she/he advised. Student attainment was based on the percentage of faculty rating an adequate ability or above for their students.	80%	73%	**Student Outcome Adequately Met.** **Evaluation** - There appears to be a mismatch between faculty and student ratings of Student Outcome C learning outcomes as related to the capstone design projects. Students think that they are adequately applying the engineering design process to a product, process, or system, yet faculty advisors believe that students can be doing better. **Action** – The development of the capstone design process scoring rubric in the spring 2012 semester helped not only for assessment purposes but also with more clearly establishing design process expectations for capstone projects. This is helping design instructors, capstone faculty advisors, and capstone students set clear expectations. The design instructors plan to use this design process scoring rubric to provide students formative feedback as well as require them to self-assess their progress during the four semester capstone design experience.
	Capstone Project Survey - Student Assessment	Evaluation was based on an online survey where each student self-rated the extent to which he/she demonstrated an ability to achieve the learning outcomes (5-pt scale) aligning with Student Outcome C. Student attainment was based on the percentage of students rating an adequate ability or above for herself/himself.	80%	99%	
	Alumni Survey	Evaluation is based on an online survey where each alumnus reflects and self-rates the extent to which she/he agrees (5-pt scale) that the JMU engineering curriculum enhanced their abilities to achieve Student Outcome C. Although the Alumni Survey has been developed, it has not been administered yet. Student attainment will be based on the percentage of Alumni agreeing or strongly agreeing.	80%	NA	**Action** – Pilot the Alumni Survey in the spring of 2013 semester.

Figure 5: Summary for indirect assessments of Student Outcome C.

VI. CONCLUSION

In this paper, we presented a thorough assessment plan being utilized in the Department of Engineering at James Madison University. The plan incorporates qualitative and quantitative assessment measures, involves all program faculty in the collection and analysis of data, and outlines a manageable structure for maintenance of the process. The assessment plan was successfully used for the department's first-time ABET accreditation review in 2012. The ABET program evaluation team described the assessment plan "as the most thorough assessment plan they had seen in their 20 plus year as ABET evaluators and a plan they would take back to share with their own engineering departments. The plan itself is also subject to a continuous improvement process, and future work will include implementing methods to organize the collection of assessment data in an online format. The approach presented in this paper is adaptable to other programs and the hope is that this information can aid other engineering programs.

ACKNOWLEDGMENT

The authors would like to acknowledge the support of the National Science Foundation Awards #DUE-0837465 (NSF CCLI – "Design and Implementation of an Innovative Problem-based Learning Model and Assessment Tools in Undergraduate Engineering Education") and #EEC-0846468 (NSF CAREER – "Characterizing, Understanding, and Integrating Complex Problem Solving in Engineering Education"). The views expressed in this paper are those of the authors and do not necessarily represent those of the National Science Foundation. We would also like to thank the students and faculty who participated in this effort.

Peer Assessment in Experiential Learning

Assessing Tacit and Explicit Skills in Agile Software Engineering Capstone Projects

***Abstract*—To prepare students for real-life software engineering projects, many higher-education institutions offer courses that simulate working life to varying degrees. As software engineering requires not only technical, but also inter- and intrapersonal skills, these skills should also be assessed. Assessing soft skills is challenging, especially when project-based and experiential learning are the primary pedagogical approaches. Previous work suggests that including students in the assessment process can yield a more complete picture of student performance. This paper presents experiences with developing and using a peer assessment framework that provides a 360-degree view on students' project performance. Our framework has been explicitly constructed to accommodate and evaluate tacit skills that are relevant in agile software development. The framework has been evaluated with 18 bachelors- and 11 masters-level capstone projects, totaling 176 students working in self-organized teams. We found that the framework eases teacher workload and allows a more thorough assessment of students' skills. We suggest including self- and peer assessment into software capstone projects alongside other, more traditional schemes like productivity metrics, and discuss challenges and opportunities in defining learning goals for tacit and social skills.**

Keywords—Peer assessment; assessment metrics; self-assessment; case study; capstone project; experiential learning; project-based learning; tacit skills; teamwork; computer science education; agile software engineering.

I. Introduction

It is well known that there exists a gap between what engineering students learn and what is expected from them as they graduate [1], [2], [3]. The expectation gap [4] is especially visible in software engineering education, where practices learned while studying may even have to be unlearned later [5].

Among the expected skills are the abilities to read social cues, regulate emotional expression, and to engage in constructive dialogue with project stakeholders to discover tacit knowledge. These so-called *soft skills* are particularly important in software engineering projects that rely more on informal communication than document-driven and plan-based approaches. They are important for building and maintaining cohesion in development teams, working with external teams, and for involving other project participants and stakeholders in the software development process.

The gaps in communication and teamwork skills of new engineers were discussed already in the 1990s [6], and the most relevant skills required from entry-level IT personnel still include personal attributes such as problem solving, critical and creative thinking, and team skills and communication [7]. Teamwork and communication is also emphasized in the emerging agile methodologies, where interaction between individuals is valued over processes and tools [8]. Ultimately, students should grow into members of their communities of practice [9], adopting the tacit skills required to function in the field. This is a notable challenge for higher education.

Teamwork is usually practiced in several projects in higher education. Perhaps the most notable project is the capstone project, which is often the culmination of a degree program. Capstone projects are typically made for real customers in as realistic settings as possible, given the constraints of the educational institution. Capstone projects provide an opportunity to assess higher-order cognitive dimensions of learning as well as affective and skill-based dimensions [10]. Even if the end product of a project is the most valuable deliverable for a customer, the whole project can be a continuous and valuable learning process for the students.

As students direct their activities based on the given assessment criteria [11], the assessment design plays a key role in what students will focus on. In a software engineering capstone project, the assessed skills and knowledge should contain: (1) elementary software engineering related skills such as requirements analysis, design, development, and validation; (2) tool related skills such as the use of a version control system, development tools, and process management tools; and (3) process related skills such as process knowledge and how a selected process is followed. How the students utilize and benefit from these skills in a teamwork setting is moderated by several tacit, soft, and social skills.

In this paper, we present ongoing work on an assessment framework that can be used as a decision support tool to assess tacit skills together with explicit skills in capstone project environments. The framework has been built to help focus students' attention to important team-related aspects, and to help teachers assess student performance in capstone projects.

This paper is structured as follows. In Section II, we give an overview of our educational context and the learning objectives of our capstone courses, as well as discuss our motives to develop a new framework. In Section III, we describe related work on assessment of project-based education as well as self- and peer assessment, and in Section IV, we describe the framework. The evaluation of the framework is discussed in Section V through a multiple case study, and finally, in Section VI, we conclude this paper and outline future work.

II. Background

Computer Science studies at the University of Helsinki are divided into a three-year bachelor's degree, and a two-year higher master's degree. The bachelor's degree is a comprehensive computer science degree, which prepares the students for both working life and future studies. There is no "specialization track" within the bachelor's studies: every student takes courses on e.g. math, software engineering, distributed systems, as well as algorithms and machine learning.

If the students choose to pursue a master's degree, they have a variety of specialization tracks to choose from. Our focus is on the software engineering specialization track, in which students deepen their understanding on e.g. software processes and quality, agile methodologies and coaching, as well as software architecture.

A. Capstone Projects

Both the bachelor's and master's degrees contain a capstone project. The bachelor's degree studies culminate in either a 7- or a 14-week *Software Engineering Project*, during which the students work in 4–5-person teams on a project from e.g. an industry partner or a research group. The 7-week version is a full-time project, where the students are collocated at one of our labs, while the 14-week version is a part-time project, and can be partially distributed. Although the students are mentored by staff, they handle all project aspects in a self-organized manner, including project management and setting customer expectations.

The capstone project for the software engineering specialization track is the *Software Factory Project* [12], [13], which simulates a teamwork environment in contemporary software development organizations. Its design aims to shift responsibility of all aspects of project operation to the student team, in order to ensure that students are exposed to the realities of software development.

The Software Factory Project is similar to the bachelor's-level capstone project, but with some characteristics that make it more challenging. The project usually begins with more ill-defined goals. Part of the purpose is to discover, together with the customer, even which software the project is to produce, and how the software can bring value to the customer and end user. Some of the projects also operate in a distributed environment together with other Software Factory nodes at separate universities.

B. Motivation and Learning Objectives

The motivation for assessing teamwork and tacit skills arose initially during the design and development of the Software Factory Project. The tacit skills are of particular importance in such courses, and thus were set as important learning objectives of the project. One of the challenges was to design an approach to assess not only project deliverables and productivity, but also performance in terms of tacit and team skills. The lessons learned in the Software Factory were incorporated, together with results from a multi-year improvement effort [14], into the Software Engineering Project.

The main learning objective for both capstone projects was originally defined as "*the ability to become a member of a software development team, function as part of it, contribute to its development, and work as part of it towards its current mission or purpose*". In addition, the software engineering project has a specific learning objective rubric, which outlines the principal themes in the course and what is required for each level of student assessment. The rubric follows the principles of constructive alignment [15], and outlines software development related skills, as well as management and tool usage.

The effort that students put on learning is heavily determined by the assessment criteria [16], [17]. However, neither the rubric nor the main learning objective supported assessing soft skills. As the main learning objective of the capstone projects consists of a set of distinct sub-objectives, assessment requires that each of them is identified and assessed independently, preferably using a small number of traits that cover the knowledge and skills required to do well in each part of an activity [17].

Our framework is based on the cognitive domain of Bloom's revised taxonomy [18], [19], which provides guidelines for agreeing on assessment and learning objectives for a course. It outlines six levels (*remembering*, *understanding*, *applying*, *analyzing*, *evaluating*, and *creating*), which are ordered from simpler to more complex; the original idea was that mastering a "higher" category requires the mastery of the previous categories.

Based on the six levels defined by the cognitive domain in Bloom's revised taxonomy, we outlined the following team skills that each participant focuses on: *presence*, *activity*, *eagerness*, *devotion*, *contribution*, and *expert maturity*. In addition, the bachelor's-level software engineering projects put additional focus on the participant behavior and its influence on *process* and *result*. A more comprehensive description of these team skills is given in Section IV.

III. Related work

Several studies have examined self- and peer assessment of teamwork in regular courses, and assessment of teamwork in projects, including capstone-like courses. Here, we briefly present some of the issues examined and results found.

One of the most fundamental questions regarding assessment is that of its purpose. Naturally, assessment can serve multiple purposes simultaneously; it can help rank students with respect to their performance, allowing selection to be made in different stages of an educational system, and it can provide important feedback to students regarding their study performance. When assessment is tied to specific learning objectives, students' activities can be directed towards activities that build knowledge and skills that are deemed relevant.

Assessment can be used on the systemic level to evaluate learning programs in terms of how well they support achievement of learning outcomes [20]. The nature of capstone projects as comprehensive experiences means that they allow assessing a wide range of abilities; they are indicative of learning program strengths and weaknesses. Analysis of capstone project outcomes can provide valuable insights for improving learning programs, and thus, improving student learning. Payne et al. suggest assessing student readiness for capstone courses in order to gather feedback on both the presence of necessary background knowledge, skills, and dispositions, and the ability to apply them to capstone courses [10]. They outline critical concepts and skills that students must be taught to assure their success in capstone courses, noting that educators and researchers should set up continuous feedback frameworks that could be used to transfer knowledge to core-course faculty on the level of preparation the students believe they have for the upcoming capstone experience.

A pertinent question is how to actually assess capstone projects: what is to be assessed and how? One approach is to map project deliverables and artifacts to general and specific learning outcomes and rubrics, and then assess the deliverables with respect to the rubric, as proposed by Murray et al. [20]. As an example, Murray et al. describe the goals of information systems capstone projects: students should be able to i) understand that projects require collaboration as well as individual effort, ii) participate as contributing members of a development team, iii) apply teamwork skills in development and implementation of a system, iv) demonstrate acknowledgment of and respect for the team members, and v) identify the qualities needed to be an an effective leader, and explain the roles of leadership and teamwork in system development and implementation. The artifacts used to evaluate these outcomes include individual reports, peer evaluations, and weekly status forms.

Self- and peer assessments appears to be viewed favorably by many teachers and researchers in terms of how well it includes students into the assessment process. For instance, Fellenz finds that peer evaluation can improve the quality of the students' experience and increase their engagement in the learning task [21]. However, a particular concern in assessing teamwork skills is the accuracy of assessment. Through a review of assessment literature, Van Duzer and McMartin [22] identified two primary types of bias as especially relevant for self-assessment and peer evaluation: self-enhancement, where one's own performance is evaluated as unreasonably optimistic, and downward comparison, a general tendency for positive self-bias and negative other-bias. Similar results are reported in many works. For example, Ryan et al. compared peer and self-evaluations of class participation against those of professors [23]. They found that faculty grades tended to be higher than peer grades, and that self-evaluation grades were typically higher than faculty grades. This study used a forced ranking system for students to rank each other while faculty did not use forced ranking.

Van Duzer and McMartin suggest some approaches to reduce self-enhancement and downward comparison biases [22]. Using language shared by respondents and testers in assessment criteria helps to reduce misinterpretation and thus improves the validity of the assessment process. Correlating self-assessments with scores by multiple raters allows evaluation of instrument reliability. Designing questions so that they rate past performance, not expected future performance, improves reliability by reducing the effect of downward comparison. Finally, asking respondents to make comparisons with an explicit group of known individuals rather than an abstract group when social comparisons are required, also improves reliability. Qualitative analysis while developing the instrument is necessary to understand the meaning of the assessment to participants. Van Duzer and McMartin developed a process with both quantitative and qualitative parts for improving and tailoring teamwork skill assessment in specific environments. They found a dramatic improvement in sensitivity when applying the process to their own instrument.

A number of approaches and frameworks for self- and peer assessment have been described in the literature. Willey and Freeman report on a tool that facilitates formative assessment via self- and peer assessment [24]. They report that formative feedback encouraged development of teamwork skills, and also discouraged free-riding and sabotage, thus promoting academic honesty. They argue that while self- and peer assessment is often implemented as summative assessment, even better outcomes may be achieved by using them as formative assessment. They observe that the administrative burden of applying self- and peer assessment can often outweigh the perceived benefit. Furthermore, they observe that feedback is often given long after the assessable work has been completed, which means that students' attention may already have shifted to other tasks.

Beyerlein et al. [25] describe an assessment framework for capstone design courses. Their framework is based on a conceptual model of knowledge representation and expertise development. They strive to examine students' performance and growth from several perspectives. They examine growth in personal knowledge and skills applied in problem solving. They examine professional development through goal-driven initiative, competence in problem-solving, integrity and professionalism, and ongoing reflection. Also, they examine team processes and dynamics as well as productivity by determining whether team resources are used strategically, and decisions made add real value to the project. They also examine how well students are able to formulate solution requirements, consider stakeholder needs, and formalize these into specifications. Finally, they evaluate deliverables in terms of desired functionality, economic benefits, feasibility of implementation, and favorable impact on society.

Another concern is students' motivation to rate their peers. Friedman et al. found that students who provided categorical ratings (multiple scores on different categories or dimensions) multiple times during a course experienced the lowest motivation to rate their peers, while students who provided holistic ratings (a single score) multiple times reported the highest motivation [26]. We may hypothesize that respondent fatigue plays a role here: a small number of items is less likely to feel overwhelming. The type of item may also be important: describing a particular behavior and asking the respondent to indicate its frequency is usually recommended – an approach used, e.g., in rating a system developed by Clark et al. [27].

Finally, also related to practical concerns, is the burden of manual work in collecting and analyzing self- and peer assessment data. Naturally, online questionnaires and semi-automated analysis tools can remove much of this manual work. Some reports exist on complete systems for self- and peer assessment management. The SPARK system, described by Freeman and McKenzie [28], emphasizes fairness in group work assessment and reduced administrative burden through automation. Similarly, the CATME system, described by Ohland et al. [29], provides automation to reduce teacher workload, but places greater emphasis on using behavioral anchors in the assessment itself. The SMARTER system [30] extends CATME and attempts to link educational research with teaching faculty actions to enhance learning of teamwork skills.

IV. Framework for Assessing Tacit Skills

Our Framework for Assessing Tacit Skills consists of a questionnaire whose items can be used (e.g. by weighted averaging) to provide assessment decision support for teachers. The framework enables assessment of tacit skills through nine indicators, used for both self- and peer assessment. We categorized the indicators to represent six different tacit skills, and decided that the assessment should impose as little overhead as possible for all participants and thus should be implemented as a short online questionnaire.

The framework factors, questionnaire items, and scales are shown in Table I. The questionnaire, which is filled in by the students, project coach, and the client, allows rating each student based on the questionnaire items. Once the questionnaire has been answered, the answers are exported for further data-analysis, where a set of scripts is used to e.g. suggest overall grades based on a given weighting, or to indicate students that have been free-riding.

The questionnaire is structured along six factors, beginning from basic factors and progressing towards higher levels of involvement and skills. The first factor, presence, is a prerequisite for becoming a member of the development team. The activity factor implies that a person is not only present, but also actively involved in the project. Eagerness reflects the attitude that the person takes towards the project: is the person not only active but also taking initiative and displaying a positive desire to get things done. Devotion reflects a deeper level of commitment: the person not only takes the initiative but actually invests effort into carrying out planned tasks. Contribution reflects actual impact on the project, whether in the form of code, documentation, or other deliverables, or in the form of project management, customer communication, or support tasks. Finally, expert maturity reflects an overall assessment of how the person performed in their role. We purposefully chose to leave the definition of this factor quite open and broad, in order to allow each individual to assess it according to the specific conditions of each particular project.

While we appreciate the objectivity and wide coverage of the approach described by Murray et al. [20] and other similarly detailed assessment schemes, we suspect that both students and teachers can quickly be overwhelmed by the amount of effort required to produce and analyze the assessment artifacts, resulting in both less effort being available for project work and formative assessment and guidance. It also feels counter to the philosophy of Agile software development methodology to employ a heavy-weight assessment framework – after all, agile projects purposely do not define artifacts to be produced until there is a proven need to produce them.

Three main criteria were defined for the framework. First, the framework should ease teacher workload. The framework should function as a support tool for teachers during assessment, and it should support assessment of project-based courses even when teachers cannot constantly observe students' activities. Second, it should allow systematic assessment of students' skills; each factor in the framework can be thought of as building on top of the previous factors. Finally, it should be easy to detect attempted misuse of the framework, so that teachers can be confident that they may use the results as valid decision support information.

V. Evaluation

The framework has been evaluated iteratively during its development. It was first evaluated in several projects in the Software Factory, and later also in the Software Engineering Project. In this section, we report on the evaluation procedures and present the most relevant evaluation results. We then discuss the validity and limitations of our evaluation and present results from evaluating the framework from a teacher perspective.

As noted, the motive for assessing tacit skills arose during the design of the Software Factory. We first conducted a pilot project in spring 2010 with 11 students, during which the framework dimensions were developed. Then, the framework was deployed to 11 consecutive Software Factory projects with a total of 77 students. The evaluation of the framework in the Software Engineering Project started in fall 2011, after which a total of 18 projects with a total of 88 students have been both evaluated by the framework and given their evaluation of the framework. Since the latter project is mandatory for all bachelor's-level students, we wanted to gain reasonable confidence that the framework worked well before deploying it there. As part of that deployment, we found that the Software Engineering Project students did not perceive teamwork-related skills as important. For example, competitive situations arose where several strong individuals attempted to pull the project in their desired direction. For this reason, factors regarding individual behavior in relation to the group were added.

Our evaluation strategy is laid out as follows. Ultimately, the objective is to find out whether the framework is suitable for the purpose of influencing learning of teamwork skills through assessment. However, before actually determining its effect on learning, we want to understand whether the framework is otherwise suitable for use in capstone projects. This includes evaluating the accuracy of assessment and utility of the framework as a decision support tool: does the framework adequately guard against biases such as self-enhancement and downward comparison, does it adequately reflect rater's understanding of the factors, and does it produce results that are in line with teachers' expert evaluations, taking into account the rich, qualitative observational data obtained when guiding students in the capstone projects?

To perform this evaluation, we proceed as follows. We check the association between self- and peer ratings to determine whether a bias is visible (see Table II). Peer ratings should help dampen bias in self-ratings. We check association between the different rating factors. There should be discernible differences between the factors both in self- and peer ratings; they should not have perfect correlation. However, there should be some association between the factors that are in fact conceptually related.

Table II shows correlations between self- and peer assessments in both the Software Factory (SF) and the Software Engineering Project (SP). Most of these correlations are as expected: there is a large degree of correlation but there are differences in the gradings. However, some correlations stand out from the others. In SF, there is quite low correlation on eagerness, and self-ratings tend to be higher (mean: 0.863) than peer ratings (mean: 0.743). In SP, self-ratings tend less towards the highest grade (mean: 0.788) and peer ratings are similar in distribution (mean: 0.786). In our interpretation, students

TABLE I. FRAMEWORK FACTORS, QUESTIONNAIRE ITEMS, AND SCALES.

Factor	Questionnaire item	Scale
Presence	How many days per week did you work on this project? How many hours did you spend on the entire project in total? (Round to nearest hour.) How much was each team member present? Also rate your own presence.	1 – Was not present at all 2 – Was sometimes present 3 – Was moderately present 4 – Was nearly always present 5 – Was always present 0 – I don't know
Activity	How actively did each team member participate in the project? Also rate your own activity.	1 – Was not active at all 2 – Was somewhat inactive 3 – Was moderately active 4 – Was quite active 5 – Was very active 0 – I don't know
Eagerness	Eagerness: a positive feeling of wanting to push ahead with something. How eager was each team member to participate in the course? Also rate your own eagerness.	1 – Was not eager at all 2 – Was a little eager 3 – Was moderately eager 4 – Was quite eager 5 – Was very eager 0 – I don't know
Devotion	Devotion: commitment to some purpose; "the devotion of his time and wealth to our project" How devoted was each team member to the course? Also rate your own devotion.	1 – Was not devoted at all 2 – Was a little devoted 3 – Was moderately devoted 4 – Was quite devoted 5 – Was very devoted 0 – I don't know
Contribution	How much did each team member contribute to the deliverables (code, documentation, tests, bugs, plans, or anything else that the project produced)? Also rate your own productivity.	1 – Did not contribute at all 2 – Contributed a little 3 – Contributed moderately 4 – Contributed quite much 5 – Contributed very much 0 – I don't know
Expert Maturity	Each team member has acted as a software development expert with some specific focus area. How mature was each team member in their expert role? Also rate your own maturity.	1 – Very low expert maturity 2 – Low expert maturity 3 – Neutral expert maturity 4 – Some expert maturity 5 – High expert maturity 0 – I don't know
Process (only BSc project)	Group dynamics: each member can influence the team spirit and the end result with their social behavior. How did the group behavior of each member influence the sensed meaningfulness of the project work?	1 – Influenced negatively 2 – Did not influence 3 – Influenced a little 4 – Influenced quite much 5 – Influenced very much 0 – I don't know
Result (only BSc project)	How did the group behavior of each member influence the end quality of the project work?	1 – Influenced negatively 2 – Did not influence 3 – Influenced a little 4 – Influenced quite much 5 – Influenced very much 0 – I don't know

TABLE II. CORRELATIONS BETWEEN SELF- AND PEER RATINGS ON DIFFERENT FRAMEWORK DIMENSIONS IN SOFTWARE FACTORY (SF) AND SOFTWARE ENGINEERING PROJECT (SP), WITH CORRESPONDING P-VALUES.

Dimension	Correlation between self- and peer rating	p-value
Presence (SF)	0.492	< 0.001
Presence (SP)	0.457	< 0.001
Activity (SF)	0.531	< 0.001
Activity (SP)	0.544	< 0.001
Eagerness (SF)	0.279	0.017
Eagerness (SP)	0.473	< 0.001
Devotion (SF)	0.433	< 0.001
Devotion (SP)	0.333	0.002
Contribution (SF)	0.582	< 0.001
Contribution (SP)	0.376	< 0.001
Expert maturity (SF)	0.461	< 0.001
Expert maturity (SP)	0.207	0.062
Contribution to meaningfulness (SP)	0.487	< 0.001
Contribution to quality (SP)	0.370	0.002

in SP could be less inclined to penalize each other, perhaps because their level of experience is lower and the course is mandatory – they may not want to give low ratings to each other on eagerness given that situation.

On devotion and contribution, the trend is similar: in SF, the correlation is stronger than in SP. In the SP data, high peer ratings were more common than in the SF data. In SF, roughly one third of students rated their peers at average expert maturity, while more than two thirds of SP students assigned each other the two highest scores. This may indicate that the competitiveness among students in the SF is higher. We observe that this information allows the teacher to assess the amount of bias in responses and that there appears to be agreement on the meaning of the dimensions.

Next, we consider the association between the variables. In the self-evaluation scores, presence correlates somewhat with activity and eagerness but less with devotion, contribution, and least with expert maturity. This could indicate that students do see these factors as separate. Activity correlates quite strongly with eagerness, devotion, and expert maturity. Devotion correlates strongly with contribution and expert maturity. Contribution correlates most strongly with expert maturity.

In the peer evaluation scores, all factors are moderately to strongly correlated. In SF, the strongest (≥ 0.9) correlations are i) activity with eagerness (0.930), devotion (0.932), and contribution (0.943); ii) eagerness with devotion (0.912) and contribution (0.911); iii) devotion with contribution (0.939); and iv) contribution with expert maturity (0.906; $p < 0.001$ in all cases). In SP, the correlations are smaller but still quite strong. The order of strength is roughly the same. We interpret these results as supporting the intended structure of the factors.

In SP, the two added factors had moderate to low correlation between self- and peer evaluation. On contribution to meaningfulness, self- and peer evaluations had a moderate correlation (0.487), while on contribution to quality, the correlation was lower (0.370). In the latter, there may be bias toward thinking that one's own contribution is the most important, and therefore one rates the others lower.

A. *Validity*

The validity of the framework is limited by the fact that it uses a questionnaire-based approach. Respondents are asked to recall their own behavior and that of their teammates, and this recall may not be perfect. However, more fundamentally, the validity is ultimately relative to context in which the instrument is deployed. The purpose of the framework is to function as a decision support tool, and teacher judgment should be used to determine the final assessment. As MacLellan notes, validity concerns not the assessment instrument used or the resulting scores as such, but rather the inferences which are derived from them [31].

To lend more validity to such inferences, the framework should provide a way to detect whether the data may be biased or incorrect. The most common reason besides unintentional bias is students' attempts to artificially influence their grades. We found some cases of attempted subversion, where a small number of students systematically rated themselves with the highest scores and others with the lowest scores. These cases were easily detected using simple, semi-automatically produced outlier analysis.

B. *Teacher satisfaction*

In our context, we have evaluated the framework with three different teachers. While the results of this evaluation are experiential and cannot be generalized, we find it important to report on these experiences to enable other teachers to determine whether our approach is of value in their context.

Our first finding relates to the goal of easing the teacher's workload. We found the framework to be non-intrusive and supporting formative assessment and feedback during the capstone courses. The framework required no extra effort during the courses, and the teachers were able to devote their time to in-situ instruction. At the end of the course, some administrative effort was needed to administer the on-line questionnaire, collect the results, and perform the required data analysis. However, since many of these tasks were automated or semi-automated, teachers could focus on the intellectual side of summative assessment: interpretation of the numeric results and comparison of them to other assessment sources, including notes taken during the course.

One of the teachers voiced concerns regarding fairness and comparability between students and projects. However, we found that when used as a decision-support tool for assessment, the framework did not introduce any fairness concerns. This was also reflected in students' attitudes – all students were given the same opportunity to grade themselves and each other, and the teacher validated the results so that unfair biases were accounted for in the final grade. Cross-project comparability is still an issue, however, but it is not unique to this framework. Each capstone project is inherently different, and maintaining the level of realism often desired in such projects means that comparisons of performance are difficult.

VI. CONCLUSIONS AND FUTURE WORK

In this article, we have described our tacit skills assessment framework, which is an easy-to-use decision support utility for evaluating students' teamwork proficiency. The framework has been evaluated with data from 18 bachelor's and 11 master's-level capstone projects, where it has been found to provide reasonable support for teachers in evaluating tacit, social, and teamwork skills. We found that the framework guarded against rater bias, that its dimensions were well understood, and that it matched teachers' expert ratings. Our results are relevant in the context of project-based courses emphasizing experiential learning and agile methodologies.

We suggest including self- and peer assessment into software capstone projects. However, although technically possible, one should not base assessment of students in capstone projects only on the values provided by the self- and peer ratings. We suggest using additional criteria that takes into account several other data sources, such as version control system commits and their quality. In addition, feedback on the overall project can be obtained from the customer as well as a possible team lead or coach. Aggregating scores into a final grade requires experimentation and the inclusion of teacher judgment.

In case participants display behavior that is not seen as beneficial for the team, additional assessment criteria can be added to the framework due to it's small size. As an example, a few participants in our current bachelor's level software engineering projects have displayed a tendency for "safety seeking", where individuals have avoided working on tasks that require learning new tools and practices. Additional incentives for moving away from the comfort zone have been introduced via a new assessment criteria "How well did the participant handle tasks that required learning new tools and practices?".

We are currently considering a replication study to evaluate the framework in a Software Factory in another country, as well as evaluating approaches to make the framework easier to use. Other possible directions include formative assessment support, and determining the association between framework factors and objectively measurable metrics such as code metrics.

Assessment of Engineering Faculty Performance in the Developing Academically Autonomous Environment – VIT, Pune, India – A Case Study

Prof. Ashutosh Marathe
Dean – Quality Assurance
Management Representative – ISO 9001:2008
Vishwakarma Institute of Technology
(An Autonomous Institute Affiliated to University of Pune)
Pune, India
ashutosh.marathe@vit.edu

Abstract— **The necessity of Documenting and quantifying the accountability of faculty in Higher Education Institutes (HEI) is gathering momentum in countries all around the globe. In India, where Academic Autonomy is slowing spreading its wings outside the Indian Institute of Technologies, National Institute of Technologies and Government Engineering colleges, into the group of Private unaided Engineering Institutions, the need is felt to develop a rubric for assessing faculty performance in a Quantitative manner. Addressing to that need, various attributes are identified which are essential for assimilating a 'complete faculty performance'. This paper details out these efforts and its outcomes in one of the leading Private Engineering Autonomous Institute in the academically progressive western part of the country. The teaching performance of the faculty along with academic, co-curricular, extension and research activities is quantified into a credit based assessment system (CBAS). This system is run under Quality Management Systems adopted at the Institute. This faculty performance assessment is observed to have helped in identifying better performing as well as poor performing faculty. Also the targets for the subsequent Academic year can be set up with clarity and transparency**

Index Terms— Higher Education Institutes (HEI); Faculty Performance; Academic Development; Co-curricular and Extra-curricular contribution; Research contribution; performance Points (PP); Performance index (PI) ; Weightage based Indexing (WBI); Credit Based Faculty Assessment

I. INTRODUCTION

The Indian Higher Education System is a matured and established system. The strong emphasis on basics of Mathematics and Sciences at school level has traditionally assisted the Engineers to comprehend the Engineering concepts effectively. The contribution of Indian Engineers in Academics as well in Industry all across the globe is well recognized and respected. The traditional methods of teaching – learning with an emphasis on classroom teaching supplemented by laboratory practices have been the backbone. Yet over the last 2 decades, with globalization and emerging opportunities, the number of opportunities for able and competent Engineers has increased many folds. Many authors such as [1] have commented about this issue from a similar if not identical perspective.

Also with the advent of ICT (Information and Communication Technology) based practices, the modern teachers also have had to equip themselves to suit the needs of the new generation of Engineering students. While the knowledge management infrastructure through the use of ICT has grown, we still need to rethink of conceptual network, research agenda, strategies and models that are more adaptive and responsive [2]

In order to ensure that the local, National and Global need of engineers is met with in sufficient numbers, there has been a planned growth in the number of Higher Education Institutes (HEI) [3].

The role of the Engineering teacher is also changing into a facilitator rather than only a classroom or laboratory advisor.

For academically competent Institute such as the one considered here, Academic autonomy is granted. The Academic decisions can be taken autonomously by the Institute. Hence after the absorption of the admitted students at the First Year of Undergraduate level, the Institute designs its curriculum, sets up its own Question papers and carries out assessment and awards grades to the students at the end of 4 years of Undergraduate Engineering course. The student performance is mapped in terms of a Cumulative Performance Index (CPI) on a scale of 0 to 10. While executing this entire activity, the role of a faculty in the multi-faceted development of student is very critical. Hence as a quality conscious and progressive Institute, specific efforts are taken to monitor and evaluate the faculty performance in the campus on the basis of a novel assessment mechanism. The application of quantificational method helps to improve the effect of performance evaluation of staff members in the Institute [4].Authors in [5] share a similar opinion that a well-structured performance appraisal system that is based on quantifiable objectives & standards can lead to achieving a high level of accountability. According to the Author of this FIE conference paper, this is the blending of various appraisal areas for the holistic development of the faculty, thereby consequently the student.

II. IDENTIFIED AREAS IN THE ASSESSMENT SCHEME

The modern faculty in a progressive and developing Institute is expected to contribute in Quality Teaching as well as other essential areas. For an Institute with around 4000 students, running 23 programs (UG, PG and PhD combined) the appointed faculty is expected to commit and support the technical growth of the student as well as Institute growth.

Various elements of effective performance appraisal were identified and exploration of domains and dimensions of faculty performance was made in [6]. The major domains commonly identified were teaching, service & research along with faculty development and administration in some cases in the same paper.

With these broad set of ideas in the Assessment scheme the following domain areas suitable for the Institute working culture as shown in Fig. 1 are considered.

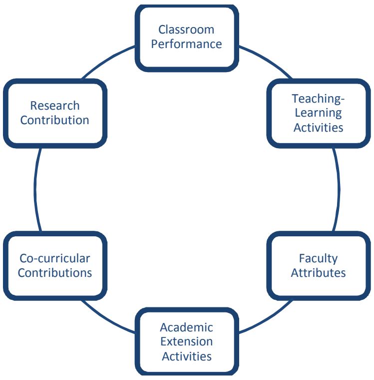

Fig. 1 – Areas considered for Assessment Scheme

A. Classroom Performance of the faculty – on the basis of the Staff Classroom performance feedback given by the students across the entire Academic year, the quantified performance rating called Performance Index (PI) is calculated.

B. Teaching and Learning Activities – The faculty involvement in Teaching learning, the adherence to academic deadline, amendment of course contents etc. along with efforts taken for slow learners are considered.

C. Faculty Attributes – An Engineering Faculty is a highly Intellectual, sensitive human being. While teaching the courses, keeping abreast with emerging technical areas is equally necessary for the faculty. The faculty as an individual, faculty playing the role as a colleague is as important in the faculty growth as well as in sustenance of the quality of the deliverables. This fact is also mapped in Faculty attributes.

D. Academic Extension Activities –Design and development of in-house projects, laboratory setups, development of Additional supplementary Course material, providing additional learning opportunities beyond the syllabus to students is as important. The liaison of the faculty with Industry around is vital, for the experiential learning of the students. In that regards, efforts taken by the faculty to provide Internship opportunities, or sandwich training or arrangement of a useful Industrial visit is considered under these activities.

E. Co-curricular Contributions - The typical organizational skills for scheduling and executing Conferences, Workshops, Short Term Training Programs for faculty, refresher courses for Industry, Certificate Courses for community around as a service to Society are all encouraged and recorded. Work carried out on the platforms of technical bodies such as IEEE, SAE, ASME, ISA etc. is considered. The Entrepreneurship initiatives taken by faculty are weighed highly.

Besides this the faculty is expected to contribute in various statutory or incidental committees at Department level or the Institute level. Based on the nature of work, corresponding 'credits' are given to the faculty.

F. Research Contribution - Although the Institute is predominantly an Undergraduate Teaching Institute, a lot of emphasis is given on Research initiatives and significant outcomes are expected from senior faculty involved in research on National and International forums. Various areas of research were discussed during the evolution of the format and considered worthy to be included. It is seen that not only does it help in quantification of the performances, they act as clues for junior faculty

Typical areas such as Publications, Consultancy, Patents, Technology Transfer, Innovations, Research Guidance etc. were considered. The assigned credits and other details are provided in the later part of the paper.

The domain areas D & E are equally important as highlighted by author in [7]

III. IMPLEMENTATION DETAILS

Area A – Classroom Performance of the faculty :

This area is of significant interest amongst academicians. The authors in [8] enlisted the common strengths and weaknesses amongst faculty, and also presented implications for continuous quality improvement.

In the chosen Institute, Faculty Feedback on the basis of regularity, delivery of basic concepts, ability of explanation of applications, communication skills, blackboard & multimedia presentation, interactiveness, class control etc. is carried out. The students rate the faculty performance on a scale of 0 to 10.

Such feedback is compiled on a question wise basis for the entire division . The faculty performance for the entire Institute faculty is ranked for each question. Performances above average and those below average are awarded positive and negative Performance points (PP) .The group of faculty in a certain band are identified on the basis of Gaussian distribution.

The ranked performances are obtained and graded for all questions. However based on the significance and impact of each question a Weightage based Indexing (WBI) is done. E.g. a greater scalar multiplier is used for question based on Communication skill, presentation and delivery of concepts while the weightage for regularity is less. Once the scaling is done, an overall performance Index is calculated.

A sample table for obtaining Performance Index as a resultant is as shown in Fig. 2

Sr. No.	**Initial**	**PP For Q1**	**PP For Q2**	**Q1*1.25 (a)**	**Q2*1.5 (b)**	**PI (a) + b)**
1	SJ	2	-1	2.5	-1.5	1
2	MK	-3	-4	-3.75	-6	-9.75
3	MP	6	8	7.5	12	19.5
4	AM	8	7	10	10.5	20.5

Fig. 2 – Sample Performance Index Calculation

This feedback activity is carried out 4 times in the academic year. The performances of all 4 feedbacks are combined and the final Performance Index is calculated. The entire activity is shown in the flow chart as shown in fig. 3

PI Calculation for One Feedback(n)

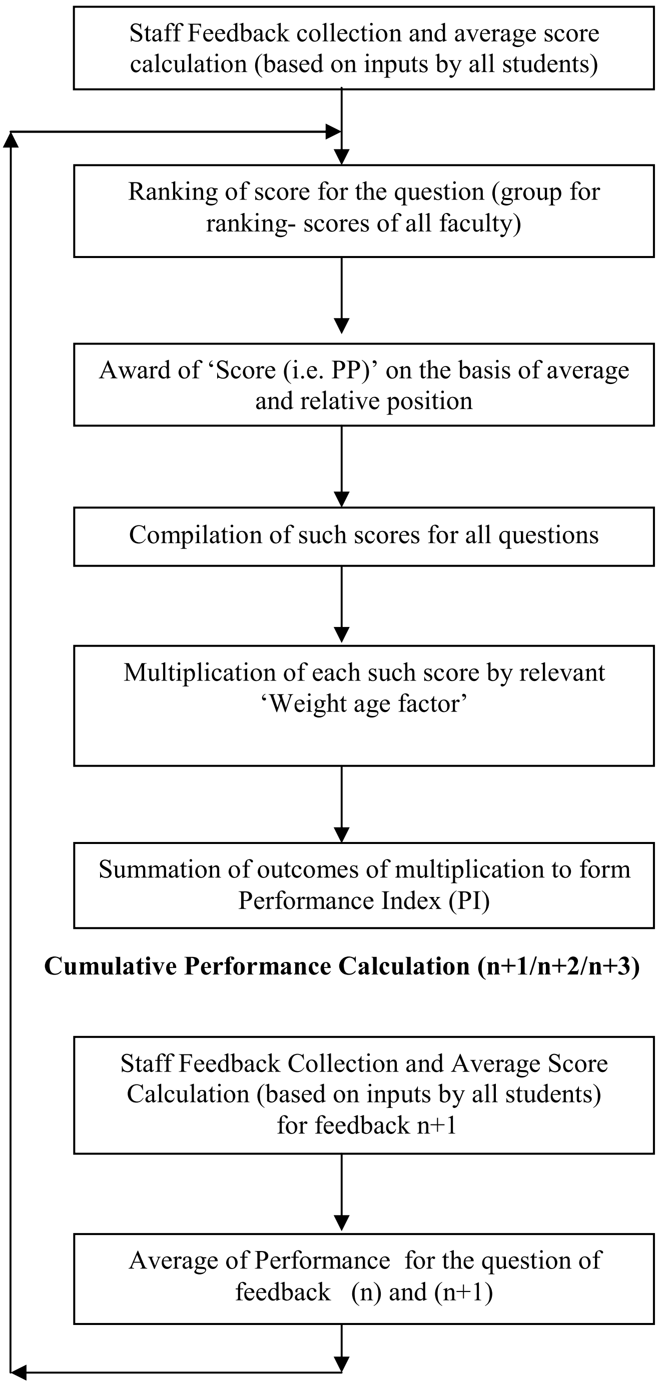

Fig. 3 – Flowchart – calculation of Performance Index

Areas B to F –

For Other areas , formats as shown in fig. 4 are designed. Based on the significance of the parameters credits are assigned.

fig. 4 (a) Area B : Teaching and Learning Activities

Sr. No.	**Parameter**	**Credits**
1	100 % conduction of assigned teaching load	10
2	Adherence to the paper setting and assessment deadlines (End Sem. Exam, Mid Sem. Exam, Class Test, etc.)	4
3	Course file and its regular updation	2
4	Release and assessment of Home Assignment as per schedule	2
5	Extra efforts for slow learners	2
	Total Number of Credits	**20**
	Performance Index (PI) = $(S_1 \times C_1 + \ldots\ldots + S_5 \times C_5) / 20$	

fig. 4 (b) Area C: Faculty Attributes

Sr. No.	**Parameter**	**Credits**
1	Teaching performance	4
2	Technical knowledge of subjects	4
3	Discipline	2
4	Regularity & punctuality	2
5	Attitude towards colleagues	2
6	Attitude towards students	2
7	Motivation towards work	2
8	Awareness of technical education sector	2
9	Willingness to accept responsibility and take decisions	2
10	Willingness to contribute besides office hours as per need	2
11	Willingness to learn	2
12	Ability to do and get good quality work done	2
13	Behavioral aspects	2
	Total Number of Credits	**30**
	Performance Index (PI) = $(S_1 \times C_1 + \ldots\ldots + S_{13} \times C_{13}) / 30$	

fig. 4 (c) Area D: Academic Extension Activities

Sr. No.	Parameter		Credits
1	Syllabus enrichment by providing additional resources to students		2
2	Use of participatory and innovative teaching - learning methodologies		2
3	Contribution towards theory and laboratory course development		2 / course
4	Contribution towards GP / PD / SD / OE / Elective course development		2 /course
5	Conduct of Continuing Education Program		4 / program
6	Design and development of Diploma courses		4 /course
7	Design & development of Certificate courses		2 /course
8	Development of quality in-house projects		2 /project
9	Academic resource person		2 / session
10	Creation of industry exposure opportunities for students		
	a)	Internship	2 / group
	b)	Sandwich training	4 / student
	c)	Industrial visit	2 / visit
11	Attending faculty development program		2 / week
12	Attending industrial training of minimum one month's duration		6 / month

Fig. 4 (d)Area E : Co-Curricular Contributions

Sr. No.	Parameter		Credits (Per Activity)
1	Organizing Short Term Training Programs (Minimum 1 week)		10 for Co-ordinator / week 2 for team members / week
2	Organizing Workshops		1 for Co-ordinator / day
3	Organizing conferences		
	a)	International	10 for Co-ordinator 3 for Team Members
	b)	National	6 for Co-ordinator 2 for Team Members
3	Organizing guest lecture		1 / lecture
4	Services to community		2 for Co-ordinator 1 for Team Members / day

	b) National	6
I.R.G. (Internal Revenue Generation)		
1	Self sustained activities	3 credit per Rs. 25000 institute share
Development of Laboratory Experimental Setup		
1	As a part of curriculum development	4/ experimental set-up
2	As a Joint Venture with companies	6/ setup

IV. RESULTS

1. Classroom Performance of faculty

A tabular mapping of the same on the basis of various areas is done as under. Each column represents a parameter and each entry is the Performance Point (PP) given to the faculty

Staff	Regularity	Delivery	Communication	Presentation
AH	-2	8	7	9
GN	8	8	9	1
IK	6	7	8	7
DD	-6	-6	-5	-4
SG	9	1	-1	-2

In the actual database, 196 faculty for the current Academic year are considered.

Variance is calculated for all faculty to highlight the abnormality rank in a certain area.

Important conclusions such as the following can be drawn i) for faculty AH – the performance is excellent except the Regularity. ii) for faculty GN –presentation skills need to be improved. iii) faculty IK has a steady performance iv) faculty DD has a steady but poor performance v) faculty SG has only got excellent regularity

In the actual database applying the method for 196 faculty members , conclusions are derived such as

i) No. of faculty requiring communication skill training – 22
ii) No. of faculty requiring inputs for improving presentation skills – 15
iii) No. of faculty needing subject specific technical training – 18

The feedback is given by around 4000 students every time, hence covers out individual biases towards faculty.

In case of credit based activities, listed in Results pt. No. 2, 3 & 4, the faculty self Appraisal is followed by appraisal by mentor and Head of Department. This averages out self bias if any. The claims made by faculty are verified through documentation support.

2. Teaching – learning activity & Faculty Attributes -

As can be seen from the table listed above, the performance of the faculty is calculated using a Performance Index (PI) , while the faculty earns 20 and 30 credits resp. in these 2 areas.

The faculty is expected to perform on all parameters in the Teaching – learning areas.

The scores in the two areas mentioned above are recorded for all 196 faculty.

3. Academic Extension Activities and co-curricular contributions

These are open ended areas for faculty to earn credits. Based on the requirements of the Department or the Institute, as well as individual interests and abilities, the faculty members tend to involve themselves in a variety of Academic Extension activities, as well as in many co-curricular contributory areas.

4. Research Activities

As shown in the table, a faculty is encouraged to be involved in a number of research activities.

The Institute offers the faculty all basic support desired to contribute the research activities.

V. OUTCOMES OF CYCLE AT THE END OF ACADEMIC YEAR

In the recently concluded Academic Year, this activity has resulted in the following outcomes shown here on Department wise basis as well as in terms of overall Institute performance

1. Classroom Performance of faculty –
Average Institute Performance Index – 13.155
The Indices for Departments are as shown below in Fig. 5

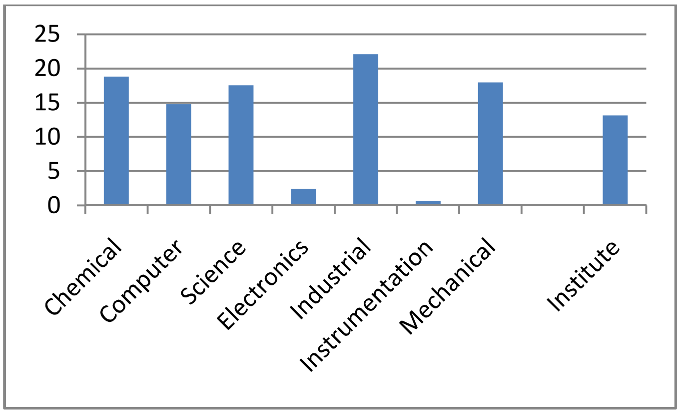

Fig. 5 – Performance Indices for Institute and Departments

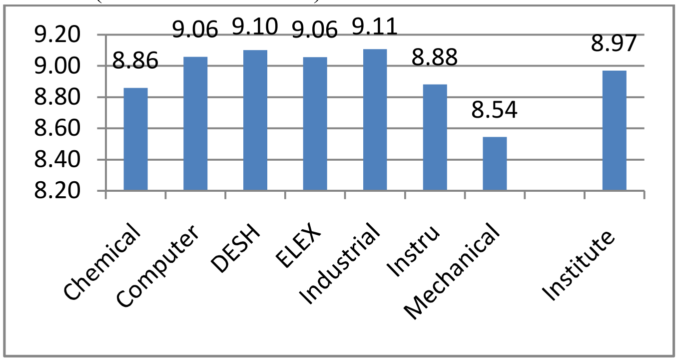
Head of Department of Instrumentation and Electronics are informed to emphasize more on improvement of Quality of Teaching – Learning.

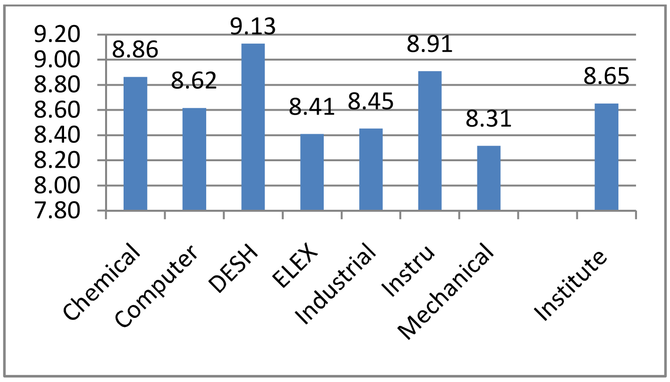
The faculty is deputed for Pedagogical training and various classroom performance improvement workshops.

A number of in-house activities are also carried out by well appraised faculty of the Institute.

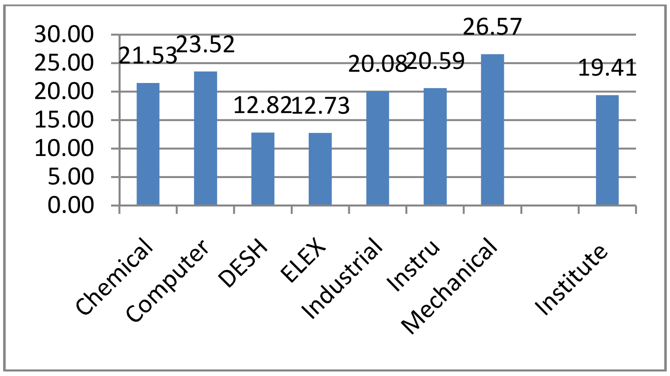
2. Teaching and Learning Activities (on a scale of 0 to 10)



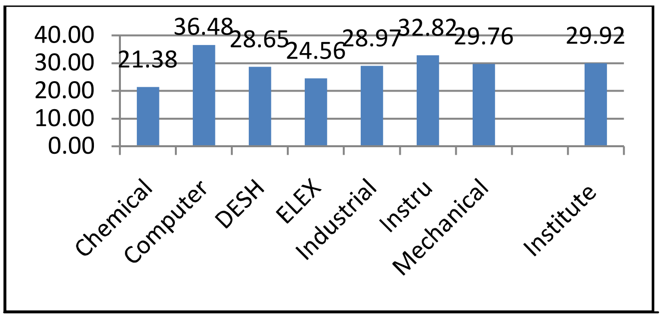
3. Faculty attributes (on a scale of 0 to 10)



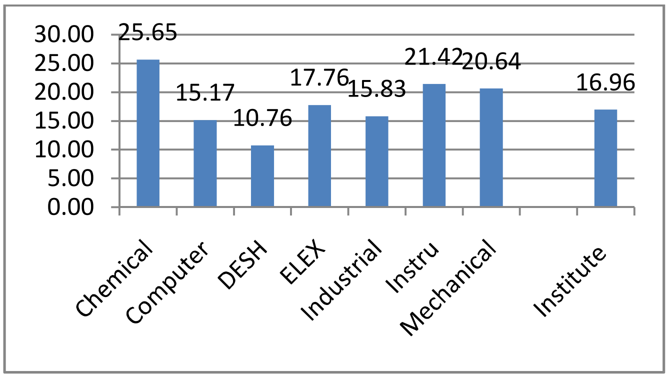
4. Academic Extension activities



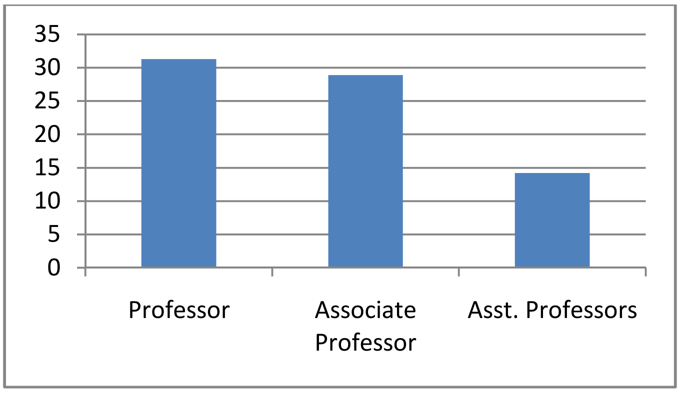
5. Co-curricular Contributions



6. Research Activities



Cadre wise Research Contributions



VI. BENEFITS

1. The planning and benchmarking in various areas or across the Departments is possible through this exhaustive analysis
2. The Institute implements ISO 9001:2008 Quality Management System. It helped streamline the entire compilation of outcomes at individual as well as Institute level
3. The preparation of documentary evidence for the National Accrediting bodies such as National Board of Accreditation (NBA) and National Assessment and Accreditation council (NAAC) is automatically done as a benefit of this activity.
4. Cadre wise targets – especially in the area of Research are given to Professors and Associate Professors in the subsequent areas.
5. Based on the identified areas of involvement of faculty, the Department and Institute activity plan is prepared.

VII. FUTURE PLANS

Some approaches such as 'Format Concept Analysis (FCA) as used by [9] are being studied for a more systematized approach. Effective conversion of the observations when collected over the span of 3 years can be made into defining the short range and long range goals for the Departments and the Institute.

Abstract— **The achievement of different university degrees (from graduate to the specialization, master's and doctoral) usually is related to the development and presentation of research results conducted by an Academic Advisor. However, their finalization or the results may be adversely affected by the lack of identification of risk that may present themselves during the process of construction and development of the research. To minimize these impacts, the present study was based on the alignment and adjustment of processes present in the Project Management Body of Knowledge (PMBoK), a specific guide that consolidates the best practices of project management from the Project Management Institute (PMI), and the use of Failure Mode and Effects Analysis (FMEA). From such elements and the identification of factors relevant to the educational institution involved and the processes related to the advisory and development of scientific research, it was sought to build a proposed risk analysis in the academic, named Academic Project Risk Management Plan (APRMP). This aims to contribute to the discussion and gathering information that can support the Advisor and the student at all stages of the research (planning, development and conclusion) that downside risks are avoided or minimized and that opportunities become clear and effective possibilities.**

Keywords—risk management; scientific research; PMBoK; advisoring.

I. Introduction

The development of scientific research constitutes a challenge for the students of higher education, graduate school, etc. especially because it has to be finished on time, with the depth degree required or even with the quality expected by the advisor. These issues affect not only the projects in academic area as projects in general. That is why it has been studied and mapped over the years by the Project Management Institute (PMI) [8], who also built project management guidelines (consolidating a guide named Project Management Body of Knowledge – PMBoK) from the best practices identified [7]. Even one of the factors influencing this scenario involves failures in risk management.

In the case of scientific research carried out for obtaining the degree, it can be point out that the risk management allows the reduction of problems throughout the investigation, and identification of factors that imply changes (whether in scope, timeline, resources , etc.), which results in increased chance of completing the search in accordance with the proposal.

The conduction of risk management is related to the mapping of factors involved in Educational Institution, especially in processes relevant to the scientific research development (under supervision) as well as the analysis of the Research Advisory Breakdown Structure (RBAS) [5] and the Academic Research Project Plan (ARPP) [5]. From this context and the use of FMEA (Failure Mode and Effects Analysis) [3]-[10] is possible, through analysis and planning meetings, set up a risk management plan in academic scientific research (RMPASR).

To deepen these introductory elements of risk management in academic research projects, this paper is organized as follows: section 2 describes the steps involved on management of scientific research projects and its overall structure; section 3 addresses from setting up risk as this is characterized in the academic field, and strategies to reduce, prevent or eliminate risks in this context; section 4 deals with the use of FMEA as a tool associated with risk management in academic scientific investigations; section 5 presents the proposal of a risk management plan for academic research; and section 6 provides the conclusions of the study as well as further work arising from this.

II. Stages for Academic Management of Scientific Research

Considering the institutional needs, as well as the people involved in the management of academic research (ie, the Advisor and the Course Coordinator, regardless of the degree involved), it becomes necessary to introduce a way of managing such process. Therefore, it can make an adaptation of processes under PMBoK [7] for the mapping and development of academic investigations.

In this sense, the Academic Management of Scientific Research Projects covers a variety of processes that can be adapted or inspired by similar elements present in PMBoK [7]. Among these are highlighted the development of a Project Charter focused on Research Advisory Breakdown Structure

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

(RBAS) [1], the own establishment of a RBAS, as well as a pertinent Dictionary [5].

A Project Charter [5] formalizes the beginning of scientific research project under the supervision of an advisor (and a co-supervisor, if applicable), gathering information relevant to its early stages, in addition to being a tool for decision during the research. This deliverable includes, therefore, the project scope for academic research, the expected results (both, from the institution or the advisor), the identification of macro tasks of scientific research (for periodic control) and the deadline for finish investigation.

Such information, upon approval, is broken down subsidizing the development of a Research Advisory Breakdown Structure (RBAS) [5]. This, through decomposition and hierarchy of elements present in the Project Charter on "work packages" [7], aims not only graphic visualization of parts of the research that can be delivered over its implementation, as well as configuration of its life cycle.

From RBAS the Dictionary can be built [PMI, 2008]. This aims to map the integral elements of RBAS and have acceptance criteria. Thus, each work unit is identified as the expected result and the degree of acceptability [5].

In fact it is possible to compare the result of the Dictionary prepared with a kind of educational rubric, i.e. a structure consisting of specific criteria (scored and described) for review [2]. Considering each of the characteristics inherent in the balance is the decomposition of a task into smaller parts, and each applicability of this strategy is a written communication (organization / textual expression) [11]. It can be inferred that such a device is aligned due to its architecture, to the pertinent Dictionary described above.

It should be highlighted also that the rubrics allow student/students in process-oriented view of the evaluation process dimensions [2], as well as contribute to the development planning of quality researches [1]. Finally, it should be noted that this proposed Dictionary is, by analogy, a kind of holistic rubric. This is because it has a single score (lower levels) for performance evaluation of student/students.

The set of deliverables detailed above, therefore, provides grants that contribute to the management plan developed for an academic research project. The latter presents, through the use of scientific language, the theoretical framework adopted, the expected results and schedule (macro activities, as well as dependencies). In order to complement this deliverable, it can also provide an attachment with the quality level required by the institution, risks and opportunities, forms of communication between people involved (students, advisors, institution; synchronous, asynchronous; face, online, hybrid, etc.) and strategies for monitoring and control a scientific research project (which provides for the preparation of meeting minutes and development of research reports).

Also is possible to emphasize that the Academic Research Management Plan, as well as other types of project deliverables, run in knowledge areas provided by the PMBoK [7]: Integration Management, Scope Management (both previously worked), Time Management, Quality Management, Communication Management, Cost Management, Procurement Management, Human Resources Management and Risk Management – theme explored in the next section.

III. The Concept of Risk to its Characterization in the Academic Research Area

According to the PMI [7], risk can be characterized as an event or uncertainty (due to one or more causes) that, if happens, resulting in positive or negative impact in the project. The origin or causal element of a specific risk may stem from a circumstantial condition or requirement of a premise of the project itself or even a restriction. From the academic point of view, it can be considered the following examples:

- Circumstantial condition – lack of specific equipment (that can be purchased, borrowed, etc. in another time);
- Requirement/Premise – fluency in a particular programming language present in the student academic curriculum;
- Restriction – time required for the research, number of members in a group of researchers, etc.

The existence of risk does not necessarily imply the change or abandonment of the project. It is necessary to analyze them in relation to the degree of its acceptability and tolerance and mapping its implications, whether these are negative or opportunities, that may be obtained from the risk probabilities calculation. In this sense, a project requires a proactive approach to risk management; otherwise the severity of the event may result in project failure [8]-[6].

Therefore, managing risks in a scientific investigation to achieve a particular degree, presents a series of advantages, among which the following:

- Construction of a reliable framework for design research and decision-making throughout their realization;
- Visualization of the threats/opportunities relevant to research (which allows to establish mechanisms for the reduction or mitigation of threats and exploiting opportunities, including taking into account the terms and requirements associated with research publication, if applicable);
- Analysis of variables that integrate the risks directly related to the issue of scientific publication selection (time, scope, research results (partial/complete), scientific publication – journal or event – impact factor, and other related topics involved in decision making);
- Reduce the number of contingencies.

From the PMBoK viewpoint [7], the risk involved in the academic research can be adapted as described below:

- Management (setting as risk management will be performed in the development of scientific research under the supervision of an advisor);

- Identification (lifting of risk to research and documentation of their specifics);
- Analysis (qualitative – classification/prioritization of risks through assessment of occurrence versus impact in the context of the project – it can be classified as low, medium or high; quantitative – measuring the probability of occurrence and consequences of the estimate for the project, which depends substantially on the experience of the advisor provision by this, and a risks knowledge base relevant to the field of research area);
- Planning (establishing procedures to analyze the opportunities and minimize possible risks to the research, i.e., in a practical way to structure alternative paths that achieve the objectives set for the research planned in the time provided and with the resources available; for this the advisor and the student/students should hold meetings with regularity).
- Monitoring (involves controlling residual risks, as well as identifying other risks not mapped to this stage and, simultaneously, the institution of plans which enable the reduction of the risks impact and evaluation of the effect of risk management throughout the academic research project).

Regarding the analysis process, it is also important to highlight the historic [6] due to previous advising procedures. This can contribute positively to the performance of the advisor as a leader and mentor of scientific research as well as for monitoring throughout the process of conducting research. Also in relation to this process, the quantitative characterization of the risks can be drawn from the use of tools such as SWOT analysis (Strengths, Weaknesses, Opportunities, Threats), Decision Tree, Brainstorming [4], Failure Mode and Effects Analysis (FMEA) [3], among others.

Another detail to consider, with regard to planning, involves drawing up a contingency plan [6]. Such proposal must also consider effects or undesired side effects due to the implementation of these measures. Considering that the preparation of contingency plan depends on the preceding steps, especially a correct analysis, that consider the FMEA framework as a complementary strategy for quantitative analysis in the academic development of scientific research.

IV. Failure Mode and Effects Analysis in the Context of Academic Development Of Scientific Research

The framework named Failure Mode and Effects Analysis (FMEA) was developed by the U.S. Army in order to eliminate problems/defects/errors in equipment that could not suffer intervention after the launch into space [3]. The FMEA framework aims to prevent failures are up in products, services, processes or systems purchased by the consumer. Thus, the FMEA is a method of examining all aspects in which failures can occur [10].

In the academic context, it is essential not only to identify potential risks depending on the type of research conducted, but also the analysis of their impact and the probability of occurrence in order to establish prevention strategies and monitoring. Therefore, it is also necessary to work with the recognition of factors that may be the generators of such risks, analyzing their dynamics over time to define mechanisms of prevention, mitigation and transfer.

The application of this framework begins with the following steps: "failure mode" (problem identified), "effect" (consequences) and "cause" (source/sources of failure). Although there is no single linearity and correlation between failures and causes, what makes a list an essential element for the construction of FMEA. From this, it is possible to classify the impact, the ability to recognize the failure (including his way of detection) and frequency of occurrence, and its product generates the Risk Priority Number (Risk Priority Number) [10].

However, it should be noted that although the contribution they can bring to the FMEA analysis and management problems in scientific research, it is necessary to choose a complement dynamic to complete the process of risk analysis. It is necessary because the FMEA turns to threats, i.e. to the negative aspects of the risk. However, its use associated with the PMBoK [PMI] can contribute in different ways, each in the risk rating (which includes strategies to Prevent, Mitigate and Transfer).

The concatenation of the elements presented in the preceding sections enabled the construction of proposal for a Risk Management Plan tailored to the specific scenario of scientific research in order to obtain an academic degree (under the supervision of an advisor).

V. Proposal of a Risk Management Plan in Academic Scientific Research

As already noted before, the development of the Risk Management Plan involves combining elements of FMEA [3] and PMBoK [7]. In this sense, the Risk Management Plan must provide information that identifies the research (theme and temporary title), the author/authors, the higher education institution where the research will be performed, course and degree of the student/students, advisor (and even co-advisor if is necessary), text versioning, and responsible for approving the plan.

Such documentation also requires the enumeration of processes relevant to risk management in scientific research, as well as the construct of a Risk Breakdown Structure for Academic Research (RBSAR), as exemplified below:

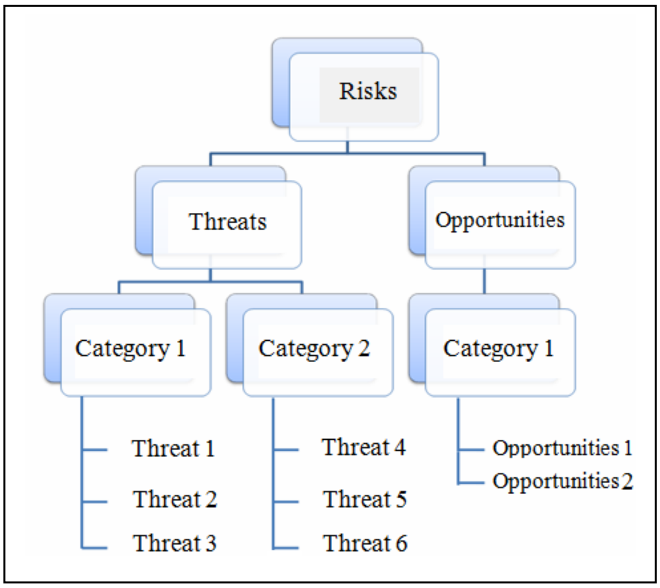

Fig. 1. Example of RBSAR

By the same token, the documentation also requires presentation of the dimensions of risk (qualitative, which involves the probability of occurrence and impact in scientific research, and the quantitative constructed based on FMEA framework).

From this, is possible to establish a plan to response to the risks identified (Table 1). This should match (in order to obtain a numeric parameter) the probability of occurrence, impact, severity (product of the probability impact for probability), the capacity of detection and identification of risk category for academic research. The product result in a risk priority number, with its dynamics must be monitored over time to allow the taking of actions required for the maintenance of academic research.

TABLE I. PLANNING RESPONSES TO RISKS INDENTIFIED

Risk <Identification of the Risk to Academic Research>							
P	***R***	***S***	***D***	***C***	***NRP***	***Description of risk response***	***T***

[a.] Label: P – Probability of Occurrence; R – Research Impact; S – Strictness (Impact versus Probability); D – Detection (Ability to identify the risk); C – Risk Category for Academic Research; NRP – Number of Risk Priority; T – Dynamic over time.

It is also worth noting that risk management should be integrated with other deliverables relevant to the scientific research development in order to establish an overview of this. This scenario is represented in Figure 2.

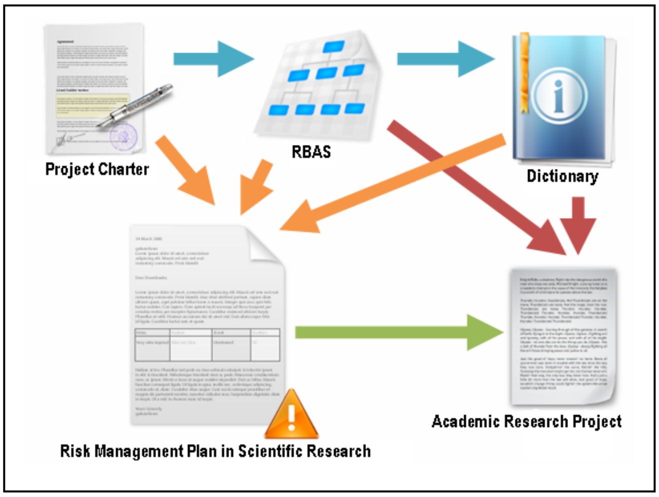

Fig. 2. Integration of deliverables of an Academic Research Project

VI. CONCLUSIONS AND FURTHER WORKS

From the analysis of elements in the area of project management and, more specifically, the PMBoK [PMI, 2008], and his combination with FMEA [3]-[10] it was possible to achieve an alignment of risk management according the specialties of scientific research development under the supervision of an advisor. This resulted in the mapping of elements that need to be included in the Risk Management Plan of Scientific Researche. It is believed that such subsidies (either in full or in part) may contribute to the reduction of uncertainties and the development and conclusion of scientific research with quality, on time schedule, and meet the established scope.

Regarding further works, it is still necessary to analyze the degree of impact exerted by the elements described in view of the proposed calibration and setting weights for these indicators that compose the proposed risk management of scientific research project.

Future studies also involve the construction of an expert system that can be used by the advisor, during the orientation process, to monitor their advisees, as well as for identifying and management of risks that may impair or constitute opportunities throughout development an academic research.

feelhs41@gmail.com

Abstract— **Modern mathematics careers are now requiring conceptual skills such as, critical thinking, modeling, and application of the content. This change in skillset needed for careers has strongly impacted mathematics curriculum and assessment. Meaningful assessment involves examining students' ability to inquire, to reason on targeted questions or tasks, and to promote conceptual understanding, not just focusing on discreet facts and principles. Mathematics assessment tools still focus solely on this procedural side of understanding mathematics instead of the equally important conceptual aspect of learning mathematics. Given that math is an active process that encourages higher-order thinking and problem solving, an assessment focusing on the growth of conceptual understanding is required. The proposed research focuses on the development of a tool that will be used to assess current U.S. calculus students' ability to apply their conceptual understanding of a mathematic concept to scientific phenomena through modeling. The assessment using Netlogo would be very useful for math educators to have good tools to assess students' conceptual understanding, as well as to develop instructional strategies used.**

Keywords—STEM; procedural knowledge; conceptual knowledge; NetLogo; Assessment

I. INTRODUCTION

Calculus is the capstone of K-12 mathematics curriculum. Within the domain of calculus, rate of change is a key concept that is introduced to students in algebra 1 and is foundational to calculus. Conceptual understanding of the reflectivity, *generativity*, and implicatively of *rate of change* is fundamental to students' study of calculus [1,2]. *Procedural* mathematics content knowledge focuses only on reciting algorithms and facts, whereas *conceptual* mathematics knowledge emphasizes students' ability to interconnect mathematics across disciplines, critically think about the content, and communicate key components of mathematics [3.4].

Mathematics assessment tools often focus solely on this *procedural* side of understanding mathematics instead of the equally important *conceptual* aspect of learning mathematics [5,6]. This is due to the restrictive nature of traditional multiple-choice assessments [7]. An alternative assessment tool that could quantify both students' *procedural* and *conceptual* understanding of mathematics could result in alternative instructional materials and methodologies.

NetLogo is a modeling computer language used to create an integrated environment. Students, acting as the modelers, are given tools to represent basic elements of a system. Then the program provides a way to simulate the interactions between these elements. With NetLogo, students write rules for hundreds or thousands of these basic elements, specifying how they should behave and interact with one another. These individual elements are referred to as *turtles* [8]. Students exploring within NetLogo have been able to develop their understanding of rates of change through modeling scientific phenomena [2;9].

II. PURPOSE OF RESEARCH

The purpose of this research is to transform a modeling unit within the NetLogo agent-based modeling program to assess students' conceptual understanding of a key mathematics concept. Students that are successful in high school calculus are likely to choose STEM fields for their college studies [10]. Students on this STEM path should be prepared to apply their understanding of various Calculus concepts to their STEM fields. Therefore, current calculus students should have the ability to connect and apply their understanding of rate of change to another STEM domain. This leads to several questions: 1. How can NetLogo be re-designed as a tool to assess students' conceptual understanding of 'rate of change'? 2. Is students' procedural understanding of rate of change a positive predictor of students' conceptual understanding of rate of change?

III. Background

A. Assessment

Current STEM curricula are beginning to promote the inclusion of higher-order thinking skills [11]. Higher-order thinking skills, related to sophisticated cognition, are difficult to measure with the use of multiple-choice tests. Standard, paper and pencil tests do not accurately measure 21st century skills. These tests are usually composed of low-level facts and recipe-like procedures [7]. This is not the only shortcoming of the current educational climate. State curriculum standards in each discipline are neither inter-related nor prioritized to emphasize core understandings and performances all students will need to succeed in the 21st century, despite the call for interrelated curriculums [11]. There is also a call for students to exhibit higher-order thinking skills, since a successful problem solver must be able to apply different approaches to a problem [12]. Students must demonstrate unusual, original, and creative solutions to various real-life problems, which is difficult on a multiple-choice test.

As a consequence of this misalignment between call for reforms and current assessments, teachers are using weak but rapid instructional methods to pass these limited scope assessments instead of preparing students for 21st century citizenship. These summative, "drive by" tests provide retrospective feedback, rather than immediate feedback that could influence future instruction [7].

Some International tests, such as Program for International Student Assessment (PISA), make attempts to emphasize core ideas and measure higher-order thinking skills. US students are scoring below many of their International peers on this test, but these test do not have the high stakes and accountability standards that state mandated standardized tests posses [7]. Therefore, these lower scores do not impact curriculum and instruction. Modern technology could provide a platform to improve US standardized tests to include assessment of higher order thinking skills, but a lack of resources, as well as, a fear of academic dishonesty has resulted in banning technology from testing. If the goal of assessment is to measure particular expectations, and the current call for students is to exhibit higher-order thinking skills, the assessments themselves need to change.

B. Modeling

Research suggests that modeling tasks "provide opportunities for greater diversity of thinking than is usually found in problem-solving tasks and that the development of students ideas occurs along multiple pathways" [12]. Students develop conceptual understanding of various mathematical concepts when they are engaged in modeling activities that require they research, create, and revise models [12,13].

Modeling is "nominally generative," meaning students are asked to use a prescribed model (single pathway) to create computed outcomes that are often mechanically compared to the actual data collected [15]. Ideal modeling occurs when the learners create a range of models and use them to generate model outcomes. In an agent-based modeling approach-student can model at the individual (elemental) level, rather than an aggregate approach [8]. Modeling tasks need to be composed of multiple-pathways and multiple-outcome tasks. The underlying constructs of othese modeling tasks should be mathematically or scientifically significant [15].

Central to computational thinking is the idea that, given a complex problem, which consists of many different, interconnected parts, one can meaningfully and sensibly decompose the problem into more solvable sub-problems [11]. Breaking down a problem is not a haphazard process. Deep understanding of the systems involved and how they interrelate is required in order to meaningfully break up the problem into pieces that still make sense in relation to the whole. Students that are successful in high school calculus are likely to choose STEM fields for their college studies [10].

Computational thinking and computational problem solving involve a process of revision and iteration. "Use-modify-create" is a pedagogical model that allows students to become familiar with a type of program by using it, then modifying it a bit to make it their own, and finally creating their own program from scratch. In this process, students are applying computational thinking to solve problems and using higher-order thinking skills.

Modeling provides a new perspective of the methodology of math [16]. A detailed analysis of modeling provides characterization of problem solving as a coherent system for constructing models in any mathematical domains. Modeling begins with a physical situation with which we wish to understand [17]. Understanding comes from making, analyzing and evaluating a model for the situation. The situation may be presented to us in any form; for example, predicting the path of a projectile in the study of quadratic functions. From examining the situation, our first task is to come up with a suitable model in diverse ways. Sometimes, we can simply adapt a familiar model to the situation. In any case, students' understanding of what constitutes a model is a useful guide for what to do. The first step of this process is to identify the system [17], then specify precisely what it is we want to model, and then identify the properties of interest and specify variables to represent them. When a model has been constructed, it must be analyzed to understand its structure and implications. The final step of analysis is validation, which is the process of assessing the adequacy of a model to represent a particular system and situation. A full assessment of the model's validity will include an assessment of what is neglected in the model as well as the accuracy of the representation.

III. Research Methodology

A design-based approach will be used to answer the question, How can NetLogo Hotlink Replay be re-designed as a tool to assess students' conceptual understanding of 'rate of change'?

Instructional designers will begin with the NetLogo modeling activity for rate of change in which students model the effects of introducing an infection into a population and manipulate various components (i.e. initial number infected, identifying the infected). While exploring with this activity, students are able to develop a conceptual understanding of the calculus topic of rate of change [18]. Researchers will use a design-based approach to repurpose this activity into an assessment of students' conceptual understanding of rate of change, using an extension of Hotlink replay [9]. Year 1 of the project will focus on development of this tool through iterations of design, utilize, and revise.

Programmers will incorporate prompts and challenges into the Hotlink replay interface. For example, students may be prompted to create a model of an infected agent entering a population and moving randomly throughout the population after viewing the visualization of their model, students may be asked to change the components such as making the graph steeper.

Student participants will be chosen from either algebra 1 classes or calculus classes at the end of the year. The participants will complete the first iteration of the assessment, then they will be interviewed on the topic of rate of change with an interview protocol that focuses on procedural (i.e. the use of slope formula to calculate slope) and conceptual (applying rate of change to graphical representations of biology concepts to make conjectures) understanding of rate of change. Qualitative analysis of the transcriptions will be done to identify evidence of conceptual and procedural understanding of rate of change. The same students will then follow a think-aloud protocol while taking iterations of the assessment. Over year 1, three iterations of design, utilize, and revise will be used to transform the modeling activity into an assessment of procedural and conceptual student understanding.

Once the assessment has been revised and the research suggests that the score associated actually matches the qualitative analysis of students' conceptual understanding of 'rate of change,' then scores on the assessment will be used to answer the second research question: Is students' procedural understanding of rate of change a positive predictor of students' conceptual understanding of rate of change?

During year 2, the algebra 1 and calculus student participants will be assessed using the designed NetLogo modeling assessment as well as taking traditional, multiple-choice assessment on the topic of rate of change. This traditional assessment will be designed mirroring the types of multiple-choice questions on traditional standardized assessments that test understanding of 'rate of change'.

The teacher participants will assign each student 4-digit number to de-identify the student scores. If collected data show normal distribution, a series of paired t-test for within group comparison will be performed to determine if significant difference existed between procedural scores versus conceptual scores. When the normality assumption is violated nonparametric method like the Wilcoxon signed ranks test will be used. We will use SPSS 21 version for analysis. The SPSS data output will demonstrate basic descriptive statistics for samples and variables, correlation table, and the matched mean difference between the pairs.

IV. Implications

Research suggests that the ideal classroom environment is the use of technology to assess student learning and inform math instructors' ability to prepare students for STEM career paths. One of the primary objectives of this proposed work is to redesign a NetLogo simulation to assess students' conceptual understanding of mathematics. This assessment will assist the educational community to establish students' understanding of rate of change and potentially design a new math curriculum. Our vision is that this assessment could result in a change in the mathematics curriculum. With the possibility of teaching students concepts earlier or have students take algebra 1 in 8th grade.

This project can potentially create a tool that will assess a skill that previous tools could not assess in mathematics. Since mathematics is key for engaging students in STEM careers and majors, having a tool that identifies the best and brightest will impact the future of the STEM field in the United States. The most innovative aspect of the proposed work is the use of NetLogo to assist student conceptual development of rate of change. This closer look at instruction using NetLogo will inform new forms of assessments designed to measure students' conceptual understanding.

Hartnell College
Salinas, California
mhornstein@hartnell.edu

***Abstract*— As a result of a partnership between the University of California Santa Cruz (UCSC) and a Hispanic-serving Institution, Hartnell College, a micro-grid and test bed facility are being constructed at Hartnell's Alisal campus. The facility will provide a real-world student training center on renewable energy technologies where students can participate in research to develop new, experimental renewable energy generation systems. Over the next several years, Hartnell's Sustainable Engineering laboratory courses will be transitioned to focus on the microgrid and test-bed. Related courses and lab modules developed at UCSC will also be integrated into the program. An early outcome of this collaborative partnership was the internship support of teams of high school and community college students working with UCSC graduate students on several different sustainable energy projects over the summer of 2012. Program mentors and interns all reported a high degree of satisfaction with their internship experience.**

Keywords—renewable energy, sustainability, microgrid, green technology, research internships, undergraduate research experiences

I. INTRODUCTION

Hartnell College, located in Salinas, California (see Fig. 1), is a Hispanic-serving, 2-year institution with an enrollment of approximately 10,000 students. Its Alisal Advanced Technology campus is bounded on three sides by agricultural fields and on one side by an underserved, urban minority neighborhood. See the lower inset in Fig. 1.

In 2011 Hartnell was awarded a 3-year grant from the National Science Foundation (NSF) to fund the Salinas Valley Consortium for Sustainable Energy, Education and Research. The aim of the Consortium is to create career pathways in electrical and sustainable design engineering. Partnering with local research institutions, non-profit organizations and high schools, a key component of this grant is to establish the sustainable energy laboratory and microgrid. To expand upon the growing success of Hartnell's sustainable engineering programming, Hartnell partnered with UCSC to develop a summer internship program focused on sustainable energy research and specifically 3 of UCSC's microgrid pilot projects in the California Central Coast region (see Fig. 1).

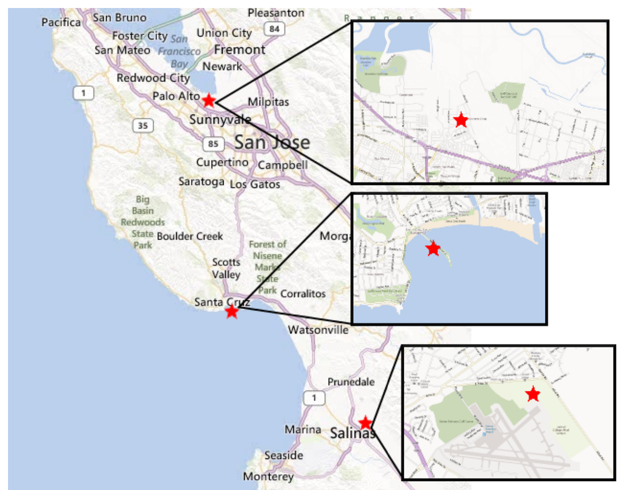

Figure 1 CenSEPs Microgrid Locations (north to south: NASA Ames, Santa Cruz Municipal Wharf, Hartnell's Alisal Campus)

The theoretical basis operationalized in conducting the internship program centers on "educational models that go beyond teaching codified "what" facts to models that emphasize "how": that train students in the transdisciplinary, collaborative ways of knowing-how." [6]

II. SUSTAINABLE ENERGY RESEARCH PROJECTS

To better prepare this unique assemblage of interns to produce high quality research outputs, all interns participated in various phases of research activities specific to each project along with a "professional development" program which discussed issues such as project presentation and project management. To complement the research activities and professional development, interns listened to presentations by energy researchers and engineering professionals relevant to the projects, and participated in field trips to renewable energy installations in the San Francisco Bay Area.

The three internship projects varied in the degree of definition and the role of interns in the projects evolved over the program. At the start of the program, after mentors introduced the projects in more detail, interns were asked to rank their first and second preference out of five possible overall projects. Students were assigned to teams of 3 to 4 interns each based on either their first or second choice project. Teams met 40 hours per week for 8 weeks and stipends motivated interns to complete tasks at project milestones.

A. Techno-economic modeling of facilities and microgrids[1]

The Alisal campus consists of three main buildings, each with its own energy demands. The energy needed to operate the industrial welding shop, multiple computer labs and servers, coupled with the lighting and HVAC system needed to condition these spaces, results in significant costs to the campus. Through energy demand models, student interns investigated opportunities to reduce energy costs, which could lead to a reduction of the campus' carbon footprint. Using HOMER micropower optimization software interns modeled the campus electrical systems. The software enabled students to understand the design trade-offs between different renewable energy system configurations, including Hartnell's microgrid, and identify the best economic scenario. Through simulations of varying configurations of wind turbines and photovoltaic arrays, students determined the optimal arrangement. The Hartnell administration will utilize this model in future energy planning for the Alisal campus.

B. Assessing electric vehicle charging station potential to store and be charged by renewable energy microgrid

Student interns conducted a feasibility study of integrating Hartnell's renewable energy microgrid with an electric vehicle (EV) charging station thereby reducing the carbon footprint of the EVs, through the leveraging of renewable sources. Using available wind and charging station data along with other assumptions, students tested the feasibility of integrating a microgrid with the charging station through extensive simulations with HOMER software. Interns determined that the planned wind-only microgrid requires additional components, including storage, in order to create a fully renewably-powered charging station. Student interns also made significant contributions to the data access platform that is in development including establishing the protocol connecting the EV station data to a centralized data collection server.

C. Designing sensor assemblies to facilitate wind turbine site selection and education modules

The goal of this research project was to establish a procedure to assess the wind energy production potential using technical criteria and converting it to a laboratory lesson. To measure wind speed, a key parameter, interns designed and erected a mobile 30-foot aluminum pole holding three equally-spaced anemometers and a temperature sensor, which was tested at multiple sites on Hartnell's Alisal campus. They also utilized acoustic sensors to establish an acoustical base line for the campus. The optimal location for the turbine was determined by the result of wind data analysis and sound pressure level recording devices using HOMER software. Student interns also updated an existing wind energy production laboratory module and created the basis for a new laboratory module on wind energy site selection to be used by both Hartnell and UCSC.

[1]Research project descriptions were adapted from each group's final Internship Symposium poster abstract.

III. RESEARCH OUTCOMES

Through the preparation and presentation of a research poster, groups shared their internship research projects in a final symposium, which convened all summer interns from all organizations taking part in the Consortium partnership. Student interns were administered pre- and post-internship surveys by an external evaluator consisting of 27 questions with a Likert scale for responses to assess their internship experience[3]. Of those interns who participated in both the pre- and post-internship surveys, 82% were male and 17% were female. Moreover 7 interns reported their ethnicity as Hispanic/Latino, followed by Caucasian/White (3 interns), Asian (1 intern), and Indian (1 intern).

A. Internship Experiences

Student interns who were administered both pre- and post-internship surveys to assess their internship experience (N=12) reported the following statistically significant ($P < .05$) changes in response to the following statements.

TABLE I. SIGNIFICANT CHANGES IN INTERN RESPONSE FROM PRE- TO POST- INTERNSHIP SURVEYS

Statement or Question	mean change	significance of change
I could use more help to get prepared for transferring to a university.	$\Delta m = -0.92$	p=.034
I am already very aware of academic scholarships, science internships, and other professional opportunities available to me.	$\Delta m = 0.75$	p=.032
I know what the work life is of a practicing scientist or engineer.	$\Delta m = 0.92$	p=.020
How confident are you now about your decision to pursue a STEM[2] career? (Note: N=11)	$\Delta m = 0.36$	p=.038

Seven of the 13 interns who completed the post-internship survey provided comments at the end of the survey. Six of the seven comments were highly positive in nature. The critical comment was constructive and offered suggestions on how to improve the effectiveness of the symposium component culminating the program.

Also of interest, further pre- and post-internship survey analysis focuses on student interns' intended university major and the highest degree to which they aspired. Analysis reveals notable changes in responses in the following statements or questions:

- Interns' plans to transfer to a 4-year institution increased from 11 to 12 interns after the internship program. Two interns participating in the survey indicated they had changed their responses regarding their intention to transfer as a result of participating in the research experience this summer from, from "not sure yet" to "yes."

[2] STEM is Science, Technology, Engineering and Mathematics.

- Most interns indicated they were considering plans to transfer to either a California State University or University of California campus in both the pre- and post-internship surveys, with two outliers considering other or private college options. This finding is consistent with overall matriculation trends for all Hartnell graduates.

- The proportion of interns who had decided on a major after the internship increased from 7 to 9 interns. Majors identified included mechanical engineering (3), Electrical Engineering (2), Civil Engineering (2), Biology (1) and Applied Physics (1).

- Asked whether the interns would be a STEM major for their bachelor's degree, 100% of interns responded "yes," an increase of 17% between pre- and post-internship.

- Four of twelve interns changed their responses when queried about their plans for the highest degree they planned to pursue as a result of their research experience this summer. "Two increased the highest degree they aspired to from 'Bachelor's Degree' in the pre-internship survey to 'Master's Degree' in the post-internship survey. Two went from 'Undecided' to either 'Bachelor's Degree' or 'Research doctorate" in the post-internship survey".[3]

The following comment summed up the experience for one intern, "It was a great satisfaction to work in the summer in what I feel passionet *[sic]* about. Thank you for providing me with the tools to continue with my career goals."[3]

IV. Conclusion

Building on previous engineering praxis work from our research center[4][5][6][7] and others[1],[8], the authors conclude that even top performing high school and community college students stand to benefit from an applied "how to do sustainable energy research" internship experience. The changes in student intern responses between pre- and post-internship surveys lead us to believe that the internship program was helpful in assisting students to clarify the expectations and pathways to a STEM-oriented major at a 4-year university, build aptitude and confidence in STEM abilities, and train interns in professional and research development. However, no change was observed in increasing consideration of local universities as a transfer possibility or identification of local universities as a top choice for interns planning to transfer, one aim of the program.

Based on the early findings of this work in progress and further reflection, the authors also recommended the following actions take place in refining the internship program for summer 2013:

1. With construction on the Hartnell microgrid now complete, program developers should focus projects on microgrid application in the Salinas Valley agriculture community.
2. Increase outreach to women students by engaging the partnering institutions' local chapters of Women in Science and Engineering and Women in Engineering.
3. Maintain a relevant and diverse field trip and guest speaker component in the program.
4. Provide feedback on Symposium structure to help increase effectiveness and efficient use of time.

Acknowledgment

The authors, first and foremost, thank the interns for their patience, perseverance and positive attitudes throughout the program. The authors also appreciate the time and expertise shared by the many professionals who came to talk with students about their career fields and answer questions about the student research projects. Finally, we thank the Hartnell staff of Andy Newton, Brenda Thrasher, Mike Thomas, Joseph Reyes, and Tito Polo for giving us access to the site, guiding us through paperwork, ordering and storing equipment, and driving to field trips. This internship program was supported by a National Science Foundation (NSF) Advanced Technological Education Grant 1104311 to Hartnell College and the course development supported through an NSF TUES / CCLI grant 1023054 to UCSC.

***Abstract*— This paper describes the use of a suitable approach to teaching generalized magnetically coupled electric circuits as an introduction chapter to the electric machines modeling and simulation course for power engineering students. The teaching methodology focuses on some common concepts and fundamentals of electrical machine theory such as machine inductances (self, leakage and mutual), equivalent circuits, magnetic circuits, iron saturation, reciprocal per unit system, state modeling and simulation, so that the modeling approach of each type of classical machine can easily be deduced from the general theory established by the chapter on magnetically coupled electric circuits.**

***Keywords*— Magnetically Coupled circuits; iron saturation; per unit system normalization, state space model, application and simulations**

I. Introduction

Magnetically coupled electric circuits are central to the operation of transformers and electrical machines, as specified by Prof. Krause et al. [1]. A good understanding of the theory underlying magnetically coupled circuits greatly simplifies both the teaching and the learning of transformers and electrical machines [2]-[4]. Therefore, for power engineering students, special attention should be paid to teaching magnetically coupled circuits, with an emphasis on their electrical machine structure, as the first chapter of the electrical machines course where transient modeling and simulations are included. The modeling of the equivalent electric circuits of electrical machines is based on magnetically coupled circuits. The modeling and simulation of electrical machines are great challenges for power system engineering students around the world. Currently, in many universities around the world, the magnetically coupled circuits are only taught in the 'electric circuits', which is a common undergraduate course for first year electrical engineering programs [2]-[4]. Although transient behaviors are included in 'electric circuits' course, the study of electric machines for undergraduate power engineering students is most of time still limited to the steady state performances [5]. Furthermore, there are not sufficient pedagogical links between the courses 'electric circuits' and many undergraduate textbooks treating electric machines which in general don't content magnetically coupled circuits [5]-[6]. Very few authors have realized the importance to insert the magnetically coupled circuits as the first chapter of their research textbook [1], [7]-[8]. However, even though the magnetically coupled circuits developed in [1], [7] included the saturation phenomenon and simulation analysis, their electrical models given in block-diagram form, are not flexible to adapt to the rotating machines study and control purposes.

As shown in the present work, the course on magnetically coupled circuits offers interesting opportunities to introduce main fundamentals of the electrical machines modeling and simulation. In this paper, generalized concepts that could be applied to all electrical machines analysis such as the state model, electrical equivalent circuits, per-unit system normalization, iron saturation, numerical simulations are introduced in a course on magnetically coupled circuits to facilitate the understanding and interest of future power engineering students commencing the study and analysis of electrical machines. Repeating these concepts over time when analyzing every type of electrical machine (redundancy principle) will increase the student's understanding of the pedagogical objectives to be achieved.

II. Equations of Generalized Magnetically Coupled Circuits

Magnetically coupled electric circuits with an adjustable number of coils are shown in Fig.1. The flux equations for n coils are given in (1) and reorganized in (2) while the voltage equations are defined in (3) [1]:

$$\begin{aligned}
\lambda_1 &= N_1\phi_{f_1} + \left(N_1/\Re_m\right)\left(N_1 i_1 + N_2 i_2 + \cdots + N_n i_n\right)\\
\lambda_2 &= N_2\phi_{f_2} + \left(N_2/\Re_m\right)\left(N_1 i_1 + N_2 i_2 + \cdots + N_n i_n\right)\\
&\cdots\\
\lambda_n &= N_n\phi_{f_n} + \left(N_n/\Re_m\right)\left(N_1 i_1 + N_2 i_2 + \cdots + N_n i_n\right)
\end{aligned} \tag{1}$$

$$\begin{aligned}
\lambda_1 &= \lambda_{11} + \lambda_{12} + \cdots + \lambda_{1n} = \left(L_{m_1} + l_1\right)i_1 + L_{12}i_2 + \cdots\\
\lambda_2 &= \lambda_{21} + \lambda_{22} + \cdots + \lambda_{2n} = L_{21}i_1 + \left(L_{m_2} + l_2\right)i_2 + \cdots\\
&\cdots\\
\lambda_n &= \lambda_{n1} + \lambda_{n2} \cdots + \lambda_{nn} = L_{n1}i_1 + \cdots + \left(L_{m_n} + l_n\right)i_n
\end{aligned} \tag{2}$$

$$\begin{aligned}
e_1 &= r_1 i_1 + L_{11}\frac{di_1}{dt} + L_{12}\frac{di_2}{dt} + \cdots + L_{1n}\frac{di_n}{dt}\\
e_2 &= r_2 i_2 + L_{21}\frac{di_1}{dt} + L_{22}\frac{di_2}{dt} + \cdots + L_{2n}\frac{di_n}{dt}\\
&\cdots\\
e_n &= r_n i_n + L_{n1}\frac{di_1}{dt} + L_{n2}\frac{di_2}{dt} + \cdots + L_{nn}\frac{di_n}{dt}
\end{aligned} \tag{3}$$

with:

$$L_{m_i} = \frac{N_i^2}{\Re} = N_i \frac{\phi_{m_i}}{i_i}; L_{ij} = L_{ji} = \frac{N_i N_j}{\Re} \;\; (i \neq j) \tag{4}$$

$$l_i = N_i \frac{\phi_{f_i}}{i_i} \;\; ; \; L_{ii} = N_i \frac{\phi_{m_i}}{i_i} + N_i \frac{\phi_{f_i}}{i_i} = L_{m_i} + l_i \tag{5}$$

The following relationships are derived between various variables and parameters of the coils:

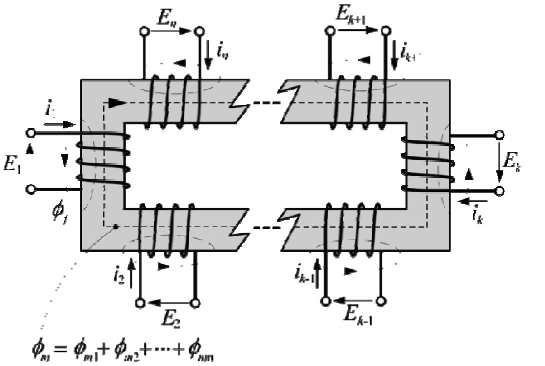

Fig.1. Coupled electric circuit with adjustable number of windings

III. Equivalent Circuit referred from Coil 1

The main objective when modeling an electrical system such as magnetically coupled circuits for the study of electrical machines is to derive flux and voltage equations such that the equivalent circuit without a galvanic link as illustrated in Fig.2 can be drawn. The Kirchhoff mesh and nodal laws can therefore be applied to the equivalent circuit model obtained for analysis and the solution of the physical magnetically coupled circuits. In order to achieve this goal, flux and voltage equations (2) and (3) will be modified so that the current, flux and voltage of a given coil can be observed or referred from coil 1. The concept of 'referred circuit' obtained by creating fictitious variables and parameters allows the galvanic link of Fig.2 to be removed between coils and, thus creates their electrical connection. In such a context, the ampere-tours ($N_j i_j$) in a given secondary coil *j* can be mathematically replaced by the fictitious primary ampere-tours ($N_1 i'_j$) so that the current in the coil *j* is given by its equivalent $i'_j = \left(N_j / N_1\right) i_j$ referred from coil 1.

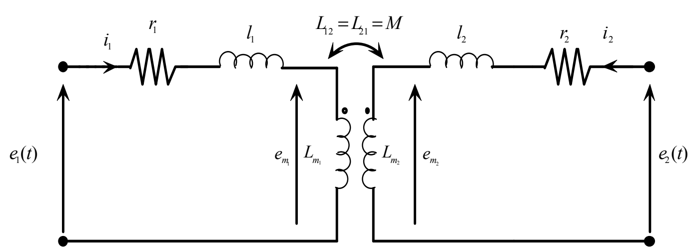

Fig. 2 Equivalent circuit of two magnetically coupled circuits without electrical connection (with a galvanic link)

$$\begin{aligned}
\lambda_1 &= \left(l_1 + L_{m_1}\right) i_1 + L_{m_1} i'_2 + L_{m_1} i'_3 + \cdots + L_{m_1} i'_n \\
\lambda'_2 &= L_{m_1} i_1 + \left(l'_2 + L_{m_1}\right) i'_2 + L_{m_1} i'_3 + \cdots + L_{m_1} i'_n \\
&\cdots \\
\lambda'_n &= L_{m_1} i_1 + L_{m_1} i'_2 + L_{m_1} i'_3 + \cdots + \left(l'_n + L_{m_1}\right) i'_n
\end{aligned} \tag{6}$$

$$e_1 = r_1 i_1 + \frac{d\lambda_1}{dt}; e'_2 = r'_2 i'_2 + \frac{d\lambda'_2}{dt}; \cdots; e'_n = r'_n i'_n + \frac{d\lambda'_n}{dt} \tag{7}$$

where:

$$\begin{aligned}
&a_{ij} = N_i / N_j; i \neq j; e'_i = a_{1i} e_j; i'_i = i_i / a_{1i} \; i \neq 1 \\
&\lambda'_i = a_{1i} \lambda_i; \;\; r'_i = a_{1i}^2 r_i; l'_i = a_{1i}^2 l_i; i \neq 1 \\
&L_{m_i} = L_{m1} / a_{1i}^2; L_{1i} = L_{i1} = L_{m_1} / a_{1i}; i \neq 1
\end{aligned} \tag{8}$$

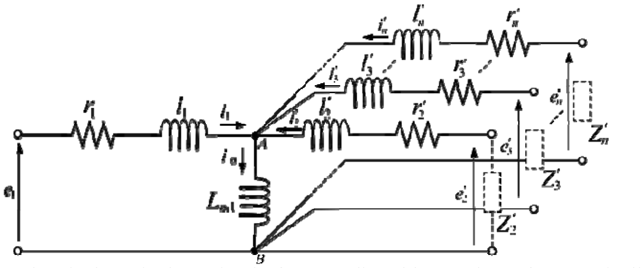

Fig.3. Electrical equivalent circuit for an adjustable number of magnetically coupled coils referred (observed) from winding #1 (primary)

According to the energy conservation principle, the power in the fictitious circuit and in the actual secondary should be the same ($e'_j i'_j = e_j i_j$). Introducing the above fictitious current and voltage referred from coil 1 in (2) and (3), the latter equations can be organized as given in (6) and (7) with the primary and secondary *j* both in motor mode (for example, in Fig.2, coils 1 and 2 absorb power from external sources). The equivalent circuit of the generalized magnetically coupled circuit of Fig.1 referred from coil 1 (in the motor mode) is given in Fig.3. It's important to observe that Fig.1 is quite close to electrical equivalent circuit of a variable reluctant synchronous machine with adjustable damper windings or multi-rotor windings induction machine. The magnetizing inductance L_{m_i} is also called the mutual inductance since $L_{m_i} = a_{ij} L_{ij}$.

IV. Normalization of Generalized Coupled Circuits: Per Unit System

A. Definition of Base Values

Normalization schemes are frequently used in power systems modeling and simulation. The per-unit systems applied for the normalization of electric machine equations are not more often clear to students. The great advantage of the normalization scheme is that the system equations are the same independently from which coil they are referred. The classical magnetically coupled circuits such as electrical machines and transformers are defined by the rated values of their individual circuits (*i*): apparent power S_{iN} (VA), voltage E_{iN} (V), current I_{iN} (A), and the rated pulsation $\omega_n = 2\pi f_n$ (rad/s); where f_n (Hz) is the nominal frequency of the primary winding voltage $e_1(t)$ (coil 1) supplied by the external network. In single-phase circuit analysis, as it's the case in this study, the base quantities for a given coil (*i*) are defined in Table 1. From this table is observed that for two arbitrary distinct coils *i* and *j*: $E_{ib} / E_{jb} = I_{jb} / I_{ib} = a_{ij} = 1 / a_{ji}$ thus:

$$E_{1b}I_{1b} = E_{2b}I_{2b} = E_{3b}I_{3b} = \cdots = E_{nb}I_{nb}$$
$$S_{1b} = S_{2b} = S_{3b} = \cdots = S_{nb} \qquad (9)$$

The above relationship (9) is fundamental and general in electrical machines analysis when system normalization is concerned. It states that: in the per-unit normalization, the VA bases of coupled circuits should be equal.

TABLE I: BASE VARIABLES OF COIL #*i*

Quantity	Base	units	Dimen.
Power	$S_{ib} = S_{iN}$	[VA]	[*ei*]
Voltage	$E_{ib} = E_{iN}$	[V]	[*e*]
Current	$I_{ib} = \frac{S_{ib}}{E_{ib}} = I_{iN}$	[A]	[*i*]
Impedance	$Z_{ib} = \frac{E_{ib}}{I_{ib}}$	[Ω]	[*z*]
Pulsation	$\omega_b = \omega_n = 2\pi f_n$	[rad/s]	[*1/t*]
Time	$T_b = \frac{1}{\omega_b}$	[s]	[*t*]
Flux	$\lambda_{ib} = E_{ib}T_b = \frac{E_{ib}}{\omega_b}$	[Wb-turns]	[*et*]
Inductance	$L_{ib} = \frac{\lambda_{ib}}{I_{ib}}$	[H]	[*et/i*]

B. Normalization of Voltage Equations

For given base voltages and currents E_{1b}, I_{1b}, E_{2b}, I_{2b}, $\cdots$, E_{nb}, I_{nb} for circuits of Fig.1, the voltages equations (3) of generalized coupled circuits can be organized as expressed in (10) where the index (*u*) indicates a per unit quantity:

$$\begin{aligned} E_{1b}e_{1u} &= r_1 I_{1b} i_{1u} + \omega_b L_{11} I_{1b} \frac{di_{1u}}{\omega_b dt} + \omega_b L_{12} I_{2b} \frac{di_{2u}}{\omega_b dt} + \cdots \\ E_{2b}e_{2u} &= r_2 I_{2b} i_{2u} + \omega_b L_{21} I_{1b} \frac{di_{1u}}{\omega_b dt} + \omega_b L_{22} I_{2b} \frac{di_{2u}}{\omega_b dt} + \cdots \\ &\cdots \\ E_{nb}e_{nu} &= r_n I_{nb} i_{nu} + \omega_b L_{n1} I_{1b} \frac{di_{1u}}{\omega_b dt} + \omega_b L_{n2} I_{2b} \frac{di_{2u}}{\omega_b dt} + \cdots \end{aligned} \qquad (10)$$

with:

$$\begin{aligned} r_{iu} &= \frac{r_i}{E_{ib}/I_{ib}} = \frac{r_i}{Z_{ib}}; L_{iiu} = \frac{L_{ii}\omega_b}{E_{ib}/I_{ib}} = \frac{L_{ii}}{\lambda_{ib}/I_{ib}} = \frac{L_{ii}}{L_{ib}} \\ L_{iiu} &= \frac{L_{ii}}{L_{ib}} = \frac{L_{ii}\omega_b}{Z_{ib}} = \frac{X_{ii}}{Z_{ib}} = X_{iiu} \end{aligned} \qquad (11)$$

According to relationships (11), the reciprocity of the mutual inductances should be preserved in (12) (since $L_{ij} = L_{ji}$). Another important result obtained from the per-unit system normalization is that mutual inductances should be equal as expressed in (13) (derived from (12)).

$$\begin{aligned} \omega_b \frac{L_{ij} I_{jb}}{E_{ib}} &= \omega_b \frac{L_{ij} I_{ib}}{E_{ib}} a_{ij} = \frac{L_{m_i}\omega_b}{Z_{ib}} = L_{m_i u}; (i \neq j) \\ \omega_b \frac{L_{ji} I_{ib}}{E_{jb}} &= \omega_b \frac{L_{ji} I_{jb}}{E_{jb}} a_{ji} = \frac{L_{m_j}\omega_b}{Z_{jb}} = L_{m_j u}; (i \neq j) \end{aligned} \qquad (12)$$

$$L_{m_1 u} = L_{m_2 u} = \cdots = L_{m_n u} = L_{mu} \qquad (13)$$

C. Normalized Equations

The voltage equations (3) in (SI system) can be organized as given in (14) in the reciprocal per-unit system (pu) without index (u) and minuscule symbols for leakage inductances. The voltage equations (14) are formatted in the matrix form (15), where J_n in (16) is an n order matrix with all entries equal 1.

$$\begin{aligned} e_1 &= r_1 i_1 + l_1 \frac{di_1}{\omega_b dt} + L_m \frac{di_1}{\omega_b dt} + L_m \frac{di_2}{\omega_b dt} + \cdots \\ e_2 &= r_2 i_2 + L_m \frac{di_1}{\omega_b dt} + l_2 \frac{di_2}{\omega_b dt} + L_m \frac{di_2}{\omega_b dt} + \cdots \\ &\cdots \\ e_n &= r_n i_n + L_m \frac{di_1}{\omega_b dt} + \cdots + L_m \frac{di_n}{\omega_b dt} + l_n \frac{di_n}{\omega_b dt} \end{aligned} \qquad (14)$$

$$e(t) = Ri(t) + \frac{1}{\omega_b}\frac{d(\lambda)}{dt} = Ri(t) + \frac{1}{\omega_b} L \frac{d(i)}{dt} \qquad (15)$$

With:

$$\begin{aligned} g &= \begin{bmatrix} g_1 & g_2 & \cdots & g_n \end{bmatrix}^T \\ R &= diag\left(r_1 \quad r_2 \quad \cdots \quad r_n\right) \\ L &= diag\left(l_1 - L_m \quad l_2 - L_m \quad \cdots \quad l_n - L_m\right) + L_m J_n \end{aligned} \qquad (16)$$

V. SATURATION MODEL OF GENERALIZED COUPLED CIRCUITS

In order to introduce the saturation phenomenon in previous coupled circuits, neglecting the voltage drop in leakage inductance l_1 and resistance r_1 , the coil #1 voltage in (14) yields:

$$e_1 = L_m \frac{1}{\omega_b}\frac{d\left(i_1 + i_2 + \cdots + i_n\right)}{dt} = L_m \frac{1}{\omega_b}\frac{d\left(i_{10}\right)}{dt} \qquad (17)$$

Assuming a coil #1 sinusoidal input voltage and current, (17) can be written into complex form (18):

$$\overline{E}_1 = jL_m \frac{1}{\omega_b}\left(\omega_b \overline{I}_{10}\right) = jL_m \overline{I}_{10} = jL_m \overline{I}_m \qquad (18)$$

In (18) the magnitude of the magnetic current I_m only depends on the magnitude of terminal voltage E_1 and not on the state of the circuit (loaded or not). Consequently, if E_1 is maintained constant, the unloaded ($i_2 = i_3 \cdots = i_n = 0$) magnetizing i_{10} current will remain the same even if other windings are loaded. Thus:

$$I_{10} = I_m \Rightarrow i_{10} = i_m = i_1 + i_2 + \cdots + i_n \quad (19)$$

$$X_m = L_m = \frac{E_{10}}{I_m} = \frac{E_{10}}{I_{10}} \quad (20)$$

Using the no-load magnetizing characteristic $E_{10} = f(I_{10})$ obtained experimentally (no load is connected to secondary coils of the coupled circuits), the magnetic saturation curve $L_m = f(i_{10})$ given in Fig.4 can be drawn point per point from (20).

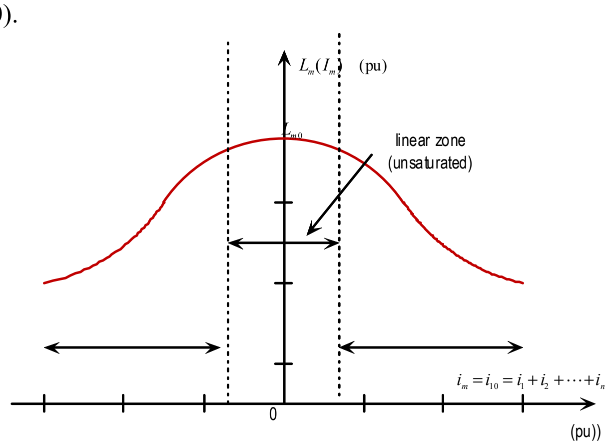

Fig.4. $L_m = f(i_{10})$ characteristic of the unloaded coupled circuits (in pu)

The curve in Fig.4 can be easily modeled as polynomial function given by (21) where parameters α_2 and α_4 are computed from curve fitting using *polyfit* function of Matlab program and the characteristic $L_m = f(i_{10})$. L_{m0} is the unsaturated magnetic inductance of the circuit which is obtained from no-load characteristic of Fig.4.

$$L_m = \frac{E_{10}}{I_m} = \frac{E_{10}}{I_{10}} = L_{m0}\left(1 + \alpha_2 I_m^2 + \alpha_4 I_m^4\right) \quad \text{(pu) (21)}$$

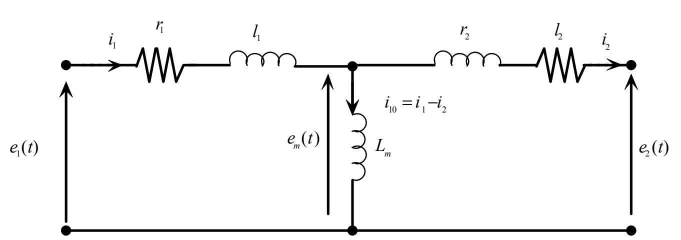

Fig.5. Equivalent circuit of two magnetically coupled circuits (transformer or per phase equivalent circuit of wound-rotor induction motor)

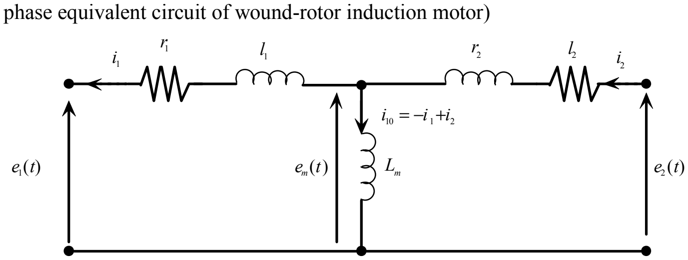

Fig.6. Equivalent circuit of two magnetically coupled circuits (AC generators)

It's to note that the magnetizing current i_{10} depends on the structure of the coupled circuits under study as shown by examples of two magnetically coupled coils of Figs.5 and 6 where it takes the following expressions respectively:

$$i_{10} = i_1 - i_2 \,; \quad i_{10} = -i_1 + i_2 \quad (23)$$

VI. Saturated State Space Modeling of Magnetically Coupled Circuits

A. State Space Model of Magnetically Coupled Circuits

Let us consider a dynamic linear system defined by the differential equation (24); the so-called standard form of the state space model of a linear dynamic system, a well-known control theory suggested for undergraduate engineering students in [9], can be summarized as given in (25). The electrical matrix equation (26) derived from (15) can be organized in standard state form (27):

$$\dot{x}(t) = \frac{dx(t)}{dt} = f(x(t), u(t), t) \quad (24)$$

$$\begin{aligned} \dot{x}(t) &= Ax(t) + Bu(t) \\ y(t) &= Cx(t) + Du(t) \end{aligned} \quad (25)$$

$$\begin{cases} i(t) = L^{-1}\lambda(t) \\ e(t) = RL^{-1}\lambda(t) + \dfrac{1}{\omega_b}\dfrac{d(\lambda)}{dt} \end{cases} \quad (26)$$

$$\begin{aligned} \frac{d(\lambda(t))}{dt} &= \left(-\omega_b R L^{-1}\right)\lambda(t) + \left(\omega_b I_n\right) e(t) \\ i(t) &= \left(L^{-1}\right)\lambda(t) \end{aligned} \quad (27)$$

with:

$$\begin{aligned} &A = -\omega_b R L^{-1};\ B = \omega_b I_n;\ C = L^{-1};\ D = \mathrm{O}_{n,n} \\ &i = [i_1 \quad i_2 \quad \cdots \quad i_n]^T;\ u = e \end{aligned} \quad (28)$$

Where $\lambda(t)$ is the state vector, $e(t)$ the input control variable and A, B, C and D, the state matrix, the state control matrix, the state output matrix and the state output control matrix respectively.

B. Saturated State Model of Magnetically Coupled Circuits

Leakages inductances in (14) $l_i; i = 1 \cdots n$ due to magnetic losses in the air gap are not concerned with the saturation phenomenon. The magnetic saturation can be taken into account in the state model (27) at each instant t_k by adapting the corresponding value $L_m(t_k)$ of the magnetic inductance computed from (21) in matrices A and C (28). The implemented process to account for saturation is the following:

1. Obtain the characteristic $E_{10} = f(i_{10})$
2. Obtain the curve $L_m = f(i_{10})$ of Fig.4
3. Obtain the reactance L_{m0} from $L_m = f(i_{10})$

4. Compute parameters α_2 and α_4 using the function *polyfit* of Matlab program and $L_m = f(i_{10})$ data
5. Define a time vector $\left[t_0 \cdots t_{k_F}\right]$ using n values for $n-1$ steps of simulation.
6. Set $k=0$; $L_m = L_{m0}$ and compute matrices A, B, C using circuit parameters and steady state conditions $\lambda_0 = \lambda(t_0)$
7. Simulate the state system (27) using the function $lsim(.)$ of Matlab control toolbox in one time step interval $[t_k \quad t_{k+1}]$.
8. Set $k=1$ and use currents obtained from step 7 to compute $i_m(t_k)$ given by (19) and $L_m(t_k)$ from (21)
9. Compute state matrices A, B, C
10. Repeat step 7 until $t_k = t_{k_F}$

VII. EXAMPLE OF NUMERICAL APPLICATION USING MATLAB

In order to provide students with a sample application, numerical simulations were performed on a 60-Hz, 110-V/55-V/55-V, and 330-VA single-phase transformer with two secondary windings (Fig.7) whose parameters are listed in Table II. Two different tests were performed. First, the two secondary windings were short-circuited and a 50-V DC voltage was applied to the primary. In the second test, the DC voltage was replaced by a 60-Hz 110-V AC voltage. Per unit inductance and resistance matrices computed form base values of Tables III and IV are respectively:

TABLE II: PARAMETERS OF THE TRANSFORMER

L_{m_1}	0.09 H	$L_{m_2} = L_{m_3}$	22.5 mH
l_1	0.01H	N_1	1000 turns
$l_2 = l_3$	2.5 mH	$N_2 = N_3$	500 turns
r_1	10 Ohms	$r_2 = r_3$	2.5 Ohms

TABLE III: BASE VARIABLES OF COIL #1

Variable	Base	Value
Voltage	$E_{1b} = E_{1n}$	110 V
Current	$I_{1b} = I_{1n} = \dfrac{S_{1b}}{E_{1b}}$	3 A
Power	$S_{1b} = E_{1n} I_{1n}$	330 VA
Impedance	$Z_{1b} = \dfrac{E_{1b}}{I_{1b}}$	36.7 Ω
Pulsation	$\omega_b = \omega_n = 2\pi f$	377 rad/s
Flux	$\lambda_{1b} = \dfrac{E_{1n}}{\omega_b}$	0.292 Wb-turn
Inductance	$L_{1b} = \dfrac{\lambda_{1b}}{I_{1b}}$	0.093 H

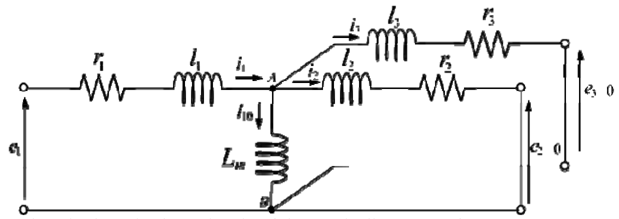

Fig.7. Electrical equivalent circuit of three windings transformer

TABLE IV: BASE VARIABLES OF COILS #2AND #3

Variable	Base	Value
Power	$S_{2b} = E_{2n} I_{2n}$	330 VA
Voltage	$E_{2b} = E_{2n}$	55 V
Current	$I_{2b} = I_{2n} = \dfrac{S_{2b}}{E_{2b}}$	6 A
Impedance	$Z_{2b} = \dfrac{E_{2b}}{I_{2b}}$	9.167 Ω
Pulsation	$\omega_b = \omega_n = 2\pi f$	377 rad/s
Flux	$\lambda_{2b} = \dfrac{E_{2n}}{\omega_b}$	0.146 Wb-turn
Inductance	$L_{2b} = \dfrac{\lambda_{2b}}{I_{2b}}$	0.0243 H

$$L = \begin{pmatrix} 1.03 & 0.93 & 0.93 \\ 0.93 & 1.03 & 0.93 \\ 0.93 & 0.93 & 1.03 \end{pmatrix}; \quad R = \begin{pmatrix} 0.272 & 0 & 0 \\ 0 & 0.272 & 0 \\ 0 & 0 & 0.272 \end{pmatrix} \quad (31)$$

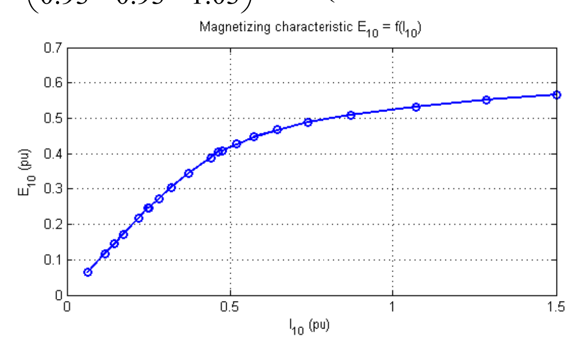

Fig.8 The no-load magnetizing characteristic of the transformer

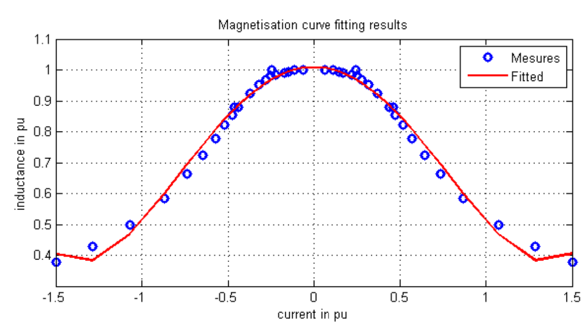

Fig.9 The no-load magnetizing characteristic $L_m = f(i_{10})$ of the transformer

In both cases, simulation of the current of each winding and the magnetizing current of the transformer was requested. The no-load saturation characteristic of the transformer is provided in Fig.8 while the curve $L_m = f(i_{10})$ is plotted in Fig.9. Voltages of the secondary windings are set to zero (short-circuit) for the first test. The primary simulated current is shown in Fig.10 while the magnetizing current and the secondary currents are given in Figs.11 and 12 respectively. It is to be noted that the two secondary windings are the same. After the peak due to the sudden applied voltage, the secondary current becomes zero (DC signal). For the second test, the sinusoidal voltage yields sinusoidal currents as shown in Figs.13-15. The magnetizing current is given by $i_{10} = i_1 - i_2 - i_3$. The impact of the saturation phenomenon is observed on various figures.

VIII. Conclusion

A suitable approach to teaching magnetically coupled circuits to power engineering undergraduate students is proposed in this paper in a more general approach. The work attempts to show that the understanding and teaching of dynamic modeling and simulation of electrical machines can be greatly improved if special attention is given to the teaching methodology adopted for magnetically coupled circuits, where various concepts in machine theory can be easily introduced. The paper emphasizes on per-unit system normalization concept frequently used in power system theory and not often well explained to students. All fundamentals raised are common to classical AC machines and can be easily well adapted to their modeling and simulation. Only simulation results are provided in this work. It is planned to carry out experimental setup to more assess the present framework study.

Real World Photovoltaic Energy Engineering

Enrique Ballester Sarrias, J.A. Saiz Jiménez, Luis M. Sánchez Ruiz
Escuela Técnica Superior de Ingeniería del Diseño (ETSID)
Universitat Politècnica de València
Valencia, Spain, lmsr@mat.upv.es

Abstract - **Photovoltaic solar energy has recently enjoyed a technical and economic progression achieving a high level of reliability. With the aim of obtaining a better knowledge of this type of energy by part of the students from the Electrical, Electronic and Mechanical Engineering Degrees of the School of Design Engineering ETSID in Valencia, Spain, they are offered an elective subject in which they are asked to conduct a "field practice" in which they design an isolated installation that will fully supply the house in which they live including. In addition they perform a photovoltaic installation connected to the electrical network.**

In both cases students must obtain market prices and find out the supply equipment commonly used. With this data they should develop a proposal similar to the one supplied to a customer requesting an installation of this kind. Hence this is a field project where factual data is required and enables students to talk to companies supplying the electrical and photovoltaic materials. These assignments include the final assessment of the cost of the power generated, so that students can identify if the final price in photovoltaic is higher or lower than the cost of electricity supplied by the electricity distribution companies.

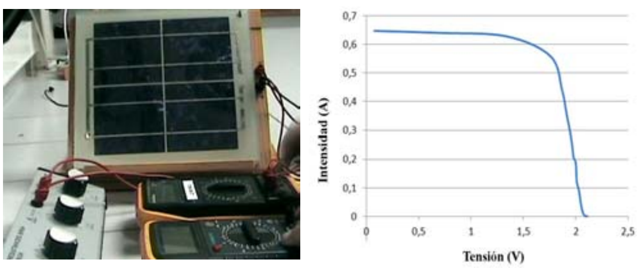
Keywords: Engineering, Electricity, Energy, Solar Photovoltaic, Field Practice

I. Introduction

Problem Based Learning enables a practical learning by means of which students learn by fulfilling tasks that make them have an active attitude in achieving their competences [1] as well as getting more committed in the process.

The Photovoltaic Energy Engineering programme at the School of Design Engineering ETSID (Valencia, Spain) gathers 120 students of Electrical, Electronic and Mechanical Departments giving them the opportunity to work and take measures on low voltage commercial photovoltaic panels, investigating their voltage V-I and power curves, [2]. Then the students check that the data provided by the manufacturers (Figure 1).

Figure 1. Small Photovoltaic solar pannels with which students do lab work



UPV facilitates the access to its solar panel located at ETSID (Figure 3). In this way UPV students see how the equipment connected directly to the main power works and are able to examine the components of the panel. The electrical energy produced is consumed directly by facilities in ETSID [3] through 6 inverters that work simultaneous and independently. ETSID solar panel of 17.5 KW has been running for 14 years, [4] and [5].

Figure 2. Photovoltaic system in UPV.

Since photovoltaic solar energy is under continuous change, it is very importand the task of students collecting relevant information about the solar panel market (including technical features of equipment and its accessories) and later on carry out two assignments.

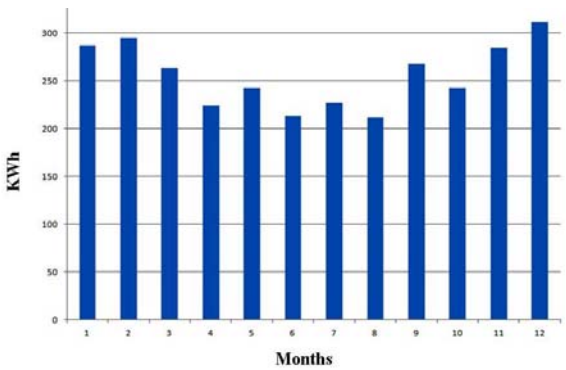
II. Description

The first assignment for students consists of designing a grid system for their own residence so that it becomes completely independent. The second part is to connect such an independent system to the general electrical system, allowing at the same time to consume the energy generated

a) Off-grid installation

The installation must be designed with the data of the student's own home. First, the student must obtain the monthly consumption of housing a full year. This data may be read from the utility bills issued and charged to them as users. But in order to get familiar with domestic electricity consumption, they are required to identify usage of electric devices (light, electronics and appliances including stand-by consumption) in their own environment and observe their daily energy consumption, [6]. Measured time multiplied by electricity voltage results in an average daily/monthly/annual energy consumption that has to be compared with the utility bills.

Figure 3. Annual domestic energy consumption



Next, the students have to design the photovoltaic system that provides energy for domestic use. The calculation of data is not complicated and follows directly from the knowledge acquired in classes. The monthly energy demand must meet the criteria taking under the consideration cases of the highest and the lowest solar radiation during the year. These values are provided by national and international websites such as IDEA [7] and PVGIS [8]. Hence the number of solar panels required is settled as well as the regulators and inverter to be used and the capacity of the batteries that guarantee the autonomy of the system. At this stage the students need to contact suppliers, obtain technical data (Figure 4), economic costs of the equipment and be able to interpret all the data.

Figure 4. Characteristics of a photovoltaic solar panel that the student must obtain from manufacturers and / or distributors

Electrical Characteristics

STC	PLUTO190-Ade	PLUTO185-Ade
Optimum Operating Voltage (Vmp)	37.8 V	37.3 V
Optimum Operating Current (Imp)	5.03 A	4.96 A
Open - Circuit Voltage (Voc)	45.4 V	45.2 V
Short - Circuit Current (Isc)	5.43 A	5.39 A
Maximum Power at STC (Pmax)	190 W	185 W
Module Efficiency	14.9%	14.5%

The outcome will also include the analysis of the economic costs of installation, this being a relevant part as each manufacturer and distributor differ in prices in beginning, depending on the type of customer, supplier and discounts given. However actual market prices are lower and very similar, with little variation among different manufacturers.

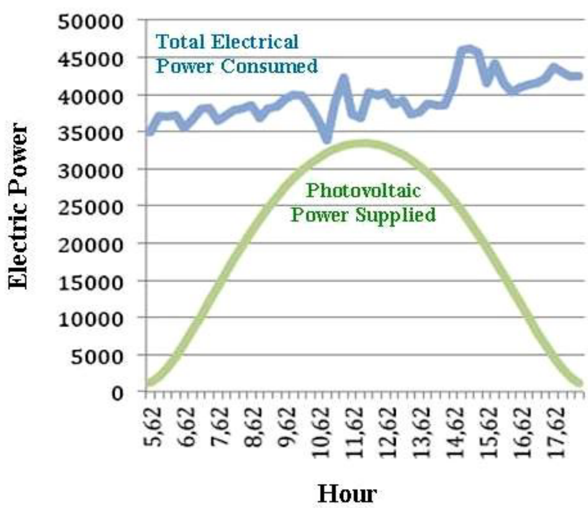
b) Installation connected to the general electrical system

The second task also concerns solar PV energy, but with a very different perspective. It is a networked installation not used to satisfy a given consumer, but seeking to produce as much energy as possible and get a direct economic benefit as the difference between the cost of installation and the income obtained each year.

The current Spanish regulation provides two options to private solar PV energy generators: selling power to the grid at market price and power consumption facilities [9]. The latter is more interesting in economic terms since the energy generated is not sold to the grid, but it does reduce the energy consumed by the facility owner. The electrical and photovoltaic calculation is conceptually the same but the implementation is very different.

The work to be performed by each student is to design the optimal photovoltaic system which in this case consists of solar panels, inverter and auxiliary equipment. This must be done taking into account this field data on market prices and specifications; in the line prior to the installation it explains isolation. Finally an estimate of the amount of energy to be produced and which may not be consumed by the user of the installation must be fulfilled.

Figure 5. Energy produced versus energy consumed



It will happen that at some given moments and/or days all the energy generated will be consumed (Figure 5) whereas in others there will be a consumption higher than what will be produced. The student must make its estimate based on actual installation criteria and the fact on whether they are dealing with a public or industrial building, a shopping center or a private house. This calculation brings out the concept of net energy balance [10].

This situation requires the student to assess the type of application and its advantages and disadvantages. The study must also consider the economic performance of installation, getting the time period in which the photovoltaic plant owner is able to recover the investment.

Additionally the student is required to obtain the cost of KWh generated over a broad time period. Initially set at 25 years, the warranty period the manufacturers usually provide for solar panels, but also asked to perform a second calculation for a period of 40 years. They should have in mind the loss of efficiency and service life of the equipment. Some of them must be replaced after a certain period of time. For example, inverters may have an estimated life of between 15 and 25 years, depending on its manufacturing technology.

This result is important because today the final cost of KWh generated is around 5 cents USA dollars. It is a fact that attracts their attention leading them to exchange information and results with other classmates. This is indeed a very low value, compared with the 19 cents that the consumer pays for the energy from power companies in Spain. It is also an interesting item that brings out the concept of grid parity, [11] and [12].

III. Results

We course check the first phase of work in which students try to solve everything through the Internet, without having to make personal calls to providers or go in person to the offices of the distributor or manufacturer. Overcoming that shyness is one of the important results of the field work, since once they have completed their degree they must do this at work continuously to obtain data providers.

The students' opinion on the subject is obtained through polls. They were asked on the usefulness of the field practice for their education. From them we learnt that 43.2% of students considered it very useful, 27.1% just useful and 12.8% that it was not a relevant contribution. It turned out that 43.7% of the last 12.8% argued that the task was too much time consuming.

It is worthwhile noting that in 78.6% of the cases there was a coincidence between the high grades of the field practice and the high grades in the subject, thus leading us to think that this field practice helps improving the education process.

The students do perform partial presentation of the field tasks which enables a close follow up of the learning process which gets its recognition in the final results.

Finally over 80% of students enrolled succeed in passing. This percentage increases to 88% if we refer to students that are incorporated from the beginning to do the field tasks.

IV. Conclusion

The field practice seems to motivate the students to work harder and be more involved in the learning process. As a result we find a very satisfactory outcome in all students, particularly interesting in mechanical and electronic engineering students, which have not taken specialty electrical subjects but showed their satisfaction with the education provided and in some cases, this lead them to ask to do their final project in the field of PV energy.

The general acceptance of these field tasks have led to design peer assessment methods [14] and self-evaluation for the next academic year, which have already successfully been applied in other subjects as diverse as Electro-pneumatic installations or Music for Image. In this way each student can take a step further and evaluate their peers as well as to assess themselves.

In order to carry out this process we are proposing that each student will present his/her work to the rest of classmates. Each student will have performed the field practice and know the effort he/she has taken up. Checking the work done by other classmates should also give each student a wider perspective to assess their own work, and be aware on whether they match the effort carried out by other students.

***Abstract*— We present an online simulator that can be used to teach the principles of thermoelectric energy conversion, and analyze the detailed performance of Peltier coolers or thermoelectric power generators with simple user interfaces [1]. The simulation tool is implemented on nanoHUB.org, so it can be run on any web interface without the need to install commercial software. The simulation tool solves the heat balance equations at the top and bottom sides of the thermoelectric device using 1D thermal network model and the electric circuit model to analyze the steady-state temperatures of the device and the thermoelectric energy conversion efficiency. Both cooling and power generation modes can be solved upon user's input. Using this simulator, users are able to optimize the performance of a thermoelectric device with a variety of different design parameters such as the device dimensions and material properties. In particular, this simulator can be very useful to teach the importance of the thermoelectric figure of merit, ZT, of the material used on the performance of the device. This simulation is also instructive to show that as material properties improve Carnot limit can be achieved at negligible output power, while efficiency at maximum output power converges to Curzon-Ahlborn limit.**

Keywords*— *online simulator; thermoelectric; cooling; power generation;

I. Introduction

As the world strives to solve the energy problem, there has been a growing interest in strengthening education in renewable energy technologies and related fields [2]. Since most of the energy technologies are interdisciplinary, conventional approaches to the higher-level teaching of such subjects may not be applicable. For example, the efficiencies of state-of-the-art energy conversion systems are determined not only by the materials used, but also by the design of device- and system-level electrical circuits connected to it. For this, an interdisciplinary education encompassing a broad range of science and engineering fields is necessary to meet the ever-rising demand of energy technology engineers and researchers.

An online simulator is a very useful method for energy technology education. First, it can provide students an easy access to the complicated energy systems in a virtual environment. Second, the operation principles or performances of the systems can be easily understood and evaluated for undergraduate students without directly solving the difficult mathematical equations. Third, online simulators can be directly used in real research activities for graduate students where the system optimization and evaluation in terms of various design parameters for the system are crucial.

One of the great examples of an energy system that can take full advantages of an online simulator for education purposes is thermoelectric (TE) energy conversion system. Recently thermoelectric energy conversion has received much attention for waste heat recovery and for micro-chip cooling applications [3]. More than 55% of energy generated in the society is wasted in the form of heat so thermoelectrics could play an important role in future energy landscape [4]. Analysis of a thermoelectric device is complicated because one needs to solve the coupled thermal and electric transport equations taking into account heat flow and electrical energy supplied to a load. An online simulator for TE devices may be very useful for students to have an easy access to devices that couple electron and heat transport and energy conversion applications.

In this paper, we present an online simulator that can be used to teach the principles of thermoelectric energy conversion, and analyze the performance of thermoelectric devices. The simulation tool can be used on any web interface without the need to install MATLAB or other commercial software, as it is implemented on nanoHUB.org with simple and easy user interface. We are currently developing several course modules at UC Santa Cruz and Purdue University that utilize this online simulator to teach undergraduate students the principles of thermoelectric energy conversion devices. Lastly, we will also show the methodology to propose student project using the online TE simulator as well as the expected outcomes and evaluation plan.

II. Simulation of Thermoelectric Devices

A. Principles and modeling of thermoelectric devices

The underlying physics of thermoelectric cooling is Peltier effect. When a current flows through an interface between two dissimilar materials, thermal energy is absorbed or dissipated depending on the direction of current flow in order to compensate the difference in thermal energy transported by electrons in the two materials. The thermal energy Q transported by a current I in a material having a Seebeck coefficient S at absolute temperature T is given by $Q=STI$. Thus, the absorbed or dissipated heat at the interface between material 1 and material 2 by the Peltier effect becomes the

This work was supported by the Center for Energy Efficient Materials, one of the Energy Frontier Research Centers of The Office of Science, U.S. Department of Energy (J.-H. B., K.Y. and A.S.), NSF TUES grant 1238565 (O. P. and A.S.), and Purdue SURF program (M.Y.).

difference of the transported thermal energies or Q_1-Q_2=(S_1-S_2)TI. In addition, there are other thermal transport effects: Joule heating and thermal conduction. The Joule heating is I^2R in a material with electrical resistance R. This heat is equally divided and propagated to the two ends of the material. When a temperature gradient is created through a material, heat conduction Q_{cond} occurs from the hot side to cold side proportional to the temperature difference ΔT, so that $Q_{\text{cond}} = \Delta T/\psi$, where ψ is the thermal resistance of the material.

Fig.1(a) shows a typical structure of a thin film TE device fabricated on a conducting substrate. A top metal contact is deposited on top surface of the thin film TE element, and a ground contact is deposited at the bottom of the substrate, so that both electrical current and heat flow vertically through the whole structure. In our simulator, we solve the heat balance equations obtained at the top surface of the TE element and at the interface between the TE element and the substrate from the 1D thermal network model shown in Fig. 1(b). The heat balance equation depicts that the Peltier heating/cooling, the Joule heating, and the heat conduction are all in balance.

It is important to include the heat and current 3D spreading effect in the substrate, because the substrate is much larger than the TE device on it. A closed-form thermal spreading resistance in a substrate is adopted from Lee *et al*. [5] with assumption of an infinitely large substrate and a perfect heat sink underneath it. The electrical spreading resistance is obtained from Vashaee *et al*. [6], which is based on ANSYS finite element simulation.

B. Simulation method and boundary conditions

A thermoelectric device works as both a cooler and a power generator. In the cooling mode, a current is injected into the TE device. Two boundary conditions can be simulated: one is that the cooling power Q_1 is known, from which T_1 and T_2 are calculated by solving the coupled heat balance equations. The other boundary condition is that the top surface temperature T_1 is known, from which T_2 and the cooling power Q_1 are calculated. Then the coefficient of performance (COP) is obtained by

$$\text{COP} = \frac{Q_1}{W}, \tag{1}$$

where W is the work done by the electrical current to achieve the cooling performance given by

$$W = IV_{OC} + I^2 R_i . \tag{2}$$

where V_{oc} is the open-circuit voltage induced internally in the device by the Seebeck effect, $V_{oc}=S_{\text{TE}}(T_1-T_2)+S_{\text{sub}}(T_2-T_{\text{amb}})$, and R_i is the total internal resistance of the device, $R_i=R_c+R_{\text{TE}}+R_{\text{sub}}$.

In the power generation mode, a heat energy Q_1 is injected into the device from the top, which creates a temperature gradient across the device and generate a voltage by the Seebeck effect. A load resistance R_L is connected to the device, so that a current flows through the load to generate a power output, $P_{\text{out}}= I^2R_L$. The current is obtained by an electrical circuit model, in which the open-circuit Seebeck voltage source has an internal resistance and is connected to the external load.

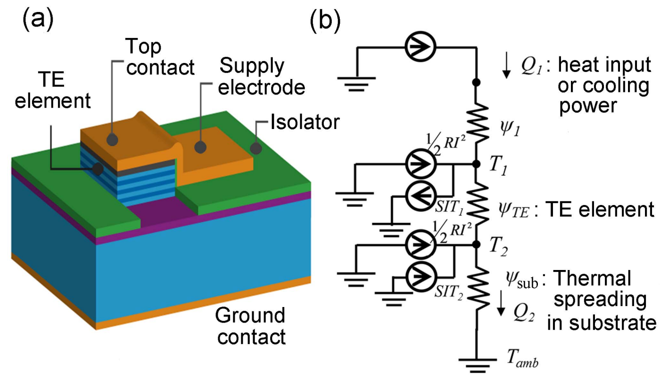

Fig. 1 (a) Schematic of a thin film TE device on a substrate and (b) the corresponding 1D thermal network model

There are two boundary conditions for the power generation mode as well. One is that the heat input Q_1 is known, and then we calculate T_1, T_2, and I by solving the coupled heat balance equations. The other option is that T_1 is known, and we calculate Q_1, T_2, and I. Then the thermoelectric energy conversion efficiency η is obtained by

$$\eta = \frac{P_{out}}{Q_1} . \tag{3}$$

In both the cooling and power generation modes, users can select an option that there is no substrate.

A practical TE module consists of multiple n-type and p-type TE elements that are connected electrically in series, and thermally in parallel [3]. The online simulator presented in this paper has also the capabilities of simulating multi-element modules having both n- and p-type elements. Users are asked to input the dimensions and material properties of the n- and p-type elements as well as the number of the elements.

C. Implementation on nanoHUB.org

We have implemented the simulator on nanoHUB.org. NanoHUB provides an easy and simple Java-based graphical user interface. We wrote the simulator core in MATLAB script, and integrated the code with the user interface of nanoHUB using Rappture toolkit [7]. Users can access and run the program by simply visiting the website. Upon the start of the program, an introduction page is shown up to give users a brief overview and instructions on how to use the simulator as shown in Fig. 2(a).

Then, users can select from a pull-down menu a simulation option in either cooling or power generation mode for single element simulation or multi-element module simulation. In the second page of the simulator (Fig. 2(b)), users are asked to choose an independent variable, for which all the outputs are calculated and plotted as its function, and the range of the independent variable to simulate, and enter material properties and dimensions of the TE elements. Then simulation is performed when the simulate button is pressed by user, and the resulting output data are plotted as a function of the independent variable as shown in Fig. 2(c) as an example.

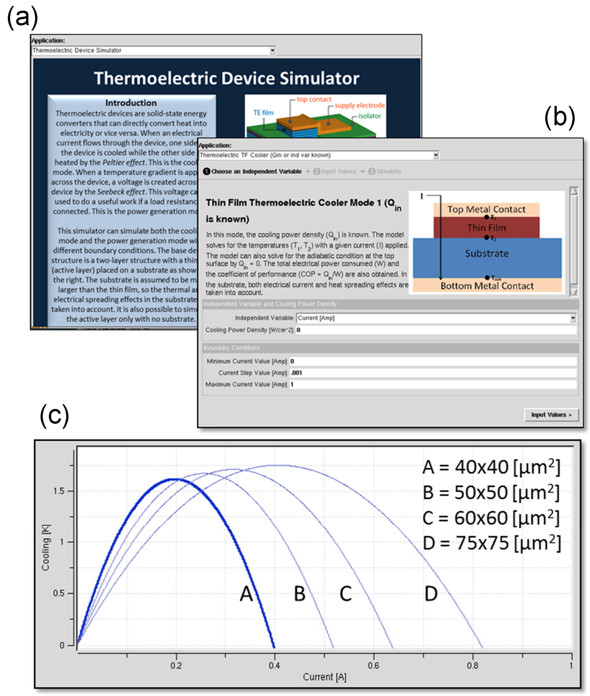

Fig. 2 (a) Introduction page of the online TE device simulator on nanoHUB.org, (b) material properties and simulation option page, and (c) an example of simulation results (net cooling vs. current) for various sizes of TE devices.

III. Practices, Evaluation and Future Work

This online simulator is built and designed for use in classes where students are taught the principles of TE devices and the detailed performance analyses of the system. For that purpose, we offer a variety of independent variables for users to choose from in this simulator, so that students can do performance optimization and comparison of TE devices in terms of the selected independent variables in a simple and easy way. For example, a user can choose the load resistance as an independent variable in the power generation mode, and find out that the power output is maximized when the load resistance is equal to the internal resistance of the device, the so-called load-matching condition. For another example, the material properties such as the Seebeck coefficient S, electrical conductivity σ, and thermal conductivity κ can be chosen as an independent variable for a user to learn how the thermoelectric energy conversion efficiency is determined as a function of those properties. This way, students can learn the importance of the figure or merit $ZT=S^2\sigma T/\kappa$ of the material for enhancing the efficiency of the device.

This simulator is suitable for undergraduate-level students who are beginning to learn the principles of thermal transport physics and thermoelectric energy conversion, as well as for graduate students who are doing research on their own design of TE devices and systems. In particular, students from materials and chemical engineering departments who grow or synthesize their new TE materials can benefit from using this simulator as they want to predict realistic performance of the future devices that utilize their materials. Additionally, the undergraduate classes in physics and electrical engineering departments are good places to use this simulator, in which students do not have to use commercial engineering software such as MATLAB or Mathematica, but simply go on the website and run the simulator. Also, this simulator can be useful as a supplementary software in conjunction with hands-on thermoelectric energy conversion experiments in introduction to renewable energy classes [8].

Students should have basic knowledge of classical physics on thermal transport and thermodynamics prior to using this simulator. Understanding of basic electrical circuits is also necessary. The simulator is very versatile and it allows students to study the limit of thermoelectric power generation as the material properties are improved. Carnot limit (1- T_{cold}/T_{hot}) can be achieved at negligible output power, while efficiency at maximum output power converges to Curzon-Ahlborn limit (1-$\sqrt{T_{cold}}/\sqrt{T_{hot}}$) [9].

A suggested method of evaluating what students have learned from the simulator is to give each student a questionnaire before and after the use of simulator, which contains a set of questions relevant to the subject of the class. Also, students can take an on-site quiz in a computer lab with the internet access at the end of the academic term, where they run the simulator in a real time and solve the problems related to the performance of TE devices. The simulator provides users functionalities that export the simulation results into text or MS Excel files. Students can generate plots with this simulator.

The online simulator has been installed for public use on nanoHUB.org [1]. It will be constantly upgraded. We are planning to use this simulator in classes at UC Santa Cruz and Purdue University and continue to upgrade it based on the feedback received back from students, researchers and instructors.

***Abstract*—This paper describes the current influence of the remote laboratory on practical learning aspects of secondary sector of education. The key challenges faced by the teaching of science include insufficient hands-on laboratory usage in classrooms. The main objective of the paper is to present learning approach of adaptation and usage of remote experiments of WebLab-Deusto in curriculum of secondary school. The activity was organized in collaboration with secondary school teachers of P. Andrés Urdaneta School. Educators can benefit from different teaching methods (collaborative, inquiry-, and project-based learning) integrated in WebLab-Deusto.**

The teaching of Ohm´s Law in Physics curriculum of secondary school was one of the topics executed during this research. The remote laboratory assignment for students was developed on Virtual Instrument Systems in Reality (VISIR) Open Lab Platform. The existing remote laboratories are more or less copies of hands-on ones. VISIR is a remote laboratory created by Blekinge Institute of technology (BTH) for designing, wiring and measurement of electric circuits. This main feature of VISIR allows one building a scenario of performing basic DC and low frequency AC circuits experiments related to Ohm's and Kirchhoff's laws. Moreover, the students will become familiar with instruments, components, manuals, data sheets, circuit wiring, and other laboratory work.

In the paper the main principle of VISIR will be presented; the remote experiments executed by students will be shown. Finally, the result of integrating of remote experiments for study in Urdaneta School will be discussed.

Keywords—remote laboratory, remote experiment, STEM, secondary education, Ohm's law, VISIR

I. Introduction

In order to successfully compete in a global economy, Europe aims to be amongst the most highly skilled regions in the world. Recent study shows that the occupational structure of EU employment of the engineering sector tends to shift towards knowledge- and skills-intensive jobs from 27.3% in 2007 to 32.4% in 2020 [1]. Industry requires well educated science, technology, engineering and mathematics (STEM) graduates. At the same time the percentage of drop off students in STEM is high - almost 30% for the science education and 50% for the engineering. Indeed the first encouragement students get in the school through the class instructions, practical assignments, laboratory work, and extra curriculum activity. A teacher is a source of knowledge and inspiration for the students in the education. Because of that teachers should have access to high quality and real-life-based resources to support student´s curiosity using up-to-date research and developments in STEM, multimedia interactive instruments including an experimental laboratory.

The OLAREX (Open Learning Approach with Remote Experiments) project consortium realized that the new strategies in the STEM educational field are needed; the knowledge and skills requirements exchange between school and industry through the university expertise should be established. For these purposes the consortium has been granted by Lifelong Learning Programme of the European Union [2].

The OLAREX started at November 2011 [3]. The institutions from different EU countries (Spain, Lithuania, Austria, Bulgaria, Hungary, and Poland) are involved in the project. For now the secondary schools teachers from all partner institutions already benefited from the first piloting session participating in the courses and modules designed during the project.

The aim of this paper is presenting the results of the implementation of the OLAREX module "Ohm´s law: How does the current flow?" and to discuss how OLAREX facilitates integration of remote experiments in teacher professional practice.

II. OLAREX Project Activity

The main project purpose is to innovatively implement ICT-based (Information and Communications Technology) learning materials, remote experiments, and e-didactic methods into formal and non-formal lifelong learning settings. It will enhance and modernize STEM curricula, foster student creativity and motivation, and develop professional skills and insights about the impact of evolving technologies.

The organized training for teachers will build the e-didactic competences in the STEM by providing remote lab work explanations, offering practically-oriented approaches for strengthening educational programs and technical practices.

This work was supported by Lifelong Learning Programme of the European Union within Key Activity 3 - ICT (OLAREX project 518987-LLP-1-2011-1-ES -KA3-KA3MP). However, any opinions, findings, conclusions, and/or recommendations are those of the investigators and do not necessarily reflect the views of the European Commission.

During the training, teachers integrate at least one learning module into their curriculum, test them in their classrooms, and encourage their students to apply what they learned in a final project. The six comprehensive learning modules with remote experiments – in English and the national languages of the partners – have been prepared based on the target groups' requirements. Learning and teaching materials have been incorporated into an e-platform - personalized learning environment.

III. NEEDS ASSESSMENT SURVEY, SPAIN, 2012

The presented survey was performed in Spain, in March-April, 2012, to analyze the knowledge and skills requested from secondary school students; a demand on teacher ICT competence development; a role of administration staff in ICT integration in school curriculum; e-learning materials and remote experiments needs as well as education methods.

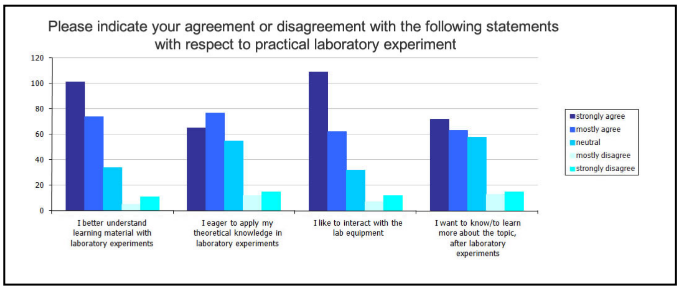
Most secondary schools in Spain show interest in remote experiments. More than 62% of the participated in survey teachers informed that they had an interest to test remote experiments in their curriculum. They also are interested to get more information about the Open Courseware and free online lectures, and how to use it in their curriculum.

At the same time, it was indicated that obstacles influencing the ICT integration in curriculum are lack of knowledge in using ICT instruments for education purposes, insufficient number of software/applications copies for educational use, and lack of knowledge on hardware and software characteristics. Usually students execute experiments in the frame of traditional hands-on laboratories. However, the laboratory equipment is expensive and its maintenance is complicated. The remote laboratory reduces the costs significantly, makes lab experiments available almost at any time and everywhere, personalizing the learning pathways [4], [5]. When the project started, the secondary schools of Basque Country, Spain, do not use remote experiments in the curriculum.

All target audiences of the survey stated a high interest in the remote laboratory and experiments believing that this tool can enhance STEM curriculum and teaching methods in class instruction and at the same time can develop a student competence which are required by industry.

242 students out of 464 participated in survey (52,4%) pointed out that they use hands-on laboratory activities and experiments laboratories in the class. Students, who had or have laboratory experiments, evaluated their experience with the words "strongly agree", "mostly agree", "neutral", "mostly disagree", "strongly disagree"- by answering on the questions :

- I better understand learning material using laboratory experiments
- I am eager for application of my theoretical knowledge in laboratory experiments
- I like to interact on the lab equipment
- I want to know/to learn more about the topic, after laboratory experiments



The results are presented on Fig. 1.

Fig. 1. Evaluation of the expirience to hands-on laboratory

The 44% of all survey participants like to interact using the laboratory equipment. 46% strongly agree and mostly agree that they better understand learning material. 37% of responders strongly agree and mostly agree that they are eager for application of their theoretical knowledge in laboratory experiments.

173 students out of 462 (37%) have heard of remotely accessible laboratories before, while 283 students (almost 63%) never have heard about it. However, despite on the huge number of those who never have heard about the remote experiments, after a brief presentation of the remote laboratory, more than 67% of all responders would be interested testing and applying remotely accessible experiments. It shows us the willingness of students to use new tools to support their practical assignments.

Teachers were another respondent group in the survey. In Spain, more than 100 teachers filled in the online questionnaire and responded that: 56% of responders do not use a practical laboratory component currently in their curriculum; while 44% apply the laboratory experiments in the class. Usually teachers apply laboratory activity in Mathematics, Biology and Technologies.

If remote experiments are available in the school, 50% responds that they are interested, 7% are very interested and 6% are completely interested applying them in class instruction (Fig.2).

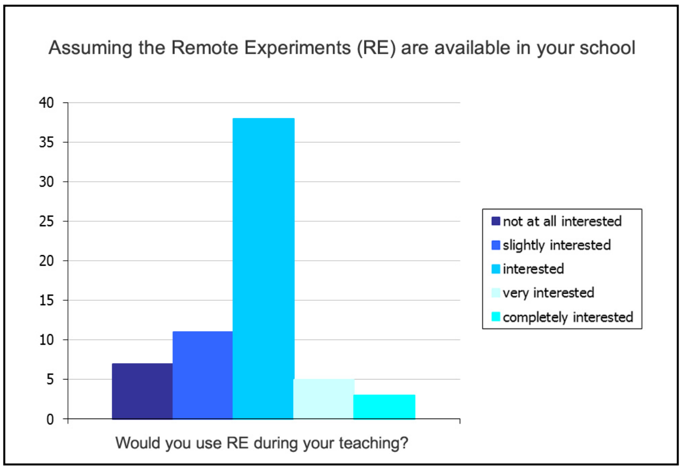


Fig. 2. Teachers´ interest to implement the remote experiment in class instruction

The main purpose of the study was to understand in the participated countries the ICT knowledge gap, necessity and willingness to apply the remote labs for learning and teaching. Based on the reports' conclusions the partners identified the methods, instruments and content approach, and expected ICT competence demands for the primary target groups: secondary school teachers and their students. The profiles of teachers, students, administrative representatives and companies responding the survey is available on the project website.

IV. Remote Experiment in Secondary School Instruction

Based on the survey, five courses on e-didactical competences for secondary school teachers were developed. One of them is "Transforming curriculum with remote experimentation: how to integrate it in secondary school classroom". This course aims to develop the competences such as the use of different types of remote and online labs, and to present them to students. During this online course the teacher activity is focused on an implementation in class instruction one of the six STEM modules:

- Black body radiation of common light sources (simulation activity)
- Farm Experiment: from an egg to a baby chick, step by step (remote experiment activity)
- Working as a computer – Logic gates (remote experiment activity)
- Analogue circuits measurements (remote experiment activity)
- How does the current flow? (remote experiment activity)
- Easy Java Simulation for Phys&Sports (simulation tool)

In this paper we will present the module "Ohm´s Law: How does the current flow?" tested in collaboration with secondary school teachers of P. Andrés Urdaneta School. The provided module is a didactic support module for implementing the remote experiments in a classroom. Teachers can use its structure as a whole element without any changes. They can apply some parts such as exercises, experiments, problems, or only ideas of topics for student´s final projects. Average learning time for the module is around 20 hours: 10 hours of theory, 5 hours of execution of exercises, tests, experiments, and one final small project (5 hours of work) are included in the module. The learning module covers following topics: electrical current, Ohm's law for direct and alternative current, electrical resistance, capacitors, signal generators, digital circuits and measurements within the VISIR. Each module unit provides both theoretical and practical approaches including a problem solving by simulations and using remote experiments.

The main learning outcomes of this activity are: (1) the skills to design experiments confirming the hypotheses; (2) the practice to work with laboratory materials and equipment, including the VISIR; (3) the knowledge of digital circuits of direct and alternating currents.

V. VISIR Open Lab Platform

Electrical experiments are common at schools and universities. Usually students execute experiments in the frame of traditional hands-on laboratories. The existing remote laboratories are more or less replicas of hands-on ones. Virtual Instrument Systems in Reality (VISIR) Open Lab Platform is a remote laboratory created by Blekinge Institute of technology (BTH) for designing, wiring and measurement of electronic circuits. A student designs circuits using virtual instruments and wires on the interface of the devices-gadgets such as: Smartphone, tablet, iPad, and PC. Then, VISIR Open Lab Platform converts the student's design into a real wired circuit and sends the measurement results to the interface of the student device. Thus, VISIR Open Lab Platform is a real electronic lab environment which can be accessed at any time and from anywhere over the Internet [6].

There are three main scenarios for practical learning using VISIR Open Lab Platform [7]. However we will only present the usage of the VISIR by secondary school students. They can use VISIR Open Lab Platform for performing basic DC and low frequency AC circuit experiments related to Ohm's and Kirchhoff's laws. Moreover, the students will become familiar with instruments, components, manuals, data sheets, circuit wiring, and other laboratory work [8].

The main part of VISIR Open Lab Platform architecture is online workbench (Fig.3) that is similar to hands-on laboratories at any school. Workbench for electrical experiments contains power sources, measuring instruments and a solderless breadboard (Fig.3). A virtual instructor protects the online workbench from student's harmful errors and damages during experiments.

The VISIR Open Lab Platform provides a virtual component box and virtual breadboard for controlling the switching matrix and for "wiring" circuits remotely using the mouse pointer. Users select components using the button "+" from the library of components and put them into the component box.

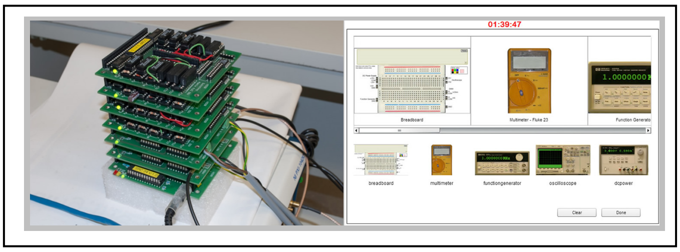

Fig. 3. The online VISIR workbench at WebLab - Deusto, University of Deusto

The VISIR Open Lab Platform offers virtual front panels of the desktop instruments and the multimeter in image format

(Fig.3). Adobe Flash animations enable students to turn the knobs and buttons, and make settings using the mouse pointer. In order to avoid misunderstanding and provide immersion of the remote experiment, the virtual panel is an exact virtual copy of devices which students use at hands-on laboratories. In order to build holistic immersion of the experiment sessions of the remote activity should be organized as a hands-on laboratory - one workbench per student or student´s team [9]. Each remote student or student´s team creates the experiment using laboratory interface and sends a message containing a description of the desired circuit and the instrument settings to the VISIR workbench (server). The experiment result or an error message is returned to the requesting client computer after performing the procedure. The student should wait in queue to execute the experiment in case of server occupation.

VI. Results of Implementation in School

The laboratory practice on remote experiments was taking place during two weeks in March 2013. Forty eight students of 2nd year of Baccalaureate (grade 11) of Urdaneta high school (Loiu, Bizkaia, Spain) [10] participated in it. A group of Urdaneta high school teachers in STEM areas have volunteered time within their busy schedules, to design and implement one curriculum topic – Ohm´s Law, which requires the laboratory practice, learning, and understanding of the technology [11].

The activity is divided into three parts. In the first part a teacher presents WebLab-Deusto remote laboratory: how to login in the remote laboratory, how does library of components work, how wire the digital equipment such as multimeter, DC power, function generator, etc. In this first part, students experiment at home in order to become comfortable with the remote experiment approach. The second part includes the work on the design of electrical circuit connected in series. The students get an exercises list including ten different series circuits that they execute using simulation tool- Falstad Analog Circuit Simulator Applet [12] and WebLab-Deusto remote laboratory, and compare the results accomplished with two different tools. This assignment allows one to study the Ohm´s law using inquiry-based learning approach as well as to analyze the difference between a simulation and a remote experiment. The next activity provides a set of experiments for parallel circuits. The students use the same instruments and report template as for the series experiments. The final project includes creating by student circuit´s schemes based on proposed requirements, designing “invented” circuits in WebLab-Deusto (Fig.4), using the components library of the WebLab-Deusto; analyzing obtained results, writing a report and a conclusion how his/her hypothesis fits the results obtained during experiments.

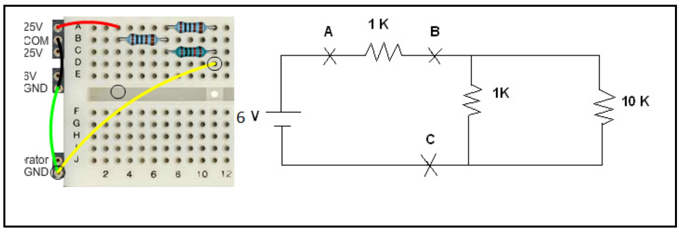

Fig. 4. Presented by Urdaneta school student circuit schema and circuits built in WebLab-Deusto environment

During the practice teacher can control an execution of an assignment by students. They can check how often students work in laboratory, how much time they spend, what errors occurred during the activity, the source of the errors - system failure or student´s mistake (Fig.5)

Fig. 5. Statistics of execution of remote experiments by student

Although the practice in environment of remote laboratory was organized for the first time, 72% of students show successfully performed exercises and laboratory work. The preliminary analysis of implementation of Remote Laboratory in class instruction in Urdaneta School shows positive feedback on presented trial: due to flexible connection to the laboratory, student´s access was massive during several days before the deadline of the final project. Most connections were done after 6pm. Such open schedule will be not possible with hands-on laboratory. Students can design circuits several times and experiment safely; discover functioning, components and equipment the remote laboratory before the actual activity will start; share and discuss their final project during lessons; obtain understanding of research cycle from hypothesis statement until analysis of the results, discussion, conclusion and report writing. However the remote laboratory needs holistic understanding of the difference between computer simulation and real experiments provided with Internet. Several sessions were needed in order students can recognize that it needs time (just several seconds) to send signals to server, complete the experiment and get it back on the screen of their computer, tablet or Smartphone. Namely, this misunderstanding was a reason of student´s disappointment on the first stage of VISIR execution at high school level. We decided in the next semester to improve the strategy of introduction of remote laboratory in secondary school classroom.

VII. Conclusions

OLAREX project contributed to teacher training on how to use remote laboratories and to improve practice at secondary schools considerably. Teachers showed great interests in using remote labs at their classes. Considerable effort was made by project consortium, and great appreciation was received by the teachers, to have both, training on application of remote labs, and having the context of ICT courses, training on integration of remote labs and facilitating teachers to do so.

In this paper we discussed the aspect of integration of remote laboratories into the secondary school curriculum using WebLab-Deusto. Thanks to modern communication instruments, common resources including remote experiments are available for students anyplace and anytime.

Our future work can be conducted in three directions: (1) provide this teaching approach to several EU countries (by providing teachers online technical and content supports); (2) improve introductory and visionary activity for remote laboratories in secondary school to allow a holistic immersion to the topic; (3) personalize the web interface of the remote laboratories and experiments. This year we have got the first results of using the remote experiment in the secondary school physics instruction. The 72% of successfully performed exercises and laboratory work students show that this tool is valuable supplementary instrument in the education of school sector. Next phase requires teacher´s individual effort and motivation. The future will reveal how these efforts will be met in local and national contexts.

Acknowledgment

We thank Olatz Alzola Colinas from Urdaneta Secondary school, Spain for her help implementing the module in her class instruction.

***Abstract*—INSIGHT, an innovate graduate STEM Fellowship Program integrates sensor technology and computer science within in a K-12 standards-based science, technology, and engineering curricula. Graduate STEM Fellows are teamed with science, technology, and physical education teachers for two years to carry out hands-on classroom activities utilizing technology and engineering practice with a focus on the use of sensors, computing, and information technology aligned with K-12 state curriculum standards. One of the projects main goals is the establishment of sensor, computing, and information technology as a foundational high school skill by accelerating the integration of sensor technology content into K-12 classrooms. This project encourages participation in engineering and technology from a wider, more diverse group of students from rural Kansas. This paper shares detailed examples of summer institute and academic-year K-12 activities that have been successful. It also provides a preliminary assessment of the project.**

***Index Terms*—cyber-physical systems; K-12 curriculum; education; real-time embedded systems; sensors**

I. Introduction

The importance of Computing Science continues to grow for our nation, economy, and security; yet conversely the topics and techniques of Computing Science are increasingly being pushed out of K-12 curriculums [1]. Kansas is no exception. While serving 477,857 students through 286 school districts, the state offers no licensure for teachers in computing science education. Those schools that do offer computer science coursework typically do so through the Career and Technical Education pathways program, yet these are sparsely implemented through the state: Web and digital communications (53 districts), Programming and Software Development (10 districts), Network Systems (2 districts), and Information Support Services (1 district). Further, these offerings are only offered on an elective basis. Finally, there are no specific requirements to teach in these pathways courses, so most teachers are drawn from other backgrounds and have minimal, if any, preparation to teach the subject.

Sensor technologies represent one route for reaching students in K-12 settings. Sensors, as an integral part of embedded systems, require broad, cross-cutting knowledge drawn from multiple disciplines [2]. Working from specific sensor uses within one of these disciplines (such as biometric or agricultural sensors) offers a way to introduce these cross-cutting technologies into more traditional class settings (i.e. physical education and agricultural education), and also introduce the Computing Science principles needed to evaluate, interpret, and act upon the sensor's output. Although integrating computing science topics into core curriculum subjects does increase the numbers of students exposed, doing so still faces many of the challenges faced by stand-alone computing science courses: rapidly changing technology, a lack of staff support, and few quality curriculum resources [4]. It is critical for the success of such a program to develop an infrastructure to support teachers as well as adapt to changing technology [5].

The National Science Foundation's program to support Graduate Teaching Fellows in K-12 Education (GK-12) provides a mechanism for establishing such an infrastructure. This program seeks to improve graduate students' communication, teaching, collaboration, and team-building skills by engaging graduate student fellows in K-12 classrooms, working directly with K-12 teachers and students. These Fellows take on the role of visiting experts, bringing their knowledge and research activities into the classroom and becoming a resource for teachers interested in expanding their methodologies, developing new curriculum materials, and integrating technology and computing science principles within their teaching. The fellows also serve as role models for the students they work with, both sharing exciting opportunities within their field and answering general questions about university student life, as shared by one fellow in his/her weekly journal:

> When I did the VR head tracking lesson, once we were done there was some free time where the science club students just asked me about what it was like being a grad student and a programmer. It was neat to see kids interested in a topic that I love, and I tried to show them some examples of code that I thought they might find neat. I also talked a bit about the limitations of Minecraft. It was something they had played, and they wanted to know why some things in that game were done the way they were. I'd done enough reading on the subject to be able to tell them, and they seemed to think it really cool that they now knew the reasons for why things were the way they were in that cube filled world.

These experiences are especially important for disadvantaged students who may not have role models from their social and family environment from which to draw [6]. As one teacher in the program observed:

> . . . we are not educating our rural students with thoughts towards these fields of study. I think alot of that has to do with exposure, there is very little in rural areas. We have teachers, nurses, professionals, but not a lot of exposure to fields that we really need our students to think about. When you ask Fifth graders what they want to do when they grow up, engineering/tech. degrees aren't usually mentioned.

When the fellows themselves are drawn from underrepresented populations (such as the female fellow from the first quote), students can better understand that STEM disciplines are not out-of-reach for themselves.

II. INSIGHT GK-12 Fellowship Program

The Infusing System Design and Sensor Technology in Education (INSIGHT) GK-12 STEM Fellowship Program at Kansas State University is a synthesis of these ideas using the focus on improving graduate students' communication skills to integrate computing skills into the core K-12 curriculum. The program helps prepare teachers to integrate sensor technologies into their everyday classroom activities by providing lessons developed with low cost and ease of implementation in mind, and through partnering teachers with graduate students in Computing Science and Biological and Agricultural Engineering. Teachers in the program are recruited from disadvantaged areas of Kansas, specifically rural and urban areas with high minority populations. Both teachers and fellows serve within the INSIGHT program for two years.

A major component of the project is the INSIGHT Summer Institute, an intensive two-week training program for both partner teachers and Fellows that introduces many of the various sensor technologies and computing science principles utilized within the project; along with hands-on lessons, pedagogical techniques and challenges, lesson planning strategies, and team-building experiences. These are the tools teachers need to implement STEM subjects within their classrooms:

> The program has helped me in several ways. I've always tried to nurture the future engineers and scientists in my class and INSIGHT along with my fellow have given me some extremely effective strategies to accomplish this. I've also greatly improved my own use of technology with my students beyond the traditional use of computers. As always, being able to cooperate and communicate with others (teachers and university personnel) is invaluable in solving problems and creating new programs and lessons.

As with many intensive training experiences, the confidence and enthusiasm generated during the two weeks begins to fade as time passes and the practical challenges involved become more obvious. This is where the partnership between an INSIGHT Teacher and Fellow comes to the fore the interaction between the two helps alleviate both the teacher's concerns about utilizing unknown technology in the classroom (as they have a technology expert who can ensure that aspect runs smoothly) and the fellow has an experienced teacher to help her/him understand how to communicate effectively with the class (and offer support should the Fellows falter). Further, it allows teachers to present STEM content within a real-world framework:

> The most noticeable impact of the INSIGHT program on my teaching is my increased awareness of and ability to connect my content to actual real-time, real-world applications. My ability to describe and discuss the ways in which new technologies are being utilized to improve both quality and efficiency of life is improving as a direct result of my INSIGHT experience.

Finally, as teachers grow more confident in the use of sensor technology within their classrooms, they can begin to take on more of the instructional tasks leading to the continuation of such efforts even after teachers have left the program at the end of their two years:

> The biggest impact the INSIGHT program has had on my teaching has been to expose me to new technology to use in my classroom. For example, [my fellow] came over today and Friday to work with my Drafting students, and taught a lesson on MIT's AppInventor. The students had an opportunity to explore the program and they ended up creating a drawing and sketching app. This was a very good experience for them, and is something I plan to use in the future.

Most of INSIGHT's contributions to a teacher's classroom strategy take the form of small curricular modules. This allows for manageable inclusion into an already-existing curriculum; facilitates the in-classroom interaction between the teacher, fellow, and students within a discrete block of time; and perhaps most importantly, allows the module to be documented and disseminated as a stand-alone lesson plan.

III. Sample Curriculuar Modules

This section offers a sampling of some of the modules that have been developed and/or delivered by INSIGHT fellows and partner teachers. Detailed lesson plans can be found online on INSIGHT's website (http://gk12.cis.ksu.edu).

A. Using WiiMotes to Learn Newton's Laws

This lesson takes advantage of the WiiMote a commercial game controller equipped with a three-axis accelerometer that uses Bluetooth to connect to a Nintendo game console. When paired with a computer and software capable of interpreting its output like the open-source application WiiPhysics, the WiiMote becomes a powerful and inexpensive sensor to use in education.

In this case, the WiiMote is mounted to the top of a toy car and launched using the tension in a bungee cord. As the car races forward, real-time acceleration data is streamed wirelessly to a computer running WiiPhysics.

The real-time data is graphed by WiiPhysics as the car is moving, helping students better understand the often-confused

Fig. 1. WiiMote mounted on a toy car.

Fig. 2. Using a rubber band for propulsion.

Fig. 3. Launching the toy car.

concepts of acceleration and velocity. Further, the collected data can be saved from the WiiPhysics application as a CSV file, allowing the students to further manipulate their data within a spreadsheet application.

WiiMotes can be mounted to a number of other apparatus to further examine in real-time the concept of acceleration, including spinning it on a rope or wheel to examine and measure centripetal force.

Further, a WiiMote equipped car can be used to explore acceleration mitigation strategies. One teacher and fellow pair

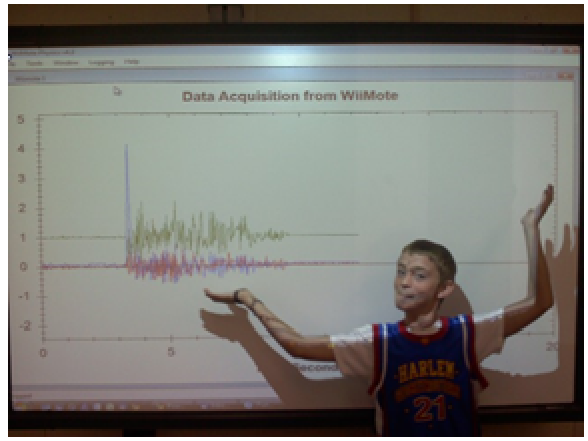

Fig. 4. Real-time data from the WiiMote captured and displayed using WiiPhysics.

carried out a crash barrier contest where students competed in building the most effective crash barrier system from kits containing popsicle sticks, straws, gumdrops, rubber bands, tape, glue, and other miscellaneous supplies. Unlike traditional implementations of such a contest in which the outcome is treated as a binary variable (i.e. in an egg drop the egg breaks or remains whole), the use of a WiiMote allows the actual deceleration to be continuously measured, resulting in a far more robust picture of how the barriers perform.

B. Catapult Design

This module utilizes the engineering design process highlighted in the upcoming Next Generation Science Standards (HS-ETS-ED) [7]. Students in an Introduction to Technology class wanted to build a catapult. Before beginning construction, the student studied historical catapult designs and identified a style that would be possible to build with the materials they had on-hand. Then, they identified the aspects of the design that they could easily alter the length of the throw arm, the angle of release, and the tension provided by the rubber bands.

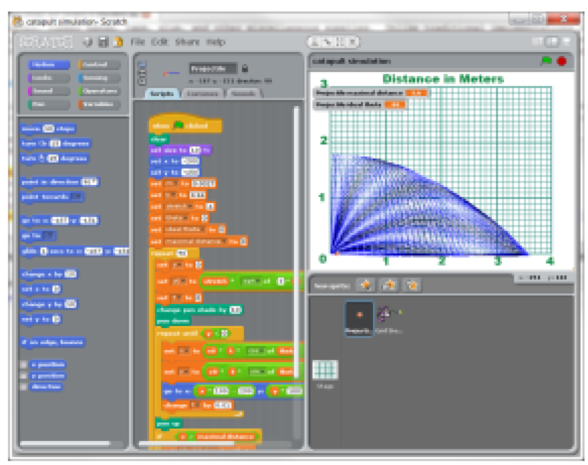

Fig. 5. Catapult simulation built using the Scratch programming language and environment.

Working from this design specification, the students programmed the ballistics calculations within the Scratch programming language, allowing them to compute the expected distance for a projectile to travel given applied values. Their fellow helped them to understand how to systematically alter these variables within their model using loops, allowing them to algorithmically identify ideal solutions. When the students expressed a difficulty interpreting the raw numbers, the fellow worked with them to incorporate visualization within their simulation animating and graphing a projectile launch conforming to the underlying mathematical model of the simulation.

Utilizing these results, the students then designed and constructed a physical catapult corresponding to their ideal design. The catapult was then test-fired, and real-world data collected on the results and compared with the computer model. Causes for discrepancies found between the real-world and computer simulation were discussed (air resistance, wind) and the model revised to account for additional factors.

C. Acceleration in Sports

WiiMotes, and their ability to measure acceleration, can also be used in other settings than the physics classroom. One unusual arena that the INSIGHT program teachers and fellows have exploited is physical education, where WiiMotes strapped to strategic locations can collect real-time acceleration data of athlete's technique. This can help an athlete understand how their technique for bowling, serving, and other activities affects their performance.

Fig. 6. Strapping a WiiMote to a bowler's arm.

INSIGHT participants have used the combination of WiiMotes and WiiPhysics to collect data from a wide range of athletic activities from badminton to water polo (where the WiiMote was sealed in a waterproof bag and placed within a cavity in the ball). Projecting the WiiPhysics real-time graph upon a wall or other surface within view of the athlete allows them to tweak their technique and immediately gain feedback on the result.

Access to real-time acceleration measurements can help diagnose and correct poor technique in student athletes; serving an important role in not only improving performance but also in preventing injuries. An important example of this can be found in weightlifting where discontinuities in an acceleration graph indicate poor form likely to lead to muscle pulls and strains. By mounting the WiiMote to the weight bar and projecting the acceleration graph within easy view of the weightlifters they can better monitor their lift.

Fig. 7. Collecting real-time acceleration data on a bowler's technique.

Fig. 8. Real-time acceleration data being measured in water polo and badminton.

Fig. 9. A WiiMote mounted to a bench-press bar, and the real-time lift data projected onto the ceiling, in easy view of the lifter.

D. Rocketry

Another thematically linked series of modules developed by our fellows tackles the field of rocketry. The first module utilizes stomp rockets foam rockets propelled by a blast of compressed air generated by stomping on a rubber bladder. These are used to develop an understanding of basic ballistic equations students measure the angle of launch and the weight of the stomper and then use these to calculate an expected distance and angle for the rocket to travel. This is compared with actual results.

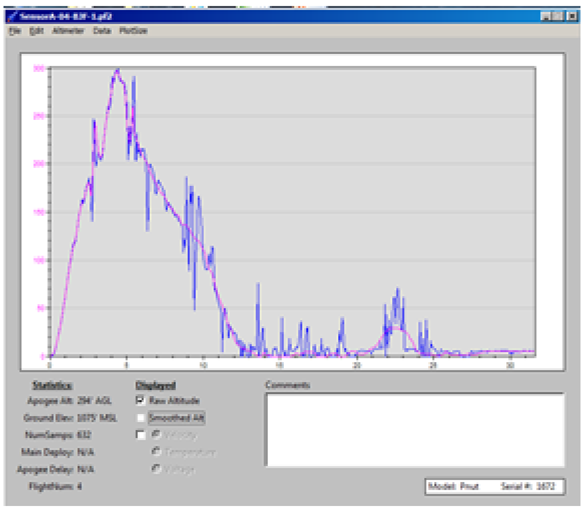

Fig. 10. Flight data measured by an in-rocket altimeter.

The follow-up module utilizes model rockets equipped with a hollow near the nosecone, within which a small altimeter board is placed. This sensor measures the altitude of the rocket as it travels along its flight path. While the students utilized pre-built rockets, another module could be incorporated within which students construct their own rockets, and attempt to maximize or minimize flight characteristics (maximum altitude, time of flight, fuel consumption, rocket weight), which again ties into the engineering design processes included in the Next Generation Science Standards [7].

IV. Results

In the 2010 school year, INSIGHT fellows and partner teachers held 49 of these curriculum modules, followed by 82 in the 2011 school year INSIGHT recruits two-year cohorts in a staggered pattern, so for the 2010 school year - our first year - we had only 6 fellows, while in 2012 we had 10, giving us a per-year average of 8.6 modules/fellow in 2010 and 8.2 modules/fellow in 2011. However, these numbers should only be considered a rough measurement of overall activity, as there is great variation in how fellows have contributed to their teachers' schools - fulfilling roles as diverse as tutoring pull-out sessions for gifted students to facilitating after-school science and engineering programs.

While the evaluation of the INSIGHT project has been largely a qualitative endeavour in the form of teacher/fellow interviews and journal statements (which are the source of the quotes appearing throughout the paper), some quantitative analysis has been performed on Likert scale response surveys given to teachers and fellows participating in the program before and after the 2012 INSIGHT Summer Institute. Only participants who answered both pre- and post-institue surveys were included in the analysis. Due to the small sample sizes and scale-limited responses, Wilcoxon signed-rank tests were performed (at .05 level of significance) for differences in pre- and post-institute responses [8].

Of especial interest is the shift in self-efficacy concerning teacher and fellow attitudes in presenting technology

TABLE I
Partner Teacher Comfort Level with Communication about Technology and Engineering

Comfort Level Statement (Measured on a 5-point Likert Scale)	Pre-Institute		Post-Institute	
	Mean	SD	Mean	SD
I am certain I can present information about sensor technology in ways that my students will understand.*	3.77	1.24	4.62	0.51
I am certain I can present information about engineering in ways that my students will understand.*	3.62	1.19	4.62	0.51
I am comfortable talking about ideas to incorporate sensor technology into the classroom with other teachers.*	4.00	1.08	4.69	0.48

*Statistically significant differences defined by Wilcoxon signed-rank tests in sample population of 13 INSIGHT partner teachers.

TABLE II
Participant Comfort Level in Helping Students Achieve Proficiency with Science and Technology Standards

Comfort Level Statement (measured on a 4-point Likert-like scale)	Pre-Institute		Post-Institute	
	Mean	SD	Mean	SD
Identify appropriate problems or opportunities for technological design.*	2.62	0.67	3.24	0.70
Propose a design and identify constraints reflected by that design.*	2.71	0.64	3.38	0.67
Compare designs and choose between alternative solutions.*	2.76	0.62	3.43	0.68
Implement a chosen design.*	2.81	0.75	3.38	0.74
Evaluate that design solution and its consequences.*	2.81	0.75	3.38	0.67
Evaluate that design solution and its consequences.*	2.86	0.65	3.29	0.64

*Statistically significant differences defined by Wilcoxon signed-rank tests with N=21 teachers and fellows.

and engineering in the classroom, and helping students gain profieciency in these subjects, as "...there is substantial evidence to suggest that, teachers' beliefs in their capacity to work effectively with technology are a significant factor in determining patterns of classroom computer use"[9]. For both teachers and fellows, clear patterns of increased confidence and comfort with these areas emerged from analysing the pre- and post-institute responses. These results can be seen in Tables I and II above.

V. Conclusion

The INSIGHT GK-12 Program has been effective in integrating sensor technologies and computing science principles into diverse K-12 classrooms, and has garnered positive feedback from all of its participants. Coupling the intensive training of the summer institute with an ongoing partnership between a teacher and a fellow has proved to be a very productive and valuable strategy. Staggering new entrants (teachers and fellows) into the program has also been an important strategy, as doing so ensures that every new cohort of teachers and fellows train side-by-side with a group of returning veterans from the previous year. This also helps to encourage out-of-the-box thinking, as the previous cohort has already tackled the often-challenging task of identifying ways in which sensors can be used in unusual settings, like physical education classes. This can in turn lead to fresh thinking from the new participants. The result is an active and imaginative community of practice, committed to integrating sensor technologies and computing science fundamentals into everyday classroom practice.

Integration of Sensors and Electrical Engineering into Secondary Geometry Curriculum

Mounir Ben Ghalia
Electrical Engineering Department
The University of Texas-Pan American
Edinburg, Texas, USA
benghalia@utpa.edu

***Abstract*— Several studies have reported on the potential benefits of integrating engineering education in K-12 curricula. Such benefits include: (i) an improved student learning and achievements in mathematics and science, (ii) an increased awareness of engineering and what engineers do, and (iii) an interest in pursuing engineering as a career. To help realize these benefits, the goals of the University of Texas-Pan American Research Experiences for Teachers in Emerging and Novel Engineering Technologies (RET-ENET) program are to: (i) engage math and science teachers in engineering research during the summer for the period of six weeks, and (ii) support the recruited teachers to translate their engineering research experiences into hands-on engineering-inspired curricula that they implement in their classrooms during the academic year. Using specific examples from the 2012 RET-ENET program, this paper discusses the activities conducted by a team of teachers who worked on a radar imaging research project and the process that led to the development of hands-on geometry lessons inspired by the research experience. The observation of the implementation of the lessons in the teachers' classrooms and the results of student assessments showed that the engineering-inspired hands-on lessons engaged students and increased their interest in learning the geometry concepts.**

Keywords— Research experience for Teachers; K-12 Geometry; Engineering content in science and mathematics instruction; Hands-on learning.

I. Introduction

New data published in the 2012 National Survey of Science and Mathematics Education report sheds new light into the serious challenges that the United States faces in its efforts to increase student achievement in math and science [1]. Out of the nearly 7,800 teachers surveyed, only one-third of middle school math teachers have a degree in mathematics or math education. The survey also shows that a large number of teachers do not feel well prepared to plan instructions that meet the needs of students at varying levels of math and science understanding. Teachers who are not well prepared are usually not comfortable with teaching challenging math or science concepts. When teachers are not comfortable with teaching a challenging content, they tend to teach the content superficially or avoid teaching the content [2]. A study has shown that teachers' discomfort and lack of confidence in teaching math concepts have a negative impact on student learning and perception of math [3].

Due to the strong link between engineering, math and science, several initiatives have been taken to introduce engineering content in K-12 math and science curriculum. The motivation behind these initiatives is twofold: (i) make a connection between math and science concepts to real-world applications to engage students and motivate them to learn math and science concepts, and (ii) promote pathways for students to be part of post-secondary STEM degree programs. There are two main approaches for infusing engineering in K-12 math and science curriculum. In the first approach, engineering is treated as a unique discipline and engineering curriculum is often offered as pre-packaged courses [4, 5]. The second approach calls for employing engineering as a tool for teaching math and science contents - that is engineering is embedded in math and science curriculum [6]. Both approaches have their merits. While there is an ongoing effort in the nation to increase K-12 math and science teachers' content knowledge, it is important to recognize that teachers can potentially become more confident to teach challenging concepts and know how to relate them to real-world engineering applications if they participate in a professional development program that gives them the opportunity to experience engineering.

To address the above discussed issues, The University of Texas-Pan American (UTPA) and several school districts in the region have formed a partnership to provide a professional development program for teachers to experience engineering research and translate the research to relevant hands-on math and science curriculum that meets state standards. This professional development program – Research Experiences for Teachers in Emerging and Novel

The author would like to acknowledge the support of the National Science Foundation through Grant CNS-1132609.

Engineering Technologies (RET-ENET) – was established in 2011 and hosted at UTPA. The first cohort of twelve middle and high school math and science teachers completed the RET-ENET program in the summer of 2012.

There is a number of papers that present the summer activities of other RET programs. However, there is a lack of published work that focuses on the various challenges that teachers face when they are asked to translate their engineering research experiences into relevant math and science curricula. Using specific examples from the 2012 UTPA RET-ENET professional development program, this paper discusses the main challenges associated with the task of translating research experiences into hands-on engineering-inspired activities that are appropriate to the subjects and grade levels the teachers teach, and that can be seamlessly integrated into the curriculum. Due to space limitation, this paper considers the activities of one single team of teachers who worked on a radar imaging research project and who, in collaboration with engineering faculty, re-designed their traditional geometry lessons to include hands-on activities that are relatable to the engineering research conducted during the summer program.

II. Overview of the RET-ENET Program and Research Questions

The RET-ENET program engages middle and high school math and science teachers in authentic engineering research experiences during a six-week summer program. Twelve middle and high school math and science teachers were selected to participate in the 2012 summer professional development program. Four engineering research projects were offered and teachers worked in trios on each project under the mentorship of an engineering faculty. The engineering research projects were in the areas of (i) nanotechnology, (ii) radar imaging, (iv) renewable energy, and (v) wireless communications. The summer program included several professional development seminars and workshops to provide the necessary tools and knowledge for teachers to conduct the assigned research projects and to help guide them to translate their research experiences into classroom activities.

This paper presents the research and curriculum activities of the team of teachers who worked on the radar imaging research project. The program research questions are:

- What roles does an active participation in authentic engineering research have on teachers' understanding of engineering and their adoption of new pedagogy?

- What influence does the mode of hands-on instruction by RET-ENET teacher participants have on their students' learning and interest in science, math, and engineering?

III. Teacher Engineering Research Activity

A team of three teachers, who teach mathematics and geometry subjects at middle and high schools in the Rio Grande Valley (RGV), worked on inverse synthetic aperture radar (ISAR) imaging [7-9]. None of three teachers has had an engineering background. They were introduced for the first time to radar imaging and were given a research task that consisted in analyzing the performance of an ISAR signature simulator by processing radar images of a three-dimensional model of a Boeing 727 and comparing them to real ISAR images of the same aircraft.

The teachers spent the first two weeks of the summer program reading background materials on ISAR imaging. A workshop was offered by the University library staff to help the teachers learn how to conduct electronic searches of technical articles. A workshop on the basics of the MATLAB software [10] was also offered by the RET-ENET management team as part of the summer professional development program activities. Teacher teams were asked to submit weekly progress reports. A weekly meeting with the program management team was held to promote discussions between all four research teams. The purpose of the weekly research meeting is three-fold: (i) teachers learn about research activities conducted by other teams, (ii) project management team monitors progress made by the teachers, and (iii) questions are answered and concerns by teachers are addressed by the program management team.

To understand the scope of the ISAR signature simulator, the radar imaging team began the research activity by generating radar images of three dimensional models of basic figures such as cubes, cylinders, and triangular prisms. The team used the basic models to start the testing the simulation software. This initial activity helped the teachers gain a better understanding of various components of the ISAR signature simulation software. The ISAR images created by such simple shapes were easy to analyze. After the teachers have felt more comfortable with the research process, they then moved to construct a model of the Boeing 727 using Blender - a 3D computer graphics software program [11]. At the end of the six-week summer program, the teachers succeeded in evaluating the quality of the ISAR signature simulator's images of the aircraft model. They completed a research report and prepared a research poster that was presented to other teachers, students, faculty, and school administrators at the end of the summer symposium held at the University.

IV. Resulting Lessons

A. Translating Research into Relevant Lesson Activities

An important component of the RET-ENT summer program engaged teachers in exploring and designing hands-on activity lessons for their math and science classrooms. Before the teachers started the summer program, neither the project management team nor the teachers had determined which of the exiting lesson plans should be redesigned and used with their students during the following academic year. On the first day of the summer program, teachers, however, were asked to identify some important concepts that their students either find difficult to understand or show no interest in learning. As teachers progressed in their research, they were asked to identify one or two important elements from their research experiences that can be linked to the concepts they teach in their classrooms. Weekly lesson development sessions were held to guide the teachers in the development of their lessons. The development of hands-on lesson plans was an iterative process. The first step of the process was to formulate an engineering connection to the math and science concepts. During the early lesson development sessions, teachers discussed their research experiences and shared ideas for lessons with other program participants and the project management team. As the summer progressed, teachers designed hands-on activities for their lessons that they discussed with their colleagues and the project management team. Throughout the lesson development sessions, inputs from teachers, engineering and education faculty were instrumental in formulating the engineering connections and shaping up the engineering-inspired hands-on lesson plans. Supplies were acquired for teachers to experiment with the various design components of their new hands-on lessons.

B. Making An Engineering Connection

To help in the design of the hands-on activities, teachers were guided to formulate concrete engineering connections to the science and mathematics concepts being taught in their lessons. More specifically, teachers had to draw from their research experiences some real-world engineering applications that can show how engineers apply the science and mathematics concepts to design new systems and solve problems. As the summer progressed, teachers became more knowledgeable about the engineering research problems they were working on and were able to improve the formulation of the engineering connections to their lessons.

After some discussions between the engineering faculty and teachers, it was found that the radar imaging problem can be related to at least three geometry concepts taught to middle and high school level classrooms. The three geometry concepts were: (i) The Pythagorean Theorem, (ii) Trigonometric Functions (SOHCAHTOA concept), and (ii) Similar Triangles.

The formulated engineering connection is stated as follows:

Math, Science, and Engineering play an indisputable role in the creation of modern measuring devices. Without some of these devices, it would be extremely difficult or even impossible to measure distances due to bad weather, hostile territories, or remoteness of location. Examples of such devices include Synthetic Aperture Radars (SAR) that are developed by Electrical Engineers. SAR technology has provided terrain structural information to geologists for mineral exploration, reconnaissance and targeting information for military operations, and oil spill boundaries on water to environmentalists. SAR systems use radio waves to create images of flying or stationary targets. These radio waves are transmitted and received by an antenna. The antenna generates the waves and sends them towards the target. Once the waves hit the target, they bounce back towards the antenna. In order to obtain clearer images, engineers must find slant range (distance from the radar to target and ground range (horizontal or ground distance from radar to target). Sometimes distances cannot be measured directly. Therefore, engineers use mathematics to find these distances. However, some trigonometric ratios and equations can only be used with right triangles. Fortunately, the radar antenna, the target, and a point of reference on the ground form a right triangle (Fig. 1).

For each lesson, the engineering connection is tailored as follows:

- *Pythagorean Theorem: Engineers use the geometric concepts of the Pythagorean Theorem to calculate distances in any right triangle model.*
- *Trigonometric Functions: Engineers use trigonometry to calculate unknown distances by using angles and known sides of a triangle.*
- *Similar Triangles: Attributes of similar figures can be used to create a scale model of the radar and target scenario. Ratios and proportions of corresponding sides can be used to test the proportionality of a scale model and to calculate distances.*

C. Hands-On Activities

Teachers often teach geometry in a procedural fashion and rarely make connections to real world applications. With input from the project management team, the teachers decided to consider an experimental set-up similar to a real-world radar system. In this setup, an infrared (IR) range sensor module is used to emulate the radar system. The IR range sensor can be used to determine distance measurements from voltage readings. A toy airplane or an airplane modeled out of clay could be used to emulate the target. To include a partial design component into the lessons, students are given the opportunity to build their own sensor modules. Each student group is given a kit (Fig.2) and instructions to build and IR-based sensor "radar" system prototype shown in Fig. 3. Students are then engaged in calibrating the sensor by collecting different measurements of distance between the sensor module and a wall and the corresponding voltage readings taken from a multi-meter (Fig. 4).

The current hands-on activities provide a new strategy to teach the geometry concepts by making them more interesting and engaging for students. Because of the formulated engineering connection between the geometry concepts and the real-world application, students see themselves playing the role of engineers to solve a problem. Teachers feel confident about the subject because they can speak from experience. This fact motivates students to learn the concepts.

D. Classroom Challenges and Learning Objectives

The classroom challenges are intended to make students feel they are "engineers". They are challenged to solve an "engineering" problem. The classroom challenge and learning objectives for each lesson are given next. The learning objectives include learning outcomes related to technology - resulting from the incorporation of the hands-on activities into the lessons.

1) Pythagorean Theorem (Grade Level: 8)

a) Classroom Challenge: Pretend you are an engineer working with NASA aviation. Under time and funding constrains, NASA has asked you to construct, calibrate, and evaluate their lastest Radar system design. The functional prototype, radar calibration results in graphical and tabular form, and distance evaluation results are due in four days!

b) Learning Objectives:At the end of the activity, students will be able to:

- Demonstrate a basic understanding of a Synthetic Aperture Radar system
- Formulate a tabular and graphical model that describes the relationship between variables
- Use the Pythagorean Theorem to calculate sides of a right triangle

2) Trigonometric Functions (Grade Level: 10):

a) Classroom Challenge: A hostile nation is preparing to launch a nuclear missile test in the coming days. We must obtain satellite images to confirm or deny this unauthorized activity before any other actions are taken. Your team is equipped with an MQ-9 Reaper, an unmanned aerial vehicle, capable of flying as high as 50,000 feet but only operational at 25,000 feet. Your UAV must fly by the hostile nation's presumed nuclear site and obtain radar images without being detected. At each station, the specifications and limitations of your UAV will be provided for you. Furthermore, the hostile nation's presumed nuclear site has been known to have a radar monitoring system. The specifications of their radar system have also been provided for you at each station. You must make the necessary measurements to figure out if your UAV will be detected by the hostile nation's radar system.

*b) Learning Objectives:*At the end of the activity, students will be able to:

- Use right triangle trigonometry to calculate unknown distances
- Use right triangle trigonometry to calculate unknown angles
- Use sensors to measure distances
- Convert voltage measurements to distance measurements
- Describe how to find unknown distances and/or angles using trigonometry.

3) Similar Triangles (Grade Level: 7)

a) Classroom Challenge: "Imagine you are an army soldier that monitors radars in a military base. You are asked to present how radar imaging is done to a group of people. Your audience is not familiar with radar imaging. You decide to use a model to help your audience better understand your presentation. Your model must be similar to the one shown in the presentation. How can a model help you present this concept?You know the angle formed by the ground range and the airplane's altitude is 90 degrees and the angle formed by the ground range and slant range is 37 degrees. How can you find the measure of the third angle in your triangle? How can you make a realistic model of the scenario? How can similarity help you construct a proportional model to make it realistic?

b) Learning Objectives:At the end of the activity, students will be able to:

- Use critical attributes of similar figures to determine if two figures are similar or not.
- Find the measure of an angle in a triangle when given the measure of the other two angles.
- Learn how technology is used to measure angles and distances.
- Connect their current learning to real-world applications in radar imaging.

E. Lesson Implementations in Teachers' Classrooms

The hands-on lesson on the Pythagorean Theorem was implemented in Memorial High School (McAllen ISD, Texas) in Fall 2012. The hands-on lesson on Similar Figures was implemented in Alonzo De Leon Middle School (McAllen ISD, Texas) in Fall 2012. The lesson on Trigonometric Functions was implemented in Jimmy Carter Early College High School (La Joya ISD, Texas) in Spring 2013.

The implementation of each lesson took four days. During the classroom implementation, students showed excitement to construct the sensor modules and learn how to use a multi-meter to measure voltage. Students used their sensors, multi-meter and TI-84 graphing calculators to measure the distance from the radar to the airplane and record it in their worksheets. Students then measured the distance using their measuring tape to compare the accuracy of their readings to that provided by the sensor. Students answered questions provided in the worksheets developed for the lesson. Students then participated in a gallery walk to view and learn about the other students' models. On the last day, students took a test to assess their learning of the taught geometry concepts and radar imaging. All students met the passing standard on the test; the passing standard on the test was 70%.

V. CONCLUSION

This paper describes the research activities of a team of math teachers recruited by the research experiences for teachers in engineering program hosted at The University of Texas-Pan American. The paper also discusses the adopted process that helped translating the gained research experience into engineering-inspired hands-on geometry lessons appropriate for middle and high school students. These activities not only engage students and increase their interest in the subject, as seen from classroom observations and assessment results, but also increase teachers' confidence to teach challenging concepts and relate them to real-world applications.

Creating a "playground" (computer network testbed) for high school students to learn, practice, and compete in cyber defense competitions

Julie A. Rursch, Doug Jacobson
Department of Electrical and Computer Engineering
Iowa State University
Ames, IA
jrursch@iastate.edu, dougj@iastate.edu

Abstract— The IT-Adventures program is designed to increase high school students' interest in information technology (IT) as a career. It allows them to learn about IT in non-threatening, extracurricular IT-Club activities using inquiry-based learning. The IT-Clubs have four tracks from which students can select to study: cyber defense, game design programming, robotics, and multimedia. This paper focuses on the cyber defense venue and the need for students to have equal access to computing equipment on which to learn about computer operating systems, networking, and information security prior to competing in a cyber defense competition (CDC) at the end of the academic year. The creation of a remotely located and managed "playground" provides uniform access to equipment across schools. This paper shares our knowledge and experience in creating the "playground".

Keywords—high school outreach, inquiry-based learning, cyber defense competition, information assurance.

I. Introduction

IT-Adventures is a highly successful high school outreach program run by Iowa State University (ISU) dedicated to increasing interest in and awareness of information technology (IT). The program, which is in its seventh year, has four tracks from which students can choose to study: cyber defense, game design programming, robotics, and multimedia [1]. This paper focuses on the cyber defense venue and the need for students to have equal access to computing equipment on which to learn about computer operating systems, networking, and information security.

As part of the IT-Adventures program, an IT-Club is created at the high school that runs as a year-long, after-school, extra-curricular activity. The inquiry-based approach [2-4] of the IT-Club is a successful method to increase student understanding of information assurance and computer/network security in a non-threatening, non-graded environment. The capstone event for students who participate is a two-day cyber defense competition (CDC) on the ISU campus.

In past years, physical access to hardware and operating systems for the students to practice with has been provided two ways. In the early years, computer hardware was donated to the program from corporations. The systems were refurbished and reshipped to the high schools to setup. This was not a scalable process. Therefore, in more recent years, the high schools were told to ask for donations of old equipment from companies geographically close to them. While this reduced the refurbishing and shipping requirements on the outreach program staff, it created inequities in what the students had at each school.

To solve this problem, the authors of this paper created a "playground" that is available to the students enrolled in the IT-Club in the fall of the year. This allows uniform access to equipment. Each IT-Club is given remote access to a network in which they can experiment; building different operating systems and installing different network services. The high school students spend the entire year remotely working in their assigned network space. Then, one month prior to the competition, the "playground" is wiped clean and the high school students can setup their competition networks for the CDC.

II. Outreach Program Background

IT-Adventures specifically targets high school students who previously have not exhibited an interest in studying IT. There are already programs available in IT-related areas such as the Lego First Tech Challenge and the Cyber Patriot Games where students who have IT knowledge can gain more knowledge. Those students and their programs are comparable to varsity athletes competing in a varsity sport. The IT-Adventures program is modeled after an intramural sport. Every student can have the opportunity to explore IT and to learn from it, not just the ones who are already good at it. This widening exposure to IT for high school students is especially important since computer-related courses are nearly non-existent in high schools across the U.S. [5].

As part of their IT-Club activities, the high school students are given access to learning materials, as well as a set of questions to explore. When the students choose to participate in the cyber defense venue, their "problem" is to compete in a state-wide CDC in the spring [1, 6-8]. The details of a CDC are discussed in Section III. Although we generally average 100 students in the cyber defense venue per year, in April 2009 the largest CDC ever hosted in any division, (collegiate or high school, on our campus or other campuses), occurred as part of the IT-Adventures program with 36 teams and 174 high school students competing.

The "playground" was developed with the support of a Department of Justice grant. The IT-Adventures program is supported by Iowa State University Department of Electrical and Computer Engineering and the Information Assurance Center.

III. PLAYGROUND CONFIGURATION

IT-Club members have remote access to the "playground" beginning in the fall of each academic year. For a majority of the year the students can use the "playground" to explore, learn, and play in a safe and controlled environment. However, during the month preceding the CDC, the "playground" becomes a competition environment. This design allows ISU to actively support the learning modules and labs because the hardware configuration is known and readily accessible by the university student workers and project staff. Additional information about the technical staff who support the "playground" is provided in Section IV.

The "playground" is built around a set of servers running ESXi 5.1. In its current configuration, there are five ESXi servers, however, the "playground" is highly configurable and could exist in other configurations depending upon equipment and number of student teams. Each of the current five ESXi servers is shown in Fig. 1 as a box composed of red dotted lines. The largest red dotted line box in the drawing depicts the ESXi server which houses the Internet-Scale Event and Attack Generation Environment (ISEAGE – pronounced ice-age) testbed, the air gap proxy, the remote desktop protocol server, and the ISO image datastore.

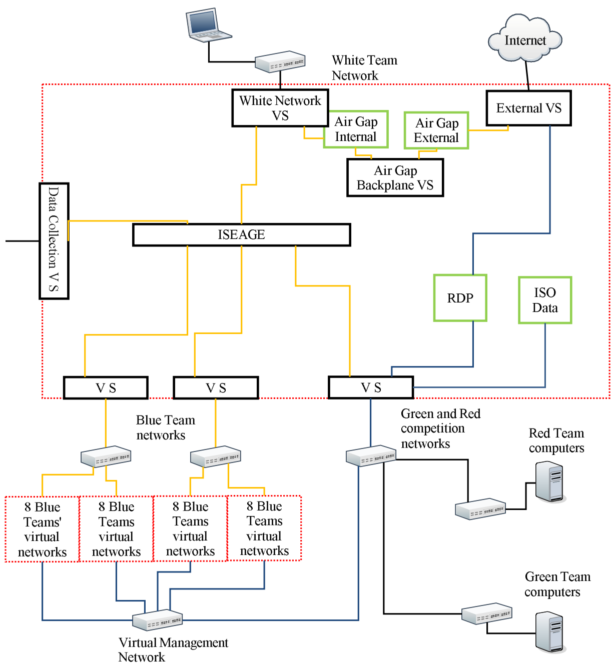

Figure 1. Playground Diagram

This ESXi server has one network interface card (NIC) connected to the Internet which allows two connections to the outside world through a virtual switch labeled external virtual switch (external VS). The first connection out of the external VS is for a remote desktop protocol (RDP) server that the high school students use to remotely connect into "playground" environment. They use the RDP server to get connected to their virtual networks through the virtual management network. In Fig. 1 the lines that connect the high school students from the external VS into the RDP server and then through to their virtual networks are blue. The high school student networks have each been pre-configured with one virtual switch in the virtual management network to allow them to start their virtual network configuration. A printed document which illustrates the remote access procedure to log into and use the "playground" was created for the high school students to reduce questions about access.

Each of four physical servers (red dotted line boxes in the bottom left of Fig. 1) have been configured in ESXi to host eight different IT-Clubs' virtual networks. With their own virtual network space they are allowed to build and configure machines in any manner using any public domain or Microsoft-based operating. Operating systems are installed through ISO images stored in the central ISO datastore, also shown in Fig. 1 connected with a blue line. Although the students use the RDP server and the virtual management network for installing servers and operating systems in their virtual networks, the machines they build and configure use the IP address space in the ISEAGE network which is discussed below. These connections are shown in yellow in Fig. 1.

The other connection to the external VS is for the air gap proxy which secures the ISEAGE network traffic that the high school students' networks generate. The set of two servers that provide the air gap is shown in the top right corner of Fig. 1. The server labeled Air Gap Internal is the only egress point for traffic leaving the ISEAGE testbed. It allows web and ftp traffic to pass out of the high school students' networks, but restricts all other traffic. By using this configuration, students are allowed to connect to the Internet to download patches or search for additional information about configuration problems, but other traffic is prevented from escaping. This provides an isolated network environment in which the student networks can run. It was constructed to avoid the inevitable misconfiguration or unwanted attacks on the real world network. The server labeled Air Gap Internal also provides the domain name service (DNS) for the high school teams' virtual networks which allows them to appear to each other to be part of the Internet.

The core of the ISEAGE testbed is a routable IP network that supports the traffic to and from the high school students' virtual networks. Because of ISEAGE's internal programming, it provides IP address space for each high school group's virtual network and allows them to experience running a network as if it were actually sitting on the Internet. ISEAGE allows to traffic appear as if it has routed through the Internet, although it stays within the ISEAGE environment. ISEAGE is unlike conventional testbeds where each router represented by either a real router or a software router running on a computer. ISEAGE supports the concept of an internal cloud network where the cloud represents a cluster of routers. If an external computer performed a traceroute it would see a number of hops between itself and server as if there were real routers between it and the server. The TTL field in the IP header would also indicate the traffic traversed multiple routers. Again, this allows the students to see traffic as if they were separated from each others' virtual network via the Internet rather than routing traffic through a single server.

Upon further examination of Fig. 1, there are additional networks that have not yet been discussed. These remaining networks are not necessary for the year-long inquiry. They are built into the “playground” to be used during the CDC event. In a CDC there are four teams of people needing network connectivity: Blue, Green, Red, and White.

The Blue Teams are the high school student teams who setup and defend their network from attackers. They also participate in numerous activities (called anomalies) throughout the competition requesting changes to their network. The team who administers these anomalies is called the Green Team.

The group who tests each student team’s network for vulnerabilities and plays the role of attackers in the competition consists is called the Red Team. They actively engage in network scanning, penetration testing and exploitation of vulnerabilities.

To win a competition, the student teams earn points based upon service uptime, usability, security, and reporting. The judges record the points earned during the completion and are called the White Team.

Fig. 1 shows that there is a virtual switch for the Green and Red teams to connect into the ISEAGE testbed to test the high school student teams’ networks for usability, as well as vulnerabilities. There is also a virtual switch to connect the White Team to monitor and score the competition.

The final connection into the ISEAGE testbed is labeled Data Collection in Fig. 1. This allows the authors to collect the traffic generated during setup, as well as during the competition for further analysis.

IV. Technical Support for Playground

Technical support for the “playground” requires both paid and unpaid undergraduate students at ISU. The primary technical support for the “playground” is provided by the undergraduate student staff members of the Information Assurance Center. They configure and maintain all the ESXi equipment, the ISEAGE network, and the support systems such as remote access and ISO images under the direction of the authors of this paper. In addition to these paid student workers, ISU also has a student organization called the Information Assurance Student Group (IASG). Volunteers from IASG, along with paid Information Assurance staff, provide the remote setup support for each of the high school IT-Clubs, as well as write the rules for the CDC and staff the actual two-day event. Remote setup support is staffed approximately 20-30 hours per week, mainly in the evening.

V. Future Work

Creating a “playground” allowed uniform access to equipment for all IT-Clubs and allowed high school students to spend the entire year remotely working in their assigned network space. This approach, while demanding additional technical support staffing on the part of the IT-Adventures program, was far superior to the ad hoc approach taken to supplying physical hardware for students in past years. The technical support staff was able to more efficiently and effectively answer questions for the high school students and the students did not have the technical road blocks of antiquated computer equipment getting in the way of learning.

The “playground” is fully implemented, but the updated learning modules to replace existing modules are still under development. The expectation is to have these new learning modules in place by Fall 2013. While there has been on-going assessment of the IT-Adventures program throughout the life of the program, additional assessment tools still must be put in place to evaluate the effectiveness of the new learning modules and the “playground”. This work begins also in Fall 2013.

In future implementations, the “playground” will include a set of vulnerable machines with which the students could learn about conducting penetration testing on their own systems. The closed environment in which the student networks exist allow the students to run tools against these systems to find the vulnerabilities and then to use tools to exploit what they have found without any traffic traversing a real world network.

Finally, while this paper focuses on the use of the “playground” in a high school setting, the “playground” can be used to support educational activities at the community college and university levels as well. We have had one community college in Iowa recreate a version of the “playground” to support their own post-secondary classroom activities. Other colleges and universities have also expressed interest in an implementation of the “playground”.

***Abstract*—The 16 critical infrastructure sectors identified by the US Department of Homeland Security employ many engineering, technology and computing graduates who increasingly face critical infrastructure protection (CIP) issues. However, most undergraduate curricula in these disciplines do not incorporate CIP in any meaningful way. This paper proposes a flexible curricular framework for integrating CIP into undergraduate education via self-contained inter-disciplinary CIP course modules; a course module is a distinct curricular unit such as a lab or teaching component for use by an instructor in existing courses without requiring any course or program modifications. The proposed course modules cover physical, human, and cyber aspects of CIP. The framework is designed for use in multiple disciplines, and the modules are designed for presentation at different levels of the undergraduate experience, with subsequent modules building on those presented earlier. This approach is intended to prepare students for careers solving problems in design, implementation, and maintenance of robust, sustainable infrastructure assets.**

Keywords— critical infrastructure protection; course modules; homeland security

I. INTRODUCTION

Critical infrastructure refers to systems and assets so vital to any country that their incapacity or destruction would result in a debilitating impact on security, the economy, national public health or safety [1].

The US Department of Homeland Security has identified 16 critical infrastructure sectors that include such functions as transportation, energy, healthcare, food and agriculture, water, financial services, emergency management, and defense, critical manufacturing and commercial facilities. Many of these sectors, such as the electric grid, fuel delivery systems, and water purification and delivery plants, are supported through the Internet, or cyber resources.,. The flexibility and advantages of cyber resources is generally recognized, but they come with a high cost: the constant threat of interruption, theft, manipulation, and destruction.

Many engineering, technology and computing graduates already work in critical sectors. Given the urgency and the necessity for critical infrastructure protection, it is not difficult to make a compelling case that these graduates will thus be facing an increasing set of critical infrastructure protection issues in their careers. While the Department of Homeland Security has prepared informational materials on these sectors and some instructional units are available for graduate students [2], undergraduate curricula do not address CIP in any meaningful way. Further, much of the available materials focus on the physical and human element of vulnerability, and not the cyber element. It is this cyber (virtual) element that is most inextricably linked to the resiliency of the system, as the real issue is not whether the system is rendered inoperable, but rather how quickly it can be restored to operability. Therefore, the less resilient the system, the greater the relative impact. Since cyber systems connect and control much of our infrastructure and resources, their resiliency is fundamental to a safe, secure and functional society.

This paper describes a curricular framework for integrating critical infrastructure protection (CIP) concepts across engineering, technology and computing. In addition, to allow this material to be reused across multiple diverse student groups, the integration is accomplished by using a set of interdisciplinary course modules. In this context, a course module is viewed as a distinct curricular unit such as a lab or teaching component, which can be used by an instructor in an existing course typically without any course or program modification approvals. These modules can be expanded as needed to prepare students for careers in problem solving, design, implementation and maintenance of robust and sustainable infrastructure assets.

II. MOTIVATING THE CURRICULAR FRAMEWORK DESIGN

How do we protect current and future resources critical to our nation's health, security and economy? If such systems are breached or compromised, how can we ensure they will be resilient, and be able to go back on-line in a minimum amount of time? Our examination of the major issues in protecting critical infrastructure indicated the emergence of three driving forces, as discussed below.

- **Reliance on complex systems.** The increased reliance on complex systems, coupled with high multivariate and unpredictable risk from natural and intentional sources is a major factor. Events such as the September 11 attacks, the Virginia earthquake, and several major hurricanes (for example, Katrina, Irene or Sandy) exposed vulnerabilities in many critical systems that

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

modern society depends on each day. Several critical infrastructures were designed for operation in a manual or analog mode and now have been retrofitted to be managed digitally through cyber based systems [3]. Future engineers, technologists, and managers need to understand how design and implementation can exacerbate vulnerability or increase resiliency. Additionally, while there is a tendency to view risk in terms of large densely populated urban centers, the reality is that these critical systems govern operations in wide cascading networks. Significant risk is thus not confined to our biggest cities. Thus, an outage in a large city where critical servers are located may cause serious disruptions in dependent smaller areas.

- **Societal changes in computing.** The rapid growth in mobile computing devices such as smartphones and tablets and the widespread adoption of cloud computing has made cyber security a concern for everyone. Moreover, issues of cyber security and the impacts of security breaches span multiple CIP sectors [4].
- **Need for a CIP-aware populace and workforce.** Employees who understand the socio-technical issues and risks faced by our modern society are in demand in both public and private sectors [5], especially given that most of the nation's critical infrastructure is privately owned [6]. Students who are exposed to CIP concepts along their educational path will graduate with necessary skills and knowledge to address risk and resiliency issues in critical infrastructure systems.

These three major issues provided the motivation for integrating CIP across several courses and disciplines, using "drop in" modules to serve as supplemental materials for vertical integration into an array of multidisciplinary courses across all years of undergraduate study. Students thus encounter relevant CIP concepts several times at increasing depth as they progress through their degree programs.

III. COURSE MODULES

This effort focused on modules, herein defined as a lab or teaching component. Modules were designed so they could be used by an instructor in an existing course without requiring formal curricular changes or approval.

The foundation of the approach is a set of self-contained instructional modules that can be "dropped into" relevant classes. The modules cover physical, human, and cyber aspects of CIP in appropriate detail, from introductory material to deeper, more technical concepts. These self-contained elements can be used in many different ways. Some examples of module usage are given below.

- **To replace obsolete or outdated material.** Computer science or engineering classes need frequent updates to keep pace with technological advances. These modules are an excellent way to replace outmoded topics with a contemporary, pressing problem of system security.
- **To enhance and strengthen existing material.** Some course topics touch on infrastructure concepts, e.g., discussions on privacy, hacking, or hardware issues such as loading. Modules would augment this material by linking theoretical concepts with the real-world systems whose security, safety, and resilience are made more or less vulnerable through software and hardware design.
- **To supplement a course with new material.** In this scenario, modules introduce a new topic for the course. Note that supplementing a course with a new module could mean other topics would be shortened or, if obsolete, dropped altogether.
- **To function as homework assignments or labs.** Because these modules are meant to be stand-alone units, including both content and assessments, they can be used as homework or supplemental assignments, and designed specifically for this purpose.

A. Curricular Goals

Although there are 16 Critical Infrastructure and Key Resource (CI/KR) sectors as defined by DHS, there are fewer pervasive themes we identified across all sectors. Hart and Ramsay [7] define a five-part framework based on policy, networks, level of hazard, level of protection and system design. Each component included physical, human and cyber (virtual) elements.

Our instructional team developed the following learning outcomes based on the objectives defined by Hart and Ramsay [7] in their CIP course guide:

- **Learning Outcome 1.** Understand national strategies and policies on CIP and Key Resources – CI/KR
- **Learning Outcome 2.** Identify key components of a complex system
- **Learning Outcome 3.** Describe the hazards present in the critical components of a complex system
- **Learning Outcome 4.** Assess the level of protection and resiliency for the components of a complex system
- **Learning Outcome 5.** Learn system design concepts to achieve the desired protection and resiliency.

B. A Sample Course Module

For illustration, we selected one of our course modules that can be used in multiple courses offered at different learning levels. Other modules being developed include level-appropriate material and exercises to provide students experience with concepts at multiple levels of detail. These modules are based on the requirements outlined in the DHS National Infrastructure Protection Plan [8].

Module: Introduction to Critical Infrastructure Protection

This course module will introduce students to basic concepts underlying critical infrastructure; its relationship to emergency management and planning; and why protecting the infrastructure is important for personal, community and national security cover topics. Students will learn that critical infrastructure/key resources encompass those physical entities and processes that make our communities function effectively. The module will also show how critical resources of energy supply, water/wastewater, transportation, telecom, emergency services/medical, facilities and finance depend upon computing, engineering and technology and our national interests are protected by securing these sectors, and demonstrate how computing, engineering and technology both support this infrastructure and provide tools of protection.

Suggested target courses for this module include introductory engineering, technology, and computing courses on networking, telecommunications, civil engineering technology, and computing security.

CIP Learning Outcomes: 1, 2

IV. Assessment and Evaluation

To ensure the course modules are effective, each module has a set of concrete achievable outcomes that will be assessed and evaluated. Evaluation data will be used for both formative and summative purposes: (1) to improve the assessment instruments and instructional modules as they are pilot tested and revised, and (2) to provide evidence that this approach enables learning at all levels. Our assessment will answer the following:

- **How easily and effectively are modules integrated into existing curricula?** Feedback from design teams and adopting instructors will evaluate module usefulness, ease of use, time to introduce the topic, and appropriateness of indicated module prerequisites.
- **How effective are the modules for students?** Student assessment will be measured through student feedback and learning gain.
- **How effectively are students in different disciplines learning the intended outcomes of each module?** Using direct assessment techniques, we will examine achievement between different discipline groups (computing, technology, and engineering majors).
- **Are the modules appropriate for each educational level?** Instructor interviews will reveal student perceptions of module delivery, value, and content.
- **To which extent is each CIP learning outcome attained?** Direct assessment measures will be collected for each module, and evaluated by CIP outcome.

Evaluation data will be used to improve the assessment instruments and instructional modules as they are deployed. For the purposes of evaluation, each module is an object of study. Both direct and indirect methods will be used to measure each outcome. Direct assessment occurs through criterion-referenced tests that measure whether students have learned the variety of intended outcomes. Indirect measures include student perception surveys and individual interviews to measure student perception of their own learning.

V. Conclusions

Recognizing that our graduates may work in business sectors facing infrastructure protection issues, a cross-disciplinary team of faculty developed a strategy to ensure that students were exposed to critical CIP issues. This effort started with course modules to introduce necessary concepts and theoretical backgrounds, and was extended to build a framework of self-contained instructional modules. The framework is intended to prepare students for careers in solving problems and issues in design, implementation, and maintenance of robust, sustainable infrastructure assets.

While these course modules fill a curricular gap, students will want, and industry will need, deeper knowledge and skills. We plan to design an interdisciplinary degree program in CIP that prepares students for careers in industry, public service, and academia. We are also exploring partnerships with local and regional governments to offer CIP instruction to emergency managers and public officials.

VI. Current Status

At present, several of the modules have been designed while others are currently under development or further revision later in 2013.

Simulating Industry:

An Innovative Software Engineering Capstone Design Course

Lynette Johns-Boast and Shayne Flint
College of Engineering and Computer Science
The Australian National University
Canberra, Australia

***Abstract*—Universities are required to produce graduates with good technical knowledge and 'employability skills' such as communication, team work, problem-solving, initiative and enterprise, planning, organizing and self-management. The capstone software development course described in this paper addresses this need. The course design contains three significant innovations: running the course for two cohorts of students in combination; requiring students to be team members in 3rd year and team leaders in their 4th (final) year; and providing assessment and incentives for individuals to pursue quality work in a group-work environment. The course design enables the creation of a simulated industrial context, the benefits of which go well beyond the usual, well-documented benefits of group project work. In order to deliver a successful outcome, students must combine academic theory and practical knowledge whilst overcoming the day-to-day challenges that face project teams. Course design enables the blending of university-based project work and work-integrated learning in an innovative context to better prepare students for participating in, and leading, multi-disciplinary teams on graduation. Outcomes have been compellingly positive for all stakeholders – students, faculty and industry partners.**

Keywords—Software Engineering, Capstone Design Course, Work-Integrated Learning, Group Project, Industry-Based Project, Peer Assessment, Peer Assisted Learning, Internship, Course Design, Curriculum

I. INTRODUCTION

Increasingly employers and society more generally are requiring universities to produce graduates with appropriate 'employability skills' such as communication, team work, problem-solving, initiative and enterprise, planning and organizing, and self-management [1]. To achieve these outcomes, universities and other tertiary institutions frequently use capstone design group project courses to help students develop these important skills.

In the early years of their engineering degree, students learn in a largely theoretical fashion. Although some institutions use approaches such as team work and problem based learning (PBL) from the first year, practice of theoretical learning is frequently limited to artificial assignments or small-scale group projects and problems which fail to demonstrate adequately the true value of important engineering activities. More frequently, however, students work individually without the opportunity to develop the team working skills along with professional skills.

Group project courses require students to work in teams and to undertake medium-sized projects, sometimes for real-world clients from outside the university environment. This enables students to take part in all aspects of the engineering process. Working in teams exposes students to the issues and problems associated with communication and team productivity. Both practice and the literature (for example [2]-[7]) suggests that project courses are highly effective in preparing students to face the real-world, as well as for consolidating learning.

Ensuring satisfactory outcomes for all stakeholders – academics (student learning, confidence in assessment); students (learning, grades, fun) and clients (product, intellectual assets) – can be a difficult task as all three have widely divergent requirements for success. Success for one may not necessarily mean success for another. Additionally, fairly assessing individual student contribution can be an even more difficult and time-consuming task [8].

The group project courses described here are a significant capstone of the software engineering degree at the Australian National University (ANU). Students participate as team members in one project in their 3rd year and as team leaders in another project in their 4th (final) year. For two consecutive semesters, small teams of five or six students, with 4th year team leaders and 3rd year team members, work with industry partners to develop solutions to contemporary, real-world problems. Student teams are closely supported throughout by experienced, industry-based mentors alongside their industry clients and faculty. Academic assessment is achieved principally through the mechanism of three gateway reviews staged through the project.

This design, combined with the assessment scheme, has allowed us to simulate an industrial context. As well as team work skills and experience, students gain practical knowledge of current industry practice which goes well beyond the technical knowledge in their other university subjects. They use software tools, programing languages and project management approaches which are prevalent in industry but not always taught at university. Students learn about the iterative nature of software development and regularly discover that a single approach does not suit all stages of their project – and thus learn through experience the value of adaptability.

Each year, course designers and coordinators work closely with industry partners to offer students a wide selection of projects which range from pure computer science and software engineering research, through developing proof of concept software to the more traditional implementation of e-Commerce and mobile applications. Software developed by students is regularly incorporated into the code base of our industry partners. Student projects win industry awards and the course itself won an Australian Council of Engineering Deans Education Excellence award.

The capstone design course described in this paper has been carefully designed to achieve the overall goal of "*help[ing] students develop leadership skills and become an effective member of a team which makes and implements appropriate engineering decisions related to the development of software systems that deliver measurable value to clients*" [9]. Each year the effectiveness of the course is assessed qualitatively, based on feedback received from students, clients, mentors and faculty.

II. Course Design

At the ANU, Bachelor of Software Engineering (BSEng) students undertake two capstone design courses – one in 3rd year and another in their 4th (final) year while Bachelor of Information Technology (BIT) students undertake a capstone design course in their 3rd (final) year. Students work on real-world problems for real-world industry partners for two consecutive semesters.

The innovation of combining the 3rd and 4th year courses into one, while at the same time working with industry partners, has enabled the creation of a simulated industrial context which provides benefits over and above the usual, well documented benefits obtained from undertaking group project work. Teams consist of five to six students: four or five 3rd year students (both BSEng and BIT) led by one or two 4th year (BSEng) students. Faculty plays the role of senior management in a notional consulting company. Within the simulation, it is assumed that the company (as represented by faculty) successfully tendered for a number of projects for which it has subsequently recruited teams. The role of the company's senior project manager is played by team mentors – who have industry and project experience. Mentors work closely with teams, especially the 4th year team leaders. Teams all work with an industry partner or university client.

Course design incorporates peer assisted learning (PAL) [3] which has been shown to be a powerful method for leveraging learning beyond the direct efforts of the teacher. To be effective, however, it requires situations that motivate the more experienced students to assist the less experienced. Combining 3rd and 4th year students on one team facilitates PAL directly, as the 4th year students have previously completed the course, and have an incentive through their shared project marks to improve their juniors' performance. PAL, lectures and structured reflection homework provide students with opportunities to share the experience of their peers' projects, increase their learning over and above their own design and implementation experiences, and to develop a community of practice [10], [11].

Since assessment is the key to student learning, the best way to change that learning is to change the assessment scheme [12]-[15]. Accordingly, the assessment scheme has been continuously refined to help us better meet the learning outcomes of the course. As the course design has developed, we have moved progressively from focusing assessment efforts on the quality of deliverables to concentrating on process and team work. The key to success in this aspect of the design was the introduction in 2008 of formal peer assessment and in 2009 project reviews in association with a holistic view of the quality of deliverables.

By design, the assessment scheme places responsibility on students to control their projects: to determine scope, schedule and deliverables. In consultation with their project's industry client, students are also responsible for establishing their own systems and software development lifecycle and project management environment. Student teams are closely supported throughout by experienced, industry-based mentors alongside their industry clients and faculty. At three key points through the project, students, industry partners, mentors and academics participate in 'gateway reviews' which examine a team's performance and project progress to provide guidance and assurance that they can progress successfully to the next stage of the project. The gateway review process also provides the principal mechanism for academic assessment.

A significant student and faculty concern related to group work is the existence of non-productive group behavior such as social loafing and free riding [16] where students who do not complete tasks as responsibly as their peers, nonetheless attain the same mark as their more responsible peers [17], [5], [18]. To overcome such problems and to improve learning, course design uses peer assessment of team colleagues to generate differential individual marks from team marks. Mentors and faculty provide feedback and mentoring to individual students and teams to help them learn from their peers' assessment and to improve team performance. Mentors also assist team leaders to use this data to mentor and develop their team members.

Clients treat students as a team of junior consultants, frequently inducting them into their organization. Clients often require that student teams comply with company processes and procedures related to how they run projects within their organization. Reminiscent of industry governance procedures, the gateway reviews involve representatives of all stakeholder groups – clients, faculty, mentors and all members of the team. As well as providing the mechanism for academic assessment the gateway review process provides meaningful feedback and guidance to the team to help them deliver real – tangible – value to clients.

Further detail related to course design can be found in two earlier papers by Johns-Boast & Flint [19], [20].

III. Significance to Engineering Education Practice

Through deliberate and intentional learning opportunities, linked with appropriate and careful assessment, our students obtain the benefits of work-integrated learning [21], [22] without either extending the length of their study or missing out on exposure to valuable content in other courses because these have been sacrificed to provide space in the curriculum for participation in internship programs for credit.

In addition to the usual and well documented benefits from undertaking group project work (for example, [23], [4], [24], [6], [25]), the industrial simulation we have created helps students fuse theory with practice and thus improves students' ability to transfer knowledge from the academic environment to the work-place and vice-versa [21], [22]. The course introduces students to the professional skills required of a competent engineer: leadership, management, communication with both peers and supervisors and teamwork in particular, as well as ethical and other responsibilities.

Unlike internships, sandwich courses and work placements where students work with a single company and frequently a single area of that company for periods of time often no longer than a semester, our students work for eight to nine months each year with different organizations and clients on different projects. Consequently their exposure to different work places, cultures, project types and teams provides them with a much wider experience than a single industrial placement would normally offer. In addition, through the greater autonomy, responsibility and decision making required of students participating in the course, our students are offered greater opportunity to develop leadership capacity than generally happens in traditional work placements and internships.

Project gateway reviews require students to defend their decisions as well as encouraging them to try things and to take risks that would not be possible in traditional internships and work placements. In consultation with their clients, students are responsible for all aspects of the management of their project. They frequently select and use a broad range of tools for project tracking, issue management, continuous integration, code review, configuration management and version control, and adopt approaches widespread in industry which they don't learn at university.

By removing many constraints from the assessment scheme and handing over complete control of their projects to students, and increasing the focus on reflection, self and peer assessment, and critical thinking, we have encouraged the development of autonomous learning [26]. Peer assessment of contribution to the team's work achieves a fair and equitable allocation of marks that adequately reflects both individual knowledge and contribution [27], [17], [5]. More importantly in terms of student learning, however, peer assessment also helps students understand and develop key skills related to team work and performance review as well as enabling 4th year students to develop mentoring skills as they work with team mentors to develop and mentor the 3rd year members of their team.

From anonymous student feedback collected since 2010, it is apparent that students value the challenges and opportunities the course provides; saying for example, that the course provides "*opportunities to learn things that aren't part of a pre-existing and highly structured course - to do something semi-original*" and that they enjoy "*the challenge ... to get something designed and built based upon what the client wants, and it gives you a great feeling of satisfaction and pride to know that you built something from scratch*".

Feedback from industry partners is consistently positive. Our partners indicate they see the projects as an "*extremely valuable pedagogical tool*" and "*an innovative educational program that is extremely beneficial for all involved*". Of real benefit from the point of view of student learning is that industry partners assert that "*the tasks that we provide for the students are not artificial or 'make-work' in any way*".

Moreover, our industry partners like that the course "*allows students to engage with industry early*", that they get to "*look over*" the students prior to employing them, and that it provides them with an opportunity "*to give back to the ANU*" as well as providing "*a means for us to corporately contribute to producing more highly skilled and capable engineering graduates. This in turn will be for the betterment of the profession and ultimately for the betterment of society as a whole*".

Faculty have also benefitted from the relationships created with industry: we have recently had a Researcher-in-Business [28] grant which grew from the organization's engagement with the academic through provision of a student project. A side benefit to the School is that by combining 3rd and 4th year classes we achieve a more efficient use of academic time and effort in class contact, project selection and management, at no extra cost in assessment.

A. Demonstrated effectiveness

The assessment scheme is designed to support the principal goal of the course: *to help students develop leadership skills and become an effective member of a team which makes and implements appropriate engineering decisions related to the development of software systems that deliver measurable value to clients* [9]. Feedback gathered since 2010 shows that all stakeholders are pleased with the outcomes delivered by the assessment scheme, especially the project review process and its ability to help students deliver real value to clients and to gain valuable experience.

Anonymous student evaluations show that students generally like the assessment scheme and understand the value of the review process and its rich formative feedback, saying for example that the "*project reviews work well because they force you to process the feedback being given and act on it (at least more than other forms of assessment I've seen). You often don't see the feedback from exams, and I often dismiss the feedback from normal assessments because it's a specific situation. But with the projects, there's a direct link between acting on the feedback and future progress and outcomes*". Students also comment that they "*really like the reviews ... [as] they were a great chance to show how our process was working (or not)*". Additionally, the review process develops students' ability to critically assess their own work as it requires them to take "*a step back from the inner workings of the project, [which] gives us an objective view of our project's progress rather than our highly subjective one*".

Students similarly note that they "*like the idea of reflections and peer assessment. It is good way to give feedback and reflect on the working of a team*" as well as liking the unstructured nature of the assessment scheme. While students acknowledge the nature of the work required by the course, they comment that despite sometimes encountering "*a lot of stress caused by the project ... it was definitely worth it*".

Feedback from our industry partners indicates that they are impressed both with the operation of the course and the quality of the students. One partner has noted that "*the course has obviously taught them [the students] about the practical components of working in the real world because the project team managers have worked well in liaising between their group and the company sponsoring the project. We asked the team to produce a mobile application ... and the team has delivered, despite many challenges being thrown at them and many unexpected working and technical obstacles appearing along the way*"; another notes that students "*experience of all the complexities ... of real world engineering in a relatively benign and supportive environment*".

The quality of the course is also demonstrated by external measures: a number of student projects have won awards at regional and national levels from the Australian Information Industry Association (AIIA) and the Australian Computer Society (ACS) and in 2012 the course itself received a "Highly Commended" award from the Australian Council of Engineering Deans (ACED) for Engineering Education Excellence.

B. Benefits to industry

Since 2004, 353 students have graduated from the program and 65 external/industry projects with 46 organisations and 26 university projects have been completed. Depending on enrolments, we run up to 13 different projects per year. Over 75% of industry partners have been start-up companies, individuals developing a proof of concept prior to formal start-up, small to medium enterprises (SME) and non-profit organisations. Based on the number of hours it is suggested that each student should spend on their project (10-12 hours per teaching week, i.e. 26 weeks), estimated hours of industry partner involvement and including overheads for mentors and faculty, we estimate that the value of each project is around $150,000. It can be argued therefore, that through the medium of these student projects the ANU provides $1 million software development assistance each year, mainly to start-ups and small and medium (SME).

When identifying benefits gained from their participation, industry partners have noted that the student projects "*generally result in the production of 'very nice to have' capability that we would probably not otherwise have been able to introduce ... [and] provide a small but worthwhile addition to the overall operational capability of the software engineering group during the course of the year*" [29]. One regular industry partner obtains a secondary benefit from participation because "*the student projects also provide opportunities for junior software engineers [in the company] ... to participate in the projects as clients and client project managers. This is an educational and career enhancing experience for those engineers".*

C. User acceptance and take up

Although the course is compulsory for many students, recently there has been increasing enrolment from students for whom it is an elective option. Furthermore, since 2010 over 83% of students who submitted responses, rated the course "Enjoyed and learned a lot" or "Enjoyed and learned something". Students' feedback includes comments that it "*was a really great course. It was practical, enjoyable and interesting (I hope all courses were like this course). The course was organised very well. It's hard to find a thing that should be changed with this course*". Furthermore, depending upon the year in which the data was collected, between 73% and 91% of students who responded said that they would recommend the course to other students.

Students value highly the freedom that the course assessment provides saying, for example, "*I liked organising things for myself and working things out by myself. I liked not having something due every 2 weeks and how there were few well-defined deliverables*". They also appreciate the efforts of the mentors and course faculty who "*spent a lot time and effort in teaching us, also really appreciate for giving us so much valuable feedbacks on our project, coz I really gain a lot in it*". Students who provide feedback generally reflect it is "*all in all, very good course*" and "*is one of my favourite courses I've done at uni*" as well as observing that "*it seems like lecturers have been tinkering with this course for years. But it's good how it is now. Don't change anything*".

Contrary to our experience when we began offering industry-based group project courses in 2002, we now have more projects put forward each year than we have student teams to undertake them. Many of our industry partners are repeat clients; half a dozen of whom have undertaken three or more projects since 2009. They like that "*it is possible to get a good outcome that can be used ... [and that it] lets me stay connected with the latest trends*" as well as stating that they "*intend to continue ... involvement into the foreseeable future*". Industry partners' involvement with the course is "*a very positive one from the point of view of the ... project team and the wider company*". A first time client said "*we had no idea on how the setup worked but the teaching staff were fantastic in making sure we were well prepared in knowing how to earn the right to welcome a project team to the company as well as how best to engage with their students, many of whom the staff work with personally ... It has been so much of a success, we want to come back for more next year. The staff have been supportive and their students superb*".

D. Difficulty and complexity

Increasingly, universities are required to produce graduates with appropriate 'employability skills' such as communication, team work, problem-solving, initiative and enterprise, planning and organisation, and self-management [1]. Frequently this is achieved by requiring students to undertake a 'sandwich course', work placement or internship. Although the benefits of a well-designed work placement course have been well documented, the literature indicates that such courses are rare [20]. We contend that the design of the ANU software engineering group project course both provides the benefits of more traditional work-integrated learning programs while overcoming many of the associated problems, as our course design provides greater control over learning outcomes than is usually possible in more traditional work-integrated learning programs. Additionally, both practice and the literature suggest group projects are also highly effective in preparing students to face the real-world and for consolidating learning [22].

Also well documented in the literature are the difficulties of providing students with both a beneficial and enjoyable group learning and team work experience [5]. To help overcome these, the course introduces students to the concepts of personality and the influence it can have on individual communication and work styles; to the stages of team development and how to move quickly and successfully through those stages to become a self-managing, highly performing team; and to the roles necessary within a team for a team to achieve success. Through the introduction of formal peer assessment the course has helped students learn about and deal with "couch potatoes" and "freeloaders" within teams [5]. These steps have helped make the whole experience a more enjoyable and productive process for students.

Developing an assessment scheme which successfully provides equitable grading of students undertaking a variety of projects, which range from the more straight forward information system implementations to highly complex and conceptually difficult research-based projects has not been an easy task. Making this task even more complex was the combination of the 3rd and 4th year courses into a single course. The combination of the project review process, which focusses on process rather than output, and peer assessment of team contribution has enabled the ANU course to achieve success. Inclusion within the assessment scheme of significant individual and team reflection ensures that students become aware of what they are learning, thus helping them develop an understanding of how this learning is applicable to future projects and in the work-place.

Another difficulty encountered is helping many students move from 'assignment mode' where work is done in short intensive bursts at the last minute to the more continuous effort required of project work. Associated with this is the difficulty of convincing students to share their work with their peers, team mentor and sometimes even their client prior to it being 'perfect' as it would be if they were submitting an assignment for assessment. This problem has been largely overcome by encouraging teams to work closely with their mentors and through the use of team repositories regulated by version control software.

IV. CONTINUOUS MONITORING AND EVALUATION

A variety of different strategies can be used to measure teaching effectiveness [30]. The effectiveness of this course has been measured qualitatively using student ratings (both formal and informal), industry partner feedback, self-evaluation, as part of Engineers Australia (EA) accreditation review of the BSEng, and through external awards won by students and the course itself.

Alongside a formal university-wide course evaluation process, students are encouraged to provide anonymous open-ended feedback at the end of the course using the Moodle learning management system (LMS). In addition to this feedback, students are encouraged to provide constructive criticism and feedback at any point during the course. At the start of each year, students are made aware of the changes that have been made in response to feedback received from the previous year's cohort.

At the end of each course, the course faculty and mentors hold a Post Implementation Review (PIR) and evaluate how well we have met the principal goal of the course: *that we will help students develop leadership skills and become an effective member of a team which makes and implements appropriate engineering decisions related to the development of software systems that deliver measurable value to clients* [9]. This goal has not changed since 2004; and neither have course outcomes: that 4th year students *will demonstrate a high level of professional judgement and application of software engineering best practice, as demonstrated through the identification, development, use and evaluation of appropriate processes and artefacts required to provide real value to the client*; while 3rd year students *will demonstrate technical competence in all aspects of the software development life cycle* [9].

The course is assessed using the concepts of constructive alignment [31] and Tyler's [32] notion that the specification of behavioural change suggests learning activities which lead to increased familiarity with the associated content. This means the PIR focuses on refining the assessment scheme to help the course better meet its learning outcomes. Input to the PIR comes from the anonymous feedback obtained through the LMS, grades, team performance based on mentors' observations, indirect feedback obtained through peer assessment and students' reflective homework, as well as feedback from clients. PIR evaluation has led to both major and minor changes to the assessment scheme. The more significant changes are discussed in the following paragraphs.

Initial course design had students responsible for developing a schedule of deliverables, some of which were mandated, and receiving only formative feedback throughout the year, with summative feedback received at the end of the project. Additionally 3rd and 4th year students had different assessment schemes. All students were required to undertake a three-hour, written examination at the conclusion of the course. The first significant change to the assessment scheme was made in 2006: summative assessment was introduced at regular points through the project, required artefacts were no longer mandated and a common assessment scheme for all students was introduced. While both 3rd and 4th year students were still required to undertake formal examination, 4th year students participated in an oral exam.

Teams had been experiencing difficulty adhering to their own deadlines for production of artefacts and deliverables. Mandating artefacts seemed to lead students to consider them to be something orthogonal to project completion, something that they were required to do for assessment purposes, but not to ensure a greater chance of project success which led to what we called the 'two project syndrome' where some teams produced one set of artefacts for the client and another for course faculty. Separate assessment schemes for 3rd and 4th year students led students to focus attention on what they perceived they were required to do to maximise their marks rather than working as productive team members and ensuring the project provided value to clients. Introduction of an oral exam for 4th year students was in response to academic concern that a final examination, especially a written examination, was not an appropriate assessment method given the goals of the course and the very different projects that students undertook. The oral examination allowed academics to determine more precisely what 4th year students did and didn't understand about conducting a software development project. The positive outcomes from the oral exam led to the introduction of the gateway review process in 2009 in place of examinations for all students.

The two most significant changes which have helped us meet learning outcomes and which we believe set our courses apart are the use of peer assessment – introduced in 2008 – and the project review process – introduced in 2009. Not only has peer assessment helped overcome many of the problems associated with group work [5] faculty have greater confidence in the validity of individual grades. More importantly, however, learning what it means to objectively assess another's contribution is a crucial part in the development of management and leadership skills. Another benefit flowing from the introduction of the project review process is the uncoupling of the academic requirements of the course from the conduct of the project.

The introduction of peer assessment as a method of deriving individual marks for team work has not only improved student enjoyment but appears to have enabled us to improve our ability to differentiate between students. Typically marks for group work cluster closely around a higher mean [33]. While student marks vary from year to year, since the introduction of peer assessment in 2008 the standard deviation from the mean of student marks has increased from 7.74 to 9.94, indicating a wider spread of marks and demonstrating the increased ability of faculty to differentiate between students.

During the most recent BSEng accreditation review carried out by Engineers Australia in 2010, the software engineering group project courses were acknowledged as enabling our students to develop strong professional skills while providing them with an opportunity for rich experiential and cooperative learning. The quality of the projects and the student teams has been externally assessed through participation in competitions run by the Australian Computer Society (ACS) and the Australian Information Industry Association (AIIA) where a number of teams have won awards at both regional and national levels. In 2012 the course itself received a "Highly Commended" award from the Australian Council of Engineering Deans (ACED) for Engineering Education Excellence.

We have not carried out a formal evaluation through survey of graduates and employers in an attempt to ascertain whether the course has made a qualitative difference to the 'employability skills' of students graduating from our programs. One of the significant problems we face with such an evaluation is the small student cohort, averaging 45 students graduating each year, many of whom move, including overseas, to accept employment. Each year, however, we collect input and feedback from our industry partners as part of the PIR conducted at the conclusion of each course. Their feedback, while not specific to the development of 'employability skills', includes statements such as "*the ANU is our primary source of junior software engineers*" and that they "*like employing ANU software engineers*" which could indicate that there is a limited source of graduates or that ANU graduates in particular are sought after, though whether that is because of this course or not we could not tell. Furthermore, the feedback indicates that our industry partners believe the course helps make our students employable as it provides "*students with an experience of all the complexities and difficulties (and rewards!) of real world engineerin*g" and that it helps students gain experience of the "*practical components of working in the real world because the project team managers have worked well in liaising between their group and the company sponsoring the project.*"

V. Conclusion

The innovative course design and assessment scheme described in this paper, result in high quality outcomes for all stakeholders – students, faculty, industry partners and the institution. We believe the ANU course design is unique: it does not appear to have been documented in engineering education elsewhere, nor are we aware of it having been used by other institutions.

The course design – combining two cohorts into one; requiring students to participate first as team members and then as team leaders; working with industry partners on real-world problems; and providing teams with mentors who have significant industrial experience – and the assessment scheme – gateway reviews to assess process and team performance, and peer assessment of contribution to generate differentiated individual marks – has enabled us to create an effective industrial simulation. The simulation provides students with opportunities and benefits that far outweigh the more usual group project capstone design courses. Students combine academic theory and practical knowledge to enable them to over-come the day-to-day challenges faced by multi-disciplinary teams; they use tools and practices prevalent in industry but frequently not taught in university; and they develop professional and team working skills. Moreover, the simulation enables our students to obtain the benefits from participating in work-integrated learning without either extending the length of study or missing out on valuable content because other courses have been sacrificed to provide space for participation in internship programs for academic credit.

Using a threaded framework to enable practical activities in Operating Systems courses

Abstract—**Teaching Operating Systems (OS) is a rather hard task, since being an OS designer is not a desired goal for most students and the subject demands a large amount of knowledge over system's details. To reduce the difficulty many courses are planned with laboratory practices, differing in how the practices are designed. Some try to implement next-to-real kernels, others use simulators, and even others use synthetic kernels. In this paper an approach based on synthetic kernels is described. It uses thread programming in order to establish control over the operating system components. This approach allows the kernel to grow following the materials presented in the course. It has been successfully applied in two different courses at our University, the first one being a basic OS course and the second one an upper level course. Results from these applications are presented.**

Keywords*—*Kernel implementation, Operating systems design courses, Operating systems laboratory, thread programming

I. Introduction

One of the hardest subjects to be taught in computer science is the design of operating systems. Besides the existence of several textbooks covering the subject, [1], [2], [3], among other successful texts, learning these concepts involve knowledge in data structures, computer architecture and networking. Although learning these contents may be left to earlier prerequisite courses, it is not desirable to leave the OS course too late in the curriculum, which demands that part of that knowledge has to be brought inside the course. The consequence is that lots of material have to be covered, and understood by students, in order to have a complete view of the technologies used to implement an operating system.

To alleviate this situation most of the courses include laboratory practices. Since the subject is quite complex, different approaches have been suggested to tackle these practices. The most relevant are:

- **Kernel implementation**, where students have to implement an actual version of an OS kernel;
- **Simulators**, where students simply simulate the operation of kernel's components;
- **Component implementation**, where students implement certain components of a kernel, but do not connect them.

Each of these approaches have pros and cons, such as allowing in-depth knowledge of the system but demanding too much effort for the kernel implementation. One way to reduce the effort is to use real kernels and organize practices that are performed over these kernels, modifying or reimplementing some portions of it. One of such kernels is Minix [3], whose implementation has more than 27,000 lines. It is easy to imagine that such large code is hard to understand in a short period of time, even if only small parts of it are addressed.

Differently from the conventional approaches, the one proposed here involves the implementation of specific components, which are compounded through a kernel emulation framework based on threads. This allows for an incremental approach towards a complete synthetic kernel while maintaining a functional system along the way. Since the implementation can be incremental, the knowledge necessary is also incremental, enabling the offer of an OS course as early as in the Sophomore year.

In the following pages one finds the description of this approach, followed by how it is deployed in two different courses offered to computer science majors. Results from these courses are presented, followed by a discussion about similar approaches. Conclusions from this experiment finalize the text.

II. Threaded Components of an OS

As previously stated, the practices intended to better understand the OS functionality are based in the implementation of its components through threads. In this section a full description about how these threads are implemented and how they are compounded in order to emulate an operating system is provided.

A. Compounding threaded components

A synthetic OS is created as a multithreaded system. This means that each of its components will be a separate thread, which is started in the occurrence of certain events in the system. This approach enables the implementation of most of the services provided by the OS as an independent component, that can be executed without the implementation of the remaining system.

Figure 1 shows the main structure used for the synthetic kernel. As one can see, the program has an infinite loop containing a function (control_unit) that returns the event that must be managed in each loop. Its output defines which thread must be started, that is, which OS component will act in that cycle. Each component is implemented by a single thread, in order to allow effective concurrency among them. Events that

```
OS_Kernel {
    Boot_init();
    while (true) {
        op = control_unit();
        switch (op) {
            case 0 : start thread A;  break;
            case 1 : start thread B;  break;
                    .
                    .
                    .
            case n : start thread N;  break;
        }
        update_status();
    }
}
```

Fig. 1. Framework for an Operating System synthetic kernel

incurr in the execution of specific threads may include calls to semaphore primitives, I/O requests, process creation, page faults, quantum-time interruptions, etc.

After starting a thread the kernel proceeds updating the system status, what includes presenting the actions to the user. This is performed by the update_status function. This function has also to schedule the next process to the CPU, based in what was the triggered event and the previous status of the system. It must be noted that the scheduler, although part of the process management, is not treated as a thread, since it has to provide a result before any other event can occur.

With this framework the instructor and students get a fully functional system, even if only few components are implemented. The parts that must be implemented are the two external functions in the framework (control_unit and update_status), the process table structures, and the desired OS components. The control_unit may be implemented through simple specifications, such as a random generator or as an input interface. The update_status can be implemented as an interface to show the system's status and eventual manipulations over the process table. It is possible for the instructor to either provide both functions in order to guarantee a customization over the kernel's inputs and outputs or request their implementation from students.

All OS components can be specified and implemented independently. They are synchronized through the access to the process table, which provides the necessary data structures to manipulate the running synthetic processes. The interactions between components are performed by calls to specific threads.

The main advantage of this approach is that the instructor can pick only the components that he/she thinks that are more important, reducing the amount of implementation needed. Another advantage is that the amount of details in each component can also be controlled by the instructor. This way students can get a hands-on practice over important components of a OS, without the burden of knowing complex details about hardware or even understanding a huge amount of code written by someone else.

B. *Creating specific threaded components*

One should have noticed that the external functions and the process table are vital parts of this approach. However, their discussion will be left to the next section, where the application of this approach in two different courses is described. Here, we are concerned only with the specification of threaded components, since they are the core of the students work even if they have to implement the whole framework.

As said before, the instructor can choose which OS components will be implemented. Surely, some components are essential, such as the process management control, but each functionality can be implemented, and verified, independently. In order to enable such scheme each thread has to be modeled as an independent piece, that access the shared process table. Therefore, each thread has to:

- Access the process table in a mutual-exclusion approach;
- Perform the necessary process table manipulation, such as blocking or releasing a process;
- Call, when necessary, the process scheduler or other OS threads.

These requisites are easily achievable. This happens because the amount of interactions between threads can be increased incrementally, starting with very simple components before proceeding to more complex ones. However, even operations much more complex such as managing virtual memory, can be easily implemented with a careful design of interactions between memory management and disk and processes management components.

III. Application of the Threaded Kernel in Specific Courses

The threaded approach just presented has been applied in two different courses offered to Computer Science majors. The first course, in which this approach has been applied since 2007, is an introductory Computer Systems course titled Foundations of Computer Systems which covers operating systems and computers networks in a single course [4]. The second course, in which the application occurred since 2009, is an advanced course titled Operating Systems Design, which is mandatory only for students following the Computer Systems track inside their major[1]. The application of this approach, including examples for each course, will be described in separated sections.

A. *Threads in the Foundations of Computer Systems course*

This is a mandatory course for students pursuing the computer science major. It is intended for students in their 4th semester in the university with knowledge in data structures and digital circuits. Since it is also an introductory course, covering a quite large amount of subjects, there is not much time available for laboratory practices. The syllabus covers these major topics:

[1]The Computer Science major is split into four tracks after sophomore year (Computer Systems, Information Systems, Digital Control and Automation, and Scientific Computing), and students have to chose one of them to get a degree [5].

1) Overview of parallel and distributed systems to establish the interactions between OS and computer networks;
2) Operating systems management components, including an introduction to concurrent programming;
3) Computer networks protocol (RM-OSI and a brief overview of TCP-IP);

The flow goes back and forth from OS to networks contents in order to show their relationships. A thorough description of this course, in its original format, can be found in [4].

The fact that it is mandatory and cover many topics is the main motivation to use an incremental approach for practices such as the one presented here. Since there is not much time available, only few components are actually implemented here. Our choice usually falls into implementing the process management, including the dispatcher, and the disk I/O management.

As a side note, assignments approaching computer networks include isolated tasks, such as the implementation of a sliding-window protocol emulation, the spanning-tree algorithm, and the ARP protocol among others.

It is possible to ensure a challenging task each year, even asking for the same components, if the algorithms for dispatching and disk scheduling are different every year. Changing these algorithms implies in modifications on how processes are managed or interact, avoiding that the practices could become repetitive. For example, in the most recent offer of this course students had to implement a priority-based dispatcher, which demands that information about the processes priority have to be stored in the process table. Dispatchers implemented in previous years included round-robin, SRTF (Shortest-Remaining Time First), and an I/O bounded priority algorithm.

Each practice (implementation) is evaluated accordingly to three rubrics: program correctness, code comments, and output interface. The first two are quite obvious and do not demand further description. The output interface is judged considering the amount of organized data is provided about the "execution" of processes in the multithreaded operating system being emulated, that is, the interface has to provide clear data to follow the program execution and check its correctness. Therefore, a graphical interface is not required and Figure 2 shows an output of a student program, during emulation.

Although the text in that figure is in Portuguese, some remarks can be drawn from it. First, it provides a system's clock in its top line, followed by a message that tells which randomly generated event will be treated (the conclusion of an I/O operation in this case), and how to react to it (doing nothing in this case since there was no process waiting for I/O)[2]. Then, it presents a process table, with information about all processes executing, where the five columns indicate the process identification (NP), status (Estado), CPU time already used (TE), number of I/O operations performed (IO), and the process priority (Pr). Therefore, it presents enough data to check the system execution, step-by-step.

[2]It should be noted that this specific situation occurred because the random generator does not check which events are feasible at any given time, what is not a correctness problem.

Fig. 3. Output produced during the execution of a second practice implementation, now including disk access requests

Figure 3 presents the interface from a different student, showing the execution of the same system, but now including the management of requests for disk access using the scan algorithm. In this interface the student presents a list of processes "running" in the system, in a tabular format containing the process ID, its priority and status (considering three possible states for a process, that is, it can be allocated to the CPU - "Execução", in the ready queue - "Pronto", or blocked - "Bloqueado"). After this it shows the list of disk I/O requests, showing the memory and disk locations, the process that requested the operation, operation status and type (input or output).

Each assignment has to be finished in a period lasting from 15 to 20 days and is executed by pairs of students. The first assignment usually takes more time since students have to implement not only the process manager but also several utility components. They also have to get acquainted with thread programming in the C language.

Since its first application, this approach for lab practices has improved the understanding of operating system concepts. Students get better prepared for written evaluations and the failure rate decreased by a large margin. Statistical data available shows that the failure rate was reduced threefold (from around 30% to 10% for classes were this approach was used).

Tables I and II show the results from a survey applied for the most recent class, which concluded in December 2012. From a total of 15 pairs of students we received answers from 10 pairs (66.67% of the total), using Google Docs forms.

TABLE I. SURVEY RESULTS ABOUT DIFFICULTY OF DESIGN PRACTICES IN THE FOUNDATIONS COURSE (% OF RESPONDENTS)

	Very hard	Hard	Median	Easy
Overall difficulty	10	30	45	15
First assignment (process management)	30	70	0	0
Second assignment (I/O management)	0	80	20	0
Average of the other assignments (computer network protocols)	0	25	40	35

TABLE II. SURVEY RESULTS ABOUT USEFULNESS OF DESIGN PRACTICES IN THE FOUNDATIONS COURSE (% OF RESPONDENTS)

	Very useful	Useful	Somewhat useful	Not useful
Overall usefulness	40	30	30	0
First assignment usefulness	40	30	20	10
Second assignment usefulness	40	30	30	0
Other assignments usefulness (computer network protocols)	35	25	30	10

From table I we can see that students had more trouble with the assignments related to OS, which confirms the notion that this is a difficult subject. It must also be noted that they felt more comfortable with the second assignment, when they already knew the framework of the emulated kernel.

Although not presented in this table, some other aspects collected from the survey must be listed here. In the first assignment students revealed that their major difficulties were related to thread programming and the understanding about what had to be implemented. In the second assignment, their difficulties were related to the I/O mechanisms and the relationship between the kernel components. Another complaint was related to the specification of the assignments, which some students had trouble in identifying the actions that their systems had to perform.

From table II it is possible to notice that students have the feeling that they learned better by implementing the components that were required in the practices. It is also possible to identify that they felt that the OS practices were a little more useful (70% of respondents) than the computer network practices (60%). It is important to notice also that this feeling could be verified in the students' grades, which improved reasonably from classes where there was no laboratory assignments.

B. Threads in the Operating Systems Design course

The same approach has been applied in a more advanced course, which is taken only by students that are in the Computer Systems track. This means that the classes are smaller and that more material can be covered in the practices. This course can be divided in two disjoint parts:

1) A theoretical view of distributed operating systems and distributed systems, including synchronization algorithms, fault tolerance and replication;
2) A design view of conventional (single processor, multiuser, multitask) operating systems, based in the threaded kernel introduced in the previous course.

```
 Processo | Quantum   | Estado
-------- Maior Prioridade --------
 03       |       | EXECUTANDO
 04       |       | PRONTO
 05       |       | PRONTO
 06       |       | PRONTO
 07       |       | PRONTO
 08       |       | PRONTO
 09       |       | PRONTO
 10       |       | PRONTO
 11       |       | PRONTO
 12       |       | PRONTO
--------- Menor Prioridade ---------
 NULL
---------- Bloqueados ----------
 01       |       | BLOQUEADO
 02       |       | BLOQUEADO
  Page fault! (pid:3)
```

Fig. 4. Snapshot of an OS emulation running memory management components

Since students enrolled here have already took the Foundations of Computer Systems course, they know in advance the structure of the threaded kernel used in the practices. This makes easier to develop each component further. Therefore, the design practices involve more components with a higher degree of interaction between them. As an example, Figure 4 presents a snapshot of executing processes with management of page misses and virtual memory, which are functions usually not implemented in the first course. In this figure we can see in the last line a message saying that the process with "pid=3" caused a page fault. In the top part of the figure this process appears as running (EXECUTANDO), and the fault will move it to the blocked processes list (Bloqueados), that contained processes 1 and 2, just before the fault.

It is also possible to see in Figure 4 that processes are organized in a two-level queue scheduler. Each queue has a different priority ("Maior Prioridade" and "Menor Prioridade") defined by the frequency of I/O requests. For that practice it was defined that when a process requested for an I/O operation it should be moved to the lower priority queue, remaining there until it executed continuously without I/O requests for 5,000 time units.

To facilitate experimentation and to allow a better understanding of the whole kernel, in this course the control_unit() function is implemented as a reader of synthetic programs. These programs use a simple syntax to map execution events in regular programs. The control_unit() function uses a "process control block - PCB" where each process has a pointer to a file containing the synthetic program. It emulates its execution by reading one line and applying the correspondent action in each function activation, until the end of the file.

Figure 5 shows a short example of a synthetic program. In its header (first five lines) we find the program's name, file identifier, original priority, file size, and a list of semaphores used by the program. After that comes the synthetic code, where the instructions "read x" and "write x" are disk access requests for the track x, "exec y" means CPU processing during y time units, "V(z)" and "P(z)" are calls to operations over semaphore z. Other synthetic instructions may include I/O operations to specific devices, e.g. printers or monitors, and process creation through fork.

```

P(t)
exec 10000
write 20
V(t)
V(s)
exec 2500
```

Fig. 5. Example of a synthetic program ran by the threaded kernel

With the synthetic commands we can represent a large amount of events that occur in a conventional system. The threads for each OS component can be specified including more complex functions, such as manipulating virtual memory, page tables and so on, as indicated by the example in figure 4. Additionally, since synthetic programs comprise what could be hundreds of bytes in a single command, page manipulation is made by establishing that each page can accommodate k synthetic commands, and that the memory has N pages available to the processes. This allows the implementation of paging mechanisms, including the treatment of page faults and address translation.

The use of synthetic programs make it easier to simulate the OS operations. Students can concentrate in them, instead of how interruptions and system calls could be generated. Although this approach could make easier the practices in the first course, we do not use synthetic programs there in order to ensure a better understanding of the hardware operation. We believe that this is important because most of the students will not take the OS Design course, having only that opportunity to be in contact with such issues. Therefore, making they work extra on managing interrupts and syscalls is a valuable effort.

We do not have a quantitative evaluation about the application of this approach in the OS Design course. However, we have qualitative insights from students that took this course in previous years, and they do not differ from those provided by the surveys applied in the Foundations of Computer Systems course. This should not be surprising since students in the advanced course are a subset of students that took the first course.

IV. Related work

As previously stated, the practices in operating system courses follow three different approaches. Here we will further discuss only the approaches based in simulation and component implementation, while a broader and more detailed review can be found in [6].

An approach based in component implementation is presented by Laadan, Nieh and Viennot [7], where they use the Linux kernel as a testbed for modifications in specific components, such as system calls or the scheduler. This is actually a continuing effort on previous works from the same group. Their approach demands, however, a large knowledge about Linux implementation.

In other direction we find the work from Robbins [8], where students can practice disk scheduling algorithms in a simulator built with this purpose. Although it is very useful for this topic, it does not address other important aspects of an OS and also do not demand any implementation from students, being simply a help for the understanding of the algorithms.

Nachos [9], is a traditional simulator used as a teaching operating system, replaced by Pintos [10]. Pintos is a full machine simulator and students are required to implement/modify small parts of it. Although several components can be targeted it is hard to understand the whole OS operation from these parts.

Finally, we have PennOS [11], where a user-level OS is simulated through the use of the *user context* library in order to enable low-level implementation of OS mechanisms without the need of special access to hardware instructions. This demands a strong knowledge about this library and low-level programming, as indicated by students reviews.

V. Conclusions

In this paper we described a multithreaded approach for laboratory practices in Operating Systems courses. This approach has been applied into two different courses taken by computer science major students, using different levels of components.

From the reports given by students, including answers to the survey applied in the intermediate level course, we can conclude that the use of threaded components allowed for:

- A better understanding of the concepts involved with the implementation and operation of an operating system;
- An improvement in the average grades in both courses in about 10%, with the rate of students failing to pass the first course dropping from an average of 30% from 1998 to 2006 to an average of 18% since then;
- A reduction in the number of students avoiding the Computer Systems track, associated with an increase in the number of students doing their graduation papers in topics related to distributed computing, from 4-6 students per year to 8-10 students nowadays.

Besides the success achieved, there are some aspects that still can be improved, such as:

- Establishment of different command architectures for the language used in synthetic programs, which would allow for their use even for a very small set of OS components;
- Creation of a common framework between the simulated components and user interface, reducing the number of components that have to be implemented by students;

- Improvement in the specification of all assignments, especially the first assignment in the Foundations course, since it is in that moment that the whole framework is defined.

Concluding, our final remark is that this approach for OS practices can be very useful, since it provides a deeper understanding about key components of an OS at the same time it does not require a large knowledge about the kernel or even programming details.

Acknowledgment

The authors want to acknowledge their gratitude with the many students that took the courses presented here. Without their readiness to take part in the practices and to learn the effective use of multithreaded programming, it would be impossible to achieve the results presented here.

Bug of the Day: Reinforcing the Importance of Testing

Daniel E. Krutz, Michael Lutz
Department of Software Engineering
Rochester Institute of Technology
Rochester, NY, USA

***Abstract*—Software engineering students typically dislike testing. In part this is due to the simplicity of the programming and design exercises in introductory computing courses - the payoff for thorough testing is not apparent. In addition, testing can be seen as tangential to what really matters: developing and documenting a design addressing the requirements, and constructing a system in conforming to the design.**

Such dismissive attitudes do not accord well with the realities of commercial software development. The cost of fixing, repairing and redistributing a flawed product can dwarf that of development.

The Software Engineering Department at the Rochester Institute of Technology (RIT) teaches (and requires) basic testing as part of its foundation courses in the first two years. In addition, it offers an upper division course on testing, giving an in-depth treatment of best-practice tools, techniques and processes. Recently we've incorporated a "Bug of the Day," which serves to broaden student awareness of the cost of software flaws. Class discussions focus on the cost of the bug, its root causes, and how it might have been discovered and repaired prior to product release.

Keywords—Software Testing, Software Engineering Education, Quality Assurance

I. Introduction

Creating software that is on time and within budget is difficult; identifying, locating and repairing bugs only adds to the difficulty. Defective software not only significantly increases the development time and cost of a system, if released, it can have catastrophic effects - up to and including death [1].

Students generally view software testing as a bland, unexciting and insignificant task [2, 3]. They feel that creating applications is fun, but reviewing the quality of an application is boring. Software testing may appear to be a time consuming, uneventful activity requiring long hours of work with few results. Furthermore, testing is not typically part of a students grade and there is a self fulfilling aspect to the view that testing is unimportant [4]. Finally, the current educational mindset is building, not breaking software [5].

By way of contrast, professional software engineers must balance software quality against product delivery on time and within budget, and testing typically accounts for over 50% of a software product's cost. Though most universities host one or more computing programs, few focus on issues related to developing high-quality, low-defect software. Testing, to the extent it is covered at all, is rarely an object of sustained focus. In particular, only a handful of programs offer a course devoted solely to software testing [6-8].

For curricula taking testing seriously, it is necessary to teach students contemporary principles, processes and practices. In addition, students need the opportunity to put what they learn into practice, using testing techniques and tools at all levels, from the individual unit to the system as a whole. However, such education is insufficient if students do not gain a deeper appreciation of the significance of testing. One way to address this concern is to incorporate material on significant software failures as part of formal coursework; at RIT we call this "The Bug of the Day" (BotD).

Prior to class, students read material describing a real world software bug and its impacts. Each class begins with a discussion of that day's bug, with the instructor serving mainly to start the discussion and keep it on track. During this time students are asked to reflect on the problem, its root causes, and how it might have been prevented. The goal is to ingrain a respect for the importance of software quality and the role of testing in any quality assurance process.

The remainder of this paper comprises five sections. Section 2 discusses the course context, including objectives supported by BotD. Section 3 describes the BotD activity in further detail, including some of the examples, guiding principles for BotD selection, some examples used in class, and associated discussion topics. Section 4 presents student feedback 4, while section 5 surveys related works. The final section summarizes our use of BotD.

II. THE TESTING COURSE CONEXT

The undergraduate software engineering program at RIT has offered an upper division software testing course since 1998. The sole prerequisite is a second year course, Introduction to Software Engineering; which introduces basic unit and functional testing in the context of a term-long, multi-iteration team project. In addition, the graduation requirement of a full year of co-operative education means most enrolled students have additional testing experience via their co-op jobs.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The course primarily serves to introduce principles and practices at the core of a disciplined testing process, and to give students experience applying contemporary testing tools and techniques. Much of this applied activity takes place in the context of a term-long testing project. With instructor guidance, teams of 4-5 students each select an open source software project, define test plans based on the available documentation and review of the code, and execute several testing iterations. At the end of the term, each group makes a presentation of their findings along with a detailed bug report. Teams are encouraged to forward their findings to the project development team.

A second objective is instilling both a sense of the importance of testing and the associated skeptical mindset that serves testers well. It is here that BotD, described in the next section, is most significant. The course meets twice a week for 110 minutes over the span of the 10-week quarter. Most class sessions have three components: a BotD discussion, a formal presentation related to testing, and a time slot devoted to a lab activity.

III. BUG OF THE DAY

A significant component of being a software engineer is how to create software that is high quality. Understanding the proper testing procedures and technologies is paramount for producing high quality software. Reviewing and understanding past instances of where defects occurred in software is beneficial for students for several reasons. Comprehending these past events and the reasoning behind them will allow students to gain experiences and knowledge which they may use when they encounter similar situations in their future careers. Additionally, these prior events will provide a real world context for the students and help to both foster their interest in software testing and reaffirm the course topics being discussed. For this reason, we created the BotD activity.

A. BUGS TO A SOFTWARE ENGINEER

System faults cause significant aggravation to end users, may lead to overall system failures and have led to billions of dollars in lost revenue [9]. Many of these defects may have been eliminated through the use of software testing [10]. Software bugs occur for a variety of reasons. Some of which include simple developer coding errors, incorrect specification understanding or incorrect requirements [11]. One of the primary goals of a software engineer is to create applications that are as defect free as possible [12, 13].

The BotD activity was a way for us to demonstrate the importance of software testing to future software engineers. Additional goals were to expose students to various testing and defect prevention techniques, to get them thinking about ways to resolve issues should they encounter a similar situation in industry and to foster student interest in the topic.

Each BotD activity was comprised of several aspects. These included a brief description of the bug, its effects and resolution taken.

B. GUIDING PRINCIPLES

The BotD examples were initially selected before the Fall term. Based upon student feedback and requests, the selected cases have been modified in the two course offerings that utilized this activity. When selecting a BotD example, several guiding principles were used. All cases should be relevant, simple and have good discussion points.

Relevant: A BotD example should represent a situation which the students could possibly face in industry. This serves two primary functions. The first is that the discussed scenario will help to educate students to instances which they are likely to encounter. Additionally, students will likely recognize these as relevant cases and thus be more inclined to both pay more attention to the bug and contribute more to the subsequent class discussion in a meaningful manner.

The instructor may strive to maintain relevance for the examples by ensuring that the discussed bugs are reasonably recent and if code is discussed make sure that it is in a language that a significant portion of the students understand. Student feedback indicated that they enjoyed discussing bugs which were fairly recent and had a technical context which they reasonably understood.

Simple: The discussed BotD should be reasonably understandable in only a brief period of time. While a student is not expected to comprehend every minute detail of the bug, they should be able to firmly understand the major points in only a five minute reading. We have found that the best examples are approximately 500 to 1000 words in length. However, this number should be shortened if the case encompases technical details.

Every student taking the course will not be at the same technical level. Some students will be far more experienced in various technologies and programming languages than others. We kept this in mind when selecting examples. The goal of the BotD activity was not to acclimate students with new technologies. The purpose is ensure that students actively think and discuss the reasons for the bug and how it could have been avoided. An overly technical or complicated example would detract from this goal.

Discussion Points: When selecting BotD examples, we strove to select cases which would have interesting and clear talking points. Some of the primary discussion points were the root cause of the error, how it could have been avoided, how its root cause could have been more quickly discovered and what would the student's recommendations be to the software group in order to avoid such instances in the future.

Instances which had reasonably clear solutions were often avoided. Examples with several possible remedies were frequently chosen since they would typically lead to a classwide, student led, informal debate over what the proper solution to the situation would be. This type of active thinking was a primary objective of the BotD activity. In the course feedback, several students indicated that while they typically do not speak up in most classes, they found themselves regularly contributing to these BotD discussions.

C. EXAMPLE #1: MARS CLIMATE ORBITER

The Mars Climate Orbiter was launched in December 1998 and was intended to collect data for approximately two earth years and serve as a relay station for five years. The cost for this NASA project was approximately $327 million. In the Fall of 1999, the orbiter reached Mars and needed to decelerate. Precise speeds and events that needed to occur were calculated in advance. After the first burn to slow the orbiter down, contact could not be reestablished and the orbiter was presumed lost [14].

A NASA analysis of the failure determined the root cause to be due to a confusion in units. A development group assumed the units of measurement to be in pounds, while the other in Newtons. One Newton is worth approximately .2248 pounds force. This miscalculation caused the orbiter to take a different trajectory than planned, one which was 170 km closer to Mars than intended. This caused the orbiter to likely burn in the upper martian atmosphere [15].

The notion that such an error could occur is often surprising to students. How could such an expensive NASA project fall prey to such a simple failure? This serves several important lessons to students. First of all, no software cases are too simple to test. Even the most basic situations are capable of leading to massive and catastrophic system failures. Additionally, if such a simple error can thwart such an expensive NASA project, then it can happen to any undertaking. Finally, in the realm of general software engineering, this case serves to solidify the importance of team communication.

Other than basic team communication, at least three other tests could have helped to avoid this bug. The first is a code review by a somewhat science-knowledgeable individual. Someone reasonably familiar with the difference between pounds and Newtons would have likely discovered this issue reasonably easily. A second possible test would be if the developed code was checked against an expected model of how the code should function or even a mock object. Finally, proper unit testing would have likely found this error at the code level.

D. EXAMPLE #2: GOOGLE MALWARE SNAFU

In early 2009, a human error at Google caused all websites to be briefly identified as possibly malicious. For a short period of time, all searches resulted in the warning “This site may be harmful to your computer”. Google soon stated that the issue was caused by “human error” when a developer designated “/” as a site that was attempting to install malware on a user’s computer. Google’s malware detection system understood this to mean that all sites on the internet were possibly malicious. Fortunately for Google, they were able to quickly roll back the update so the duration of the problem was only about 40 minutes [16].

There are several discussion points from this issue. The first is that even though this was a very minor syntax glitch, it had wide ranging ramifications and affected a significant number of internet users. This helps drive home the notion that nothing is too small to test for. If something can go wrong, it should be accounted for. Another topic of conversation is how this issue could have been avoided. While a simple response could be for the developers to ensure that they don’t make such a mistake, this is not reasonable to expect in all situations. The matter of putting a system in place to reasonably avoid an instance like this in the future is not a simple solution with a straightforward answer. Situations like this that make students think outside the box not only keep them interested in the course, but help them to come up with a wide range of possible solutions for a particular problem.

IV. STUDENT FEEDBACK

The students made their opinions clear that they both enjoyed the activity and extensively learned from it as well. At the conclusion of the course offered in the winter of 2012-2013, students were asked to anonymously fill out a survey regarding the BotD activity, the results of which are shown in Table 1. Out of 32 students who responded, all of them stated that they enjoyed the activity. 84% of the students stated that they learned a significant amount from the activity while half stated that it was their favorite part of class. Students indicated that they enjoyed the real world nature of the issues being discussed along with the impacts that software bugs may have on applications. Students also stated their enjoyment of the lighthearted nature of the activity and how the discussion was done in an informal, non-graded fashion. This made the students more at ease during this classwide exchange. Students also stated they enjoyed more recent bugs as opposed to software issues that had occurred a relatively long time ago. One interesting portion of received feedback is that a significant number of students inversely stated that either too little or too much time was devoted to the activity.

TABLE I. STUDENT COURSE EVALUATION DATA

Did you enjoy it?	**Did you learn from it?**	**Favorite Part of Class?**
32/32 (100%)	27/32 (84%)	16/32 (50%)

Following are representative samples of written feedback we have received:

The activity connected software testing concepts to reality. Discussions are fun. Became aware of some high-risk problems like handling time.

I enjoyed reading about different bugs in the real world and how how companies responded to them.

It provided us with concrete examples of how what we were studying applied in the real world, helped to demonstrate the importance of thoroughly and effectively testing applications at all levels and all stages of development, and *also showed how often proper testing is not fully done in the real world.*

A primary goal for the activity was to put student's at ease, encourage them to ask questions, make mistakes and come up with alternative solutions. A desire was to have the students want to learn, not force them to learn. This was accomplished by allowing the students to propose their own bug examples and have the students provide input on the type of issues they would like to analyze. The instructor also acted as a moderator for the discussion and created a conducive environment for a student led discussion. Students have provided substantial feedback that they enjoyed the fact that this activity was not graded, thus allowing for a more easy going, friendly and non-judgmental environment. This notion is well exemplified by the following student feedback:

The fact that there was no quiz on it and that we were able to take a break from lecture. Its nice change of pace from all the rest of the classes where you can just read something over for the first time, discuss it, learn from it, and not have to worry about being graded.

I liked being able to actively get involved in discussion and exploring different reasoning and solutions.

V. RELATED WORK

We are not aware of any existing courses which use an activity related to our "Bug of the Day" exercise. A similar activity is conducted in an Engineering Secure Software class at RIT with positive results [5]. In the context of software testing, there are numerous institutions which offer courses pertaining to software testing. While many of them have activities that discuss current software techniques and technologies, none of them are known to actively discuss real world cases in such a manner on a routine basis [6, 7, 17].

There are numerous other works which purport the need for a further emphasis on software testing and quality in the student curricula [3, 4, 18, 19]. In order to foster student interest in software testing, Preston examines the use of real world projects in information technology education. Using real world projects help in motivating students in addition to providing a more real world experience for the students [20]. Harrison [21] discusses teaching software testing from two perspectives, one being the developer and the other as the software tester. The main benefit of this is approach is that students witness the importance of testing from both viewpoints and they learn to apply testing techniques from both perspectives. Goldwater [22] discusses several fun ways to incorporate software testing into a curriculum. In his example, student projects are evaluated against a common test set in a competitive fashion.

VI. SUMMARY

Future software engineers need to understand the importance of testing in developing high-quality software, as well as the principles and practices that are the foundation of a successful testing regime. In addition to standard material on testing techniques, our course incorporates a Bug of the Day activity to reinforce the cost of letting defects seep into production software. The time devoted to in-class discussion serves to sharpen student appreciation of the need for testing, and to give them the opportunity to see how appropriate testing can be critical to system success. Students generally appreciate the inclusion of these discussions. Indeed, based on preliminary discussions of this technique, at least one colleague at another university plans to incorporate BotD in their testing course. We encourage others to consider this approach in the courses they teach.

Abstract - **Didactic experiences are very important in a Software Engineering course. We think they help to achieve at least six objectives of the course: to identify fundamental concepts of software engineering, to recognize software life cycles, models and methodologies of software development, to perform analysis of software products requirements, to design and develop a software product, to use the methodical processes of a real-world project, and to implement solutions following specific methodologies. In this paper we will show our didactic experiences in the Software Engineering Processes course. We developed a sequence of learning activities and their application (extracted from real requirements of clients and users) in different contexts such as environmental, medical and social, which results in higher levels of learning, interdisciplinary exercises and practices close to what students will face in their professional lives.**

Index Terms **-** Software Engineering, Didactic Experiences, Learning Activities, Interdisciplinary.

I. INTRODUCTION

Didactic experiences are lived events intended to teach a lesson. They are very important in a software engineering course since they help to achieve at least six objectives of the course (based on the ACM/IEEE-CS Computer Science Curricula): to identify fundamental concepts of software engineering, to recognize software life cycles and models and methodologies of software development, to perform analysis of software products requirements, to design and develop a software product, to use the methodical processes of a project, and to implement solutions following specific methodologies.

In our Software Engineering Processes course we use real-world projects as a strategy to achieve the objectives, that is, we use didactic experiences where students must build a real product needed by real clients and/or users. This strategy is not new (the reader may refer to [1, 2, 3] to see other works about this strategy), however we realize that if we combine it with other learning and interdisciplinary activities we are about to describe in this document, we maximize not only the achievement of the objectives but communication skills in interdisciplinary environments and the understanding of how computer science can contribute in different contexts of society.

Using projects as a strategy for teaching is typical in the Problem-based learning methodology (PBL). PBL has the construction of knowledge (ideas and notions) as a fundamental axis. It builds new knowledge from previous one, by planning, implementing and assessing real world projects. Some of the main characteristics of the projects of this kind of learning are [4, 5, 6, 7]: they focus on students; they are well-defined; they are related to the environment and the culture; their specific aims are related to curricula standards; results can be exposed to final users; they connect academics to non-academic (i.e. productive sector) areas; experts can provide feedback and assessment; students can think about results; and the assessment is real and periodical (portfolios, partial deliveries, papers, etc.).

This kind of learning strategy has been used (and adapted) successfully in Software Engineering courses the latter years. In [4] authors "extended the concept of integrated project based learning by focusing on the design and development of a real word project that can be utilized as a real solution". On the other hand, in [5] authors "proposed to adapt the PBL methodology that is especially designed to be integrated into software engineering classroom in order to promote collaborative learning environment". Finally, in [6] "a new learning methodology mapping the roles and phases considered in PBL methods into the roles, iterations and phases considered in the 'y' process, called yPBL" is proposed.

This document is organized as follows: section II describes the course and its objectives, where learning experiences were applied; section III presents a description of each one of the activities that we develop in the course; in section IV we show the strategies articulating these activities in order to achieve the proposed objectives; sections V, VI and VII detail the way we select the projects, how we assess the learning activities and which were the appreciations, difficulties and successes of students; finally in section VIII we provide some concluding remarks.

II. Course Description

The following didactic experiences were put into practice in the Software Engineering Process course [8]. This course was designed for middlers (we have a five year program) of Computer Science at the Pontificia Universidad Javeriana in Cali, Colombia. It is part of the fundamental core of the program, and its classes are scheduled in two 16-week sessions each semester. In this course we study processes involved in software development, we introduce different development methodologies and their application according to a context, and we encourage our students to apply the concepts and techniques learned in the course using real-world projects as an axis. In Table 1 we present the objectives of the course.

TABLE 1. OBJECTIVES OF THE COURSE

OBJECTIVE	TOPIC TO WORK
To identify the main concepts of software engineering.	· Software features and qualities. · The purpose of software engineering and its difference with computer science. · Software processes and models associated to them. · Models in the software development process.
To recognize software life cycles, development process models and software development methodologies.	· Software life cycles. · Models of software development processes. · Software development methodologies. · Advantages and disadvantages according to the context where it will be applied. · Application of an agile software development methodology to a small project.
To gather, analyze and model requirements of a medium-scale software product.	· Phases in the requirements engineering process. · Characteristics that requirements must have in a software project. · Functional and non-functional requirements in software development projects. · Software Requirements Specification Document (SRS) based on established standards. · UML diagrams to model software product requirements.
To design a medium-scale software product.	· Techniques and models in the software design process. · Software design documents based on established standards. · UML diagrams to model the application design and operation. · Design alternatives related to architecture, structure and interfaces of a software product.
To develop, validate and test a medium-scale software product.	· Good practices in software development processes. · Software verification and validation processes. · Formal methods in software development. · Construction and integration of software components according to established specifications and designs. · Evaluation and validation of software solutions according to established specifications.
To use processes of analysis, design, development, validation and maintenance of a real software project.	· Implementation of a software solution following a specific methodology from the requirements gathering to the validation of the developed product.

Learning activities have been implemented in this course since the first semester of 2011, however in each new class the methodology is adjusted and new elements or didactic situations are incorporated in order to improve the students' learning process. The experiences showed in this document include all the strategies and methodologies implemented in semester 2012-2.

III. Learning Activities

In order to achieve the objectives of the course and to accomplish the expected learning process, we proposed a sequence of activities related to each other. These activities let students to learn the theoretical background of software engineering, to apply that background into specific contexts, and to acquire the knowledge through academic reading and writing activities. The following are the activities proposed.

A. Project Fulfillment

The course uses the project-based learning approach [9, 10], focusing on ***real-world project***s of software development. This means that real clients/users of the product to develop exist and they need the product. Additionally, for the project we search topics that allow students to interact with other disciplines and that promote holistic education. Recent projects have been:

- Information system of the basin of the Pance River (Environmental, Social, Academic). 2011-1
- Information system to organize medical histories (Medical, Academic). 2011-2
- Information system to train and learn how to fill medical histories (Medical, Academic). 2012-1
- Information system for controlling social responsibility projects. (Social). 2012-2

For the topic of the projects, we give priority to those that allow students to have contact with their environment from a social, environmental or human point of view. For the project development we apply the *Rational Unified Process (RUP)* [11] software development methodology, which let us work sequentially and in a rigorous way each one of the build phases of the application.

Since we want students to know the use of agile software development methodologies [12] (topic covered on the first classes of the course) we also propose a mini-project to be developed in approximately 4 weeks. The objective of this mini-project is "to develop a small web application using the agile software development methodology (*eXtreme Programming* [13] or *Scrum* [14])". With the mini-project we expect students to apply the principles of this kind of methodology in a real small project. Recent mini-projects proposed were:

- A web page for a (amateur) coin and bills collector (Numismatics). 2012-1
- A web system called "Grandmother Recipes". 2012-2

B. Reading and Writing for Learning

In different moments of the course we use different learning strategies associated to reading and writing [15, 16]. These strategies are related to the topics of course. The following are the activities implemented:

- For reading we developed guides orienting students to analyze a particular text with a clear objective. The document is discussed in class and associated with contents of the course.

- With writing we seek students to systematize the application of software development methodologies (associating their own experiences), to deal with the use of a format and language of their own discipline, and to motivate to write their own experiences in software development for a wide public (not just the professor). To apply this strategy we developed a guide to write papers.

C. Use of ICT (Information and Communication Technology)

As a support to the course, to the topics and to student's discussions about the main project development, we have been used some tools related to ICT. The activities have been:

- Use of a learning management system (LMS) [17] to share with students the material worked in class, the proposed activities and extra support material.
- Use of a forum [18] aiming at sharing information and experiences associated to the development of the main project, at solving questions and problems from a collaborative point of view, at clarifying requirements of the software to develop, and at discussing different technical alternatives in the developing stages in order to obtain different ways to a determinate solution.

D. Theoretical Support

Finally, all the above activities have a theoretical support [19, 20] to be taught. Hence we use:

- Lectures to expose the main concepts of topics. Slides are available via the LMS. They show the theoretical concepts studied in the course.
- Individual expositions that are assigned to each student. The objectives of these expositions are to delve in a topic, to write a paper where the student presents his/her analysis of the topic, and to improve his/her oral skills. These activities come with support by the professor, giving the student feedback and extension of the knowledge.

IV. Strategies to Articulate and Develop the Learning Activities

We use the strategy of presenting the theoretical concepts and their application in real cases of software development to articulate the contents and the learning activities. Having real clients/users in projects along with important characteristics such as interdisciplinary, social responsibility and environment knowledge make students face situations they will face in their professional life, which allow the learning process to go beyond the very theoretical concepts.

The following is the description of some tasks we give to students. We believe these tasks contribute to achieve the learning objectives.

- **Presentation and study of theoretical concepts related to software development projects**. This course introduces the software development processes (requirements gathering, analysis, design, development, tests and implementation). Each one of them is studied during the semester. The theoretical part is giving by means of lectures supported by slides that are available via the LMS. It is also provided by readings and expositions students must do with help from the professor.

  With these activities we accomplish the learning objectives concerning the theoretical part and we settle the foundations to achieve all the other objectives by applying the concepts in real-world projects.

- **Fulfillment of a mini-project in order to apply the concept of agile software development methodology**. During the first 4 weeks we discuss the generalities of software life cycles and the agile software development methodology. The professor presents a global vision of the methodology, two students present the two main agile methodologies, and bibliographic material is posted in the LMS. We propose an agile software development project in which teams of students must apply the principles of one of the methodologies. Finally, we make students to write a technical paper about the experiences in the fulfillment of the mini-project, following a particular format. This activity allows students to systematize the acquired knowledge in the application of software development methodologies with their own experiences.

  As professors we help in the development of the mini-project and the writing of the results. We schedule time weekly to meet students. We think these activities help to accomplish all learning objectives from the point of view of a particular methodology that have a different style to the traditional. Additionally, they have another impacts such as improve of the reading skills, writing of technical documents and relation with interdisciplinary groups.

- **Fulfillment of a project of software development in a real scenario**. Once the mini-project is finished, we being the study of each one of the software development processes using a rigorous methodology (RUP), for which we propose the development of a project with the following characteristics:

  - The development of useful software (not just an academic exercise). We seek to resolve an existing real problem. For the semester 2012-2 the social responsibility office at the university needed an information system for managing social responsibility projects. Since this was a real-world project, it faced students to the benefits and difficulties of interact with users and clients, to

requirements gathering and to experience the application of concepts, techniques and methodologies in a software development project.
- The topic of the project intends students to be integrated in a multidisciplinary environment. They have to modify their technical language to an appropriated one in order to talk with users and clients of the project. In addition, in an intention of promoting holistic education we also seek for a topic related to social and environmental areas.
- We select a medium-scale software development project. This allows students to apply a more rigorous methodology and to work each one of the phases of the software development process the minute it is studied in class.

To ensure that students present their advances and experiences, we propose partial deliveries of the project, each one covering one or two phases of the software development. These partial deliveries are guided by document and software standards, and they have to be presented in an oral presentation to the whole class. The presentation always opens a debate and allows feedback by classmates and the professor. We also use a forum where students may share their experiences or post questions that can be resolved by another student or the professor. Finally, weekly we discuss the project (or mini-project at the beginning of the course) in a schedule especially reserved for this matter.

We believe these tasks allow accomplishing all learning objectives from a rigorous methodology point of view, that is, a point of view where each learning objective is achieved by applying the concepts taught in class in a particular phase of the software development. Likewise, these activities also help to accomplish other learning processes such as following standards, writing technical documents, relationships in interdisciplinary groups and knowledge of social and/or environmental issues in the region.

V. PROJECT SELECTION AND INTERACTION WITH CLIENTS/USERS

Finding "clients" needing some software development is an easy task. The strategy is to search and interview project managers or heads of academic areas within the topic interests of the current class. In the interviews we detect some particular needs, we define the scope of the project and we design a general guide of the project.

At the beginning of the academic semester, the client (and in most of cases future users of the system) makes a presentation of the area and his/her needs for a software development. In this first encounter information is very general and normally the difference between the language of the client and the language of students does not allow a wide comprehension of the requirements of the system. However, after a research about the work and the context related to the project, and the continuous meetings with clients and users, students acquire the ability of understanding the language from other disciplines and the ability of expressing their ideas in a non-technical way or at least in a way understandable for every people involved in the project.

Meetings, communications and other interactions with clients/users are coordinated directly by students, and supervised (and redirected if necessary) by the professor.

VI. ASSESSMENT METHODS

In this course we use different assessment strategies and tools: midterms and finals exams to assess the application of learned concepts; technical writings; the capacity of following of software development standards and methodologies; and the development of software products with some characteristics and qualities. In addition, we associate the assessment of the learning objectives to the ABET (Accreditation Board for Engineering and Technology) accreditation process, which we are implementing in the Computer Science program.

In the ABET accreditation process [21, 22], the learning activities must contribute to some abilities or student outcomes named from A to K, each one with a different weight depending on the course. The students outcomes for computer science are [23]: (A) An ability to apply knowledge of computing and mathematics appropriate to the discipline; (B) An ability to analyze a problem, and identify and define the computing requirements appropriate to its solution; (C) An ability to design, implement, and evaluate a computer-based system, process, component, or program to meet desired needs; (D) An ability to function effectively on teams to accomplish a common goal; (E) An understanding of professional, ethical, legal, security and social issues and responsibilities; (F) An ability to communicate effectively with a range of audiences; (G) An ability to analyze the local and global impact of computing on individuals, organizations, and society; (H) Recognition of the need for and an ability to engage in continuing professional development; (I) An ability to use current techniques, skills, and tools necessary for computing practice; (J) An ability to apply mathematical foundations, algorithmic principles, and computer science theory in the modeling and design of computer-based systems in a way that demonstrates comprehension of the tradeoffs involved in design choices; (K) An ability to apply design and development principles in the construction of software systems of varying complexity.

According to what we established for the course of Software Engineering Processes in the ABET accreditation process, it contributes to 8 of the 11 student outcomes. Table 2 presents the assessment instruments, the weight of each one of them and their relation with the student outcomes this course contributes to.

TABLE 2. ASSESSMENT INSTRUMENTS

ASSESSMENT INSTRUMENT	%	A	B	C	D	F	I	J	K
Homeworks and quizzes	10%	36%	26%	20%		12%		6%	
Oral presentation	5%	75%				25%			
Mini-project	10%		20%	17%	15%	9%	12%		27%
Midterm	20%	25%	45%			15%			15%
Final	20%	15%		60%		10%			15%
Project:									
First phase (requirements)	10%		60%		8%		15%		17%
Second phase (design)	10%			44%	8%		15%	33%	
Third phase (development)	15%				8%	10%	30%		52%

Each one of the instruments we use are designed to contribute to some of the student outcomes (e.g. 25% of the midterm contributes to (A) the ability to apply knowledge of computing and mathematics appropriate to the discipline, 45% to (B) the ability to analyze a problem, and identify and define the computing requirements appropriate to its solution, 15% to (F) the ability to communicate effectively with a range of audiences, and 15% to (K) the ability to apply design and development principles in the construction of software systems of varying complexity). The purpose of the assessment strategies is to verify the scope of the learning activities or expected abilities in every moment of the course.

VII. STUDENT'S APPRECIATIONS, DIFFICULTIES AND ACHIEVEMENTS

At the end of the course we make a survey with students in which we quantify (1 – 5) the fulfillment of each one of the student outcomes. Table 3 shows the result of the survey.

TABLE 3. SURVEY OF CONTRIBUTION TO THE STUDENT OUTCOMES

STUDENT OUTCOMES	A	B	C	D	E	F	G	H	I	J	K
Response Average	4.6	4.8	4.6	4.4		4.4			4.4	4.1	4.7

As the reader can see, student appreciations about the contribution of the course to student outcomes are high.

It is important to remark that the student outcomes most valued were (B) the ability to analyze a problem, and identify and define the computing requirements appropriate to its solution and (K) the ability to apply design and development principles in the construction of software systems of varying complexity. These outcomes are directly associated to developing projects, relationships with clients/users and the application of a methodology depending on the context and the complexity.

Definitely, the most difficulties students manifest are not associated to technical aspects but to the relation with clients/users (requirements understanding, scheduling of meetings, negotiations about scope, etc.) and the ability of handling documentation and standards. Once students understand what they have to do and how to follow the methodology, results are obtained quickly. Notwithstanding, at the end of the course students overcome all these and they learn valuable knowledge.

On the other hand, another difficulty to solve is the time limit to complete the software development (that is, to get to the implementation), and the academic effect (grading) of the work. For the client the highest expectation is in the product, but for the student is in the grade. We overcome this problem by proposing to conclude the project in an elective course of advanced software engineering.

VIII. CONCLUDING REMARKS

In the Software Engineering Processes course we developed a sequence of learning activities related each other. We try students to apply in real-world projects the theoretical concepts taught in class, to acquire significant experiences, and to use writing as an element to systematize their knowledge using a discipline proper language.

The integration of different activities seeking a greater and better learning such as: project-based learning, use of reading and writing as a support for learning, application of theoretical concepts from different points of view and use of ICTs, allow students to better understand the topics of the class, to experiment the result of the application in a real situation, to write the result in a proper language, and to associate the results to the environment and the context.

When students face a software development problem with real clients and users and, in top of that, from other disciplines, they found themselves in situations that we can hardly teach in a classroom. Students must adjust their technical language to interchange ideas with members of the team project, to use modeling language (e.g. UML) to express their designs, to "negotiate" with users and clients in the definition of requirements and give them different techniques to accomplish the expected objectives.

Experiences, difficulties and successes in the development of a project are discussed in class and compared to theoretical concepts. We observe how the applications of those theoretical concepts have some meaning depending on the context. Likewise, the discussion about the project development and the production of written documents allow noticing that student learning are high and their experiences are very close to what they will face in their professional lives.

This course also attains, as an additional value in the formation, that students get to know their environment from a more social, environmental and human perspective, and how from the computer science area of knowledge they can participate in any of those perspectives.

Finally, the results in all phases of the course and the opinion of the students about the experiences and acquired knowledge allow to conclude that the Software Engineering Processes course attain, by means of their learning activities, the proposed objectives.

***Abstract*—This paper reports on the category of "self-affirmation", one of the key abstracted categories identified in a qualitative study that sought to examine the factors that influence student perception of success in undergraduate Computer Science. Self-affirmation is the process whereby an individual focuses on important and positive aspects of their life with the aim of affirming their sense of self-worth and value. This positive self-regard makes individuals more accepting of negative feedback.**

The grounded theory approach employed in this substantive study provides a unique insight into the students' perspective of the key factors that influences their perceived success. Self-affirmation processes emerged as a key element of this theory and merit inclusion in future efforts to support and scaffold freshman learning in computer science.

I. Introduction

The challenges of student recruitment, retention and continued attainment in Computer Science at the undergraduate level have been of concern to faculty members and University authorities for many decades [7], [21], [8], [44], [4]. Despite much effort in this regard, these issues still remains a source of much discussion and debate in the literature [13], [29], [37], [2].

Freshman students are usually experiencing University life for the first time and may experience a period of adjustment where they develop an appropriate sense of their own responsibility for, and ownership of, their learning [20]. Students of Computer Science face additional challenges as there is often very little continuity between the subjects studied in the final years of their second level education and those encountered during the freshman years of an undergraduate degree program [17]. Moreover, many freshman students have little or no experience of the style of logical thinking that is required for courses in areas such as computer programming, computer networking and hardware systems.

We report on a key factor of a substantive qualitative study [18] that explored the prior experiences that freshman undergraduate students believe help them succeed and we identify elements of self affirmation that were common to those who perceived themselves to be successful. All participants had English as a first language and had followed the traditional entry route to University directly from second level education.

Self-affirmation [35] refers to the processes by which an individual seeks to make sense of their own actions and of the world around them. These processes are usually considered as a defensive mechanism as they may be invoked in response to the typical setbacks and negative events of daily life. For example, a student may seek to rationalise poor academic performance by deciding that they have no aptitude for the subject in question or they may accept their poor performance and use it as a motivation for change. Alternatively, an individual who has experienced adversity and become discouraged may actively seek out positive life experiences to help them counteract negative sentiment.

In this paper we explore the self-affirmation processes that influence and shape participant attitudes towards their studies, which in turn influences achievement and success. Self-affirmation varied along a continuum from strongly positive to strongly negative. Participants experienced positive feelings when they were successful in completing a computer related task or when their skill and ability was praised by academics and tutors. Each participant's belief in their own ability was affirmed as a result of these interactions. At the negative end of the continuum, participants described the influence of negative feedback as being discouraging, leading them to become anxious and worried about their decision to study computer science.

II. Background

A. *Predicting Success at the Freshman Level*

The ability to predict an individual's potential for succeeding [44] has been seen as a key factor to improving retention on Computer Science and Technology based degree programs. A wide range of factors have been considered in the effort to determine predictors of success – these factors include age, gender, mathematical ability, second level performance, previous computer experience, computer anxiety, computer attitude and computer self-efficacy [32], [15], [24], [3].

The majority of this work has been in the quantitative domain where a numerical scale is used to rate the students ability or performance, with some form of statistical analysis (e.g. factor analysis or principal component analysis) then performed to determine the most significant factors influencing success.

Many students experiencing difficulties during their first year at university cite the challenges encountered while learning to program as one of the major causes of their problems. Indeed many engineering and computer science students claim

978-1-4673-5261-1/13/$31.00

to “hate programming” and feel unable to grasp even the most basic skills [41]. Students who struggle with programming courses either fail and drop out of the course, or manage to continue but assiduously avoid future programming projects and ultimately choose a career that does not involve programming [33]. Psychological studies of programming date back over thirty years [30], [45], but appear to have had little impact on the culture of learning in a programming class. Indeed, the literature indicates that today’s students have little or no confidence in their programming abilities [37], [2]. One of the challenges for those in computing education is to design effective learning environments which result in a significant improvement in students’ attitude to, and attainment in, programming.

Many have viewed this as key to overall success on computer science and technology based degree programs and so have concentrated their efforts on predicting student success around introductory programming courses (e.g. [14], [44], [5]). This is often identified as the CS1 problem. Indeed, computer programming is a key element of the computing curriculum [40] published jointly by the ACM and the IEEE Computer Society. This curriculum provides recommendations for the structure and content of undergraduate programs in computer science and is often used by higher level educational institutions to shape the design and content of their degree programs.

B. *Self-Affirmation*

Self-affirmation theory has its roots in an exploration of dissonance processes e.g. in the dilemma faced by someone who continues to smoke cigarettes despite the over-whelming evidence linking smoking to lung cancer. Steele [35] argued that in order to reduce the impact of such a dissonance the individual need only engage in some affirmation of general self-integrity, even when that affirmation bears no relationship to the dilemma or inconsistency being faced.

Self-affirmation theory argues that those who can maintain a positive global sense of self-worth will be less threatened by conflict or insecurity in a single domain of their life. If an individual’s sense of global self-worth is temporarily bolstered then they have been shown to be more willing to tolerate threats, setbacks and negative events [9]. Self-affirmation can take place when an individual reflects on important aspects of their life that are distinct from the threatening domain or when the individual engages in activities that highlight perceived positive values or attributes that are different from the discommoding domain.

Sources of self-affirmation include social roles (e.g. being a student), values (e.g. religion), group identity (e.g. gender), central beliefs (e.g. political ideology), goals (e.g. economic success), and relationships (e.g. family, friends). Most self-affirmation occurs at a sub-conscious level, in that individuals are unaware that they are employing self-affirmation strategies as a means of coping with adversity.

Individuals strive to maintain a positive view of themselves despite the challenges and setbacks they encounter in everyday life. For example, in an effort to maintain a positive view of themselves students may attribute poor examination performance to external factors beyond their control, such as examiner bias. Coping strategies of this type can be detrimental if they stem from inaccurate views of reality that prevent an individual from developing an awareness of their personal shortcomings and deficiencies. Self affirmation is the strategy whereby one draws on one’s global sense of self-worth in order to be more accepting of life’s setbacks and threats to one’s sense of self-worth and value in the world.

In studies that explore the effect of self-affirmation individuals typically engage in activities that affirm their sense of self-worth and value prior to engaging with set tasks. These self-affirmation activities can seem rather artificial and contrived e.g. participants may be asked to list traits that were central to their essential being and self-worth; from these they then pick the trait they consider the most important and finally they write a short essay about a time they successfully demonstrated that trait [9], [16].

Despite the artificial nature of the self-affirmation activities detailed above, many studies have shown that such activities increase the participant’s self-affirmation and make them more receptive to negative feedback and criticism. For example, self-affirmation has been identified as a successful method for mitigating the effect of stereotype threat. Stereotype threat occurs when an individual experiences concern or anxiety about how their performance can confirm negative stereotypes about their social group [36]. For example, gender related math attitudes can play a significant role in undermining the interest and performance of girls and women in science, technology, engineering and math (STEM) domains [12]. Even those with positive attitudes towards the domain can be at risk of stereotype threat [28].

It has been shown that women perform more poorly on a challenging mathematics test when it is described as diagnostic of their abilities, as compared to how they perform on the same test when it is described as non-diagnostic, i.e. performance decreased in the presence of a stereotype threat [25]. However when the same test is administered to those who have taken part in self-affirmation activities prior to the test, then their performance is at a similar level to those in the non-diagnostic group. These self-affirmation activities focused on affirming a valued attribute other than mathematics. Similar results have been observed in tests conducted with college level physics students [26].

In this work we explore the category of “self-affirmation” identified in a qualitative study of factors that influence student success. These activities differ from those in traditional self-affirmation studies as they are not artificial or contrived, but rather are drawn from the real-life experiences of the participants.

III. Grounded Theory

The findings in this paper form part of a much broader qualitative study of the students’ perspective of the experiences that influence success at the undergraduate level [18]. This substantive qualitative study was carried out over a number of years and was conducted using the Grounded Theory methodology [10], [11], [38]. This methodology provides detailed systematic guidelines, analytic procedures and research strategies for the conduct of qualitative data analysis that lead to theory development.

Grounded theory requires the researcher to carry out the analysis of the data on a number of levels. Strauss's three-state approach to analysis was adopted [38]. This involves open, axial and selective coding [39]. Open coding requires the researcher to identify, name, categorize and describe any phenomena found within the text. These codes are then reviewed with the aim of grouping those with a common theme together into higher order entities, called concepts [1].

Concepts are then further analysed with the aim of gathering together those with a similar focus into more abstract groups, called categories. The process of relating categories to each other is known as axial coding. The researcher then identifies the similarities and differences that exist between the categories through a process of constant comparison.

As the researcher identifies central categories and the relationships that exist between them and their sub-categories, the focus is usually on the causal relationship between them [6]. When gathering more data will not yield further insights a point of theoretical saturation has been reached [22]. Finally, selective coding is the process of determining the central phenomenon to which all other categories can be related. Strauss and Corbin [39] view this as the central narrative or storyline which links the categories and their relationships.

An important element of any qualitative study is the trustworthiness of the results obtained. The authors each have over a decade of experience as faculty members in Computer Science and they are both active researchers in the field of Computer Science Education. Like many in this field this is not their only sphere of research activity, as they are both research active in the field of computer science. They are not only practiced in the conduct of studies involving grounded theory [19], but have also carried out qualitative investigations in the phenomenographic research tradition [34]. Their familiarity with the conduct of qualitative research and with the domain under investigation i.e. computer science, means that they are familiar with the context and environment of the study. This background provides them with the theoretical sensitivity needed to analyse the data gathered for this work.

When using the Grounded Theory methodology the theory emerges from the constant comparative techniques employed. The results obtained are corroborated and confirmed by member checking, while triangulation with the quantitative studies in the literature also strengthens the trustworthiness of the findings.

IV. Data Collection and Analysis

The grounded theory methodology is not prescriptive when it comes to data collection, indeed the researcher is encouraged to gather data from multiple sources using a wide variety of methods as this helps ensure the trustworthiness of the results obtained.

While the bulk of the data used in this study was collected through the interviewing of participants, data was also obtained from focus groups. The sample was homogeneous, as all participants were engaged in pursing the same degree program (Computer Science). In total 22 participants were interviewed, while a further 10 engaged in focus group discussions. This is a relatively large sample for a qualitative study of this nature, where samples of 15 to 20 participants are common. All interviews and focus groups meetings were recorded and subsequently this data was transcribed prior to analysis. The study was carried out in accordance with the University's ethical policies and all data was dealt with according to the relevant data protection policies.

The interview approach adopted was that described by Lofland as a "directed conversation"' [23], where the interviewer directs the conversation depending on a number of factors including the participant's current physiological state, the rapport between the researcher and the participant, the researcher's awareness of the interview process, the researcher's theoretical perspective and the topic under consideration. It is important that the researcher should not be overly-directive as this may reduce the richness and quality of the data collected.

Patton defines a focus group as "an interview with a small group of people on a specific topic" [27]. The nature of a focus group is such that the number of questions that can be asked is significantly lower than in an individual interview setting. Hence, in this work focus groups were used to seek confirmation of emerging categories or theory.

V. Evidence of Self-Affirmation

In this study self-affirmation processes are shown to influence and shape participant attitudes towards their studies, which in turn influence student perceptions of their achievement and success. Over three-quarters of those who participated in the study engaged in self-affirmation and felt that it was one of the factors that contributed to their perceived success. Self-affirmation varied along a continuum from strongly positive to strongly negative. Participants experienced positive feelings when they were successful in completing a computer related task or when their skill and ability was praised by their teachers. Many indicated that they returned to recollections of these activities and their previous successes when they found other aspects of their studies challenging.

In a qualitative study quotations are used to illustrate phenomena observed across multiple participants. Taken individually each quotation could be considered as merely anecdotal, however it is more appropriate to view each quotation as one example drawn from a much larger collection of similar observations from within the collected data. Representative quotations from the dataset are provided to illustrate each of the observed phenomenon.

The section begins with a series of quotations that illustrate some of the many, subtly different, self-affirmation processes that the participants found to be effective in helping them to succeed in their undergraduate studies. The focus of this section then shifts to negative self-affirmation, where participants describe situations in which they felt threatened and uncertain about their studies or where they did not engage in self-affirmation. Taken collectively these observations form qualitative evidence for the inclusion of self-affirmation as one of the key categories that students perceive influence their success.

One participant first commented on their positive experiences when writing computer programs:

> **Participant A:** "Writing computer programs can be really satisfying. When you are doing it and it works, you get a lot of satisfaction. It's really worthwhile and you want to do it again because it makes you feel like you've achieved something."

they then drew on these experiences to boost their ego when struggling with other aspects of their studies:

> **Participant A:** ".... so when I get stuck in electrotech, I often go back to programming because I know I can do it."

This is an example of self-affirmation where the student draws on a positive experience in a different, distinct area of computer science to affirm their sense of self and their ability.

Another student commented on how they drew on positive feedback they had received in the past to help them when they found their studies challenging:

> **Participant B:** "I was doing some stuff on the computer and my teacher was really impressed, so that made me realise I was quite good at this. Then if I'm not able to understand the problem then I know it's because it is difficult and not because I'm not any good at it. That seems to make it easier."

This student is taking responsibility for their studies and not blaming others. They accept that they may run into challenging problems during their studies. This is self-affirming behaviour as the student does not question their own ability when faced with a problem that they find difficult.

Another student engages in self-affirmation by drawing on positive feedback they have received on their work:

> **Participant C:** "When I do well on assignments then I feel really happy because I know I've got it right. So I know that I can do assignments and that I will do well on the course. It makes me feel good about myself."

This student bolsters their sense of self-worth by dwelling on the happiness they have experienced in the past.

Others talked about engaging in self-affirming activities when they find themselves struggling with their studies. The following student described how they liked to take time out to use social media when their studies were proving to be particularly challenging:

> **Participant D:** "I like to go and do something completely different... I might check on my friends pages or update my profile. Then I can go back to the problem with a clear head. It is best to take a break and then go back. I don't give up."

This participant is not only only illustrating how they engage in positive self-affirmation, they are also indicating their persistence and strong sense of self-efficacy.

Another participant talked about how personal relationships were a source of self-affirmation for them. They explained how time spent with their school friends and family helped them to take a more positive approach to their studies. This student lived close to the University during the week, but returned to their home town every weekend.

> **Participant E:** "It is a struggle to get through the week. I find I get very down because I can't keep up. However, I go home each weekend and I meet my friends on a Friday night. It is amazing how much better I feel afterwards and how much I can get done on a Saturday. It's like I suddenly can understand things when I go home."

While participant E actively sought out meetings with others as a means of self-affirmation, another participant dealt with negative feelings in relation to their studies by consciously thinking about the things that they value, reminding themselves about past academic or personal success.

> **Participant F:** "I did well in school. I was good at English and History, as well as Maths. I know I can do well. However, there are so many different things involved in programming that it just threw me completely. It was very tough. I thought it was just me, but then I realised I'm not the only one. We are all trying our best."

This student is drawing on his past academic success to help them move from a negative perspective of the value of their work to a more accurate view of reality where they acknowledge that while the subject is challenging, they are trying their best.

At the negative end of the continuum, participants described the influence of negative feedback from their teachers and peers. In relation to their university studies one of the participants rationalised their poor grades as follows:

> **Participant G:** "It's embarrassing when you don't get things and wh of this before and I don't want the others to see what mark I got, because then they'll know that I don't understand it."

This participant is feeling threatened and admits to fears of how they will be perceived by other students in their cohort . They engage in defensive mechanisms by attributing the source of their failure to the fact that they not met the subject before. This is unlikely to capture the full picture, as most students in the group are in a similar position. This participant has not engaged in self-affirmation and is unlikely to be able to learn from their mistakes as they are unwilling to reflect upon all possible reasons for their lack of success.

Another participant described their reaction to negative feedback from a demonstrator:

> **Participant H:** "The demonstrators aren't the best. One of them is very sarcastic and he always makes me feel like I know nothing. He doesn't seem to know how to get down to your level. He don't explain things and they say you should know it from your notes. I always feel very stupid afterwards."

This participant is indicating how they are left with negative thoughts and beliefs about their ability after laboratory classes. Unlike some of the participants quoted above, this student does not seem able to counter these feelings by recourse to self-affirmation.

One participant expressed how they started to doubt their decision to study computer science when they tried to learn how to program on their own:

> **Participant I:** "I tried to teach myself how to program last summer. I found it really tough and I was really worried that I'd be bad at it and that I'd chosen the wrong course."

This student's sense of their aptitude for the domain has been eroded by their inability to learn how to program on their own. They lack confidence in their ability to program and seem unable to place this single setback into a wider context e.g. this may be the student's first attempt at independent self-study and they may not yet realise that computer science is not just about learning to program.

These negative self-affirmation influences are not only linked to the participants experience on their own; some reported how comments by others caused them to worry:

> **Participant J:** "My parents didn't really want me to study computer science. They didn't think I'd be good at it, so I was a bit worried at first."

This student's defensive bias is drawn from the value they place on the advice received from their parents. This is not surprising as the most persuasive domain of self-affirmation is personal relationships [31].

In the following quotation the participant explains how they rationalised their concerns about doing well in mathematics:

> **Participant K:** "In school I used to feel annoyed when I didn't do well. I don't think he was a very good teacher and I wasn't the only one who didn't like him; though some of the others got A1's. It was quite hard to focus to be honest. I knew I had to get a C in honours maths. That was really my main concern for the whole of sixth year, well for fifth year as well. I didn't think I'd get it. I was really, really concerned about it."

This participant is acting in a defensive manner, devaluing the ability of their teacher even though they admit that others in their class group had got very high grades. In order to make feel better the student places the blame on an external factor, in this case the teacher, so that they do not have to address any influential internal factors such as their preparation for the examination and the effort they put in throughout the year.

Self-affirmation is a well-established theory, however it is often used within the classroom in rather contrived, artifical ways. The representative quotations above provide real-world examples of how computer science students attitudes towards their studies are influenced by their engagement in self-affirmation. Educators seeking to help students who are feeling uncertain or discouraged can draw on these more practical self-affirmation techniques to help counteract their students' negative attitudes and beliefs.

VI. Conclusion

It is natural for people to wish to protect their personal sense of their self-worth and ability, for example, students are likely to become defensive when faced with evidence of negative academic performance. This can lead them to seek to place the blame on external factors e.g. examiner impartiality, rather than internal factors e.g. their own skill. This may give them a biased world view and restrict their ability to learn from their mistakes. Self-affirmation theory explains how a person's innate defensive mechanisms can be overcome when they affirm alternate sources of self-worth [35].

The effect of self-affirmation has been verified in rather contrived experiments where participants engage in self-affirmation by writing short essays about values that are important to them [9], [16]. More recently, studies have confirmed that people engage in self-affirmation in the creation of their social media profiles [42], [43].

This paper has explored self-affirmation from a different perspective; providing real-world evidence of self-affirmation in action, both at a conscious and sub-conscious level. In this study the participants' descriptions of how they engaged in a wide variety of forms of self-affirmation to help them overcome academic challenges and setbacks led to the emergence of self-affirmation as one of the key categories in the emergent grounded theory of learner perceptions of successful engagement in undergraduate computer science [18].

This paper is unique in its exploration of real-life engagement in self-affirmation and how this influences student perceptions of their own success. Consequently self-affirmation should form part of all future efforts to support and scaffold learning in computer science.

Deciding to Stay: The Intersection of Sex and Race/Ethnicity

Elizabeth Litzler, Catherine Samuelson
University of Washington, elitzler@uw.edu, catesam@uw.edu

***Abstract*— While much of prior research has focused on understanding the reasons students leave engineering, and therefore talk to those students who switched out of an engineering major, this study contributes the new perspective of students who seriously considered leaving but ultimately decided to stay in their engineering major. The qualitative analysis suggests that about one-third of students seriously considered leaving engineering but ultimately decided to stay. The reasons students decided to stay in engineering fell into eight main categories, with the most common reasons being the rewards that will come with an engineering degree; enjoyment of engineering; or an aversion to quitting or desire to prove that you can do it. Differences in rationales were discovered between males and females, between different race/ethnicity groups and at the intersection of sex and race/ethnicity.**

Keywords—retention; engineering; diversity

I. Introduction

Diversifying the engineering field continues to be a struggle. Improving the representation of engineering students from historically underrepresented race/ethnicity, sex, class, disability, groups etc., should yield greater diversity of thought in the field as a whole. Recent research has indicated that more diverse work teams produce better outcomes and are better problem solvers than teams of high ability that do not consider a diversity of perspectives [1-4]. As written by Professor Scott E. Page, "If people think alike then no matter how smart they are, they most likely will get stuck at the same locally optimal solutions. Finding new and better solutions, innovating, requires thinking differently. That's why diversity powers innovation" [5]. Increasing diversity in engineering as well as science, technology, and mathematics fields would drive technical innovation and improve U.S. chances to remain competitive.

Understanding the experiences of racial and ethnic minorities in engineering has been difficult because there are relatively few people from underrepresented groups in engineering. And as society becomes more diverse and multi-racial, we need to re-conceptualize prior ways of thinking about racial and ethnic identities. For example, only a little over a decade ago on the 2000 Census, the US Government finally began collecting and examining race/ethnicity with a multi-cultural perspective by allowing US Census respondents to indicate more than one race or ethnicity on the form.

One theoretical perspective suggests that people who share a common culture are part of a status group. Different status groups generally have different levels of status in the social order and different values and traditions [6,7]. Diverse undergraduate students in engineering may identify with multiple status groups. The context of student interactions and the context of engineering itself may result in certain aspects of student identities becoming temporarily more salient than others. An understanding of how status group values can impact the reasons students stay in engineering provides a new perspective to the field.

Research shows that undergraduate students regularly change their majors, and engineering students, in particular, often consider leaving the major for a different one. The reasons why students consider leaving but nevertheless decide to stay are relevant to understanding what can be done to keep students who are already in engineering. This paper will examine the following research questions:

- To what extent did students report that they considered leaving?
- For what reasons did students remain in their engineering major?
- Are certain factors more important for students from certain racial/ethnic and/or gender groups?

This exploratory analysis helps us understand what experiences and/or how status group values might result in students deciding to stay in engineering, enabling schools to focus on what works. This paper concentrates specifically on sex and race/ethnicity status groups. The research results from this qualitative analysis will ultimately contribute to the creation of a more inclusive engineering education environment for women and men of all races and ethnicities.

II. Background

A. How Status Groups Inform Our Understanding

When examining the experiences of students with different identities, an understanding of the role of status groups can help. Status groups are a unit of analysis used to denote groups of people who share a common culture, or a sense of status equality based on participation in the common culture [6,7]. Note, however, that status groups can be fluid and change based on circumstances [6].

According to Weber, status groups can come from differences in life situation due to positional power, in addition to other situations [7]. In engineering, it could be argued that men, in general, and White and Asian/Asian American men in particular, are the status group in control of engineering education. Status groups continually struggle for advantage, and the dominant groups' values become the de facto culture that non-dominant groups struggle against. This theoretical perspective suggests that students from non-dominant status groups (such as women, underrepresented minorities, students with disabilities, etc.) will experience the dominant status culture in different ways, and that students' perceptions of their experiences will be shaped by their own status culture values.

B. *Why Students Stay or Leave*

Much research in engineering education has focused on why students leave the field.

Student academic performance, particularly in freshman and sophomore gatekeeping courses, plays a key role in student persistence in engineering programs, particularly for students who experience difficulties in these classes [8-13]. Academic and social integration of college students has been found to contribute to student retention [14-17]. Formal and informal aspects of social life, including co-curricular activities and other personal interactions on campus, as well as formal and informal aspects of academic life, such as faculty-student learning interactions in and out of class, respectively influence social and academic integration [16-18].

Students who switch out of engineering majors tend to have less confidence in their study habits, enjoy studying engineering less than those who stay, and are less likely to believe that graduating with an engineering degree will guarantee them a career [8]. They express concerns about the kinds of work that will be available to them in engineering and the lifestyles of those careers [13]. The more confident students are that they will find engineering work satisfying and aligned with their interests and values, the greater their intentions to remain in engineering beyond graduation [19]. Many minority students, in particular, report strong feelings of obligation to serve and repay their communities for support received [13].

Ethnic minority students may face additional challenges, such as differences in ethnic/cultural values and socialization, internalization of negative stereotypes, ethnic isolation and perceptions of racism, and/or inadequate program support [13,20-22]. Many students of color face specific challenges as a result of being underrepresented minorities in engineering undergraduate programs. They may also lack peers, faculty role models and mentors [13,23].

Existing literature regarding student persistence in undergraduate engineering programs does not offer a lot of insight into the experiences of underrepresented groups, especially ethnic minority men and women.

III. Research Methods

This qualitative inquiry, which is part of a larger mixed methods research project funded by the Alfred P. Sloan Foundation, known as the Project to Assess Climate in Engineering (PACE), focuses on making sense of the realities and experiences of undergraduate engineering students using an interpretive perspective [24]. Qualitative interview approaches have been successful in elucidating the perspectives of STEM students from underrepresented groups [25-27].

A. *Sample*

In 2008 and 2009, currently enrolled engineering students 18 years of age or older were invited to participate in one-on-one interviews based on a stratified random sample. This project analyzed interviews with 116 undergraduate engineering students (63 women, 53 men, and 34 men and women from underrepresented race/ethnic groups.) An appropriate qualitative study sample size is one that sufficiently answers the research question(s) [28]. The analytic sample for this paper includes the 41 students who shared that they had seriously considered leaving engineering. Of the 41 students, 22 were women and 19 were men. In terms of ethnic breakdown, the number of students who self-identified as members of underrepresented groups ranged from two to eight, and those who identified as White made up the majority of participants. Students also represented various engineering program stages including first through fifth year. See Table I.

The students come from 13 US universities, ranging in size from 1,904 to 50,995 students, with an average enrollment of 24,682 students. Seventy percent are public universities, sixty-two percent are designated "very high research activity" under the Carnegie Classification, and eight percent are Minority-Serving Institutions.

B. *Procedures*

Semi-structured one-on-one interviews were conducted with participants to gain an understanding of student experiences in their own words, allowing the researchers and participants to engage in conversations with purpose (Merriam, 1998). These were conducted and audio-recorded at each participating institution by trained PACE research team members and consultants. Questions on the interview protocol that were useful in this analysis included: Have you ever considered leaving engineering? When? Why? What changed your mind? What motivates you to continue in engineering?

TABLE I. STUDY PARTICIPANTS

Race/Ethnicity	**Demographics**		
	Men	***Women***	***Yr. in School***
African American/Black	1	3	1^{st}(1), 3^{rd}(3)
American Indian	2	0	2^{nd}(1), 4^{th}(1)
Asian/Asian American	3	2	1^{st}(1), 3^{rd}(1), 4^{th}(3)
Asian Indian	1	2	1^{st}(1), 2^{nd}(1), 5^{th}(1)
Hispanic/Latino	3	5	1^{st}(3), 2^{nd}(2), 3^{rd}(2), 4^{th}(1)
White	9	10	1^{st}(1), 2nd(5), 3rd(1)), 4th(9), 5^{th}(3)

This work was made possible by a grant from the Alfred P. Sloan Foundation.

C. Analysis

Data analysis, using NVivo 9 qualitative data analysis software, utilized a combination of both open and focused coding methods [29]. Research questions provided a lens for the notation of ideas and themes, as well as for code generation [29]. This led to organizing and grouping data by theme and relationship to other data, moving from general to specific themes and vice versa, in order to understand the phenomenon being studied [30]. Throughout the process, we looked for patterns, themes, and regularities, along with contrasts, paradoxes and irregularities. Data displays were enlisted for organizing and exploring the data [30,31]. Analytic memo writing was used during the analytic process to help interrogate, systematically explore, and make sense of the data [30].

IV. FINDINGS

This section moves from general result descriptions to increasing disaggregation of the results by sex and race/ethnicity in order to provide context for the more specific findings. The findings described below are organized into four main sections: overall results (trends for all students who seriously considered leaving, but decided to stay), differences by sex, and by race/ethnicity, and intersections of sex and race/ethnicity. While percentages are used to indicate trends in the data, keep in mind that the percentages are based on relatively small numbers.

A. Overall Results

Of the total 116 currently enrolled engineering undergraduate students interviewed for the larger PACE study, 41 (35%) indicated that they seriously considered leaving engineering. A total of 36% of the men and 35% of the women had seriously considered leaving, which demonstrates very little gender difference within our qualitative sample. However, greater differences were seen among racial/ethnic groups. In order of ascending prevalence, the percentage of each group to seriously consider leaving is: 31% of Whites, 36% of African American/Blacks, 38% of Asians/Asian Americans, 40% of Hispanics/Latinos, 50% of Asian Indians, and 66% of American Indians.

Students were motivated to continue in their engineering programs for multiple reasons, including: the rewards of an engineering degree [Rewards of Degree], enjoyment and/or interest in engineering [Enjoyment of Engineering], aversion to quitting or proving they can do it [Aversion to Quitting/Prove Can Do It], adjusting and realizing it gets better [Adjusting/It Gets Better], the support and encouragement of friends and family[Friends/Family], alternative options were less or not at all appealing [Alternative Options Less Appealing], and co-op and/or internship experiences [Co-op/Internship Experience]. In total, 90% of participants described two or more reasons for staying and 39% described three or more reasons. This results in a multifaceted understanding of student reasons. See Table II.

TABLE II. REASONS FOR STAYING IN ENGINEERING, BY SEX

Reasons	Prevalence of Reasons		
	Total (out of 41)	***Women (out of 22)***	***Men (out of 19)***
Rewards of Degree	31 (76%)	19 (86%)	12 (63%)
Enjoyment of Engineering	18 (44%)	8 (36%)	10 (53%)
Aversion to Quitting/ Prove Can Do It	14 (34%)	9 (41%)	5 (26%)
Came This Far/Too Late to Turn Back	12 (29%)	7 (32%)	5 (26%)
Adjusting/It Gets Better	10 (24%)	6 (27%)	4 (21%)
Friends/Family	8 (20%)	6 (27%)	3 (16%)
Alternative Options Less Appealing	7 (17%)	6 (27%)	1 (5%)
Co-op/Internship Experience	5 (12%)	4 (18%)	1 (5%)

The most common reason for staying in engineering (indicated by 76% of participants) was that an engineering degree had a lot to offer students [Rewards of Degree], including helping students realize their career goals, contribute something important to society, prepare for many different careers, as well as provide good job prospects, job security, salary, and a sense of pride.

The second most common reason for staying in engineering (indicated by 44% of participants) was the enjoyment of and interest in engineering [Enjoyment of Engineering]. Students described deriving gratification from solving puzzles, fixing things, working with materials, applying science and math, and learning new material. These students see engineering as a field one could never get bored in, given the many interesting possibilities. The third most common motivator expressed by students (34% of participants) was an aversion to quitting or a desire to prove they could make it through engineering and earn a degree [Aversion to Quitting/Prove can do it]. This points to a more negative rationale for making the decision to stay in engineering.

B. Differences by Sex

When the responses are examined by sex, the most common motivator is still Rewards of Degree for both men (63%) and women (86%). However, women were more likely to indicate this than men (Table II). Men also described motivation to stay in engineering due to Enjoyment of Engineering (53%), as this Hispanic/Latino man explains: *Despite the difficulty of a lot of my classes, I actually enjoy it. I enjoy learning, doing it, actually performing and seeing it. What makes me also is as an engineer I can be a more impact to society. One of my biggest goals is to help make change…I really want to be an influence for good in the world, so that is why I want to be an engineer.* A total of 58% of all men indicated one of these two factors; the other reasons for staying were much less frequently indicated among men.

Women provided a more multifaceted view of the reasons they stay in engineering, with the least common reason (Co-op/Internship Experience) still expressed by 18%. This White woman's comment offers an example:

Freshman year, I think I almost left five times, but each time the new major I thought of, I didn't really want either. [I] kept thinking I'd change my mind, but there's nothing else I wanted more than engineering, [so] I just kept staying in it…And then once I got a job in engineering too, like an internship, I ended up liking that a lot. I don't really like the classes in school very much, but I did like the internship…So it [was] like, well if I get through classes, I can find a job that I really like in engineering, so I might as well stick through these torturous classes and everything and then I might really enjoy what I'm doing afterwards, so it makes it worth it. [What motivates me to continue in engineering] I guess [is] just to get through it. I'll graduate in less than a year, so it's just like you just do the homework and do the classes and just finish it and then you'll graduate and move on. I mean, it's not that bad sometimes, but also it's bad. I do really like the kids though, so that really helps. Makes it fun.

Unlike the men, women's second most frequently indicated reason for staying in engineering was Aversion to Quitting/ Prove Can Do It (41%). The majority of women (55%) described three to five motivators for staying in engineering, 45% provided two reasons, and no women had fewer than two reasons. On the other hand, 21% of men indicated three to four motivations for staying and another 21% talked about only one reason for staying, while no men offered more than four reasons.

C. Differences by Race/Ethnicity

Looking at distinctions by ethnicity, Rewards of Degree still stands out as the most common factor motivating students to stay in engineering for most groups. Exceptions include American Indian students, who indicated Enjoyment of Engineering with similar frequency to Rewards of Degree. Asian Indian students expressed Aversion to Quitting/Prove Can Do It just as commonly as they indicated Rewards of Degree. Different from all other groups, Asian/Asian American students' most common response (60%) was Alternative Options Less Appealing. See Table III.

Additional distinctions emerge when we look beyond the most common motivators. For example, the second most common reason expressed by African American/Black students (3 out of 4) was Came This Far/Too Late to Turn Back. Whereas half of Hispanic/Latino students' indicated both Enjoyment of Engineering and Aversion to Quitting/Prove Can Do It, second in prevalence to Rewards of Degree. The second most common reason for Asian/Asian American students (indicated by 40%) reflects one of the most common reasons for other groups, Rewards of Degree. In the case of White students, 10 out of 19 discussed Enjoyment of Engineering, making this their second most common response.

TABLE III. REASONS FOR STAYING IN ENGINEERING, BY RACE/ETHNICITY

Reasons	**Prevalence of Reasons**					
	African American/ Black (out of 4)	***American Indian (out of 2)***	***Asian/ Asian American (out of 5)***	***Asian Indian (out of 3)***	***Hispanic/ Latino (out of 8)***	***White (out of 19)***
Rewards of Degree	100%	100%	40%	67%	88%	74%
Enjoyment of Engineering	0%	100%	20%	33%	50%	53%
Aversion to Quitting/ Prove Can Do It	0%	50%	20%	67%	50%	32%
Came This Far/Too Late to Turn Back	75%	50%	20%	33%	25%	21%
Adjusting/It Gets Better	50%	0%	0%	0%	25%	32%
Friends/ Family	25%	0%	20%	0%	25%	26%
Alternative Options Less Appealing	0%	0%	60%	0%	0%	21%
Co-op/ Internship Experience	0%	0%	20%	0%	0%	21%

D. Intersections of Sex and Race/Ethnicity

Looking at how ethnicity and sex intersect sheds light on some additional distinctions among students. In addition to Rewards of Degree, all three African American/Black women indicated Came This Far/Too Late to Turn Back, which led them to decide they may as well finish their engineering programs. In contrast, in addition to Rewards of Degree, the one African American/Black man reported that Adjusting/It Gets Better played a key role in his decision to stay:

I guess I wasn't so ready for the level of work, so it took a while to get adjusted. That's been probably the only issues -- like believing that I can actually do this stuff…I guess after my first semester; after my initial shock of -- seeing college is not too bad. I picked up the studying, so I kind of knew what I had to do to get good grades. [I] felt a little more confident…You always hear that engineers make more money coming out of college; they're more likely to get jobs. So, I figure if you're going to go to school for four years you might as well make the best out of it [because] I know in the long run I have a whole life ahead of me, so that makes all the big difference

The second most common reasons given by Hispanic/Latina women as to what motivates them to continue in engineering remained the same as the whole group -- Enjoyment of Engineering and Aversion to Quitting/Prove Can Do It. The third most common motivators for Hispanic/Latina women were: Came This Far/Too Late to Turn Back and Friends/Family. In contrast, Hispanic/Latino men's second most common reasons were spread evenly across three reasons: Enjoyment of Engineering, Aversion to Quitting/Prove Can Do It, and Adjusting/It Gets Better.

Responses from Asian/Asian American women were distinct from Asian/Asian American men in that their most common response reflected the overall group [Alternative Options Less Appealing], while men's responses were spread evenly across multiple responses. For example, this Asian/Asian American woman described her motivation this way: *Well, I can't really think of what else I would want to do. So, that was probably a factor. I do feel accomplished when I do well in a class or feel like I'm learning. So, at least I'm learning. Because I've taken just general, like literature or science arts classes, LSA classes and it's just a lot more boring. I'd rather be doing engineering.*

Finally, White student responses also differed by sex. Both Rewards of Degree and Enjoyment of Engineering were expressed by the same number of White men. While White women's second most common response reflected that of women overall [Aversion to Quitting/Prove Can Do It], the next most common responses varied. In this case, the third most common responses expressed by White women were: Alternative Options Less Appealing, Enjoyment of Engineering, Adjusting/It Gets Better, and Co-op/Internship Experience as reasons for staying in engineering. Following closely behind is being motivated by Friends/Family. Interestingly, only one White woman mentioned Came This Far/Too Late to Turn Back as a reason for staying.

Very few distinctions were found among Asian Indian students when we examined the disaggregated trends by sex and race/ethnicity.

V. Conclusion

This qualitative analysis expands current research on retention and attrition, and the results ultimately can contribute to the creation of a more inclusive engineering education environment for women and men of all races and ethnicities. While much of prior research has focused on understanding the reasons students leave engineering, and therefore talk to those students who switched out of an engineering major, this study contributes the new perspective of students who seriously considered leaving but who ultimately decided to stay in their engineering major. This presents important information for institutions offering engineering degrees that can help them better serve and retain a diverse population of undergraduates.

The data indicated that of the total 116 currently enrolled engineering undergraduate students interviewed for the larger PACE study, 41 (35%) had seriously considered leaving engineering. While distinctions between gender groups were negligible, notable is the high prevalence for considering leaving among certain ethnic groups. However, all forty-one students expressed determination to complete their degree, identifying various reasons for staying. Eight different themes emerged from the analysis of students' reasons for staying in engineering despite having seriously considered leaving Institutions could benefit from considering how to address these various factors to contribute to increased retention, by emphasizing and reiterating the rewards of an engineering degree, providing support for students to learn about what is involved in pursuing an engineering degree and adjusting accordingly.

While Rewards of Degree stood out as the most common motivator overall, certain factors were more salient and certain patterns emerged for students from particular gender and/or racial/ethnic groups. For example, more men (53%) than women (36%) indicated that Enjoyment of Engineering motivated them to continue (second most common response from men); whereas more women (41%) than men (26%) reported Aversion to Quitting/Prove Can Do It (second most common response from women) as a reason to stay. As members of the dominant status culture, men may not feel the same need to prove themselves that women do, accounting for the difference examined above. In some ways, since men lack the daily struggle against the dominant culture, they can stay for reasons such as the love of engineering work, rather than a more negative orientation such as an aversion to quitting or desire to prove oneself. This signifies that until there is a massive culture shift in engineering overall, as well as within specific engineering departments, women will likely continue to express less intrinsic motivation for staying in engineering.

Women also conveyed a more multifaceted view of the reasons they stay in engineering, with the majority describing three to five motivators for staying. Not even a quarter of men, on the other hand, indicated three to four reasons for staying, and no men mentioned more than four reasons, implying a more straightforward process for making the decision to stay in engineering. Could it be that the more barriers a status group has to overcome, the more complex their stories become about why they stayed in engineering? For women, there are many more barriers to staying in engineering, resulting in complex descriptions of what kept them in the major. This speaks to the need for institutions to examine the various barriers that may be facing women at their particular schools and develop means for addressing and reducing them to better support women.

The Aversion to Quitting/Prove Can Do It theme illustrates how contrasting viewpoints could potentially result in differential workforce outcomes. Some of the reasons in this category tended toward a more negative-orientation, such as students not wanting to be a 'quitter', being raised to finish what they started, and not wanting to 'fail' at something. Others indicated more of a survivor instinct, like realizing that getting through this meant they could get through anything, wanting to prove that women could be engineers, or expressing a desire to challenge oneself. While the latter indicates more of an aspiration to continue in the field and pursue the goal of becoming an engineer, despite the barriers, the former could portend that a student may actually leave the field after graduation and not pursue an engineering career. This illuminates how seemingly minor distinctions in student perspectives could potentially result in very different outcomes. If institutions could identify students likely to graduate yet not likely to pursue an engineering career, they could then create interventions specific to the needs of these students. This could result in a wider range of individuals pursuing engineering careers, which could positively impact the field overall.

Student rationales for staying differed quite a bit by race/ethnicity and some distinctions become even more pronounced when looking at how race/ethnicity and sex intersect. For example, African American/Black women and men's second most common motivators both reflect some level of struggle, yet there is a somewhat different orientation towards this struggle for women than for men. African American/Black women indicated Came This Far/Too Late to Turn Back. This reason, which for all three female African American/Black engineers was combined with Rewards of Degree as motivation to stay, implies a somewhat negative or unhappy experience yet a strong 'eyes on the prize' orientation. The one African American/Black man also indicated an orientation toward the 'prize' of Rewards of Degree; however, his stance toward his experience was framed more positively in that he talked about Adjusting/It Gets Better.

Much like with women in general, this could signify that African American/Black women face additional barriers compared to African American/Black men, and as such have a harder time adjusting and feeling like things get better. Conducting additional research focused specifically on African American/Black women, or both African American/Black women and men, could help unpack this phenomenon to not only determine what additional barriers these women may face, but contribute to potential strategies for reducing them.

Two of the three Hispanic/Latina women described really liking the challenge of engineering, which fits into the theme Aversion to Quitting/Prove Can Do It, and these same two women also described Enjoyment of Engineering. The one Hispanic/Latina woman who discussed her reason for staying as more akin to an aversion to quitting (rather than proving oneself), did not describe Enjoyment of Engineering as a reason for staying. This could indicate that this student faced additional barriers or different barriers which negatively impacted her experience and detracted from her enjoyment. Delving deeper into Hispanic/Latino and other underrepresented student experiences could help explicate impacts on student attitudes, persistence, and decisions to pursue engineering careers.

The fact that the most common rationale for Asian/Asian American students was Alternative Options Less Appealing feeds into some stereotypes around the push for Asians/Asian Americans to achieve in a science or engineering field. For example, one Asian/Asian American male described being motivated because: *I'm good at it, I can't find anything else that I'd be equally as good at, or that would satisfy – or that would bring me to my goals to where I wish to be in life.* Interestingly, this remained the most common response among Asian/Asian American women, whereas Asian/Asian American men's responses spread evenly across multiple reasons. The results indicate that Asian/Asian American students likely bring their own racial/ethnic status culture values into engineering, as evidenced by their different primary reasons for staying compared to other racial/ethnic groups.

The significance of the multifaceted reasons for staying in engineering among White women (versus White men) should be considered in more detail. For example, how do different combinations of responses help us understand a higher-order rationale for staying in engineering? Further, how can institutions respond to these differences and better support women and encourage them not only to persist in engineering programs, but also pursue careers in engineering?

The differences described above highlight complexities that can exist for students when deciding whether or not to stay in engineering. This work also builds upon prior research. For example, the importance of academic integration for retention is echoed in this study, particularly for students who described needing time to adjust and that things got better for them as time went along [14,16]. Burtner's findings are highlighted here in that the rewards of an engineering degree, including the likelihood of a stable, lucrative career are in the forefront of most students' minds when thinking about what motivated them to stay in engineering [8]. This African American/Black female highlights these points:

Okay, so part of [what motivates me to continue is] that I don't really have very much longer to go; I only have two more semesters. It just doesn't make sense to me to switch out at this point, because you definitely can't get another degree in two semesters. And I think I've sort of found my place in the department; I've created my group of study friends, and found my mentor, and I'm doing research that I like to do, and sort of becoming a little more active in the department…it's just become a little bit more friendly to me. I feel like it's a large department; we have 150 students in my graduating class. So I think it would be really easy to just fade into the background. But now that I'm feeling like there are a few people in the department who I actually have a connection to I'm enjoying it more. And it's also really cool that in these classes we're starting to reference material from previous classes, so everything is being put in perspective.

Differences among gender and racial/ethnic groups, as well as among different gendered racial/ethnic groups, point to the need for differentiated support for engineering students. They also elucidate distinctions among underrepresented groups, and the need to recognize groups as distinct, versus treating them as one subset of engineering students, and addressing their issues through this broad lens. Additional research focused on developing a deeper understanding of the distinct experiences of underrepresented student groups is much needed.

This exploratory analysis helps us understand what experiences or how status group values might result in students deciding to stay in engineering, enabling schools to focus on what works. Analysis for this paper indicated the complexity of student responses regarding what motivates them to stay in engineering. However, there is more work to be done in examining the combinations of reasons that students gave, with an eye toward understanding how multiple reasons given by a student can create a full-bodied picture of that student's motivation for staying in engineering.

***Abstract*— The development of social responsibility, both personally and professionally, is critical in the movement toward developing more holistic engineers, as called for by many professional engineering societies to address the complex problems that face our society. This paper presents correlations between engineering students' religious beliefs and their views of personal and professional social responsibility. Data were gathered from 895 engineering respondents to the Engineering Professional Responsibility Assessment tool and from 25 semi-structure interviews with engineering students. It was found that students who considered themselves 'very active' in their religious preference had stronger beliefs of their ability and personal obligation to help others, and in a professional sense of obligation to help others as engineers.**

Keywords—Social Responsibility, Service, Religion, Spirituality, Ethics, Morality, Engineering Identity

I. Introduction

The relationship between individuals' spirituality and higher education is complex, and is a subject that is largely avoided, especially in engineering. Many professional engineering societies, however, are calling for the development of more holistic engineers [1], including skills such as "consideration of others, respect, sensitivity, thoughtfulness, thoroughness, and tolerance" [2, p. 172]. For some students these skills and how they see themselves as engineers is rooted in their religious beliefs, especially how they view their social, ethical, and moral responsibilities as an engineer. Examining the correlation between students' religious beliefs and their views of personal and professional social responsibility starts the conversation for what role engineering educators can play towards developing more holistic engineers.

The term 'social responsibility' has been used in many different ways in engineering education research. Studies use this term to focus on civic duty [3], the development of democratic views [4], cheating [5] or social considerations which are critical for engineers to consider [6]. For this study, social responsibility is seen as an obligation to be aware of the impacts of engineering work on others and to see engineering problems from the perspectives of others, with special consideration for underserved populations [7]. Because this perspective of social responsibility focuses on objectivity, or the ability to step outside of one's self to see issues from another's perspective [7, 8], religious views are an interesting element to examine when looking at the development of social responsibility in engineering students as many religions challenge their members to adopt similar foundational perspectives.

There have been, however, very few studies which have looked specifically at the relationship between engineering and religious beliefs. Beyond engineering, several studies have recently looked at the role of spirituality in the college experiences of students. Some point to an increased number of students engaging in spiritual or religious practices in college [9, 10]. With respect to the role of the institution in student spirituality, the National Study of College Students' Search for Meaning and Purpose found that "educational experiences and practices that promote spiritual development – especially service learning, interdisciplinary courses, study abroad, self-reflection, and meditation – have uniformly positive effects on traditional college outcomes" [11]. Findings from the 2012 National Survey of Student Engagement showed that 31% of seniors across all disciplines (n=327,946) felt that their institution contributed to their developing a deepening sense of spirituality 'quite a bit' or 'very much', while only 20% of engineers (n=20,012) said the same [12]. Correlations between volunteerism and religiosity have been mixed [13, 14], but studies have correlated institutional religious affiliation with gains in students' ethical development [15].

Connections between engineering and religious beliefs can be seen by looking at some religiously affiliated institutions. George Fox University advertises that they "prepare technically competent and broadly educated engineers for a life of responsible service emerging from a Christian worldview" [16]. The mission statement of the College of Engineering at the University of Notre Dame states:

"Consistent with the University's Catholic mission and heritage, the College of Engineering's mission is founded on the principle that the creation and transfer of knowledge should reflect a profound and complete respect for the dignity of all persons and for the greater common good of humanity… To that end, the college will continue to engage

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

in transformational research in its core competencies… as they address the important needs of humanity, while inspiring students of all levels to scholarship and service" [17]

Several non-profit organizations also work to establish strong connections between one's religious identity and their engineering abilities. Engineering Missionaries International and Global Appropriate Technology Ministries are two which help facilitate "discipline-specific service" through a lens of using ones' gifts from God to serve those who are less fortunate. For those who hold those religious perspectives, the connection between the personal and professional can become seamless, critically informing that individual's engineering identity.

Because the connections between religious or spiritual beliefs and engineering identity can be strong for some individuals, it is important examine those relationship, especially when considering the development of holistic engineers. This study seeks to examine those correlations in engineering students. Specifically, to see how one's religious or spiritual preference plays a role in their views of personal and professional social responsibility in engineering.

II. METHODS

A. Survey Tool

The Engineering Professional Responsibility Assessment (EPRA) survey was developed to gauge students' attitudes and beliefs regarding personal and professional responsibility based upon the Professional Social Responsibility Development Model [7]. EPRA consists of 49 7-point Likert questions (Strongly Disagree to Strongly Agree), questions about the importance of different job attributes, motivations and limitations for engaging in community service, previous volunteer experiences, and demographic information. Students are also asked, in an open box question, to describe any other life experiences that had influenced their beliefs of community service and social responsibility. Reliability and validity are in the process of being established for the EPRA tool.

EPRA was developed to address three realms for the development of personal and professional social responsibility: Personal Social Awareness, Professional Development, and Professional Connectedness (which is a combination of the previous two). The Personal Social Awareness realm is rooted in Schwartz's model for the development of altruistic behavior [18]. This realm consists of three construct (Awareness, Ability, and Connectedness) which describe 1) recognition that there are others that need help, 2) recognition of one's ability to help, and 3) a feeling of moral or social obligation to help others, respectively. The Professional Development realm also consists of three constructs (Base Skills, Professional Ability, and Analyze) and draws from a combination of Schwartz and from Ramsey's model which incorporates social considerations into the scientific process [19, 20]. Base Skills (Base) construct addresses student views of the importance of both technical and professional skills in engineering, while Professional Ability (ProfAb) and Analyze describe a recognition that engineers or the engineering profession has the ability to help others and a recognition of the importance to including social aspects into the engineering process, respectively. The third realm, Professional Connectedness, consists of two constructs – Professional Connectedness (ProfCon) and Costs/Benefits (CB). This realm is cyclical whereby an individual weighs the costs and benefits of engaging in actions of service based upon their prior beliefs of the moral or social obligation to help as a professional. Based upon acting (or not) an individual's beliefs of obligation deepen (or not) and the cycle begins again. This realm draws from both Schwartz and Ramsey, and also from Delve et al.'s Service Learning Model which describes the deepening internalization of social issues through engagement [21]. Data from EPRA were examined through participant average scores for each of these eight constructs.

EPRA has evolved through pilot studies conducted at the University of Colorado Boulder. Through student feedback in the open box responses, it became apparent that religion was a significant influence for some students; therefore the demographic questions about religious preference were added into the final version. The specific wording for the four religious preferences was piloted on a group of engineering and non-engineering students and alumni before going out as part of the larger survey.

B. Survey Participants

As part of a larger study, the EPRA tool was distributed to engineering students at five different institutions in the Fall 2012 semester. The data from this distribution was used for this paper. Institutional characteristics for each university are provided in Table I. The survey was electronically distributed to first-year, senior and graduate students in Civil, Mechanical, and Environmental Engineering, with a $5 incentive for completion (except at one school, were incentives were not permitted). Each survey was open for three weeks at the beginning of the semester. In total, 895 students completed at least 90% of the survey. The Likert data were considered as ordinal data and averages and two-tailed pair t-tests were used to examine the significance of the differences of means [22, 23]. Student responses to the open ended question about other influences on their views of social responsibility were also examined using a mixture of emergent and *a priori* coding, guided by the study research questions.

C. Student Interviews

In addition to the EPRA results, data from 25 interviews with engineering students was used. These interviews were semi-structured and lasted 30 to 60 minutes and were conducted concurrent with the pilot study of EPRA and before the EPRA distribution used for this paper. Interviews

TABLE I. INSTITUTIONAL CHARACHTERISTICS

ID	Control	Carnegie Classification
School A	Public	High undergraduate, large 4-yr, primarily nonresidential, RU/VH
School B	Public	High undergraduate, Medium 4-yr, primarily residential, RU/H
School C	Private not-for-profit	Majority undergraduate, Medium 4-yr, highly residential, RU/VH
School D	Public	High undergraduate, Large 4-yr, highly residential, RU/H
School E	Military Academy	Exclusively undergraduate, Medium 4-yr, highly residential, Bac/A&S

were recorded, transcribed, and analyzed using emergent thematic coding techniques [24]. Students were consented prior to each interview, consistent with IRB protocols. The majority of interview participants were senior and graduate students in Mechanical, Civil and Environmental Engineering. One of the participants was a junior student in Civil engineering and another was a graduate student in Aerospace Engineering. Ten of the participants were females. Interview questions focused on why students chose engineering as a major, what their career aspirations were, how they saw engineering interacting with society, how they defined social responsibility, and which life experiences formed the foundation of their views.

III. RESULTS & DISCUSSION

A. Survey Results

At the end of the survey, students were asked a series of demographic information, including their religious preference. Response numbers for each of the five religious preference options are given in Table II. If they chose "religious, affiliated with an organized religion" then they were prompted to say how active they considered themselves to be in the practice of their religious preference ('very active', 'somewhat active', 'not very active', or 'not active').

Response rates by demographic are shown in Table III. Distributions were similar across female and male students.

TABLE II. RESPONSE NUMBERS FOR RELIGIOUS PREFERENCE

Religious Preference	Response Rates	
	N	*%*
Religious, affiliated with an organized religion (i.e. Christian, Muslim, Jewish, Hindu, Buddhist, etc.)	387	43
Spiritual but not affiliated with an organized religion (i.e. Humanist, Agnostic, etc.)	130	15
Atheist	105	12
Indifferent or not religious	226	25
Prefer not to say	47	5

More Civil and Mechanical engineers considered themselves 'religious' (47% and 46%, respectively) compared to Environmental engineers (32%). Environmental engineers reported as being more 'indifferent' and 'spiritual' than Civil or Mechanical students. Schools B and E both had significantly higher number of students reporting that they were 'religious' (67% and 70%, respectively) than the other three schools (A-34%, C-34%, and D-25%). We hypothesize that the military nature of School E is correlated with a more traditionally religious population of students.

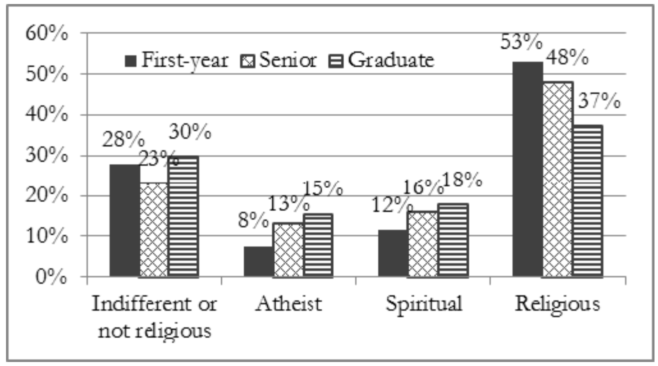

Fig. 1 Religious preference response rates by academic rank

Fig. 1 shows the distribution of religious preferences by academic rank. It is interesting to note that the percentage of students who say they are 'religious' decreases from first-year students, to seniors and graduate students. This could be due to first-year students still having strong affiliation with their parents' religion, while the students who are further along in their schooling have formed their own identity, straying from their familial influences. This is interesting when considering how schools affect religious formation. Traditionally, the standard practice is for universities to be 'hands off' when it comes to personal

TABLE III. RESPONSE NUMBERS FOR RELIGIOUS PREFERENCE BY DEMOGRAPHIC SPLIT

Demographic	Religious Preference			
	Religious	*Spiritual*	*Atheist*	*Indifferent or not religious*
Male (n=563)	44%	14%	15%	27%
Female (n=280)	48%	18%	7%	27%
Civil Engr. (n=227)	50%	13%	11%	26%
Mechanical Engr. (n=407)	49%	15%	14%	23%
Environmental Engr. (n=156)	34%	21%	12%	33%
School A (n=292)	34%	20%	16%	30%
School B (n=276)	67%	9%	8%	16%
School C (n=138)	34%	16%	16%	34%
School D (n=96)	25%	21%	11%	43%
School E (n=46)	70%	13%	7%	11%

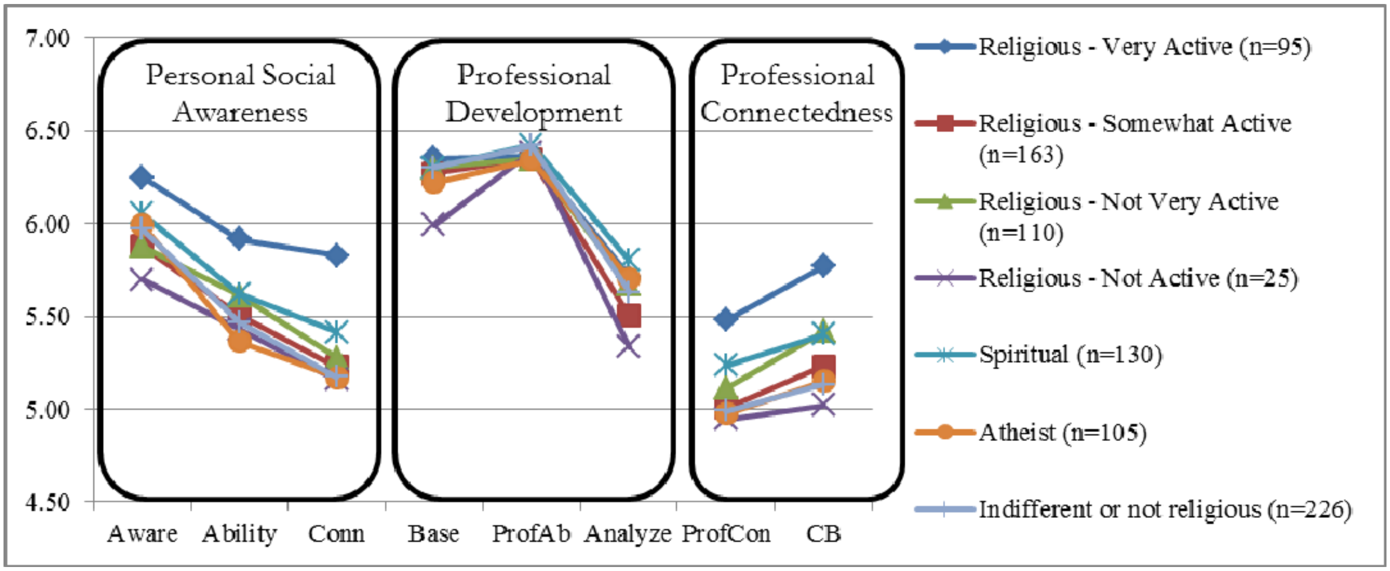

Fig. 2 Construct Averages by Religious Preference and Activeness

religious preferences, which could explain why students tend to disassociate with formal religious beliefs as they progress through college.

Of the 387 students who responded as ‘religious’, the distribution was as follows: ‘very active’ – 95, ‘somewhat active’ – 163, ‘not very active’ – 110, ‘not active’ – 25, ‘prefer not to say’ – 8. As seen in Fig. 2, those who reported that they were active in their religious preference had significantly higher construct averages than all other religious activeness as well as those who responded as ‘spiritual’, ‘Atheist’ or ‘indifferent’ in all Personal Social Awareness and Professional Connectedness constructs (significance determined with two-tailed t-tests, $p<0.05$). These two realms deal with issues of awareness of those in need and feelings of personal and professional obligation to help them. All groups were similar in the Professional Development realm (with the exception of Base Skills for ‘Religious – Not Active’, which is lower), suggesting that views of the engineering profession are not influenced by religious preference, until ideas of moral or social obligation are considered (ProfCon).

Similarly to religious preference, students were asked to share what elements motivated them to engage in community service from a prescribed list. The list included options such as “to meet new people”, “to build my resume”, “to help others”, “for an international experience (to travel)” and “because of my religious beliefs.” Fig. 3 presents construct averages based upon if “because of my religious beliefs” was checked as a motivation or not. Similar to the ‘Religious-very active’ group, those who were motivated by their religious beliefs (n=174) had significantly higher construct average in the Personal Social Awareness and Professional Connectedness realms ($p<0.05$). The majority (90%) of the respondents who checked this box also reported that they were religious, 80% were ‘very’ or ‘somewhat active’, so religious activeness was a confounding factor with participant motivation by religious beliefs.

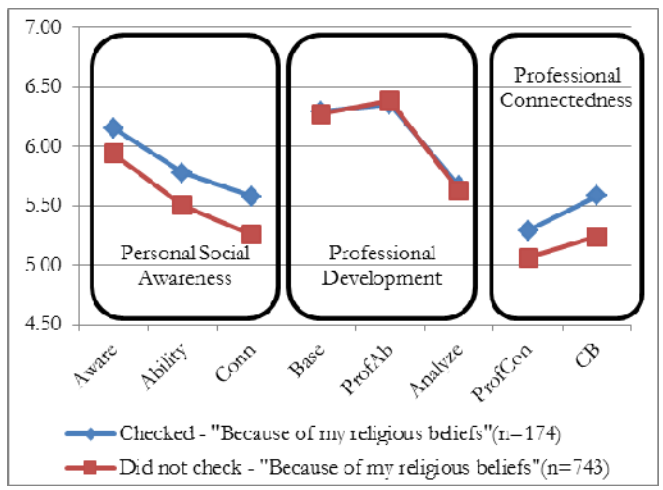

Fig. 3 Construct Averages by Motivation "Because of Religious Beliefs"

Using student responses to the short answer open box question about any other life experiences that had influenced views of social responsibility, 79 of the 730 responses included a reference to religious or spiritual practices. The majority of these 79 comments related to being raised in a certain faith, going on mission trips, volunteering through church activities, or going to religious primary or secondary schools. One student wrote directly, “my Christian faith prompts me to serve others.” Another student wrote in more detail about how their religious perspective influenced their views of obligation, saying “I also volunteer regularly for services within my church, and my experiences there have strongly implanted in me that it is my moral and spiritual duty to serve others, be they more or less fortunate than myself.”

Of those students who wrote a response relating to religion, 78% reported that they were religious and 41% of those were 'very active.' Therefore, of the 95 students who said that they were very active in their religious preference, nearly one third volunteered information about their religious preference as an influence to their views on community service and social responsibility. From the other three activeness levels for those who reported themselves as religious, only 28 (out of 298) mentioned something relating to religion in their open response. While there is no evidence of causation in the Likert data, some students do directly relate their high social responsibility to their religion in the short answers. This supports the notion that for some students, their religious preference plays a central role in the development of personal and professional social responsibility and the view of themselves as engineers.

Similar to previous studies, there was little correlation between students' religious preference and their engagement in volunteer activities, except for 'short term on-site service trips'. Given the majority of the write-in responses associated with religion, this difference is probably because of mission trips associated with religious organizations.

B. *Student Interviews*

Twenty-five students were interviewed as part of the larger study, focused on the development of social responsibility. The interviews were never designed to address religion, but seven students did talk about religion or spirituality, mostly when talking about influences to their foundational beliefs about personal and professional social responsibility. One student said about influences in his life:

"I guess the main thing probably would be just my family. My family's Lutheran, so just as a kid we were constantly doing things through church groups and doing community service that way… So, those values (of service) are kind of instilled in me, I guess, just because of the way that I was raised. So I feel like I just kind of want to now continue that because I've seen how rewarding it can be."

Here this student is pointing to his religious upbringing as instilling values of service in him that he has carried into his adult life. This student also talked significantly about how the engineering professional should take on pro bono work and that, while not required, service was an obligation of professional engineers. For this student, the values from his upbringing tied to his professional views, whereby if you have the ability and skills, you should help others. Several other students talked about how their views of social responsibility were influenced by their religious upbringing. One student talked about how she found peace at her church and often retreated there to escape the stresses of school and her mechanical engineering program. Perhaps if it had been asked explicitly, there would be more data regarding the ways in which students' religious preferences affected their views of themselves as engineers, but these seven students point to that relationship by their responses. More targeted interviews would be useful to further explore this connection.

IV. CONCLUSION

This paper presents exploratory findings that relate students' religious beliefs to their attitudes towards personal and professional social responsibility in engineering. For some students, their religious preferences relate to their views, and affect the ways in which they see themselves as engineers in society. The number of students who reported that they were 'religious' decreased with higher academic ranks, suggesting that views are changing through college away from organized religions. Also, students who reported that they were 'very active' in their religious preference had significantly higher construct averages with respect to Personal Social Awareness and Professional Connectedness than all other students. There were, however, very few differences in volunteerism based upon religious preferences, aligning with what previous studies had found.

While it is difficult to know the role that the engineering educational system should play in students' religious or spiritual development, it is clear that, when looking at issues of ethical and moral obligations for engineers, religious preference must be considered. Traditionally universities and engineering departments stay clear of religious issues in the classroom, but perhaps there is a place for engineering instructors to build upon students' existing foundational beliefs, including religion, to develop more aware, ethical, and moral engineers for the future. Hopefully, this study opens the door for other investigations into how religion and spirituality play into engineering identity and the social responsibility of the engineering profession.

ACKNOWLEDGMENT

This research has been supported by a grant from the National Science Foundation (#1158863) and by an institutional fellowship for Excellence in STEM Education. Additionally, thank for institutional support to distribute this survey, to the students who took time to honestly complete the survey and those who engaged in interviews with the researcher.

***Abstract*—To increase the number of science, technology, engineering, and mathematics (STEM) graduates, educators need to identify ways to increase student persistence from entry until graduation. The objectives of this study are to determine (1) if motivation affects learning outcomes in engineering service courses and (2) whether students' level of motivation tracks with specific engineering disciplines. Students enrolled in a sophomore-level engineering service course were surveyed to examine their motivation in engineering service courses and to assess the relationship between their motivation and their achievement and desire to persist in the engineering discipline. The survey measures for self-efficacy, task value, and achievement goals in engineering were created and evaluated during an initial pilot study. Initial results showed internal consistency among the items in each measure.**

***Keywords*—student motivation; self-efficacy; task value; achievement goal; academic achievement; intentions to persist; engineering service course**

I. Introduction

Attrition of undergraduate students in engineering programs is at its highest level during the first two years [1, 2]. In most engineering programs, undergraduate students are required to take entry-level engineering courses that are not discipline specific and are therefore considered service courses. Service courses are often characterized as having large class sizes (> 50 students) [3]. Students in these courses have indicated that compared with other courses in their discipline, service courses have a more demanding course load and they have smaller amounts of interaction with instructors in these courses [1]. Engineering students develop personal beliefs and attitudes about engineering during these service courses that influence their decision to persist within their current engineering discipline. Student motivation in these courses is worth examining to better understand its relationship to academic achievement and intentions to persist in engineering. Examining whether these relationships differ as a function of gender, class-standing, and engineering sub-discipline (major) is also warranted.

Though engineering students' motivation has been examined in previous research, most researchers use omnibus measures or measures for engineering-related domains such as mathematics and science [e.g., 4]. Our study seeks to determine the relationship of motivation constructs (i.e., self-efficacy, task value, achievement goals) to achievement and persistence using measures providing clear activities and tasks in engineering and not only in engineering-related domains. Ultimately, we want to know which motivation construct better predicts student achievement and intent to persist in engineering.

II. Theoretical Framework

With interest in multiple motivation constructs, we begin by examining students' engineering self-efficacy. Using social cognitive theory as our framework, we propose that students' continued matriculation in engineering programs may be due (in part) to their self-efficacy - the belief they hold about their capabilities. Social cognitive theory is based on the view that personal factors, behavioral factors, and environmental factors are interconnected and affect one another [5]. Bandura's [5] research showed that the belief individuals hold in their capability to bring about results is a primary motivator in a variety of life situations. Self-efficacy helps determine the amount of effort people exert in an activity, and their persistence and resilience in the face of adversity [6]. Students who believe they are capable of performing certain engineering tasks are typically more motivated to complete them [5].

III. Method and Participants

Participants for this ongoing study include students enrolled in an introductory materials science and engineering (MSE) service course at a large southeastern research-intensive university. Table 1 shows the respondents' demographics.

TABLE I. Characteristics of Respondents

Factor	Fall 2012 (N = 64)	Spring 2013 (N = 97)
Gender		
Male	64.1 %	71.1 %
Female	35.9 %	28.9 %
Class-Standing		
Sophomore	59.4 %	52.6 %
Junior	29.7 %	41.2 %
Senior	7.8 %	6.2 %

Funding for this research was supplied by the National Science Foundation, EEC Award #1240327.

Pursuing 2nd Degree	3.1 %	0 %
Academic Major		
Bioengineering	32.8 %	12.4 %
Industrial Engineering	1.6 %	27.8 %
Materials Science & Engineering	18.8 %	12.4 %
Mechanical Engineering	43.8 %	45.4 %
Other	3.0 %	2.1 %

The pilot survey was administered in the fall semester of 2012. A revised survey was administered to another cohort of students at the beginning of the spring 2013 semester. After evaluation of the initial self-efficacy scales, most items were retained. One item originally considered a source of self-efficacy (i.e., I can use engineering tools to assist me in completing engineering assignments) was added to the general engineering self-efficacy scale. The data collection instruments used for this study were approved by the institution's Institutional Review Board.

Students were asked to complete an online survey about their attitudes and beliefs about engineering. Survey items were either created or adapted from validated measures. Engineering self-efficacy measures (i.e., general engineering self-efficacy, engineering skills self-efficacy, and materials science engineering [MSE] self-efficacy) were designed in consultation with experts in engineering education and self-efficacy and in keeping with Bandura's [7] guidelines for constructing self-efficacy scales. Using a 6-point Likert-like scale (1 = *completely uncertain*, 6 = *completely certain*), students indicated the level of certainty that they can do specific engineering tasks. Table 2 shows examples of items in each scale. The scales were found to be reliable with Cronbach's alpha values greater than 0.70 [8] (Table 3).

TABLE II. EXAMPLE OF ITEMS IN EACH SELF-EFFICACY SCALE

Scale	**Example**
General Engineering Self-Efficacy	I can do a good job on almost all my engineering coursework if I do not give up.
Engineering Skills Self-Efficacy	I can design new things.
Materials Science & Engineering Self Efficacy	I can explain the difference between primary and secondary bonding in materials.

TABLE III. RELIABILITIES OF ENGINEERING SELF-EFFICACY SCALES

Scale	**Alpha**	
	Fall 2012	***Spring 2013***
General Engineering Self-Efficacy	0.93	0.91
Engineering Skills Self-Efficacy	0.92	0.94
Materials Science & Engineering Self Efficacy	0.94	0.96

To examine the relationship between self-efficacy and academic achievement, students' grades in the service course were obtained. Two dimensions of intentions to persist in engineering were measured, namely, academic persistence (intent to graduate with an undergraduate engineering degree) and professional persistence (intent to practice engineering for at least three years after graduation) [9].

IV. PRELIMINARY RESULTS AND DISCUSSION

Zero-order correlations were calculated among the variables of interest. General engineering self-efficacy was positively related to grades in fall 2012 ($r = 0.42$, $p < 0.01$) and to MSE self-efficacy ($r = 0.35$, $p < 0.01$). Previous studies have shown a positive relationship between self-efficacy and academic achievement [10, 11]. Successful academic performance in an introductory class in MSE calls for the execution of MSE-related skills (e.g., identifying effects of defects on mechanical properties of solids) and general engineering tasks (e.g., learning engineering concepts) [12]. Spring 2013 grades are not available at this time and will be included in the correlational analysis when obtained. In the spring semester of 2013, general engineering self-efficacy and engineering skills self-efficacy were significantly related to professional persistence ($r = 0.31$, $p < 0.01$; $r = 0.42$, $p < 0.01$, respectively). Judgments of capabilities matched to specific outcomes afford the greatest prediction of behavioral outcomes such as practicing engineering [13]. Being able to perform general and specific engineering skills necessary for engineering practice likely solidifies students' intentions to be engineers. On the other hand, none of the three engineering self-efficacy measures was significantly related to academic persistence. This result suggests that other factors may motivate students to enroll in engineering courses and to complete their engineering degrees.

Independent-samples *t* tests revealed significant gender differences in participants' engineering skills self-efficacy and MSE self-efficacy. Men ($M = 4.89$, $SD = 0.67$) reported significantly higher engineering skills self-efficacy scores than women ($M = 4.54$, $SD = 0.66$), $t(95) = 2.38$, $p < .05$. Men ($M = 3.25$, $SD = 0.99$) also reported significantly higher MSE self-efficacy scores than women ($M = 2.53$, $SD = 0.83$), $t(95) = 3.34$, $p < .01$. Our findings are consistent with other studies that found significant gender differences in students' self-efficacy in engineering [14, 15]. Previous work has shown that women seem to report a lack of self-efficacy related to specific areas of skill, knowledge, or ability [16].

Due to the small number of senior students in the sample ($n = 6$), class-standing groups were collapsed into two categories: lowerclassmen (i.e., freshmen and sophomores) and upperclassmen (i.e., juniors and seniors). The independent-samples *t* test revealed a significant mean difference between upperclassmen and lowerclassmen. Upperclassmen reported higher general self-efficacy scores ($M = 5.07$, $SD = 0.69$) than lowerclassmen ($M = 4.80$, $SD = 0.64$), $t(95) = 2.08$, $p < .05$. This result echoes previous findings that lowerclassmen have significantly lower self-efficacy [17]. Students further along in their engineering programs might be expected to have higher engineering self-efficacy due to their successful completion of requirements in their engineering programs compared to those students who are just beginning to take courses in their major.

To understand the effect of student major on self-efficacy, an analysis of variance was performed. Results of the analysis of variance revealed a significant difference in engineering skills self-efficacy as a function of students' engineering major, $F(4, 92) = 2.69$, $p < .05$ (see Table 4 for mean values). Considering that each engineering sub-discipline requires the mastery of specialized skill sets, students may possess specific skills and beliefs about those skills depending on their major. Some engineering skills may be more relevant to one major, and therefore students in that major have more opportunities to demonstrate those skills. This possibility could explain differences in self-efficacy levels.

TABLE IV. ENGINEERING SKILLS SELF-EFFICACY MEAN SCORES BY ENGINEERING MAJOR

Engineering Major	N	Mean	Standard Deviation
Bioengineering	12	4.69	0.57
Industrial Engineering	27	4.78	0.78
Materials Science & Engineering	12	5.15	0.46
Mechanical Engineering	44	5.00	0.68

V. CONCLUSIONS AND FUTURE WORK

Through this initial and ongoing work, we have created an instrument to assess undergraduate students' engineering self-efficacy. Initial data suggest that there is a positive correlation between efficacy beliefs in general engineering and specific to MSE. Significant differences in the mean values reported as a function of gender, class-standing, and engineering sub-discipline were also found. Engineering self-efficacy was positively associated with achievement (term grades).

Our preliminary findings suggest a positive relationship between engineering self-efficacy and academic achievement. Further examination of motivation in relation to academic persistence is also necessary. Examining multiple motivation variables may be helpful for understanding the educational goals that engineering students pursue [18]. In addition to self-efficacy, we will examine the *value* students place on the tasks to be mastered and the achievement goals they have. Researchers have shown that task values are related to course plans and enrollment decisions [19] and that achievement goals are related to enrollment in major courses and to academic performance [18]. However, few have examined these constructs in the domain of engineering. Our hope is to include diverse motivation constructs to help us better understand engineering students' academic performance and intentions to persist in engineering.

ACKNOWLEDGMENT

The authors would like to thank Dr. J. Martin (Department of Engineering and Science Education, Clemson University) for helpful discussions.

Measuring Student Engagement in Thermodynamics Courses

Patrick A. Tebbe, Stewart Ross, Jeffrey R. Pribyl
Minnesota State University, Mankato, patrick.tebbe@mnsu.edu, stewart.ross@mnsu.edu, jeffrey.pribyl@mnsu.edu

***Abstract*— This paper will discuss an on-going NSF-CCLI grant that addresses improvements in student pedagogy and educational materials for the engineering thermodynamics curriculum by completing development of an online material titled "Engaged in Thermodynamics". The Engaged material is a textbook supplement based on actual engineering facilities and equipment. During Fall 2012 an engagement Opinionnaire was administered in two separate, and distinct, thermodynamics courses. Results indicate a student perception that preparing better for a course leads to improved performance in the course. However, there was no correlation between students' desire to learn and the amount of questions they ask in class. Regarding student interest, the results indicated it was higher for the course that used the Engaged material. Additional data collection and student focus groups will be ongoing.**

Keywords— active learning, pedagogies of engagement, problem based learning, thermodynamics.

I. Introduction

As the basis for this paper we will limit our dialogue to the thermo-fluid components of the engineering curriculum, specifically thermodynamics. Many of the thermo-fluids courses tend to be taught with lecture based teaching methods and textbooks. Thermodynamics, in particular, is prone to elicit a negative impression from students "who perceive the subject as dry and abstract [1]." To address this, a Course, Curriculum, and Laboratory Improvement (CCLI) Phase I grant was received from NSF to study the creation of course material for thermodynamics which would bring more real world content into the classroom. By basing a textbook supplement on actual engineering facilities it was hoped that there would be greater inquiry-based or student centered learning, student expectations of real world content would be better met, and an increase in overall engagement would result. Based on promising assessment and feedback from students a Phase II grant for full development was awarded.

The Engaged material is a textbook supplement based on actual engineering facilities and equipment. It expands on the case study concept by including skills-based problems (see Fig. 1) that can be used in place of traditional homework problems but written in the context of the real-world environment, as well as additional design problems based on design methods and actual solutions at real facilities. Accompanying supplementary and background information promotes increased inquiry-based or student-centered learning, better addresses student real world expectations, and leads to an increase in overall student engagement. The development of

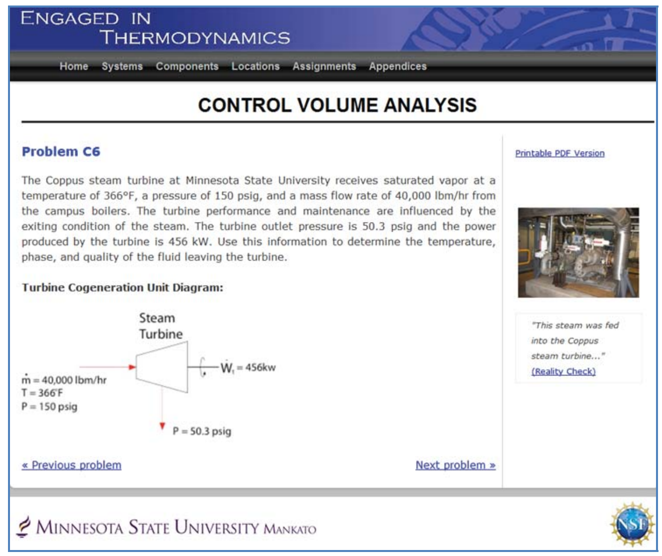

Fig. 1. Example of a skill based problem for an actual steam turbine.

the Engaged in Thermodynamics material has been detailed in a number of papers [2,3]. There is great pedagogical flexibility in allowing varying levels of use by the faculty member. The connection to reality is achieved by formulating the problems within the real world setting.

Results from Phase 1 of this project demonstrated that students who finish the semester with higher levels of engagement performed better. This portion of the research seeks to determine if students who use the expanded Engaged material are in fact more interested and engaged in the course.

II. Assessing Student Engagement

To assess the impact on student engagement a quick, yet simple, tool was required. One of the most popular methods of measuring student engagement is the National Survey of Student Engagement (NSSE). The NSSE survey focuses on aspects of student participation in activities as an indication of engagement and pedagogical quality [4]. While the NSSE survey is a well-documented instrument it was decided that it was too time intensive to provide the quick assessment snapshot this project was seeking. Using this, and other, surveys as a guide and with substantial feedback from undergraduate students a shortened survey was created. It consists of five questions measured on a 5-point Likert scale

TABLE I. QUESTIONS ON THE STUDENT OPINIONNAIRE.

1. Compared to other courses in engineering, do you find yourself wanting to learn more in this course?
2. Compared to other courses in engineering, are you asking more questions about the material? (in and outside of class)
3. Compared to other courses in engineering, do you talk/think more about the material in this course?
4. Compared to other courses in engineering, do you find you are preparing better for this class?
5. How well do you think you are doing in this course so far?

(Table I). In their current form these questions have been referred to as an "Opinionnaire".

During Fall 2012, the engagement Opinionnaire was administered in two separate, and distinct, thermodynamics courses (each at a different institution). The survey was given near the end of the semester. Basic statistics on the results are shown in Table II. A value of 5 indicates a positive response and a value of 1 indicates a negative response. The primary difference between the two courses was size (N = 51 versus N = 5). In addition, Course A made use of the Engaged in Thermodynamics material while Course B did not. The average response concerning students "wanting to learn more" (#1) was higher for Course A, which made use of the Engaged material, but Course B had higher performance expectations (#5). Average responses for questions #2-4 were essentially identical for the two courses.

Correlations between the five opinionnaire questions were conducted to help understand these results (Table II). For both courses, the correlation coefficient between question #1 and #2 was essentially zero. This would seem to indicate that there is no correlation between students' desire to learn and the amount of questions they ask in class. The correlations between question #3 and #4 for the two courses were 0.46 and 0.78, respectively. This indicates a moderate to high correlation between students talking about the material and preparing for class. Similarly the correlation between questions #4 and #5 indicated a moderate to high correlation, with values of 0.49 and 0.78 respectively. This indicates, at least a student perception, that preparing better for a course correlates to performance in the course. Taking these two correlations together one might conclude there would also be a positive correlation between questions #2 or #3 and #5. In other words, that an increase in asking more questions in class or thinking about the material more would result in an increase in performance. However, while positive correlations were found these were weaker and ranged from 0.19 to 0.36.

III. DISCUSSION

Based on these results, impromptu discussions were held with students at the authors' institution. A possible justification for having an interest in the material but a lack of activity in class was sought. The students did indicate that they are often very interested in a class and the material but they

TABLE II. RESPONSES FOR THE OPINIONNAIRE QUESTIONS.

Course A (N=51)	#1	#2	#3	#4	#5
Average	3.8	3.3	3.7	2.9	3.0
Std Dev	1.2	1.2	1.1	1.2	0.9
Correlation to #2	0.08		0.48	0.29	0.19
Correlation to #3	0.28	0.48		0.46	0.27
Correlation to #4	0.37	0.29	0.46		0.49
Correlation to #5	0.26	0.19	0.27	0.49	
Course B (N=5)	#1	#2	#3	#4	#5
Average	3.2	3.3	3.7	2.8	3.4
Std Dev	1.5	1.6	1.2	1.0	1.3
Correlation to #2	-0.03		0.37	0.54	0.3
Correlation to #3	0.04	0.37		0.78	0.37
Correlation to #4	0.44	0.54	0.78		0.78
Correlation to #5	0.54	0.3	0.37	0.78	

may not devote much activity to it for other reasons (e.g. time commitment for other courses).

Engagement has no universally accepted definition. The NSSE associated definition looks at "the frequency with which students participate in activities that represent educational practice" [5]. Other terms that have been used for engagement include "quality of effort", "involvement", and the related term "motivation". Motivation in turn has been defined as a relationship between interest, value, and autonomy [6]. It has also been pointed out that "most students will not struggle to achieve a deep understanding of material that they cannot readily connect to their interests and the problems they are likely to be called upon to solve as professionals' [7].

Engagement may be too complex an issue to be solved solely with the Engaged in Thermodynamics material. The material itself appears to currently serve as a motivator. The situational factors of a course and how the material is used will still be the determining engagement factors. However, when considering the combination of interest, value, and autonomy the material is very well positioned.

IV. FUTURE WORK

Currently the assessment data is limited. Additional data will be collected during Spring 2013 and the following academic year. As part of this process focus groups are planned with both instructors and students. The information gathered will help to identify links between classroom practices, methods of using the Engaged in Thermodynamics material, and the resulting impact on student motivation and engagement. Specific attention will be paid to feedback on the three aspects of interest, value, and autonomy. During the next year the material will continue to be developed. This will involve the addition of new real world scenarios and additional information on actual engineering installations.

ACKNOWLEDGMENT

The Effects of Extra Credit Opportunities on Student Procrastination

Anthony Allevato and Stephen H. Edwards
Department of Computer Science
Virginia Tech
Blacksburg, Virginia 24061, USA
Email: allevato@vt.edu, edwards@cs.vt.edu

***Abstract*—Many techniques have been attempted to encourage students to exercise better time management on class projects, such as staging an assignment into multiple deliverables, requiring students to keep records of the time they spend, and offering extra credit for early completion. This paper reports on a study of the effects of offering extra credit for early completion. Students in an introductory course completed four programming assignments throughout the term. For two assignments, no extra credit was offered. For the other two, students were offered a 10% bonus if they finished at least three days before the deadline. While one might expect this incentive to encourage students to shift their work habits, we found that there was no positive change in their time management. In fact, students started on the assignments where extra credit was offered *later* than on those where it was not offered. This leads us to believe that there were other pressures or concerns that outweigh the possibility of earning a bonus on an assignment, so that this kind of incentive only helps students who already manage their time well.**

Keywords—Procrastination, extra credit, study habits, programmer productivity, student performance, programming assignment.

I. Introduction

Everyone procrastinates. But a significant number of students procrastinate so much on assigned projects that it makes them more likely to turn in work late, receive lower scores, and even experience stress and illness. Some studies indicate that up to 95% of undergraduates procrastinate on coursework to some degree [1][2][3][4], while 20-30% exhibit chronic or severe procrastination [3]. Instructors know that procrastination can have adverse consequences, particularly on project-based assignments that take a significant amount of time outside of class to complete. As a result, many educators have tried a variety of strategies to combat poor time management choices. Some of the techniques that have been attempted to encourage or force students to exercise better time management habits include: staging an assignment into multiple deliverables with individual deadlines, requiring students track the time they spend on an assignment and plan out schedules for how they will allocate time to complete an assignment, and offering extra credit for early completion of an assignment. Yet, within engineering education, there has been relatively little experimental validation of the effects that such techniques have on student procrastination. While these techniques are often practiced in the classroom, there has been relatively little direct research on their effectiveness.

This research-in-practice paper reports on a study that analyzed the effects of one of the simplest techniques that educators employ in practice: offering extra credit for early completion. This experiment was carried out in an introductory computer science course where students completed four programming project assignments over the course of the semester. Half of the assignments were given normally, with no extra credit incentives for time management. The other half allowed students to earn a 10% extra credit bonus for completing their work early, offered as an incentive to encourage better time management. However, the results of this study indicated that the extra credit bonus had no significant effect on how early students began working on their assignments, or how early they completed them. This result suggests that there were other pressures or concerns that affected student choices, outweighing the possible extra credit bonus. Instead, this kind of extra credit incentive may not have the effect that instructors desire, and may only benefit the students who already manage their time well.

Section II summarizes previous work related to time management in computer science project assignments. Section III describes the study method employed, with results and discussion presented in Section IV. Section V summarizes the results, suggesting that instructors need to consider other factors before using extra credit as a time management incentive.

II. Related Work

A. Previous Work on Programming Habits

Edwards et al. [5] analyzed a five-year data set of student work on programming assignments—the largest dataset of its kind—in order to draw conclusions about effective and ineffective habits of novice programmers. This study provided valuable insight into the time management habits of students and how their performance on assignments was driven by those habits.

This study examined student submissions to programming assignments in the first three introductory CS courses at one university over a five-year period. Students who consistently performed well (over 80%) on all assignments for a particular course and students who consistently performed poorly (below 80%) on all assignments for a course were eliminated from the dataset, leaving only students who performed well on some assignments and poorly on others. The study then used a within-subjects comparison to determine whether changes in habits were associated with changes in performance. Because the within-subjects nature of the comparison controlled for differences in individual abilities, observed differences were

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

most likely due to other factors affecting how the students pursued their assignments. This reduced data set included 3,437 programs written by 623 students across 105 assignments.

As students worked on their assignments, they were allowed to self-check their work using an on-line assignment feedback system as many times as they wished, making corrections and refining their work before turning in their final submission. Students averaged 14 submissions on each program they completed, and timestamps from these efforts provided a window into how early students began working, how much time they spent refining their work, and when they completed their final program submission.

In summary, the study of Edwards et al. found a statistically significant difference ($N = 3437, F(1,1) = 227.2, p < 0.0001$) in the time of the student's first submission attempt when students scored above 80% (the A/B group) and when they scored below 80% (the C/D/F group). The A/B group started on average 64.9 hours before the assignment's deadline ($\sigma = 72.0$), while the C/D/F group started on average 29.6 hours before the deadline ($\sigma = 61.6$). Approximately two-thirds of the A/B scores were received when students made their first submission at least a day in advance of the deadline, while a similar proportion of the C/D/F scores were received when students did not make a submission until the day of the deadline or later. Since assignments in different courses were available to students for different lengths of time depending on their difficulty, this earlier study also normalized the starting times and finishing times of students by the length of time each assignment was available, producing similar results.

From this study, it seems clear that when students began working earlier on an assignment, they were more likely to score higher, while when the same students started later, they were more likely to score lower—a result that replicates general studies of procrastination [2].

B. Improving Bad Habits

These results suggest that the mere act of starting earlier on an assignment is associated with improved student performance. Since both groups spent roughly the same amount of time on the assignments, the difference in performance might then be attributable to increased stress as the deadline approaches or a student's inability to seek out sufficient help from instructors or TAs at the last minute. Given this evidence, how might an instructor seek to improve those behaviors for at-risk students? What incentives might be offered, or what policies can be enacted, in order to encourage students to start and finish their work earlier?

Several approaches to improving student time management have been explored by educators. Students can be directed to academic enrichment resources at their university; many schools provide short seminars or courses intended to help students learn to manage their time and workload in multiple classes [4]. Instructors can also present students with the results of studies, such as the one by Edwards et al., although the mere act of presenting statistics as proof to students may not motivate them. Dividing large projects into multiple staged deliverables [6] can be useful in preventing students from waiting until the last minute to start, as can requiring them to keep detailed records of the time that they spent working on the assignment [7].

While these approaches have met with varying degrees of success, they all tend to require an additional (and sometimes significant) investment of time an effort on the part of instructors or teaching staff. Instead, many instructors look for other interventions that do not require additional contact hours or course staffing. Extra credit incentives are often viewed as an easy, low-cost alternative, since they can be added to assignments with little effort, even if they are not as effective as more intensive strategies. Therefore, the study reported in this paper focuses on the extra credit approach to investigate its impact.

C. Extra Credit Incentives

Extra credit opportunities are commonly used to reward students who go above and beyond the requirements of an assignment [8], or to attempt to affect changes in student behaviors. In computer science courses at Virginia Tech for example, instructors have sometimes given additional points to students who finish their work ahead of the deadline. Through an automated assignment processing system such as Web-CAT [9], such a bonus can be automatically applied to each student's submission.

James Stodder raises some concerns about the ethics of such incentives, especially those that affect grades in the class [10]. Although his teaching and research is in the area of economics, his concerns about grading students on behavior that might be driven by luck are valid across many disciplines. We must also be careful when crafting extra credit opportunities to ensure that they can be—and have a good chance of being—attempted by students at all ability levels in the class, or if only the most advanced students will be able to earn it, further stretching the gap between them and the weaker students. Extra credit offered for work beyond what was required on the assignment might only be earned by students who were already advanced and/or creative. On the other hand, a bonus for completing the assignment sufficiently far in advance is something that students at all ability levels have a chance to earn—they need only imagine that the extra credit deadline is the true deadline and shift their work habits accordingly.

Intuitively, we might assume that offering students extra credit to finish earlier would result in a positive shift in the starting (and finishing) times of students on the assignments, as well as a positive shift in performance because the data above showed that students perform better when they start and finish earlier. In the following sections, we present our findings after carrying out an experiment to test this hypothesis.

III. Method

In Spring 2012, we collected data in CS 1044, a C++ programming course taken by a wide variety of engineering and business students at Virginia Tech. There were four programming projects assigned throughout the semester. The amount of time that students were able to work on the assignment, from its original posting to its deadline, was about two weeks on average—with the exception of the second project, which was available for approximately four weeks due to a spring break period.

The four projects in the course were, in order: writing a perpetual calendar (CALENDAR), performing basic image manipulation (IMAGES), computing the odds of a series of lottery games (LOTTERY1), and extending the lottery game to use more advanced data structures and algorithms (LOTTERY2).

The CALENDAR and IMAGES projects had no extra credit opportunities. After they were completed, all students received the following extra credit opportunity for the remaining two assignments, LOTTERY1 and LOTTERY2: Final submissions completed at least three days before the deadline were granted an extra 10 points (scores that would exceed 100% were not capped). All programming assignment due dates fell on Wednesdays, so the extra credit deadline would therefore be on a Sunday night, at the end of the weekend.

While it is common for projects to increase in difficulty as time progresses in the course, it is important to note that the two shortest assignments, in terms of the amount of program code written by students, were the first and third assignments (one in each group). Further, the assignment that required the longest solutions from students was the second assignment (in the non-incentive group). As a result, even though there might be effects due to the ordering of the assignments, the effort required to complete the assignments, as measured by the sizes of student programs, was comparable between the two treatment conditions.

Two decisions had to be made regarding the nature of this bonus. First, how far in advance of the deadline should the bonus be applied? The data above indicate that students perform better if they make their first submission even just one day in advance of the assignment's deadline. However, we did not simply want to reward behavior that fell right on the threshold of what the earlier study indicated, but instead aimed to affect a larger change in student work habits. For this reason, we chose **three days before the deadline** as the cutoff for the bonus.

Second, how big should the bonus be? A bonus that is too small might be ignored by students, whereas a bonus that is too large might have an undesirable effect on the grade distribution in the course. Programming projects in this course comprised 50% of the student's overall score. Earning the 10% bonus on both programming assignments where it was available thus corresponds to a 2.5% increase in a student's overall score—potentially, a large change. Students were not made explicitly aware of this fact, however; only those who made the effort to do the calculations themselves ahead of time would see this.

As in the earlier experiment reported in Section II-A, students submitted work electronically through an assignment processing system, and timestamps for all attempts at each program were recorded. The complete CS 1044 data set includes 1,083 programs authored by 285 students over the four assignments given in the course. Using the same 80% split point from [5], all program grades were partitioned into A/B and C/D/F groups. Students who consistently scored in either the A/B group or consistently scored in the C/D/F group were removed to allow a within-subjects comparison. After this pruning, 202 program grades from 55 students remained–a much smaller proportion than in the earlier study. This appears to be the result of some degree of "grade inflation" on the programming assignments in the course, so 80% might not be the ideal split point for this particular course. However, the notion of a student "doing well" is typically not relative to the other students in the course, but rather it depends only on that particular student's score, so the remainder of this study continues with the same 80% point used for partitioning in earlier work.

IV. RESULTS AND DISCUSSION

Before evaluating the extra credit opportunity, we wished to see if the trends in Section II-A also held for the students in this course. While students did start earlier when they scored better (mean = 91.7 hours for A/B grades, 57.6 hours for C/D/F grades), this difference was not statistically significant at the $\alpha = 0.05$ level ($N = 202$, $t = -1.76$, $p = 0.08$). This is likely due to the much smaller size of this data set compared to the one in Section II-A. However, there was a statisticaly significant difference in the times when assignments were completed, with students finishing 68.0 hours before the deadline on average when they achieved A/B scores, but only 25.2 hours before the deadline when achieving C/D/F scores ($N = 202$, $t = -2.81$, $p = 0.0054$). There was no significant difference in the overall time spent between the two groups, however.

Of the 285 students in the class, 56 (19.6%) started all four projects at least 3 days before the deadline, and 39 (13.7%) of them finished all four before that threshold. 122 students (42.8%) earned extra credit by finishing at least one of the final two assignments before the threshold. 107 of them, however, had also completed at least one of the first two assignments before the 3-day threshold as well. On the other end of the spectrum, there were 74 students (26.0%) who finished all four projects within 3 days of the deadline or after it had passed.

A. Behavior With and Without Extra Credit

We compared the effects that the extra credit opportunity had on students' starting and finishing times by looking for differences between the assignments that had extra credit and those that did not. There was a statistically significant difference ($N = 202$, $t = 3.71$, $p = 0.0003$) between the start times when students were working on programs where no incentive was offered (mean = 101.9 hours) compared to programs where extra credit was available for early completion (mean = 55.2 hours). Unfortunately, this difference is in the opposite direction than expected—students started *later* on the two assignments where extra credit was available.

These differences persisted, even among the larger population of 285 students in the course ($N = 1083$, $F(1,1) = 115.77$, $p < 0.0001$). The mean start time among all students for the assignments with no extra credit was 5.67 days ($\sigma = 5.80$); for the assignments with extra credit, the mean was 3.25 days ($\sigma = 3.85$). In other words, students started earlier on average on the assignments where extra credit was *not* offered.

Similarly, there was a statically significant difference in when students finished when extra credit was available ($N = 202$, $t = 3.75$, $p = 0.003$). In the smaller within-subjects comparison, students completed their work on programs where no incentive was offered an average of 76.8 hours ahead of the deadline, but the same students completed the assignments where extra credit was available an average of 26.4 hours ahead of the deadline. Again, this difference was in the opposite direction of the incentives offered.

Again, this same difference was present in the larger group of all students ($N = 1083$, $F(1, 1) = 104.83$, $p < 0.0001$). The mean finish time for all students on the assignments with no extra credit was 4.54 days ($\sigma = 5.30$); for the assignments with extra credit, the mean was 2.38 days ($\sigma = 3.39$). As before, students on average finished earlier on the assignments where extra credit was not offered.

Finally, in the within-subjects pool of 55 students, we examined how many of their assignments were completed more than three days ahead of the deadline. In the first two assignments where no incentives were offered, 66.3% of the assignments completed by these students were turned in at least three days ahead. For the second two assignments that included extra credit incentives, 80.6% of the assignments were completed at least three days ahead of the deadline. This difference was statistically significant ($N = 202$, $\chi^2 = 5.31$, $p = 0.0212$). Thus, at least some of the students—those who sometimes achieved higher scores and sometimes lower—may have been affected by the incentive. This trend was not present when considering the entire class of 285 students, however, where 48.4% of the assignments without incentives were completed at least three days early, while only 34.5% of the assignments where extra credit was offered were completed this early.

Seeing that there is a difference of roughly only a day between the mean start and finish times of assignments with and without incentives encouraged us to look into the time spent on the assignments as well. We found no significant difference in time spent between the two groups ($N = 1083$, $F(1, 1) = 3.029$, $p = 0.0821$). The mean time spent on the assignments without extra credit was 1.12 days ($\sigma = 2.85$); on assignments with extra credit, the mean time spent was 0.87 days ($\sigma = 1.97$). In fact, there were 348 scoring submissions to the extra credit assignments where the bonus was not earned because the student worked beyond that threshold. 75% of those submissions were by students who spent less than a day between their first submission and final submission to that assignment. Given the fact that the assignments were available for two weeks or more, many of these students probably could have shifted forward the time that they worked on the assignments and earned the bonus. This indicates that the extra credit did not provide as great a motivation as we had hoped it would.

B. Other Factors

Since the extra credit opportunity does not appear to be a significant motivating factor in the way students managed their time on these assignments, what other factors might have come into play? One possibility is that the difficulty of the assignments, or the amount of effort involved, outweighed any effects that the extra credit opportunity might have had.

In this course, the instructor's intuition is that the first assignment, CALENDAR, was the easiest, and that the second assignment, IMAGES, might have been a bit too ambitious, and

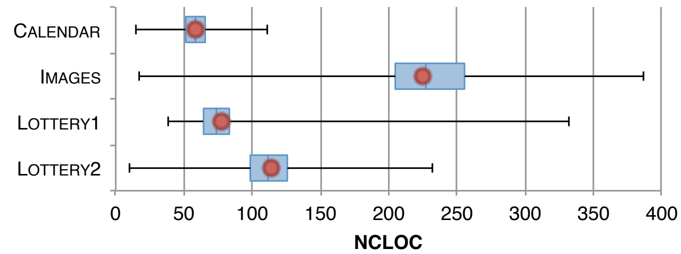

Fig. 1. Box-and-whisker plot showing NCLOC distributions for each of the four programming assignments.

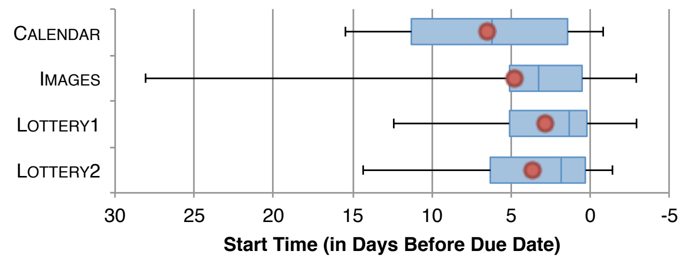

Fig. 2. Box-and-whisker plot showing distributions of start times (in days) for each of the four programming assignments.

in retrospect it was the most difficult in the course. LOTTERY1 and LOTTERY2 fell in the middle, as a way of pulling back slightly when students experienced significant difficulty with IMAGES.

To quantify this notion of difficulty, we can examine the number of non-commented lines of code (NCLOC) that students wrote for each assignment. Presumably, more difficult assignments require more effort to complete, and that effort is directly related to the number of lines of code that students were required to write.

We found that the four assignments did have significantly different NCLOC ($N = 1081$, $F(3, 3) = 1516.33$, $p < 0.0001$). Tukey's HSD test indicates that each of the four assignments is significantly different from the others. In increasing NCLOC order, CALENDAR had a mean NCLOC of 58.6 ($\sigma = 12.1$), LOTTERY1 had a mean NCLOC of 76.9 ($\sigma = 24.7$), LOTTERY2 had a mean NCLOC of 113.6 ($\sigma = 26.7$), and IMAGES had a mean NCLOC of 224.9 ($\sigma = 54.0$). These results are consistent with the instructor's impression of the relative difficulty of the assignments. Figure 1 shows the distribution for each assignment in more detail.

Figure 2 shows the start times across each of the four assignments, which are significantly different ($N = 1083$, $F(3, 3) = 55.00$, $p < 0.0001$). Tukey's HSD test indicates that CALENDAR and IMAGES differ significantly from everything else; LOTTERY1 and LOTTERY2 differ significantly from the former two but not from each other. The assignment with mean start time furthest ahead of the due date was the first one in the course, CALENDAR ($\mu = 6.54$ days, $\sigma = 5.29$). This is perhaps not a surprising result; students might have had more flexibility at the beginning of the semester to manage their time

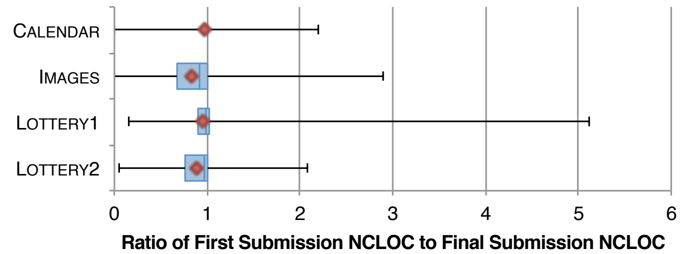

Fig. 3. Box-and-whisker plot showing distributions of the first/final NCLOC ratios for each of the four programming assignments.

between this and other classes they were taking. They may also have been less able to accurately estimate the amount of time that such an assignment would take and erred on the side of caution.

Recall that the time of the first submission does not represent the true time that the student started on the project. One way to estimate the amount of effort that a student has put into an assignment before their first submission is to compute the ratio of NCLOC in his or her first submission to NCLOC in his or her final submission.

In programming courses where students are expected to test their code using a prescribed methodology (such as writing JUnit test cases), they are able to get significant feedback during local development. Due to this, students in these courses typically have a considerable portion of their solution already written when they being submitting to Web-CAT and this first/final ratio is very close to 1. The remaining development time between first and final submissions is then devoted to debugging rather than writing large amounts of new code.

In the CS 1044 course, students were not required to follow any particular testing methodology; the only feedback they received outside of Web-CAT was from executing the program in its entirety with different inputs. However, the first/final NCLOC ratios for the assignments in this course do not appear to reflect a difference in that regard. Figure 3 shows the distribution of first/final NCLOC for students in the class, per assignment.

We found a significant difference between these ratios across the four assignments ($N = 1082$, $F(3, 3) = 14.465$, $p < 0.0001$). Tukey's HSD test indicated that Calendar and Lottery1 are significantly different from Images and Lottery2. More importantly, however, is the observation that the 25th percentile for any of the assignments is never less than 0.67. In other words, a vast majority of students in the class already had written at least two thirds of the code that makes up their final submission by the time they started submitting anything to Web-CAT. This indicates that students did spend an appreciable amount of time working on the assignments before the time of their first submission.

Despite these findings, we found no significant difference between first/final NCLOC when we compared the assignments with extra credit to those without ($N = 1082$, $F(1, 1) = 0.0668$, $p = 0.796$). The mean first/final NCLOC for submissions to assignments without extra credit was 0.907

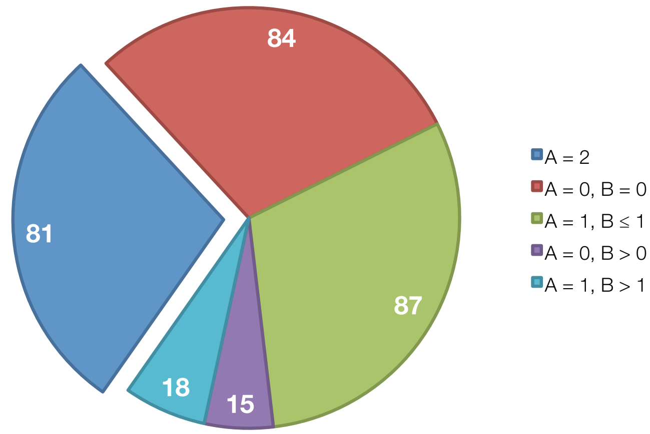

Fig. 4. Students grouped by time-based behavior on assignments. "A" represents the number of assignments where extra credit was not offered that a student finished at least three days early. "B" represents the number of assignments where extra credit was offered that a student finished at least three days early.

($\sigma = 0.291$); the mean for assignments with extra credit is almost identical, at 0.912 ($\sigma = 0.299$). Thus, it does not appear that students made a larger relative effort before their first submission on the extra credit assignments than they did on the ones without, so we have no evidence that they *started* significantly earlier.

V. Conclusions

Figure 4 breaks down the students in the class based on their time management habits on the assignments with and without extra credit. Out of the 285 students in the class where the extra credit was offered, 99 (34.7%) did not finish the first two assignments until within three days of the deadline (or after the deadline). Of those 99 students, only 11 finished one of the final two assignments before the extra credit deadline, and four finished both before the extra credit deadline. Likewise, 105 students (36.8%) finished one of the first two assignments at least three days before the deadline; 18 of them went on to finish both of the final two assignments before the extra credit deadline. In other words, there were 204 students (71.6%) in the class whose behavior could have strictly improved as a result of the incentive, but only 33 of them showed such an improvement. On the other end of the spectrum, there were 81 students (28.4%) who finished the first two assignments more than three days before the deadline, but 42 of them regressed on the final two assignments; 25 of them finished only one assignment before the extra credit deadline, and 17 of them did not finish either assignment before the extra credit deadline.

In other words, the offered bonus did not appear to have any positive effect on student behavior class-wide. It is true that of the 55 students who scored well on some assignments and poorly on others, there was a significant difference in their likelihood of turning in the assignments with incentives early. However, the number of students affected by this incentive was small compared to the class as a whole, and this trend is no longer visible when taking the entire population into consideration.

Students did not start significantly earlier on the assignments where extra credit was offered, even though those assignments required less effort to complete than one that came before them. Of the students in the class who earned extra credit on at least one of the two assignments where it was offered by finishing their work early, over 87% of those students had also completed one of the previous assignments just as early, when extra credit was not being offered. Therefore, we conclude that any potential incentive power of the extra credit opportunity was overshadowed by other factors that were not examined here. Given that students were not taking this course in isolation, we must consider the possibility that outside forces, such as deadline pressures in other courses, had a greater impact on their ability to manage their time in our course.

Further, for instructors considering how to address time management in their own courses, this study suggests that extra credit incentives may not be an effective choice. Some students may be affected by the incentive, but overall, extra credit did not produce a significant shift in student behavior. While extra credit is desirable because of the low effort and low cost of implementation, lack of demonstrable effectiveness overall suggests that instructors should also consider whether such incentives merely give a boost to students who already have good work habits, without providing much benefit to the students who procrastinate the most. As Stodder [10] warns, such incentives may be counterproductive, especially if they do not motivate many students to change behavior. Instead, further work is needed to evaluate competing alternatives to address procrastination on class projects, in order to find an intervention strategy that has the desired effect while also remaining within acceptable cost boundaries.

***Abstract*—Context: It is common practice in academia to have students work with "toy" projects in software engineering courses. One way to make such courses more realistic and reduce the gap between academic courses and industry needs is getting students involved in Open Source Projects with faculty supervision. Objective: This study aims to summarize existing information on how open source projects have been used to facilitate students' learning of software engineering. Method: A systematic mapping study was undertaken by identifying, filtering and classifying primary studies using a predefined strategy. Results: 53 papers were selected and classified. The main results were: a) most studies focus on comprehensive software engineering courses, although some papers deal with specific areas; b) the most prevalent approach was the traditional project method; c) surveys are the main learning assessment instrument, especially for student self-assessment; d) conferences are the typical publication venue; and e) more than half of the studies were published in the last five years. Conclusions: The resulting map gives an overview of the existing initiatives in this context and shows gaps where further research can be pursued.**

I. Introduction

Learning software engineering (SE) entails more than acquiring content knowledge. It usually implies learning a set of skills and attitudes towards software production that are hard for students to master inside academia. For instance, it involves taking part in a long-term effort of software production lasting more than the usual four-month academic term. It also requires authentic environments and situations, where novices learn from experts, teams are assembled for different activities, customers communicate with team members, and team members practice skills such as communication, leadership, negotiation, and decision making.

Although there are initiatives to strenghten the ties between undergraduate programs and industry (e.g., co-op programs [1]), they do not solve the need for practicing concepts and skills as they are acquired in regular courses. Software engineering faculty usually approach the subject with "toy problems" whose size and complexity are managed at the expense of authenticity.

One approach that is gaining momentum in SE courses is getting students involved in open source software projects (OSP) with faculty supervision. Student participation can account for the practical section of SE courses. Open source projects allow practicing skills and attitudes required in such courses. Various OSP provide an authentic environment where experts and novices interact, work structure is well-defined, and real products are under development. Furthermore, most SE knowledge areas can be covered with this approach.

However, regardless of the authentic environment provided by an open source software project, it is the activities that students perform that ultimately leads them to significant learning. Skills and attitudes are better acquired with learning challenges, provision of resources, adequate advising, and follow-up. The more actively students behave in a project, the more likely they will master the content knowledge in their courses. It seems, thus, that active learning practices are a good combination with taking part in OSP to learn SE.

In this context, this study aims to review the literature of software engineering education related to OSP, and to uncover the experiences where OSP were used to facilitate learning of SE concepts, especially with active learning approaches. In the literature, we usually find examples of open source software used in academia as a development tool or a computer lab environment. However, in this study, our intent is to uncover studies where students actively work with OSP, analyzing their source code, proposing and implementing changes, testing, and participating in their communities. To reach this goal, we performed a systematic mapping study [2].

Systematic mapping studies are secondary studies similar to systematic reviews. In both, primary studies are searched in indexed scientific databases, selected and classified according to objective criteria. The main difference is that while systematic reviews examine primary studies in-depth, aiming to generate conclusions about a particular research question, mapping studies mainly intend to categorize them, usually providing a visual summary of results [2]. Not only evidence clusters are identified, but also evidence gaps where additional research could be conducted are uncovered [3].

In this study, we identified primary studies by means of a pre-defined search strategy performed in digital libraries, followed by a multi-step selection process to exclude duplicate studies and retain papers relevant to the study goal, and a classification procedure based on dimensions of interest. As a result, 53 papers were selected and classified. The main findings were: a) most studies focus on comprehensive software engineering courses (38 articles), although there are some studies on specific areas, e.g., design/architecture, evolution, tests and software development; b) there is seldom explicit information about a pedagogical theory or framework used as a basis to the studies, and the most prevalent approach is the traditional project method; c) when learning is assessed,surveys

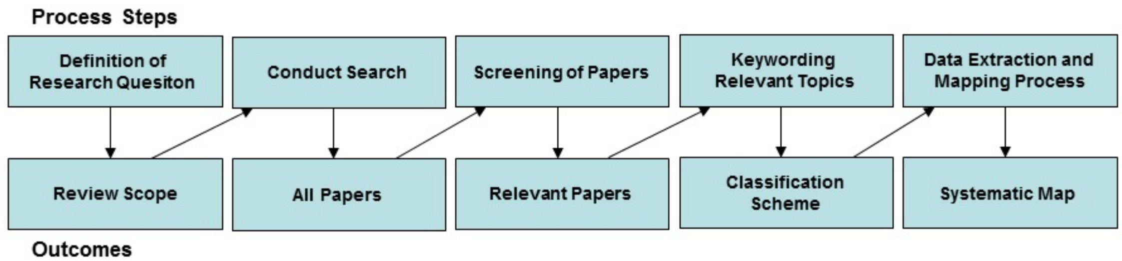

Fig. 1: The systematic mapping process, adapted from Petersen et al [2].

are widely used, mainly for student self-assessment, but other instruments are also applied; d) conferences are the typical venue where papers are published; and e) more than half of the selected studies has been published in the last five years (8 in 2008, 11 in 2009, 2 in 2010, 9 in 2011 and 5 in 2012), showing the community's recent interest in the topic.

This paper is organized as follows. Section II presents an overview of the mapping study process. Section III presents the main results and a discussion of the main findings and limitations. Finally, Section IV presents conclusions and areas for further research.

II. The Systematic Mapping Study Process

We performed a systematic mapping study [2] [4] to examine the extent and range of research activities related to the use of OSP in software engineering education. Figure 1, adapted from Petersen et al [2], describes the process used in our mapping study. The rest of this section describes how we performed each step of the process.

Definition of Research Questions. Several research questions were derived to allow for a broad view and cover the main topics of interest within this work. The main question to be answered was:

RQ1. How are Open Source Projects used in Software Engineering Education?

There is a bulk of literature on the use of open source software projects for pedagogical purposes and we aim to uncover the experiences where such projects were used to foster learning of software engineering. Since there are several knowledge areas in software engineering [5], we also would like to find out which topics are mostly covered or addressed by such initiatives (e.g., software engineering in general, requirements, modeling, design, quality, maintenance, among others).

The second and third questions focus on specific pedagogical aspects:

RQ2. Are there any initiatives that combine open source projects with active learning in software engineering courses?

RQ3. How is student learning assessed in such initiatives?

Conduct Search. The search string used in our mapping study was built using the following steps, defined by Kitchenham et al [6]: (a) derive major terms from the main question, by identifying the population and intervention; (b) identify alternative spellings and synonyms; (c) check keywords from known studies; (d) use the Boolean OR to incorporate alternative spellings and synonyms, finally (e) use the Boolean AND to link the major terms. To obtain a broad coverage, special attention was given to identify alternative spellings and synonyms. The resulting search string is presented in Table I.

TABLE I: Search String

The search strategy included the following scientific electronic databases: Compendex[1], IEEE Xplore[2], ACM[3], Scopus[4], Springer[5] and Elsevier[6]. These libraries are important sources for software engineering and computer science studies, indexing relevant conferences and journals. Furthermore, their search engines support automatic search based on different criteria and string formats – which may help to ensure adequate coverage.

With the search string, we applied automated searches against paper *title*, *abstract* and *keywords*. The standard search string had to be gauged for each database, to cope with different word stemming and syntax requirements.

The search was performed from 1st to 15th October, 2012. As a result, we identified 2204 papers, discarded 1099 duplicates (many studies were indexed by more than one digital library) and selected 1105 papers for screening.

Screening of papers. The main goal of the screening process is to select relevant studies that properly address the research

TABLE II: Research Types

Category	Description
Experience report	Paper describes the authors' personal experience using a particular approach, explaining what and how something has been done in practice. It usually includes lessons learned.
Case study	An empirical inquiry that investigates a phenomenon within its real-life context. Paper may deal with single or multiple cases, may include quantitative evidence, relies on multiple sources of evidence, and benefits from the prior development of theoretical propositions.
Action research	Interactive inquiry process that balances problem solving actions implemented in a collaborative context with data-driven collaborative analysis or research to understand underlying causes enabling future predictions about personal and organizational change.
Experiment/Quasi-experiment	A collection of research designs that use manipulation and controlled testing to understand causal processes. Generally, one or more variables are manipulated to determine their effect on a dependent variable.
Survey	Encompasses any measurement procedures that involve asking questions of respondents, generally by sampling them from a population. Most common types of surveys use questionnaires or interviews.
Opinion paper	These papers express the personal opinion of somebody whether a certain approach is good or bad, or how things should been done. They do not rely on related work and research methodologies.
Solution proposal	A solution for a problem is proposed, the solution can be either novel or a significant extension of an existing technique. The potential benefits and the applicability of the solution are shown by an example or a good line of argumentation.
Philosophical paper	These papers sketch a new way of looking at existing things by structuring the field in form of a taxonomy or conceptual framework.
Literature review	Critical and in-depth evaluation of previous research. It is a summary and synopsis of a particular area of research.

TABLE III: Learning Approaches

Category	Description
Does not apply	Paper is not related to an experience where a learning approach is needed.
Not specified	Authors do not state the learning approach used.
Active learning (general)	General term that refers to several models of education that focus the responsibility of learning on learners. Usually students engage in higher-order thinking tasks such as analysis, synthesis, and evaluation.
Case-based learning	Approach where students develop skills in analytical thinking and reflective judgment by reading and discussing complex, real-life scenarios. A case is already organized and synthesized for students.
Game-based learning	Learning that involves students in some sort of competition or achievement in relationship to an educational goal. Attempts to increase student motivation by providing a playful environment.
Peer/Group/Team learning	Educational practices in which students interact with other students to attain educational goals. Such approaches enhance the value of interaction and information sharing among peers.
Problem-/Project-/Inquiry-based learning	A collection of approaches that use projects or problems to drive the learning process. Students learn about a subject through the experience of problem solving, by working in groups with the help of facilitators. Assessment is performance-based and authentic.
Studio-based learning	Approach from professional education, where students undertake a project under the supervision of a master designer. It uses a learning cycle of construction, presentation, critique and response, that is repeated until project completion.
Other	Other approaches different from the previous categories.

questions. This means that inclusion and exclusion criteria must be carefully chosen and applied to the data retrieved. In our screening process, 4 inclusion criteria (IC) and 20 exclusion criteria (EC) were used, among them:

- IC 1. Studies that address the use of OSP to learn/teach Software Engineering should be included, regardless of their use being in SE programs or in other programs;
- EC 1. Documents not written in English should be excluded (the universality of this language supports reproducibility);
- EC 2. Documents whose full text is not available should be excluded;
- EC 3. Studies whose main content is not related to learning or teaching Software Engineering should be excluded.

The whole set of inclusion and exclusion criteria can be found in our mapping study website[7].

After we searched the papers and eliminated the duplicates, we applied two filters. In the first, two of the authors screened the remaining papers. Each reviewer examined title and abstract of each paper, and marked it as included or excluded, using the previous criteria. Subsequently the results were compared. A third reviewer analyzed conflicts and took the final decision. In this first step, 156 papers were included. In the second filter, two reviewers reexamined the remaining studies, skimming through introduction and conclusion. A third reviewer compared their results, and again, took the final decision. A total of 53 papers were selected as primary studies to be considered for answering the research questions.

TABLE IV: Assessment Perspective

Category	Description	#
Does not apply	Work is not related to an experience where assessment is necessary.	15
Not specified	No assessment is mentioned in the paper.	10
Student perspective	Students assess their learning by either self- or peer evaluation.	23
Faculty perspective	Students are assessed by faculty or teaching assistants.	14
Product perspective	Specific criteria are defined to assess students products.	2

Classification Scheme. Our classification scheme was developed by means of keywording relevant topics addressed by the research questions RQ1, RQ2 and RQ3, and refined during reading of the papers. As a result, the following facets were defined for classification purposes:

- *Software Engineering Area*, i.e., the SE topic(s) addressed in the study (software engineering in general, requirements, modeling and analysis, design and architecture, quality, testing, evolution and maintenance, development and construction, process, management

[7]http://sites.google.com/site/dmcnascimento/fie2013

TABLE V: Assessment Type

Category	Description	#
Does not apply	Work is not related to an experience where assessment is needed.	15
None	No assessment instrument is mentioned in the paper.	12
Exams	Students are assessed by means of written exams.	2
Reports	Students should write a report for assessment.	8
Software artifacts	Students are assessed through developed software artifacts.	12
Passing Tests	Automated tests such as unit tests are used to assess performed work.	1
Interviews	Interviews are conducted to assess learning.	5
Seminars	Students are assessed by their performance in seminars.	7
Portfolio	Students should produce a portfolio as result of their work.	0
Exercises	Students are assessed by means of exercises.	2
Surveys	A survey is conducted to assess learning.	18

and configuration management), based on the SWEBOK [5];

- *Research Type*, i.e., the research approach used in the papers. Table II provides a description of each category, adapted from Petersen et al [2];
- *Learning Approach*, i.e., which pedagogical approach was applied together with OSP in SE courses. Table III presents a description of each category;
- *Assessment Perspective*, i.e., the perspective from which student learning is evaluated – see Table IV;
- *Assessment Type*, i.e., the assessment instrument applied to verify student learning – see Table V;

The item "does not apply" was added to some facets to deal with situations in which no categorization could be applied.

Data Extraction. The data extraction strategy was designed to gather the information required to address the objectives of this study. Each paper accepted by the screening process was fully read to collect the required data. The extracted information was title, author(s), venue and year of publication for each selected paper, as well as the required information to classify it according to each defined facet. For some facets (e.g., software engineering area, assessment perspective and assessment type), studies were classified in more than one category.

III. Mapping

In this section, data extraction results are presented (Section III-A) and discussed (Section III-B) based on the previously defined facets and research questions. Some limitations of the mapping study are also discussed (Section III-C).

A. Outcomes

One of the main contributions of mapping studies is the *map*, usually a bubble plot representation of different facets or perspectives. Figure 2 presents the map for this study.

Since the main purpose of our mapping study was to find out how open source projects have been used in software engineering courses (RQ1) – and we were also interested in the learning approaches used (RQ2), we decided to arrange the map as a combination of the *Software Engineering Area* facet with the *Learning Approach* and *Research Type* facets (Figure 2). Other information can be found in our previously cited mapping study website.

Open Source Projects in Software Engineering Education. Concerning the *Research Type* facet, most papers fit into the *Solution Proposal* category, with 31 studies standing for 58.5% of the selected papers. Regarding the *Software Engineering Area* facet, 71.7% of the papers address *Software Engineering in general* (Figure 2).

Only 15 studies focus on specific software engineering areas such as design/architecture with 7 papers [7], [8], [9], [10], [11], [12], [13] and Evolution/Maintenance with 5 papers [14], [15], [16], [10], [17]. We did not find any paper relating open source software projects with specific knowledge areas such as requirements, process, project management or configuration management, which is the reason why they are not shown in the map. Conlon and Hulick [18] discussed the feasibility of building or buying software, contrasting it with the possibility of "downloading" software, encouraging students to analyze such questions.

Some studies were hard to classify within the Research Type facet, because their goals were not clear. For instance, Toth [19] presents a solution proposal but also discusses learned lessons. Likewise, Gehringer [20] states it presents the results of a *Survey*, but it is more likely to be categorized as an *Opinion Paper*.

Very few studies paid explicit attention to research methodology: Jaccheri and Osterlie [21] applied the action research method, while Krogstie [22] and McCartney [17] used the case study method.

We classified some studies in more than one category in the same facet, leading to different totals in the map. For instance, the studies [23], [8], [10] were categorized twice in the *Software Engineering Area* facet.

Learning Approaches in Software Engineering Education. Concerning the learning approach, Figure 2 shows that most selected studies – 22 studies (41.5%) – applied the traditional *Project Method*.

Two studies have explicitely mentioned the use of *Active Learning* [24], [12], while four studies mentioned *Project-Based Learning* [25], [26], [27], [28], but neither presented detailed explanations on how these approaches were applied. Papers [29] and [30] used *Service Learning* and *Collaborative Learning*, respectively, and were concerned with how these methods were applied.

Assessment of student learning. Tables IV and V help to answer the research question on the assessment of student learning (RQ3).

Table IV shows that 25 studies (47.2%) do not deal with the assessment of student learning; from these studies, only 15 describe an experience where assessment was not needed. The student perspective was more frequently used than the faculty perspective, and 17% of the studies applied both perspectives.

Table V presents results related to the instruments used for assessment. The most used instrument was the *Survey*, with 18 studies, followed by *Software Artifacts* with 12 studies, even though other instruments were used as well. *Surveys* and

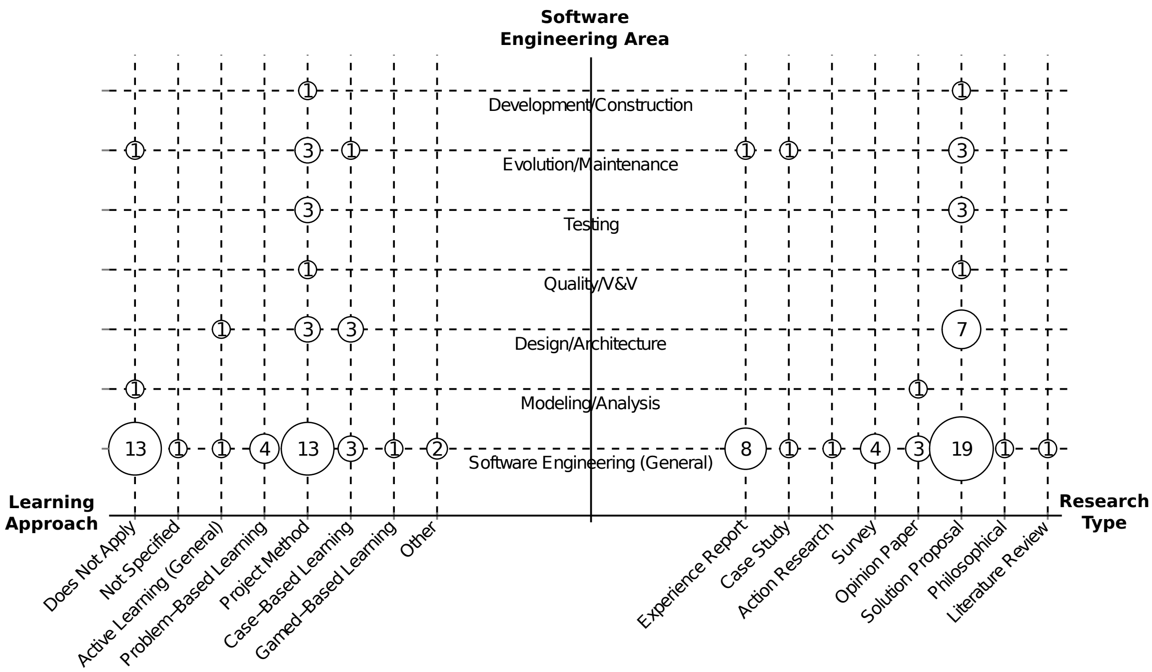

Fig. 2: Learning Approach *versus* Software Engineering Area *versus* Research Type

Interviews were the main instruments used to gather student feedback on their perception about their own learning.

Only Butcha and colleagues [14] presented detailed criteria related to the evaluation of students outcomes. Paper [31] was about software tests and the evaluation criterion was that the developed tests should find bugs. Paper [32] talks about the students' opinion about the course, and instructor's opinion about students' results, even though it did not mention the instruments used. Two studies addressed the *Peer Review* assessment type [33], [13].

Temporal View and Publication Sources. Figure 3 shows how this theme has been approached along the years. Conferences have been the typical venue for publishing results (42 studies). Discussions addressing open source software and software education begin to show up in 1998, although the term "public software" [34] was used instead of "open source". Nevertheless, more than half of the selected studies has been published in the last five years (8 in 2008, 11 in 2009, 2 in 2010, 9 in 2011 and 5 in 2012). Finally, the main forums on the theme that emerged from our mapping study were ITiCSE - Annual Conference on Innovation and Technology in Computer Science (8 studies), FIE - Frontiers in Education Conference (7 studies) and SIGCSE - ACM Technical Symposium on Computer Science Education (4 studies).

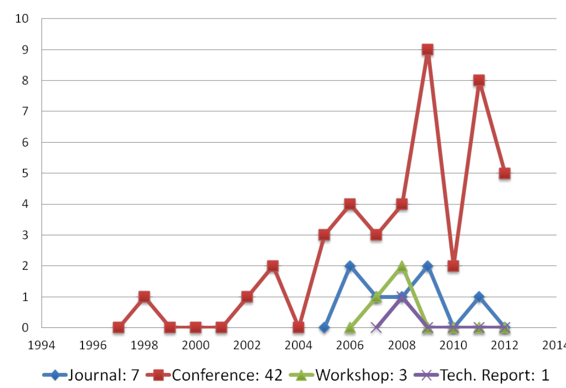

Fig. 3: Publications *versus* Venue *versus* Year

B. Discussion

Need for research methodology. One of our main findings is that most studies are not concerned with research methodology: among the relevant selected papers, two of them used case studies, only one used action research, and none of them considered the use of experiments. This happens in contrast with the recent growth of evidence-based software engineering. Software engineering research has been submitted to an increasing scientific rigor in the last few years. Furthermore, software engineering education is also an interdisciplinary area that can benefit not only from software engineering research methods, but also from research approaches of areas such as sociology, anthropology, pedagogy and communication. Therefore, it seems important to pursue interdisciplinary research, and to identify which research methods are more appropriate in this intersection.

Learning approaches for particular SE areas. Due to the number of available open source software systems, ranging in different sizes, domains and complexity, we believe they are an important source of examples to learn software design, architecture and quality [35]. However, we found very few studies using case-based learning, three of them related to design and architecture, one to evolution and three to software engineering in general.

No study focused on learning requirements, configuration management and project management areas. Nonetheless, if we recall that OSP also deal with management and requirements traceability, that developers in OSP largely use configuration management tools, and that they must deal with time and effort estimation, it seems that these specific areas would benefit from open source projects.

We also believe that additional work in other areas such as evolution, quality, design and testing is important, especially in proposals dealing with active learning approaches.

Assessment. It is important to state that student assessment deserves more thorough work, by establishing objective criteria to evaluate students' products, and defining learning objectives in terms of performed tasks, desired skills and attitudes. Finally, both student and faculty perspectives are needed to formative evaluation. Thus, they must be combined in the assessment repertoire of SE education.

C. Limitations

Results of this study must be interpreted within the following limitations: (a) publications that were available after October 2 and 15, 2012 were not accounted for; (b) results may be subject to the limitations of the automated search engines of each digital library used (IEEE, ACM, Scopus, Springer, Science Direct and Engineering Village); (c) only studies written in English were selected; (d) the classification of each paper with respect to the *Research Type* facet was not straightforward (e.g., many studies are related to experience report, opinion paper and proposal of solution); and (e) due the lack of time, the classification of each study was performed by only one reviewer.

IV. CONCLUSION

This work presents a mapping study that summarizes and categorizes information on how open source projects have been used in the context of software engineering education. The goal was not verify the use of open source software as a tool or computer environment, but to identify initiatives where students participate in the development effort of open source software, because this allows students to deal with real projects, often large and complex, such as the ones they will find when working in industry.

Results show some trends and issues in the research community: popularity of solution proposals as main research type; few papers focusing on specific software engineering areas; use of the traditional project method as the main learning approach, and lack of criteria to evaluate students' learning based on their outcomes or developed skills. These trends and issues provide future directions for research.

We plan to perform snow-balling to assure improved coverage of this mapping study, and, with improved results, to extract additional data and classify the studies according to other facets such as: level of control of the OSP, how the OSP is chosen, reasons to introduce OSP in the courses, and how the approach is included in the curriculum.

Abstract— **Preparing students for the communication realities of software development is as difficult as it is important. Training in specific genres of oral and written communication is vital, but successful software developers must also design their communication, choosing appropriate genres and styles to fit the audience and context. We introduce a pattern language for classifying and describing communication strategies. Communication Patterns serve both as an approach for rigorous qualitative analysis and as a library of established practices that students can draw from. The approach has clear links to software design patterns and highlights the fact that communication, like software, is a designed artifact. We focus on two software projects from our case study repository, using Communication Patterns. The two case studies have a great deal of overlap in objectives, stakeholders, responsibilities and timescales, but the outcomes are drastically different. Through patterns, we assess communication at strategic and tactical levels, and we find major differences in communication choices. We also discuss our attempts to expose students to Communication Patterns in the classroom. We conclude with a look at future efforts to deepen our pattern library and diversify our approaches to building and using them.**

Keywords—Software Engineering; Communication; Design Patterns; Case Studies

I. Introduction

As computer science and software engineering educators, we are charged with preparing students for the challenges of the software industry. There is a consensus among software professionals that some of the biggest challenges in this relatively new field lie in the decidedly old technology of communication - oral, written, and otherwise - between humans. The sheer invisibility of software and the constant change of the technology make it difficult to build a common vocabulary. Software development is complex, due not only to the functionality of the software itself, but also to the competing and often conflicting goals of different stakeholders. The wide range of application areas draws together stakeholders with different backgrounds. Moreover, software developers work in a world of incomplete, imperfect information, and they must be proactive in seeking input from other stakeholders [1].

Although many professional software engineers are effective communicators, they typically do not have practice in articulating what it is that makes communication effective (or ineffective). That is, their knowledge remains at a tacit level, from which it is difficult to impart to students. A major obstacle is the lack of a common language for discussing the specialized forms of communication that take place in software teams and between developers and other stakeholders. "Whereof one cannot speak, thereof one must be silent." [2]

The situation is improving. Agile development methods in particular stress the importance of flexible communication practices, deployed as the developers see fit (in contrast to the static organization and communication practices of waterfall development). Ward Cunningham's WikiWikiWeb, the "original wiki", contains a wealth of named patterns for agile practices, many of which fall into the domain of communication [3]. The Scrum framework is notable in this respect for the way in which it names - and therefore honors - particular communication practices (standup meetings, retrospectives) that would otherwise remain tacit and invisible to students [4].

Of course, instruction in communication has long been part of the computer science and software engineering curricula, but typically there has been a divide between the formal, highly technical documentation taught within the disciplines and the "softer" (but no less important) instruction that is typically provided through ancillary courses. A recent positive development is a project to bring the expertise of writing instructors into the computer science and software engineering curricula [5]. This project has produced a repository of assignments that engage students in authentic communication activities. Some initial effort has been made to categorize the genres of communication that arise in software development settings [6].

We enthusiastically endorse this focus on training students in relevant genres of communication, but our focus is slightly different. We are concerned with the senior student who - armed with an array of communication skills - engages in a team software project, with its intimidating mixture of freedom and responsibility. She must think both strategically and tactically about the current problem at hand and the form of

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

communication that will solve it most effectively. This is not a new concern: Aristotle alludes to it in his definition of rhetoric ("the faculty of observing in any given case the available means of persuasion"[7]) , and modern rhetoricians like Linda Flower conceive of communication as “strategies for problem solving” [8]. Students in computing disciplines enjoy problem solving and are well versed in principled approaches to solving technical problems. We want to give them similar tools for problem solving in the communication arena.

II. Communication Patterns

The architect and designer Christopher Alexander used the term “pattern language” for his process of identifying and using recurring structures and design [9], then famously introduced the possibility of patterns for software design. The most popular and familiar product of this crossover is the concept of Design Patterns [10] that are used in object-oriented design by using customizable classes at different levels of abstraction for problem solving. As Alexander describes it, “[e]ach pattern describes a problem that occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice.” Hence patterns denote the essence of solutions to problems without overspecifying them - a key advantage when dealing with the fluid nature of the “softer” aspects of software development. A pattern language approach was used to analyze the recurrences of configurations of roles in software organizations, “using patterns in a generative way” [11]. As with natural language, patterns from within an established pattern language can be combined or morphed into new patterns when new situations are encountered. This was applied to the concept of Organizational Patterns [12].

We introduce Communication Patterns as a tool for rigorous qualitative and quantitative analysis of software project communication [13], at varying levels of abstraction. In particular, we distinguish between *strategic* and *tactical* patterns.

Strategic patterns represent high-level communication choices that practitioners can make at a time and place outside of the communication act itself. For instance, Scrum instills certain communicative practices as required components of a sprint: an example would be the retrospective activity that follows the completion of a sprint, where team members each answer predefined questions: what went well, what could be improved, what should be changed in the process for next sprint. Another strategic choice is the style of daily meetings, requiring participants to stand and thereby keeping the length of meetings minimal.

Tactical patterns represent lower-level decisions taken while the communication is taking place: for instance, during a face-to-face meeting, or during the shared editing of a document. Again taking Scrum as an example, the structure of daily meetings is determined at a strategic level, but after the preliminary standup component, where each participant answers the “questions three”, there is a strategic choice to let participants choose the next activities to do. In action, this “free time” is an opportunity for participants to act tactically, choosing (for instance) to engage in pair programming, ad-hoc brainstorming, whiteboard sketching, and so on.

Each communication pattern describes a set of properties associated with a communicative act. Patterns may define particular genres of communication (for instance, client demo, requirements gathering session, burndown chart), but others describe properties that cut across genre (for instance, given “brainstorming session” as the genre, whether to perform the act synchronously with a facilitator, synchronously with all participants acting collectively, or asynchronously with participants providing input independently). In this way, patterns can be overlaid on one another, and a single communication act can be the combination of multiple patterns.

Each pattern captures particular aspects of the communication act, along various axes of interest. Table I describes the main attributes and the general structure of a communication pattern. We use the six basic journalist questions of *who, what, where, when, why and how* as a guide to determine what we capture about the communication. These aspects of communication vary from the objective (medium of communication – telephonic, video, face-to-face) to the subjective (style – informal, formal).

TABLE I. Communication Pattern Structure and Attributes

Attribute Category	Attribute of Communication Pattern
What	Established Scope (Input)
	Expected Result (Output)
Who	Type of participants
	Number of Participants
	Direction
	Role or Authority
	Shared knowledge or goals
How	Style
	Type of Artifact
Where	Medium
	Physical Location
When	Duration
	Synchrony
	Frequency
Why	Perceived Benefits
	Associated Risks

The expected scope of performing the communication act can be considered the input, like a meeting agenda or bug report, and the results produced can be considered the output, whether it is a written document or a change to one like a design change or code change, or an implicit decision or solution.

The duration of the communication act can vary from very short like a quick chat in the hallway or of a pre-defined length like a fixed time meeting. The frequency of occurrence of the communication act forms a part of the "when" attribute. Whether the nature of the communication act is synchronous like a face-to-face meeting or asynchronous like email may contribute to its urgency.

The attributes under the question of "who" describe whether the participants in the communication act are actively contributing, as in a directed presentation where the presenter is the main contributor and the attendees may be reactionary contributors, whether there is a hierarchy of authority and position among them or whether they are equal contributors like in a brainstorming session. The nature of the communication pattern is also determined by what the participants of the communication act have in common: whether they share the same goals but have different types of knowledge, like different teams collaborating on the overall system design, or if the participants share knowledge, like within a team working on a component, etc.

The nature of the communication is also determined by the presence of an *artifact*. An artifact can be any object affecting, assisting or documenting the communication. It can range from formal design documents, presentations to informal meeting notes or sketches on a whiteboard to explain ideas. Artifacts often become central to the communication act and even evolve as the communication does.

III. Communication Patterns in Case Studies

In earlier work, we developed detailed case studies in communication, based on real, "home grown" student capstone projects [1]. To illustrate the use of Communication Patterns, we use two connected case studies from our repository. The two case studies are referred to as *Seabase I* and *Seabase II*. As part of the Seabase project, teams from Computer Science and Mechanical Engineering worked with Mechanical Engineering professors to develop control software for a crane mounted on a ship for the US Navy. The data for the Seabase I project is primarily in the form of emails and detailed meeting minutes, whereas the bulk of the Seabase II project data is available as emails and recorded conversations.

Seabase I refers to the first three-person Computer Science team which participated in the project over the course of a semester. A second, similarly structured team which we call Seabase II took over where the Seabase I team left off and completed the project over the next semester. One student was a member of both the teams. Their immediate client was a professor in the Mechanical Engineering department Dr. Hank Taylor, who represented the interests of the US Navy, the sponsors. (All names in the case studies are pseudonymous.)

The Seabase I team consists of JoAnn, Bob and Ken and the Seabase II team consists of Bob (from Seabase I), Denise and Justin. From the overall impressions, it appears Seabase I did not succeed as a project, as the team did not produce the desired crane controller code and Seabase II appears to be a relative success as the team produces the code deliverables. It also appears that the Seabase I team spent a lot of time stuck in "requirements churn" while the Seabase II team spent significantly more time on the code.

The broad forms of communication in a student project are typically limited to face-to-face meetings with the client or internal to the team, email and occasionally phone conversations. The two projects were similar in terms of the forms of communication employed, time span of the project and the stakeholders involved. These similarities allow for fair comparison of communication patterns in the projects.

If we look at the difference in Communication Patterns across the two case studies, then more differences in behavior emerge. One major different between the two projects was in choice of focus. The Seabase I team's efforts were directed towards determining whether to pursue "the big picture" or "jump into coding" and dealt with many different types of stakeholders, and conflicting requirements. The Seabase II team started with established requirements and immediately wanted to "jump into code" and dealt primarily with one stakeholder.

At a finer granularity, the communication patterns allow us more insight into the communication choices that took place in the case studies. As the major types of strategic communication in the context of a student project tend to be limited to face-to-face meetings and emails, a lot of the attributes concerning the medium of communication, number of participants and role and authority hierarchy of participants are common across most of the patterns. However, differences in style, synchrony, scope, artifact, expectations and results emerge. Reading through the case studies, we encounter not only patterns but also *antipatterns* – commonly occurring but counterproductive communication choices. Some examples of patterns and antipatterns are discussed here.

Unheeded Request (antipattern): This antipattern occurs when requests are repeatedly acknowledged but not answered. It is associated with an asynchronous communication mode, where the requester cannot achieve an immediate confirmation or acknowledgement; in the time after a request is made, communication on other topics fills the void, and no response to the request emerges. In particular, the asynchronous *Remote checkin* pattern that Dr. Taylor and the team employed is susceptible to Unheeded Request.

Dr. Taylor, the client, repeatedly asked the Seabase I team to familiarize themselves with the programming environment MATLAB at several moments over the course of the project. Internally, the team acknowledged his request, but no team member followed up on it, and replies on the topic of MATLAB were left out in favor of discussion of other matters. By the end of the semester, the team members had still not learned MATLAB. Excerpts from the Seabase I case study are presented in Table II.

TABLE II. UNHEEDED REQUEST

Occurrence	Excerpts
Seabase I Week 3	(excerpt from Meeting Minutes) TO DO LIST -share the matlab app and check it out, check out simulink in helpdesk, try to get familiar with d-space -do flow plan/chart of functions that are needed
Seabase I Week 5	(excerpt from Meeting Minutes) TO DO LIST *4.* LEARN matlab (faculty are starting to ask about it) – (JoAnn) *5.* pass matlab cd around (Bob)
Seabase I Week 7	(excerpt from Meeting Minutes) TO DO LIST 1. learn Matlab/simulink - all
Seabase I Week 9	(excerpt from Meeting Minutes) SUMMARY -Really should run the simulation Hank sent early in the term, read the readme and it will tell how to run it exactly -Its CODE to set up the scheme in matlab, not click and drop GOALS for [next meeting] -have tried simulation (see above) -have spent at least four hours with matlab *DETAIL* -Later suggestions from Hank: when playing with demos in matlab, try adding an … Do an empty scheme in matlab that is similar to the crane … as our next goal or deliverable
Seabase I Week 10	(excerpt from Meeting Minutes) *SUMMARY* -Have one teammate become an expert in matlab s-functions *GOALS for this meeting:* -Get empty prototype in matlab going - all

Tutoring Session (pattern): This is the pattern of synchronous learning in the presence of a tutor. The Seabase II team, when tasked with learning MATLAB, spent some time trying to learn from Hank's directions and reference material, but solicited Hank's time to ask specific questions about the language and platform where Hank (in the role of the tutor) resolved their queries through demonstration. Ironically, the team realized that the MATLAB portion of the code only sets up the initial flow of control for the C code and did not require extensive MATLAB knowledge. They were then able to work on the controller code. The different participants were able to arrive at shared knowledge.

Artifact Facilitated Discussion: This pattern occurs when the presence of an artifact, like a diagram, or piece of code, or design document becomes the centre of discussion and facilitates and captures the understanding of the participants. It is associated with communication situations where participants have large gaps in their shared knowledge. It requires a synchronous communication setting, so participants can confirm understanding with each other through the "catalyst" of the artifact.

The Seabase II team made the "flowchart" of the existing sample code that client, Dr. Taylor, asked for. This served them in many ways. It demonstrated to Dr. Taylor that the team understands the code clearly and was serious about getting the project done – hence an instance of the *Show Your Work* pattern. It became the subject of discussion and most code related questions were referred back to the chart and helped ground what they knew and needed to know. All communication between the Seabase II team and Dr. Taylor after the creation of the "flowchart" diagram was primarily centered around the diagram of the code that the diagram refers to. The client and the CS team members would often point to different places in the chart to describe what they are talking about.

The Seabase I team had also been repeatedly asked by the client to produce a flowchart, but they did not produce anything that would impress the client (another instance of *Unheeded Request*). Excerpts from the Seabase II case study for artifact-facilitated discussion are presented in Table III.

TABLE III. ARTIFACT FACILITATED DISCUSSION

Occurrence	Excerpt
Seabase II Week 4	(excerpt from conversation) Dr. Taylor: Do you know from that [the chart] what values you will need? (They look at the diagram and discuss some input parameters like sway, swing angle, hoist, lock, etc.) Dr. Taylor: It might be a good idea to have this picture when you talk to them.
Seabase II Week 6	(excerpt from conversation) Denise: This is where we need some help. So this is what happens in the code [pointing at Denise's chart] [Denise explains on her chart that she has color coded based on which locks are her responsibility and how the chart describes the blocks.] Dr. Taylor: Can you show me some example within the code? This is great. Don't throw this out. Is this hand-drawn?
Seabase II Week 9	(excerpt from conversation) [They are looking at the diagram and Denise is explaining.] [Denise explains how init runs and affects other S-functions. Dr. Taylor asks what some of the functions do. Especially init.] Dr. Taylor: Oh that is sweet! That makes sense now. So when this one is high, that value becomes high and this one goes low, that value is low. I finally get it. Dr. Taylor: What is setup? [Denise explains what setup is.] Dr. Taylor: I love it. I love it! The beauty of something like this is that I can understand it. Someone with a high level of knowledge of how the code or the function works can look at it and completely understand it.

Translation to Familiar (antipattern): This antipattern occurs when participants translate a term to a familiar version, due to differences in perception of the term in their respective domains or because of desire to change to a more convenient form. It is associated with communication situations where there are gaps in shared knowledge.

TABLE IV. TRANSLATION TO FAMILIAR

Occurrence	Excerpt
Seabase I Week 4	(excerpt from Meeting Minutes) • good starting point might be to take the existing code, which has no flow chart, and flow chart it out so ME's have way to see what's happening with the control… • CS team come up with block diagram of how to chunk the functions into s-functions and write the s-functions and test.
Seabase I Week 6	(excerpt from Meeting Minutes) 1. Dave thinks old fashioned control flow graph is overwhelming and unreadable and could be some UML instead 2. use case diagram not helpful, feasibility study not helpful 3. could do UML activity diagram or state chart diagram, might be helpful 4. Bob thinks Dr. Taylor might want a block diagram, not exactly a flowchart

The Seabase I team discussed with Dr. Taylor, the client, about the need for a "flowchart" explaining what the current code does. As the Seabase II team eventually discovers, Dr. Taylor's intended meaning for this term is a high-level block diagram indicating input and output. The term "flowchart", however, gets translated to different terms like "control flow graph" or "activity diagram" – each of which have a specific meaning within the team's "comfort zone" of computer science, but which entail more detail and effort. Excerpts from the Seabase I case study illustrating the translation to familiar pattern are shared in Table IV.

TABLE V. DECIDING GRANULARITY OF FOCUS

Occurrence	Excerpt
Seabase I Week 3	(excerpt from Meeting Minutes) • general discussion of how quickly move into coding or working with matlab, thinking we should be doing more planning and big picture and maybe UML and such, rather then leaping into coding as sounds like Dr. Taylor thinks we should??
Seabase II Week 1	(excerpt from conversation) Dr. Taylor: …we could start talking about the big picture a little bit. Denise: Are we building a model like this or are we building one S function or do we have it plug into a larger system? Dr. Taylor: … And you would want to do both - learning Matlab and dissecting the code simultaneously… Learning the code will be kind of orthogonal and more challenging. Denise: We are programmers; we are just dying to rip into the code. Dr. Taylor: Is that so? That's good…

Deciding granularity of focus: The pattern of discussing and determining which granularity to focus on for the project is an interesting pattern. Participants can get caught in the repeating pattern of reviewing granularity of operation but spending more time reviewing than actually operating. Both projects discuss and decide whether they should be focusing on the "big picture" or they should be "jumping into code".

The Seabase I team discusses it repeatedly and decides to divide the team and focus at different granularities. The Seabase II team also decides about dividing up the team and operating at different foci and followed up with it both sets of operations for looking at the big picture and making the overall system diagram and jumping into code. Table V describes some excerpts from both case studies of the discussion about granularity of focus.

IV. THE CLASSROOM EXPERIENCE

In two pilot studies, we exposed computer science and software engineering students to the notion of communication patterns. In earlier work, we engaged senior-level software engineering students in open-ended investigation of communication using our case studies [1]. Here we were interested in seeing what happens if we bring instruction earlier in the curriculum and frame the investigation in the context of our pattern language.

Two separate instances and two different classes – a senior level course and a junior level course, were selected to allow students to be familiar with communication patterns. The junior level course is a team software project course, required for computer science and software engineering students, where teams of three students each work on a common project given by the instructor. The senior level course is a lecture-based course on software process and management, required only for software engineering students. In both the classes, we were given two sessions of seventy-five minutes each to present our material and engage students in activities.

A. Activities

The first session in both courses was introduced students to the communication pattern idea through the Seabase I case study and motivated them to identify communication patterns of their own from the material. A brief description of communication patterns was given, with examples taken from the Seabase I case study. Students in groups of 3-4 identified patterns in different sections of the story and presented the patterns they identified with the class.

For homework between the first and second sessions, they identified patterns from their personal experiences of working in teams for software development. In preparation for the second session, they were also asked to read part of the Seabase II case study and identify patterns. Many students shared their experiences from industry or working in teams for class projects, and they identified different types of communication patterns they employed.

In the second session, the students compared communication patterns in the Seabase I and II case studies. The emphasis in this session was moving from identification to assessment: what choices were effective, and which were less so? They were divided into groups of 3-5 and asked to find communication patterns that were different from the ones already identified and presented in the material. The groups that presented them discussed the merits of the identified communication patterns.

For the junior level course, a Seabase I *vs*. Seabase II timeline was constructed on the whiteboard and patterns were plotted on it using paper and tape. The occurrences of patterns, their order and relationship with each other were plotted, to get a visual overview of communication in the entire project. Then students voted for their favorite patterns and the selected patterns were discussed further for their merit. Students identified different attributes of the selected patterns and discussed what attributes they would change to improve it.

There was a consensus that in both projects, making requests to the client more "directly" would have clarified some uncertainties earlier. When we pressed them for a strategy to increase directness, there were no concrete ideas forthcoming, so we guided them toward a "structured questions" pattern. Some students suggested switching to a more "professional" tone. In one instance, a Seabase I team member chose to broach an uncomfortable question through a phone call to the client, rather than the usual medium of email. Some students questioned this decision, and the topic of appropriate situations for synchronous ad hoc communication like a phone call was discussed.

In both the classes, the discussion was quite lively, and the students were able to identify many different types of patterns with ease, specially strategic and tactical patterns. However, for the material that they were supposed to turn in as homework assignments, the answers were minimal for many students.

In both attempts, we were able to get students to identify communication patterns but not really use them in many different ways and their purpose as an analytical tool was not explored.

For the junior level class, we administered pre- and post-evaluation surveys to determine attitudes towards the importance of communication. 16 students in all responded: 4 with the pre-evaluation survey only, 1 with the post-evaluation survey only, and 11 with both surveys. Students were presented with statements about communication and were asked how much they agreed with the statement on a Likert scale of 7 points ranging from -3 to +3. The statements were designed to assess the student's attitudes towards the importance of communication in the software context, whether communication can be improved, whether the communication patterns idea was easy to understand, whether they thought the communication patterns were useful, whether the case studies were a good tool to illustrate the communication patterns and whether they were satisfied with the current level of communication instruction in the curriculum. We also asked the students open ended questions about their experiences of working in teams for software development and their perception of the different types of activities involved in the software context.

For the senior level class, the level of exposure to industry and software development in teams experience was captured in the first homework assignment.

B. Findings

The responses to the survey questions indicated that a large majority of students consider communication something that can be analyzed and improved, and something that they as future software developers must have responsibility for. There was movement in attitudes in the pre- and post-evaluation results, but the sample size was too small for it to be significant. In the survey after the two sessions, all students indicated that communication patterns are easy to identify, and a large but smaller majority stated that they are easy to understand and useful.

We share some excerpts from the attitude assessment surveys given to juniors. In the survey to assess attitudes towards communication, one student wrote "It is the nature of the major, those who are software developers or programmers in general lack basic communication skills / social skills." and went on to say "Communication is natural and you are either good at it or you are not. I feel that the assigned task to complete is, by far, more important than how we '*communicate'* about it". This statement raises an interesting speculation: do some students diminish the value of communication in their field because of an impression that it cannot be learned or improved? We can see that the importance of communication in the software process was not necessarily evident to all the students even after exposure to the communication patterns idea in the case study framework.

In the junior level course, among the 4 respondents with internship experience, we find a more amenable to considering communication in the software project context. One student who had two software internships shared their impressions and reflections on the software process in industry, "Two programmers discussing a fix for a bug often looks like a bullfight, I admit…", their impression of work in teams, "As I understand it, most teams spend far more time arguing, flailing wildly on their keyboards, etc." and the place for good communication "The better you know the *people* in your team, the better you communicate."

When asked to make a chart describing their impression of the time taken by major activities in a typical software project in the industry, the student with multiple internship experiences estimated ~20% time on "status updates for all members", ~15% of time on "current events chat", ~30% of time "discussing present issues, assigning work, etc." and ~35% "working on code and design, working together as needed, resolve bugs where possible, any code work". In contrast, a student without industry experience described the main kinds of activity in professional software teams as ~35% of time "programming", ~15% of time "refining code", ~20% of time "testing", ~12% "implementation details", ~18% "design details". We see that exposure to industry tends to make the students appreciate the place and importance of communication as opposed to students who have not had software project experience in the industry, where the belief is that programming, implementing, testing and design are the main function and communication is not a primary focus.

C. Conclusions

In both the classes, we feel that the time constraint of only two sessions was insufficient for explaining the importance of communication and of communication patterns. More time is needed to discuss why students would use communication patterns, how communication is important in the big picture, and how the communication patterns are meant to be a tool to analyze communication in software projects.

We conclude that with students earlier in their career we must make a better case for the importance of communication, and demonstrate that communicating effectively will be part of a software professional's job regardless of their role or position. It would help if students are given an opportunity to use communication patterns in their own team project contexts. This could be done relatively easily in the junior software project course, by including exercises that ask students to reflect on their own team communication.

We are pleased to see that communication patterns appear to be easy to use and understand. They allow the students to think about communication analytically through relatable student case studies. Many students still do not believe that communication as a whole in the software project context is important, but prolonged exposure to communication patterns in student case studies or in industry software project situations should help motivate a greater appreciation of the realities of the software development process.

V. FUTURE WORK

Our pattern concept is still in a proof of concept stage. To make it a truly useful tool, we must enrich our library of patterns with more real project examples. One source we intend to target is the vast array of open source software projects. Open source projects capture communication in different forms than traditional industry projects and their nature of organization and activities is also different.

As part of the classroom activities, the timeline of the communication patterns in the two projects was plotted. It helped serve as an artifact for discussion but also allowed us to observe the "pattern of communication patterns", displaying the times in the project characterized by bursts of communication acts and the type of communication in that occurred in different phases. The "shape" of a project indicated by patterns of patterns can help determine "hot spots" of communication activity, establish correlations between patterns, and define classes of software project along communication lines.

We feel that it is important for students to identify pattern instances, as well as new patterns, on their own, but we would like to build more structure into this discovery process. We intend to explore the POGIL technique [14] for inquiry driven learning. POGIL provides a framework for guided learning by inquiry, with an established team structure and process. In addition to keeping students on track, it provides a good model of team communication.

***Abstract*—The complexity and importance of learning programming fundamentals (*i.e.*, sequences of sentences that express actions, conditions, and repetitions in computing) for undergraduate students has motivated the development of an intense educational research area. One frequently studied problem is the difficulty in the learning of traditional context-free grammars which are present, for example, in programming languages such as Pascal and C. This study experimentally investigates the use of natural language in the learning of programming fundamentals by two groups of undergraduate students without prior knowledge of programming and compares its use with that of a traditional grammar language. Results suggest that the use of natural language is a good alternative, despite the small differences, to the use of traditional programming languages defined by context-free grammars. This alternative is attractive and promising because the student does not need to learn a formal grammar to learn the fundamentals of programming.**

Keywords—programming fundamentals learning; CS1; natural language programming; human factors.

I. Introduction

The learning of programming fundamentals (*i.e.*, sequences of sentences that express actions, conditions, and repetitions in computing) by undergraduate students is a notoriously difficult task. Programming languages such as C and Pascal are often used for this purpose. These languages are defined by grammatical constructions typical of the context-free class in the Chomsky hierarchy [1]. The main features of these languages are: (i) the generation of nested sentences that may be imperative, conditional (*e.g.*, "if"), or repetitive (*e.g.*, "while"); (ii) the existence of markers for the beginning (*e.g.*, "begin" or "{") and the ending (*e.g.*, "end" or "}") of blocks of sentences; (iii) the use of balanced parentheses to change the priority of operations within expressions; and (iv) the explicit declaration of the subject (the thing about which something is said) in all clauses by means of parameters and arguments of functions and procedures.

Natural language grammars, on the other hand, differ from context-free grammars in that they: (i) do not usually produce texts with nested sentences; (ii) use capital letters to mark the beginning of a sentence; (iii) use punctuation (*e.g.*, periods and question marks) to mark the end of a sentence, and use commas to separate clauses within a sentence; (iv) allow the generation of expressions composed of articles, prepositions, and adverbs; and (v) allow the writing of sentences in which the subject is not explicitly stated.

This study investigates the use of natural language in the learning of programming fundamentals and compares its use with that of a language with traditional grammar. A microworld composed of robots, walls, and disks was used as the source of problems, and two languages (and corresponding compilers) were developed: one following a classical context-free grammar notation (MRt), and the other with a grammar similar to that of the Portuguese language (MRp). The learning of programming fundamentals was experimentally investigated using two groups of undergraduate students with no previous experience in programming. Group I used the MRt language, and Group II used the MRp language.

One of the main contributions of this work is the way the study was planned. With the intent of studying only the effects of the type of grammar between groups, the experiment was carefully designed so that all other variables that might affect learning remained constant, with the type of grammar being the only variable to be measured.

The rest of this paper is organized as follows. Section II describes the two main streams of research in the field that motivated this study. The materials and methods used in the experiments are described in detail in Section III. In particular, the languages created are presented, along with the precautions taken to isolate the type of grammar from other variables. Finally, Sections IV and V present results, discussion, and conclusions.

II. Related Work

This study was motivated by the difficulties that novices face when learning the grammar of traditional programming languages. On this issue, there seems to be two main streams of research that are noteworthy. One of them is characterized by an attempt to facilitate the understanding of traditional programming language grammars, a line of research that has been extensively explored to date.

Contributions along this line range from the proposal of new pedagogical components [2] aimed at the development of programming skills in general and at the learning of specific language grammars, such as Interactive Learning Objects (ILOs) [3], for example, which draw on software visualization

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

work from the early 1980s, to visual programming platforms that show graphical representations of the program in a flow control diagram (flowchart) (*e.g.*, [4]). In the meantime, other alternatives have been proposed, such as new didactic methods and software tools which exemplify how the involvement of eyesight, hearing, and kinesthesia can help in the teaching and learning of a programming language grammar [5]; the use of 3D object animation, along with the development of an editor with a drag-and-drop tool to make it easier to write programs [6, 7, 8]; and the suggestion that writing the solution of a problem in English before coding reduces the cognitive load for novices, thus enabling them to better cope with the difficulties of learning of programming language grammars [9].

The second line of research investigates how languages for novices might be designed which are in line with their natural way of thinking about programming. The very idea of closing the gap between programming languages and natural language grammars has found support in some empirical studies [10, 11, 12], which show that novices writing in English exhibit fairly advanced problem-solving skills, but that programming languages pose barriers that create difficulties for them in expressing these same skills in programming. In addition, studies [13] have used knowledge from the field of human-computer interaction (HCI) to understand how people think about programming tasks when trying to create a new program or trying to find and fix bugs in existing programs. Finally, Metaphor [14] and Pegasus [15] are examples of efforts to develop natural language programming systems (for a brief overview of the contributions and challenges of redesigning programming languages to make them more accessible to beginners, see [16]).

III. MATERIALS AND METHODS

The World of the Robots (Fig. 1) was designed for the experiments we describe here. This source of problems is an adaptation of the Karel's World [17]. It is made up of a rectangular board representing the "world", robots that can move within this "world", walls, and disks. The World of the Robots creates a source of problems related to the movement and manipulation of objects (disks) on a board possibly including barriers formed by walls. A robot can perform the following elementary operations: move forward, rotate 90º degrees left, and collect or drop a disk (at the robot's position). It can also test whether the space in front of it is clear (*i.e.*, if there is no wall before it), if it is sitting above a disk, and if there are any disks in its bag (each robot has a bag where it keeps its collected disks). It can also check whether it is pointing north, south, east, or west.

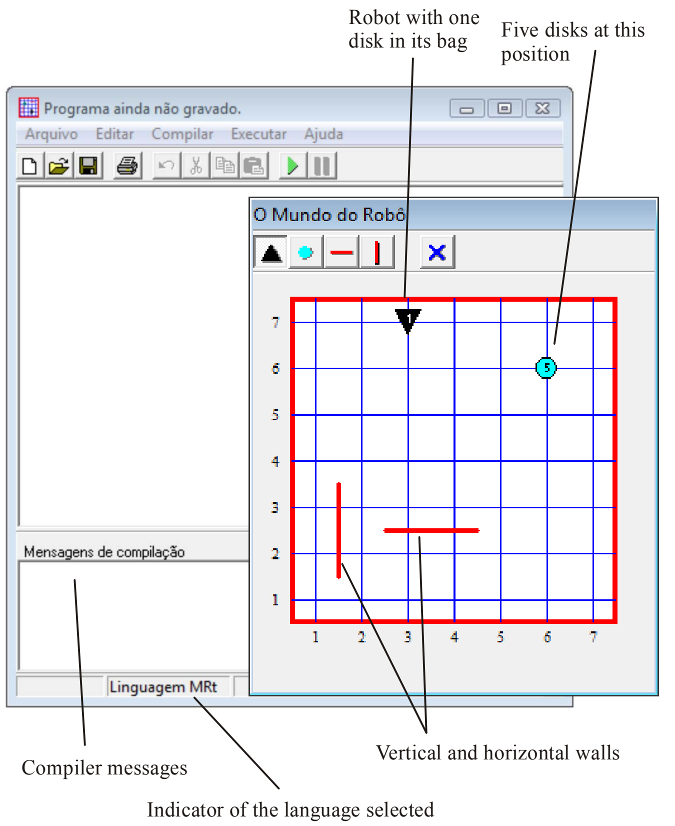

Fig. 1. The Integrated Programming Environment Developed.

The following components of the integrated programming environment were also developed: a graphical editor, used to design configurations for the World of the Robots; a text editor to edit programs; compilers for both languages used in the experiments (MRt and MRp); and a debugger (Fig. 1). By selecting buttons on the graphical editor toolbar, the user can create and delete robots, disks, and vertical and horizontal walls. In response to a request to execute a program, the programming environment shows an animation of the programmed movements. The program can also be run in debug mode to trace the execution of the source code, line by line, and to view the corresponding animation in the World of the Robots.

A. MRt Language

MRt was designed with the traditional flow-control structures of the imperative paradigm based on a context-free grammar, as found in programming languages like Pascal and C. Thus[1]:

- Sentences such as *MoveForward(r)*, *TurnLeft(r)*, *TakeDisk(r)*, and *DropDisk(r)* make a robot *r*, respectively, move one step forward, turn left 90º, and catch or drop a disk in its current position.
- Boolean expressions using the operators *and*, *or*, and *not* can be built up from Boolean functions such as

[1] The languages developed in this work use Portuguese terms. To facilitate the reading of this article, these terms have been translated into English sentences.

FrontClear(r), OnDisk(r), ThereAreDisksInBag(r), HeadsNorth(r), HeadsSouth(r), HeadsEast(r), and *HeadsWest(r)*, which evaluate to true or false, respectively, if before the robot *r* there is no wall; if *r* is on top of a disk; if there is at least one disk in the bag of the robot; and if *r* points north, south, east, or west.

- Conditional sentences, such as *if FrontClear(r) then MoveForward(r) else TurnLeft(r)*, test whether the space in front of robot *r* is clear and, if so, make the robot move forward, or else make it turn left.
- Repetitive sentences, like *while FrontClear(r) and OnDisk(r) do TakeDisk(r)*, repeat an instruction. In this case the robot named *r* should collect a disk if there is one at its position and the space before it is clear.
- Sets of sentences can be grouped by means of a sentence that begins with the word *begin* and ends with the word *end*.

An example of a complete program in MRt language is shown in Fig. 2. The program solves the problem of making a robot find a disk within a rectangular circuit. The initial orientation (north, south, east, or west) of the robot is unknown. A possible initial problem configuration is shown in Fig. 3.

```
while not HeadsWest (r) do
  TurnLeft (r);

while not OnDisk (r) do
begin
  if FrontClear (r) then
    MoveForward (r)
  else
    TurnLeft (r)
end
```

```
programa AcharDisco;
Usa r: Robô;
início
   enquanto não ApontaParaOeste (r) faça
      GirarEsquerda (r);

   enquanto não EstaSobreDisco (r) faça
      se FrenteEstáLivre (r) então
         AndarFrente (r)
      senão
         GirarEsquerda (r)
fim.
```

Fig. 2. A program written in the MRt language.

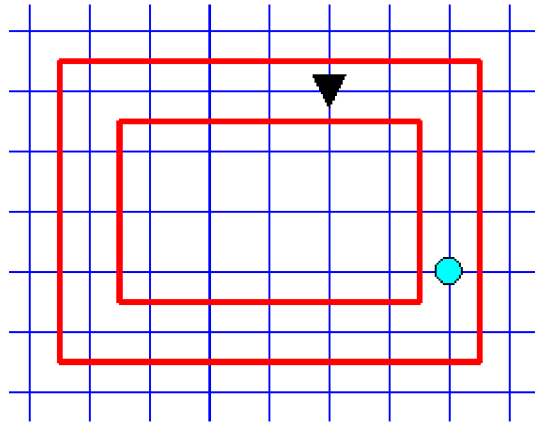

Fig. 3. An initial problem configuration.

B. MRp Language

The MRp language was designed to allow the generation of sentences similar to those of Portuguese. The body of a program written in MRp consists of a sequence of zero or more sentences, each ending with a dot. Every sentence consists of one or more clauses, separated by commas or by the conjunction *and*. For example, *Make the robot r turn left, move forward and drop a disk* is a sentence consisting of three clauses: (1) *make the robot r turn left*, (2) *move forward*, and (4) *drop a disk.*

A clause always has a subject, that is, the thing to which it refers. The subject may be explicitly declared as *r*, as in the clause *make the robot r turn left*, or it may be implicit, as in the clauses *move forward* and *drop a disk*. In the MRp language, implicit subjects always refer to the subject of the preceding clause. In the example, the subject of clauses *move forward* and *drop a disk* is therefore *r*, the subject of *make the robot r turn left.*

Here are some examples of sentences and clauses in the MRp language and their meanings:

- *If there is no disk in the bag of the robot r and the robot is on top of a disk, then collect the disk, or else turn left.* This sentence determines that the robot named *r* should collect a disk if it is currently above one and its bag is empty. Otherwise, it should turn left.
- *While there are disks in the bag of the robot r, drop a disk*. The meaning of this sentence is to have the robot named *r* empty its bag, putting all the disks in its current position.
- *While the space in front of the robot r is clear, make it move forward and if it's on a disk, collect the disk*. This sentence makes robot *r* keep on collecting disks that are in front of it until it hits a wall.

An example of a complete program in the MRp language, to solve the problem of making a robot find a disk within a rectangular circuit, is given in Fig. 4. A possible initial configuration of the problem is shown in Fig. 3.

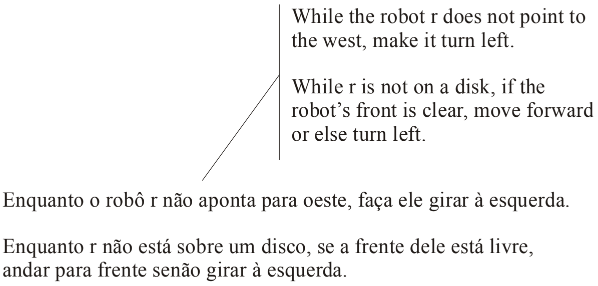

Fig. 4. A program written in the MRp language.

C. *Subjects*

Twenty-two volunteers participated in the study. All subjects were first-year students in undergraduate courses in a Brazilian university. Among these, 13 (59%) were male and 9 (41%) female, of whom 11 (50%) were studying exact or applied sciences and 11 (50%) were from the social sciences, with ages ranging from 17 to 28 (average 20 and median 18). Moreover, none of the participants had prior knowledge of programming, as determined by a questionnaire.

D. *Hypothesis*

The hypothesis tested was:

> The use of MRp language (with grammar similar to a natural language) is as favorable as the use of MRt language (with a traditional context-free grammar) to the learning of programming fundamentals.

E. *Experimental Setup*

Initially, participants were randomly divided into two groups:

- Group I: Participants studying programming fundamentals using the MRp language; and
- Group II: Participants studying programming fundamentals using the MRt language.

The experiment was conducted in two phases, occurring in the morning (phase 1) and afternoon (phase 2) periods of the same day, with a lunch break of 1.5 hour between phases.

In phase 1, each group participated in a 3.5 hour lesson, with a 15 minute break halfway through. The lessons discussed details of the World of the Robots and the concepts of sequence of sentences, and sentences that express actions, conditions and repetitions present in the programming language to be used by each group. Before the 15 minute break, participants performed an exercise in which they had to deal with these concepts. The experimenter interacted with the participants individually during the time that each tried to solve the exercise and subsequently developed and explained a possible solution. Students were given a text describing all the issues covered in the classroom, and thus, during the lesson, their only concern was taking additional notes on the subject matter.

In Phase 2, students took part in a test. The test took up to two hours, and consisted of four questions that described problems. They were then asked to write programs to solve these problems. Both groups received the same test, consisting of four questions:

- Question 1 evaluated the use of a sequence of sentences and could be answered with a sequence of sentences expressing elementary actions.
- Question 2 evaluated the use of conditional sentences and could be answered with one or more sentences expressing conditions.
- Question 3 evaluated the use of sentences denoting repetitions and could be answered with sentences describing a repetition of elementary actions.
- Question 4 evaluated the combined use of sentences expressing actions, conditions, and repetitions and could be answered with sentences expressing the repetition of clauses describing conditions and actions.

The test is fully presented in Appendix A. The questions answered by the participants were independently reviewed by two of the researchers and were assigned a score from 0 to 5. Inconsistencies were settled by the researchers in a meeting.

F. *Constant Factors and Other Precautions*

Because only the grammar of the programming language for the two groups was planned to vary, the following factors were held constant:

- The "World of the Robots" domain as the source of problems.
- The semantics of the MRp and MRt programming languages.
- The programming environment.
- The dynamics of the experiment (see section E).
- The experimenter administering the experiments.
- The problems addressed in phase 1 (lesson) and phase 2 (test) of the experiments (Appendix A).

As a way to avoid bias in the resulting data set, additional measures were also taken, such as:

- Restricting the experiment to the time interval comprising morning and afternoon, thereby reducing the interference of external sources, to the extent that the entire experiment took place in a single day.
- Splitting up subjects into two groups of 11 students, to facilitate the interaction between them and the experimenter, thus reducing the natural difficulty in communicating with large numbers of students.
- Designing the programming languages used in the experiments so that their statements could be written in Portuguese, the subjects' native tongue.

- Choosing the World of the Robots as the source of problems, because of the small number of involved concepts and also because these concepts are fairly intuitive.

IV. Results and Discussion

Table I shows the mean and standard deviation scores for both groups on a scale from 0 (insufficient) to 5 (excellent). Means and standard deviations were almost identical: 3.91 ± 0.79 for Group I and 3.98 ± 0.82 for Group II. The results showed no statistically significant differences between these averages (Student's $t = 0.20$ with significance level $p = 0.85$). This means that the proposed hypothesis could not be rejected.

TABLE I. Results (mean and standard deviation) of the test

Group	*n*	Mean (0 – 5) ± SD
I	11	3.91 ± 0.79
II	11	3.98 ± 0.82

Separating the syntactic and semantic aspects of the solutions, *i.e.*, isolating analyzing syntax and semantic mistakes, resulted in the mean and standard deviations shown in Table II. Still, the data show no statistically significant difference with regards to aspects of syntactic correctness ($t = 0.64$ with significance level $p = 0.53$) or semantic accuracy ($t = 0.22$ with significance level $p = 0.83$). In other words, the hypothesis is also confirmed with respect to a comparison between the syntactic aspects of the languages or between their semantic aspects.

TABLE II. Mean and standard deviation of test scores relative to syntactic and semantic aspects

Group	Syntax mean (0-5) ± SD	Semantic mean (0-5) ± SD
I	4.02 ± 0.93	3.80 ± 0.84
II	4.25 ± 0.72	3.70 ± 1.05

Appendices B and C present in detail the scores obtained by each student in Groups I and II.

V. Conclusions

These results show that, for the population studied, the use of natural languages is an alternative, not better or worse, to the use of traditional programming languages defined by context-free grammars. This alternative is attractive and promising because the student does not need to learn a formal grammar to learn the fundamentals of programming. Using a natural language as the first programming language enables the student to focus on the logic of the solution, thus decreasing his level of effort in writing a program.

Natural language programming is also an alternative for end-user programming environments, *i.e.*, environments that include programming and are targeted at users whose main interest may not be intrinsically computational. For example, Scratch [18] has been used for educational and entertainment purposes for children to create interactive stories, music, works of art, and games. Scratch tries to alleviate the difficulties in syntactic development of programs by dragging-and-dropping blocks of sentences. The use of natural language makes solutions like these unnecessary.

Signs to mark the beginning and end of blocks of sentences are used to organize the structure of a program written in a traditional context-free language, allowing also the nesting of sentences and the resolution of ambiguity. The absence of these context-free language elements in natural language forces the writing of texts which are often less structured. For example, consider the text in natural language *Make the robot r move forward until it finds a wall. While it is walking forward, make it pick up a disk at each position where it passes*. The two actions (*move forward* and *pick up a disk*) were structured in two sentences. Typically, in a context-free language, these actions are structured in a single block within a single repetitive sentence. Future research by the authors will investigate the relationship between the structure of programs written in natural language and in traditional context-free languages. A better understanding of this phenomenon may help in the development of better compilers for natural language and also improve programming courses based on context-free languages.

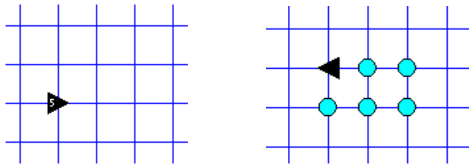
Finally, educators can use in courses and researchers can use in other studies the programming languages, compilers, and integrated programming environments that have been developed for these experiments. These will be made available to the community under a General Public License.

Acknowledgment

We would like to thank all subjects that volunteered to the experiment for their invaluable contribution to this work.

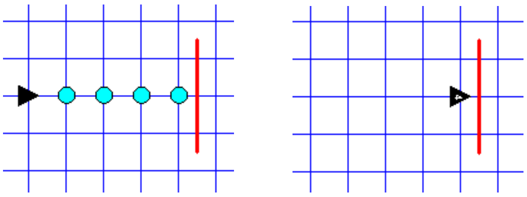
Appendix A. The Test Questions

Question 1: Write a program to signal a path with disks. The left figure presents an initial configuration in the World of the Robots and the right figure the final configuration that must be reached after executing the program.

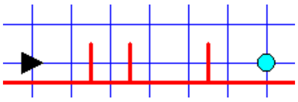


Question 2: Write a program that makes the robot *r* point north. You do not know the initial configuration of the robot in the World, in other words, you do not know whether the robot is currently pointing north, south, east or west.

Question 3: Write a program to make the robot *r* take all disks in a line situated before it until it reaches a wall. The figures show a possible starting (left) and final (right) condition. These figures are only an example. Your program must work with lines with an undetermined number of disks.



Question 4: Write a program to make the robot *r* jump over barriers such as those in the figure until it finds a disk. Again, this figure is merely illustrative. Your program must address an undetermined number of barriers at unknown positions. The barriers are always equal in size to those indicated in the figure.



APPENDIX B. SCORES OBTAINED BY STUDENTS IN GROUP I

Student	Syntax score (0 - 5)	Semantic score (0 - 5)	Global score (0 - 5)
A1	4.25	4.50	4.38

***Abstract*—In this paper we describe action research on our third year Algorithms, Data structures and Complexity course, in which students have considered dynamic programming hard in comparison to the other topics. Attempting to amend this, we wanted to know which difficulties the students encountered, where they gained their knowledge, and which tasks they were most certain that they could perform after the course. Such work resides in the didactics of the subject taught, but the general methods of attacking perceived difficulties in a course can be tried on any course.**

We identified subtasks that could be taught separately, and adapted the lectures to Pattern Oriented Instruction in order to help students cope with the cognitive complexity of solving problems using dynamic programming. For this, we prepared new clicker questions, visualisations and a lab assignment. We also constructed self-efficacy items on the course goals for dynamic programming, and administered them before and after the teaching and learning activities.

Among the self-efficacy items, determining the evaluation order and solving a problem with dynamic programming with no hints had the lowest score after the course. As for the activities, arguing correctness of a solution was something many students claimed that they did not learn anywhere. Students considered the lab exercise most useful, but they also learned a lot from the other activities.

I. Introduction

The course in which the experiments of this paper took place is a third year course in the 5-year Master of Computer Science and Engineering program at KTH in Stockholm, dealing with algorithms, data structures and complexity: ADC. Previous experience indicates that dynamic programming (below abbreviated dynprog) is considered difficult among the students. This work uses an action research approach.

A. Research questions

The questions that are addressed in this work are:

- Q1 What is perceived as difficult with dynprog?
- Q2 Which abilities do students judge they have after the course?
- Q3 Which of our activities do they believe to have helped them achieve those abilities?

We will not make an exhaustive examination of these questions, and the students are not interviewed on these topics. Rather, we ask them how well they believe they can perform tasks which we have defined, and where they have learned that. If they do not know things listed in the course goals after the course ends, we consider these subparts difficult. Items that students are less confident they can manage are also counted as difficult compared to the rest of the course contents.

B. Contribution

The contribution of this work is split into several areas. The answer to *What is difficult?* is in itself interesting to teachers, and our means of finding answers to this exemplifies teaching improvement attempts. We also compare our guesses and assumptions with students' answers. The self-efficacy instrument that we have used is not final, nor tested for internal reliability and validity, but it is still a partial result. The experience was also a small scale experiment with Pattern Oriented Instruction.

II. Background

A. The course

The part of ADC that is relevant to this paper is the first 18 lectures, 7 tutorials and 3 computer lab sessions on algorithm construction methods, and especially lectures 9 and 10 and tutorials 3 and 4 plus one computer lab exercise, all of which deal with dynprog. Each lecture is 45 minutes, and each lab or tutorial session is 2 x 45 min. The computer lab exercise is compulsory, performed in pairs, automatically checked for correctness and verbally presented to a teaching assistant (TA) in lab. ADC uses continuous assessment. The lab exercise, together with an individual, written home assignment which the students afterwards present personally to one teacher or TA, constitute the major part of the assessed student work on the topic. There are also supplementary tasks for those who are unhappy with their grades. The course is graded on a scale from A to E, or F for fail, and there are course goals and criteria connected with each grade. These are presented in a matrix and a flow chart on the course home page, and addressed on lectures and during peer review. Towards the end of the course, there is a written exam for lower grade content and an oral exam for those who aspire to higher grades. In the end, how well your work meets the criteria decides your grade, so *what* work you have fulfilled, and how well you performed, matters – not just the percentage of total work. The author has been one of the TAs on this course.

B. Our guesses on what was difficult, or why

Recursion, a well known "difficult task", is part of the problem solving strategy of dynprog. Previous years' experiences suggest that the difficult parts of dynprog are finding a recurrence relation based on some structure of the desired solution, and tackling the complexity of solving a problem completely from scratch, without hints. Many students also struggle with, or avoid, any tasks involving "argue correctness" or "prove". Being able to cope with many dimensions – problems where a simple two-dimensional matrix is not sufficient to hold every subproblem that matters to the solution, is necessary for some problems.

C. Recursion and dynamic programming

The subject of recursion has attracted educational researchers' interest for a long time. In the 1980s Kahney and Eisenstadt [1] contributed by studying students' and other programmers' answers to problems involving recursion. Their results are further described by Kahney in [2], and describe a set of "mental models" of recursion that students had, out of which one was capable of capturing the things instructors want students to know about recursion, and some were not only incomplete, but misleading. Around the same time, Ford [3] concludes that iteration is really a special case of recursion, and that recursion is a generalised control structure in programs. Similar arguments are also used by others: recursion is an example of the paradigm "Divide, Conquer and Glue", and when using iteration, the glue step is missing and students get erroneous pre-images of the paradigm [4]. Scholtz et al. [5] claim that the difficulties with recursion are connected to understanding the passive flow, whereas other authors are investigating misunderstandings that can occur around base cases [6]. They also note that recursion *is* a difficult topic for students. Many authors dwell on the topic of where in the first course recursion should appear, or how recursion is related to iteration, the computational model, or similar issues.

Ginat et al [7] suggest that less focus on the computational model, and more focus on the abstract level and the algorithm in theory can help students not to mistrust recursion as a method or their own abilities on recursion. As an algorithm construction method, dynprog follows that recommendation. It does not deal with passive flow, and the algorithm construction task indeed treats recursion as an abstract phenomenon.

Dynprog can be seen as an alternative method for constructing algorithms where recursion can be used. Sometimes, keeping a table of all hitherto calculated values in a recursive algorithm speeds up calculations significantly, for instance with simple sequences like the Fibonacci numbers. This technique is called *memoisation*. Instead of doing memoisation, there is also the option of changing the algorithm so that calculations are made in "reversed" order - starting with the base cases and building increasingly complex subproblem solutions. This is the method named *dynamic programming* [8]. In this case, the recursive calls are not needed. Hence, dynprog is a technique that alters recursion into iteration. If students are more comfortable with iteration, this should only help. On the other hand, for someone who wants to think of iterations, the concept of "finding an evaluation order" is not all too clear. Also, it can be easily imagined that difficulties in discerning base cases for a recurrence relation makes the dynprog approach uncomfortable.

D. Pattern Oriented Instruction

Since coping with many aspects of a problem at the same time might be difficult, and since teaching everything at once might lead students to focus entirely on the algorithm that is constructed, and less on the construction process, we tried using Pattern Oriented Instruction(POI). POI is based on cognitive psychology theories on construction and organisation of knowledge in schemata. A schema is a connected chunk of "information", that has been constructed by repeated experiences which share some common ingredients. When, for instance, solving a complex problem, we are processing several different types of information at the same time. This is called cognitive load, and if the cognitive load gets too heavy, our problem solving skills are heavily reduced. When having seen the same type of problem many times before, we are able to process many interconnected pieces of information as one unit, a "chunk", which reduces cognitive load. A pattern is either distilled from several different experiences with certain ingredients in common, or generalised from some specialised example of a phenomenon. It can be employed in teaching to enhance the learners' ability to create new schemata. POI deals with structuring the teaching and the content in a way that facilitates the creation of schemata, which can later be processed as chunks.

POI preparations focus on identification, selection, progression and comparison of problems and patterns. The students get to meet with increasingly complex problems, encompassing different patterns already familiar. The comparison of problem characteristics is central, and patters are first introduced and later revisited in a different setting. The effect of POI on students' abilities in problem solving, abstraction and analogical reasoning in particular, are investigated by Muller and Haberman [9], [10], [11] and the effect on problem decomposition and solution construction abilities by Muller, Haberman and Ginat in [12].

E. Clickers and response cards

The use of clickers (or Audience Response Systems, or "voting" systems) for pedagogical or administrative purposes is widespread in the world today [13]. Among the reasons for using them is "anonymity", but since the systems are often built in a way that admits excessive data collection and even scoring on an individual level, it is worth noting that this anonymity is only towards peers, not towards the teacher. In other words, if the student is afraid of speaking up and answering questions on lectures because it could expose him or her to *the other students*, the argument is valid. If students don't want to expose possible lacks of knowledge to teachers, the system can actually be a greater threat, as temporary misunderstandings might be recorded and later graded. However, there are desirable benefits to clicker systems: they provide means for student activity; everyone gets to think and answer the questions, not just the fastest responder; the results of the small polls allows the teacher to address misunderstandings directly; and they provide formative feedback to the students. They also incentivise the teacher to plan good questions that are suitable for this type of exercise. The use of response cards, predecessors of clickers of sorts, has been studied academically since the 1960s, and have proven to have effect on student grades and student participation [14]. We have gradually included response cards in the course during the two past years, and it has been much appreciated by the students. We have employed cards of different colours which are administered to the students in the beginning of lectures. The votes are still made simultaneously, and the feeling of being exposed seems not to be present among our students, according to their evaluation responses.

F. Self-efficacy

In contrast with self esteem or confidence, self-efficacy is described as an individual's confidence in his or her own ability to, at a given moment, perform actions in order to achieve some desired outcome. The term was introduced by Albert Bandura in the 1970s and is further developed by him in [15]. The phrasing of the self-efficacy items should be direct and not involve guesses about the future or some sort of inherent capabilities of the subject to the study. Self-efficacy beliefs are not static - on the contrary, they change with the individual's experience. It is self confidence of a sort, but situated and very localised in time and subject area contents. These characteristics have given self-efficacy a role in education. The score of a self-efficacy test is known to be an important predictor of success [16]. There are studies in how self-efficacy correlates with performance [17], how self-efficacy changes during studies[18], and how it correlates with other factors around the individual [19].

We knew of no established instruments measuring self-efficacy for theoretic computer science. In mathematics, self-efficacy instruments have been developed [17], [16] and also in programming [18], [19], which is another related area.

III. Method

A. Plan the new course activities

Previous years, other aspects of this course have been reworked, and after that, students complained that dynprog seemed unreasonably difficult compared to other content. For this experiment, the short part of the course that dealt with dynprog had to be planned with a new perspective. We used visualisations of dynprog, a completely new lab exercise and clicker questions for the lectures. TAs were instructed on the plans and the goals of the new partitioning of the contents, and new tutorial session material was prepared. The new lab assignment was to modify and speed up a program that calculated the edit distance between two words. The system Kattis, described in [20] was used for automated online testing, and theory questions which would prepare the students for the optimisations needed were prepared. The visualisations shown in the introductory lecture exemplified calculation of the "degenerate" case of dynprog, the Fibonacci numbers, recursively, with memoisation and with dynprog.

For this "simplest" version of dynprog problems, number sequences, the order in which to calculate the answers seems natural, and coincides with the order you would calculate different subproblems when using memoisation - save each value the first time you need it, but use the recurrence as basis for your algorithm.

B. New structure the course content

We started by identifying what difficulties we could encounter, and what different dimensions we could allow to vary and needed examples of. The task of solving a dynprog problem can be thought of as solving three different tasks: 1) Finding a structure for the solution, 2) expressing a recurrence relation, and 3) defining and proving an evaluation order with the properties that we will always have solved "smaller" subproblems whenever we solve a "larger" problem, and that the evaluation order renders the same result as the recurrence relation would produce.

To help comparing and distinguishing various characteristics of problems, we identified what could vary between different dynprog problems: whether the history needed to be saved during computations or not; whether the evaluation order was intuitive or more intricate; whether new values depended on the indices of the elements to be calculated, or on some input, or both; whether the previous subproblems to be used for each calculation were the most recently calculated subproblems, or if some special method was needed to find relevant subproblems (for instance, "jump", skip cells, in a matrix of previously calculated values); the number of dimensions for the subproblems (do they fit in a sequence, matrix, higher order); that there could be several different recurrence relations for the same problem and that the same recurrence relation could be the basis of several differently posed questions; the "location" of the base cases, "the location" of the answer after calculation; whether only a number, or the entire path to that number was needed for the solution (constructive solution), and different combinations and variations of these features.

These were only the dynprog specific variations. Another important variation is in the structure of a problem, or rather, of its solutions. If subproblems do not overlap, divide-and-conquer is generally a better method than dynprog, and if they do overlap, dynprog might be best. A greedy solution can sometimes be proven to be the superior option. These algorithm construction methods are also covered in the first part of the course, and assessed on the same written home assignment.

C. Prototypes and patterns in dynamic programming

For the lectures, we decided to separate two phases of constructing a dynamic programming algorithm: 1) Recognising the structure of the problem and create a recurrence relation and 2) Finding and proving an evaluation order for a given recurrence relation. This was done to direct more attention to the evaluation order and correctness arguments. At the same time, we wanted to refer to prototype problems. Some of these had already been used in the course, and others were introduced as a complement to these. The prototype problems we chose were: Fibonacci (sequences), 2-dimensional recurrences without input (2-dimensional sequences), 2-dimensional recurrences with input, (values decided from input), Longest increasing subsequence (index and input dependent, need to save full history) Matrix chain multiplication (base cases on the diagonal, construction of the solution), Swamp walk (different questions, same "solution"), Coins (different recursions for the same problem, focus on proving correctness), Longest common substring (argue correctness of recurrence relation and algorithm, construct the solution, compare to 2D-with input that rendered the same recurrence relation) and Floyd-Warshall's algorithm for finding all shortest paths in a graph (more than two dimensions used). We do not argue that these problems are *the best possible* set of prototype problems, but they contained examples of the variations we wanted to show and most of them had appeared in one form or another on the lectures previous years, only not as explicit representatives of some technique(s) each.

D. Surveys

Several different surveys and questionnaires were administered throughout the course. Their content and goals are described in this section.

1) Self-efficacy surveys: We would like to know whether students find any of the different tasks we believe are involved in dynprog especially hard, and whether students improve their self-efficacy during the course. Based on the ADC goals, the guidelines by Bandura in [21], and supported by the spirit of knowledge taxonomies such as Bloom's taxonomy [22], we have constructed a 10 item self-efficacy scale on dynprog, together with an 8 item scale on complexity that is further described in [23]. The students are asked to grade their self efficacy on the course's dynprog contents on a scale between 0 and 100. This was done on lectures, before and after the section of the course that was part of the experiment. 110 and 79 students responded, respectively, and 68 responded to both. This survey was not anonymous, but the students were promised that it would not count towards grading, and that no one would read the material until after the course was finished. This is naturally a limitation in the usability of the responses for that year, possibly introducing errors in the form of more polished or adjusted answers from students. On the other hand, we wanted to both be able to see individual trends between the two occasions, and retain the option to later compare self-efficacy beliefs with results: both their predictive value from the first occasion, since it is known that self-efficacy affects motivation and possibly performance, and also possible correlations between results and self-efficacy beliefs after the teaching and learning activities.

2) Home assignment cover page: Together with the homework assignment, the students got a cover page to attach to their homework, with two types of questions. One half was a participation statement, and contained questions on what sessions or activities the student had attended in the dynprog part of the course, and the other half was a "Where was what learned" part, and contained a matrix where students could mark where they had learned to master different aspects of dynprog: on their own, on lectures, on tutorials, from visualisations, from the peer assessed theory questions before the lab assignment, from the lab assignment, or if they still did not master it.

3) Course surveys: At the peer reviewed, pseudonymous theory exam, a final survey on the course was distributed in two versions, one with pre-defined answer options, and one with free-text questions. The students were randomly assigned one of these, and the one with pre-defined answer options is the one we present here. There was also, as always at our school, an online course, where some questions were about related issues. This survey is completely anonymous, done on the students' own time, and has higher non-response rate.

E. Student results and comparisons

The written homework assignment is graded A-E, so the grades might have improved if the teaching was much improved. There is also another, similar homework assignment on complexity, which can be used for comparison. The grade on the assignment, however, is based on the performance on three algorithm construction tasks, out of which one had a good dynprog approach. Yet another task was possible to solve with dynprog, but as this was far less efficient than another method, and this task was meant to assess the students' ability to choose the best methods for new problems, the use of dynprog here did not improve the grade (unless the student proved here but not on the previous task that he or she could use dynprog.)

IV. Results

A. The self-efficacy instrument

One of the instructions from Bandura was that the items on a self-efficacy scale should be of increasing complexity, or level of challenge. If by this we mean that ideally, the items should be ordered so that the answer values was a non-increasing sequence, this was not achieved. As the relative scores for the different items was what we wanted to investigate, the order is not of crucial importance to us. Some items could be rephrased to make them easier to understand for someone unfamiliar with dynprog. The items were (translated from Swedish):

1) I could understand dynprog algorithms as presented to me by teachers or in books.
2) I could decide whether an algorithm is based on the algorithm construction method dynprog.
3) I could construct an algorithm that calculates a recurrence relation, using dynprog.
4) I could explain to an average peer why dynprog is better than a recursive procedure when implementing an algorithm to compute the Fibonacci numbers.

item	1	2	3	4	5	6	7	8	9	10
pretest average	76	49	70	88	34	49	71	69	47	36
posttest average	90	84	87	95	68	78	88	80	67	65
threshold = 25										
less certain	0	0	4	3	3	8	2	6	5	3
no change	45	21	35	52	22	21	40	42	34	21
more certain	23	47	29	13	43	39	26	20	29	44
threshold = 50										
less certain	0	0	1	1	2	1	0	2	3	0
no change	64	46	60	62	39	40	61	58	50	47
more certain	4	22	7	5	27	27	7	8	15	21

TABLE I
NUMBER OF STUDENTS INCREASING THEIR SELF-EFFICACY VALUES FOR ITEMS 1–10. (N=68)

5) I could choose a suitable evaluation order for dynprog for a recursive relation that depends on separate input (and not only on indices).
6) I could explain why dynprog with my evaluation order solves the same problem as does the recursion.
7) I could implement a dynprog algorithm that is presented as pseudo code, in some programming language.
8) I could determine from the problem statement whether a problem should be recursively solved , without it being stated anywhere, if I got some time to investigate it.
9) I could construct a dynprog algorithm that solves a problem presented to me in natural language, without recursion.
10) I could construct the solution to a problem if I have a dynprog algorithm that determines that the solution exists.

Along with the instructions, the values 0, 25, 50, 75 and 100 were interpreted in words, and the students had the instruction to mark 0 where they had never heard of some concept before. The students were also introduced to the scale and to using it by some simple examples, which had nothing to do with the course: “I could lift X”, where X was allowed values like “a pen”, “my laptop”, “this chair” and “the lecturer”.

The results of the self-efficacy surveys can be seen in Table I. Only responses from students who handed in both surveys are included. For some of the items, the students had high confidence in knowing them already at the beginning of the first lecture on the topic, especially item 4. We decided to just look for increases or decreases of at least 25, which had distinctly different interpretations according to the instructions. For comparison, we also present results where students had changed their answers with 50 or more. Items 1, 3, 7 and 8 also had rather high average values at the first lecture. Naturally, only a few students could increase their confidence a lot on these items. For all but the first two items, it also occurred that some students (at most 8) *decreased* their confidence in their ability, for all of these except from 7 and 10, also when the threshold was 50. The decrease in confidence could suggest that student actually became less skilled in tampering with certain tasks after the teaching and learning activities. This, though, would be quite an achievement of negative sorts for the teaching, and seems unlikely. Another interpretation is that students became aware of details or whole dimensions they had previously not seen, and hence became less certain that they could cope with some tasks. For instance for item 6, which is a milder version of proving correctness, some students might not have seen the need to prove this, and underestimated the difficulty of the task. On the online course survey, some of the comments about the course and the homeworks reveal that proving correctness is still considered difficult. Also, after having tried some of the tasks in the survey for real, some might have more realistic estimates of their abilities.

For items 2, 5, 6 and 10, more than half of the responding students increased their confidence, and about 30 percent increased it by at least 30 %. It seems that what students perceived that they learned, was to recognise a dynprog approach, to modify a recursive approach to a dynprog approach by the means of determining an evaluation order, and to explain why this still solved the same problem as the recursive algorithm, and also to modify dynprog algorithms to save more history and answer with more detailed answers. This, the tenth item, might have been a distinction that students had not considered before, and not really thought of.

The items 5, 9 and 10 had the lowest average scores at both occasions, but the similarly low scores on item 2 and 6 at the first survey had increased more the second survey. Still, as mentioned before, item 6 has special characteristics and could be investigated more. According to these surveys, out of the investigated items, the students perceive it most difficult to find a suitable evaluation order, construct a dynprog algorithm from scratch, and modifying an algorithm that answers “42” to one that answers “the best value 42 is obtained by making these decisions”, and also to argue correctness, although on this item many students improved their (self estimated) abilities.

B. Course survey at exam

The results from the previous section also include what students believe they know after the part of the course that dealt with dynprog. The responses from the students who got the closed form questions at the final exam survey are presented in Table II. Students were in general very positive to the “clicker questions”, but also towards the visualisations and the computer lab assignment, a little more positive in general speculation than in their particular case on whether these activities contributed to learning dynprog. Particularly beneficial, according to the responses, is working with the computer lab assignment. No one complained about the lack of privacy of the clicker votes, neither at the exam survey nor on the anonymous online survey.

C. Home assignment cover page

A more detailed view on what students on an earlier occasion believed that they learned, and where, is presented in Table III. These are the percentages of students (148 in total) who handed in the homework assignment. On the cover page they had to complete this matrix and some questions on what activities students had attended. They were allowed to mark

1. Was the pedagogical purpose of the activity clear?

	yes	questionable	no
clicker questions	90%	6%	1%
visualisations	81%	10%	1%
computer lab	79%	14%	1%

2. Did you find the activity meaningful?

	yes very	yes somewhat	not particularly	not at all
clicker questions	59%	36%	3%	0%
visualizations	40%	40%	10%	1%
computer lab	54%	40%	3%	0%

3. Did you learn dynprog by working with the activity?

	yes	no
clicker questions	66%	17%
visualizations	51%	24%
computer lab	87%	9%

4. Do you think that activities like this one can make it easier to learn dynprog?

	yes	no
clicker questions	76%	9%
visualizations	73%	6%
computer lab	90%	4%

5. Did the activity add something to the course?

	yes	no
clicker questions	94%	1%
visualizations	71%	6%
computer lab	96%	1%
self-efficacy surveys	17%	39 %

TABLE II

ACTIVITY SURVEY RESULTS. (DON'T KNOW OR BLANK OMITTED.)

Where did you learn to…
1. …tell if an algorithm is based on dynprog?
2. …tell if a problem can be tackled by dynprog?
3. …construct a recurrence relation for a simple problem?
4. …choose an evaluation order given the recursion?
5. …construct a solution given a dynprog algorithm that finds the optimal value?
6. …motivate the correctness of a dynprog-based solution to a problem?

	already knew or learned by myself	lectures	tutorial sessions	lab theory assignments	lab	homework 1	still haven't learned this
1.	18%	57%	30%	39%	42%	19%	0%
2.	16%	50%	30%	34%	37%	24%	1%
3.	72%	24%	19%	9%	6%	16%	1%
4.	26%	49%	29%	26%	25%	22%	4%
5.	11%	37%	23%	15%	32%	22%	15%
6.	6%	43%	17%	11%	15%	29%	24%

TABLE III

WHERE DIFFERENT TASKS WERE PERCEIVED TO HAVE BEEN LEARNED. (N=148)

Activities attended	mean grade hw1	hw2
>4	1.9	2.4
<2 and ≤ 4	1.2	1.5
≤ 2	0.68	0.84

TABLE IV

COMPARISON OF STUDENT PERFORMANCES AT HOMEWORK 1 AND 2 (HW1 AND HW2) GROUPED BY THE NUMBER OF ACTIVITIES ATTENDED.

several options, for instance, they could have learned to tell if an algorithm was based on dynprog both on lectures and by their own efforts.

Judged from this, all of the activities contributed to learning, but construction of recurrence relations for simple problems is not considered as hard, or at least, not considered to require the teachers' attention. Just as in the self-efficacy surveys, modifying an algorithm to output the construction of the solution rather than only an optimal value, is still difficult to some of the students, here 15 %. A quarter of the group found it difficult to argue correctness at this point. Since the question was not posed identically on the self-efficacy survey, the answers are not totally comparable. The fourth row in Table III shows that only 4 percent judged that they still could not find an evaluation order. This suggests that students who are not too certain that they could perform this task, still do not respond with "I still haven't learned this", or that they later re-evaluated their ability to choose an evaluation order.

Concerning the homework *results*, and any impact our methods might have had, in Table IV, the mean grades (where A counts as 5, and linearly down to 0 for F) for homework 1 and 2 are shown for the groups of first time students who had attended different number of activities, where the lab assignment was counted as 1.5 if submitted early. Homework 2 was on complexity. The grades are usually similar on both homeworks, but this year many students handed in a less efficient solution (based on dynprog) for one of the problems, and hence did not get the highest grade for this. The most ambitious students might have read too much into our questions on dynprog. These results are mostly telling that active students get higher grades, and show no special benefit for dynprog problems.

V. DISCUSSION

A. *Student activity and lots of evaluation intervention*

Surveys are often anonymous, but the concept of *self-assessment* in teaching is not usually associated with anonymity. It can be used as a means of facilitating learning, and it is possible that among the learning activities we provided this year was self-assessment. Some students indicated this, so this perspective was included in the exam survey. Most students, however, considered it an alien thought that their completing a lot of surveys had contributed to them learning dynprog. Even so, in making students reflect on their own abilities, this type of questions could help (a minority of them) to learn, or reduce administrative work load on the teachers. For instance exam wrappers (to be completed upon recovery of their graded assignment) are suggested to be used for such reasons by some institutions[1].

We plan to continue distributing the surveys, to monitor possible effects by altered teaching methods, and for the

[1]http://www.duq.edu/about/centers-and-institutes/center-for-teaching-excellence/teaching-and-learning/exam-wrappers

possible pedagogical gains. Although the criteria for each grade are specified in the course information, questions on what students felt certain that they could do also contribute to communicating the teachers' aims to students by building a list of distinct abilities that the teachers value.

VI. Conclusion and future work

The contribution of this paper in a general perspective is to show how to improve teaching of some particular concept, by an action research approach, aside from exemplifying methods for finding out how students feel about their own ability. The main contribution resides in the theoretical computer science didactics area. Ouf of a teacher-selected sample of abilities, which we deemed needed to solve problems with dynamic programming, we have investigated which activities students find more difficult to learn or to master, what they feel confident that they know, and where they learned the things that they know.

Returning to the questions in the introduction, for Q3 (which activities students thought contributed to learning) we can conclude that a variety of activities was good. Both mandatory activities, like the homework and the lab assignment, and optional ones like lectures, tutorial sessions and visualisations were considered helpful for learning. Regarding Q2 (what abilities the students felt that they had after the course), most students are confident that they can recognise dynprog, explain what it is, construct simple recurrence relations and implement dynprog algorithms. They are less certain that they can find a good evaluation order for a recurrence relation, solve a problem from scratch or motivate correctness, which constitute our answers to Q1.

Compared to what the teachers expected, this is both similar and different. The correctness part was expected, but fewer students than expected experienced difficulties with finding a recurrence relation. Further, other, or more detailed questions can be asked to find out more about this.

Next time this course is given, the prototypes will be refined and more emphasised. Correctness and writing pseudocode (i.e., describing ones algorithm on an appropriate level of detail) will get special attention.

Abstract— **In India, unlike the Western world, the universities have several engineering institutes affiliated to them that are geographically spread across large provinces. Gujarat Technological University (GTU) is one such example, that caters to the technical education needs of the state of Gujarat (size of Arizona) with a population of 65 million. More than one hundred such institutes offering undergraduate and graduate programs and about same number of 'Polytechnics' offering engineering diploma programs are affiliated to GTU. Around 100 thousand students take admissions every year in the 55 different technology programs being offered. Since examination and certification is the main responsibility of the University, it becomes necessary to conduct centrally administered end-of-the-term examinations every semester. This necessitates the curriculum for each program to be same in all the institutes. Hence, curriculum design became a centralized task to address the needs of today's globalized industry and also fulfill the aspirations and capabilities of the students, belonging to different strata of the society. Since curriculum designers and implementers are not the same in this experiment, a need-based curriculum model became imperative to be developed that could convey clearly and uniformly the intentions of the designers in letter and spirit to all curriculum implementers and stakeholders.**

In this backdrop, NITTTR Bhopal one of the four premium institutes established by the Government of India for quality improvement of the technical education, was assigned the task by GTU in 2012 to completely re-design the curriculum of twenty five engineering diploma programs to produce 'work ready' personnel. The authors were the core members of the core team who undertook this task. This paper highlights the challenges and opportunities faced by the engineering education system due to fast changes taking place in society, industry and education, for which an innovative outcome-based curriculum model was evolved to address these challenges and harness the opportunities. This paper discusses the various facets of the philosophy, approach and structure of this curriculum model evolved for this purpose. It also briefly describes the planning, designing, implementation and evaluation of the curriculum development process, as well as some of the strategies adapted in this innovative curriculum model.

Keywords—Outcome-based Curriculum; Competencies; MMS Type Industry; R&D Type Industry, Program Structure; Programme Outcome; Course Outcome; Domain; GTU; NITTTR Bhopal

I. INTRODUCTION

With liberalization, globalization and privatization of Indian economy in early 1990s, there was a spur in growth in all sectors of the Indian economy. This expanding economy needed thousands of appropriately skilled technical workforce and government owned engineering education institutes could not produce that many. This prompted the government to loosen its strings and allow greater private sector participation in the engineering education system. Much of the private sector saw this as a great opportunity to undertake a lucrative business and opened engineering education institutes to make profit rather than consider it as a social cause. A considerable number of such self-financed engineering institutes sprung up and affiliated themselves to the 'generic universities' (for recognition/accreditation of degrees awarded by the industry) in different parts of the country.

Many of these self-financed engineering institutes are owned by individuals or groups of persons coming together as so-called 'co-operatives' or 'trusts/societies' without having any noble aim or experience of imparting quality engineering education [2], but earning profit being the primary motive. This situation fuelled and spiralled the sudden splurge of large number of engineering education institutes all over the country whose quality became questionable for several reasons discussed briefly in this paper.

Due to the greater social status attached to engineering degrees in India, the parents are ready to send their wards to such institutes even though they levy more fees than the highly subsidized government engineering institutes. This is so because, the spending power of the people have greatly improved due to the developing economy [14], even if their wards were not fit for undertaking engineering studies.

In this scenario the quality of technical education system began to deteriorate and many deformities and discrepancies crept in. To stem this downward slide some of the State Governments established the 'technological universities' in an effort to bring some semblance to the system. But this also posed some new challenges due to the sheer size of the large number of institutes affiliated to them. Therefore GTU (Gujarat Technological University), one such university in the Western part of India assigned the task of developing the appropriate curricular strategies to deal with these challenges to National Institute of Technical Teachers' Training and Research (NITTTR) Bhopal, and the authors as the core design team took up this task of curriculum development.

To begin with, the team was entrusted to address the curricular issues of the engineering diploma programs being offered by GTU. After analyzing the scenario, the authors developed and implemented this model of 'outcome-based curriculum', keeping in view the challenges and opportunities thrown open by the rapidly changing social, industrial and educational environment.

II. TECHNOLOGICAL UNIVERSITIES OF INDIA

It would be relevant to understand the creation of the 'technological universities' in India, a unique feature in the Indian context. The 'generic universities' (awarding different types of diplomas and degrees) - to which most of the private engineering education institutes were initially affiliated with, neither had any expertise to monitor the quality of these institutes nor was it their main focus (as the number of basic humanities and science colleges associated to them were relatively many times more as compared to these newly started engineering education institutes). This situation raised several questions about the quality of engineering education and in such a scenario the concept of 'technological universities' exclusively catering to the needs of the engineering education got evolved in India [8]. Presently, many of the large states (provinces) of India have established government legislated (managed by Govt.) 'technological universities' which affiliate engineering education institutes.

The government's main intention of the creating such technological universities was to bring a large number of engineering colleges and polytechnic colleges under a single umbrella so that the good quality curriculum may be framed, to be uniformly implemented and assessed to fulfill the essential needs of the two broad categories of industries – R and D (research and development) type of industries and the MMS (manufacturing, marketing and servicing) type of industries [4]. It was also envisaged that technological universities would be able to pool the best talent available in the region in every branch of engineering to develop world class learning resources and laboratories to pursue advance researches.

By the time the state government legislated 'technological universities' took shape, the number of engineering institutes also had increased several fold within a very short period. The rapid changes taking place in society, growth in economy and the establishment of such technological universities provided new opportunities as well as posed new challenges [1].

Many of these private engineering institutes and polytechnics prefer to affiliate themselves with the state government legislated 'technological universities' awarding undergraduate and diploma engineering degrees. This is because the Indian society and industry has more trust in the degrees awarded by the government legislated universities rather than private ones and hence most of the parents like to admit their children only in such institutes that are affiliated to government legislated 'technological universities'. Further, the industry also generally gives greater credit to government awarded degrees rather than those from the private.

However, these mega state legislated universities affiliating hundreds of engineering education institutes also have some inherent problems because of the geographical spread of these large numbers of affiliated institutes. The common syllabi applicable to all students across the state become difficult to implement uniformly and effectively to develop the capabilities and needs as envisaged. This is the genesis of the 'outcome-based' curriculum project which NITTTR Bhopal is undertaking and discussed over here.

III. CHALLENGES OF GUJARAT TECHNOLOGICAL UNIVERSITY

The young Gujarat Technological University (GTU) was established in 2007 and currently, it has a whopping 200 engineering and polytechnic colleges affiliated to it with about 400,000 students studying in them. These institutes offer bachelor's degree and diploma in 31 and 25 different branches of engineering respectively. Some of them also offer graduate and Ph.D. engineering programs.

In India, in the last three decades there have been drastic changes in the society, industry and engineering education system that has posed new challenges. However, the philosophy and approach of curriculum development remained aloof to these changes. By the fall of 2011, GTU realized the need for a complete reengineering of the curricula of its 25 engineering diploma programs to begin with (and later for curriculum restructuring for undergraduate programs in 2013) and NITTTR, Bhopal – which is established by Government of India for the development of the technical education system of the country was given this task, where the authors work.

The authors along with other members of the core team studied the changed situation and analyzed the challenges faced by the engineering education system in general and GTU in particular, which are discussed below:

A. Knowledge Explosion and Ease of Access

There is an increase in volume of knowledge associated with every discipline of engineering due to advancement of technology. For example, till few decades ago, in electrical engineering it was necessary to teach only thermal, hydro and nuclear power generation in detail, but now wind and solar energy has also become commercially viable and hence it has become essential to include these technologies in detail in the curriculum. Similarly, knowledge of power electronics has become essential for electrical engineers because of increased application of power electronics in electrical drives and transmission systems. Similarly, many other new materials/ procedures/technologies have been added in the realm of electrical engineering. Moreover, these methods/ materials/ machines, whether old and now both co-exist making it imperative to teach both and this tends to make curriculum cumbersome. Such knowledge explosion exists in nearly all other branches of engineering for which an innovative curriculum design became necessary.

Further, some inter-disciplinary courses, which were not part of the basic engineering education 30-40 years ago have become quite important such as courses related to computers, entrepreneurship, environment, management and others. The key issue was how to handle the increasing body of knowledge in every branch of engineering, as the period of study for an UG or engineering diploma program is always fixed of 4 or 3 years duration respectively.

In this complex scenario, where the body of knowledge is increasing day-by-day and quality of the entry-level students is deteriorating gradually, it was a big challenge for the authors to design appropriate curriculum.

B. Changed Expectations of Industry

Over last three decades the expected competency profile of engineers has changed due to market conditions and technological up gradations, followed by the changing work culture in the industries which made lifelong learning an imperative professional duty for engineers. They are expected to be good lifelong learners for learning emerging technologies. Similarly, they are supposed to handle different kinds of jobs as companies are forced to change their product profile and organizational structure due to changing marketing conditions. This also requires them to acquire new competencies and skills time-to-time. Educationists agree that for developing lifelong learning skills, opportunities must be provided within the curriculum itself for self-directed and experiential learning [5]. Most of the technical education system in India is 'teacher centered' focusing on learning only from books with the help of teachers, as against the much needed 'student centred'. This situation warranted a complete reengineering of the curriculum [12].

As more and more industrial organisations are shifting from 'hierarchical organizational structures' towards 'flat structures', many of the times the employees are required to take decisions and work in teams, both as leaders as well as members. Such situations demand better communication and decision making skills. However, the present structure of curriculum does not have enough scope for such learning experiences which can develop team working, leadership, decision making and communication skills. [10]

C. Geographical Spread

Being quite a large technological university catering for more than 200 institutes spread over extensive geographical area (196,024 square kms.) to plan, design and implement the curriculum has been a challenge for the curriculum development team. There is a marked difference in the quality of infrastructure (especially laboratories and library) across the institutes between rural ones and urban [11]. This geographical spread means that some of the institutes are located in or around big cities and students and faculty members of these institutes have access and exposure to nearby industries. Some of institutes are in remote areas, where interaction with industries is minimal. Because of these variations, the abilities of students and teachers widely differ from one institute to another [13].

Because of this situation, the expectations of students from the curriculum also differ widely. It has been found that if curriculum seems difficult to some students they may adopt superficial methods of learning. Whereas, if curriculum seems too easy to some, they will feel bored with it quickly. Therefore, the design of this innovative curriculum was to provide enough choices to motivate majority of students to choose courses according to their needs and harness the opportunity due to the nearby industries and to pose a moderate challenge to the most of them. 'Moderate challenge' is a must for in-depth and enjoyable learning. [Eraut].

D. Poor Quality of Entry-Level Students

Another problem posed by the proliferation of private engineering institutions is the less number of good students for diploma engineering programs. The Indian society, especially the middle class, accords better social status to bachelor degree in engineering rather than engineering diploma programs. Since there is more number of private engineering colleges, most of the students (irrespective of their aptitude and abilities) take admissions in undergraduate programs, even paying higher fees, as their 'neo rich' parents can afford. This has resulted in only academically or financially poor students joining the engineering diploma programs, since it is of lesser duration i.e. only of three years and that to after the 10^{th} grade. This helps them to get jobs earlier than the bachelor engineering students albeit at a lower level of hierarchy and salary [1].

E. Specialised Knowledge Growth in Various Sectors of Economy

The last few decades have transformed the Indian economy and it has grown in leaps and bounds due to public-private partnership (PPP) and globalization. Due to new knowledge being added to the body of knowledge, new specializations in the so-called conventional branches of engineering emerged in many sectors. In other words, the industry wants more specialized and competent persons to cater to the changing needs of different sectors of economy, rather than only generic engineers in civil, mechanical and other branches of engineering [10]. Moreover with more technology specializations, the economic scenario has changed and every sector has become large enough to provide specialist engineering employment opportunities in sufficient numbers on regular basis.

Therefore, there is enough scope for a greater number of specialized breed of technical workforce required to work in the new and changed technological and industrial scenario. For example, the civil engineers are required to have the expertise in four major specialized areas such as, 'Building Construction' (residential and commercial buildings), 'Transportation' (i.e. highways, railways, docks and harbours and Airports), 'Water Resource Management' and 'Irrigation' (Dams and Canal System), 'Environment and Public Health Engineering' (Drinking water, Sewerage, Effluent and Solid West Management). The current civil engineering syllabus attempts to develop expertise in all these areas leading to a generic civil engineering degree, with which the industry is not satisfied at all. In earlier times, such generic civil engineering degrees were required as there were limited job opportunities.

Moreover, the technological advances in each of these sectors has increased so much that the entire amount of knowledge cannot be included in the same time span which is always constant. Therefore, from employment point of view as well as meting out justice to the body of knowledge, there is a strong case for specialised engineering diploma in civil engineering such as the following:.

1) *Civil Engineering Diploma with specialization in Building Construction*
2) *Civil Engineering Diploma with specialization in Transportation Engineering*
3) *Civil Engineering Diploma with specialization in Water Resource Management*
4) *Civil Engineering Diploma with specialization in Environment Conservation*

Similar examples are seen in other branches of engineering and these curricular issues have been addressed in this innovative GTU curriculum model.

F. Curriculum for Greater Mobility for Jobs and Higher Education

The proportion of Indian population below the age of 20 is considerably more as compared to that in other parts of the world. This has created a situation of demographic dividend for India [6]. This means that India is in a position to supply workforce to other parts of the world as many of the better performing graduates from India are already taking up employment in Europe, USA, Middle East and Far East Asia, Africa and Australia. In addition to this, there is perception that the higher education in developed countries is better which is substantiated by the increasing number of Indian students taking admissions for higher education in Europe, USA, Canada and Australia. In this scenario, it was high time that India fell in line and designed curricula to match the Washington Accord for undergraduate programs and Sydney Accord for Engineering Diploma Programs [2] as these accords ensure the minimum level of quality and desired uniformity to render greater global mobility of individuals for jobs and higher education.

IV. Curricular Innovations vis-à-vis Challenges

In order to address the issues discussed in the previous section, the challenge with the core team was, what curriculum design is to be adapted for the engineering diploma programs offered by GTU. Several rounds of workshops were conducted by the core team with the stakeholders in which the following probable solutions emerged.

1) The existing curriculum did not provide clearly stated learning outcomes. Centralized development of curricula requires that it should give enough clarity to all concerned – first to the student, then to the teachers and the industry, followed by all the other stakeholders. This meant that the curriculum should explicitly state as to what are the observable and measurable 'competencies' expected by the industry which are to be developed in the students after the course of study. Such 'competencies' comprising of measurable 'Course outcomes' in the 'cognitive domain', measureable associated practical outcomes in the form of exercises in the 'psychomotor domain' and measurable social skills related to the 'affective domain' will help the students and teachers in knowing the 'length, breadth and depth' of the course necessary to achieve the competency [9].

2) In a large state like Gujarat, where students come from urban, semi-urban and rural backgrounds, job opportunities also differ in different parts of the state. Hence, the students' interests and abilities are also different requiring the curriculum design to have enough choices to cater to these differing needs. It was decided to provide sufficient options in the curriculum.

3) Another problem noticed in the existing curriculum was that, some of the foundation courses such as 'Physics', 'Chemistry', 'Mathematics', 'Drawing' and 'Workshop Practice' were common for every engineering program. Even those concepts and principles not required for that branch of engineering were being taught. For example, 'electricity and magnetism' was being taught in the course of 'Physics' to civil engineering students to the same depth as to electrical engineering students. Again, in the course of Chemistry 'cement' was being taught to mechanical engineering students to the same depth as to civil engineering students.

Similarly, the course of 'machine drawing' was being taught to electronics engineering students. In 'Mathematics' some topics which would never be used by the students of that branch of engineering was being taught and assessed. Same was true for the course of 'Workshop Practice' course where electrical engineering students were asked to work on 'lathe machine' which they would never do in their career. Because of this approach considerable amount of content which is not directly relevant was being taught to students. The authors formulated program specific courses of 'Physics', 'Chemistry', 'Mathematics', 'Engineering Drawing' and 'Workshop Practice'. This did away with the less relevant content thereby creating space for more relevant courses.

4) To cater to the poor quality of entry level students, curriculum should have enough space (especially in initial semesters) for giving practice to cement some of the fundamental concepts which they should have acquired from the school. Poor intake quality also means that teachers would require more efforts to make sure that students acquire core competencies, which would require for the provision of more tutorials in the new curriculum. This was achieved by making some of the advanced courses as optional to create more space for practice/tutorials in core competencies. Moreover, some of the traditional courses were shifted to later semesters in the new curriculum, thus creating more space for tutorials.

5) The industry needs 'work-ready' graduates with competencies not only in technological areas but also in the areas of communication, team working, decision making and lifelong learning. For development of these generic competencies, work-based learning experiences such as 'project work', 'problem-based learning', 'seminars', 'industrial visits/training', 'case studies', 'maintaining reflective portfolios' are some of the strategies incorporated in this innovative curriculum, which also require relatively more time[15]. This situation again warrants reduction in curriculum content judiciously to create more space and time for such assignments, which was made possible again by using the mechanism of converting some of the advanced courses in the new curriculum as optional.

6) Knowledge explosion and its easy access on the internet provide us both a challenge and an opportunity. It is neither feasible to teach every aspect related to the concerned program nor is it required to be taught, as it is easily accessible to learn by the student on the tap of the finger. This situation warrants that instead of transferring every bit of knowledge to students, they should be provided with opportunities to learn to access and apply the knowledge. The opportunities envisaged in this new curriculum are through micro, mini and major project assignments, problem-based learning, seminars and others. Provision of time for these activities was made in the curriculum, and this was done by reducing the number of advanced courses and concentrating mainly on core courses.

7) Emergence of new technology courses where earlier technology courses still co-exist, addition of inter-disciplinary special courses related to computers, environment, entrepreneurship, and management have made the curriculum too cumbersome. This problem was compounded with the poor quality of entry-level of students. In this situation, an option was to reduce the number of advanced courses so that core courses may be taught in detail with provision of tutorials for more practice.

In this situation, the authors suggested to keep only awareness level courses for all specializations related to the concerned engineering program. And further encourage the students to learn advanced courses related to any one of the chosen stream or specialization (as students are given the choice to choose a stream within the same program). This design helped in reducing the number of advanced courses while ensuring that students possess basic knowledge of all the streams related to that branch of engineering but is competent enough in his/her chosen stream and be work ready for employment soon after graduation.

8) As mentioned earlier, growth in many sectors of the economy have created large number of specialized jobs and hence special programs related to that particular sector are not only feasible but are very much needed. To address this issue, 'stream specific' engineering programs within the same engineering program were created some examples are given below for illustrating the concept further:

a) Mechanical Engineering Diploma with specialization in 'Manufacturing' (machining, casting, forging, fabrication including CAD/CAM)

b) Mechanical Engineering Diploma with specialization in 'Thermal Engineering (Air Conditioning and Refrigeration, Power Plant Engineering)

c) Mechanical Engineering Diploma with specialization in 'Automobile'

d) Electrical Engineering Diploma with specialization in 'Industrial Drives'

e) Electrical Engineering Diploma with specialization in 'Power Systems' (generation, transmission and distribution).

9) To avail the global opportunities of jobs and higher education it is essential that engineering education programs are in tune with Washington Accord for UG programs and Sydney Accord for engineering diploma programs. The National Board of Accreditation (an autonomous statutory body created by Government of India) has brought in the criteria for accreditation in line with these international accords [7]. The cardinal feature of these accords are that the engineering education should be 'outcome-based' by which 'program outcomes' and 'course outcomes' are in observable and measurable terms to be implemented and assessed in such a way that students are able to achieve these outcomes by the time they graduate.

In this backdrop, it became essential to design a curriculum based on competency (or outcome)-based education. This design rendered the curriculum to be explicit and understood equally well by all stakeholders to gauge its depth and scope in the same spirit as envisaged by the curriculum designers. However, the competency-based education requires that students should be given enough time and work-based learning opportunities to hone the all the skills in all the three domains of learning (i.e. cognitive, psychomotor and affective) and to integrate them holistically while performing in real life situations [3]. To meet these requirements the core team evolved a design to accommodate this time and space requirement within the curriculum, which was a major, but interesting challenge.

V. GUIDELINES FOR INNOVATIVE CURRICULM

In the backdrop of the discussions thus far, some guidelines and criteria for this innovative curriculum design for engineering diploma programmes were evolved which are stated in this section. Few of the terms used by the Indian industry are adapted in this curriculum design. The term 'competency' is the one which the industry generally uses for the 'observable and measurable' abilities required in the engineers and there will be several for each occupation. The term 'outcome' is what educationists and curriculum design team also used in the educational context to separate them out in different domains of learning:

a) Curriculum to be outcome-based where competencies / program outcomes and course outcomes are measurable.

b) The competencies/program outcomes to be based on the needs of the industry.

c) The course outcomes emerging out of the competencies/program outcome not only ensures its achievement, but also lead to the identification of the topics and sub-topics.

d) Foundation courses such as 'Physics', 'Chemistry', 'Mathematics', 'Engineering Drawing' and 'Engineering Workshop's to be program specific. Even if the course name may remain the same, course code will differentiate them. For example, separate courses to be created on engineering workshop for civil, electrical and mechanical engineering programs.

e) Tutorial classes for key and difficult courses such as 'Mathematics', 'Engineering Mechanics', 'Electrical Networks', 'Strength of Materials', 'Theory of Machines' and others were envisaged.

f) Provisions to be in place for micro, mini and major projects, problem-based learning, seminars, and internet-based assignments to develop technical and generic competencies in students. These activities to be undertaken by students in self directed learning mode and teachers to function only as facilitators so that students develop lifelong learning skills.

g) Space to be created in the curriculum for tutorials and self-learning activities by eliminating obsolete and trivial topics.

h) The number of advanced courses to be reduced or kept as optional courses so that sufficient space is created to develop the core technical and generic competencies necessary for that occupation/program.

i) In the final two semesters, students to choose a particular stream for specialization within the concerned program wherein three advanced courses are to be offered.

j) Students also to choose their major project from the same stream to ensure development of competencies in the area of specialization.

k) For accommodating certain advanced courses, only awareness level courses of important streams of the concerned program to be included in the curriculum in the final two semesters.

l) The curriculum to include the instructional strategies, detailed list of learning resources - books, software, websites, equipment and instruments with broad specifications; so that every stakeholder is able to implement the curriculum in letter and spirit.

m) The assessment scheme for each course to be well defined for progressive and end-of-the-term examination. Specification table for assessment of course outcomes related to the cognitive skills to be included.

n) The course outcomes ensuring the achievement of the competency/program outcome related to the psychomotor domain to be well defined in the form of practical exercises matching with outcomes to be listed starting with 'action verbs'.

VI. CURRICULUM DEVELOPMENT PROCEDURE

Based on the discussed guidelines, the 'NITTTR-GTU Engineering Diploma Curriculum Development Model-2012' illustrated in Fig.1 was adapted as explained below:

During phase-1 (see Fig.1), in consultation with few industry experts a team of experienced engineering teachers and the NITTTR core team designed twenty-five questionnaires containing the lists of competencies for twenty-five different occupations. In these questionnaires respondents were asked to rate the competencies on a scale of 1 to 5 depending upon their relevance. Information regarding latest materials/ machines/methods and software being used in the industry was also asked.

In phase-2, to validate the identified competencies, the questionnaires were administered to 600 industries both of the MMS (Manufacturing, Marketing, Service) type as well as R and D (Research and Development) type across the state of Gujarat. These were then statistically analyzed to rank the competencies relevant to the 25 engineering diploma programs. Based on these rankings competencies were classified as essential, desirable and trivial. It was decided to have courses related to essential competencies as core courses while courses required for desirable competencies as part of optional courses.

Based on the analysis in phase-2, program structures for the 25 engineering diploma programs were formulated in phase-3, which also involved sequencing of the courses, allocation of credits and marks to each course in the respective program, and balancing the various courses for a holistic outlook. The title of units to be included in each course was also decided at this stage so that an overall picture of the topics to be included in each program emerged, ensuring that nothing important was missed out or nothing trivial was added. These program structures were then displayed on GTU website for suggestions/comments from the stakeholders, on the basis of which the program structures were finalized. This whole exercise was undertaken through a series of workshops.

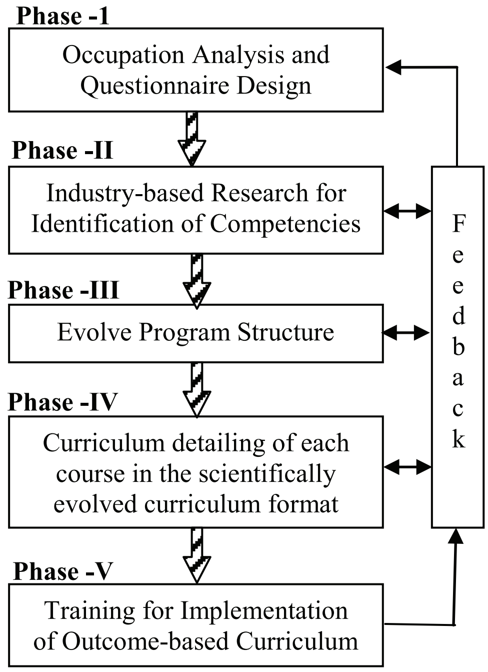

Fig. 1.'NITTTR-GTU Engineering Diploma Curriculum Development Model -2012'

The most time consuming exercise was phase-4, wherein each course was detailed out in a format (discussed in section VII) developed for this design. This was a massive exercise in which tens of teachers sat through a number of 3-day workshops spread over several weeks to develop each course (totaling around 700 courses for 25 programs) curriculum. The subject expert teachers were first trained by NITTTR core team to address all the issues discussed in the preceding sections in developing the course details. Then each developed course curriculum was edited and validated by NITTTR experts.

In phase-5 the engineering and science teachers from various regions of the state of Gujarat who were involved in the various curriculum development workshops of the various courses became resource persons to train the other teachers from different institutes of the state in the implementation of this innovative curriculum in letter and spirit.

VII. Curriculm Development Format

In order to fulfill the guidelines of the outcome-based curriculum and to develop the industry specific competencies and associated skills, 10-point curriculum detailing format was evolved, the sub-heads of which are given below (details available at GTU website):

1) Rationale

2) Competency (Programme Outcomes)

3) Teaching and Examination Scheme (Example)

Teaching Scheme			Total Credits	Examination Scheme				
				Theory Marks		Practical Marks		Total Marks
L	T	P	C	ESE	PA	ESE	PA	150
3	2	2	7	70	30	20	30	

Legends: L-Lecture; **T** – Tutorial/Teacher Guided Student Activity; **P** - Practical; C – Credit; **ESE** - End Semester Examination; **PA** - Progressive Assessment

4) Course Details (Example)

Unit	Major Learning Outcomes (course outcomes)	Topics and Sub-topics
Unit – I Transducer Basics	1a. State the basic requirements of transducers	1.1 Basic requirements of transducers
	1b. Describe the static characteristics of transducers	1.2 Static characteristics - accuracy, precision, error,
Unit– II		

5) Suggested Specification Table with Hours and Marks

Unit No.	Unit Title	Teaching Hours	Distribution of Theory Marks			
			R Level	U Level	A Level	Total
I		06	08	06	00	14
II						
III						
IV						
V						
	Total	42	12	46	12	70

Legends: R = Remember; U = Understand; A = Application and above levels (Revised Bloom's taxonomy)

6) Suggested List of Practical Exercises (Example)

S. No.	Unit No.	Practical Exercises (Course Outcomes)	Hours
1	III	Test thermocouple	2
2	III	Test the RTD	2
3			

7) Suggested List of Proposed Student Activities

8) Special Instructional Strategy (If any)

9) Suggested Learning Resources

A. List of Books with authors and publishers

B. List of Major Equipment/ Instrument with Broad Specifications

C. List of Software/Learning Websites

10) Course Curriculum Contributors

VIII. Conclusion

One uniqueness of this experiment is that it is being developed and implemented in real time as seen on the GTU website: http://www.gtu.ac.in/syllabus/NEW_DE_SchemeSyllabus.htm Another feature is that the formative evaluation is being undertaken (see Fig.1) and the informal feedback from the stakeholders is quite encouraging. Still another feature is that the self-directed and e-learning by the students is built into the design. Other features can be considered at the presentation. A formal impact study will also be undertaken soon.

Acknowledgment

Authors are thankful to Prof. Akshai Agarwal, Vice-Chancellor, GTU for his trust and confidence in NITTTR, Bhopal, by assigning this task and the respective Deans and program committee members for their whole hearted co-operation at various levels. The authors are also thankful to GCCI (Gujarat Chamber of Commerce and Industries) who provided help in getting necessary data from the 600 industries belonging to different sectors in the state of Gujarat. The authors would also like to bring on record, the support of the Office of Commissioner of Technical Education, Government of Gujarat state for extending the resources required for this massive task.

Women in Computing

A Case Study About Kuwait

Rehab El-Bahey, Amir Zeid
American University of Kuwait,
relbahey@auk.edu.kw, azeid@auk.edu.kw

Abstract— **Female under-representation in the field of computing has been a global concern. According to recent research studies in the US, females are less likely than males to consider a career or a degree in computer-related fields. Opposite trends have been appearing in other parts of the world showing a high female turnout in computer studies. One of those countries is Kuwait, a small country situated in the Persian Gulf. According the UNESCO Institute for Statistics, the percentage of female graduates in tertiary education in Kuwait has reached 69% in 2009 (80% in science related disciplines). Female undergraduate enrollment in computing studies in Kuwait is in the range of 40 to 50 percent, which is considerably high compared to other parts of the world. In this paper, we present a case study about women in computing in Kuwait, through which we highlight their motivations for studying computer science and information systems. A survey was conducted among male and female university students in Kuwait about attitudes and perceptions on females in computing and reasons for joining computer studies. The results were analyzed and compared to similar studies in the US.**

Keywords—gender issues in computing; Kuwait; socio-cultural influences

I. INTRODUCTION

The difficulty to attract females to the computer science (CS) field has been a long standing problem around many parts of the world, especially the United States. In 1995, females comprised only 28% of those awarded CS bachelor's degrees in the United States. This percentage has even shrunk to 21% by 2006 [1] leaving a question lingering over the reasons behind this gender gap. Research studies have revealed a number of interrelated factors contributing to the declining representation of females in the field of computer science worldwide. These could include sociocultural, pedagogical, and psychological factors. However, the way these factors operate and interact with each other could differ from one culture to another [2].

A number of studies comparing women representation in CS across different nations have highlighted cultural factors as major contributors to the existing gender divide in those nations [3]. Arab countries, however, have not yet been included into those studies, up to the authors' knowledge. This research paper is an initial attempt to understand the perceptions of Arab students about computers and computer studies.

Initial secondary data in the Arab world show that the last few years are witnessing an increased demand for CS education and careers across many countries of the Arab world. Reasons and explanations behind this increased demand are yet to be studied.

Kuwait is one of those countries witnessing a rise in women participation in the field of CS. In order to understand the circumstances surrounding this fact, it is pertinent to examine the educational environment in Kuwait. This will be highlighted in the following section.

The rest of this paper is organized as follows:

- Section 2 includes country background and research environment.
- Section 3 includes a literature review of similar research in different parts of the world.
- Section 4 introduces the research idea and methodology.
- Section 5 includes results of the conducted surveys.
- Section 6 includes discussions and analysis of the findings.
- Section 7 concludes the paper and recommends areas of future research.

II. COUNTRY BACKGROUND AND RESEARCH ENVIRONMENT

A. *The Educational Environment in Kuwait*

Kuwait is a small country situated in the Persian Gulf and is part of the Gulf Cooperation Council [GCC] that incorporates: Bahrain, Kuwait, Oman, Qatar, Saudi Arabia and UAE [4]. With a 40% expat population, the government of Kuwait is working hard to encourage local employment and to generate qualified local caliber. Within this context, the Kuwaiti government is reinforcing educational reform at all levels [5].

Unlike most private schools in Kuwait, the public schools are segregated by gender starting the first grade. The gender segregation law has been recently amended to include also private and public higher education institutes including, the American University of Kuwait (AUK), which will be part of this study. By means of the new law, all private universities/colleges and branches of foreign universities started to apply gender segregation in all departments, disciplines and students activities [6].

B. The IT Employement Market in Kuwait

Employment in governmental organizations in Kuwait is considered the most prestigious and income generating employment option. Within the IT job market, computer engineers are the most demanded and come at the top of the pay scale [7]. Computer scientists, however, do not fall within the same category with computer engineers. So, students choosing between both majors would sometimes prefer computer engineering for being the most employable choice. Since computer engineering is offered only in one governmental and one private university in Kuwait, students enrolled in other universities may consider computer science as an alternative. This will be manifested in the results of our study, at a later stage of this paper.

C. Status of Women in Kuwait

Despite the ongoing debate around gender segregation in schools, Kuwait remains among the top performers in the Arab Region when it comes to narrowing the gender gap and empowering women. According to the Global Gender Gap Report 2012 [8], Kuwait ranks 2nd in the Arab world (after the United Arab Emirates) on the Global gender gap index.

Kuwaiti women comprise 70% of university students and 40% represent the Kuwaiti workforce. They are present in all professional fields including Education, Medicine, Business, Journalism, Banking and the Government Sectors.

According the UNESCO Institute for Statistics [9] , the percentage of female graduates in tertiary education in Kuwait has reached 69% in 2009 while the female tertiary graduates as percentage of all graduates in science has reached 80%. Interestingly, 37.1% of science researchers in Kuwait are women [6].

According to 2011 Kuwait Private Universities Council (PUC) records, women enrolled in undergraduate CS and information systems (IS) majors in some private universities in Kuwait has exceeded 50% [6], which is considerably high compared to other parts of the world. This raises a question on how Kuwait females develop interest in computer studies; and whether this is related to socio-cultural and pedagogical factors.

In this paper we attempt to answer these questions though understanding the difference between males and females when it comes to their relationship to computers and technology. At this stage of our research, we do not aim to develop hypotheses. The initial results will rather help set direction for future research through underpinning the factors that have greatest influence on females' attachment or detachment from computers and technology. Furthermore, our observations can help adjust "pedagogical, administrative, and social methods aimed at both attracting and retaining women students" [10].

III. LITERATURE REVIEW

Due to its multidisciplinary nature, the field of females in computing has received attention by scholars in various fields, including computer science, education, and women studies [10]. Research efforts in this area can be summarized under four main domains:

- Trying to identify the misperceptions about female abilities in computing [10, 11].
- Analyzing male and female intrinsic interest in computers and computing [12].
- Investigating decision making and motivation [10] to study computer among both genders.
- Examining solutions to generate more interest in computing among women [13, 14, 15].

A. Misperceptions About Females And Computing

- Evidence shows that both females and males believe that that males have better computing abilities than females [16, 17].
- A "Biased social environment" nurtures the assumption that computing is predominantly a male field [12].
- Due to stereotyping, a gap exists between women's perceived abilities and their actual performance. Once they start studying CS, female students realize that their performance is better than what they expected [10].
- CS students are perceived to be geeks, socially uninvolved, "have a single-minded focus" and no interest in social activities. These stereotypes deter females from studying computing [10].
- Research shows that linking success to ability instead of effort may lead to disappointment and withdrawal from the challenge. Counting on effort and hard work creates a momentum to continue and go through the challenge [18]. So females should never define their relationship with studying computing in terms of ability or inability.

B. Decision Drivers And Actual Performance

- Motivation to enrolling in CS varies among different cultural groups. American students make their choice based on passion, while other nationalities studying in the US base their decision on pragmatic reasons, like potential careers [11, 12].
- Non-American students, especially those from Asian countries, believe that hard work, rather than ability, is the driver for success in computing [10, 11]
- It is important that students and faculty understand that motivations for studying computing can change "from pragmatism to intellectual pleasure" if the experience is rewarding and engaging [11].

C. *Interest In Computing*

- Males perceive computers in the context of gaming, fun, software architecture. They have interest in computers as appealing objects and in computing as a process [10, 11].
- Females appreciate the fun aspect of computers but focus more on their broader uses and utilitarian aspects [10, 11] .
- Family has a significant role in shaping male and female interest in computers at an early stage [10].

D. *Proposed Solutions*

Introducing single-gender classes was one of the proposed solutions to generate female interest in computing [13, 14, 15, 19]. In Kuwait, observing performance in single-sex versus co-ed classrooms, single sex classrooms showed better performance among both genders [13]. In their study about Mauritius, Adams, et al. [15] relate the high representation of women in computer science to the separate gender education at Mauritian high schools, which "permits Mauritian women to discover their academic strengths and weaknesses in an environment that is separate from (but equal to) that of Mauritian men" [15]. Similarly, some experiments have proven that introducing female-only computing classes within a co-ed environment could be a good strategy for increasing male and female interest in computing studies [20]. Implemented in Sweden, this idea proved to be successful in attracting and recruiting more women in the field of computing [21]. In Malaysia, studies show that females outnumber males in the field of Computer Science [22]. The study aimed at showing if Malaysian males and females perceive CS in the same way. The study shows that both genders enjoy CS and feel prepared for the programs at the same level [22]. The case in Kuwait may be similar since the number of females is relatively high in CS.

Other research studies focused on administrative and pedagogical strategies to boost female confidence in their abilities. Fisher [10] noted that females "prefer to learn about computers in a purposeful context." Developing curricula in line with this philosophy may engage females' interest in computing [11]. A recent study conducted in Kuwait [13] shows that females tend to be more engaged with programing when assigned projects serving female interests, like fashion, children, or household.

In light of the forgoing literature, we attempt in this paper to explore the perceptions and misperceptions about the field of computing among males and females in Kuwait. We also aim to identify the key factors that attract females to computing.

IV. METHODOLOGY

A. *Procedure*

A survey was conducted among a small sample of male and female students from public and private universities in Kuwait. The survey was administered online through Survey Monkey (an online surveying and analysis tool). Referral sampling techniques were used, starting with at least two students and one professor from each participating university. To boost the sample, personalized emails were also sent to CS and IS students in some universities. In addition, university Facebook pages were used to call for participation in the survey.

B. *Sample*

The sample consisted of male and female subjects with the following profiles:

- Students majoring in computer science (CS) and information systems (IS) (drawn from private and public universities in Kuwait).
- Fresh graduates of both CS and IS employed within the fields of CS or IS.

C. *Tools*

A questionnaire was developed to measure two parameters:

- Male and female attitudes towards computer science and Information Systems
- Male and female decision drivers for studying CS & IS.

The questionnaire consisted of two sections; a set of closed ended categorical questions, and a set of even-point Likert scale questions. The first section of the questionnaire aimed at discovering the reasons behind joining the field of computer science. The list of choices provided was based on the results of exploratory focus groups and one-on-one interviews conducted among USA and Kuwait CS female students.

The second section of the survey aimed at discovering the attitudes and perceptions of computing through a 4-point Likert scale. The survey questions were adapted from the Wiebe, Williams, Yang and Miller instrument [23], which was based on the Fennema-Sherman mathematics attitude scale [19].

Mid-point responses have been omitted from the Likert scale. This has proven useful in attitude questions as it helps avoid social desirability, arising from the inclination to choose middle ground responses [24]. Reverse scoring was applied to negative questions to maintain consistency. We only used questions addressing the gender construct, which serve the purpose of our study.

D. *Responses*

The study rendered 65 responses, which is a sufficient number considering the following reasons:

- The number of computer science students across Kuwait does not exceed 300 students.
- The survey is not intended to provide quantitative statistical data. But rather, to identify parameters that need future investigation.

V. KEY FINDINGS

A. Reasons for Studying Computer Science/Information Systems

Fig. 1 reflects the motivations of both males and females for joining CS/IS majors. The reasons mentioned most frequently were career and future considerations, followed by the best alternative for Engineering and government scholarships. Other reasons, related to parent advice or interaction with friends or professors rendered lower scores. Interest in computers/videogames/programming was a common answer in the open ended part of the question that was left open for "Other Reasons". This has been added to the graph below for the sake of comparison.

Male and female scores came very close on most of the reasons, with a slightly higher male reference to career related reasons. The two reasons which were totally dominated by males were Interest in computers/videogames/ programming; and Interaction with CS/IS friends.

B. Attitudes Toward Females In Computing

The attitude question (Fig. 2, 3) is evenly split into 4 positive statements and 4 negative statements. Statements were given a score from 1-4 based on a Likert scale (where 4 corresponds to "Strongly Agree" and 1 corresponds to "Strongly Disagree"). As indicated in Fig. 2 positive statements about females in computing received high scoring, while negative statements received low scoring. The statement that remained clearly in the middle zone was "*It makes sense that there are more men than women in computer science"*.

Fig.3 shows the same results broken down by gender. Females scored higher than males on all positive statements, while males score higher than females on all negative statements. Both genders showed a clear disagreement on the statement: *It is hard to believe that female could be a genius in computer science.* Relevance and indications of these results will be discussed in the next section of this paper.

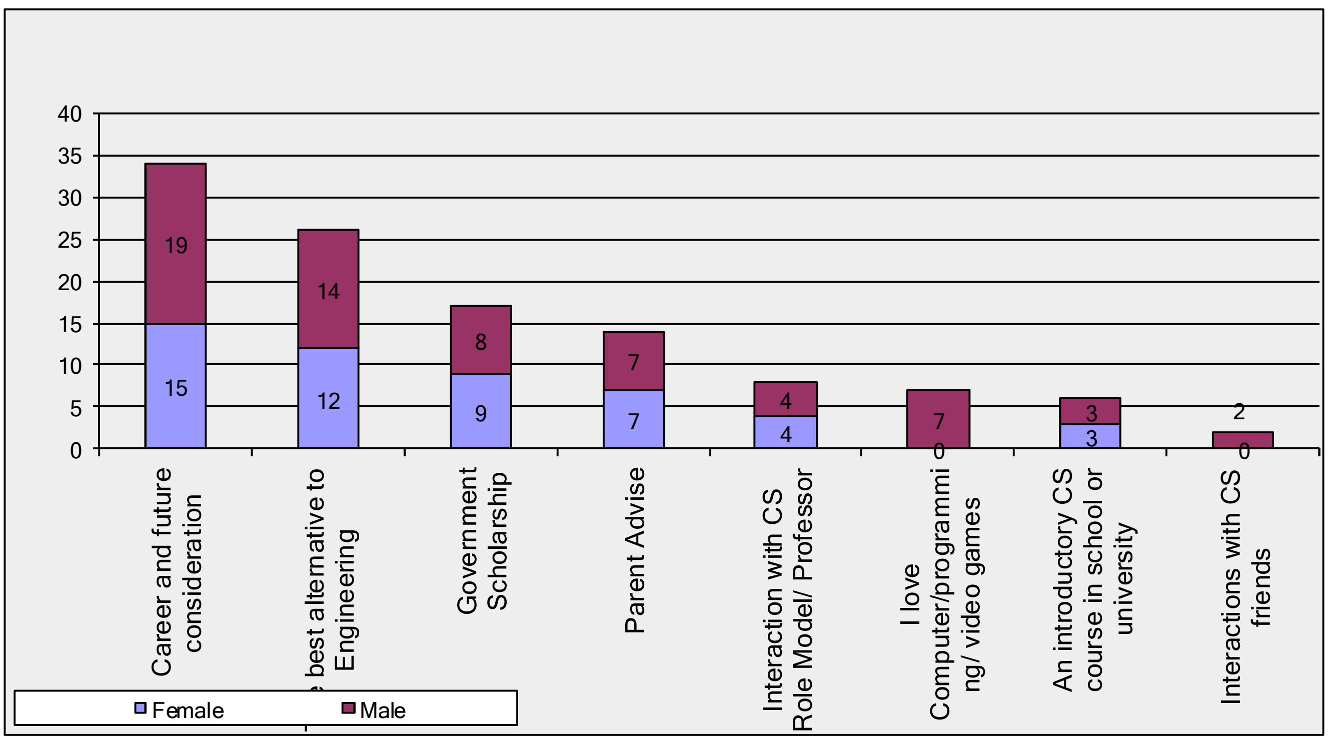

Fig. 1. Reasons for joinging Computer Science/Information Systems

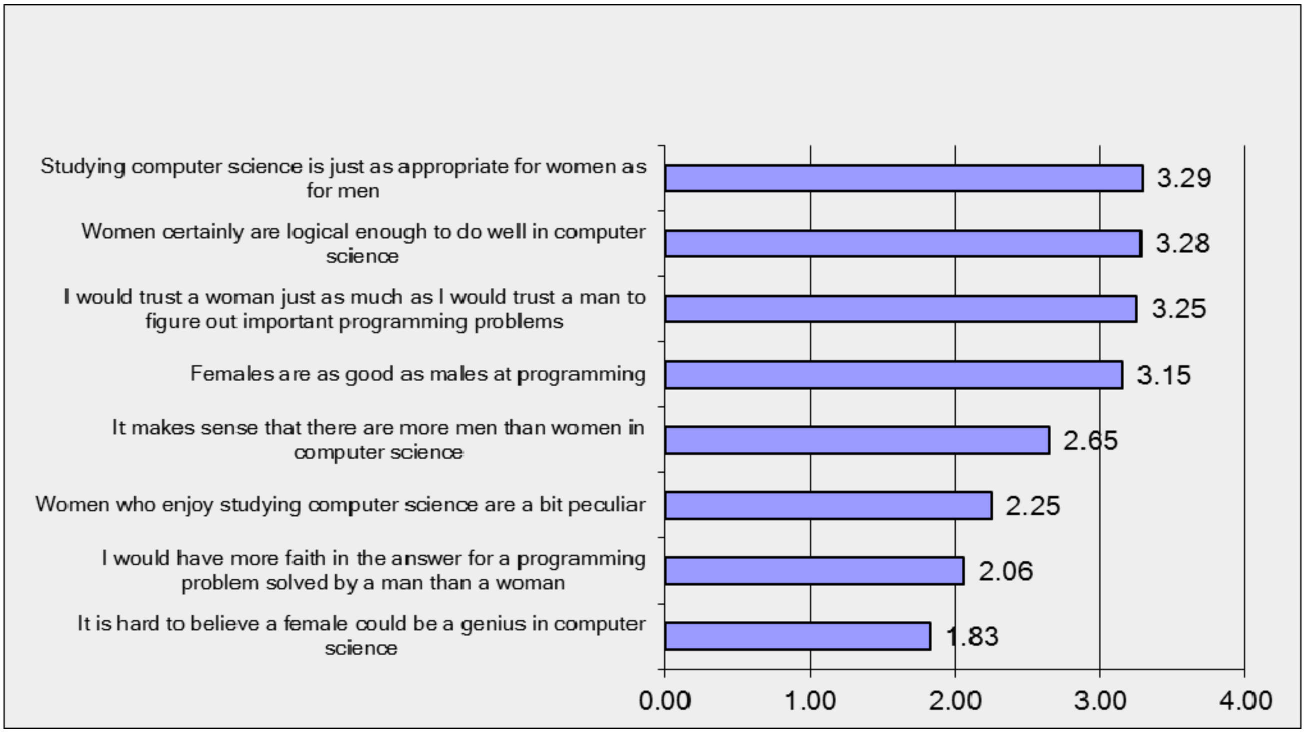

Fig.2. Attitudes and perceptions about females in computing

Fig. 3. Attitudes and perceptions about females in computing – males vs. females.

VI. DISCUSSION

In light of the findings shown in the previous section, we may assume that both males and females based their choice of CS/IS on more pragmatic factors (career and government scholarships) rather than interest in the field. Socio-cultural factors (role models, peer influence, or parent advice) were not among the top influential factors. It is surprising to see such a result, especially in a collectivist society like Kuwait, where social conformity and peer influence play significant roles in shaping people's preferences [25].

Whereas the scores of both gender closely match on most of the reasons for studying CS/IS, it is interesting to see that reasons related to passion with computers and programming were associated with males. Although, it scored lower, peer influence was a factor mentioned only by males.

When comparing Kuwait to the US (Table 1), females in both countries show common motivations for choosing CS/IS. This is not the case with males, whose results imply more inclination to pragmatic factors in Kuwait.

Moving to the attitudes and perceptions, the overall results in Fig.2 indicate that perceptions about females in computing were positive among both genders. However, by examining the detailed graph in Fig. 3, we noticed some gender bias in both positive and negative attitude statements.

As the figure indicates, males scored lower than females on positive attitude questions and higher than females on negative attitude questions. This indicates that the negative perceptions against females in computing are higher among male respondents. However, these perceptions do not have a significant effect on the overall average due to the high number of female respondents, approaching 50% of our sample.

As this figure increases, females' confidence in their abilities eventually generates more interest in the field. This relationship between confidence and interest has also been noted by Margolis et al. [12]:

> *"Our research identifies a "chicken and egg" problem that affects a female student as she thinks about her interest in computer science: ..is it lack of interest due to lack of confidence? Or is it lack of confidence due to lack of interest? It is hard to disentangle one influence from the other, to know how they interact"*

This relationship does not only exist within the CS female student population, but is also projected to the male students. From our results, we can contentedly claim that negative male attitudes toward females in computing still exist but they are being diluted by the increasing number of females joining the field. The balance that is starting to happen between the numbers of females and males in CS/IS in Kuwait is automatically limiting the effect of negative stereotyping that turns females away from computing in other parts of the world. Research on stereotypes strongly supports our conclusion. Recent studies demonstrate how "stereotypes, even those that people are not consciously aware of, can influence the careers of women and minorities" [25]. According to these studies, stereotypes can also bring down the "self-esteem, motivation, and intellectual performance of women and minorities through a process called stereotype threat" [25].

TABLE 1: DRIVERS FOR MAJORING IN COMPUTING- KUWAIT VS. USA

Categories	**Primary Drivers for majoring in CS/IS**	**Other Motivators**
USA Males	Intrinsic interest in computers	Introductory Classes Peer influence
KWT Males	Promising career Best alternative to engineering Government scholarships Intrinsic interest in computers and programing Parent advise	Interaction with role models Introductory classes Peer influence
USA Females	Promising career Interaction with role models Parent advise	Intrinsic interest
KWT Females	Promising career Best alternative to engineering Government scholarships Parent advise	Interaction with role models Introductory classes

VII. CONCLUSION

Putting it all together, we can say that the increasing percentage of females in CS and IS majors and professions in Kuwait might have been initially triggered by governmental incentives and openness of the job market. Over the past few years, the established presence of females in the field has created trust and confidence in their abilities among their gender group as well as their male counterparts. This, in turn, has eliminated the effect of negative stereotyping that turns off females in many other parts of the world.

Motivations to join computing among Kuwait males are very different from those of US males. The former group has pure pragmatic reasons, while the latter group has intrinsic interest in the process of computing. In females, the difference is not significant. Both Kuwaiti and US females choose computing for pragmatic reasons or socio-cultural influences.

Research on motivation gives us ideas on how pragmatism can change into intellectual pleasure through a rewarding experience. Creating a new female territory in the world of computing can get females more interested and engaged in the field. This can be done by remodeling educational curricula or introducing female-only classes. Research into this area and its cultural adaptations is still at an early stage. More research and case studies are needed to investigate the best practices in establishing female-friendly computing environments in both academia and industry.

Preliminary Analysis of an Appealing Program for Outstanding Students at the School of Design Engineering (ETSID) of Valencia

E. Ballester, L. Contat, L.M. Sánchez Ruiz
Escuela Técnica Superior de Ingeniería del Diseño (ETSID)
Universitat Politècnica de València, Spain, lmsr@mat.upv.es

Abstract— **During the 2010/2011 academic year, the Universities of the Valencia region (Spain) started up a pioneer experience in Spanish Higher Education: the High Academic Performance Groups (in Spanish, the so-called ARA groups "Grupos de Alto Rendimiento Académico") aiming to support and attract the brightest students with the best skills, so that they can achieve a high academic performance.**

The Universitat Politècnica de València (UPV), as a result of its commitment to promote its quality and internationalization, has taken part in this project from the dawn of its implementation. Since then, ARA groups have been set up in five of the UPV Bachelor Degrees, two of them being offered at the School of Design Engineering (ETSID). In this work, we analyse the implementation process of the ARA groups at ETSID since 2010/2011, outlining some of the future strategies that should be taken into account for their consolidation.

Keywords: academic performance; engineering education

I. Introduction

During 2010/2011, the Regional Government of Valencia (Spain), in collaboration with five the public Universities of this region, started up a pioneer experience in Spanish Higher Education: the High Academic Performance Groups (in Spanish, the so-called ARA "Alto Rendimiento Académico" groups) [1].

The purpose of this ARA project is to support and attract the brightest students with the best skills [2-4], so that they can achieve a high academic performance [5], thus promoting their training as highly-qualified professionals.

In order to make this program appealing to students, some complementary activities and specific curricular benefits have been included in the educational offer of these ARA groups from the very beginning such as:

a) At least 50% of the core subjects are taught in English.

b) Participation in these groups is included as a major in the Diploma Supplement [6] (accompanying European higher education diplomas).

c) Participation in these groups is taken into account for mobility grants.

Moreover, during each academic year, seminars for the development of transversal competencies, lectures by renowned experts and visits to relevant companies are offered to ARA students.

Obviously, students aiming to join an ARA group must have a good academic record and a good command of English.

The Universitat Politècnica de València (UPV), as a result of its commitment to increase its quality and promote internationalization [7], has taken part in this project from the dawn of its implementation.

Since then, ARA groups have been set up in the following UPV Bachelor Degrees: Business Administration and Management, Biotechnology, Computer Engineering, Aerospace Engineering, and Industrial Electronics and Automation Engineering, these two latter being offered at the School of Design Engineering (ETSID) [8].

In this work, we focus on the analysis of the implementation process of the ARA groups that is being carried out at ETSID since 2010/2011.

We also outline the future strategies that should be had in mind for the consolidation of these ARA groups at ETSID, based upon the English proficiency of the students of these groups and the evolution of their academic performance, compared to other groups of the same year and degree.

II. Description

This preliminary analysis on the academic performance of the ARA groups has been performed on the basis of the grades percentage and the following average overall rates:

Performance rate = (nº pass students / nº enrolled students) x100

Fail rate = (nº fail students / nº enrolled students) x100

Dropout rate = (nº dropouts / nº enrolled students) x100

In particular, this analysis aims at comparing these indicators between first-year students of the ARA and non-ARA groups of the ETSID Bachelor Engineering (BEng) degrees in Aerospace Engineering, and in Industrial Electronics and Automation Engineering, during the first two consecutive years of implementation of these innovative groups (Table 1).

TABLE 1. Enrolled students in the first-year of the ETSID BEng degrees.

	2010/2011		2011/2012	
BEng Degree	ARA	Non-ARA	ARA	Non-ARA
Aerospace	94	-	44	63
Ind. Electronics & Automation	36	133	40	117

"Vicerrectorado de Profesorado y Ordenación Académica" of the Universitat Politècnica de València (Spain)

III. RESULTS

ARA groups were first implemented during the 2010/2011 academic year.

During this year, in the degree in Industrial Electronics and Automation Engineering, the newly created ARA group co-existed with traditional non-ARA groups, due to the large number of students that happened to be enrolled in this degree (Table 1).

In contrast, in the Aerospace Engineering degree no other groups were offered apart from the ARA group.

During this first implementation year, only 50% of the core subjects were taught in English in both ARA groups at ETSID.

And in order to be able to join an ARA group, a B2 English level (according to the Common European Framework of Reference for Languages, CEFR [9]) was strongly recommended for students, but not mandatory.

On the other hand, the fact that registration was performed according to admission grades to university ensured that all ARA students had a good academic record.

This good academic record was especially true in the Aerospace ARA group where, in addition, all the students accessing this degree are A-B levels.

Academic results during 2010/2011 revealed a higher performance rate and a lower dropout rate in the Electronics ARA group than in the other first-year groups of this degree (Table 2). This improvement approaches 3% for both rates.

In what concerns the Aerospace ARA group, the academic results were also found to be good during this first implementation year, displaying a performance rate close to 95% and fail and dropout rates lower or equal to 3% (Table 2).

However, some problems were detected in this ARA group concerning the appropriate follow-up of the subjects taught in English, by the students with a poor command of English.

Consequently, the following improvement proposals were raised for the implementation of these ARA groups during the 2011/2012 academic year:

a) Both degrees should offer the possibility of engaging either an ARA or non-ARA group.

b) Both ARA groups should extend English teaching to all the core subjects.

TABLE 2. Academic performance in the first-year of the ETSID BEng degrees.

		2010/2011		2011/2012	
BEng Degree	Rate	ARA	Non-ARA	ARA	Non-ARA
Aerospace	Performance	94.7%	-	99.3%	94.3%
	Fail	2.3%	-	0.7%	0%
	Dropout	3.0%	-	0%	5.7%
Industrial Electronics & Automation	Performance	80.0%	77.3%	86.3%	82.7%
	Fail	11.2%	11.0%	11.2%	8.6%
	Dropout	8.7%	11.7%	2.5%	8.7%

As a consequence ARA groups were therefore offered during the 2011/2012 academic year fulfilling the aforementioned guidelines.

Once again, a B2 English level [9] was strongly recommended, but it was not considered to be a mandatory condition for any student willing to join an ARA group.

Nevertheless, during the first semester of the 2011/2012 academic year, all first-year ARA students performed a compulsory English test with the goal of really checking their proficiency in English.

Results of this test revealed that while 95% of the Aerospace ARA students proved to have an appropriate command of English, only 48% of the Industrial Electronics and Automation Engineering ARA students had sufficient English fluency.

From these results, it followed that evidence of a good command of English should be demanded to all the students wishing to join an ARA group.

On the other hand, the analysis of the academic results of the ARA groups during 2011/2012 showed that the performance rate in the ARA groups of both degrees, the BEng Aerospace Engineering and BEng Industrial Electronics and Automation Engineering, was again higher than that corresponding to the non-ARA groups (Table 2).

The average percentage of students who passed was increased in about 5% and 4% in the Aerospace and Electronics ARA groups, respectively.

Moreover, the dropout rate was found to decrease in about 6% in both ARA groups compared with that of the other groups.

However, on average, the percentage of students who failed was somewhat higher in the ARA groups of both degrees, probably as a consequence of the lower dropout rate of these groups.

The analysis of the academic results of this pioneer experience was completed with the determination of the grades percentage for the ARA and non-ARA groups of both degrees (Figs. 1 and 2).

These results showed that, although the overall number of students who passed was higher in general in the ARA groups, as it has been previously described, the number of very good grades (A and B) in the ARA groups of both degrees was just slightly higher to that of non-ARA groups during the 2011/2012 academic year.

And surprisingly, in the case of the Industrial Electronics and Automation Engineering ARA group the number of good grades was even lower during 2010/2011.

Since the ARA project is an innovative experience aiming at supporting the brightest students, a logical consequence should be to have an increasing number of excellent records in the ARA groups.

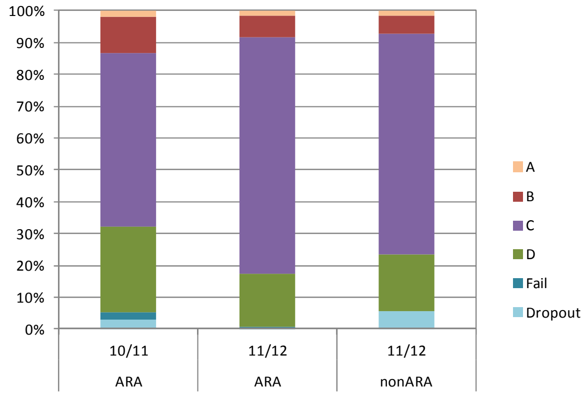

FIGURE 1. First-year grades of the BEng degree in Aerospace Engineering.

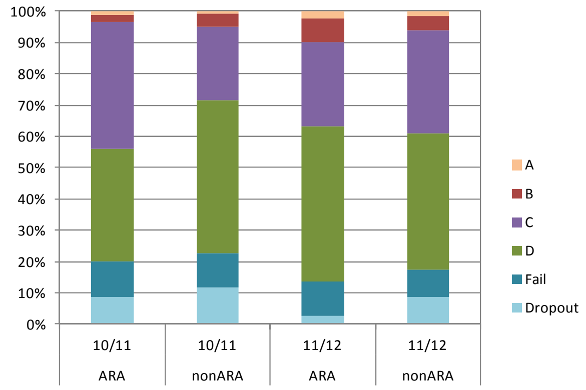

FIGURE 2. First-year grades of the BEng degree in Industrial Electronics and Automation Engineering.

As a result, the following admission requirements were settled for all students feeling like joining to join ARA groups during the 2012/2013 academic year:

a) Applicants should provide proof of their English language proficiency (either through an English level test or an officially recognized certificate).

b) In order to try to improve the academic excellence of these groups, only students who have passed all the subjects may stay in an ARA group during the following year.

c) Excellent students in the non-ARA group and willing to join the ARA group should be allowed to do so at the beginning of their second academic year.

IV. CONCLUSION

This work has provided a preliminary analysis of the implementation process of the innovative ARA groups that is being performed at ETSID since 2010/2011.

In general, academic results of the ARA groups are so far encouraging.

These results have revealed a higher performance rate and a lower dropout rate in the ARA groups, although this in turn seems to have subsequently led to a somewhat higher fail rate in these groups.

Based upon this analysis, initial strategies have been undertaken for the consolidation of these ARA groups that are mainly focused in attracting the brightest students to ARA groups and ensuring a good English command.

In the future, the effectiveness of the adopted strategies will be regularly monitored, thus contributing to the continuous improvement of this program.

In addition, as ARA groups are progressively implemented in subsequent years of study, this analysis will be addressed to second, third and fourth-year students, too.

Introduction of Entrepreneurship and Innovation subjects in a Computer Science course in Brazil

Eduardo Felipe Zecca da Cruz, Alexandre Alvaro
Departamento de Computação de Sorocaba (DComp)
Universidade Federal de São Carlos (UFSCar) – Sorocaba
Sorocaba – SP – Brasil
duhzecca@gmail.com, alvaro@ufscar.br

***Abstract*—The recent changes in the world and in technology present both challenges and opportunities to the computer education, which must be adapted / change to meet these challenges. More and more computer courses strive to include entrepreneurship and innovation in the curriculum. However, integrating entrepreneurship and innovation education in computing curriculum could have a significant effect on the creativity, innovativeness, leadership and entrepreneurial intentions of computing undergraduates. In this way, this paper present a view on teaching entrepreneurship to computer science students and describe an experience in introducing entrepreneurship and innovation in computing curriculum in a computer science course at Brazil.**

Index Terms — Entrepreneurship, startups, education, Brazil.

Introduction

The recent global changes in current world order stands out new challenges and opportunities to the computer science education. The existing environment is very different from one decade ago. The technologies, processes, methods and tools have been changing with the globalization, research and development. New interdisciplinary fields like sustainability, social remarks, bioinformatics and robotics has become reality to the computing and is even more influenced by Communication and Information Technology (CIT) [1].

On the other hand, young people face to several challenges in your lives; the rapid technologic advanced, multifaceted carrier, the life style changes and assume greater personal responsibility for achieving "success" in his personal and professional life. Young people need a higher education background, which will give them the qualities, skills and personality to mitigate the challenges during the professional timeline [2]. In Latin America, the young has a big responsibility to achieve successful and is almost inadmissible fail, whether in choice of profession or in whatever segment [3].

Related to these challenges, the computer industry is one of the most dynamic and it is becoming reality to several different areas. So, the introduction to the entrepreneurship education in computer science curriculum could be significant effect in creativity, innovation, leadership and entrepreneurship intentions to the students. Historically, the entrepreneurship education has fueled the generation of innovation and technological advantages. Therefore, the entrepreneurship education for computer science curriculum significantly increases the ability of the students lifelong and desire to innovate [3].

According to Global Entrepreneurship Monitor [4], the lack of education is the main barrier to the entrepreneurship. The problem in computer science degree is that the curriculum focus in technical lectures instead of complementing with business lectures in order to instigate the business creation during the course. Fry and Leman [5] comment that nowadays the renowned university in US, Europe and China solving this problem introducing lectures in the context of entrepreneurship in curriculum. Additionally, a research about entrepreneurship formal education and preview experience in entrepreneurship related that its increases the self-reliance in students, either to a job in a company as creating your own business [6].

In this context, this paper presents one initiative of computer science degree from UFSCar (Federal University of São Carlos), Sorocaba campus, in development of a lecture about Entrepreneurship and Innovation in CIT (Communication and Information Technology) such as the impact that could be observed during theses 3 years in this lecture. Section 2 shows the related work in literature; Section 3 presents the concepts about entrepreneurship and innovation in CIT; Section 4 describes the teaching methodology; Section 5 presents the main results achieved and lessons learned during this course; and, finally, Section 6 presents the concluding remarks and directions for future work.

Related Work

In literature there are some works that related several universities, mainly in US, Europe and China, trying to promote entrepreneurship and innovation. The initiatives could be mentioned in the following areas: (i) introduce technical abilities with non-technical areas like innovation, entrepreneurship, leadership, communication and business model (Mexico University [7], Arizona State University [8], Florida Atlantic University [9], Zhejiang University at China [10], program together with Hofstra University at EUA and Qatar University [11], State University of North Carolina [12], a set of universities from China [13]); (ii) development of startup acceleration and incubation centers (province of West Java at Indonésia [14]); (iii) achievement of studies in order to identify problems, challenges and case of success in introduction entrepreneurship and innovation in computer

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

courses (Baylor University [5], Polytechnic University of Valencia [3], regional universities from China [15], a set of universities from China [16]).

Additionally, the Stanford[1], the Harvard[2] and the MIT[3] are the main pillars of the entrepreneurship education in US. These renowned universities mix technical with non- technical skills, where the focus is on entrepreneurship, innovation, leadership and merchant areas. From these three universities some startups were created like Yahoo!, Microsoft, Apple, Google, Facebook, among others.

The MIT's programs, although open to students from engineering and science, was centered in Sloan School of Management; the Harvard program's is also allocated in Business School; and the Stanford program's is performed by Engineering School. The MIT and Harvard offers a wide range of courses, looking for introducing management and business techniques based on available technologies. The course uses a variety of teaching methods: study cases, internship, lectures, external evaluations of students task by venture capitalists and hands-on projects. All courses involve teamwork and focus on presentation techniques.

The Stanford Technology Ventures Program (STVP) is hosted by Stanford School of Engineering. It is the main education program on entrepreneurship based on non-technical abilities like merchant opportunities, business, leadership, etc. To do so, the program offers introductory and advanced courses in marketing, financial, strategy and innovation.

In both, the MIT, the Harvard and the Stanford, the entrepreneurship education is part of the formal curriculum and the business activities are funded by the school. In Brazil, a few universities have this kind of initiatives in Engineering or Computer graduation degree. There are three cases that should be mentioned: (i) Federal University of Pernambuco (UFPE), where the students from bachelor's degree in computer science have the option to choose the Entrepreneurship course besides the optative course available; (ii) Federal University of Minas Gerais (UFMG) and (iii) Federal University of Bahia (UFBA), where it is also offers the optative "Entrepreneurship" course in computer science degree. Even so, these courses offer the entrepreneurship and innovation course as optional in curriculum. At this point the case of UFSCar (Federal University of São Carlos) – Sorocaba is different because it is a required course in the curriculum. This may have influence due to the recent creation of the computer science degree in this university (five years ago) and the young teachers who arrived with desire to change the way education is provided.

Entrepreneueurship and Innovation in CIT

Entrepreneurship is the process to start a new business based on a product or a service. People immersed in this process are driven by the desire to innovate and change the way things are done (status quo). The most common stages of a startup are: thinking in an idea, identifying opportunities and feasibility analysis (i.e. validating hypothesis in the market), defining the resources (i.e. people, tools, strategies, etc.), design, development and acceleration of the idea in the market, collect market feedback, improve the product or service, rapid growth and consequent spin-off from startup to the market [11].

In last years, the scientific and technological innovation has established as one of the most important factors to ensure growth, competitiveness and high profitability businesses. There are several evidences for the importance of this issue and many studies support the view that innovation is the key to survival in competitive environments. New processes and products, new business models, creating new markets, attracting and retaining talent or enhance the image before partners, new customers and investors, represent some of the results of innovation.

Moreover, the Information Technology and Communication (ICT) have contributed to institution (public or private) becoming more agile in its processes. ICT can be considered as a way to the process of technology-based innovation, increasing productivity and competitiveness.

However, for a long time Brazil failed to exploit their potential in entrepreneurship and technological innovation. In part because government policy had started to invest in RD&I (Research, Development & Innovation) late, and partly because the education and culture of the people in this area have never been focused as a priority. Public universities in Brazil, which are considered as the main sources of qualified professionals, have no dynamism in the process of formation their students and curriculum changes. This can be seen by the amount of curriculum that is not updated frequently in several educational institutions of the country.

Teaching Methosology

The Pedagogical Project (PP) of bachelor degree in computer science from UFSCar - Sorocaba was developed considering issues such as sustainability [17], entrepreneurship, innovation and business management. The project was developed in compliance with curriculum guidelines determined by the Brazilian Computer Society [18]. Moreover, the PP agenda determines that the student's education should be based not only on technical elements, allowing to work not only as a developer or technology broadcaster, but also as an agent of change the society.

The PP's is designed considering two disciplines in the area of entrepreneurship: Small Business Management, and Entrepreneurship and Innovation in ICT. The first discipline bringing all the basic knowledge necessary in order to the student have notions of managing any business in its initial phase. The second seeks to instigate the entrepreneurial profile of the students aiming to introduce non-technical concepts as a way to complement the technical courses of the curriculum. Thus, the focus of this paper is related to the experiences of the second discipline, which has been conducted since 2010, and so far, three groups have done it and attended almost 200 students.

[1] http://www.gsb.stanford.edu/

[2] http://www.hbs.edu/

[3] http://mitsloan.mit.edu/

The related work (presented on Section 2), mainly considering the experiences at Stanford, Harvard and MIT – references in the entrepreneurship area around the world – and adding the experience of the author of this paper as a spectator, competitor and judge of several startup competitions in Brazil (Brazil Challenge4, Call to Innovation5, Buscapé Challenge6, I2P7, FGV Latin Moot Corp8, Telefonica Wayra9, RBS Entrepreneurship and Innovation10, IG Startup11 and Startup Weekend12) it could be defined a teaching methodology appropriate to the course. The main idea of the course is to encourage and provide a way to the students create startups during the semester. To do that, it was created a startup competition during the course where it is the main scenario of creation, evolution, feedback, development and implementation of student's ideas. At the end, a panel of judges evaluates the projects and the three best may win some kind of award or receive invitation to participate of an acceleration process in one of our partners.

The teaching methodology was detailed in 4 major steps: Theory, Idea Design, Idea Development and Presentation. Figure 1 shows these 4 major steps and related topics during the course.

The **Theory** step aimed at bringing Entrepreneurship and Innovation concepts in order to the students familiarize themselves with the topic: understand what is a startup, what challenges are relevant in the context of Brazil, the expectations of the market, the competition, what techniques are used for creating a startup, and analysis of cases in order to understand all the processes around a successful startup in the market. The sections of a business plan are explored in order to show what an entrepreneur need to worry, considering several business models on the market as a way to illustrate ways to remunerate the business. After that, Lean Startup concepts [19] are presented and compared with the "old model" of creating startups as a way to show how the creation of "agile startups" – failing fast and learning fast – makes sense today. Finally, the concepts of intellectual property were presented as a way to the students understands their rights under the trademarks, patents and software registration considering Brazilian laws and the difference around the world.

The **Idea Design** step shows a set of market trends for startups, both reputable consultancy (e.g. McKinsey, IBM, Trend Watching, ARC Chart, etc.) as renowned investors / persons around the world (e.g. Steve Blank, Guy Kawazaki, Warren Buffet, Steve Jobs, Romero Rodrigues, etc.); and many speakers / entrepreneur from São Paulo, Campinas, Sorocaba region are invited to speak and tell your experiences in his/her startup creation. With this content all students are encouraged to think about any technological-based idea for projects and do pitch`s in 1 minute for the whole room (usually between 30% - 40% have some idea in the room). After all pitch`s, the students have a time to convince other students about your idea in order to join their project team and create the startup co-founder team (up to 4 students). With startup's team composed, the students begin working on the first presentation of the idea, which is based on Guy Kawazaki[13] guide (reference in the area of investment in the U.S.): 5/5/30 - 5 minutes, 5 slides and 30 points. Once done the presentation, students receive feedback from their ideas as a way to start the development. Some videos of entrepreneurs and / or investors are presented as a way to show the challenges, obstacles, failures and successes issues from startups around the globe.

In the **Idea Development** step, the students looking to understanding better all the details necessary for its startup like merchant, business model, competitors, value proposition, differential competitive, among others. Moreover, the students need to define the hypothesis that should be tested in the market, looking for fail fast and learn fast (one of the main premises of Lean Startup principles [19]). For that, they need understanding more about business model.

According to Osterwalder and Pigneur [20], a business model describes the rationale of how an organization creates, delivers, and captures value. To do that, they created a methodology, called Business Model Canvas (BMC), which was composed of 9 areas in order to help the co-founders to obtain a better knowledge of several important aspects of your startup. The areas are: 1. Customer Segments; 2. Value Proposition; 3. Channels; 4. Customer Relationship; 5. Revenue Streams; 6. Key Resources; 7. Key Activities; 8. Key Partners; and 9. Cost Structure. After developed the BMC, each group presents to the room as a way to gather feedback and learn collectively from all BMC's created in the course.

Additionally, a core component of Lean Startup methodology is the build-measure-learn feedback loop. The first step is figuring out the problem that needs to be solved and then developing a minimum viable product (MVP) to begin the process of learning as quickly as possible. Once the MVP is established, a startup can work on tuning the engine. This will involve measurement and learning and must include actionable metrics that can demonstrate cause and effect question [19]. So, the students must define and develop a MVP in order to validate the market and collect feedback as soon as they can. This will help them evolve the product / service that ara proposed, decreasing the elapsed time and money.

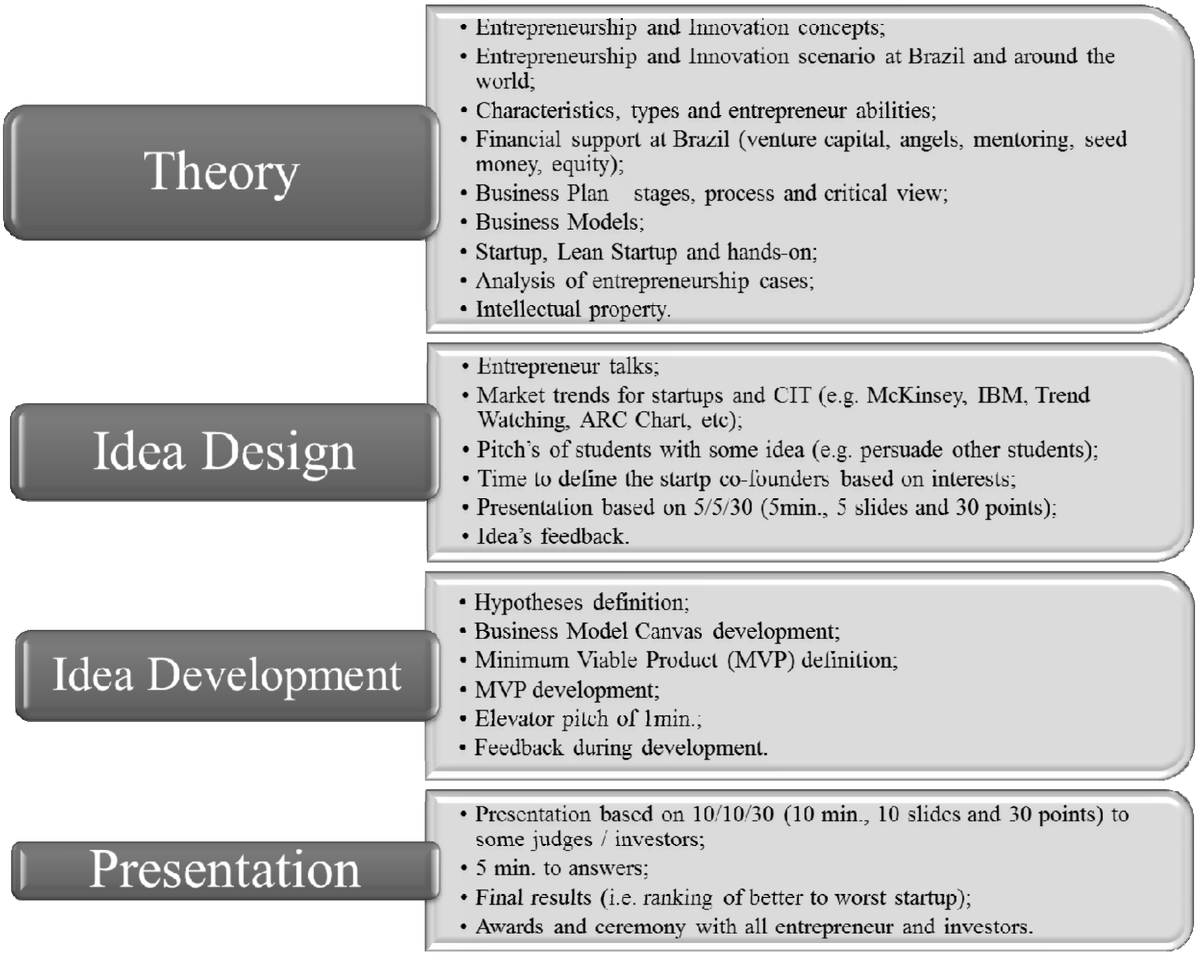

FIGURE 1
TEACHING METHODOLOGY.

At end, the students are encouraged to submit a pitch of only 1 minute; i.e. try to summarize everything they have learned and presents in 1 minute, which is a very difficult and arduous for students however has an impressive result. This video is usually available on Youtube / Vimeo so all students can watch the pitch's in the next classes.

Finally, the **Presentation** step aims to organize a day where all the students will present their projects in 10/10/30 (10 minutes, 10 slides and 30 points) for a panel of judges consisting of up to 6 persons: teacher, one teacher invited from UFSCar – Sorocaba and 4 entrepreneurs and / or investors in the market. The purpose of this day is to assess students regarding your startups to identify those with the greatest opportunity *versus* possibility to leave to the market. So, a ranking of startups is defined and the 3 better are rewarded in some way. In 2010, it was awarded with a pen-drive and digital camera, and in 2011 it was awarded with incubation for 2 months in a partner company and, in 2012 the course finished in February and, probably, the first project will be incubated in Sorocaba city Incubator and the other two will receive an award.

RESULTS AND LESSONS LEARNED

The main expectation of this course, since its inception, was to bring a privileged knowledge to the students of bachelor degree in computer science from UFSCar – Sorocaba, looking for instigate them to create technology-based startups, even if only during the discipline and nothing else. However, some students are more interested in the subject and end up taking the ideas developed during the course forward. In this sense, three ideas extrapolated activities in the discipline and are being developed by students:

- **Brochure:** An iOS app that displays the prices of the products in supermarkets around you (e.g. 20km from you), classifying them by product category. You can get more information of the product and the location of the market. This application was submitted to the Buscapé Challenge "Your Idea Value 1 million." This app was not selected however there was an idea selected that is 90% equal to this in more evolved stage of development[14]. So, the students are developing the

[14] http://www.meucarrinho.com.br

final version of this product in order to put it online to download in Apple Store.

FIGURE 2
BROCHURE PRINT SCREEN.

- **EcoManager**: A web system that intends to perform the solid waste management of a city. This system has to meet the government's determination through the National Policy on Solid Waste, which every city must manage their waste properly until 2014. This project won the Award of Greenpeace Challenge for Smart Cities[15]. Now, the students are finishing its first version in order to put in a city hall of Sorocaba in beta test.

FIGURE 3
ECOMANAGER PRINT SCREEN (*in portuguese*).

- **Flagging**: An android app that manager the "hot points" of a city. The users can check-in a place near his/her (e.g. 10km) and say if it is good or not. Based on that, the point in the map above increase or decrease. So, everyone could identify the hot points (i.e. restaurants, bars, clubs, etc) that are good to go or not to go now.

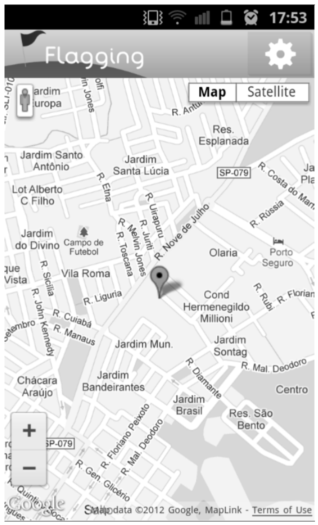

FIGURE 4
FLAGGING PRINT SCREEN.

Still on, a group of four students became interested in the area and initiated the creation of the Junior Company from computer science course at UFSCar – Sorocaba. In the 2nd half of 2011, one of projects of the course was the creation of the Junior Company, creating your business plan, statute and selecting students to operate the startup.

Furthermore, since 2010 it was applied a survey in order to understand the impact of this kind of course into the life of the students. Now it will be presented the composition of the 3 last surveys applied to this course which totally 182 students answered. Additionally, the answers were anonymous which do not intimidate them to answer the survey.

First, it is intends to know what is the knowledgement in entrepreneurship area from the students. Figure 5 show that 59% of the students don't have any knowledge in the begging of the course. Actually, this shows the Brazilian entrepreneurship reality once the entrepreneurship bubble has becoming since 2011/2012 in Brazil and the next courses will be impacted from those experiences acquired in the market by the students.

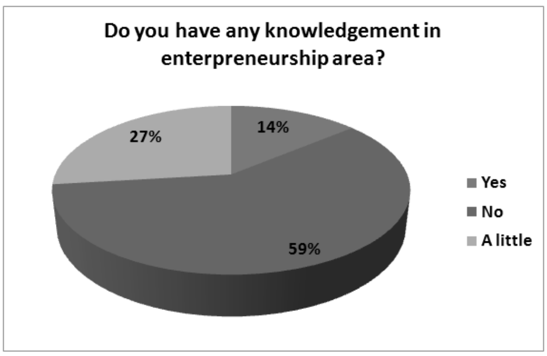

FIGURE 5
KNOWLEDGEMENTE IN ENTERPRENEURSHIP AREA.

[15] http://g1.globo.com/pernambuco/noticia/2012/06/equipe-de-sao-paulo-vence-no-recife-desafio-de-cidades-inteligentes.html (*in portuguese*)

Second, we try to identify what is the expectation of the students during the course. This help us to verify what the intentions of the students in the begging of the course and if there are some changes during the course (related to Figure 8). According Figure 6, 44% answered that would like to be entrepreneur; however 29% were interested only in grade. This should be worked more during the course in order to decrease this interesting of the students. Some insight to do so is try to eliminate the grade from this course and the investor will evaluate the startups and give points to each one; if there are any that do not receive points should doing again the course in the next year.

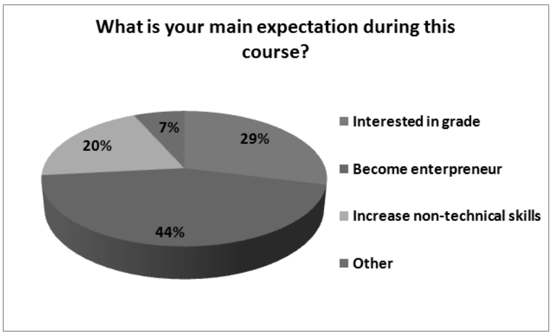

FIGURE 6
EXPECTATION FROM THE STUDENTS.

Third, it is intends to know if this course instigate the entrepreneurial skills in the students. The major answer (Figure 7 shows around 83% from Yes and Substantial) say yes but it is necessary increase this vision of the students in order to demonstrate that the leadership, customer development, business and communication skills are so important to the professional / entrepreneur nowadays. More talks from the market could help this factor and will be increased in the next course.

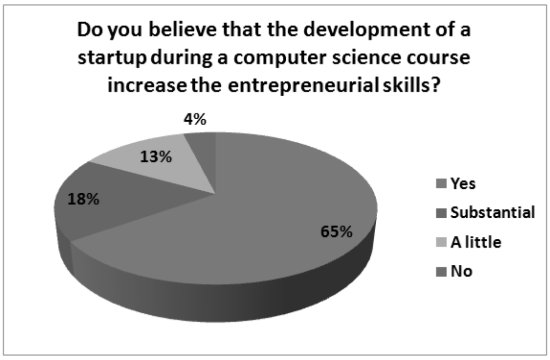

FIGURE 7
ENTERPRENEURIAL SKILLS.

At last, we try to map if the course influenced the students in its carrier decision. According to the Figure 8, 38% intends to create its own business. We believe that this is amazing, considering that the course happened only in the last 3 years. The goal is achieving around 70% in this metric however it should spend more 5 years to achieve that.

Thought these survey we could identify some aspects that should be increased during the course, like show the importance of non-technical skills to computer science students, approximate the students to its customer / market and partnership with investor in order to the projects developed could be really launched to the market. However, the results achieved until now can show the importance of this kind of course to a computing curricula.

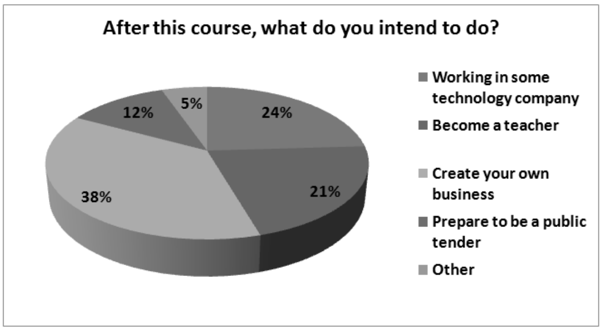

FIGURE 8
INTENTITIONS AFTER FINISHED THE COURSE.

Additionally, several lessons could be learned during the execution of this course. The intention is to learn from what went wrong and seek to improve the course. So, there are some lessons learned:

- Some theoretical basis is critical to engage students in beginning and it is essential hands-on knowledge by the teacher in order to perform a set of dynamics with students;
- Multidisciplinary is very interesting for the entrepreneurship as a way to complement the skills of co-founders. As the discipline happens in the bachelor's degree in computer science, becomes difficult to obtain this multidisciplinary. However, it has been started some partnerships with other courses from UFSCar – Sorocaba (like business administration and economics) which courses that happens in the same semester and have complementarity to technical skills from computer science;
- Networking in the area is essential to attract entrepreneurs, investors and mentors to talk and join the final judge, as well as industry partners as a way to encourage students through a set of awards and acceleration support of the startups;
- The teacher must have previously entrepreneurship education and innovation as well as experience in entrepreneur area (i.e. be entrepreneur), joined in contest startups, talking to investors, made pitch's in the market, know the market, i.e. have the entrepreneurial profile in order to talk the same language of the market with your students; and
- The method of the course should be executed in a systematic ways in order to provide better assessments

and comparisons of the data obtained in the course year after year.

Concluding Remarks and Future Work

Entrepreneurship and innovation education is becoming the future trend of modern higher education reform [21]. Universities must move with the times and develop new ideas, seeking to develop and/or accelerate startups, especially for higher education institutions in a set of areas of computing / business. The universities must be care to the problems existing into the market and work with real problems during the courser and research in order to create solutions that can be very useful to the society. With creation of new business, everyone wins: the society wins with the return of the investment (ROI) (i.e. taxes paid), the university awarded with the generation of applied research and attracting more resources for research, and market gains with the human resource development high capable. Although it looks like normal to do so in some countries, in Brazil it is very difficult to find universities thinking in the future of its university and doing (real) research together with the industry.

Thus the computer courses in Brazil should be more practical. If we are compared to universities in the world, Brazilian universities do not focus so much on courses that develop practical activities together with students. These activities that resemble those performed on a day-to-day life of an entrepreneur and give an adequate view of what are the challenges that these future entrepreneurs will face.

In this way, the UFSCar - Sorocaba has been working hard at introducing entrepreneurship, innovation and intellectual property in order to strengthen and complement the knowledge of both the students of bachelor degree in computer science and society as a whole through the creation of Startup Club[16], where monthly meetings are held (Startup Day) through multidisciplinary partnerships near Sorocaba / São Paulo city.

Acknowledgment

I would like to thanks some partners that inspired / helped me build this course, like Silvio Meira, Augusto Camargo, C.E.S.A.R. (http://www.cesar.org.br) and UFPE (http://www.cin.ufpe.br). Still, this work was partially supported by the FAPESP, grant 2012/10157-1.

Abstract *— Following the new trend in education, more focused on a global perspective, COPEC - Science and Education Research Council is offering an MBA, online, in Social Engineering for all Countries of CPLP - Portuguese Language Countries Community. The goal is to cover these countries' engineers, which are also seeking for opportunities, as the majority are countries of growing economy based on their very rich resources. The idea of an online program is the possibility of reaching a broader audience and at the same time of enriching the experience of offering and implementing a program that can disseminate ideas and concepts, which fits the needs of the target audience. The Education Research Team of COPEC is convinced that Engineers with proper knowledge and skills can take action in order to solve social problems, as engineers are problem solvers.*

Keywords *— Online education; science and technology; research; public economy; population growth*

I. Introduction

Political environment is full of challenges and crises of deep consequences to society as well as to the environment and it has a strong incidence in terms of decision making in any field. It means that taking decisions is becoming more and more complex and difficult due to the fact that the implications are felt in a faster way and in a larger community. For engineers, the decision process is even more complex once the implications have serious impact not only to the target customers but also to the society as a whole and to the environment. This is an aspect that shows the necessity for engineers to search for the acquisition of an ability to respond to social necessities having in mind the cultural aspects when developing a project.

The effects of this aspect in engineering education imply a different approach providing the future engineers with notions on policy, ethics and social sciences, which are so important to prepare them to the future work market that will require the respect and promotion of society and environment as assets [1].

Most of social groups have ambiguous understanding about science and technology; some understand it as responsible for the environmental deterioration and the voracious capitalism and others as the ones responsible for the better quality of life with the improvement of health systems, agricultural production and other accomplishments. Both perceptions are not far from the reality. In any case, the impacts can be seen along the history and more recently with the sophistication of the so called "information society". This particular "information society" shows how strong the impact of any technology introduced in the society can be. Real time communication and brutal amount of information available have changed drastically how people relate, make business and study [2].

The proposal of COPEC - Science and Education Research Council for the next five years is the offering of MBA by Distance Learning due to the new global education demand. The new programs will be delivered in Portuguese in a first moment, for all Countries of CPLP - Portuguese Language Countries Community. The idea is to cover these countries that also are seeking for opportunities, as the majority of them are growing and are very rich countries. The first group of programs is: MBA in Social Engineering and MBA in International Engineering Educator, both with International Recognition.

II. THE SOCIAL ENGINEERING PROGRAM – MBA OFFERED BY COPEC

Thanks to technology it is possible to conciliate work and studies once online programs are available for all and in every possible way. It is the era of the so called information society. The design of a project now requires knowledge about the social as well as the environmental impacts, so engineers should be capable of learning how to work close to governments and communities, addressing the results of the projects to solve social problems or at least to prevent new ones[3].

In response to this necessity, COPEC - Science and Education Research Council has developed a MBA in Social Engineering. It is an MBA program offered by distance that fulfills the urban demand of engineers to solve social problems which are outcomes of urbanization and environmental issues in cities.

The program is directed to engineers interested in acting in this field-offering consultancy for construction companies, industrial enterprises, city halls and governmental housing organizations, etc. It is an interdisciplinary program that prepares engineers to work in projects dealing with the social aspects of projects. The program is developed in modules: two modules per semester. The scores and the final project presentation online establish the final approval of a student. An online chat with students provides teaching and guiding for the development of projects in a broader perspective. The MBA is taught almost using case studies—whereby students discuss real dilemmas faced by actual companies. The debates are online and last for three or four days. The professor opens up the debate by asking questions and the students then begin discussing the case [4].

As the target audience is spread over different continents, the cases are discussed in an Internet forum. Students enter the discussion at the time that is best for them. It can be early in the morning before going to work, sometimes in the evening or even late at night. Usually they will be involved for two or three hours every day. The choice of asynchronous learning mode of delivery is due to the fact that so participants access course materials on their own schedule and so it is more flexible [5]. However, there is the possibility of a present module for pertinent seminars and visits to companies and sites with the goal to enhance the acquisition of knowledge and experience in the field.

III. ASSESSMENT

The evaluation of learning is continuous, prioritizing qualitative aspects related to the process of learning and student development observed during the conduct of the proposed activities.

To guide the evaluation process, make it transparent, able to contribute to the promotion and regulation of learning, it is necessary that the performance indicators are defined in terms of teaching, explained and negotiated with students from the beginning of the course, order directing all efforts of the technical staff, teachers and students themselves to achieve the desired performance.

The self-assessment will be fostered and developed through procedures that allow students to monitor their progress, as well as the identification of points to improve, practice deemed essential to learning autonomously [6].

The result of the evaluation process will be expressed in words:

- Optimal: able to play, highlighting the competencies required by the profile professional conclusion;
- Good: able to perform to the satisfaction, the skills required by the professional profile completion;
- Insufficient: still not able to play at least the required skills the professional profile of completion.

The endorsement will be awarded per module, considering the criteria and indicators performance related to the powers provided in each, which integrate professional competencies described in the profile completion below.

IV. ADMISSION REQUIREMENTS

The basic candidate requirement for admission is:

To have a bachelor's degree in civil engineering. However, the program encourages applicants from diverse backgrounds, including (but not limited to) engineering, environmental science, management and economy. Applicants may need to complete prerequisite courses. A faculty advisor will determine the specific requirements on an individual basis depending on the student's educational background and work experience [7].

V. CANDIDATE PROFILE

- Taste for related themes to the sciences of mathematics and physics and technological ones of civil engineering.
- Interest in solving problems in engineering in coastal and estuary environment principally the ones that involves the coast and constructions.
- Capability of questioning.
- Affinity and discipline for the activity of research [8].

VI. EXPECTED OUTCOMES OF THE PROGRAM PROFESSIONAL PROFILE

The engineer with an MBA in social engineering should present some characteristics as a professional. These expected characteristics are:

- Search constant updating and self-development through study and research, to propose innovations, identify and incorporate with criticism, new methods, techniques and technologies to their actions and respond to everyday situations and with unprecedented flexibility, creativity, resourcefulness as well as social and cultural.
- Taking professional attitude consistent with the principles governing the work area, working in multidisciplinary teams and relating appropriately with other professionals, clients and suppliers.

- Manage the career with initiative and in an entrepreneurial way, to provide services or organizations to conduct own business.
- Acting responsibly, committing to the principles of ethics, environmental sustainability, the preservation of health and social development, directing its activities to the values expressed in the professional ethos, which results in quality and commitment with work well done.

These characteristics are important because a social engineer will deal with the aspects of human life that are imperative for the future of young generations. The achievements have a huge impact on how life will develop in a region or community in the years to come. Specialists working in the field of social engineering can make a huge contribution to the overall engineering profession [9].

VII. Objectives of Program

The main objectives of this social engineering graduation program are:

- to prepare engineering researchers and professionals in administrative positions who work in areas related to policy to design and implement in national territory socio-economic systems and to develop the integrated theories and methods of these areas;
- to increase logical thinking, sense of social ethics, social assessment capability;
- to start thinking without any preconceived notions;
- to look for innovative problem solving .

VIII. Final Discussions

At this point some discussions should take place. We start with the definition of science, which states that it is a process of inquiry that involves questioning, hypothesizing, investigating, gathering evidence, organizing data, testing, refining, predicting, explaining and communicating. So the development of science is a long process that requires some personal skills that can be fostered along the education period of the human being. The achievement of knowledge in order to make science respond to human needs results in technology that men use to make life better. Due to the challenging characteristics of scientific knowledge application and development it is possible to say that it is in constant construction. This is what makes science and technology development so interesting and enticing for those professionals who are always seeking for new ways of working, meaning more effectively.

Presently the bachelor diploma is not enough to obtain success in a career. No doubt that a third degree diploma opens some doors. Therefore it means not only the possibility of earning more money but also to reach an upper status, socially speaking. However as the work market is more than ever extremely competitive and mutant life long learning is something that professionals should pursue.

It is a fact that online learning is not for everyone at this point of human development stage. It is very difficult to juggle work, family and study. Plenty of self-discipline is necessary. However, the idea to study at any time any place that suits the students best is very appealing. Another aspect is that it gives an opportunity for bright students in different remote parts of the world to access a top-quality education program, which would otherwise be unavailable to them. Distance-learning students tend to apply what they have learnt immediately in their work, making their studies more practical.

Competitive modern marketplace demands rapid change and innovation, for which distance education programs can act as a catalyst. It is a lifelong learning environment once it provides the students the opportunity to receive equal education regardless of income status, area of residence, gender, race, age, or cost per student. The proposed program delivered by COPEC constitutes another opportunity for engineers to acquire knowledge in their fields of expertise to defeat social problems mainly faced by urban agglomerations derived by the global population growth.

Critical Support for Upper Division Transfer Students in Engineering and Computer Science

Mary R. Anderson-Rowland
Arizona State University, Mary.Anderson@asu.edu

Abstract – **A Motivated Engineering Transfer Students (METS) Program at Arizona State University (ASU) was established to aid the transition, retention, and graduation of engineering and computer science community college transfer students. The METS Program provides critical support in the form of an Academic Success and Professional Development (ASAP) Class and a METS Center to help provide academic and social support, as well as scholarships. In this paper, we look specifically at the impact of the METS Center for transfer students and the impact on transfer students of the $4K per year scholarship funded by NSF grants.**

The ASAP Class transfer students were surveyed to evaluate the Center and scholarships. The transfer students were asked: "How does the METS Center help you?" and "How did the METS scholarship help you?" The top three identified benefits of the METS Center were: a place to meet/connect with other transfer students, the use of computers and free printing, and the ability to get information about internships.

The top student benefits of the METS scholarship are not having to work as much, not having to take out a loan and, for some students, not having to work. The scholarship benefits did not differ by gender.

Index Terms – Academic Scholarship Program, Professional Development, Scholarships, Transfer Center, Transfer Students.

I. INTRODUCTION

Picture a tiny goldfish jumping from a small fish bowl to a larger and much higher, fishbowl. This is truly a leap of faith. There is not only the fright of being out of water for a short time and the endurance to make the jump, but also the unknown of: being able to land in the bowl or missing it altogether, how supportive the new environment will be, and the nature of the interactions with a whole new school of fish. The new university community college (CC) transfer student in engineering and computer science feels like a freshman all over again, fears the large classes, is aware that the class pace may be much faster, knows that the "easy" classes have been taken, and doesn't know where to find resources. [1]

Much has been written recently about transfer students and their care, especially in engineering and computer science, since President Obama announced in 2001 that there is a critical national demand for more engineers. [2] Henceforth, in this paper, the term "engineering" shall also include computer science. The U.S. Education Department reports that only 60% of students entering four year institutions earn a Bachelor's degree in six years, but only 31 percent of public community college students go on to complete either an associate or a bachelor's degree in six years. [3] This is a large waste of talent.

To solve this problem, there is much for the CCs to do, but there is also work for the CCs and four-year schools to do together, as well as for four-year schools to do after the transfer students arrive: to encourage them to stay in engineering and to graduate. Major steps that CCs in Arizona have taken include adding engineering courses to their curriculum and designing Associate Degrees for engineering so that transfer students can come to the four-year school as a junior in engineering. Articulation agreements are needed between the two-year and the four-year schools to accomplish this. Arizona has complete articulation agreements between the three state universities and the 21 Arizona community colleges.

In this paper we will concentrate on what the four-year school can and should be doing to maximize the graduation rate of transfer students and to be sending them directly on to graduate school. A major reason that most students attend a CC is due to finances and the fact that tuition is much lower at a CC than at a college/university. [1] Therefore, it is obvious that a major need for most transfer students is financial help. [4] Financial help in the forms of scholarships, fellowships, internships, and paid research and intern positions are very important, but financial support alone is not enough.

One study showed that transfer students are less likely to be engaged in the campus life of the receiving four-year institution. The author suggested that "creating social capital for CC transfer students is one way to reestablish the social interest that has been displaced as a result of transferring." Due to their diversity and uniqueness, the author further

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

suggested that specifically designed support programs to increase retention, integration, and graduation rates at the four-year school are needed. [5] We have done exactly this.

In Tinto's latest book, "Completing College," he points to four critical areas upon which college completion depends: high expectations, support, assessment with frequent feedback, and involvement. The support that is needed includes academic, social, and, perhaps, financial. [6] Our program is based on these four critical areas.

A Motivated Engineering Transfer Students (METS) Program at Arizona State University (ASU) was begun in 2003 to smooth the transition for engineering and computer science CC students to the university as they take this "leap of faith". Additionally, once they have "landed," the METS Program provides critical support for their retention, graduation, and graduate school attendance. The first Academic Scholarship Program for full-time, upper division engineering and computer science students in the Ira A. Fulton Schools of Engineering at ASU was begun in fall 2002. The next year, a second Academic Scholarship Program was added for transfer students only and the first program continued with non-transfer students. These programs have continued until present with current NSF grants (#1060226 and #0728695, respectively). In 2008, we received an NSF STEP grant (#0856834) to partner with five non-metropolitan CCs in Arizona. Some scholarship money was built into this grant, so we also have these transfer students in our Academic Scholarship Program. For the 2012-2013 year, the ASU Women & Philanthropy group awarded money to ASU to help fund additional scholarships for transfer students.

These Academic Scholarship Programs are open to upper division students who have at least a 3.0 GPA and have unmet financial need as determined by FAFSA. The students must be enrolled full-time in engineering or computer science in the Fulton Schools and be a U.S. citizen, permanent resident, or refugee. An emphasis is placed on diversity and historically at least 60% of the program scholarships have been awarded to women or underrepresented minority students.

The first critical area stated by Tinto as necessary for college student retention was "high expectations." We have high expectations for our transfer students from the time we first see them on a visit to a CC classroom or when they visit at ASU. We tell the students that we expect them to graduate and to go directly on to graduate school.

The second Tinto critical area for college retention success is "support: academic, social, and financial, as needed." Let us first consider the financial support. Over 90% of the CC transfer students to ASU in engineering have unmet financial need. This should not be surprising since a primary reason that students attend a community college is due to the much lower tuition rates and the proximity to their home, saving commuter, board, and room costs. The selected students are given an academic year scholarship of $4,000. This scholarship is renewable until they graduate with a Bachelor's degree and through four semesters of graduate school if they continue their full-time studies in the Ira A. Fulton Schools of Engineering and continue to qualify for the scholarship.

In terms of academic and social support, over the years the author has developed a successful Academic Success and Professional Development Class which has helped to yield high rates for graduation and graduate school enrollment. Scholarship students must enroll in this class each semester they hold the scholarship. The class changed from a one-credit class to a two-credit class in spring 2013. The class credit does not count on a Program of Study, but the grade does count in the GPA. Assignments are given that help the student to acclimate, learn about their professors, to write a resume, and to navigate a career fair, all designed to make them better students and to provide them with information about doing research and going to graduate school. The class also includes time management, speakers from industry with advanced degrees, portfolios, and career planning. The primary help for their academics comes through the time management and the Guaranteed 4.0 Plan by Donna O. Johnson. [7] Through this system the students "learn to learn." The social and networking support is strengthened by holding each of the six 75-minute classes (per semester) six times so that there are no more than 30 students in a meeting and so that there is at least one meeting time that fits with the student's schedule.

In addition to the scholarship students, each semester additional students enroll in the success course. Word-of-mouth has brought both transfer and non-transfer students to enroll to learn about topics that can help them. Students who have taken the course are pleased to see how they can earn better grades in less time. Through two of the NSF grants (#0856834 and #1060226), $300 scholarships are awarded to transfer students and non-transfer students who are qualified to take the course. Each year we receive many more applications from qualified applicants than we have scholarships. We have learned that $300 is enough to entice a student to take the course. The students admit that if they had known ahead of time how valuable the course was, they would have taken it for free. However, since it is impossible to know the course value ahead of time, the students also admit that the $300 was the incentive they needed to actually enroll in the course [7]. Since the class is especially helpful to first semester transfer students, it is interesting to note there were only 84 scholarship students among the 179 students enrolled in the course during fall 2012. More about the programs can be found in additional references [8-12]

The students are given additional support through mentoring by peers in the program, as well as by "informal counselors," successful transfer students who work in the METS Center, the METS Center director, and the PI and co-PIs on the grants. Career Services present to the students in a meeting each year and is also available to help with resumes, interviewing, career fairs, negotiating, and finding an internship.

Our action on Tinto's third point, "assessment with frequent feedback" has already been mentioned. We do this through the class assignments and try to return the assignments within a week.

Tinto's fourth point is "involvement." In order to promote networking, we do an ice breaker at the beginning of each meeting. A typical question would be, "What are your main concerns between now and the end of the semester?" It is comforting for students to learn that they are not the only one struggling with a particular class. We encourage the students to be in a study group for each class. Additionally, networking is encouraged through our METS Center. This Center includes a study room with computers and limited free printing, a reception area for students with desks for the Center workers, a conference room where the Academic Success class is taught, and an office for the METS Center Director. The Center accommodates about 45 students per day and enrolls over 400 students in an academic year. Enrolled students receive a weekly newsletter with information including internships and success tips

The purpose of the METS program for transfer students is to retain and to graduate the participants, to expand their understanding of the engineering profession, and to have the students go right on to graduate school full-time. The program has shown great success: currently 95% of the scholarship students (transfer and non-transfer) are graduating. To understand this success, we note that the graduation rate for upper division transfer students in engineering is 70% for males and 64% for females. In addition, while the national rate of newly-degreed engineers going on to graduate school is less than 20%, during the past three years, 50% of the non-transfer and transfer students have gone directly to graduate school full-time. Less than 15% of upper division transfer students generally go directly to graduate school. Additional students are continuing part-time. In this study, we wished to quantify how the transfer students viewed the METS Center and how the scholarship affected their life.

II. THE SURVEY

An on-line survey was given to the 133 transfer students enrolled in the FSE 394 Academic Success course during fall 2012. A response was given by 119 (89.5%) of the transfer students, 24 females and 95 males. Two of the questions on the survey were focused on the value of the METS Center programs and the effect of the METS scholarships. We will focus on these two questions. We need to note that some of these students were not in this class due to their own interest: some had been told by an advisor to take this course in place of an ASU 101 Orientation Course required of all ASU students. Although these students were generally glad to not have to take a class with freshmen, some were not particularly happy to have to take any such course which did not count in their program of study and which had challenging assignments.

The students were asked "How has the METS Center helped you?" on the survey, to check all reasons on a list that applied to them, and to add any other reasons. Table I gives the METS Center benefits that were listed on the survey. Figures1 and 2 show the breakdown of these benefits as selected by gender.

Table I. METS Center Benefits Listed in FSE 394 Fall 2012 Transfer Student Survey

"How has the METS Center helped you?"	
1	Place to meet other transfer students/connect with other transfer student
2	Networking
3	Computers and free printing
4	Informal mentoring by METS Center staff
5	Staff helpful as resources
6	FSE 394 Academic Success Class
7	Workshops in the METS Center
8	Information about internships
9	Information about jobs
10	Information about research opportunities for undergraduate students
11	Form study groups
12	Have a place to eat lunch
13	Have a place to study
14	Meet for academic scholarship meeting
15	Other: (please list)

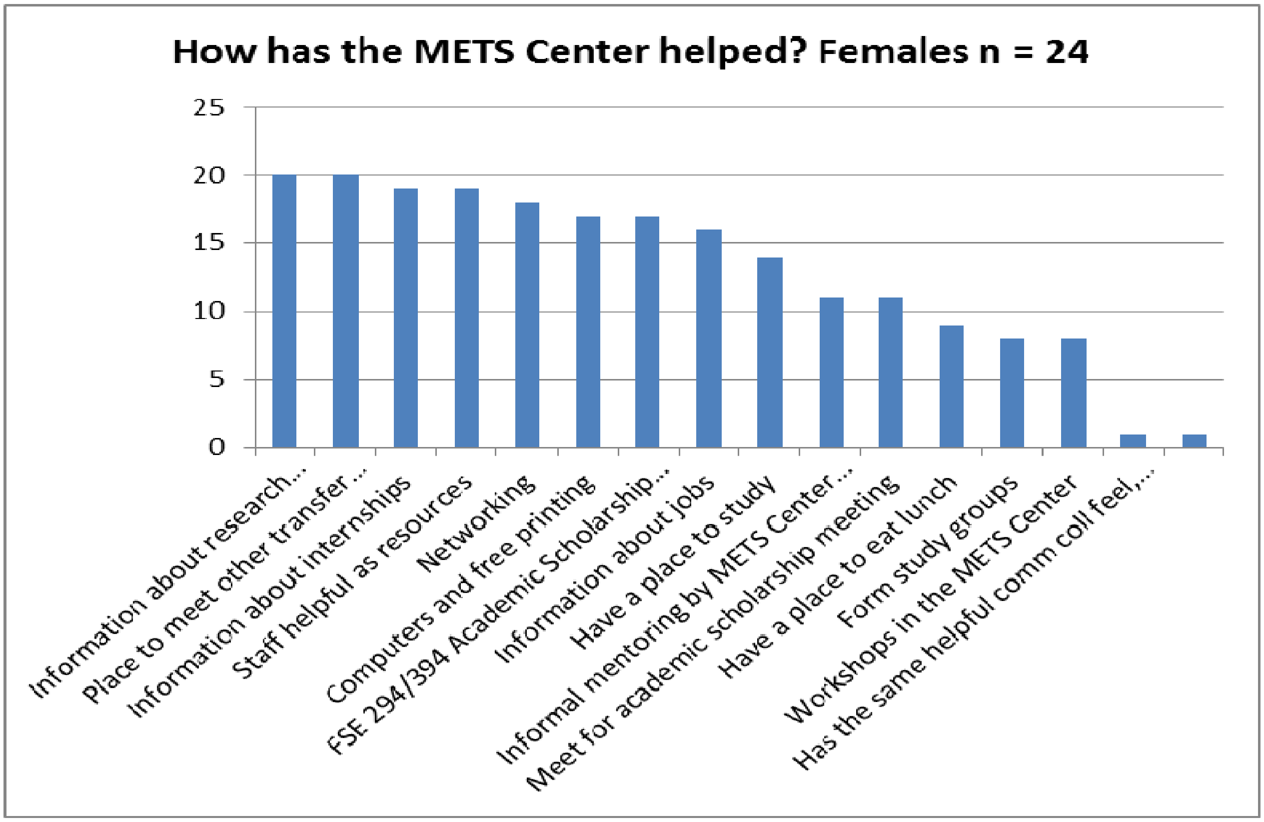

Fig. 1. How the METS Center helped the female transfer students in FSE 394 in Fall 2012.

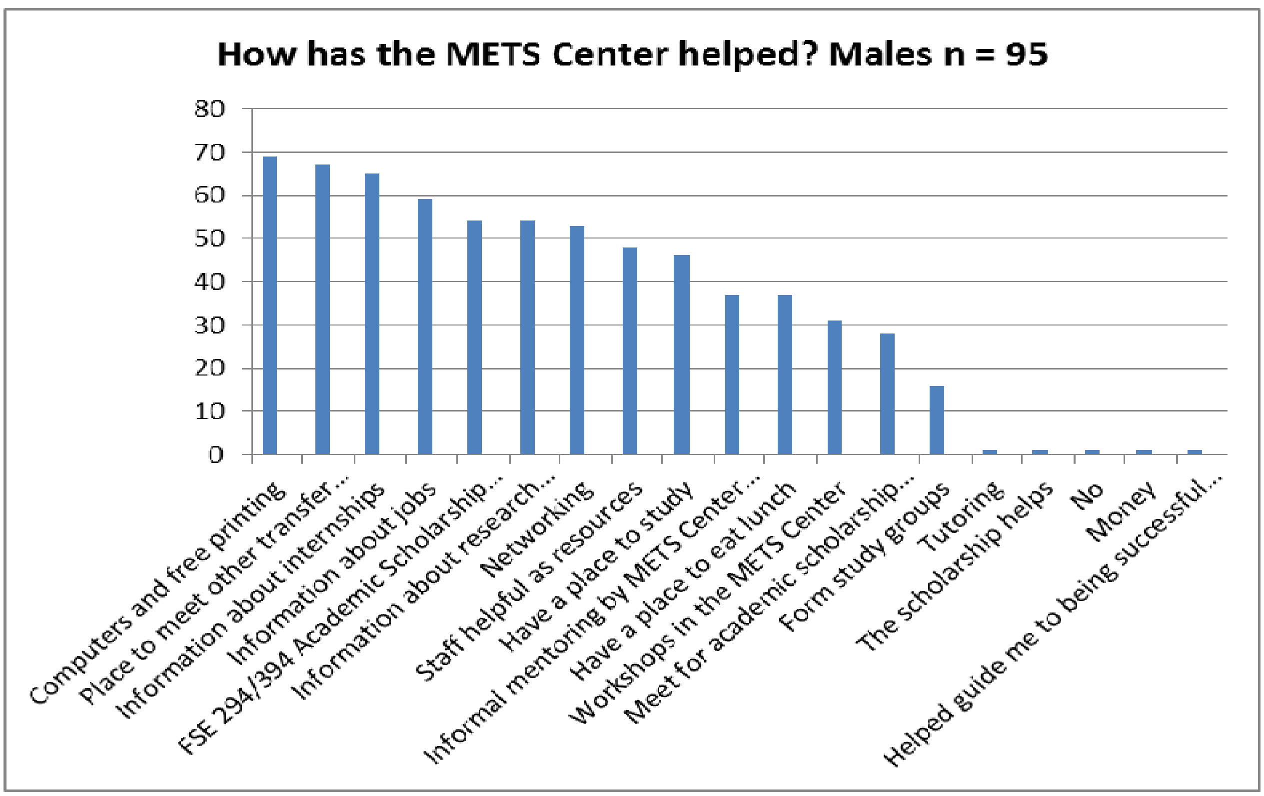

Fig. 2. How the METS Center helped the female transfer students in FSE 394 in Fall 2012.

There were several additional METS Center benefits listed by the survey students. A female transfer student wrote: “has same helpful community college feeling, except for FSE.” It is not clear if FSE, the Academic Success class is mentioned as a positive or negative difference. Another female wrote: “METS is like family...I feel safe...it’s like a home away from home.” There were five additional benefits named by males:” tutoring,” “the scholarship helps,” “none,” “money,” and “helped guide me to being successful at ASU.”

Table II lists the options for the second question: “How did the METS Scholarship help you?” Sixty-nine of the 119 transfer survey students (58%) had scholarships, 15 females and 54 males.

Table II. Scholarship benefits listed in FSE 394 Fall 2012 transfer students survey

“How has the METS Scholarship helped you?”	
1	Did not have to work because of scholarship
2	Did not have to work as much because of scholarship
3	Did not have to take a loan because of the scholarship
4	Scholarship did not help
5	Other: (please list)

The scholarship survey question results by gender are as follows:

Table III. Scholarship benefits identified by FSE 394 Fall 2012 transfer students with scholarship by gender

Benefit	**Females (n=15)**	**Males (n=54)**
Did not have to work as much	12 (80%)	35 (65%)
Did not have to take a loan	9 (60%)	22 (41%)
Did not have to work	2 (13%)	17 (31%)
Other	1 (7%)	5 (9%)

Other reasons included: “Lowers my stress significantly” by a female. Four positive “other” male reasons were: ”Eased overall financial burden,” “Loan not as great,” “Helped me to receive less loans and made me more comfortable without working,” and “Couldn’t have succeeded without scholarship. Full-time work would have been too much with 16 credits.” On the other hand, one male said “Scholarship did not help.”

III. SURVEY ANALYSIS AND RESULTS

It is assumed that when the students ranked these benefits, the METS Center was considered a generic name for both the physical METS Center and the Academic Success and Professional Development Class activities. The percentages and ranks of the METS Center benefits are given by gender in Table IV, along with P-values. The top 9 METS Center benefits that the students identified were the same for females and males, although the individual rankings varied. If we consider the top 5 reasons, which were chosen by 75% or more of the females, there are only two matches to the males’ top 5: a place to meet other transfer students and internship information. Males had computers and free printing as their most important benefit, while females had this ranked tied for sixth and seventh. Job information was in the top 5 for males, while this was ranked eighth by the females.

Table IV. METS Center benefits by gender and p-value: n=24 for females and n=95 for males

Benefit and P-value	**# F**	**%**	**Rank**	**# M**	**%**	**Rank**
***Research information	20	83	1.5	54	57	5.5
Place to meet other transfers	20	83	1.5	67	71	2
Internship information	19	79	3.5	65	68	3
***Staff helpful resource	19	79	3.5	48	51	8
**Networking	18	75	5	53	56	7
Computers and free printing	17	71	6.5	69	73	1
Academic Scholarship Class	17	71	6.5	54	57	5.5
Job information	16	67	8	59	62	4
Have a place to study	14	58	9	46	48	9
Informal mentoring	11	46	10.5	37	39	10.5
*Academic Success meeting	11	46	10.5	28	30	13
Have a place to eat lunch	9	37	12	37	39	10.5
*Form study groups	8	33	13.5	16	17	14
Workshops in METS Center	8	33	13.5	31	33	12

*** p-value < .02; ** .05 ≤ p-value < .11; * .11 ≤ p-value ≤ .15

Over half of the females appreciated the top 9 benefits including information about research, a place to meet other transfers, internship information, the staff as resources, the networking, computers and free printing, the Academic Scholarship class, information about jobs, and a place to study On the other hand, over half of the males only appreciated eight benefits, although 46% appreciated the METS Center as a place to study as their ninth most valuable benefit.

Table V clarifies the p-value differences between females and males relative to METS Center Benefits

Table V. P-values with normal approximation and Fisher’s exact test for significant gender differences and trends in METS Center benefits

Benefit	**P-value Normal approx**	**P-value Fisher’s exact**
***Staff as helpful resources	.003	.012
***Research information	.004	.019
**Networking	.060	.106
*Form study groups	.111	.089
*Academic Success meetings	.144	.148

In all of the cases worth noting where there is a difference between the percentage of females and the percentage of males selecting a benefit, the percentage of females is higher. From Table IV we can see that females (79%) considered the helpful resources given by the METS staff in a statistically significant higher percentage than did the males (51%). Similarly, a higher percentage of females (83%) considered gaining research information from the METS Center as a benefit than did males (57%). Another difference, although not as significant, is networking (valued by 75% of the females and only 56% of the males). Two other categories that may be noted as possible trends are the formation of study groups (valued by 33% of females and only 17% of males) and Academic Success meetings (valued by 46% of females and only 30% of males). This last category should be clarified in any future surveys to distinguish between if the benefit is from the Academic class itself or that the meetings of the Academic class are conveniently held in the METS Center.

The scholarship benefits were ranked in the same order by both genders. The largest benefit was that the students did not have to work as much because of the scholarship. This was true for 47 (68.1%) of the students. Thirty-one students (44.9%) did not have to take a loan because of the scholarship. Nineteen students (27.5%) reported that they did not have to work because of the scholarship. One male student said that the scholarship did not help. It is assumed this implies that the scholarship was not enough to cover all costs and the student still struggled financially. One female added that having the scholarship lowered her stress significantly. We assume that part of this was due to the fact that the student knew the scholarship would continue as long as she did well in school. This would be a good benefit to add to future surveys.

Table VI displays the scholarship benefits by gender and the p-values for significant differences in the benefits by gender.

Table VI. Scholarship Benefits by Gender and P-value: n=15 for females and n=54 for males

Benefit and P-value	# F	%	Rank	# M	%	Rank
Did not have to work as much	12	80	1	35	65	1
Did not have to take a loan	9	65	2	22	41	2
*Did not have to work	2	13	3	17	31	3
Other: less stress	1	7	4	3	6	4
Smaller loan				2		
Did not help				1		

*p-value = .093 (normal approximation), .206 (Fisher's exact test)

The only hint of a statistical difference in the scholarship effect by gender is in the percentage of females (13%) and males (31%) who did not have to work after receiving the METS scholarship. The p-value is .093 if we use the common normal approximation test, but only .206 if we use Fisher's exact test because the one sample is rather small. This could be considered a trend and something to watch in the future.

It appears that the students appreciate the benefits of the METS Center and programs. There was not much difference between females and males. Over half of the females noted 9 benefits of help to them, while only 8 benefits were named by over 50% of the males. The benefit noted by over half of the females and not by over half of the males (46%) was "having a place to study."

It was satisfying to note that 30% of the scholarship holders did not have to work. We have found that working too many hours is the primary reason that transfer students do not do well academically. Part-time jobs that are initially limited to 20 hours per week can suddenly demand 30 or more hours to the academic detriment of the student. Over 68% of the scholarship students did not have to work as much because of the scholarship. This is good. The scholarships also prevented 45% of the scholarship holders from taking out a loan. It appears that the scholarships are being used well.

IV. CONCLUSIONS AND FUTURE WORK

These survey items helped to verify that the METS Center and its program are doing well with the students. There was also an opportunity for the students to give suggestions on how the METS programs could be improved. This data has not yet been analyzed, but will be in light of the two questions in this paper. It would be interesting to break this data down further to see if the satisfaction by scholarship holders was higher than that for students without a scholarship and for students who were required to take the course as a substitute orientation course. We will also look to see if there are any differences between the results of underrepresented minority students and non-minorities. We know from past experience that it sometimes takes two semesters for students to buy in to approaching learning as a system (a central theme for the Academic Success class) and to use the 4.0 Plan to their advantage.

The response of the scholarship students was very gratifying. The $4,000 scholarships toward a tuition of $10,000 is doing what it is supposed to do. In future surveys the stress reduction caused by a scholarship and the other benefits named by the students will be included as possible benefits. The biggest challenge for the program going forward is scholarship money. Not only are we receiving more scholarship applications each year from capable, qualified students, but the NSF S-STEM grant for transfer students ends summer 2013. We are seeking additional sources for scholarship support.

Special thanks go to Mr. Carlos Flores, graduate assistant, who put the survey on-line, sorted data, and prepared the histograms.

Abstract: **One of the main causes of desertion in engineering programs is the poor student academic performance in basic courses. One of these courses is Statics, which is taught at the undergraduate level. Between 2009 and 2011 about 30% of students did not get a satisfactory grade to pass the course and a high percentage of these students deserted from their engineering program at EAFIT University.**

The evolution of computer systems and the Internet progress have enabled educators to develop software to support teaching and learning processes. For instance, educational software like E-learning platforms now allow teachers and students to interact through collaborative and friendly environments that can result in improvement on student learning outcomes and therefore improvement in their final results. Various learning tools based on problem-based learning approaches have been developed for the Statics area. These systems usually pose problems for students to solve; however, the problems usually used to evaluate and certify student knowledge are different from those used by the students during their training process. This is aimed at focusing students' attention to the use of analytical skills instead of memorizing processes.

This paper describes the results of using a computer system to support training and assessment processes to convey concepts related to a Statics course using an existing open source tool and implementing a dynamic assessment generation scheme (i.e., generation of multiple versions of the same problem using algorithms with variables). This system has been used in the Statics courses during two academic periods in 2012 involving the participation of 400 students. The results of this experiment are compared with performance results of students from previous years who used traditional practice and assessment methods such as solving tasks in conventional paper and pencil tests. Results have had a positive impact in student grades and retention.

Keywords: computer systems, desertion, engineering, reprobation, training and assessment processes

I. Introduction

One of the main causes of desertion in engineering programs at universities is the poor performance of students in basic courses [1, 2, 3]. One of these courses is Statics, which is taught in the following undergraduate programs at EAFIT University: Mechanical, Civil and Production Engineering. From 2009 to 2011, about 30% of students did not get a satisfactory grade at the end of the Statics course and a high percentage of these students deserted from their engineering program.

Researchers [2, 3, 4, 5] have identified and discussed some causes of learning difficulty in some basic courses such as Statics and various solutions have been proposed to make the learning process more effective and motivating. One of the causes for students' failure and subsequent drop out is attributed to the misalignment between the elements involved in the process of training and evaluation systems; these elements are organized differently by teachers and students [6]. From the point of view of the teacher, first (s)he defines the learning objectives and then (s)he defines the process of planning instruction, selecting resources and activities and finally planning the evaluation. From the point of view of students, the assessment is the starting point of learning process and according to their beliefs, they plan their learning activities.

An alternative to achieve align training processes and assessment processes consists of linking both processes so the students find useful to make training efforts to achieve good results in the evaluation. This can be supported by the use of computerized assessment systems that help students in their preparation while measuring their level of knowledge on the subject.

This paper describes the result of using an online assessment system [7] to support training and evaluation processes. This system was implemented using open source tools. It implements a dynamic schema of assessment generation. The rest of this paper is organized as follows: section 2 defines the process of training and evaluation implemented in the system, section 3 describes computer evaluation systems, section 4 presents the implementation of an automatic task generation system, section 5 describes the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

study, section 6 reports of the results. Conclusions are presented in section 7.

II. Training and Evaluation Processes

The subject of Statics has a wide variety of text books [8, 9, 10, 11] which are the main tools that teachers use in preparing lessons and assessments, and for the students in preparing their learning plans.

A number of workshops have been designed to help student focus on learning the concepts rather than memorizing solutions to particular problems. However, sometimes there is no a good alignment between the assessments designed by the teacher and the activities the students do to get prepared for these assessments, which results in high course failure rates. This problem can be addressed by implementing a dynamic assessment approach [12, 13].

A dynamic assessment system that implements automatic generation of tasks has been implemented to help students to improve their performance on the Statics course [7]. This system offers tasks on relevant topics to be used for students in their preparation. These practice tasks have equivalent difficulty levels but with different contexts and variables those tasks are included in the teacher designed tests. This way students can be assigned different types of problems for a particular test.

By changing task parameters, the system can generate countless tests for students to practice. Thus, students have more opportunities to improve their conceptual and procedural knowledge on the subject.

III. Computer-based Evaluation systems

Computer automated assessment (e-assessment) [14] has been used in contexts such as professional certifications [15], certification tests of general knowledge [16], language testing [17], online courses [18], among others. These assessments can be administered by E-learning platforms [19], which are computer systems that have modules for managing administrative and academic tracking [20]. E-Learning platforms allow user interaction with Internet content. Platforms such as Moodle, Dokeos, Blackboard, Chamilo [21, 22, 23, 24] among other have transformed educational practices energizing the teaching-learning processes and supporting distance education schemes. The assessment modules on E-Learning platforms are implemented in standard formats that allow interoperability of assessments [25, 26]. Currently, great efforts are made to implement these systems in web-based schemes using technologies such as Cloud Computing [27].

The individualization of the assessments, which consists in assigning a different test to each student, has been implemented using computer systems. An example of this is Calculated Question Type [28], which includes variables that take different values each time the test is generated.

IV. Implementation of an automatic generation task system.

The system developed allows students to practice the concepts of the course by solving problems. The system generates a variety of problems modeled for each course topic using algorithms that generate different versions of these problems and deliver them to students using an E-learning platform. Students interact with the questions as part of workshops and teachers also use the system to assess student outcomes and track all interactions in the system.

The system generates questions automatically by assigning different values to variables involved, varying situations and solution strategies. The system also has an automatic plotter that creates images for particular problems.

The proposed evaluation system was designed to be used in different e-learning platforms. In the Statics course the system has been used with two E-learning platforms: Chamilo and Moodle.

Initially the system was designed to be used as an independent system. The generator produces the questions for tests; teachers import them into a bank of questions to be used in an LMS platform (see Figure 1). Currently a plugin that will automatically perform some of these test configuration processes is under development.

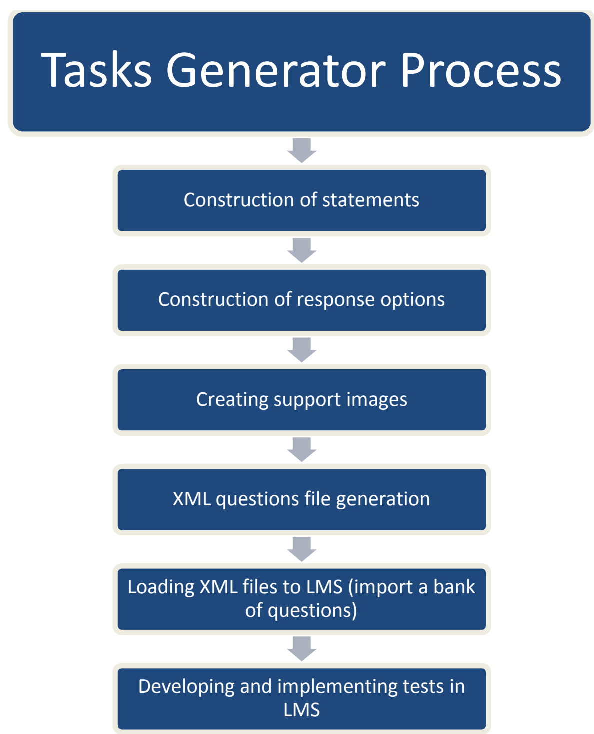

Fig. 1. Process of creation of a new test

Users are classified in three different groups: teachers, coordinators and students. Teachers are involved in various stages of the process, first the construction of the engine by providing input to the development team to design and implement problem solving algorithms, and also in the administration of test results submitted by the students through the system (see Figure 2).

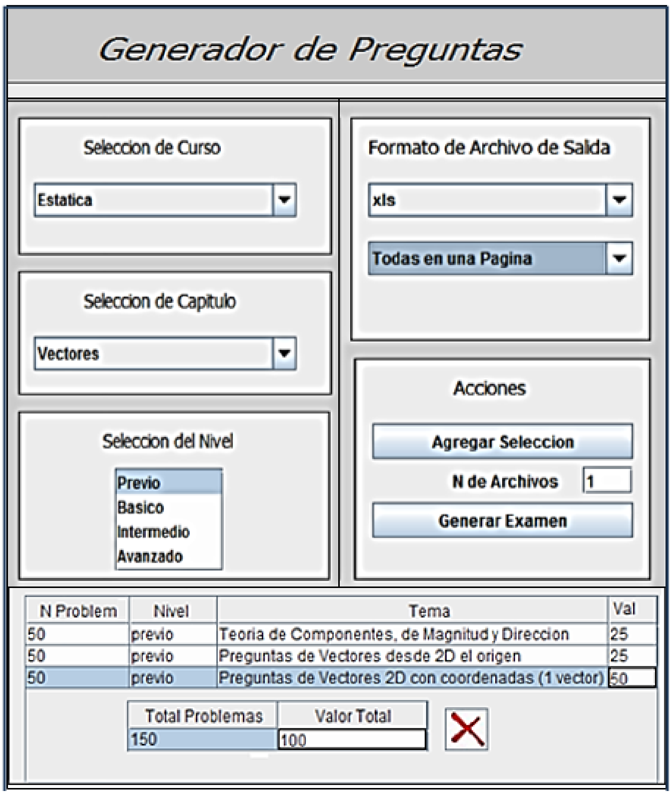

Fig. 2. Interfaces for coordinators and teachers to create a test.

Coordinators, with the help of teachers of the course, are responsible for pre-set tests; this means that they can change the parameters of an evaluation. Parameters available include: subjects, duration, date, difficulty level, and number of attempts (see Figure 3).

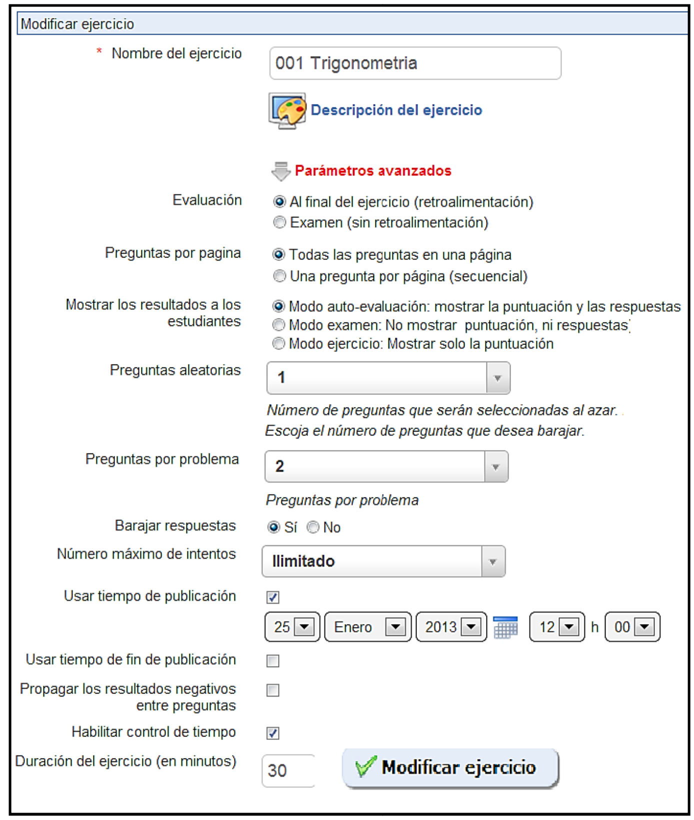

Fig. 3. Interfaces for coordinators and teachers to configure a test.

Students can interact with the system in two different ways. The first way is called training mode where students can select the topic and problem type therefore the system generates a test to practice. The second way is called evaluation mode, in which students answer previously configured tests created by coordinators and teachers (see Figure 4).

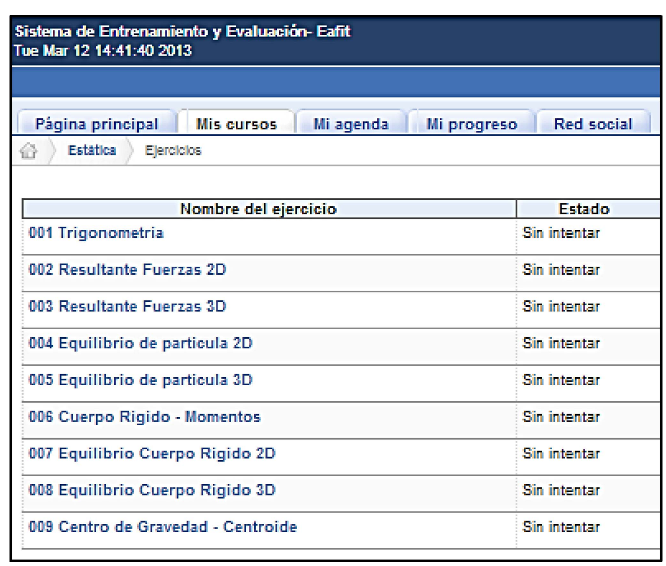

Fig. 4. Interface for students to select a test.

Processes of automatic generation of tasks was designed for being used in the web and implemented in Java language [29]. The generator algorithm produces various versions of the task by modifying the variables previously defined using random values within particular ranges. The variation includes also graphs and text that accompany the tasks generated.

According to the question format (i.e., multiple choice, matching, true or false and open written response) the correct solution must be programmed. Incorrect options are also programmed based on students' most common errors. This helps identify student misconceptions (see Figure 5). Data of students' wrong responses is not used, but all of this information is stored in the results database.

The program output is a file in one of the following formats: txt, xls, pdf and XML [30]. The XML formats like XmlMoodle [25] and QTI2 [26] are powerful and useful to transfer question and complete tests between different platforms. QTI2 is supported by many E-learning platforms.

Some instructional systems include: simulation tools (myphysicslab [31]), online courses platforms (WileyPlus [32], Connect Mcgraw Hill [33], and Courseconnect Pearson [34]). Most of these systems are commercial products which cannot be easily changed or adapted. Instead the approach presented here is flexible and affordable.

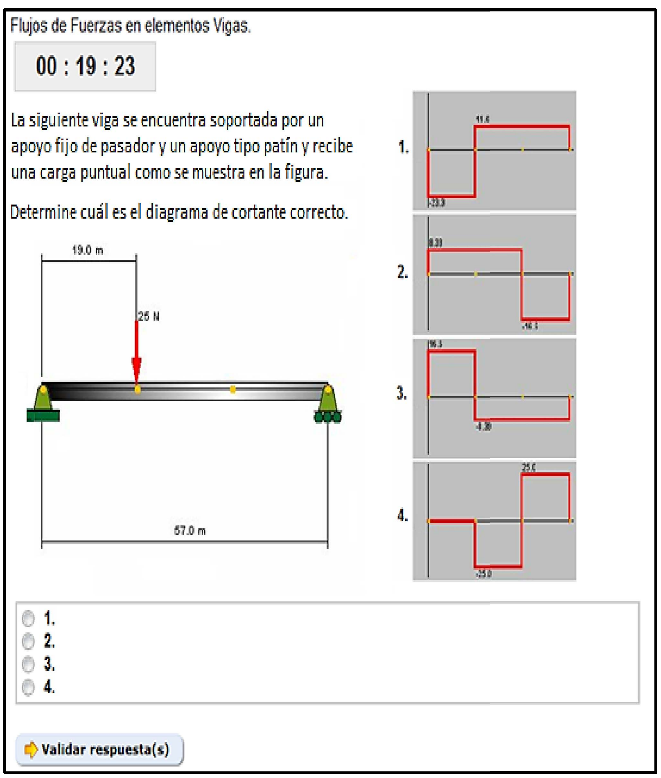

Fig.5. Example of a generated problem (response options correspond to the figures on the right).

V. DESCRIPTION OF THE STUDY

The subject of Statics and other engineering basic courses have high levels of student failure [1], with percentages close to 30%. The course is offered at the EAFIT University to about 200 students each semester in three different engineering programs. Success on the course objectives is determined by students' performance on various tests administered by the courses coordinators. Students pass the course when they achieve a success rate of 60% (a score of 3.0 on an absolute scale from 0 to 5.0).

In 2011, the Mechanical Engineering Department at EAFIT University took the initiative to change some aspects of the course through the implementation of a system for training and evaluation. The objectives were to provide a tool to improve the acquisition of knowledge and consequently improving the performance of students in the class of Statics. Further it stimulates the uptake of Information and Communication Technologies in the institution.

This system has been used in Statics courses during the 2 semesters of 2012, with the participation of 384 students from 12 different groups. The results of this experiment are compared with the results of other students from previous years who were evaluated without using the system for training and evaluation that uses the automatic task generation engine [12].

The system was introduced in 2012. It was used by students as a practice system. Student performance accounted for 20% of the final grade. On average each student solved 40 questions on each topic.

Data for this study includes result of tests of students from 2006 to 2012. The first 5 years (2006-2010) correspond to students who did not use the proposed evaluation system, 2011 students used a preliminary version of the system and 2012 includes data from students who used the system. The scores averages per year for all students are shown in Figure 6.

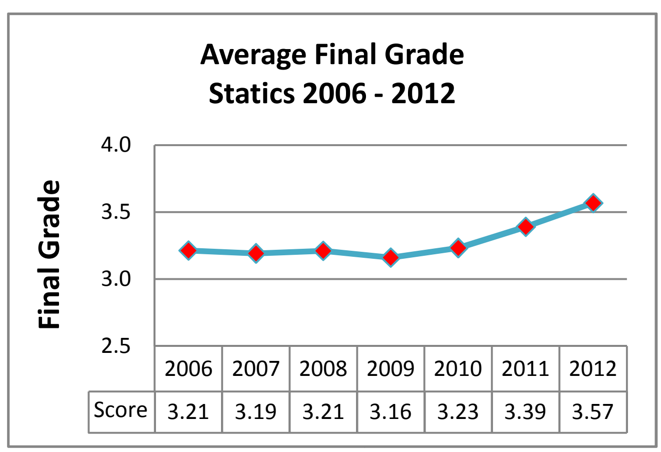

Fig. 6. Average Statics grade for 2006 to 2012.

The failure rate for a group IR in an academic period is calculated by the formula: IR = (RA / TA) x100 where (RA) is the number of students who did not get the minimum score and (TA) is the number of students formally enrolled in the course. The figure 7 shows the percentage by year of the students that failed the class in (2006-2012).

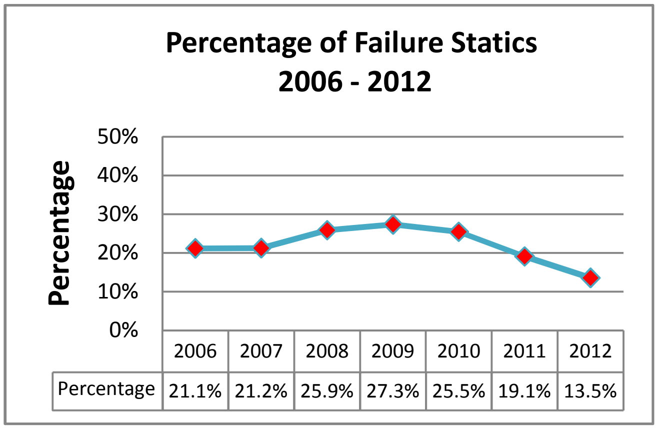

Fig. 7. Static fail rates for each year from 2006 to 2012.

Between 2006 and 2010 the students were evaluated with paper and pencil tests. During 2011 and 2012 students were evaluated with a combination of paper and pencil tests taken from the guide books, and computerized tests created by the automatic task generation system.

For the analysis two samples have been selected. The first sample (sample 1) includes the results of 1290 students, who were the total enrolled in the course between years 2006 and 2010, and the second (sample 2) includes 384 student, who were the total enrolled in the course in 2012.

2011 students were not included in the analysis of the results because that year the system was in a building phase and students used a preliminary version of the system. A comparison of the results was made to measure the changes in students' scores averages of the e-learning evaluation platform on the subject.

Finally a statistical analysis was performed and it includes tests to see if the data of the two samples follows a normal distribution, medians comparison, average analysis, and effect size test were made.

It is important to mention that the final course test is a pencil and paper test and its difficulty level has been kept the same throughout the years.

VI. Results

The figures 8 and 9 show the frequency histogram and the normal distribution fit for the sample 1 and sample 2.

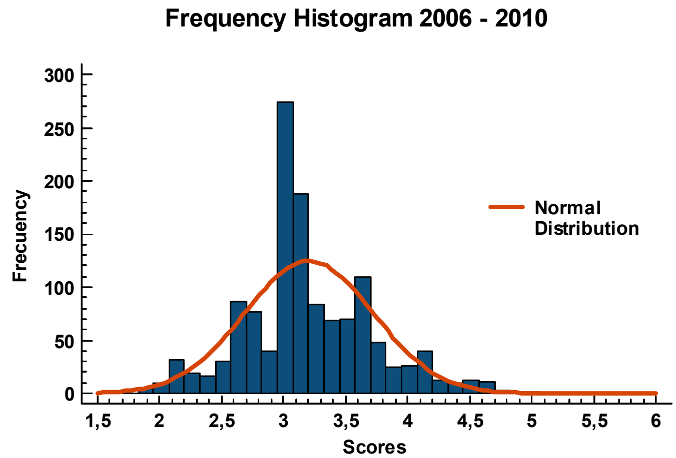

Fig. 8. Frecuency Histogram for sample 1.

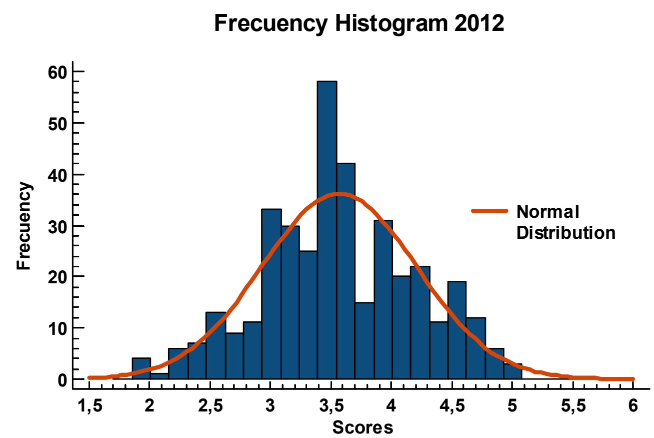

Fig. 9. Frecuency Histogram for sample 2

Table I shows the results of the Goodness of fit test (Kolmogorov–Smirnov) [35], which check the normality of samples.

TABLE I. Results of Goodness of fit test

	Sample 1	Sample 2
D max	0,107	0,063
D min	0,104	0,054
DN	0,107	0,063
Value-P	0,0	0,099

The P-value of sample 1 is less than 0.05, because of this the hypothesis that sample 1 data comes from a normal distribution should be rejected with 95% confidence. For sample 2 the P-value is greater than or equal to 0.05, the hypotheses cannot be rejected then sample 2 data comes from a normal distribution with 95% confidence.

Since the goodness of fit test for sample 1 did not fit a normal distribution, an average comparison between each sample cannot be done, then a comparison of medians test through Mann-Whitney (Wilcoxon) [36] was done. The results of this test are shown in Table II.

- Null hypothesis (1):

$$\text{Median sample } 1 = \text{Median sample } 2 \quad (1)$$

- Alternative hypothesis (2):

$$\text{Median sample } 1 \neq \text{Median sample } 2 \quad (2)$$

TABLE II. RESULTS OF MANN-WHITNEY (WILCOXON) TEST

Median Comparison	Sample 1	Sample 2
Median	3,1	3,5
Average Range	770,67	1066,62
W	331551	
P-value	0	

As the P-value is less than 0.05, then the Null hypothesis can be rejected with alpha = 0.05. There is a statistically significant difference between the medians with a confidence of 95.0%.

Finally to determine how significant the difference between the samples averages is, the effect size is calculated in (3).

$$d = \frac{\bar{x}_1 - \bar{x}_2}{s} \quad (3)$$

Where x1 and x2 are the averages of samples and “S” is the control standard deviation. The results of this test are shown in Table III.

TABLE III RESULTS OF COHEN EFFECT SIZE TEST

	Sample 1	Sample 2
Average	3.20	3.56
S	0.52	0.64
effect size	0.62	

It was found that the sample effect size is equal to 0.62, which is a moderate effect size.

After validate statically the reliability of data, the results of the differences between the averages scores and between the failure rates for two samples are shown in the Figures 10 and 11.

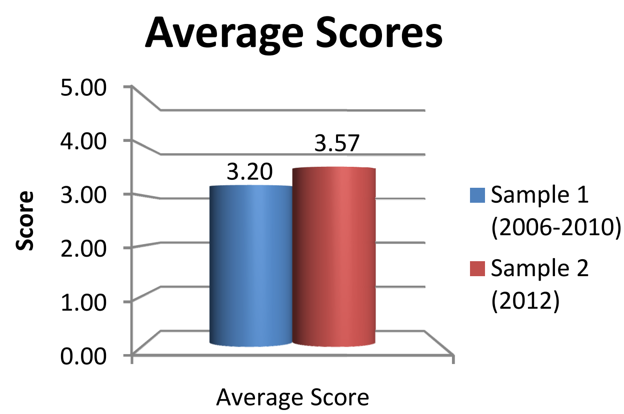

Fig. 10. Average scores for two samples.

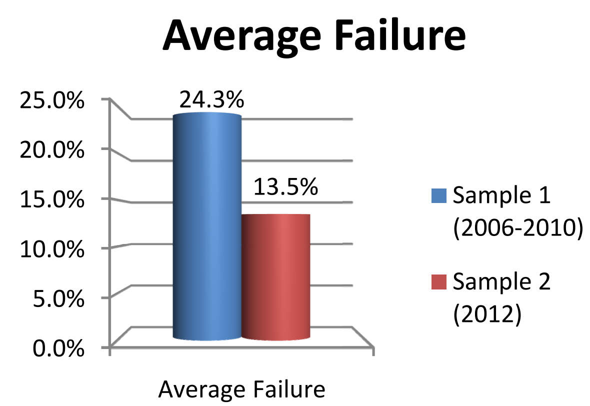

Fig. 11. Average Failure for two samples.

VII. CONCLUSIONS AND FUTURE WORK

The Statics grades for 2012 increased about 8% compared to those from 2006-2010. In addition, the percentage of failure has considerable decreased in 2011 and 2012 about 11% compared to those from 2006-2010. This is expected to have an influence in reducing dropout rates of engineering programs Mechanical, Civil and Production engineering. However, more information is needed to measure the impact of the system on dropout rates (e.g., other information on student progress, instructional changes in other classes, and teacher effects).

It should be noted that the subject of Statics is not the only subject that has high levels of failure. Also, other non-academic aspects influence desertion of academic programs.

Some students did not use the system for continuous assessment. More research needs to be done to find out why these students did not take full advantage of the system.

Part of the success of the system can be attributed to an increase in student motivation generated by the system.

Students appreciated the opportunity to use the system in other places outside the University. The LMS platform logs shows that a high percentage of the connections comes from outside the university

The development of the tool has generated interest from other academic departments and studies are in progress to adapt the system in other core subjects.

***Abstract*—Adoption research has guided the development of a classification and rating system for assessment instruments valuable to the engineering education community. The ASSESS website enables users to search for instruments that measure outcomes of interest and that possess desired characteristics. The website classifies instruments by outcomes assessed, technical features, instrument format, and administration parameters. Instrument descriptions and ratings are displayed in forms useful to both experienced and inexperienced users seeking instruments for specific needs. The user community contributes to ASSESS by rating instruments and suggesting others for development or inclusion. ASSESS developers invite user input to make ASSESS highly valuable to the engineering education community.**

Keywords—assessment; engineering education; assessment instruments; outcomes

I. Introduction

The engineering education community increasingly faces the need to assess outcomes of instructional practices or to assess impacts of student characteristics, institutional culture, or educational innovations on student learning and retention. Importantly, institutional and program accreditation require assessment of student outcomes, and many grant proposals require assessment of student learning outcomes. However, the typical engineering faculty member lacks training in assessment of educational outcomes and is unaware of instruments available for assessing these outcomes.

This work-in-progress paper describes how results of adoption research are used to create a practical tool enabling the engineering education community to identify assessment instruments meeting their needs. Adoption research focused on a prototype of ASSESS[1], a web-based assessment instrument information system, to define requirements for a completed system attractive to the engineering education community. The paper summarizes needs defined by the community, describes the system designed to meet these needs, and invites readers to contribute to the refinement and adoption of the completed web-based ASSESS system.

II. Research Goals

The goal of the ASSESS project is to create an online repository of engineering education assessment instrument information that helps users identify assessment instruments meeting their needs and grows the evaluation capacity of the engineering education community. The development of the ASSESS online repository was guided by adoption research, which studied the perspectives of potential users of ASSESS. Diffusion of Innovations (DI) theory was used as a framework for this study, seeking to:

- Capture multiple perspectives of the innovation during the development phase to develop and refine ASSESS.
- Determine the relative importance of DI characteristics in technological educational innovations.

III. Methodology

A. Theoretical Framework

Adoption research was conducted using Roger's Diffusion of Innovations theory as a framework for interviews and surveys used to define needs of users [1][2][3]. Therefore, questions probed information needs and functionality desired by users in categories of:

- *Relative advantage*. Providing advantages over existing methods of finding assessment instruments.
- *Compatibility*. Matching needs, experiences, and views of users.
- *Complexity*. Giving users' perceptions of simple system operation and understandable results.
- *Trialability*. Providing new users opportunities to try the system at low cost before committing to greater use.
- *Observability*. Making results of using the system immediately visible to users.

B. Adoption Research Data Collection

Engineering educators, researchers, and evaluators (all potential users of ASSESS) were included in participant groups

[1] Appraisal System for Superior Engineering Education Evaluation-instrument Sharing and Scholarship

(PG) for the adoption research. (See Table I.) The first group had participated in a 2009 workshop of the *Inventory of Evaluation Tools for Engineering Education Projects (NSF DUE grant 0839898)* focused on defining the need for and content of a database for engineering education evaluation instruments. Of nine participants, all had already been exposed to the idea of ASSESS, but not to the website itself.

TABLE I. ADOPTION RESEARCH PARTICIPANTS AND SETTING

PG	Descriptions of Adoption Research Conditions		
	Participant Description	***No.***	***Website Status***
1	Previous workshop attendees who contributed to initial concept of ASSESS	9	Initial prototype site with basic functionality and detailed information on 10 instruments
2	ASEE-ERM Division members with possible exposure to ASSESS through conferences	10	Prototype site with additional search features and outlines of pages for rating and learning
3	ASEE-ERM Division members with possible exposure to ASSESS through conferences	4	Prototype site with additional instruments, improved search features, added content

Participant groups 2 and 3, with ten and four individuals, respectively, were selected from the Educational Research and Methods (ERM) Division of the American Society for Engineering Education (ASEE). These individuals may have had exposure to ASSESS through conference presentations.

The three participant groups were asked to view and provide feedback on the ASSESS development website at three different stages in its development. PG 1 viewed the prototype website when it had basic functionality to display instrument information and conduct searches for instruments with only 10 instruments fully described. PG 2 and PG 3 viewed the website later with increased functionality and some additional content.

Participant groups were interviewed via individual recorded telephone conversations for 10 to 20 minutes using questions derived from the five DI characteristics— multiple questions associated with each characteristic. In addition, general questions were used to determine the interviewee's background with assessment instruments.

C. Data Analysis Methods

Interviews were recorded, transcribed, and analyzed using Atlas TI software [4]. Because participant responses were similar across the three sets of interviews, data from all three groups were analyzed together. Data analysis was done in a series of steps with increasing depth as described by Krathwohl [5]:

- Transcriptions were first read to understand overall responses and initial (descriptive) coding was done.
- Data were coded for responses that mapped to one of five DI characteristics.
- Data were recoded at an interpretive level– good or bad.
- Data were analyzed to identify code patterns of activities, themes, and causal links.
- Responses were categorized with tags for reasoning behind categorization (e.g., complexity-good-simple).
- Responses were grouped using interviewee's language to better guide website development.
- For each category and corresponding DI characteristic, a "high" or "medium" or "low" ranking was used to indicate the importance of the responses.

IV. RESULTS AND DISCUSSION

A. Adoption Research Results

Results of data analysis were grouped into six categories using interviewees' terminology: *expectations of instrument inclusion*, *available information*, c*ommunity features*, *use as an alternative*, *searchability*, and *functionality of design*. Table II summarizes data that indicate for these six groups and for the DI categories: (a) whether summed responses were positive (+) or negative (-) and (b) if the resulting numbers, as a percentage, occurred in categories at low (<25%), medium (25 to 75%), or high (>75%) frequencies.

TABLE II. INTERVIEWEE FEEDBACK ON ASSESS

Group	DI Categories				
	Relative Adv.	***Compat -ibility***	***Complex -ity***	***Trial-ability***	***Observ-ability***
Expectations of Inclusion	- High	- Low			
Available Information	+ Med	+ Med	- High		
Community Features	+ Med	+ Low			+ Low
Use as an Alternative	+ High	+ Med		+ High	+ High
Searchability		+ Med	+ Low	- Low	
Functionality of Design	+ Med	- Low	+ Med	+ Low	- Med

High rating for *expectations of instrument inclusion* (and *relative advantage*) indicated the importance that ASSESS include instruments of the types desired by the user. The negative ranking resulted from the small number of instruments and lack of qualitative instruments in ASSESS when viewed during the study.

Positive ratings for *available information* indicated that users were pleased with the range of information provided for an instrument, and they felt they could learn from this information. Several respondents felt that some information and terminology was confusing and would need better explanation (negative *complexity*).

Community features were mentioned infrequently but positively. Respondents were pleased with the features allowing them to suggest instruments and to provide reviews on instruments. People desire to know if others are using an instrument successfully.

High positive rankings for *use as an alternative* indicate that users saw distinct advantages to ASSESS over other methods for finding assessment instruments. They especially like the idea of going to one place to find information on a range of available instruments. Many liked ASSESS's *trialability*, being able to use it without subscriptions or login. Some respondents see advantages in the ease with which one can direct others to the ASSESS website.

Searchability received generally positive rankings. Users found the keyword and category searches familiar. Some were disappointed in not finding instruments specifically for their disciplines. Some encountered difficulties when modifying searches. One concern was that *searchability* would decrease as the number of instruments increased.

Functionality of design received mixed but generally positive rankings. Users liked that website functionality followed familiar conventions. Concerns included how users could find the site and that the site contains information about instruments but not the instruments themselves.

It is noted that *relative advantage*, *compatibility*, and *complexity* received the most user responses or the most negative responses, indicating that these characteristics are most important to ASSESS's adoption.

V. Research Transfer

The ASSESS development team used the adoption research results to guide refinement and enhancements of the website illustrated in Figure 1. Major changes implemented in ASSESS with guidance from adoption research are described below.

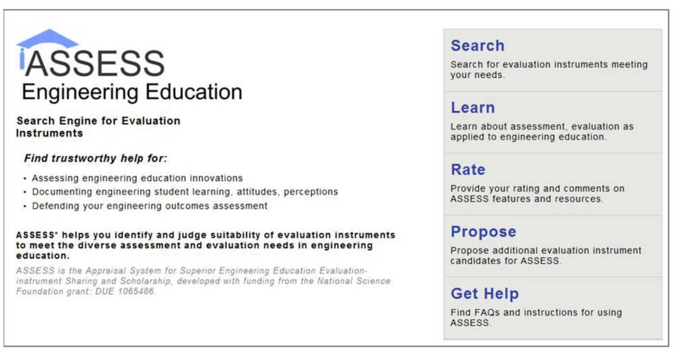

Fig. 1. ASSESS website home page.

A. Relative Advantage

The most important *relative advantage* of ASSESS over other methods is its offering helpful information on many instruments at one site. Subsequent to receiving adoption research results, the development team added new instruments (now nearly 150 total), provided more information on instruments in ASSESS, and developed procedures that yield instrument ratings with high inter-rater reliability. The team invited members of ASEE-ERM to suggest instruments for inclusion, and other potential users are being contacted to suggest new instruments. Information on an instrument will be checked for accuracy by inviting instrument owners or authors to provide missing information or correct errors in ASSESS website information. The website now contains a feature by which users can suggest instruments to add to ASSESS.

B. Compatibility

The development team addressed concerns about ASSESS *compatibility* through solicitation of a broader set of instruments. The team will now go directly to contacts in engineering education and in disciplinary engineering fields to request instruments useful to them, including qualitative and quantitative instruments. These instruments will address specific needs of educational researchers and engineering faculty who need to assess learning in their disciplines.

C. Complexity

The development team addressed *complexity* of ASSESS by refining search and rating features. Searches may be done by keywords or by advanced searches that allow selection of multiple characteristics of instruments. Search results are sortable by amount of evidence found for uses in engineering, reliability, or validity. Users may also easily provide ratings for instrument usability and site feedback. Simplified website language and a glossary will minimize user confusion.

VI. Conclusions

The adoption research conducted to determine potential user perceptions of ASSESS identified characteristics of this type of technology most important to its adoption by the engineering education community: *relative advantage*, *compatibility*, and *complexity*. This research has enabled the ASSESS project developers to address issues important to users so that the website, when made public, is found attractive for adoption by the community. Because the website empowers the community to contribute and shape it, ASSESS has potential to gain broad support needed for sustainability. Interested users are encouraged to contact the authors of this paper or visit the site and provide input at: http://assess.tidee.org.

A Methodology to Teach Exemplary Coding Style Considering Students' Coding Style Feature Contains Fluctuations

Asako Ohno
Osaka Sangyo University, Japan
E-mail: ohno@eic.osaka-sandai.ac.jp

***Abstract*—Readable source code should contain a relatively small amount of latent bugs and should be easy to maintain. However, it is difficult for a teacher to teach all students to write code in accordance with a certain coding style because each of them naturally has his/her own different coding styles, and the teacher needs to advise them considering their original coding styles. To deal with this issue, the CM algorithm is introduced, which was originally developed to detect source code plagiarism in Java programming classes. It quantifies a student's coding style feature by using a set of hidden Markov models called coding models. Coding models quantify a person's code writing style as that person's coding style feature. In this paper, an attempt to apply the CM algorithm for facilitating coding style instruction is reported. Experimental results showed that the coding models provided information that was useful for teaching coding styles.**

I. Introduction

A primary objective of programming classes is to teach students to write source code by following the grammar and syntax of a programming language. Currently, students can write code without learning coding styles; however, to be good programmers, it is essential that they be knowledgeable about coding styles and write readable code. Readable source codes are easier to maintain: they should not contain latent bugs that cause errors or are difficult to detect. Ambler [1] noted that beginners can increase their Java programming skill very significantly by following the coding standards and investing a lot of time in writing high-quality source codes from the beginning of their learning experience. Thus, in terms of improving students' programming skills, writing such code without using the auto-formatters is as effective as learning programming grammar, syntax, and algorithms.

However, it is often difficult to teach students proper coding styles because they write their source codes in their own way. As a result, unless they are very skilled programmers, students find it difficult to follow strictly a coding style guide or a style produced by an auto-formatter; this, in turn, may cause them to take a longer time to write source code.

In this paper, a teaching method that uses the quantified features of the individual code writing style of a student as obtained by applying the *CM algorithm* [2] is proposed. In Section II, the definition and procedure of the proposed method is explained. In Section III, the experimental results are presented. Finally, in Section IV, the conclusions are given.

II. About Proposed Method

A. Application of CM Algorithm

The CM algorithm was originally developed to detect plagiarism in programming classes. It simulates the process of visually searching for a certain pattern of token sequences that commonly occur in the same author's source code to check whether the given source codes are produced by the same author. It quantifies the programmer's *coding style feature* instead of the content feature of a source code. This unique approach enables a teacher to grasp the perspective and the gist of a student's coding style visually and to compare it with other students' coding style or an exemplar coding style. In addition, a stochastic model is suitable for representing features that appear in common among token sequences where the occurrence pattern of the tokens shows fluctuation.

B. Definition and Procedure of the Method

A source code consists of tokens o_t, each of which is categorized into one of three groups as shown in Table I. The tokens used in most Java source codes, such as "{," are treated as one of 14 *basing-point tokens* $o^b_{n_b}(1 \leq n_b \leq 14)$. The adjacent tokens of $o^b_{n_b}$, such as 1-letter spaces are categorized as *identification tokens* $o^i_{n_i}(1 \leq n_i \leq 6)$, and the remainder are *other tokens* $o^o_{n_o}(n_o = 1)$. A *coding style feature* of an author A_α is defined as the occurrence pattern of $o^i_{n_i}$ before or after each one of $o^b_{n_b}$ in token subsequences generated from a normalized source code by using $o^o_{n_o}$ as delimiters.

The coding style feature of A_α is represented by parameters of a set of *coding models* M_α consisting of 14 forward coding models M^α_F and 14 backward coding models M^α_B [2] as

$$M_\alpha = \left\{M^\alpha_p | p = \{F, B\}\right\} \quad (1)$$

$$M^\alpha_p = \left\{M^\alpha_{p,n_b} | 1 \leq n_b \leq 14\right\} \quad (2)$$

where p indicates the forward or backward coding model.

M^α_{p,n_b} consists of three states, $s_i(1 \leq i \leq 3)$, and has the three parameters: *initial probability* π_i, *transition probability* $a_{i,j}(i < j \leq 3)$, and *observation probability* $b_i(o_t)$, where $o_t = \left\{o^i_{n_i}, o^b_{n_b}, o^o_{n_o}\right\}$ and $0.0 \leq \pi_i, a_{i,j}, b_i(o_t) \leq 1.0$.

Figures 1 and 2 show the forward and backward coding models that represent parts of the coding style feature of A_α corresponding to the basing-point token o^b_1 ("{"). As shown in Figure 1, $o^i_{n_i}$ in Table I such as o^i_1 can be observed in s_2

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

TABLE I
THREE CATEGORIES OF TOKENS

Categories o_t	No.	Tokens
Identification tokens $o^i_{n_i}$	1	o^i_1: 1-letter space
	2	o^i_2: 2-letter space
	3	o^i_3: 3-letter space
	4	o^i_4: 4-letter space
	5	o^i_5: tab
	6	o^i_6: linefeed
Basing-point tokens $o^b_{n_b}$	1	o^b_1: opening brace (e.g., "{")
	2	o^b_2: closing brace (e.g., "}")
	3	o^b_3: opening round bracket (e.g., "(")
	4	o^b_4: closing round bracket (e.g., ")")
	5	o^b_5: opening square bracket (e.g., "[")
	6	o^b_6: closing square bracket (e.g., "]")
	7	o^b_7: arithmetic operators (e.g., "+")
	8	o^b_8: assignment operators (e.g., "=")
	9	o^b_9: comparative operators (e.g., "<")
	10	o^b_{10}: logical and bit-wise operators (e.g., "!")
	11	o^b_{11}: comments
	12	o^b_{12}: colon (e.g., ":")
	13	o^b_{13}: comma (e.g., ",")
	14	o^b_{14}: semicolon (e.g., ";")
Other tokens $o^o_{n_o}$	1	o^o_1: reserved words, identifiers, delimiters, etc.

and o^b_1 can be observed in s_3 whereas only o^o_1 is observed in s_1. Figure 2 shows that o^b_1 in s_1, $o^i_{n_i}$ in s_2, and only o^o_1 in s_3 are observable in M^α_B. π_1 is always 1.0 in both M^α_F and M^α_B.

Each of the coding models is small-scaled and represents only a simplified token occurrence tendency corresponding to one of the 14 basing-point tokens as a part of a programmer's complex coding style. $M^\alpha_{F,1}$ shown in Figure 1 represent only which one or which combinations of the tokens out of six kinds of $o^i_{n_i}$ are observed between o^o_1 and o^b_1, and $M^\alpha_{F,2}$ in Figure 2 represents which one or which combinations of $o^i_{n_i}$ are observed between o^b_1 and o^o_1. There are 13 other pairs of M^α_{F,n_b} and M^α_{B,n_b} to represent 13 other kinds of coding styles regarding the 13 other $o^b_{n_b}$. In this way, the partial and overall features of A_α's complex coding style are represented.

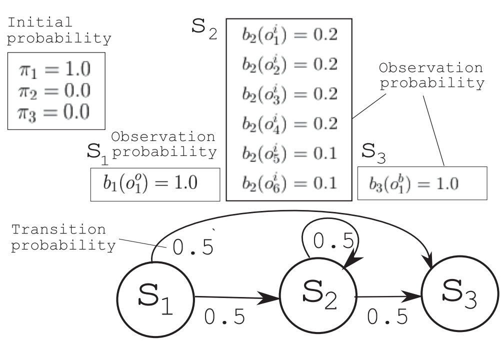

Fig. 1. One of the forward coding models $M^\alpha_{F,1}$

The following process to generate the learning data to train M_α is conducted. We tokenize the n-th source code of A_α to generate a token sequence D^α_n and apply 14 different normalizations to generate D^α_{n,n_b} consisting of $o^i_{n_i}, o^b_{n_b}$, and $o^o_{n_o}$. Then, we clip out a number of token subsequences $d^{\alpha,p}_{n,n_b,n_s}$ from D^α_{n,n_b}. When generating learning data for $M^\alpha_{p,1}$, $o^b_{n_b}$, except for o^b_1, such as o^b_2, are all treated as o^o_1.

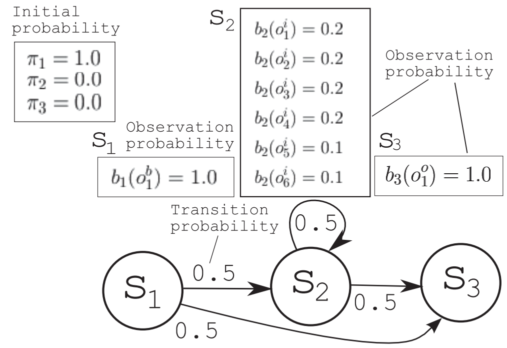

Fig. 2. One of the backward coding models $M^\alpha_{B,1}$

$$D^\alpha_n = \left\{D^\alpha_{n,n_b} \mid 1 \le n_b \le 14\right\} \quad (3)$$

$$D^\alpha_{n,n_b} = \left\{d^{\alpha,p}_{n,n_b,n_s} \mid n_s = \text{ \# of subsequences}\right\} \quad (4)$$

$$d^{\alpha,p}_{n,n_b,n_s} = \left\{o_t \mid 1 \le t \le l_{n_s}\right\} \quad (5)$$

where l_{n_s} is a length of the n_s-th subsequence.

The procedure of generating learning data $d^{\alpha,p}_{n,n_b,n_s}$ for $M^\alpha_{F,1}$ is as follows. (1) Choose o^b_1 out of 14 $o^b_{n_b}$ as a *current basing-point token*, (2) apply normalization by transforming all $o^b_{n_b}$ besides o^b_1 into o^o_1, (3) search for o^b_1 from the beginning of D^α_{n,n_b}. (4) After finding o^b_1, step back until o^o_1 is reached. Here, o^o_1 is treated as a delimiter and a line of o^o_1 are treated as a single appearance of o^o_1. (5) Then, start collecting tokens after o^o_1 until o^b_1 is reached. For example, in Figure 3, the token before "{" is ")," which should be represented as o^o_1 when the current basing-point token is o^b_1. Therefore, one of the subsequences $d^{\alpha,F}_{n,1,n_s}$ to be used as input data for $M^\alpha_{F,1}$ is "o^o_1, o^b_1". As another example, the tokens after o^b_1 are, in sequence, o^i_1, o^i_6, and o^i_5, before reaching o^o_1 ("int"). Therefore, the input data for $M^\alpha_{B,1}$ is "o^b_1, o^i_1, o^i_6, o^i_5, o^o_1."

The processes is continued to clip $d^{\alpha,p}_{n,1,n_s}$ in parallel until the end of $D^\alpha_{n,1}$ is reached. Then, the current basing-point token is changed to o^b_2, and the above process from the beginning of $D^\alpha_{n,2}$ is repeated to collect $d^{\alpha,p}_{n,2,n_s}$ as the learning data of $M^\alpha_{p,2}$. M_α is trained the corresponding parts of the coding style features of A_α, by inputting $d^{\alpha,p}_{n,n_b,n_s}$ and updating its parameters according to the learning algorithm of hidden Markov models [2][3]. In this method, the parameters of M^α_{p,n_b} and $M^{\alpha'}_{p,n_b}$ are compared to check the difference between a student's coding style feature and an exemplar coding style feature. Thus, a teacher can provide instructions about coding styles according to each student's original coding style feature.

III. EXPERIMENT

A. Settings

12 students $A_\alpha (1 \le \alpha \le 12)$ were provided with 10 basic Java exercises, and were required to produce 12 sets of 10 Java source codes $D^\alpha_n (1 \le n \le 10)$ under supervision to ensure that each set of source codes would be written in each of the students' own coding styles. First, copies of D^α_n were made and formatted according to *Eclipse 2.1 format* by using

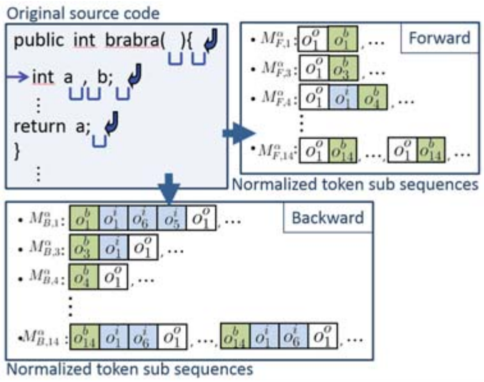

Fig. 3. How to generate input data for each of the 28 coding models

the formatting capability of Eclipse IDE [4]; some additional formatting such as inserting a single space before ")" and after "=" was also applied to generate a set of exemplar source codes $D_n^{\alpha'}$. We trained M_α and $M_{\alpha'}$ by inputting D_n^α and $D_n^{\alpha'}$, and compared the parameters of M_{p,n_b}^α and $M_{p,n_b}^{\alpha'}$.

B. Results

Figure 4 shows the parameters of $M_{F,1}^1$, $M_{F,1}^5$, and $M_{F,1}^{10}$ (red bars) and $M_{F,1}^{1'}$, $M_{F,1}^{5'}$, and $M_{F,1}^{10'}$ (blue bars), respectively. Figure 5 shows the parameters of $M_{B,1}^1$, $M_{B,1}^5$, and $M_{B,1}^{10}$ (red) and $M_{B,1}^{1'}$, $M_{B,1}^{5'}$, and $M_{B,1}^{10'}$ (blue). The types of parameters are shown on the x-axes and their values are shown on the y-axes of the graphs. π_i, b_1, and b_3 are not used, because the values are always the same.

From the graphs, the partial similarity and difference between the coding style feature of A_α and $A_{\alpha'}$ can easily be read. For example, the forward coding style of A_1 and A_5 are similar to each other and quite different from their exemplar coding styles $A_{1'}$ and $A_{5'}$, whereas A_{10} is different from A_1 and A_5 but similar to $A_{10'}$. A_5 and A_{10} occasionally insert no $o_{n_i}^i$ before o_1^b and at other times insert o_1^i, whereas the exemplar always inserts o_1^i, o_4^i, o_5^i, or o_6^i. The parameters of M_5 and $M_{5'}$ in Figure 5 indicate that the part of the coding style feature of A_5 regarding o_1^b is quite similar to the exemplar coding style feature, except that the student sometimes inserts o_1^i, o_2^i, o_3^i, or o_4^i, which does not occur in the exemplar coding style. Overall, there are very small differences among the backward coding styles of A_1, A_5, and A_{10}, and they are all also quite similar to the exemplar coding style.

The graph representations of the coding style help a teacher to provide instructions to students according to their features. D_n^α and $D_n^{\alpha'}$ were inspected visually and it was confirmed that the same difference between the coding style features of A_α and the exemplar exists as represented by the graphs.

IV. Conclusion

In this study, a method that measures a similarity between a student's and exemplar coding style features which can be used to improve a student's coding style is developed and tested.

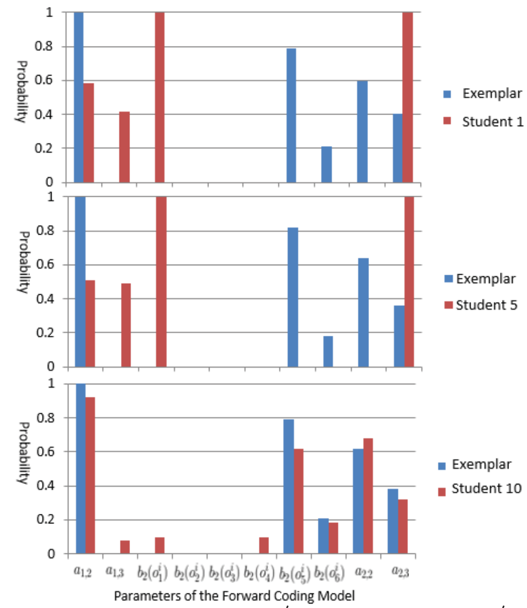

Fig. 4. Parameters of $M_{F,1}^1$ and $M_{F,1}^{1'}$ (top), $M_{F,1}^5$ and $M_{F,1}^{5'}$ (middle), and $M_{F,1}^{10}$ and $M_{F,1}^{10'}$ (bottom), respectively

Teaching an Introductory Programming Course Using Hybrid e-learning Approach

Asad Azemi, Mathew Bodek, and Gary Chinn
Pennsylvania State University, azemi@psu.edu, mjb14@psu.edu, chinn@psu.edu

***Abstract* - The usefulness of hybrid delivery in education has long been realized, and with the advancement of computer and communication technologies and the introduction of Web-based authoring tools, its effectiveness has been further extended. In this regard, it has affected traditional distance learning by transforming the learning experience from a static videotape delivery to a more dynamic format by adding/substituting the web as the delivery media. In this paper, we report our initial results based on offering an introductory computer programming course for engineers using Matlab; via hybrid e-learning including virtual face-to-face, for distance course delivery. We present the challenges that teaching a programming course brings about using a hybrid methodology with synchronous online delivery component. Details of this work, including design and delivery issues, student and course assessment, and required technology, as applied to a computer programming course, are included in the paper.**

***Keywords - distance learning, e-learning, virtual delivery, hybrid delivery*.**

I. INTRODUCTION

In our previous work [1], we reported our proposed hybrid e-learning approach to enhance distance learning and address some of the difficulties that have been reported with web-based deliveries. In this work, we report our initial findings and describe our next development plan. We first start with brief background information. The Internet "revolution" has formed an efficient and convenient way of managing many aspects of our lives, among them a new media for teaching and learning. Online learning has affected the traditional distance-learning format by transforming it from a static paper or videotape-based delivery to a more dynamic format by adding/substituting the web as the delivery media. While some studies reported high levels of student satisfaction with web-based course delivery [2]-[5], others found that students preferred the more familiar classroom-based environment [6]-[7]. Some of the difficulties associated with web-based learning, as reported by students going back a decade ago, still exist. They include: the feeling of isolation due to a lack of interaction with peers or faculty; lack of prompt feedback about processes and progress in the course; and a need for students to better manage their time in order keep abreast of the course requirements [8]-[9]. This project partially initiated based on our belief that by using a "hybrid" or "blended" e-learning approach, we would be able to address some of these concerns. Our approach could be considered enhanced distance education, with some distinct differences/requirements and added features. It is worth pointing out that among the published studies in this area, some define "hybrid" as a combination of "face-to-face" and "asynchronous" [10]-[11] and some like ours, taking a more general approach, as "synchronous" and "asynchronous" [12]-[13].

As was pointed out in [1], the initial idea for this project originated from trying to find a cost effective model/solution to the problem of under-enrolled engineering courses across Commonwealth Campuses at Penn State University. The idea of offering cross-campus courses has been entertained several times before by using Pic-Tel video technology, where students were able to watch an instructor deliver a lecture on a television set, or its updated delivery version called Video Learning Network (VLN). The major problem with these approaches is that the necessary interaction during the programming process, vital to student success in a computer-programming course, is difficult to achieve, as these systems are not designed for such requirements.

II. IMPLEMENTATION PLAN

This section focuses on the modifications that we have made, to the original approach as described in [1], for the second delivery attempt or planning to make in the next scheduled offering. For clarity, brief descriptions of the sections that have remained intact are included.

A. Course Selection

As described in [1], the project was designed to deliver CMPSC 200 (programming with Matlab), which is a required course for mechanical, and bioengineering students, and is recommended/accepted by civil, industrial, and biological engineering departments. Due to under-enrolled expectation, for this course, at Commonwealth Campuses of Penn State, it has not been available to some students and is only offered at the main campus, University Park. The main objective of this project is to improve student access to academic specialties across the college by using a cost effective model.

B. Hardware-Software Requirements

The hardware and software requirements/recommendations included the Adobe Connect [14] platform for virtual face-to-face delivery. We required web cameras and headsets for students. The instructor's computer included a dual screen for better control and delivery of the course. As anticipated, the quality of the Internet connection (available bandwidth) played an important role.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

C. Design and Delivery

The following includes points that are relevant to our current discussions, for more details on design and delivery considerations please refer to [1].

- Fourteen students from three campuses enrolled in the course during the first two delivery attempts.
- Students enrolled in the course were informed about course delivery methodology and the requirements for student participation, via email two weeks before the beginning of the semester.
- Support for online delivery classes was obtained. An e-learning specialist was assigned to help the instructor with design and delivery of the course.
- A short training video on how to use Adobe Connect was made for students. During the first online session, basic points were reviewed and practiced.
- Course syllabus included the number of synchronous class teachings/discussion, the amount of expected asynchronous learning by students, expected conduct during the synchronous delivery, and grading and attendance policies.
- Course delivery was through Penn State's E-learning cooperative and we have committed to a three-year delivery of this course.
- A programming team project using Matlab's GUI was added to the course design described in [1].
- Peer evaluation, using VoiceThread [15], for the team project was added to the design describe in [1].
- Students were encouraged to post their programming questions using ScreenR [16]. This was added to the design described in [1].

D. Teaching Process and Resources

Only the points relevant to our current discussion are included in this section for more details please refer to [1].

- The course included a textbook for reference and homework assignments [17].
- Pre-recorded short-lecture weekly videos were made available to students.
- Students were asked to watch the videos, read the textbook, and take a readiness assessment before the beginning of each synchronous lecture (to measure the learning level from the asynchronous portion). The readiness assessment questions changed from concept questions to short programming questions from first delivery to the second delivery.
- The synchronous delivery portions were designed to cover the topics that needed to be emphasized based on the questions that were missed by a 40% percentage of students during the first delivery and focused mostly on problem solving/programming rather than lecture delivery during the second delivery.
- Students were required to take a post assessment questionnaire that included short programs, a day after the synchronous meeting. The result of this assessment was used by the instructor to evaluate the effectiveness of the on-line segment.
- Weekly online programming quizzes (asynchronous) were included in the course.
- Exams included programming and concept type questions.
- ANGEL [18] (A New Global Environment for Learning) was used as the CMS tool for this course.

In our previous work, we indicated that the synchronous portion should be designed and conducted as a discussion and problem solving session and not on information delivery. The information delivery portion is expected to be handled by the e-lectures, recorded videos, and tested by online quizzes and activities during the asynchronous part.

III. Student and Course Assessments

The following integrated, but separately assessable components were used in the assessment process:

- Class participation and student contribution during the synchronous delivery mode (bonus point: up to 4% added)
- Homework assignments (13.7% of the final grade)
- Course GUI Project (9% of the grade)
- Project Presentation at a campus event and/or symposium (bonus point: up to 1.8%)
- Readiness- and post-assessments (13.7% of the final grade)
- Examinations and on-line quizzes (63.6% of the final grade)

IV. Remarks and Conclusions

The online synchronous delivery segment was modified, due to the assessment at the end of the first delivery, from review/short lecture to review/programming practice. The main reasons for this modification is presented below:

1. The underlying assumption for the proposed methodology was that students would review/study the posted/pre-recorded lecture material, and the online synchronous sessions would be used to answer their questions. After a few weeks during the first delivery, we found out that this was not the case. Consequently, due to the overwhelming request by students, the synchronous sessions changed to lecture delivery meetings, which was not our intent.
2. Unfamiliarity of the enrolled students with expected study plans for "online" courses and their approach to the class like a traditional face-to-face course.

We need to point out that CMPSC 200 is a programming course that is taken by third semester undergraduate students, and most students did not have any experience with online course offerings. Their approach to studying and preparations for this course was reflective of their college level experience. Based on exit interviews, we modified the synchronous delivery modules after the first delivery and we are planning to introduce/expand the following changes during the upcoming delivery:

- Provide an in-depth discussion with students regarding how to study for an online programming course. Students would be required to acknowledge the requirements and learning process.
- Produce several "dynamically worked-out problems" based on a model that we developed before [19].
- Change the online sessions from once to twice per week, focusing on problem solving. Students are expected to post/email their questions 24 hours before the meetings. These meetings will be recorded and would be available to all students. Attending at least one of the sessions is mandatory.
- Host a brief online meeting with each student every three weeks, going over his/her progress.

Abstract— **Education can take advantage of e-Infrastructures to provide teachers with new opportunities to increase students' motivation and engagement while they learn. Nevertheless, teachers need to find, integrate and customize the resources provided by e-Infrastructures in an easy way. This paper presents ViSH Editor, an innovative web-based e-Learning authoring tool that aims to allow teachers to create new learning objects using e-Infrastructure resources. These new learning objects are called Virtual Excursions and are created as reusable, granular and interoperable learning objects. This way they can be reused to build new ones and they can be integrated in websites or Learning Management Systems. Details about the design, development and the tool itself are explained in this paper as well as the concept, structure and metadata of the new learning objects. Lastly, some real examples of how to enrich learning using Virtual Excursions are exposed.**

Keywords— authoring tool; learning objects; e-Infrastructures

I. INTRODUCTION

The European Commission considers that e-Infrastructures are essential to foster scientific excellence and stimulate the development of high-quality human capital and therefore they must have a place in education and training [1]. According to [2] an e-Infrastructure consists of computational systems, data management, advanced instruments, visualization environments and people, all linked together by software and advanced networks to improve scholarly productivity and enable knowledge breakthroughs and discoveries not otherwise possible. In education, e-Infrastructures can be used to provide unprecedented access to educational resources including experts, online activities, games and virtual environments [3]. Therefore, e-Infrastructures can greatly expand learning and teaching opportunities for students and teachers [4]. For instance, they can allow interacting in real time with resources such as microscopes, virtual laboratories, webcams or tools of professional science like simulations, data sets or remote equipment. Teachers can combine virtual resources like these and traditional F2F (Face to Face) teaching in order to enrich the learning experience in an effective way taking advantage of technology without renouncing to the benefits of in-person teaching [5]. Hence, e-Infrastructures can be used in blended learning, supplementing traditional classroom activities and providing enhanced learning materials. According to [6], this is especially useful for science, technology, engineering and mathematics (STEM) disciplines as the best way to provide this kind of education is to use a blended approach.

Nevertheless, it is difficult to find accessible educational e-Infrastructure resources. Moreover, although sometimes teachers can find an appropriate one, they need to customize and link it with other educational contents (e.g. text, images or videos) in order to make it more pedagogical and to adapt it to different knowledge levels and requirements of different classes. Additionally, if teachers want to improve the quality of their own teaching materials by using e-Infrastructure resources, they should integrate both. Therefore in spite of all e-Infrastructure benefits in education, teachers usually end up using classical resources, which provide less engaging experiences, or generating their own resources from scratch.

Taking all this into account, providing e-Infrastructure resources as content units that can be individually adapted and integrated into existing teaching materials and curricula of teachers was identified as the main challenge when the GLOBAL excursion (Extended Curriculum for Science Infrastructure Online) project started. GLOBAL excursion is a European project which main aim is to enrich science teaching in European schools. Via a central web portal, called Virtual Science Hub (ViSH), we provide scientists, teachers and their pupils a package of activities, materials and tools for enabling the integration of e-Infrastructures into school curricula.

In order to allow teachers to create enhanced learning materials through integrating e-Infrastructure resources we have developed an e-Learning authoring tool called ViSH Editor. This tool will be presented in this paper. The content generated by this authoring tool is a new learning object called Virtual Excursion which will be also explained.

The rest of the paper is organized as follows. The next section reviews related work of authoring tools as well as learning objects. Section 3 introduces the GLOBAL excursion project. Section 4 shows an overview of the ViSH platform. Section 5 and 6 explain the generated learning object and the ViSH Editor authoring tool. The last section finishes with some concluding remarks together with an outlook on future work.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

II. RELATED WORK

Before content can be accessed, shared or reused, it must be created. Authoring tools aim to enable authors to create this content. An authoring tool can be defined as a software application that allows authors to create their own content and deliver it to the end users. As a general rule in the case of an e-Learning authoring tool, the authors are teachers, the end users are students and the content is a learning resource created following a learning object content model. An official definition of learning object (hereafter LO) can be found in the learning object metadata (LOM) standard [7], which defines a LO as "any entity, digital or non digital that may be used for learning, education or training". However, this is not an universal definition since LO definitions and specifications considerably vary depending on the content model [8]. The primary purpose for creating these resources as LOs is to facilitate reuse [9]. The major benefit of reusing LOs is to reduce time and to enable cost-effective development by reusing learning materials instead of repeatedly authoring them. Moreover, digital LOs may even enhance the quality in comparison with those developed from scratch [10]. The potential of a LO for reuse increases as its size or granularity decreases [11]. Thereby learning resources should be sufficiently large to be of educational value but also be small enough to be effectively reused [12]. LOs can be combined among them to build more complex ones forming a hierarchy. For instance, a slideshow can be created by linking single slides together. Furthermore, each of these slides can be created at the same time by linking other LOs such as a paragraph of text, a picture or a video. This creation process can be referred to as authoring by aggregation [11]. Also, these LOs are known as granular LOs and the different hierarchy levels are called aggregation or granularity levels. Learning object models define these levels of granularity and specify how the components can be aggregated as well as the properties of these components [13]. One very important aspect of LOs is metadata, where a description of the content is included in order to improve their reusability, discoverability and interoperability. Standards also play an essential role for an authoring tool to achieve the interoperability of the resulting LOs. For this reason, the learning resources created by most authoring tools can be exported or are built conforming to some e-Learning standard such as SCORM (Sharable Content Object Reference Model) [14] or AICC (Aviation Industry Computer-Based Training Committee). However, there also exist some e-Learning authoring tools that do not include support for e-learning standards. Since authoring tools offer a diverse variety of features, the process of selecting one to create the LOs might be hard. As [15] points out, the criteria for choosing the most suitable authoring tool should be based on the particular needs of the end users, taking into account capabilities such as automated programming, interoperability, standards, question types and media and file support. This is especially important in low-tech teaching contexts, where teachers are not computer specialists and also have poor IT (Information Technology) support. Under these conditions, it is still possible to get excellent results by using the appropriate models and authoring tools [16]. An authoring tool can provide a differentiating value not only adapting to their target users' needs but also by integrating novel learning resources such as e-Infrastructures.

Several e-Infrastructures (e.g. DEISA [17], EGI [18], OSG [19], XSEDE [20]) exist nowadays with the foremost aim of sharing computing resources and data between scientists. However, the potential impact of e-Infrastructures in education is at least as significant as that in other disciplines [4], and hence, as time goes by, more projects [21] [22] are carried out to provide more e-Infrastructures for education. Finally, bearing in mind that a LO can be formed by aggregation, these e-Infrastructure resources can be linked with other LOs through authoring tools to increase their educational value.

III. GLOBAL EXCURSION PROJECT

The European Commission has defined the advancement of STEM related skills as one of the priorities for the period 2014-2020 [23]. Furthermore, it has shown in several reports its concern about the way science teaching is currently being performed [1]. Bearing all this in mind, and considering that e-Infrastructures are recognized by the European Commission as a key to a knowledge-based economy and social cohesion that need to have a place in education, the GLOBAL excursion project (http://www.globalexcursion-project.eu) was proposed and approved.

Together with end users, GLOBAL excursion develops a common understanding, teaching use cases, as well as pedagogical and technical artifacts. The aim of this project is to provide students and their educators (teachers, parents, etc.) across Europe with a range of e-Infrastructures and access to expert knowledge on its usage for a joyful exploration of e-Science. Another goal of the project is to improve science curricula by enriching school's existing teaching and learning materials.

The e-Infrastructure providers participating in the project were initially three, the Institute for Biocomputation and Physics of Complex Systems (BIFI) from Spain, the Nanoscience Centre from the University of Cambridge (UCAM) from the United Kingdom and the Computer and Automation Research Institute (SZTAKI) from Hungary. Other scientific centers are expected to participate in the near future. The materials currently provided by these partners are based on the following topics: biotechnology and biology from BIFI, grid computing and volunteer computing from STZAKI and nanoscience from UCAM.

IV. VIRTUAL SCIENCE HUB

Virtual Science Hub, or ViSH in short form, is a social collaborative e-Learning platform in which all GLOBAL excursion activities take place. It provides a social network where teachers and scientists can share their resources, know each other and collaborate. The other main aim of the ViSH platform is to create and share enhanced LOs taking advantage of e-Infrastructures for education, providing this way more engaging experiences to students. These new LOs, which we have called Virtual Excursions, are created using the ViSH Editor authoring tool. Fig. 1 represents the different actions that are carried out to create a Virtual Excursion.

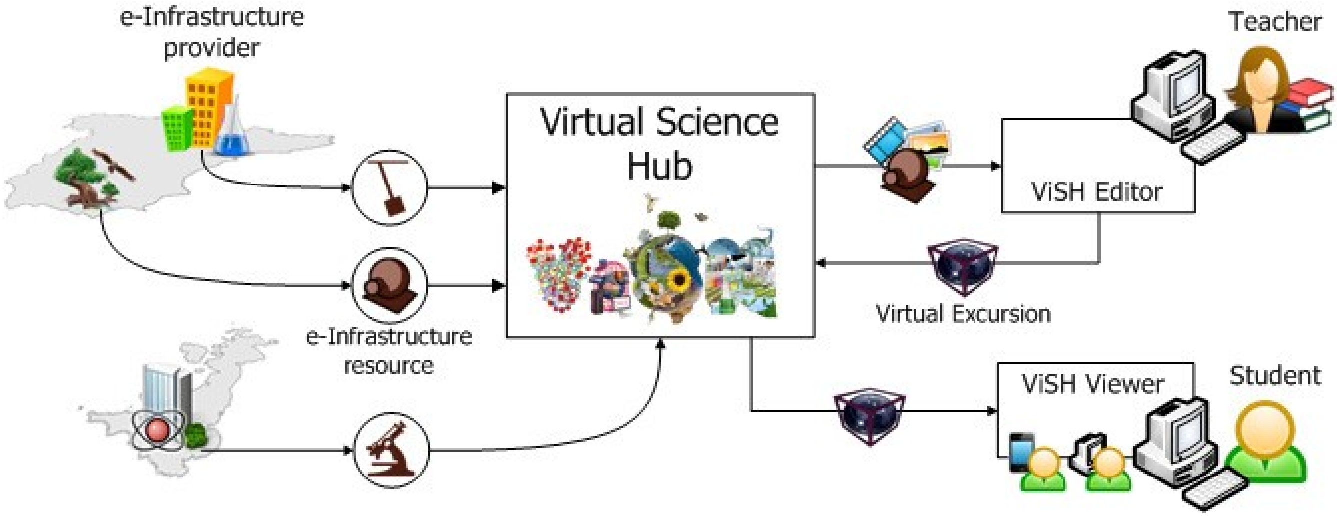

Fig. 1. Virtual Excursion generation

Besides providing the social network and the authoring tool, ViSH also provides a learning object repository (LOR) that stores both LOs and their metadata. The e-Infrastructure providers use this LOR to upload their resources. Once the e-Infrastructure resources have been stored in the LOR, they are available to be used in any Virtual Excursion. Teachers can create a Virtual Excursion online using the ViSH Editor web-based authoring tool. They can add any resource of the LOR as well as resources from external services like Flickr or YouTube to compose the excursion. When teachers finish the creation task, they can publish the excursion into the ViSH or save it as a draft for keeping it private and finishing it later. Anyway, the excursion created is stored in the ViSH LOR with the rest of the LOs. From the moment an excursion is published, it can be accessed by anyone, even without being registered in the platform. The published Virtual Excursions can also be cloned by other registered users, and of course, they can be edited or removed by their owners at any time.

To explore a Virtual Excursion users just have to load a lightweight web application called ViSH Viewer [24]. ViSH Viewer is a module of ViSH Editor used for previewing the Virtual Excursions while they are being created, but it can also work standalone. It allows users to view and interact with the Virtual Excursions (or with any other LO generated via ViSH Editor) from any device using only a web browser without any installation or previous configuration being needed. For this reason, we can also refer to the LOs generated by ViSH Editor as multi-device LOs. Using a lightweight web application is especially important for handled devices which usually have lower power processing.

ViSH has been completely designed by the project members following a participatory design process [25] whereby the user requirements were identified. It is open source and has been developed using the latest technologies on top of the social network framework Social Stream [26], which is also open source and provides common social network features such as contacts, walls, posts, comments, documents, privacy and permissions management, private and instant messaging, groups and so on.

ViSH is currently in production at http://vishub.org. It is free for end users to register, enter the community and enjoy the experience.

V. The Virtual Excursions

A. Definition

Conceptually, a Virtual Excursion is defined as a tour through some digital context by teachers and pupils on a given topic that is attractive and has an educational purpose [27]. A Virtual Excursion provides a new way to explore science in class allowing students and teachers to access and control experimental equipment of research laboratories at remote sites, explore natural parks, museums or any other infrastructure with educational or cultural interest which would be too expensive or non-viable to visit in person [24]. In practice, Virtual Excursions are created by teachers or scientific organizations using the ViSH Editor authoring tool as reusable, granular and interoperable LOs.

B. Structure

LOs can be combined among them to build more complex ones forming a hierarchy. Regarding the aggregation levels (i.e. hierarchy levels) to which a LO belongs we can differentiate between coarse-grained and fine-grained or granular LOs [28]. Thereby, granular or fine-grained LOs are those that belong to the most granular or atomic aggregation level. The LOM [7] standard contemplates four aggregation levels to describe LO granularity.

The Virtual Excursion LO is defining conforming to its own learning object model. This model defines four levels of granularity based on the LOM standard with small differences according to the scheme of Fig. 2:

- The first level, which corresponds to the most granular or atomic level, includes raw media files like text, images, videos or flash objects and single elements like a website, a document or a 3D object. More sophisticated

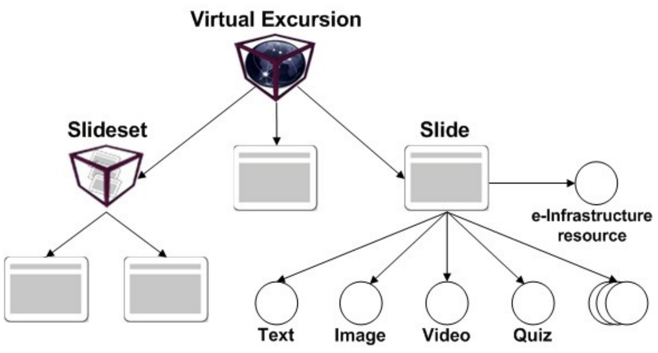

Fig. 2. Virtual Excursion aggregation levels

elements such as quizzes or e-Infrastructure resources belong to the first level too.

- The second level covers only one LO called "slide" that consists of a collection of level 1 LOs.
- The third level includes any LO that is built as a composition of level 2 LOs (i.e. "slides"). These LOs are identified under the name of "slidesets".
- Finally, the fourth level corresponds to the Virtual Excursion LO. A Virtual Excursion can contain level 3 LOs or directly a slide without using a slideset as a wrapper. Nevertheless, it cannot contain other Virtual Excursions. These are the main differences with respect to the LOM specification.

So, according to this structure, e-Infrastructure resources are fine-grained LOs. This means that they can be reused in multiple Virtual Excursions or slidesets through the slides. On the other hand, slides LOs can be used as components or building blocks of more complex LOs such as virtual experiments [29] or educational games [30].

Lastly, considering that LO metadata describes relevant characteristics of the LO to which it applies and can be used to facilitate its searching, retrieval and evaluation, Virtual Excursions are tagged with metadata based on LOM standard.

VI. ViSH Editor

ViSH Editor is a web-based e-Learning authoring tool that aims to create and edit Virtual Excursions. It is open source and the code is available at http://github.com/ging/vish_editor. Today, it is available to end users through the ViSH platform.

A. *Interface and basic features*

ViSH Editor is based on the WYSIWYG (What You See Is What You Get) paradigm. It provides a usable and user friendly web interface designed with low-tech teaching contexts (where teachers are not computer specialists and also may have poor IT support) in mind. The user interface (UI) is mainly based on graphics but also have few textual elements (Fig. 3). ViSH Editor presents the Virtual Excursion as a slideshow, on which users can add new slides and move or remove the existing ones. Each slide is created from a template selected by the user. Inside a slide users can insert different resources and/or generate their own content. All of the inserted

Fig. 3. User Interface of ViSH Editor

resources can be moved using the drag and drop technique. Furthermore, other actions can be performed over the distinct resources such as resize, zoom or hyperlink aggregation. Despite usability and user experience studies point out that ViSH Editor interface is very intuitive, a walkthrough is available for novice users to get started with the tool and learn new features. In addition, context-sensitive help is always available, providing help for the specific situation of the user. Users can preview the Virtual Excursion while they are creating it at any time. Also they can save the excursion as a draft to continue completing it later. In summary ViSH Editor assists teachers (or any other user) in the process of creating and publishing a Virtual Excursion.

B. *Resources and own content*

ViSH Editor allows users to insert many types of resources: images, videos, websites, PDF files, flash objects, etc. Any resource can be inserted via its URL. Also, ViSH Editor provides interfaces to search resources in the ViSH LOR as well as in external services like Flickr, YouTube or Vimeo.

Fig. 4 illustrates a search in the ViSH LOR. A catalogue of e-Infrastructures obtained from the ViSH LOR is also available. ViSH Editor facilitates the access and integration of these e-Infrastructures by managing the connections with live streamings and interacting with the web services and the particular interfaces of the e-Infrastructure resources. Moreover, users can upload their own resources to the ViSH. The slidesets and slides LOs of other Virtual Excursions can be also inserted. More types of resources are expected to be available to be integrated. For instance, the next coming version will have the functionality of insert and convert PowerPoint or PDF presentations in Virtual Excursions.

Besides adding resources, teachers can generate their own contents. They can insert paragraphs of text using a WYSIWYG rich text editor. Also, they can create their own quizzes to evaluate the acquired knowledge of the students. These quizzes can be inserted inside a slide as any other

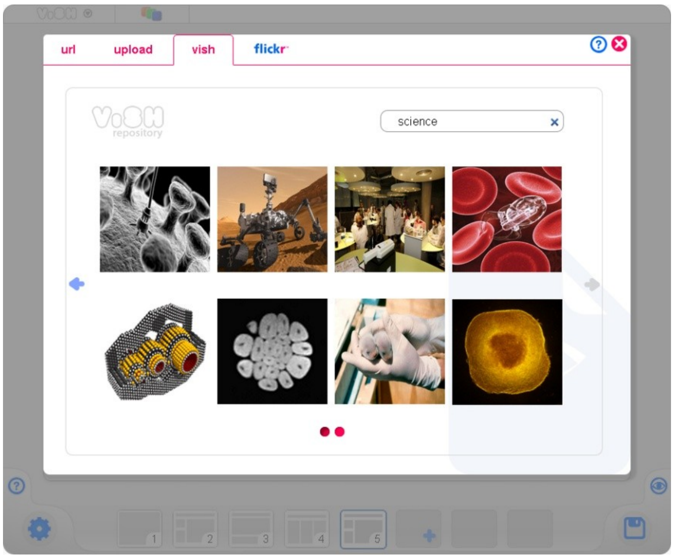

Fig. 4. Searching resources in ViSH Editor

content and hence they can be combined with any other resource. The questions can be true-false, multiple choice or open ended. Self-assessment is also possible. The results are stored and they can be accessed both in real time to be discussed in class or later to be analyzed in detail. The teacher can represent the data in many ways such as a bar graph or a pie chart.

C. *Metadata*

ViSH Editor also facilitates authors to fill the metadata of the Virtual Excursion LOs. They can indicate several metadata elements: Title, Description, Author, Language, Avatar (an image to identify the excursion visually), Tags (that act as keywords for the ViSH search engine) and others related to pedagogical qualities: Subject, Age Range, Educational Objectives and Acquired Competencies. There are other metadata elements that are inferred rather than specified by the author. For instance: metadata elements related to the structure or technical requirements, version, contributors, etc.

D. *Creating slidesets*

Besides creating Virtual Excursions, ViSH Editor can be used to generate other LOs called slidesets. These LOs are built using the slides LO as components and at the same time, they can be used to be part of an excursion as a conventional slide. Three slidesets can be created in the current version: flashcards [29], virtual tours and educational games [30].

To create a flashcard users select an image background (from ViSH LOR or Flickr, via URL or uploading it) and above it hot zones representing by arrows to link the slides. This way the slides will not have to be consumed in order but they will appear when touching or clicking on a hot zone.

Virtual tours are quite similar but instead of a static image background users can use an interactive map. They can search for any address and add locations representing by pins to which the slides will be linked.

Finally the same way the slides can be linked to hot zones in images or maps, they can be linked to actions or events in a game. A role-playing web game was developed where the teacher can link the slides to specific actions in the game, like “touch a blackboard” or “talk to some character”. When the player performs any of these actions the slides appear. This way the game is customizable with the content from the slides.

E. *Interoperability*

The Virtual Excursions and their metadata are saved in the ViSH LOR in JSON format. However, in order to increase their interoperability, they can be downloaded as SCORM. So, they can be integrated in any Learning Management System (LMS) that supports this standard (e.g. Moodle or Blackboard). This way the students will have the excursions integrated with the rest of the resources that they use for their daily learning.

Moreover, all of the LOs generated by ViSH Editor provide an API (Application Programming Interface) which allows third party web applications to communicate with them and to use advanced functionalities (e.g. event notifications, advance slides, etc). Thereby they can be integrated in any website or web application. In the ViSH scenario this API has been used to integrate the Virtual Excursions with a videoconference tool called MashMe (http://mashme.tv). This integration allows teachers to share Virtual Excursions synchronously in real time with any other users.

F. *Technology and implementation*

ViSH Editor is a web application based on HTML5 [31], the new standard for the web. For this reason, any HTML5 compliant web browser can run the web tool and hence create Virtual Excursions. ViSH Editor has been developed as a JavaScript library and a set of HTML pages and CSS (Cascading Style Sheets) files. Despite it is a client-side application, some tasks (e.g. upload files) need a server backend. However, ViSH Editor is not tied to any specific backend technology, in fact we have developed two different implementations using Ruby on Rails and Node.js.

G. *Virtual Excursion examples*

Finally, to have a better understanding of how ViSH Editor can help teachers to create enhanced LOs through the use of e-Infrastructures resources, we present in this section some examples of Virtual Excursions.

The first example (illustrated in Fig. 5) is a Virtual Excursion to learn about physics in which students have the chance of accessing and controlling remotely three different instruments of a real physics laboratory: a pendulum, a pulley and a spring. First off to create this excursion, the teacher has written some physics exercises which are formulated at the beginning. Then, he/she has searched and included the e-Infrastructure resources, which were previously uploaded to ViSH by BIFI. Lastly, the teacher has created some quizzes to collect their students’ answers. This way the students can compare their theoretical calculations with the measurements of the real systems before they answer the quizzes.

Many other Virtual Excursions have been created in the ViSH platform by teachers and scientific organizations.

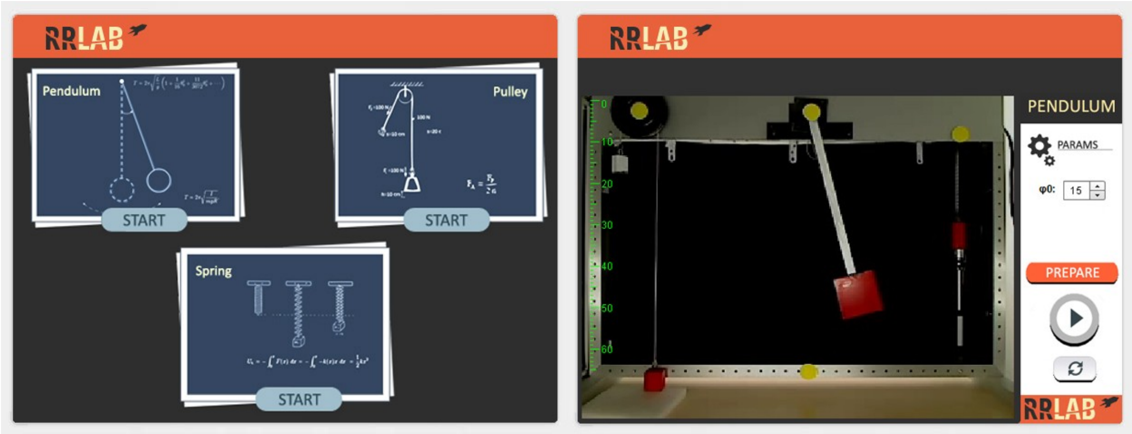

Fig. 5. Virtual Excursion of a Remote Physics Laboratory

For instance, a virtual visit to the Doñana Biological Reserve where students can observe a huge variety of animal species through live webcams.

Another interesting example is one where students can observe in real time the video output of different microscopes provided by the Nanoscience Centre of UCAM as well as receive explanations of the researcher who will be operating the microscope.

VII. Conclusions and Future Work

In this paper we have presented ViSH Editor, an innovative web-based e-Learning authoring tool to create enhanced LOs called Virtual Excursions using e-Infrastructure resources. ViSH Editor creates Virtual Excursions as reusable and granular LOs. It also provides several mechanisms to integrate them into websites, third party services and LMSs. Lastly, we have exposed some examples of how to enrich learning using Virtual Excursions.

From our experience with ViSH Editor, where we had to develop several tailored solutions to facilitate access to selected e-Infrastructures, we believe that providing a standardized way to access e-Infrastructures resources is one of the main challenges to promote the use of e-Infrastructures in education.

On the other hand, an authoring tool should be adapted to the needs of their end users to be successful. So, if the end user is a teacher, who does not have to be a computer specialist, the authoring tool must provide a simple, intuitive and user friendly interface including context-sensitive help and optional walkthroughs.

Authoring tools can play an important role in modern e-Learning platforms creating and maintaining didactic contents. In collaborative environments, the reusability of these contents is the cornerstone. Thereby these contents should be created following a learning object model that defines appropriately the granularity levels, the structure and the metadata. Moreover, several efforts should be undertaken to achieve interoperability, especially with LMSs by using e-Learning standards.

The Virtual Excursions created via ViSH Editor are a great example of how technology can enhance learning, but there are some future works that can be performed to bring new contributions in order to keep improving.

First off, based on our experiences, we plan to define a standard for e-Infrastructure access and develop and test it in real cases. Also, we want to define a model to integrate the existing learning objects into games, building a bridge between game developers and teachers. Finally we will carry out an evaluation of the use of the Virtual Excursions in the classroom to measure their educational impact.

Acknowledgment

We wish to acknowledge our gratitude and appreciation to all the GLOBAL excursion project partners, and each one of the project team members, for their contribution during the development of various ideas and concepts presented in this paper. We also would like to thank the SAAN project (TIN2010-19138) for funding this work.

Both effects reinforce learning and reaffirm the position of teacher-student couple.**

Keywords—eLearning; remote laboratories; modular tool; practice; distributed learning; reusability; distance education

I. INTRODUCTION

The ability for accessing learning tools at any time and from anywhere is highly increasing. Technologies such as Internet and mobile devices provide universal integration of teaching and learning. For scientific or engineering subjects, the use of real resources through online laboratories is another step towards bringing the students to the practical laboratory sessions, [1]. These platforms show how teacher and student share a common work space in which they work together to solve problems. UNED (Spanish University for Distance Education) is working on the development of techniques that facilitate the building of remote laboratories and their access, both for students and for teacher.

The development requires establishing a learning environment based on modular scaffolding tools. The objective is grouping those elements needed to build the experiments and the laboratory activities, by using modular tools, making easy their use in a simple and intuitive way. Experience from existing projects on other fields has been used and has been merged with collaborative and tracking features, [2]. These features, offered by social networks and learning analytics on learning environments, together with the development of an API, have led to the definition of a new concept of work space and on-line distributed experiences.

This work space is oriented to learning and it covers the whole experiences of teaching-learning in real laboratories. By using it, the teacher can design and implement a great variety of experiments using the provided devices. The system allows the use of specially designed widgets (basic blocks) and technical documentation that exists, into a multidisciplinary network of laboratories. The student accesses the system from a fixed or mobile terminal; using a standard mobile Internet browser; safely and at any time, from anywhere, with any others resources, because tools needed are on server side.

This modular development allows the teacher to include new blocks in the system. These new blocks can be reused by other teachers for other activities, optimizing and increasing the original utility (open life cycle) into the system. The system uses the philosophy of reusable learning objects but taking it to the field of development of remote laboratories packaging [3].

The system has a laboratory structure based on the students' age; each teacher can select the optimal laboratory configuration that best suits his/her needs at any time. Free software tools have been used when possible through the entire project.

The opinions of learning professionals and students have been taken into account for designing user interfaces and developing API utilities and the packaging system of laboratories. Current experience shows that the interaction of the students with these tools make them more receptive to learning, regardless of their age. It also helps them to understand more easily abstract concepts in engineering and science subjects, associating these abstract concepts with daily life.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

It is also relevant that students can commit mistakes without any real risk. Moreover as the system will facilitate the building of customized reusable laboratory practices for teachers, these will be motivated to use them in their classrooms whenever possible. Both effects reinforce learning and reaffirm the position of teacher-student couple.

The rest of the paper is organized as follows: section II shows the previous experience on UNED working on distance learning, section III shows how this experience put the basis to design tools to improve distance learning, section IV describes the use of a couple of examples and the importance of both sides, teachers and students, section V show the importance of the feedback cycle among modularity, reuse and generalization of this tool. And finally section VI explains the importance of this path to improve the existed tools and to motivate to teacher and student along the educational and training process.

II. Previous Experience as a Basis

During the last 40 years the UNED (Spanish University for Distance Education) has shown that distance learning is possible and greatly enriches traditional teaching. UNED has been using the typical traditional classroom learning tools and combined with other specific tools for distance learning. The objective has always been to bring closer theory to practice for students, [4].

At the same time, and given the importance of university education as social engine for business, economic and as point of integration, UNED has always tried to bring students to the appropriate level for their access to the labour market as fast and skilled as possible, [5], especially in certain areas such as engineering, [6].

Such experiences have focused not only in university, but have gone further, engaging in activities to promote, into pre-university environments, the interest about engineering among students and teachers in primary and secondary schools, [7], making spreading a fundamental tool in the education system.

During that time UNED has accumulated experiences, both on the student and the teacher side, to improve these tools. Today, after several decades of online technologies, the accumulated knowledge is being integrated into a system to standardize all the knowledge and make the most for education, both on the side of the teacher and the student's side. Several stages, analysed below, have been followed to reach this point.

A. Detection of needs of students and teachers

Firstly, the teachers need a working environment that allows continuous tracking of the progress of their students. This involves establishing a user management system to identify each of the students uniquely and let store all their information while they use the available educational tools. Learning analytics is key at this stage, [8].

In addition there should be a similar tool that allows monitor progress of teachers. For this, a similar system to that of the students must allow to know, in each case, which student group is assigned to a specific teacher and what is the teacher's progress in class, face to face and/or virtual classes.

Finally an adequate space where students and teachers could plan their sessions must be implemented. In this space the teacher can establish the proper scheduling of practice, theory and tutoring hours. In the case of students, to keep track of the lessons to study, practices to comply or exams to be performed. If this space is structured taking into account the needs of students and relying on their ability to engage in the process, [9], their motivation to study will increase and they will become an essential gear of the system, even in pre-university ages, in support of their teachers.

It is also important to take into account the management and evaluation of the rating of students and teachers, which will allow detecting system failure to proceed to correct them.

B. Review of current systems based on the needs

Once the needs are established it is necessary to review the current system. In the case of UNED, the current system meets most of the requirements mentioned in the previous section, except that in some cases the different systems that manage those needs are spread across the network and information technology that is currently used.

Nowadays, the possibility of using wireless systems for connecting laboratories and the practice experiments, [10], or the existence of mobile devices with the widespread use of the Internet, [11], has allowed that engineering in particular, and by extension other disciplines, use all the resources at their disposal to improve their formation paths, [12].

That situation obliges teachers and students to access different parts of the system to test different things. In some cases that is not a problem, but in all cases obliged to take the time that otherwise could be used in other activities: improvement of material, more attention to the tutorials or just to organize the university classes daily.

C. Finding a unified solution

It is at that point where it feels the need of finding and implementing a unified solution. A solution that will be useful for both the teacher and the student and, at the same time, will be sufficiently widespread to be used in the largest number of subjects and courses, and specific enough to be useful. UNED and specifically DIEEC (Department of Industrial Electrical Electronics and Control Engineering) is working currently in this kind of solution.

III. Setting the Right Environment

Since the value of the system aims to promote distance education as an integration tool, Internet is a key tool. For this DIEEC into UNED has developed a portal which encompasses several of the tools to be used, by students and teachers in the day-to-day teaching of engineering disciplines, because only through practice, [13], you can get to know in depth the importance of this discipline in the real world.

Figure 1 shows the gateway quoted. It has a self-explanatory structure and lists the various sections in function of the characteristics of each of them: Virtual and Remote Laboratories, Learning Management Systems, Mobile

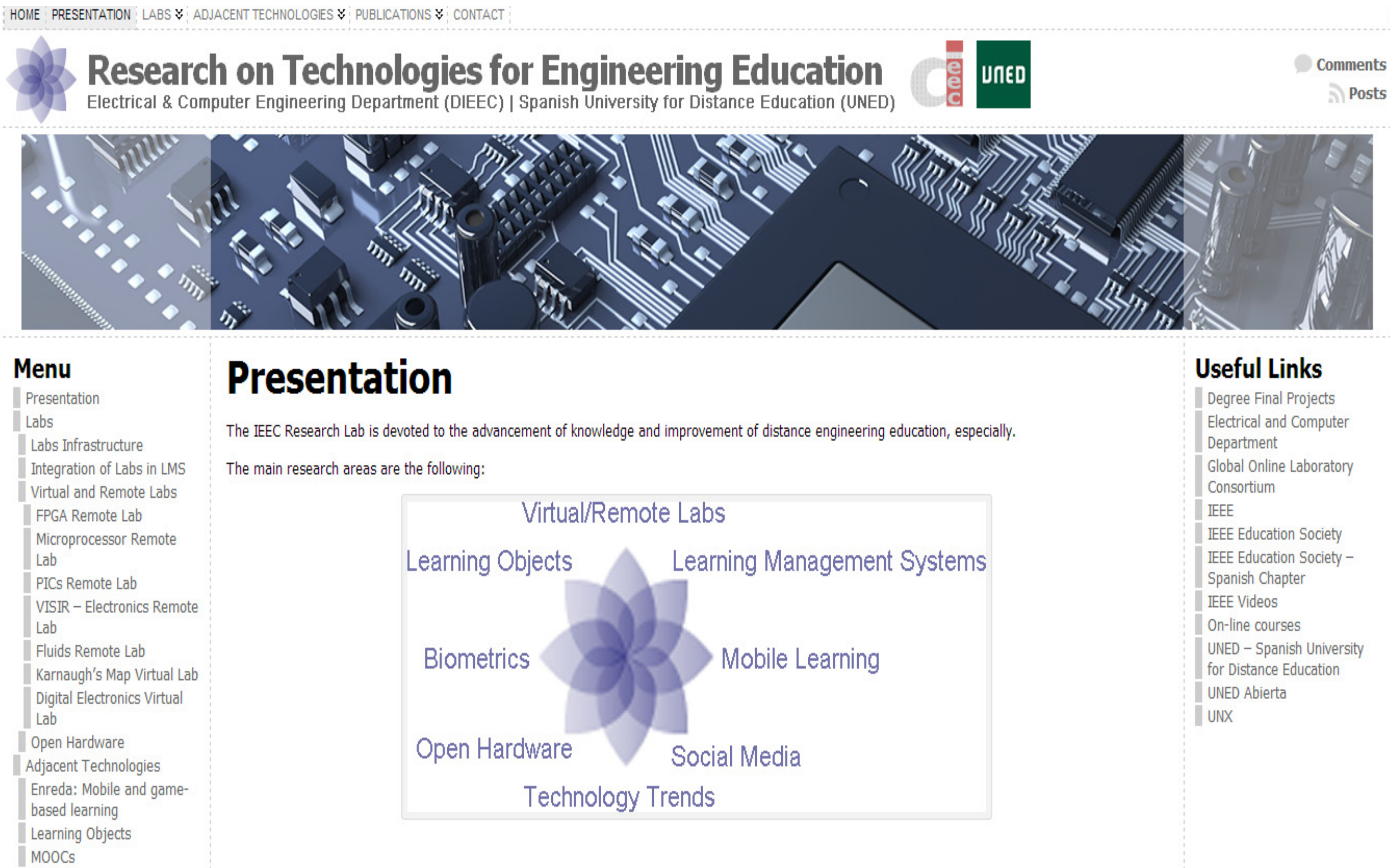

Fig. 1 Main page of the portal (source: http://ohm.ieec.uned.es/portal/)

Learning, Learning Objects, etc. Each of these sections has its own web tour.

This paper focus a little more on the section of remote and virtual laboratories, to show the performance of the system and practical applications for the learning and teaching processes.

The above environment should be useful for both teachers and learners. The different approaches must be properly integrated to get things working properly and maximize its use. In that sense must at least meet the following requirements:

1) For teachers

It is needed that this environment complements the classes, strengthen the theory and serve to demonstrate real-time performance of the technology used. Following these point, the system must be:

a) Ease of Use: For its use does not cause loss of time in class and the teacher does not need to spend too much time learning how to use it.

b) Interactive: To fulfil the characteristics solving exercises in real time. Also the system must be able to demonstrate that different changes in the data or initial hypotheses cause different output behaviour in the system.

c) Visually attractive: With a friendly interface for faster data input or load.

d) Reliable: Reducing the number of malfunctions to avoid wasting time during class.

e) Decisive: Given a load or input, the system should always have an immediate exit, and if loops appear it should indicate it to not get hung up indefinitely. There is nothing more annoying than waiting for a result that never comes out.

2) For students

It is necessary for the students to access the system to check by themselves how it works. Therefore, the system must be:

a) Consistent with what is taught in class: Since the system is understood as a practical continuation of the class.

b) Available 24 hours 7 days a week: Given the profile of the students of UNED, the possibility of practices at any time of day and any day of the week is essential and is the basic nature of distance learning.

c) Intuitive and easy to use: As in the case of a teacher, the students want to test what they have learned, and do not want to spend hours learning to use a system with a complex interface. The system should be a tool, not the long process of acquisition of a skill. For this purpouse every laboratory has a video, linked into the website refered on Figure 1, showing how must be used.

d) Clear error handling: For the use of the system may be the student has not got a teacher available all time, for that reason, the system itself must have a clear and defined error handling. Error messages can not be ambiguous, they must be concrete: "You must load the file", "Connection to the system has lost", "You are in wait queue", etc. Wide enough explanatory messages will avoid the stress caused to the student and it will allowd to use their time more productively.

With the above requirements as basic, the system can get going with some assurance and relief that it will be useful for both the student and the teacher.

Following the exposed above, the scaffolding is sustained by:

a) theory on class, presentation of the laboratory's website,

Covering these objectives the laboratories would be ready to use and to offer to the students and teachers for their training.

IV. From Theory to Practice

While there is still much work ahead, several tools developed using the philosophy described above can currently be used. Figure 2 shows the main screen of a virtual laboratory.

1) Case I: Digital Electronics Virtual Lab

The role of the laboratory is to demonstrate the operation of a virtual digital electronics system.

The lab shows the symbolic structure of its different logic gates with its various NAND, XOR, etc., and under quoted structure shows also its virtual operation use modifying the inputs and showing the relevant outputs based on the progress of a virtual clock that runs it.

The clock pulses are marking the advance of output graphics. Finally, the outline of a state automaton ends by

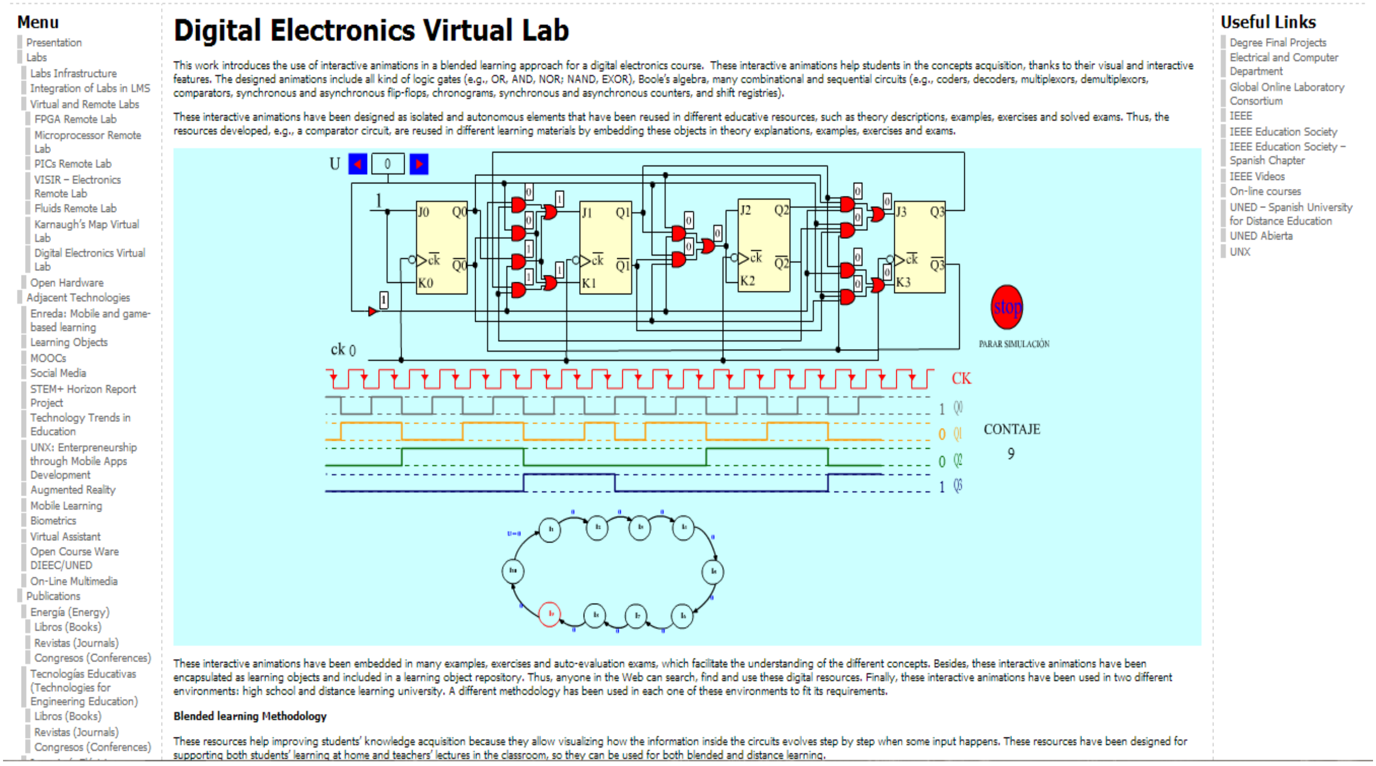

Fig. 2 Virtual remote lab example (source: http://ohm.ieec.uned.es/portal/)

b) students learn to use use of the different laboratories following the instructions into the website,

c) students give a feedback of the use of the laboratories preparing an academic work using it,

d) teacher and students discuss about the experience and the works prepared.

complete explanation of the system.

The usefulness of the system is clear. After a theoretical lesson about different types of logic gates, microprocessors, etc., some notes on state automata, and the importance of clock cycles, access to this virtual laboratory completes the class.

2) Case II: PICs Remote Lab

The second scenario is a real and not virtual laboratory. In this case, as shown in Figure 3, there is a physical place that is a board with PICs that is always available to students and the teacher. Access to it is managed through queues, and access to the board itself is performed through a simple user interface that allows students to upload the source code to be loaded into the test board.

The process is managed through advance reservation by the student that has entitled to use it for slots of about 45 minutes. As the availability is 7 days a week and 24 hours a day, the students can easily plan their study schedule.

Moreover, the teacher can use the same tool to teach a virtual class using a live practice without having to be physically in the laboratory.

The possibility of unlimited access during and outside of the regular academic hours, the intuitive use, the access from mobile devices and the availability of test exercises from the first moment, provokes that the students feel motivated to use the tool and get used to see it as an ideal complement to the study sessions of theory.

The students that have used the laboratories since the open of the project on 2012, are studying, every year, Industrial Engineering at UNED. The laboratories are being used on three subjects: *Microprocessors & Microcontrollers, Advanced Digitals Systems & Microprocessors*, and *Advanced Electronics Systems*. Using the feedback, about 80% of them think that laboratories were useful to understand the theory learned, and 60% showed interest; after use the laboratories; on depth into the subject; more than academic needs required to pass the subject.

Fig. 3 Real remote lab example (source: http://ohm.ieec.uned.es/portal/?page_id=100)

The advantage of the system in both cases is that both, theory and practice, are accessible from the same web portal. By accessing each laboratory, the student can see an explaining video showing how to use the available tools and doing a journey through the repository of available tools for the student. One of these tools is the access to the theory and several solved exercises and ready to use.

This facilitates the teacher the organization and delivery of its class, and the student the theory, query and planning the study hours.

The ease of use, the possibility of planning, the option to have a class always available on line, makes the teacher feels motivated to use this new educational tool and find widespread use in all disciplines who teaches and where possible fit it.

V. Modularity, Generalization and Reuse

The tools described previously are tools that UNED is currently using in their daily classes. The next goal is to turn this system into something more powerful, capable of spreading to other disciplines and not just engineering and more widespread among teachers. Figure 4 provides cycle relationship between these three factors. It is so interesting to analyse the possibilities of this system.

A. Modularity

Nowadays, and respecting the previous design, the system allows creating new spaces within the main portal site to gradually increase the number of existing laboratories. While this gives certain modularity, the system must be clearly improved and efforts are conducting in that line.

The most relevant aspect will be to design laboratories according to the age of students whom it may concern, their previous training and future training needs. However once a laboratory is created, it is always easier to adapt it to playing with different educational levels and simplifying content if necessary.

That's one of the keys to the modularity and scalability of a system, [14], and it allows its use becomes widespread as quickly as possible.

The design of predefined templates to help teachers with the creation of new spaces into web portal or the integration of new laboratories are priorities reflected in investment in research that the UNED has been done in this direction through national and international projects.

B. *Generalization*

At this point the key is to facilitate the use of the system for first time by the teachers. Once they see its usefulness, it is clear that the generalization step will be much easier and faster. While there may be some initial reluctance, especially by those teachers who may have less contact with IT, these will be outweighed by the benefits that eventually brings the system for lesson planning in general and particular practices.

C. *Reuse*

Actually this is the easy part if you get the other two. The more teachers to use the system, more modules will be prepared and will be generalized use.

This will facilitate the reuse of existing modules and in turn attract new teachers who want to use the system in their classes. Only when they start to reuse the education modules and start sharing tools, [15], it will can speak of a true generalization of the system.

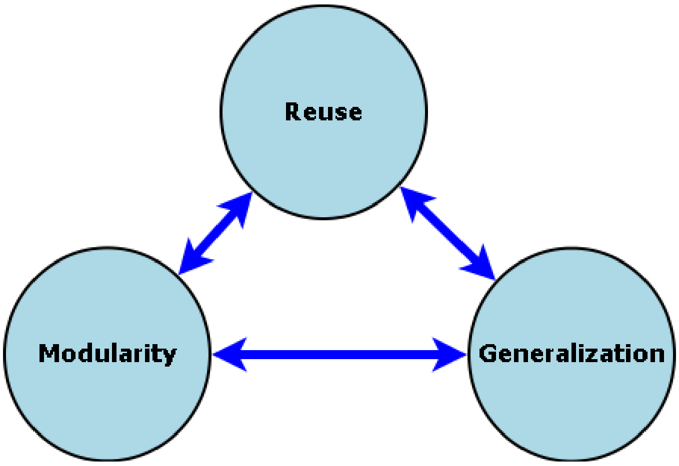

Fig. 4 Feedback cycle

As Figure 4 shows, the system is fed by the feedback provided for use by teachers.

On the other hand the use by students also increase more demand of this system on teachers improves its quality, [16]. Once again this shows the important relationship between students and teachers in sharing learning tools.

It is important to emphasise that the two points of view are necessary to improve the system. On one hand the growing experience of the teaching staff in using the IT as educational tools allows to correct errors (many of them based on an overly technical system) by detecting errors in use every day, or incorporation of new tools with suggestions from teachers.

From the point of view of the student, Learning Analytics technologies allow the system to discern which tools are used, and which are more problematic for students. At the same way just as the existence of a feedback with the student and suggestions provided by them will further enhance the knowledge of the actual use of the system. With that information is much easier to improve the system to continue to promote its use among the educational community.

VI. Conclusions

The extensive training experience in distance education techniques treasured by the UNED has been designed the development of new technologies that facilitate the learning process both for teachers and for students.

UNED has developed systems in recent years following these ideas, to ensure modularity for future generalization. Several of these efforts have been made in engineering courses and specifically on remote electronics laboratories. This work has shown several of them, the feedback from students about its use, and their importance for both students and teachers.

With experience in the use of these tools has been concluded that the time, independence, improved planning, universal access through mobile and fixed devices, and its use as a supplement to the class received theory, promotes integration of the educational path.

At the same time, our experience has led to increase the motivation on the teachers, who have seen facilitated their teaching and have been able to practice classes without physical access to a laboratory. Also for students, who have been able to use laboratory tools from their own homes without incurring on material costs, or displacement, or potential risks of electrical installation, and increasing their motivational feelings about the subject to learn.

While there is still much work to do, at the moment and given the success of the system, it is already working on the generalization, not only among engineering courses, but also among many other disciplines.

At the same time it is looking for the possibility of increasing the existing laboratory modules. UNED is expecting that students, who have already used the existing ones, contribute with their suggestions or even create new modules and designs through their final year projects.

Finally, it exists also a spread collaboration with other institutions nationally and internationally to reuse existing laboratories.

All these actions encourage UNED to continue working on improving these systems and continue to demonstrate that teaching is a two-path-address: teachers and students, and only by the integration of their needs, a successful learning path can be achieved.

ACKNOWLEDGEMENT

The authors acknowledge the support provided by the Engineering Science School of UNED, the Computer Science School of UNED, the UNED Rectorate, and the IEEE Student Branch of UNED, and Techno-Museum project and IEEE Foundation.

Authors are especially grateful to the Electrical and Computer Engineering Department (DIEEC) of UNED for its support and advice in the preparation of this paper.

Online Engineering Course Design, Part I:

Toward Asynchronous, Web-based Delivery of a First Course in Thermodynamics

***Abstract*— As part one in a series of two, this paper describes the development of a web-based [1] first course in thermodynamics. The course is conceptualized, designed and course materials are introduced to engineering students by a team of practitioner – researchers. The course builds from previous work concerning the development of web-based thermodynamic cycle teaching modules for undergraduate mechanical engineering students [2] and relevant educational literature. The design goals for the online course are that it a) be delivered primarily through asynchronous means and b) fulfill requirements of ABET accredited degree programs in civil, electrical and mechanical engineering as is accomplished by the current face-to-face course.**

The course design team, consisting of engineering faculty, administrators, and instructional design professionals, used a collaborative approach to move the online course through concept, development to initial introduction. As constructed, example segments ("exemplar modules") were introduced within the current face-to face Thermodynamics I course to witness student reactions and solicit feedback. Once this feedback is filtered back and addressed in the design, the course will be implemented and evaluated in whole within the civil, electrical and mechanical undergraduate engineering programs. The full implementation, evaluation and results will be the focus of a part two paper.

Keywords—online engineering education, asynchronous delivery, constructivism

I. Introduction

As Porter [3] suggests, the idea of *tradition* within mainstream education - as in the "traditional" way of learning or the "traditional classroom"- is changing rapidly. The practice of an established time and location where learning occurs continues to be challenged. The requirement for an immovable, physical classroom is steadily giving way to an acceptance of virtual meeting spaces where learners engage with course materials and each other through electronic communication and Internet-based technology. With this evolution, online learning is forming a basis of its own educational paradigm.

Despite an acknowledged need to produce more engineering professionals in this country, engineering education in the United States has been slow to embrace online learning. As noted in [4], most of the available online engineering degree programs exist only at the master's and certificate levels. Significantly more limited online options are available at the pre-engineering (associate degree) and bachelor's degree levels. Increased fiscal pressure on our nation's colleges and universities, combined with never before seen challenges of educating the "net generation" [5], underscores the imperative for engineering educators and administrators to jointly agree that the online waters are fine and it is time to venture in.

Yet, teaching with technology is hazardous duty [5]. To be successful, online educators must approach curricular design with equal parts caution and insight. Insight does not come for free; rather it comes at the expense of experience. Thus, to make web-based engineering education a viable reality, we believe that there is a strong need for more examples of its implementation, including both the successes and failures, to be published within the literature [5]. This effort, in turn, will require more support, training and resources for these faculty who often have to "…relearn how to teach in a new [online] environment…" as they redesign their courses into something akin to a "computer product" [6].

In undertaking this two part paper series, our goal is to describe and document one attempt at developing, implementing (part I) and evaluating (part II) a fully asynchronous and online introductory course in thermodynamics. In this manner, we hope to help build a knowledge base in this area within the engineering educational literature. At our institution, Thermodynamics I is a required, sophomore level course for undergraduate students pursuing bachelor's degrees in mechanical engineering and an elective for students in civil and electrical engineering. The course has a single co-requisite of enrollment in the multivariable calculus course. As one of the first courses in our undergraduate engineering curriculum to undergo this sort of extensive redesign, we reflect on our process and outcomes with the hope developing useful insight for others involved in similar ventures.

II. Building on Prior Work

Previous work [2] describes the development and pilot testing of a one credit hour multimedia course covering the final third of a traditional introductory thermodynamics course. The complete multimedia course included eight modules, each consisting of approximately thirty pages, covering a variety of thermodynamic cycles. Audio, text, graphics and animations were used to create the modules, which were delivered in CD-ROM format or over the Internet.

Seventy-one students participated in an independent learning exercise by learning the Rankine Cycle using one of the modules delivered over the Internet. Results showed that these students performed as well on a single final examination question as students in a previous semester who were exposed to the material delivered in a traditional lecture format. The authors [2] further described that three students, who had successfully completed the entire one credit hour course, performed well on the same final examination given to students in the traditional lecture-based class. A survey of all students showed that they preferred the traditional lecture format. Students felt that attending lectures forced them to learn the material at a reasonable pace. They were fearful they would procrastinate if required to learn the material on their own over the Internet.

Prior work [2] influenced the current work in a few important ways. First, the results provided us indication that, while students may prefer traditional learning environments, they can effectively learn thermodynamics concepts and problem solving skills via online course materials. Second, student preference for traditional learning environments prompted us to consider student affective outcomes, in addition to performance outcomes, during the design and assessment of the online course. Finally, the cycle animations and online content constructed under the previous work were revised and implemented within the current work.

III. Online Course Development as Group Process

Teaching is a complex, time consuming and risky endeavor. Instructors in higher education may take years, or even careers, to develop their subject matter expertise and refine their courses [6]. Engineering instructors assigned to the development of a required course, such as Thermodynamics I, often work in conjunction with a program's ABET committee to insure the content aligns with appropriate Student Outcomes criteria [7]. (Formerly called the Accreditation Board for Engineering and Technology, ABET changed its name in 2005 [8].) Anecdotally speaking, however, engineering instructors typically enjoy full freedom, and bear full responsibility, for defining *how* teaching will occur with little oversight from administration. In this way, the ideal of curriculum as "group process" [9] is infrequently realized throughout the entirety of engineering curriculum design.

The prospect of redesigning a proven, traditionally taught course into a web-based version of itself can be a great source of anxiety for post-secondary instructors. Current expectations of online course design has eclipsed those of the days when simply porting course materials to website was adequate. Online instruction today involves teaching the "what" of traditional courses in a whole new way to a different generation of student. Meeting these new expectations requires not only subject matter expertise, but also knowledge of pedagogy, learning theory and technology implementation. As discussed in [6, 10], teachers tend to teach in the ways they were taught. Since most post-secondary teachers employed today have never experienced online instruction, they are faced with designing a complex, interactive "computer product" with which they have no relevant experience.

In light of these concerns, we chose to adopt a collaborative team approach, taking care to include principle stakeholders of the curriculum design outcome. Teaming enabled collaboration between key instructional, technology and administrative stakeholders of the course: engineering faculty experienced in teaching undergraduate thermodynamics, instructional design and technology professionals responsible for online course delivery within the distance education branch of the university, and administrators responsible for the delivery of the pre-professional undergraduate engineering curriculum. Student stakeholders were also given voice in the process: Students enrolled in the current Thermodynamics I course worked with exemplar modules and provided feedback that was subsequently woven back into the online course design. In this manner, the online course was built from the inside out, insuring that learner, instructor, administration, and technology infrastructure requirements were jointly and continuously addressed by the course design.

A. *Engineering Faculty Collaboration*

Two faculty members in the College of Engineering, one an instructor in the distance delivered pre-professional engineering program and one a full professor and Senior Associate Dean within the engineering college, took responsibility for selecting and sequencing course content, developing learning activities and assessments, and developing the website for the course. Each had several years of experience teaching Thermodynamics I within the college; both were teaching Thermodynamics I during the 2012-2013 academic year. One brought recent experience teaching with technology as distance education faculty. The second brought subject matter expertise, having taught Thermodynamics I over many years at multiple institutions and worked professionally in areas directly related to thermodynamics. Her experiences developing web-based modules for teaching thermodynamic cycles to undergraduates [2] proved beneficial and insightful.

B. Instructional Designer Collaboration and Support

As an integral member of the design team, a senior instructional designer from our institution's Center for Innovative Design and Instruction (CIDI) provided ongoing support of the course design and implementation. Support involved direct assistance with the technical implementation of the course, including integration of external tools, creation and refinement of simulation content, and help with user-interface design. Working daily with the design, development, and maintenance of online courses, he was able to provide guidance on best practices in online teaching, the feasibility of development timelines, and possible solutions to challenges.

C. Administrative Support

Administrative participation must expand from traditional support roles in order to accommodate a successful online teaching and learning environment [11]. Administration must exhibit strong commitment to web-based curriculum by providing adequate infrastructure, planning, resources, time and training to promote faculty to not only to participate in online course design but also to embrace an online pedagogy.

As part of our collaborative development approach, the Associate Dean for Undergraduate Affairs within the College of Engineering also played an important role in the development of the online thermodynamics course. Having primary responsibility for the operation of the pre-professional engineering program, he brought to the team not only knowledge of curricular requirements, but also insight, based on data driven assessment of the current engineering curriculum, into the areas wherein the course could be improved so as to better meet the needs of the students. His presence and active participation on the development team helped to highlight a serious commitment within the college of engineering to developing and deploying innovative and effective online instruction.

D. Student Feedback

During the primary development phase, two online "exemplar" modules and updated cycle animations from prior work [2] were introduced to engineering students enrolled in the Spring 2013 face-to-face Thermodynamics I course as additional (non required) learning material. This preliminary data, gathered from the learning management system (LMS) as students worked with the online modules, suggested that students were actively accessing the online material primarily at critical junctions in the course. There was moderate activity during regular intervals until a homework assignment is due, at which time participation increases. The activity is substantially increased prior to a major exam.

While this usage pattern is considered, at least in part, a result of piecemeal introduction of the online modules to students enrolled in a traditionally taught course (the students have not enrolled in an online class), the preliminary data leads us to ask and consider additional questions concerning the student experience within the online material: How do the students use the information? How much time is spent on each activity? Why do some students access the information often and others do not? Currently, we are working with CIDI professionals to develop methods to access LMS data to answer these questions. Preliminary data also suggest that online course performance should not be evaluated solely on student academic achievement while in the course, but rather online student assessment should account for their preparedness for participating in online course (i.e. student readiness for learning in an asynchronous, web-based environment). The latter approach may provide a more meaningful assessment of the online materials.

In order to get more direct feedback on student opinion of these online materials introduced during the semester, an end of course survey was assigned to the Spring 2013 Thermodynamics I students by the instructor. The survey consisted of both Likert scale and open-ended questions and was conducted within the course LMS. Survey questions queried student impressions of the learning effectiveness and ease of use of the online material. The overall survey response rate was 74% (113/152) as reported by the LMS. Students completing the survey received full credit for the assignment.

What we saw in the student responses was significant by-in, not only to the approach we took to designing our online web-site, learning environment and materials, but also to the very notion of learning thermodynamic in a web-based environment. Almost half (48%) of the respondents reported that they used the supplemental (i.e. not required) online materials about or more than half of the time. Significant groups of students responded that the Piazza online learning forum (37%) and the cycle simulations (52%) were beneficial to them as learning tools. A large number of students (77%) either agreed or strongly agreed that they were able to understand and follow the online materials. Moreover, 72% either agreed or strongly agreed that the advantages of the online components outweighed the disadvantages.

IV. THE INFLUENCE OF CONSTRUCTIVISM

Online course design is neither necessarily behaviorist nor constructivist. The choice of pedagogical approach is entirely in the hands of the curriculum developers. Porter [3] notes that a blending or balance of behaviorist and constructivist approaches is most often seen in online courses. Based on personal philosophies about learning and previous experience in web-enhanced classrooms, the design of this course was heavily influenced by constructivist learning theory and Chickering and Gamson's "Seven Principles" for teaching in undergraduate education [12, 13].

A. Constructivism: A Learning Theory

Constructivism is a theory of learning and not an approach to teaching or instructional practice [14]. While this idea is often heard, it is an important one to reiterate because it helps to focus attention on how people learn instead of on how people teach. Recognizing this distinction is critically important when designing an online course, since the role of the educator changes drastically in online instruction away from the traditional instructor archetype. Instead of teaching in an online course, instructors become coaches, mentors and facilitators of the curriculum [15]. As a learning theory, constructivism can influence the design of student activities, experiences and assessments and thus can inform a learner-centered approach to teaching [3].

Constructivism stands distinct from the more traditional learning theories of behaviorism and maturationism [16]. Instead of behaviors or skills, concept development and deep understanding are the primary objectives; stages are viewed not as developmental but rather as a result of active reorganization of knowledge on the part of the learner [16]. The constructivist paradigm is fundamentally non-positivist and requires that we relinquish the idea that the world exists in a singular, "immutable" or unchanging fashion. While there is no "…pat set of instructional techniques that can be abstracted from the theory and proposed as a constructivist approach to teaching" [16], Fosnot describes some general constructivist principles that informed our educational strategies:

- Learning is development, not the result of development
- "Disequilibrium" facilitates learning
- Challenging investigations in realistic settings should be offered to allow the learner to explore and generate possibilities
- Reflective abstraction is the driving force of learning
- Dialogue within a community engenders further thinking
- Learning proceeds to the development of cognitive structures

In carefully studying these principles, one can easily discern some common themes. First, learning is a time dependent process requiring adequate practice. Learning activities should present significant learning challenges, yet allow enough time so that each learner can go through a process of mistake-making and "disequilibrium" until knowledge restructuring, or the adaptation of current knowledge to new knowledge, occurs.

Second, learning is an active process requiring not only sufficient time, but also sufficient time on task. Learners must actively explore content and create their own knowledge connections in order to achieve deep understanding. Learning activities are most beneficial when they are authentic and realistic.

Third, learner reflection is key to understanding. Learners should be encouraged to think about their thinking and build their metacognitive skills. In addition, learners should reflect on what they have learned in relation to what they currently know in order to make connections and resolve cognitive disequilibrium.

Finally, learning is a social endeavor. Interaction within a community of learners generates new knowledge and deepens understanding. Interaction includes feedback from the instructor as well as discussion and group problem solving with peers. Engagement within a learning community feeds learner extrinsic motivation and supports diverse ways of learning.

It is informative to recognize the congruencies between these general constructivist principles and the "seven principles for good practice in undergraduate education" proposed by Chickering and Gamson [12]. According to these widely accepted principles, good practice:

1. Encourages contact between students and faculty
2. Develops reciprocity and cooperation among students
3. Encourages active learning
4. Gives prompt feedback
5. Emphasizes time on task
6. Communicates high expectations
7. Respects diverse talents and ways of learning

Thus, the constructivist principles for learning can be seen as underpinning these widely accepted principles for good teaching practice. Additionally, as is found in [13], use of Internet technologies and electronic communication tools readily help to promote these good teaching practices defined by Chickering and Gamson [12].

B. *Benefit of Constructivism to Online Course Design*

Perhaps one of the most important benefits of adopting a constructivist framework in online course design is that it helps focus attention on an issue labeled as one of the most critical to the success of online course instruction [4, 6, 17]: the establishment of a learning community in an environment where instructors and students will, most likely, never meet in person. As Garrison and Cleveland-Innes [18] discuss, student interaction is commonly accepted to be a critical component within any learning process and, thus, has been an important topic for early research within online education. The promise of always newer, faster, easier communication technologies resulted in an early focus on the connection and participation of learners, or social presence, within virtual learning environments.

Recent research [18-20] suggests that social interaction, by itself, is not enough to promote deep and meaningful learning. New studies discuss that one of the critical requirements for building strong virtual learning communities, in addition to social presence, is *teaching presence*. Teaching presence [18] includes actions taken by the instructor to a) design and organize the course in order to set clear expectations, appropriate learning activities and congruent assessment, b) facilitate student-centered discussion that is guided yet not dominated by the instructor, and c) provide direction instruction only at the appropriate moments. Thus, we see the application of a constructivist framework as a means to facilitate the development of a strong sense of teaching presence within our online course.

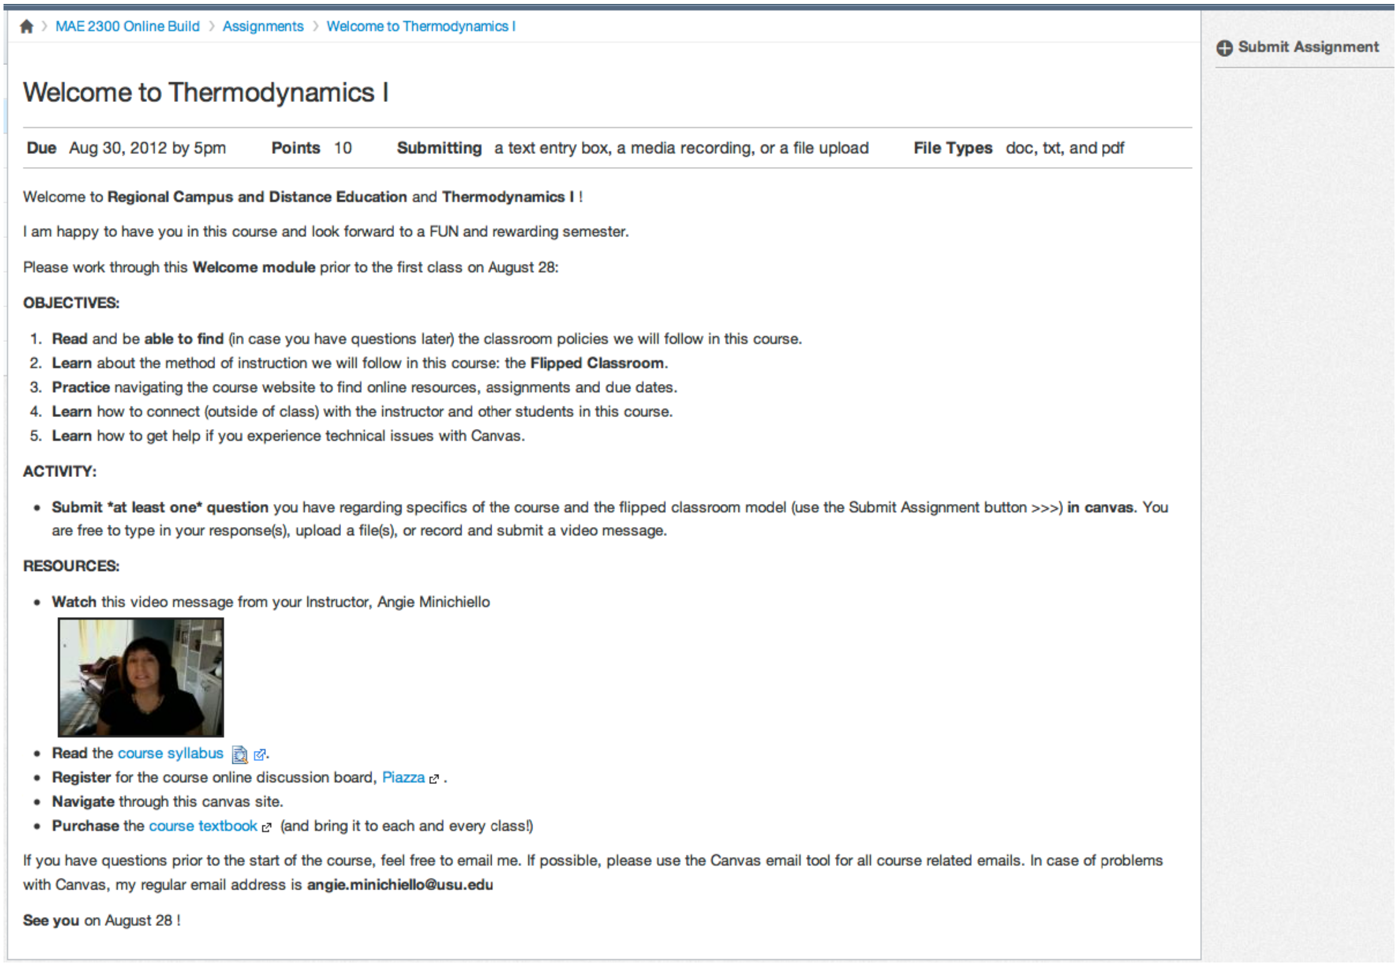

Fig. 1. Assignment –Centered Online Welcome Module.

C. Examples of Constructivism in Course Design

The application of a constructivist framework in our online course design may be best shown through examples.

1) Assignment–Centered Modular Design: The underlying structure of the online course is a set of ten weekly online learning modules accessed through a course homepage. Each learning module is built around a weekly assignment that is electronically submitted by students to the instructor. The framework for each module is the same and follows the OAR Model of Instructional Design [21], specifically developed for delivery of online courses in higher education using learning management systems (LMS). The acronym "OAR" respresents objectives, activities and resources.

In our course, modules are constructed within the "Assignments" tool in Instructure Canvas instead of the more traditional design choice of the "Learning Modules" tool. The Assignments tool was selected in order to place the contents of an entire learning module, including objectives, activities, multiple resources and the assignment submission link, all on one online page. In doing so, we attempt to leverage the capabilities of the LMS to streamline navigation and organize course content for the learner.

Use of the OAR model and Assignments tool facilitates a constructivist-style learning environment. Content is organized and accessible so as to facilitate time on task and the creation of knowledge structures. Multiple resources in varied formats (text, audio, video, virtual manipulative) are consistently provided to allow students to construct their knowledge and complete assigned activities in a manner that best suits their personal learning style. A screen shot display of the course online Welcome Module is provided in Figure 1.

2) Beautiful Homework Presentations: A variation of the "Beautiful Homework" assignments presented by Eschenbach [22] is used to provide students the opportunity to reflect upon and readdress conceptual understandings of key problems. At least once during the course, students present, in a online synchronous session, the conceptual framework and solution procedure for an assigned problem.

Beautiful Homework problems are assigned out of a larger weekly homework assignment that has been graded by the instructor and returned to students with feedback. Oral and visual presentation to a group of peers compels student presenters to revisit and deeply understand the concepts and nuances of the assigned problem. In this way, student presenters become the class experts on their assigned problems. Students are encouraged to be creative and present their solutions in unique and meaningful ways. In many cases, students voluntarily present multiple solution techniques, thereby creating new knowledge structures and linking them with existing or prior knowledge. Content from student presentations is posted to the course website and is frequently referred to during exam reviews.

3) Student Centered Discussion Forum: To foster dialogue among students in the course at any time of the day (or night), our online course implements a freely available online question and answer forum, Piazza [23]. As a wiki-based online tool, Piazza has capability not only for students to co-construct solutions, but also for instructors to facilitate virtual classroom interactions by a) endorsing student questions and responses, b) redirecting or correcting student responses, or c) simply answering student questions directly. In this manner, the instructor can easily promote an open discourse among students in a course, interjecting with direct instruction only when required to insure understanding. Posting to Piazza is a required part of weekly assignments until such time that the learning community discourse becomes self sustaining. At that time, participation in Piazza becomes voluntary.

V. TEACHING WITH TECHNOLOGY

Teaching with technology plays a significant role in online learning [4]. Online instructors need access to sufficient technology support and expertise in order to be successful in their attempts to design and implement online courses [6]. Additionally, as discussed in [24, 25], institutional adoption of newer web-based LMS significantly benefits online instructors by providing easy means of automating many administrative aspects of online course delivery as well as allowing for easier communication and feedback. Use of such automated features reduces technology barriers for online instructors and helps to facilitate the online curriculum for learners.

Our institution has invested in a strong infrastructure of technology and support for delivering and maintaining fully asynchronous, online courses. Our LMS, Instructure Canvas, is student-centric in its design, providing students with collaborative resources, the ability to receive instant notifications, options for evaluating how performance will affect their final grades, and ready access to materials and interactions via mobile devices. The same affordances are given to teachers, along with tools that speed the grading and assignment markup process. Canvas benefits from integrated multimedia tools that enable audio and video instruction and interaction at all levels of the system for both teachers and students. It also integrates with numerous existing external tools, such as the Piazza discussion board [23]—a resource used extensively and to great effect in our online class.

Additional tools are licensed at the institutional and state levels to provide further options for instructors to expand the capability of their courses. These include multimedia repositories, enterprise lecture capture solutions, quiz editing resources, options for videoconferencing, and more. For online students, the institution provides extensive support services, including access to e-tutoring, library services, proctoring services, advising, and more. For online teachers, the university has purchased access to 24/7 tier 1 technical support from Instructure. This enables teachers to respond to technological challenges in their courses whenever they arise.

VI. ONLINE COURSE FORMAL EVALUATION

Evaluation of an online curriculum is a critical component of its implementation as it facilitates a successful learning experience for online students as well as helps the larger teaching and learning community assess what quality online course delivery looks like. We cannot assume that quality online instruction mirrors the traditional notions of quality teaching. As Peercy and Cramer [5] discuss:

> *There is a persistent perception that the highest quality instruction is delivered the old fashioned way with a wise and experienced faculty member engaging face-to-face with the inquiring mind of an eager, well-prepared student. It is a nice image and sometimes it is true, but more often it is not (p.627).*

A. Institutional Infrastructure for Course Evaluation

In Fall 2011, our institution adopted The IDEA Center Student Ratings of Instruction system to assess course effectiveness with a focus on learning and curricular objectives [26]. The IDEA system requests students to provide feedback on their progress in achieving specific learning objectives in each course in which they are enrolled. This feedback is statistically analyzed by the IDEA Center and results are given back to the faculty and administration responsible for delivery of the course. The IDEA system has a "… documented history of reliability and validity… [that] provides specific feedback on teaching methods and practice" [26]. This formal student end of course evaluation is one method we will use to evaluate our online course during its pilot in the Fall 2013/Spring 2014.

B. Online Course Targeted Surveys and Focus Groups

Additionally, we will develop and deploy a student survey framed by the eleven online course evaluation categories proposed by the IDEA Center [27]:

- Course design/course materials
- Online activities
- Interactions with the instructor
- Student interactions

- Student characteristics
- Instructor use of technology
- Technology and learning
- Technology support
- Learning Outcomes
- Open-ended/ free response

These categories will form the basis for mid and end-of-term survey questions to be given to students enrolled in the Fall 2013 and Spring 2014 semester pilots of the online course. Together with surveys, focus groups of students in the pilot courses will be formed and interviewed to deeply explore students' satisfaction and affective outcomes with the online course. In this way, both quantitative and qualitative data will be gathered to guide future online course development and improvement efforts.

Finally, our formal course evaluation plan includes gathering student performance data directly from the LMS using built-in analytics tools as well as APIs for extracting additional performance data and reports. Some of the data we are targeting includes students' last login, their use of specific course items, their adherence to course deadlines, their interactions with the instructor, their performance on specific assessment items and linked outcomes, and their final grades in prerequisite classes.

In combining data from all of these sources (IDEA course evaluations, targeted student surveys and focus groups, LMS performance data) we will construct a strong, balanced picture of the strengths and weaknesses of our course. We will use this data in an iterative process of evaluating, improving, and re-evaluating to maintain an online learning environment that responds appropriately to our students' needs.

VII. SUMMARY

In this part I paper, we describe efforts to redesign a traditionally taught, introductory thermodynamics course into a fully asynchronous, online version. Reflection on our efforts has helped to highlight four important considerations for online course development: a collaborative development effort, adoption of an instructional framework supportive to online learning, infrastructure that supports teaching with technology, and implementation of effective course evaluation at multiple points throughout the development process. Part II of this paper will provide analysis of course evaluation data in order to provide recommendations for future engineering online course development.

An Autonomous Articulating Desktop Robot for Proctoring Remote Online Examinations

Warren A. Rosen and M. Eric Carr
Engineering Technology Program
Drexel University
Philadelphia, PA, USA

Abstract—**In this paper we describe a new low-cost, autonomous desktop robot for proctoring examinations in online/distance learning courses. The robot is attached to the student's computer via a USB port and monitors the examination environment using a webcam that articulates in both altitude and azimuth together with an array of acoustic sensors that provides audio directionality. The examination may be monitored in real time by a live proctor via the Internet or the data may be recorded for future review. Authentication of the identity of the test taker is accomplished using the webcam and simple, reliable ear recognition techniques. This eliminates the need for expensive digital fingerprint hardware.**

Keywords—online education; distance learning; academic integrity; cheating; remote proctoring

I. Introduction

Online education is now an integral part of the higher education landscape. In fact, the growth rate for online student enrollments now far exceeds the growth rate of the overall higher education student population. This growth is not projected to slow down, particularly with the advent of Massive Open Online Courses (MOOCs). As of 2012, 32% of all students have taken at least some or all of their classes online [1], and online education is now a multi-billion dollar market.

Academic integrity is an important consideration in online/distance learning courses due to the inherent opportunities for cheating. This problem is of particular concern in science and engineering courses, first because the students in these courses have the technical skills to cheat in ever more creative ways, and, second, because engineering students apparently cheat in greater numbers than those in many other curricula. As many as 81% of engineering students report having engaged in "serious" cheating [2], and this number is likely to increase with the increasing availability of online courses.

In this paper we review the available data on the incidence of cheating as well as the advantages and limitations of currently available technologies for reducing its prevalence. We then describe a new low-cost, autonomous desktop robot for proctoring examinations in online/distance learning courses. The robot is attached to the student's computer via a USB port and monitors the examination environment using a webcam that articulates in both altitude and azimuth together with an array of acoustic sensors that provides audio directionality. The examination may be monitored in real time by a live proctor via the Internet or the data may be recorded for future review. The acoustic sensors are used to identify and direct the camera toward interesting acoustic events and to flag these events in the video record for subsequent review. The robot's webcam could also be used to scan and transmit student solutions involving diagrams or detailed equations. These could later be compared to a mailed-in version if desired. Authentication of the identity of the test taker is an important and potentially expensive issue in online testing. In our system authentication is accomplished using the webcam and simple, reliable ear recognition techniques. This eliminates the need for expensive digital fingerprint hardware.

II. Prevalence of Cheating

Research into the rate of student cheating, both in in-class and online courses, has produced a wide range of results, all of them disheartening. Davis and Ludvigson reviewed three studies and found that the number of students who report having cheated on at least one exam is between 40 and 60% [3], Stearns evaluated five studies of cheating by college students and found that between 65 and 100% report having cheated at least once [4], and Whitley evaluated 107 studies and found an average of 70% [5]. Two studies found that over 80% of college students reported having engaged in "Serious Cheating" [2, 6]. There are a number of reasons that can account for the wide variation in results. These include the types of questions asked, personal beliefs of the students, their perceptions of the incidence of cheating, students' understanding of what constitutes cheating, the emphasis placed on academic integrity by the faculty and institution, and how the students regard the fairness of the exam, course load, or instructor. Students also tend to believe that limiting cheating is the responsibility of the instructor or institution rather than the students themselves [7].

The data for engineering and science students are particularly discouraging. McCabe surveyed over 4,000 students at 31 campuses and found that 81% of engineering students admitted to serious cheating and 51% reported serious cheating on an exam. For science majors the numbers were 73 and 45%, respectively. The engineers were surpassed only by business majors (88 and 64%, respectively) [2].

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

There is comparatively little data on cheating in online courses. One might think that cheating in online courses would be worse than in in-class courses due to the relative ease of cheating but the available data give mixed results, probably for the same reasons responsible for the variation in surveys of cheating in face-to-face classes, but also because some students may feel freer to deny cheating in an online environment. Stuber-McEwen, Wiseley, and Hoggatt surveyed 225 students at a single mid-sized university and found that online cheating was actually reported less than in face-to-face courses [8]. Watson and Sottile surveyed 635 graduate and undergraduate students at a single university and found no significant difference between reported rates of cheating in online and in-class courses [9]. However, they did find the reported incidence of students receiving answers from another person during a test or quiz was significantly higher for online classes.

Harmon, Lambrinos, and Buffolino looked at six studies evaluating students' perceptions about the incidence of cheating [10]. Students' perceptions are important because they may be more likely to cheat when they believe cheating is prevalent. In three studies of students' about the incidence of cheating one found that students perceived less cheating in online classes, one found that students perceived more cheating, and one found that students perceived about the same level of cheating. Interestingly, the remaining three studies looked at students' perceptions of cheating in unproctored vs. proctored exams in both online and in-class exams. They concluded that

> "On balance, the results of these three studies imply that cheating risk is greater in unproctored than proctored assessments. The six studies, considered as a group, imply cheating risk is less correlated with instructional format (online v f2f), and more correlated with unproctored online assessments."
>
> This level of cheating has two important consequences. First, it impacts the student's long-term view of professional and ethical behavior. Second, many instructors, particularly in STEM subjects, are reluctant to teach online courses due to the poor reliability of online test scores and their inability to give detailed test questions.

III. Currently Available Technologies

Techniques aimed at suppressing cheating in online classes break down into four categories. These categories include techniques that authenticate the identity of the test taker, make it difficult to cheat, detect cheating when it occurs, or a combination of these. Given the technical abilities of many students, and engineering and science students in particular, it's unlikely that any system for preventing cheating will be completely foolproof. The goal is to increase the uncertainty of detection to an unacceptable level for the potential cheater.

As a result of the passage of the 2008 Higher Education Act, U.S. accreditors are now required to ensure that institutions with distance education programs have policies to verify the identity of distance learning students [11]. As a result, many data security corporations are developing innovative authentication techniques as a path to penetrate the growing online market. Some examples include

> Acxiom Information Security Services—multiple-choice security questions/quizzes for students; questions are based largely on a student's prior address history (now teamed with Learning House to provide audio and visual proctoring) [12];
>
> Digital-Persona—digital fingerprint scanner and software; students can log in to campus networks, access university-based websites, access Blackboard [13];
>
> Fujitsu PalmSecure—vein recognition, which identifies individuals from the veins in the palms of their hands [14].

Authentication, while important, does not preclude other methods of cheating such as sharing of information or using unauthorized sources (books, webpages, etc.). Efforts to address this problem include requiring the students to travel to specific exam sites or recruiting remote proctors, modifying the exam conditions in some way (e.g., instituting time limits or locking down the computer with respect to communications or web access, giving different exam questions to different students, etc.), or monitoring the exam environment (for example, using audio monitors and/or fixed cameras, as in several of the techniques described above).

The first method defeats the purpose of distance learning and may not be feasible for very remote students, and hiring remote proctors can be expensive and subject to abuse. The second can be time consuming (although some textbook publishers are beginning to offer banks of questions that can be mixed to provide differentiated tests) and distorts the testing procedure by limiting the kinds and format of test questions that can be asked, and locking down the computer does not preclude using a second computer or a second person at the test site.

Several companies are now offering sophisticated technologies for identifying the test taker and monitoring their behavior during the exam. Kryterion Inc. offers Webassessor, which monitors test taking. In addition to audio and video monitoring, the program uses a complex algorithm that analyzes and flags aberrant behavior, keystroke activity and response time [15].

Coursera, a company that offers MOOCs available from 62 universities, provides a keystroke system to recognize individual students' typing patterns using error patterns, typing speed, and how long specific keys are held down [16]. Coursera has teamed with Proctor U, an online test-taking company that pays proctors to monitor the student with a webcam trained on the student's face in real time [17]. At the beginning of each test the proctor asks the test taker to scan the room with the web camera to detect unauthorized materials such as books or other people in the room.

The systems described above do not provide continuous monitoring of the test environment. To address this issue, Software Secure Inc. developed the Securexam Remote Proctor. This device uses a conic mirror to project a 360° image of the room downward to a webcam connected to the test taker's computer via a USB port. It also has fingerprint scanner and audio monitoring. The system's software records a continuous image and can restrict the computer's functionality during a test to, e.g., limit access to selected websites [18]. The image is, however highly distorted and does not cover the ceiling of the test room.

All of the systems described above may be susceptible to a sophisticated attack strategy, for example, by installing the software on a virtual machine located inside the student's computer.

IV. The Exam Proctor Robot

To address some of the problems identified in the last section we have developed an autonomous articulating desktop robot for proctoring exams in online/distance learning courses. A prototype of the robot is shown in Fig. 1. The robot is about 5 inches in diameter and 7 inches high. In the figure, a clear dome is used for testing; a half-silvered dome would be used during a test to obscure the student's view of the camera. The robot is attached to and powered by the student's computer via a USB port and monitors the examination environment using a webcam that articulates in both altitude and azimuth for full 360-degree coverage. The robot also uses an array of acoustic sensors to provide 3-dimensional audio directionality to detect and record acoustic events.

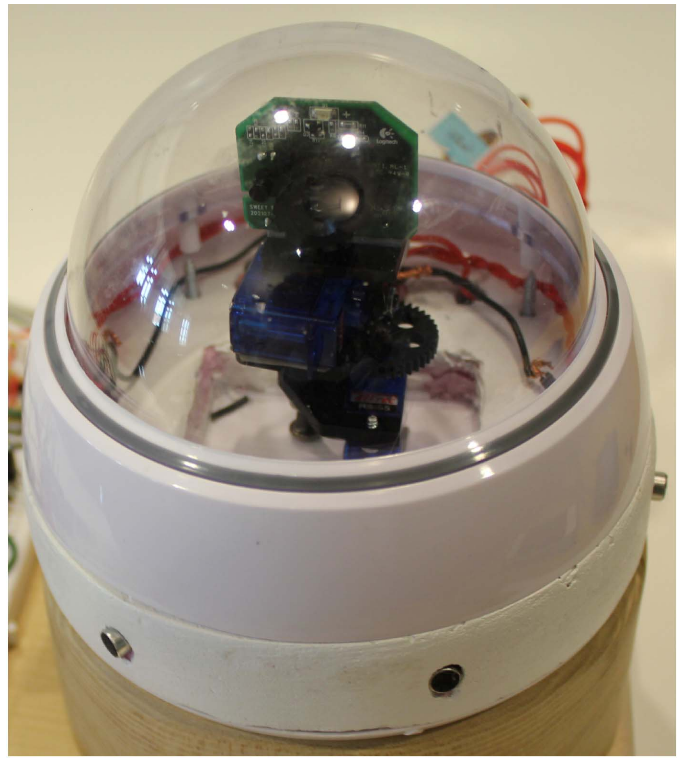

Fig. 1. Prototype of the exam proctor robot. The robot measures 5 inches in diameter by 7 inches high.

The examination may be monitored in two modes, real time and autonomous. In real time a proctor may monitor the exam and communicate with the student via the Internet. In autonomous mode the webcam continuously sweeps the test environment in a random pattern but will momentarily scan the area surrounding any anomalous acoustic events that are detected. Audio and video data are recorded and transmitted to the proctor after completion of the exam for future review. The locations of interesting acoustic events are flagged in the video signal. Also, the webcam is periodically aimed at the computer screen to verify that, for example, the software is not running in a virtual machine.

The prototype system uses an Arduino microcontroller board that can function as a limited HTTP client or server. As a client, it has the ability to pull an IP address via DHCP, download a page from a predetermined URL, and parse that page for relevant data. Once the data has been retrieved, it can then be used for any given purpose locally. In this case, we are using the data to control the position of altitude and azimuth servomotors that aim the webcam.

Ethernet, TCP/IP, and HTTP client libraries allow downloading of a simple text file from an arbitrary Web server. This text file is formatted as follows:

```
!X#####~~
!Y#####~~
```

where ## represents an unsigned 16-bit integer in decimal format. (Leading zeros are not needed; the number itself can be from one to five bytes in length.) Once the two numbers are retrieved and parsed, they are scaled as needed and then used as the input to the Servo libraries (also built in to the Arduino IDE). These configure the appropriate pins as digital outputs and set up the PWM units to send the correct width pulses to the servos, moving them to the requested position.

By continually polling the Web server once every few seconds, the Arduino can update the servo positions – and therefore the camera's target – according to the remote proctor's directions.

To authenticate the identity of the test taker, simple ear recognition software is used. At the beginning of the exam webcam is aimed at the test taker, who is instructed to turn to present a profile and brush away any hair that is covering the ear. This provides accurate authentication at no additional hardware cost. Ear recognition techniques have been found to be more that 95% accurate [19]. In our tests with live volunteers, the system correctly identified four out of four test subjects.

The robot provides a flexible and powerful test administration system. It will support a variety of test formats ranging from open or limited Internet to closed book/closed notes. It could also support written exams with solutions in the form of complex diagrams or equations. For such exams the robot could scan the completed exam and then instruct the student to place the hardcopy inside a pre-supplied addressed envelope that is sealed and signed while being recorded. It would also simplify the administration of frequent short quizzes that would be less prone to cheating than conventional homework assignments. The approach has the added advantage that it produces an archival record of the test in case questions of academic integrity arise at a later time. We estimate that in quantity the robot would cost about $35 to produce, and could be sold for about the cost of a textbook.

A two-component software suite to accompany the robot is currently being developed. The first component is a heavily-customized distribution of Ubuntu Linux (or a similar, free/open-source distribution of Linux) running from a bootable DVD-ROM on the student's PC or Intel-based Macintosh computer or a computer at a designated test site. The customized, kiosk-like operating system mutually authenticates with the robot unit and allows the creation of a secure, verifiable remote-site testing environment for high-stakes certification exams. Students will be able to plug the robot into their computer, boot to the included test DVD-ROM, and the test environment software will automatically start. The software and robot will use public-key authentication techniques to mutually authenticate each other (to combat spoofing and/or reverse engineering of the protocols etc); the test software will provide its full functionality with a robot connected via USB to the PC; and the robot will only complete the authentication sequence when in communication with a genuine copy of the proctor software. In addition, the software will contact the instructor's server for an authentication key to verify that the distribution disk has not been tampered with.

The second component is a Graphical User Interface (GUI). The GUI is a key component in this development. An important requirement for the GUI is to provide a clear and comprehensive view of the workflow involved in developing the test, quiz, or assignment. The GUI will provide a visual representation of the workflow allowing the instructor to interactively choose to start at the beginning or to start on subtasks. The GUI will allow the user to define his or her own workflow and to use it interactively. The ability to define workflows allows the user to transfer expertise to the tool that can then be reused repeatedly. The GUI should support the invocation of external applications and the marshalling of data to them as well as the unmarshalling of data from the external applications. Some of the external tools the GUI should support include such standard applications as Bb Visa, Blackboard (and Blackboard NG), and Moodle. When completed the GUI will seamlessly support the performance of all needed tasks ranging from test or assignment development and definition of test conditions such as allowable Internet access (accessible URLs. etc.) or use of texts or course notes, email access, etc.

At the beginning of the course the software will scan the student's computer to determine the availability of needed resources, such as memory and power available from the USB port. The computer will also scan the computer for any needed drivers not found on the boot disk. This information will be reported back to the course instructor for appropriate action. For example, for students with older PCs only USB 1.0 might be available, which might be insufficient to power the robot. These students could then be provided a double USB cable or a wall-powered USB 2.0 hub. Similarly, if disk space is an issue the student could be provided an external USB memory stick controlled by the test application.

V. CONCLUSIONS

Cheating in online classes is a major problem, particularly with respect to cheating on examinations. In this paper we have reviewed the available data on the prevalence of cheating in both online and face-to-face classes. We have also reviewed some of the available technology used to suppress cheating in online classes. Finally, we have described a new low-cost autonomous desktop robot that can be used to monitor exams in these courses.

Changing Perceptions: Do Engineering Activities Make a Difference in K-12 Environments?

David Reeping[1], Kenneth Reid[2]

Department of Engineering Education
Ohio Northern University
525 S Main St., Ada, OH 45810

[1]d-reeping@onu.edu
[2]k-reid@onu.edu

Abstract— **K-12 educators often incorporate projects into the science curriculum. Students conduct the activity, fill out answers on a corresponding lab sheet, strive toward results, and then move on to a new topic. With such an abrupt change in pace and lack of assessment, a question emerges: do these activities have a lasting impact on student learning or are these labs extraneous additions to the general curriculum?**

In an effort to integrate engineering concepts into a middle school environment, sixth graders were tasked with a design lab popularly known as "the marshmallow challenge," which requires student teams to construct a tower from uncooked spaghetti, tape, and a single marshmallow.

Approximately two months after the activity, the students who participated were asked to take a survey with four components: identification, opinion, objective, and open ended. The fifteen question survey was designed to determine if students enjoyed the activity and if students retained information from the short lecture before the activity.

The results for the objective portion were averaged between classes and compared; this paper presents an analysis of those scores. Also, commonalities between written student responses are examined and discussed.

These results are applicable to schools wishing to evaluate the effectiveness of brief activities similar to "the marshmallow challenge."

Keywords— **K-12 Engineering, activities, design lab, STEM, science standards**

I. Introduction

In the K-12 environment, students are typically tasked to conduct labs for a science class, turn it a worksheet, and then stampede into the next lesson after they complete the activity. Since this transition is so quick, it's possible that all meaning of the activity is lost due to the vague relevance to the rest of the curriculum. To investigate, students were instructed to conduct an engineering activity and take a short test concerning details of the lab about two months after the activity. The questions on this test were meant to assess vocabulary introduced to the class on the day of the activity. Another section of the test was devoted to collect feedback from the "engineering day" to improve the presentation for future labs.

II. Theoretical Framework

Recently, efforts have been made to slip engineering into the K-12 environment through the back door. With upcoming revisions to science standards, these efforts will become more and more prevalent. In fact, notable curricula like "Engineering is Elementary" and "Project Lead the Way" have made impacts across numerous states by increasing student interest in engineering both in and out of school [1, 2]. Another subtle way of introducing important concepts into the K-12 setting is through hands-on, engineering-like activities such as Model-Eliciting Activities (MEAs). These activities are math problems that are applicable to real world scenarios and involve students collaborating to create an appropriate model that describes a certain situation [3]. Since engineers use modeling constantly during the design process, the use of MEAs to educate students in the field would be a fairly easy addition. Each of these methods involves some degree of "hands on" learning.

Naturally, a support system for "hands on" learning already exists and is implemented in most science classes to some degree. Le Buffe praises this method, claiming that it "makes science vivid, meaningful and fun for most students" [4]. In fact, Wasserstein found that 27% of middle school students rated "hands on" science activities as their most memorable work [5]. High school science classes should not be left out though, considering the infrequency of "hands on" opportunities in this grade band. With this said, Piburn and Baker warn teachers to avoid the abstraction of content in science, especially in the higher grades. Students need context for the material—something physical—not just preaching theory [6].

On a more special occasion, students may be treated to visits by professionals or undergraduate/graduate students running programs like STEM academies through a university engineering outreach program [7]. STEM academies can range in levels of complexity and span of time spent at the school. For example, a project such as "Engineering Adventures" could include multiple modules covering a wide array of topics ranging from product design to controlling invasive species [2]. It has been demonstrated through quantitative studies that these modules do indeed provide a positive impact on student learning and motivation to study engineering [8]. However, these programs are long term and often require large amounts of time dedicated to running the modules with students. Determining the impact of a single session on student perceptions of engineering would allow curricula designers to make informed decisions on the value of short term STEM academies and adjust accordingly.

III. Engineering Activity: the marshmallow Challenge

The 6th graders were tasked to do a lab known as "the marshmallow challenge" that was originally a design challenge introduced by Peter Skillman and popularized by Tom Wujec at a TED conference in 2010 [9]. Today, it is commonly used as a team building exercise in businesses and universities. Both the engineering applications and team dynamic components were examined for this lab activity.

The goal of "the marshmallow challenge" is to build the tallest free standing structure using the following items in a premade kit in under 18 minutes:

- 20 sticks of spaghetti
- 1 yard of tape
- 1 foot of string (modified from 1 yard in Wujec's original instructions)
- 1 marshmallow

However, there is a clever twist that elevates this challenge to a different level. For the structure to qualify, *the marshmallow must be at the highest point.* Also, the following rules apply: students can use as much or as little of the kit as they wish and items in the kit can be manipulated in any way (i.e. breaking spaghetti sticks in half), except the marshmallow must remain whole.

A. Observations

The final designs across the three sections began to exhibit some similarities. As expected, the last class did the best at demonstrating the value of self-reinforcing geometric shapes like triangles. However, earlier classes seemed to understand this concept to a point, but fell short in delivery. The students were not taught this explicitly during the opening lesson, but were most likely clued in through the latent curriculum that an iterative design project creates.

By sharing experiences with the later sections, a sort of "communal design" project was created—where the group of students working separately eventually converged to one design pattern as time went by and information was passed from class to class. When comparing the average height of the "communal design" structures to the average height of those that do not follow the pattern, the average for "communal" structures is 18.65 inches while the "non-communal" average is 13.83 inches—a spread of almost 5 inches. One group's design was disqualified for being a supported structure, but was averaged into the "non-communal" values since it was standing and measured anyway—unlike three other disqualified structures. Perhaps the structures would have grown in height and become more similar if more classes were involved [10]

IV. Methods

In the study two months after the activity, a total of 42 students across three classes of sixth graders were given a test online totaling 8 questions covering concepts learned during "the marshmallow challenge" activity. Additionally, students were asked to report their opinions through 4 open ended questions and respond to 4 statements on a five point Likert scale. The test was developed by the investigators to correspond with material covered during the 40 minute session. Both the activity and test were conducted during a normal school day under normal school conditions. Students were given a brief review session the day before the test, but no questions were disclosed.

V. Engineers Build Things, Work in the Sun, Mix Chemicals…

What does an engineer do? This question can be polarizing for a variety of reasons, and in the open response question, the common misconceptions didn't seem to appear as frequently. Generally, twenty one answers contained the following concept at some point: "*engineer builds, fixes, or designs things.*" Four students were a bit more specific: "*engineers apply math and scientific principles to solve problems.*" In five answers, the students distinguished between the different engineering disciplines. Also, whenever a pronoun was used in place of "an engineer," it was always "he," while two students referred to the possibility of a female engineer.

In addition, five students mentioned engineers "improve society's quality of life." While these students did not go into detail, one could infer that they are referring to the grand challenges [11], which were mentioned in the lecture introducing the marshmallow challenge. Through this lens, engineers are seen as the social handymen of this modern day society.

In fact, the students touched on each major dimension of engineering discussed in a paper by Figueiredo. These four dimensions describe an engineer as a *scientist, sociologist, designer, and maker or "doer"* [12]. As stated indirectly by the middle school students, these four dimensions paint the complete picture of the engineer rather than in disparate parts as usual.

The next question was, "*How would you describe engineering to a friend?*" Results for this question were fairly similar, with a notable example. One sixth grader explained that "an engineer is a kind of mechanical doctor or scientist[;] they can fix machines and invent them." Since this question was fairly similar in nature to the last, the rest of the answers were essentially recycled responses. It was not until the students answered the final open response question that the misconceptions started to surface.

VI. What do you want to be when you grow up? An Engineer?

The final question in the open ended section asked the student the following question: "*Do you think you want to be an engineer when you grow up? Why or why not?*" While it is a harmless question to ask, the responses occasionally tend to hold a great deal of passion by revolving around an idealized profession or personal goal. Further, there is a distinct possibility of response bias, where students would tend to give the answer they perceive the researcher desires. To minimize this, the instrument was administered by the classroom teacher rather than the researcher. Among the responses, the students shared their aspirations of becoming doctors, veterinarians, teachers, professional athletes, animators, and authors—as expected.

This question also revealed student misconceptions about engineering. One student had this to say, "I'm not that much of a building guy, and I don't like to work in the sun all day long." While this was not the only instance of the profession being misrepresented, phrases and words such as "fixing machines," "building," and, "architecture" appeared frequently. A paper examining students' perceptions of engineers through a "draw an engineer" study reveals a similar trend; similar verbs like "build" and "fix" were used by students frequently in one-on-one interviews [13].

Numerous students also dismissed engineering as a profession based on their disdain for the math involved. Twelve responses expressed incapability in one or many skill sets such as math and designing. Additionally, four students thought that engineering seemed to be a boring profession, devoid of any excitement. Quite a few students weeded themselves out of becoming an engineer based on arguments from a list of nonexistent prerequisites. Students believe that being an engineer requires superior sketching abilities and that their minds need to be bursting at the seams with creativity.

On the other hand, some of the responses painted the profession in a more positive light. Two students added that one of their family members was an engineer—both gave the most detailed answers as to why they would choose engineering as a career. Ten students claimed to some extent that they would be interested in being an engineer when they grow up. More hands-on activities could shift the number of students either way—especially when the math involved is exposed in context.

VII. Administering an Objective Test

In addition to the survey, an eight question objective portion including questions on content from the "engineering day" lecture before the activity. Since the test was administered in different sessions, it is possible that the lapse in time is significant. For this reason, it is difficult to find a meaningful comparison between the sections. Yet, the results can still be commented on.

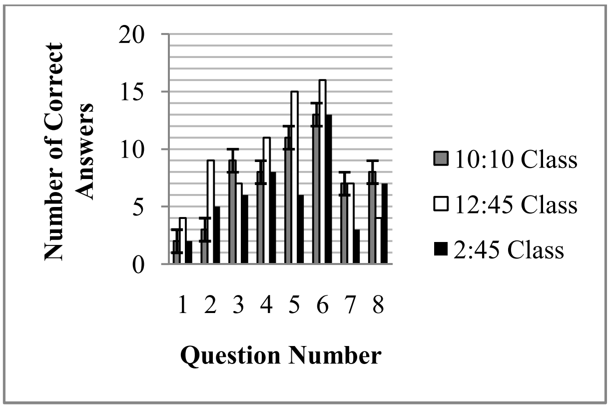

Fig. 1. Number of correct answers given by students in each section.

The following eight questions were given to each sixth grade class.

1) *Good criteria should be ________*
   - *quantifiable*
   - *related to design*
   - *opposite to constraints*
   - *descriptions*
2) *We want to design a roller coaster, which of the following would be good criteria in a list to work from?*
   - *Fun, cheap to build, and tall*
   - *Should be taller than the other coasters, attract a lot of customers.*
   - *Have the tallest height be 200 feet, be able to seat 20 people per train.*
   - *Get good reputation in the park, not too intimidating for small children.*
3) *If a luxury car is only offered in pink, this would be an example of a poor _______.*
   - *criterion*
   - *design quality*
   - *constraint*
   - *idea*
4) *Requiring the marshmallow to be at the highest point in your design is included in the _______. (Note: It was not a limitation, it was a requirement).*
   - *constraints*
   - *criteria*
5) *Would the limited materials be a constraint or part of the criteria?*
   - *constraint*
   - *criteria*

6) *Every design we have today has experienced some degree of failure.*
   - *True*
   - *False*
7) *The marshmallow was a metaphor for something in the context of the lab. What does it represent?*
   - *important issues*
   - *facts*
   - *criteria and constraints*
   - *hidden assumptions*
8) *"The Marshmallow Challenge" emphasizes the value of _______.*
   - *design and prototyping*
   - *structures*
   - *criteria and constraints*
   - *drawing*

For the 10:10 Class, there was a double submission; to compensate, error bars denoting a variance of ±1 overlays each representation of their number of correct answers. The 12:45 and 2:45 sections did not have any problems with the survey.

Of all the questions, number one, "*Good criteria should be…*" was intended to be a fairly straightforward "fill in the blank." During the introduction, emphasis was made that good criteria should be able to have a number assigned to it—in other words, quantifiable. Surprisingly, less than a fifth of the participants answered correctly. However, one option, "related to design," is applicable enough that it may also be a valid answer. While "quantifiable" is qualified by "*good* criteria," "related to design" is qualified by "*criteria*" alone. Therefore, both answers are technically right—raising the percentage correct to about 84%.

While the second question, "*We want to build a roller coaster, which of the following would be good criteria in a list to work from?"* was an application of the first, the percentage correct was 37%, compared to the previous 19%. An incorrect option D, "*get good reputation in the park, not too intimidating for small children*," was unusually popular—more responses than option A and B combined. The object of this question was to determine whether or not students could identify good criteria, but they were unable to distinguish between criteria that are quantifiable and criteria that are already quantified.

The following questions, all concerned engineering design as well, specifically criteria and constraints. In fact, these two concepts were topics from the introduction the class was given prior to the activity. For example, question five asked the following: "*Would the limited materials be a constraint or part of the criteria?"* Since students learned the definition of constraint to be a limitation on design, that should be the correct answer. In the results, nearly all of the students in the first and second class responded with constraint; yet, slightly under half of the third class had the right answer.

However, "the marshmallow challenge" is not designed to illustrate these concepts; instead, its purpose was to help the participants become aware of the hidden assumptions in a project. This fact was explained after the activity had ended, but did the students make that connection or refer to the introduction for the activity's purpose?

Student responses to "*The marshmallow was a metaphor for something in the context of the lab. What does it represent?*" provide some insight as to which part of the lesson had the most impact. Option D, hidden assumptions, is the correct answer; however, with "criteria and constraints" placed in option C, the intention is that students will be torn between the two choices and pick the most applicable to their recollection of the activity. Scores for question seven proved that this intentional trick did create cognitive dissonance with the students; both option C and D had 17 responses (7 for A and 2 for B).

The last question, "*The Marshmallow Challenge emphasizes the value of…"* functions in the same manner—with "criteria and constraints" as option C as well. For the responses to the last question, the results were as follows: 35% of students associated the activity with the brief lesson before, 44% of students picked the *correct* answer, "designing and prototyping" while the remaining 21% picked option B, "structures." Therefore, 79% of the students recognized the significance of the lesson—a promising number despite two months had passed since the activity.

VIII. What did the Students Think?

In the opinion section of the survey, four questions were set up using the 5 level Likert scale—strongly agree to strongly disagree. In conjunction with the open ended responses, the results from this section of the survey can be analyzed for certain characteristics or attitudes found in the student's writing. For this set of questions, the following statements were posed:

- I enjoyed "the marshmallow challenge" activity
- The information was presented clearly and in a way I could understand
- I'm interested in learning more about engineering
- I'm interested in doing more engineering related labs and activities

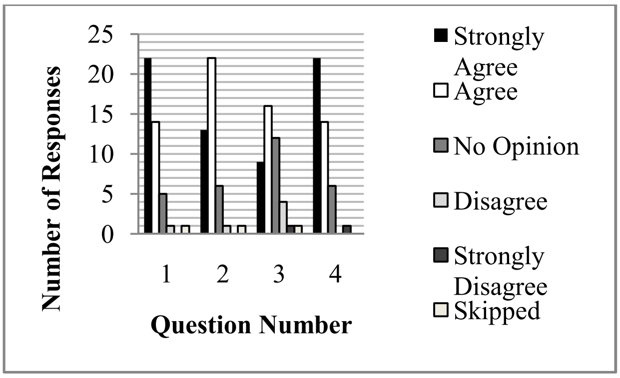

Fig. 2. Responses to opinion questions based on the Likert Scale (1-5). Results are taken in aggregate.

A. I Enjoyed "The Marshmallow Challenge" Activity

With the law of averages, it's expected that not everyone will enjoy a certain activity—this is no exception. For this lab, 86% of the students praised the activity and reported with a positive response, either agree or strongly agree. 12% of participants had no opinion either way while only one student was unsatisfied. With 98% of students receptive to the activity, learning outcomes seem more likely to be successful.

B. The Information Was Presented Clearly and in a Way I Could Understand

When giving a short introduction to engineering and then conducting a lab at such a fast pace, one would expect some students to tune out the information. Thankfully, students seemed to grasp the concepts and responded positively on the survey—83% answered with agree or strongly agree. Again, only one student couldn't follow while 14% had a neutral stance.

C. I'm Interested in Learning More About Engineering

For this statement, the results were a bit mixed. 60% of the class expressed interest in learning more about engineering while 29% answered with indifference and 12% responded negatively. The source of the disinterest can be somewhat ambiguous; yet, the open-ended responses provide some perspective. As stated earlier, some students have a "dream job" already in mind. In that sense, other career pitches end up fading into white noise. If the same question was posed to high school or college students with more uncertain career goals, maybe their interest in learning about a different field would be significantly higher.

D. I'm Interested in Doing More Engineering Related Labs and Activities

Since conducting an engineering lab is a conduit for learning about engineering, one would expect the responses to be the same as the answers from the previous question. Yet, 89% of the students reported that they would be interested in doing more activities in the future, 14% were indifferent, and one student was completely uninterested. Regardless, as long as students are excited about doing an activity intended to instruct, positive learning outcomes are likely to be fulfilled.

IX. CONCLUSION

While the sample size is relatively small, the application to K-12 is immense with the onset of new science standards. It is advantageous for science and math teachers to gain a fundamental understanding of engineering concepts and become comfortable with the subject matter. Through outreaches similar to this, a body of research can be formed to determine which activities and models work best in the K-12 classroom environment.

After verifying student perceptions with the survey, it can be inferred that a hands on activity such as the "the marshmallow challenge" activity with a short grounding lecture for perspective does have a positive effect by giving students a better understanding of the engineering profession—more so than one would expect. K-12 instructors should continue this method of enrichment to determine which activities are more apt to benefit experimental learning and advance STEM education.

***Abstract*— This study investigated middle school students' conceptions of engineering. Participants were sixth through eighth grade members of afterschool engineering clubs. Thus, the study contributes to understanding middle school students' knowledge of engineering, and also to how afterschool activities shape students' conceptions of engineering. Researchers have increasingly attended to students' perceptions of themselves as engineers, and their attitudes towards engineering majors and careers. However, little research has investigated middle school students' conceptions of engineering– what engineering is and what engineers do. The purpose of this study was to understand how middle school students who join afterschool engineering clubs conceptualize engineering and how engineering afterschool club experiences influence students' conceptions of engineering. The results of our study indicate that many participants had limited conceptions of engineering and suggest a need to connect design activities with knowledge of engineering.**

Keywords—Middle school, middle grades, conceptions of engineering, K-12 engineering education

I. INTRODUCTION

Recent interest in K-12 engineering education has prompted development of outreach programs designed to increase pre-college students' awareness and understanding of engineering. Afterschool programs may be instrumental in increasing students majoring in STEM fields [1, 2], perhaps because college students' choice to major in STEM fields is related to a growing interest in mathematics and science rather than enrollment or achievement [3]. However, inaccurate conception of what engineering entails may lead to dropping out of engineering degree programs and pursuing engineering careers. It is therefore important to understand students' early conceptions of engineering and how educational experiences influence those conceptions. The purpose of this study was to understand how middle school students who join afterschool engineering clubs conceptualize engineering and how club experiences influence students' conceptions of engineering. Two questions guided the research:

1) What conceptions of engineering do middle school students' involved in engineering afterschool clubs hold?

2) What influences these students' conceptions of engineering?

II. BACKGROUND

K-12 engineering education has made great strides in the past decade, making its way into the public eye and into K-12 local, state, and national curriculum standards, principles, and frameworks [e.g., 4, 5]. However, knowledge and practices of engineering continue to have low visibility in schools, and few people conceive of engineering as a K-12 subject. A national survey found that introductory engineering courses are still rare in American high schools and there is little reason to think that that is any less true in elementary and middle schools. Currently, engineering education at the K-12 level is largely delivered through outreach programs. The National Research Council [5] reported that what students experience in engineering instruction "does not always align with generally accepted ideas about the discipline and practice of engineering" (p. 4).

Rising attention to K-12 engineering education has prompted interest among educators and researchers in assessing students' conceptions of engineering. K-12 students' conceptions of what engineers do, have primarily been investigated in elementary contexts, often with participants who have not been exposed to engineering education interventions. Cunningham, Lachapelle, and Lindgren-Streicher [6] explored the conceptions of engineering of more than 500 first through fifth grade students (60% of who qualified for free-or-reduced lunch) in a district that had not made any efforts to teach engineering concepts. Based on students' conceptions and misconceptions about the work that engineers do, these researchers created a table with 16 images and descriptions of people at work and asked students to circle the kinds of work that engineers do. They also asked students to complete the sentence, "An engineer is a person who…" Participants tended to conceive of engineers as auto mechanics and construction workers. The authors suggested that a tendency to associate repair of automobile engines with engineers was likely influenced by the phonetic association of the two words. Capobianco, Diefes-Dux, Mena, and Weller [7] reported similar trends. In their study of approximately 400 first through fifth graders, they found that engineers were primarily associated with laborers, mechanics and technicians—those who fixed things. These results were obtained through administration of the Draw an Engineer Test prior to an engineering education intervention in one inter-city and one suburban school setting in the northeast US. In a rare pre-post study, Carr and Diefes-Dux [8] administered the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Draw-an-Engineer Test to second, third, and fourth graders. These authors found a common conceptual thread centered around manual labor (building) and those who fix things, as well as drivers. In a post-test following an engineering curriculum intervention, about half the participants had moved away from a manual labor conception to a design conception of engineering.

Fewer researchers have investigated middle school students' conceptions of engineering. In one exception, Fralick, Kearn, Thompson and Lyons [9] obtained results similar to Carr and Diefex-Dux when they administered the draw and engineer test to middle school students. In another noteworthy exception, Welty and Stricker [10] asked seventh and eighth graders "What does the word engineering mean to you?" Responses revealed that the number of number of references to designing, creating and inventing increased from pre to post-engineering intervention, indicating that design activities associated with the intervention may have helped dispel students' previous misconceptions.

English, Dawes, Hudson, and Byers [11] posed the question, "How can the nature of engineering and engineering practice be made visible to young learners?" We hoped to shed light on this issue through our investigation of engineering conceptions held by middle school students engaged in an engineering afterschool program.

III. METHOD

A. Participants and Context

Study participants were middle school students participating in engineering clubs in eight Southwestern U.S. schools in one urban district. The clubs were open to all middle school students. Of the 108 club members who participated in the study, 68 were eighth-graders, 25 were seventh-graders, and 15 were sixth-graders; 48% were female; 64% were Hispanic, 13% White, 7% African American, 7% Asian, and 2% Native American. Of these students, 73% were eligible for free or reduced lunch.

Participants were part of a university-based engineering outreach program. The program involves a club-like afterschool model primarily focused on schools with a high percentage of low-income students. Its objective is to provide an opportunity for low-income, first generation and historically under-represented minority students to explore STEM college majors and career interests with a group of peers interested in attending college. Two large state universities were involved in administration of the program. Near the beginning of the school year, teachers attended a workshop where they learn about each challenge along with ideas on how to promote and implement them amongst their club members. Students chose one of nine team-based design challenges and competed in state-wide completions. The engineering afterschool clubs typically meet once a week for one to two hours, working in teams of two to four students to develop their ideas and devices. During the first couple of months of the spring semester, state regional competitions are held so that teams from different schools can compete against one another and prepared for the state final competition in April. Local volunteer engineers act as judges during the regional and state competitions. The clubs were part of a national organization. Thus, in many ways, this club context is similar to others operating across the country and to those described in past research.

B. Data Collection

The afterschool clubs had been operating for at least six weeks before data collection began. All participants completed a survey composed of Likert items (5-point scale) and open-ended questions related to students' demographics, knowledge, practices, and perceptions of engineering and to students' experiences related to club activities. Forty-eight students were randomly recruited to participate in one-on-one interviews. Only open-ended survey items and interview questions pertaining to students conceptions of engineering were analyzed for the purposes of the present study.

C. Data Analysis

After all interviews were transcribed, a coding scheme to address the research questions related to students' conceptions of engineers was created. We took a Structure-Behavior-Function approach [12, 13] to coding students' conceptions of engineering by trying to account for students' understanding not only of what products engineers are associated with, but also what they do (the processes/behaviors in which they engage), and why they do it (the purpose/functions associated with engineering). Analysis began with the two authors meeting to read through the transcripts, comparing within and across student responses to two interview questions (What do you know about engineering and what engineers do? What kinds of engineering activities do you do outside of the club? (at home? at school?). Reading through interview transcripts, we negotiated our understanding of students' descriptions of structures, processes, and functions associated with engineering. After coming to consensus about how to define and operationalize these constructs, the first author then coded all the interviews and recorded frequencies of codes, using NVIVO 9 to organize the data. Re-reading the interview transcripts, we looked for evidence related to our second research question, "What influences students conceptions of engineering," identifying all sources of influence. Finally, the first author examined the open-ended survey questions and identified themes before comparing survey responses with interview data.

IV. RESULTS

Qualitative analysis of open-ended survey questions and interview responses revealed four themes.

First, students spontaneously described structures, processes, and functions associated with engineering (see Table 1). The top five structures to which students referred in their interviews were cars (coded 20 times), buildings (coded 18 times), bridges (coded 7 times), computers (coded 5 times), suggesting that students' conceptions of engineering are highly influenced by mechanical, civil and electronic engineering fields. Most students also spontaneously mentioned processes associated with engineering. These included overarching processes (fixing things [that break], building, creating, maintaining) as well as sub-processes. Fewer students referred to functions of engineering: to improve on things to make them easier, better, safer, faster, or more efficient); to help people, to make life easier, to make the world better. The function of engineering to solve problems was explicitly mentioned by only four students.

Second, students' conceptions of engineering can be clustered under four prototypes, engineer as (a) repair person who fixes and maintains things, (b) scientist who studies things, (c) builder who makes things, and (d) designer who invents or improves things (see Table 2 for examples). These categories were first identified based on coding of the interview transcripts. However, an open-ended question on the survey asked students their definition of an engineer. This question reinforced the prevalence of these categories. Of the 108 students who completed the survey, only one made no response to this question; ten other responses could not be categorized. Of the other 97 students, 6 gave responses that clearly showed a conception of engineer as scientist; 12 described engineers as people who fix things; 42 responses displayed students' conceptions of engineers as people who build or make things; and 46 conceptualized engineers as designers (note, some responses fell into two categories).

Third, despite the fact that students were all engaged in engineering club activities, their conceptions varied substantially in sophistication. Some students did not recognize the term engineering despite their club participation. Some of the least developed conceptions of engineering came from sixth grade students whose answer to the interview question, "What do you know about engineering and what engineers do?" seemed to reveal that they were unfamiliar with the term "engineering" even though they were in an engineering club. For example, one student responded with the following:

Student: *They help people.*

Interviewer: *How do they help people?*

Student: *When they're hurt… And when you take them to the hospital.*

Or, as another student responded,

I could take a guess. I think it's about science and math and I think that's the only thing I know that it means something about math and science. You make stuff, build stuff.

This lack of conceptual development can be contrasted with one of the most sophisticated conceptions in an interview:

From what I know in my nine years of schooling, basically, engineering, for me, is just making things, making plans, creating things to make life and tasks more easier and efficient… Like a civil engineer, they work to make for an example, parking lots. They work to make parking lots more efficient so that there's less space wasted and more people can get around easier. Or, another engineer, an electrical engineer works to see if they can have more electricity flowing through a certain place and also have the least amount of safety – I mean the most amount of safety possible.

Thus, students varied significantly in the sophistication of their explicit conceptions of engineering, despite the commonality of their experience in an engineering afterschool club.

The fourth theme relates to our second research question of what influences students' conceptions of engineering. Students differed in whether their conceptions of engineering were influenced primarily by home experiences or by school experiences. An open-ended survey question asked students whether they did any engineering activities outside of their afterschool club. Of the 107 students who responded to this question, 64 indicated that they did not do any engineering activities outside of their afterschool club; 43 indicated that they did participate in engineering activities beyond the club. Although most students did not elaborate, 14 described activities they did at home. Most home connections were based on helping family members build or repair things (e.g., fixing cars, home repair, landscaping) or creating fun projects with family members (e.g., building rockets). They also reported working on engineering projects alone (e.g., "I break objects to see the mechanics," build or fix toys, program computers).

TABLE 1 STUDENT-IDENTIFIED STRUCTURES, PROCESSES, AND FUNCTIONS

Engineered Structures		*Processes*		*Functions*	
Type	*#**	*Types*	*#*	*Types*	*#*
Civil (buildings, water transportation, roads, dams, parking lots, bridges)	37	Build stuff Create, invent, design Fix, maintain	25 21 10	Improve on previous products	10
Mechanical (cars, trains, engines, turbines)	35	Study things	5		
Electrical (cell phones, I-iPod, computers)	17	*subprocesses* Use science	 9	Help people	6
Aerospace(airplanes, NASA satellites, Mars Rover, rockets**)	7	and/or math Make blueprints Make models or	 2	Make life easier	6
Biomedical (prosthetics**, medicines)	7	prototypes Do experiments Test/plan	2 3 3	Make the world better	3
Environmental (rainwater harvesting**)	1	Use tools Work as a team	2 2	Solve problems	4

*number of instances

TABLE 2. PROTOTYPICAL CONCEPTIONS OF ENGINEERS

Repair Person	*Scientist*	*Builder*	*Designer*
Fixes and maintains stuff	Studies stuff	Makes stuff	Invents and improves stuff
"With cars, some of them fix the engines or see what's wrong with it."	"They make new objects to study different topics, like if they're trying to study something, to get more evidence from a science experiment"	"They're scientists who build stuff, and who do experiments and help other people."	"Like a television. They've made it new over the years. First there was black and gray, and then they made it into color, and then into 3D. And like cells phones…"

Interview transcripts also revealed home influence, whether that influence resulted in a conception of engineer as designer, as in the following interview;

> *Well, I have a basic idea about what engineers do like there's different types of engineers. When I grow up I want to be, I'm planning on being an engineer, an aeronautical engineer. I guess there's like civic, civil, civil or civic engineers, that do road construction or bridges and I have a pretty general idea about what they do. I know engineers, they're basic engineers, their goal is to help solve problems in modern day, just fix things that should be fixed or improve upon things that we already have. Stuff like that. [My dad] used to be an engineer. He used to be an aircraft engineer.*

or resulted in a conception of engineering as mechanic, as revealed in this response to the question "What engineering activities do you do outside of the club?"

> *Fixing my bike; finding tools and fixing it…I change the tire like every month…And I help my dad do the cars; I give him the tools.*

School experiences of engineering were overwhelmingly club-related. In the open-ended survey question, only seven students reported doing any engineering activities in their other classes or in other outreach programs. The influence of engineering club activities was not explicit in most descriptions of engineering in student interviews. Most students' descriptions of engineering did not explicitly reference the collaborative engineering challenge activities with which they were engaged. Structures associated with club engineering challenges (windmills/turbines-3, rockets-3, prosthetic arms-2, water transportation-2, rainwater harvesting-1; Bridges-7) were included in only 10 interviewees' description of engineering (an equal number of interviewees explicitly referenced home influences in their description of engineering; there was no overlap among students who referenced home influences and those who mentioned structures associated with club design challenges). The majority of students did not include any club challenges in their descriptions of engineering. Much like the students' conceptions shaped by home experiences, students' conceptions shaped by club experiences varied in sophistication. The following is one of the most sophisticated conceptions of engineering that was explicitly shaped by club experiences of designing a windmill and a prosthetic arm.

> *Engineering has to do with science and physics and it's a lot of work and a lot of aerodynamics they have to go through for it. And you have to learn about gravity also because the project that we're doing when you learn about how gravity will work with – like with force pushing towards it (the windmill). And engineers figure out new ways how to make things work better for people in different ways, I guess. Like one of the projects that you can do in [our club] is a prosthetic arm. And they have already made prosthetic arms. And I think that's really cool because prosthetic arms have helped a lot of people, people who have been in war and their arms blew off or their legs. And other people who have just been born like that.*

Students varied in the extent to which they explicitly recognized the collaborative design challenges associated with the engineering club as engineering.

V. DISCUSSION

The results of this study indicate that many of the afterschool engineering club participants held misconceptions and limited conceptions of engineering and engineers. Despite their participation in engineering after school clubs that had been meeting at least once a week for at least six weeks, many students conceived of engineers as builders, repairpersons, or scientists. Few students identified more than two or three examples of things that engineers design, and many failed to include mention of any club challenges in their description of engineering.

That making and building and fixing were prevalent in students' conceptions of engineering may be an artifact of their general experience with the engineered world. When individuals pass by a construction zone, they are not likely to see actions associated with building than actions associated with designing. In the case of the participants in this study, these tendencies may be especially strong because few of their parents were engineers, but many of their parents were construction workers or mechanics. Thus, these conceptions of engineering were doubly reinforced by their experiences of the world. Previous research indicates that about a quarter of Americans conceptualize engineers as builders [14]; children's conceptions may map on to their parents' conceptions. Students' conceptions of engineering may also be related to their developmental trajectories. Building is a concrete activity that young students can easily picture in their head, whereas the act of designing is more abstract. Some middle school students may be yet be facile with abstract thinking. Finally, students' conceptions of engineering as building may be an artifact of their club participation. Students' misconceptions may be reinforced by prolonged attention to production processes if they are not preceded and followed by sustained attention to problem definition and idea generation processes.

Results of previous analysis indicated that these students were highly interested in engineering. They had joined the club out of interest and they reported enjoying the club activities [15]. We see these as positive signs, given the importance of growing interest in students' matriculating into STEM college majors. It appears that club participation was meeting at least one important goal or engineering education that makes a positive difference in sustaining long-term engagement in pursuing engineering careers. But sustaining effort towards engineering degree majors also requires knowledge and accurate conceptions of what engineering entails and there may be more work for engineering initiatives in this area.

It seemed to us that students' explicit conceptions of engineering were not as informed as they might be by their engineering club experiences. Informal observations of club meetings, as well as our previous experience working with and observing in these and similar settings, we tentatively suggest that the nature of students' club experiences were based largely around the building and testing aspects of the engineering process. Young students frequently try the first thing that comes to mind when asked to design and create a product. They spend little time with problem definition or idea generation, quickly moving into production. These students were involved in engineering in a concrete way. However, particularly for students who have limited or no contact with professional engineers, and for students whose exposure to engineering concepts and practices is largely limited to club experiences, these activities may not transfer easily to generalized conceptions of engineering and may not be reaching the student in terms of stimulating their association between the challenges and engineering as it is practiced in the larger world.

We also see positive value in some of students' non-standard views of engineering, particularly when those views were influenced by home and community experiences. For one, previous analysis indicated that students highly value opportunities to build things that the afterschool engineering club setting afforded. Thus, their conceptions of engineers as builders and makers may have supported their decision to join an engineering club. Additionally, when students come to engineering clubs with home experiences they identify as engineering-related, their identity as engineering club members and potential future engineers may be strengthened; particularly when the activities and practices they experience in the clubs match the conceptions they bring. Also, many students bring funds of knowledge [16] that apply directly to the skills and practices they will use in engineering club activities.

A. Limitations and Future Research

Doubtless, some of these results are an artifact of the research methods. Pre-post measures were not collected, so we cannot tell how much students' conceptions of engineering changed due to their participation in the after school engineering clubs, nor did we compare the responses of club members with non-club members. Future research should address these issues. Further analysis should also attempt to take into account individual differences such as which of the nine clubs an individual attended as well as other demographic variation.

Based in part on the findings reported here, we suggest that more scholarly attention needs to be paid to students' funds of knowledge [16] as they pertain to conceptions of engineering, particularly to funds of knowledge that are embedded in students' experiences and practices in their home communities. Understanding what students bring with them to engineering education settings might inform the design of engineering interventions, particularly of collaborative engineering design challenges.

We are curious as to the correlation between student's engagement in engineering practices and the formal cognitive conceptualization of engineering that students are able to articulate. Because we used open-ended survey and interview questions, there were few cognitive cues for students in the study materials as to what the researchers may have wanted in the way of a "correct" response. This was purposeful, as we did not want to lead students to our definition of engineering, for instance, by using research protocols that involve more recognition or pre-determined categorization strategies. Rather, we were interested in students' conceptions of engineering as it was potentially being shaped by their participation in engineering afterschool club experiences. It is likely that if pressed further, students would have revealed more conceptions of engineering that more closely resemble standard concepts and practices. Based in part on the findings reported here as well as on K-12 engineering frameworks [4,5], we are in the process of developing a scaled measure to assess students' conceptual knowledge related to engineering practices, including structures, behaviors (processes), and functions (purposes). An observational study comparing students' explicit conceptions of engineering and their actual engineering practices as enacted in club activities would also be a useful next step.

It is worth noting that in our data, references to persons for whom engineered products are designed (i.e., the voice of the customer) were rare, as were descriptions of engineering "habits of mind" such as systems thinking, creativity, and collaboration [5]. While these may have been internalized and assumed by students, or otherwise not uncovered through our research methods, it is also possible that the interdisciplinary nature of engineering, particularly its social aspects, may be getting lost in standards that emphasize the correlations between engineering and science practices. These are important issues for future research, given recent attention to engineering habits of mind.

B. Implications for Practice

Based on the findings of our study, we suggest that educators, researchers, and other K-12 engineering education stakeholders consider the following questions:

One, how can educators capitalize on the funds of knowledge related to engineering that students bring from their home communities? How can they use our understanding of these funds of knowledge to inform educational practice? One thing that might help is simply becoming more aware of what experiences are influencing students' conceptions of engineering and finding ways to capitalize on those experiences. Another idea is to expose students to community-based engineering projects, for instance, through books such as, William Kamkwamba's "*The Boy Who Harvested the Wind*," or through newspaper articles or other media sources. Such practices might help students broaden and deepen their conceptions of engineering and connect them to their own community practices.

Two, how can we help students construct more standard conceptions that match current K-12 standards and the real-life work of engineers? How can we do so without disrupting the autonomy and hands-on experiences that may be critically important for attracting students to engineering afterschool clubs [13]? Interjecting more cycles of doing and reflecting might facilitate this goal. Educators might, for example, consider reflection activities that can support transfer of students' hands-on building experiences. Public design critiques in which students present, defend, and elicit suggestions from peers about their works in progress might support such reflection.

Three, how can we help students transfer engineering design practices to conceptions of engineering to support their trajectories toward continued engineering studies, STEM majors, and STEM careers? Integrating brief descriptions of relevant information pertaining to engineering fields into the specification sheets for specific design challenges might help students make more explicit connections between their design challenges and the work of professional engineers. Design challenges need to convey the notion of what engineers do, how they do it, and why they do it (structures-behaviors-and functions). We have noticed that here are few resources accessible to young students that show clearly how engineers fit into the creation of the designed world and that facilitate appreciation for planning and design processes. K-12 engineering education stakeholders can make important inroads in the creation of such resources.

Learning to Manage Uncertainty in Collaborative Engineering Design Projects:

Lessons from a fifth grade class

***Abstract*—Collaborative engineering design projects are fraught with subjective uncertainty associated with task issues ranging from understanding math and science concepts, to manipulating technological and digital tools and evaluating design ideas. Also, engineering design projects are contexts in which uncertainty is likely to stem from social issues as students encounter unfamiliar sociocultural practices and as individuals with diverse histories, beliefs, motivations, expectations, and values attempt to share the small space of a classroom. This qualitative discourse analytic study relies on observations and interviews to examine how social and task uncertainty management varied across three groups of students engaged in a collaborative design project. Specifically we asked, (1) how do groups vary in their management of uncertainty during engineering design projects; and (2) how does variation in uncertainty management influence groups' design practices and products? Data were drawn from a larger project that took place over one-school year in an ethnically and academically diverse public fifth grade class in the U.S.**

Keywords—elementary school, engineering, design projects, uncertainty, uncertainty management, peer interaction

I. INTRODUCTION

Guided by communication and sociocultural theories, this qualitative discourse analytic study relied on observations and interviews to examine how students in one fifth grade class managed uncertainty experienced during collaborative engineering design projects. Taking the collaborative group as our unit of analysis, we focused on three four-member teams. Research questions guiding this exploratory analysis included: (1) How do groups vary in their management of uncertainty during engineering design projects?; and (2) How does variation in uncertainty management influence groups' design practices and design products?

II. BACKGROUND

Collaborative engineering design projects are fraught with subjective uncertainty associated with task issues ranging from understanding math and science concepts, to manipulating technological and digital tools and evaluating design ideas. Also, engineering design projects are contexts in which uncertainty is likely to stem from social issues as students encounter unfamiliar sociocultural practices and as individuals with diverse histories, beliefs, motivations, expectations, and values attempt to share the small space of a classroom. Thus, learning to participate in engineering design practices may require students to learn to manage feelings of uncertainty associated with engineering practices.

Subjective uncertainty is a state of mind, sometimes revealed in one's words or actions and sometimes not, associated with a judgment that one is confused about or unsure of something, either because one does not know or understand something that could be known, or because the "something" is inherently probabilistic, ambiguous, or unknowable. Uncertainty can also pertain to one's sense of not being sure of one's value judgment or preference. Feelings of uncertainty can induce a wide range of cognitive, affective, and behavioral responses. Cognitively, "[un]certainty can both empower and incapacitate" [1]. Uncertainty often prompts negative affective responses but can also induce positive emotions. Uncertainty can facilitate action, but it can also prohibit action [2].

Uncertainty has been recognized as an experience permeating design endeavors because of the inherent complexity and ambiguity of design processes [3-5]. Previous studies have identifies ways expert designers manage uncertainty [6-10] and the difficulties that college-level engineering students have managing uncertainty associated with task issues [11-13]. Little research exists on how expert designers or adult students manage social uncertainty in collaborative design contexts.

Previous analyses have indicated that fifth grade students experience much uncertainty as they participate in collaborative engineering projects and that this uncertainty creates communication challenges related to task, relational, and identity issues [14]. Students manage uncertainty through tactics for reducing, ignoring, maintaining, or purposefully increasing it [15]. Individuals vary in their propensities for managing uncertainty primarily in terms of their willingness and ability to acknowledge uncertainty and their range of strategies for managing uncertainty [16]. At the same time, social interaction can be a source and resource for coping with perceived probabilistic and evaluative uncertainty [17]. Thus, peer support is crucial for helping students enact management strategies in collaborative learning projects [18].

In the current study, we are interested not only in how individuals manage uncertainty, but also in how groups manage uncertainty during the collaborative engineering design process. Previous researchers have argued that different sociocultural groups develop norms for how members are allowed to manage uncertainty, and what actions are expected and appropriate [19, 20]. Thus, this study is grounded in socially oriented theories of learning that focus on interactional patterns in collaborative learning groups [e.g., 21-23]. We conceptualize small groups of students collaborating on engineering projects as complex systems embedded in larger classroom systems and group members as interdependent self-regulating agents [e.g., 24-28]. Complexity theories emphasize the critical role of interactions in how systems unfold, causing us to consider the reciprocal interdependences of individual and social processes in shaping human activity [29].

III. Method

Data were drawn from a year-long research project in an ethnically and academically diverse fifth grade class in a suburban neighborhood in a public U.S. school. Students engaged in three collaborative robotic engineering projects across the year, switching group membership for each project. Only Project 3, the focal project for this study, can be classified as a design task. Groups were tasked to design, build, and program a robot to address an environmental problem. Three focal groups, each comprised of four members, were selected for close observation by the first author. Each group was diverse in gender, ethnicity, and academic achievement. Field notes and video recordings of each group were conducted across the 14 days of the design project. Multiple semi-structured interviews were conducted with the 12 focal students, and artifacts associate with the project were collected.

Our methods of analysis can best be described as involving an interpretivist qualitative approach [30, 31] with a focus on naturally-occurring discourse to characterize and compare patterns of uncertainty management in the three focal groups. Analysis was ongoing throughout data collection; field notes were expanded, usually within 24 hours after an observation, rough transcriptions were made, and memos created. We draw from interactional sociolinguistics because of its focus on how people construct the social significance of events they jointly create through their interaction, how individuals act and build on each other's actions, communicate their intentions and convey their interpretations of others' intentions in contextualized settings [32-35]. We also draw from communication theory to characterize interactions related to social and task uncertainty [3, 14]. Taking a page from Van Boxtel [36], we are analyzing each group's processes for managing social and task uncertainty as they (a) talk about concepts related to their engineering design project, (b) make elaborative contributions, (c) attempt to achieve shared understanding, and (d) make use of available tools.

Finally, we use cross-case analysis [37] to compare patterns of uncertainty management, individual learning (based on a coding scheme developed through consultation with content experts), and robotic products (based on evaluation by two expert reviewers) within and across groups.

IV. Preliminary Results and Next Steps

Although analysis is ongoing, we tentatively suggest that, over time, groups developed unique patterns of managing uncertainty. Learning in each group was situated in the specific context of that group [38] and was oriented around the goal of building robots successfully. Although the initial physical surroundings were much the same for every group, the social relations were unique to each group. As students participated in and contributed to communal activity, the members of a group co-constructed knowledge of what it means to do robotics and of how to do robotics. Through joint interaction, members also co-constructed practices for managing uncertainty.

Initial analysis suggests that the three focal groups can be characterized as having their own unique patterns for managing uncertainty, patterns that were shaped by both the propensities of the individual members and by the social interactions among them. Briefly, a pervasive pattern that emerged in the Water Washer Group was to disparage uncertainty and side with the most powerful group member. As a group, members exhibited a strong need for immediate consensus; the need to revolve social uncertainty seemed a strong motivator for action. Uncertainty management in the Recycling Rover group took the form of introducing and questioning new design ideas, acknowledging uncertainty by expressing doubt and checking understanding of group member's ideas. In the Trash Claw group a strong desire to learn exhibited by three out of four members was held in tension by a dynamic of vying for social and intellectual power by the two female group members. A need to resolve social uncertainty by one group member reinforced by another member's reluctance to acknowledge uncertainty inhibited the introduction and uptake of uncertainty and new design ideas.

Contrasting group patterns of uncertainty management revealed that the engineering design teams not only made use of different strategies to manage uncertainty, but they also managed uncertainty about different things. Members of the Water Washer group seemed to focus on gaining consensus about shared decisions about actions to be taken (i.e., What are you doing?), while the Recycling Rover group seemed more concerned about developing a shared understanding of their joint ideas (i.e., What are you thinking?) and the Claw Grabber group concentrated on reducing uncertainty related immediately presenting problems. Initial analysis suggests that groups differed also in the extent to which and the ways in which they used sketching to manage uncertainty. Further analysis will continue to explore this issue.

V. Discussion

Analysis is ongoing. Discourse analysis of the first two design sessions is complete, final group products have been evaluated by two expert reviewers, and initial themes have been identified. We are in the process of coding additional transcripts of group sessions and coding interviews for evidence of individual learning. We are continually comparing within and across groups.

Students' capacities to perform in small-group systems is not simply a matter of individual strengths or the quality of the sets of strategies individuals who comprise a group have developed, but also of the interaction among group members and between individuals and the academic task. Uncertainty management is dialogical, relational, and reciprocally influencing. As members of a collaborative engineering design group interacted, they provided feedback to one another, feedback from which individual agents learned, adjusting their behaviors on an ongoing basis.

Pedagogical Application of RFID Technology for Hard of Hearing Children during Mathematics and Science Learning Activities

Min-Chi, Kao
Department of Special Education
National Taichung University of Education
Taichung, Taiwan

***Abstract*—The purposes of this work-in-progress paper are to explore the effect of using RFID technology to assist hard of hearing children learning mathematics and science and the pedagogical implications of using RFID technology to maximize conceptual understanding of mathematics and science for hard of hearing children. Taking into consideration the children's visual learning characteristics, we present a system that uses RFID-tagged lab objects to help young hard of hearing children do operation task during exploration. The preliminary experimental results and the questionnaire results to evaluate the effectiveness of using this system are discussed. Perceived benefits to hard of hearing children up to ten years of age are presented. The use of RFID technology can enhance instructional opportunities for educators in teaching primary STEM and extend learning opportunities for deaf and hard of hearing students.**

Keywords—children; hard of hearing; RFID

I. INTRODUCTION

Hard of hearing children experience various difficulties in conventional mathematics and science instruction. Mathematics and science lessons involve technical terms and demonstrations to illustrate the concept being taught. The technical words may have no concrete referent. Hard of hearing children have less exposure to acquire the words from incidental learning. If hard of hearing children are unfamiliar with the meanings of some words, even non-technical terms, some comprehension will be lost. In particular, hard of hearing children with poor lexicon and limited knowledge are vulnerable to difficulties with acquisition of mathematics and science.

For hard of hearing children, amplification may or may not help sufficiently. Hard of hearing children may miss some words of a sentence or pieces of information of hands-on activities. When the children still try to understand previous concept, the instructor may move to the next concept. If the experience is repeated with missing auditory information, then comprehension will be seriously impaired. Although hard of hearing children can absorb some class lecture material to the extent they can by instructors' slides on presentations and writing on blackboard, the children have a fragmented view of what information that need to convey to all children. Hard of hearing children desperately need what has been said in class is repeated.

Several suggestions have been made in the literature on how to accommodate the difficulties experienced by deaf and hard of hearing students in inquiry-based science activities [10]. Physical manipulation of objects, combination of simplified text and explanations with pictorial or animated content, and additional practice on vocabulary and content graphic organizers are effective means to accommodate [1, 4]. Easterbrooks and Stephenson [2] suggested adding visual prompts, graphic organizers, and lower-level reading materials in the use of scaffolding.

The use of radio frequency identification (RFID) technology for creation of various educational interactive applications is possible [3, 11]. Augmenting the RFID tags with additional sensors could respond intelligently to people's needs [9, 8, 7]. Alex Pentland at MIT Media Lab had pioneered work in Smart Rooms that help users navigate cyberspace [8]. In recent years, the MIT Media Lab has started using RFID technology to help guide and track visitors to different exhibits when they are in the building.

Educators and researchers have looked for creative ways to assist deaf and hard of hearing children, and have paid attention to emerging instructional technologies. There are little studies that appear in the literature on the use of RFID technology in the education of deaf and hard of hearing children. Hancock, Parton and their research team [5, 6] developed a physical world hyperlinking teaching system using RFID-tagged toys to teach American Sign Language to deaf preschoolers. An initial set of 500 real-world objects with RFID tags were constructed to initiate instructional contents, such as a video of an individual signing that object's word, as well as several pictures of the object. Deaf preschoolers could not only practice their words, but also encourage their hearing parents to learn to sign as well.

II. METHODS

Taking into consideration the hard of hearing children's visual learning characteristics, we are developing a teaching system with RFID-tagged lab objects to help the young children do operation task and explore concepts during hands-on experiments. Each object in lab activities is equipped with a unique RFID tag to help the children learn how to use the materials and equipment needed and procedures to follow in an experiment. Make sets of RFID-tagged cards for children and introduce the steps of an experimental procedure, give demonstration experiments. Add technical words, even non-technical words, to RFID tags to explain their meanings. A small RFID interrogator is connected to a laptop computer which provides visuals, such as science experiment videos, pictures, illustrations, the schematic representations of concepts and relationships, or other references. When any of the objects is scanned, the embedded RFID tag thus triggers the system to launch a matching digital content on a computer screen. It gives children a visual clue what to do. The system can record and measure the frequency of use of the different RFID tags among individuals during the exploration, and thus the instructor may gauge the level of individual child comprehension of mathematics and science concepts.

The observations are from the science camp held by Yuan T. Lee Foundation Science Education for All, Taiwan. The foundation has began its Science Camp for Hearing Impaired Children since 2012. The camp has depended on volunteers to run all the math and science activities. A total of 20 subjects attending the camp, 12 males, 8 females, age range 7-10 years (grades 1-3) were chosen to participate in this study. Seven of them are pediatric cochlear implant recipients. Questionnaires regarding to situational hearing handicap are conducted.

III. PRELIMINARY RESULT

The hard of hearing children demonstrate an increase in positive behaviors, and in the motivation to learn. The children participate actively to the math and science inquiry activities. By using laptop computer with RFID technology, the children could not only practice mathematics and science vocabulary words but also facilitate acquiring and understanding mathematics and science concepts.

IV. CONCLUSION

RFID technology improves the hard of hearing children's learning experience in activities. Although the proposed system is at beginning stage of the development and the number of the hard of hearing subjects is small, it would increase participation in the math and science activities and promote active learning for hard of hearing children. The use of RFID technology can enhance instructional opportunities for educators in teaching primary STEM and extend learning opportunities for deaf and hard of hearing students.

General Engineering: An Innovative Program for the Region

Jean-Claude Thomassian
Engineering Department
jthomassian@ieee.org

***Abstract*—This paper describes the efforts of designing an innovative interdisciplinary general engineering program which was recently introduced as part of the newly shaped engineering department at the American University of Iraq in Sulaimani (AUIS). Current progress includes building a state- of-the-art science building that will accommodate the physics and chemistry laboratory, completing the construction of the engineering basement that will accommodate state-of-the-art laboratories to complement engineering fundamentals and capstone courses, and meeting staffing needs. The objective of the program is to create an ABET-accredited program that is unique to the region and serves the development of the region's economy and people. The paper describes the details of the general engineering program, curriculum development, laboratory facilities, experiences, faculty and staff needs. It also touches upon the theme of global engineer. A concluding section is offered that presents the development and implementation of such a program in a rapidly developing post-conflict society in the Kurdistan region of Iraq.**

Keywords—Curriculum Development; Engineering Education; General Engineering; Innovative Program; Post Conflict.

I. Introduction

The General Engineering curriculum at the American University of Iraq in Sulaimani (AUIS) is a non-specialized innovative interdisciplinary program offering a BS degree with no designation. The program is established with a sound theoretical base complemented by practical laboratory work to strengthen professional practice. AUIS was established in 2007 and currently has enrollment exceeding 500 students drawn from all regions of the country with a projected steady growth in the coming years. AUIS is situated on more than 400 acres of land and is Iraq's only private, not-for-profit university based on the American model of higher education, with all courses taught in English. There are also ambitious plans to begin adding degree programs in civil, mechanical, and petroleum engineering. Engineering computing was offered Fall 2012 for the first time.

The design of the general engineering program incorporates fundamental preparation associated with the traditional engineering disciplines (civil, chemical, electrical, and mechanical), includes a practical component in laboratory experiences to go along with course fundamentals, and presents capstone basics in the areas of design, economic evaluation and industrial practice. The program is also designed to house additional concentrations leading to postgraduate certificates in areas of focus of interest in the region, such as petroleum exploration and production.
Recent developments include completion of a state-of-the-art science building that houses the physics and chemistry laboratory, finishing up the engineering basement to house state-of-the-art laboratories to accompany engineering fundamental and capstone courses, and meeting staffing needs. The educational objectives of the engineering degree program are: 1) providing students with a broad, sound fundamental education in engineering and the sciences, 2) blending practice and design with the fundamentals to equip graduates with the skills needed to function in professional engineering careers, and 3) inspiring students to continue their education through graduate study and lifelong learning.

II. General Engineering Curriculum Design

The General Engineering Program is based on a one-year liberal core education plus three years of courses in science, mathematics and engineering fundamentals. Table 1 describes the general engineering degree curriculum with a total of 131 credit hours to complete.

The freshman year focuses on the liberal arts core curriculum with pre-calculus in the second semester of the freshmen year. The engineering segment of the degree program encompasses the sophomore, junior and senior years, which include a year of science, a year of engineering fundamentals, and a year of engineering design.
The senior year is intended to include a capstone on the general engineering degree program which includes the following courses:

1. Transport Phenomena – includes heat transfer
2. Engineering Economics – covers economics and business methods for engineers
3. Technical Writing – a technical communications course
4. Design – a capstone course intended to include collaboration with industrial customers
5. Engineering Laboratory – a capstone course that includes a design and build project
6. Introduction to Petroleum Engineering – an introductory course to petroleum exploration
7. Material Science – includes a practical lab component

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The diverse educational and cultural backgrounds of AUIS students, with English being their second or third language, focus on industrial internships, and the nature of the design year ought to strengthen AUIS students develop much sought after skills of global competence. [1]

III. CHARACTERISTICS OF A GLOBAL ENGINEER

Over the past several decades, the world has seen significant developments in and progress in technology, multinational corporations, free trade agreements, and newly developed regions that were previously off limits. These developments have increased global connectedness, making for an interdependent world and a globalization of the workforce. As an excellent example of globalization in engineering, the design of the Boeing 787 Dreamliner incorporates subcontracted assemblies from all over the world such as:

- wing, Mitsubishi (Japan)
- horizontal stabilizers, Alenia Aeronautica (Italy)
- wingtip, Korea Aerospace Industries (South Korea)
- Aft fuselage, Boeing (USA)
- passenger doors, Latécoère (France)
- cargo access and crew escape doors, Saab (Sweden)
- software development, HCL Enterprise (India)
- wiring, Labinal (France)
- tail fin, Boeing (USA)
- movable trailing edge, Boeing (Australia)
- landing gear doors, Boeing (Canada)
- main cabin lighting, Diehl Luftfahrt Elektronik (Germany)
- engines, Rolls-Royce (England)
- engines, GE (USA)

It is evident from the above list that the Boeing 787 Dreamliner is a globally developed and assembled product. The major subassemblies are from all over the world, and managing a project of this magnitude requires engineers with a broad set of competencies, capable of managing a global supply chain.

Parkinson [2] addressed what it means for engineering graduates to have global competence and identified 13 features as follows:

1. can appreciate other cultures
2. able to communicate across cultures
3. familiar with the history, government, and economic systems of several target countries
4. can speak a second language at a conversational level
5. can speak a second language at a technical level
6. proficient working in or directing a team with ethnic and cultural diversity
7. can effectively deal with ethical issues arising from cultural or national differences
8. understands cultural differences relating to product design, manufacture, and use
9. has an understanding of the connectedness of the world and the workings of the global economy
10. understands the implications of cultural differences on how engineering tasks might be approached
11. has some exposure to international aspects of topics such as supply chain management, intellectual property, liability and risk, and business practices
12. has had a chance to practice engineering in a global context, whether through an international internship, a

project, or some other form of experience
13. views one's self as a "citizens of the world," as well as of a particular country

Moreover, since it might not be possible to develop all of these features in an already crowded engineering curriculum, Parkinson[2] further surveyed university administrators and faculty and representatives from industry and governments, offered some preliminary results based on a sum of five rankings. The most significant features of global competence were:

1. can appreciate other cultures
2. proficient working in or directing a team with ethnic and cultural diversity
3. able to communicate across cultures
4. has had a chance to practice engineering in a global context
5. can effectively deal with ethical issues arising from cultural or national differences

The senior year of the general engineering curriculum is designed to incorporate a capstone experience calling for active engagement in practical learning of engineering work through direct collaboration with industrial customers on design problems. Some of the most significant features of global competence, such as proficiency working in or directing a team with ethnic and cultural diversity and the ability to communicate across cultures, fits well within the capstone context since most of AUIS student come from multicultural backgrounds. Also, many of the engineers working in companies in the region are foreign nationals, so student design teams collaborating with industrial customers might also learn to effectively deal with ethical issues arising from cultural or national differences while working on their capstone projects.

IV. Laboratory Facilities

Figure 1 below shows the actual layout of the engineering laboratory facilities currently being constructed in the basement of the Academic building. Descriptions of each of the rooms are also provided below the figure.

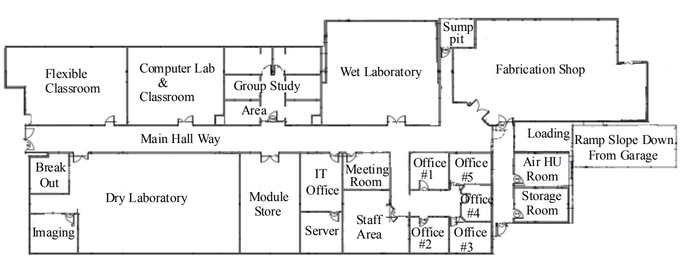

Fig. 1. Layout of Engineering Laboratory Facilities

Flexible Classroom used as a close, convenient classroom equipped for student demonstrations and presentations.

The Computer Lab & Classroom will be equipped with computers and software for computer-aided-design and data analysis

Dry Laboratory boasts generic labstations with test equipment, computers and data acquisition instruments to support courses with experiments such as circuits and electronics

Wet Laboratory includes fixed equipment for experiments in fluids, thermodynamics, and transport phenomena. It also includes a fume hood.

Group Study Area includes small conference rooms for four to six students with computers and whiteboards

Fabrication Shop has a separate student area, staff area, wood shop equipment, machine shop equipment, and prototyping equipment.

Module Store will be used for storing portable experimental modules on shelves that can be placed on carts and moved to the Dry Lab to customize labstations for specific uses.

Staff Area includes offices for administrative, IT, and other support staff.

V. Staffing Needs

Proper staffing has to be put in place in order to support and maintain all the course components of the general engineering degree curriculum. Once the program is fully deployed, the physics and chemistry sequences will require at least two teaching assignments per semester, along with several science laboratory support staff. The mathematics sequence will require at least three teaching assignments per semester.

The engineering sophomore year requires one teaching assignments in the fall and one teaching assignment in the spring. The junior year requires four teaching assignments in the fall and four teaching assignments in the spring. The senior year requires three teaching assignments in the fall and four teaching assignments in the spring. Furthermore, there is the need for two support staff for the engineering laboratory.

In the senior year, there are two further teaching assignments needed, one in the fall for technical writing and another in the spring for a humanities and social sciences technical elective course.

The total instructional load per semester for the engineering courses would be eight teaching assignments in the fall semester and nine in the spring semester for engineering faculty members.

The required teaching assignments for math, science, and engineering may double if classes are subdivided a result of increased enrollment in the general engineering program.

VI. Conclusion

This paper illustrated the efforts of implementing a general engineering curriculum at AUIS. There are numerous General Engineering programs in the United States and around the world that offer Bachelor of Science degrees without a specific designation that produce well sought-after engineering graduates. The multidisciplinary program at AUIS offers students design experience through professional practice, which should help them to attain some of the most significant features of global competence. The engineering program at AUIS includes a rigorous theoretical education in fundamental engineering science and mathematics, complemented with practical laboratory work, communication and teamwork skills to satisfy an industrial capstone project.

Abstract—**Engineering approaches to indentify and reverse electrical instabilities of the injured heart have lead to innovative diagnostic and therapeutic solutions. Therefore, curricula of Biomedical Engineering (BME) courses include cardiac electrophysiology. This paper describes a virtual laboratory designed for the study of the generation of the electrocardiogram (ECG) based on cellular electrophysiology. In detail, the virtual lab includes (1) an equivalent source model for cardiac cells, (2) a formulation of the mathematical relationship between the transmembrane potential and the transmembrane current, (3) the determination of resulting extracellular potentials, and (4) the calculation of the ECG by a weighted summation of transmembrane currents. Since these tasks require specific presumption and knowledge concerning cardiac geometry, a geometrical model was constructed using anatomical stylized segments of the left ventricle. Propagation parameters control the activation sequence as well as velocity and direction for anisotropic conduction. In order to verify the developed models and algorithms simulation results were compared against experimentally obtained data under various physiological conditions. Although there is considerable scatter in the measurements, the comparison indicates that a definite relationship exists between measured and computed waveforms. Simulations interactively show physiological and pathophysiological changes in the ECGs for various user setting of the cell function. In conclusion, the interactive laboratory enables the user to study the relationship between the electric activity of cardiac cells and the resulting extracellular potentials including the ECGs on the body surface. Students increase their knowledge of cardiac electrophysiology, applied electrical circuit theory and the understanding of differential equations as well as numerical methods for solving them.**

Keywords—Biomedical Engineering, virtual laboratory, simulation, heart model, electrocardiogram

I. INTRODUCTION

Engineering approaches to indentify and reverse electrical instabilities of the injured heart have lead to innovative diagnostic and therapeutic solutions. Therefore, curricula of BME courses include cardiac electrophysiology to provide a framework for understanding the genesis of the electrical signals themselves. In contrast to other engineering disciplines, experimental approaches in BME require noninvasive and invasive procedures on living systems. Thus, computer modeling is an essential tool for describing and analyzing biological systems [1]. One of the major challenges to teaching cardiac electrophysiology is gaining an understanding of the link between the electrocardiogram (ECG) and cellular electrophysiology. This paper describes a virtual laboratory, called Cell2ECG, and related projects, designed to simulate the genesis of cardiac electrical potentials under various physiological and pathophysiological conditions. The interdisciplinary approach of Cell2ECG includes cardiac electrophysiology as well as electrical circuit theory, mathematics and software development.

II. CONCEPT

The prediction of the ECG on the body surface requires knowledge of (1) cellular basics of electrical activation in the heart; (2) the sequence of these activations; (3) geometry and conductivity of the heart; and (4) a biophysical model describing current flow in the heart and current flow from the heart, through the intervening tissues, to the body surface. Therefore, Cell2ECG specifically incorporates

- a geometrical model of the heart,
- a biophysical model of an equivalent source generator,
- a simulation tool for action potentials (APs), and
- a simulation tool for specifying the propagation of electrical excitation in the heart.

In addition, a database of experimental data [2] is included in order to validate the results of the simulation. Based on these modules, the students are required to complete three experimental projects to estimate (1) a transmembrane current, (2) an extracellular potential, and (3) an ECG.

In contrast to more sophisticated simulations [3-5], the simple mathematical theory of the model allows [6] the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

students to implement a numerical solution for these projects. The simulation tools are based on LabVIEW/Mathscript, since it provides access to powerful programming and visualization functions and the students have had previous experience in this environment. The modular structure of the tools allows it to be easily modified or extended to other projects that are related to cardiac electrophysiology. Therefore, Cell2ECG should encourage active learning, group discussion, and problem solving skills.

III. MODELLS AND SIMULATION TOOLS

A. *The Heart Model*

The model is focused on the left ventricle (LV) since the effects of the right ventricle are not essential for understanding the genesis of the ECG. According to a modification of the Solomon-Selvester model [7], the LV is divided into three levels (apical, middle and basal) and four sections (quadrants) resulting in 12 segments (Fig. 1). Each of these 12 segments consists of endocardial, mid-myocardial, and epicardial layers of identical cells.

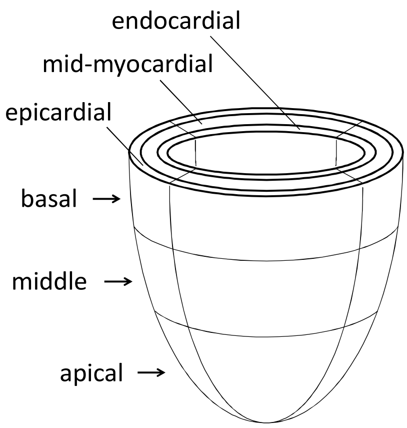

Fig. 1: Model of the left ventricle (LV). The LV is divided into quadrant-segments in the apical, middle, and basal level in accordance with the International Society of Computerized Electrocardiology (ISCE) nomenclature of myocardial wall segments [7]. All 12 segments are assemblies of endocardial, mid-myocardial, and epicardial layers.

B. *The Source Model*

For each segment of the heart model, an endocardial, mid-myocardial, and epicardial layer was approximated by a two-dimensional sheet of electrically coupled elements. Each element is modeled by a 2D-repetitive network of length Δx and Δy with the current source Im (transmembrane current) as described by the core-conductor approximation [8]. The network topology allows parameters governing propagation to be addressed easily and avoids computationally burdensome modeling. For the sake of mathematical simplicity and without losing the conceptual basis, Fig. 2 illustrates the one-dimensional case.

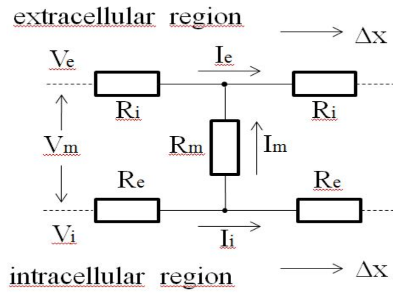

Fig. 2: Equivalent circuit of an element. Potential, resistance, and current are expressed per unit length Δx. Currents Ii and Ie are driven by the potential gradient Vm= Ve-Vi.
Vi, Ve: intracellular and extracellular potential, respectively
Ri, Re: the intracellular and extracellular potential, respectively.
Ii, Ie: intracellular and extracellular current, respectively
Vm: transmembrane potential
Im: transmembrane current

According to Fig. 2, the intracellular and extracellular current, Ii and Ie, respectively, are driven by potential gradients, so that,

$$Re \cdot Ie = \partial Ve/\partial x \quad (1)$$

$$Re \cdot Ii = \partial Vi/\partial x \quad (2)$$

where Ri and Re stand for the intracellular and extracellular resistance, respectively, and Vi and Ve for the intracellular and extracellular potential, respectively. By definition,

$$Vm = Ve - Vi \quad (3)$$

Taking the derivative on both sides of (1) and (2) produces,

$$Re \cdot Ie = \partial^2 Ve/\partial x^2 \quad (4)$$

$$Ri \cdot Ii = \partial^2 Vi/\partial x^2 \quad (5)$$

Since the total current must be preserved per unit length, the change in Ii and Ie must precisely equal the transmembrane current, Im (application of Kirchhoff's current law). In mathematical terms,

$$Im = \partial Ie/\partial x \quad (6)$$

$$Im = -\partial Ii/\partial x \quad (7)$$

Replacement of (6) and (7) in (4) and (5), respectively, yields,

$$Re \cdot Im = \partial^2 Ie/\partial x^2 \quad (8)$$

$$Ri \cdot Im = -\partial^2 Ii/\partial x^2 \quad (9)$$

Summation of (8) and (9) and recalling (3) leads to,

$$Im = 1/(Re+Ri) \cdot \partial^2 Vm/\partial x^2 \quad (10)$$

Including the extracellular current flow in the y direction, superposition of both results in,

$$Im = 1/(Re+Ri) \cdot [\partial^2 Vm/\partial x^2 + \partial^2 Vm/\partial y^2] \quad (11)$$

Thus, the transmembrane current density is directly proportional to the second spatial derivative of the transmembrane potential.

C. Simulation of APs

The transmembrane potential remains constant (resting membrane potential) without exterior influences. However, as the result of a local stimulus, an action potential (AP) is generated by the cell. In order to simulate the transmembrane current in the equivalent source model an estimation of the transmembrane potential, in particular for the AP, is required (11).

As proposed by [9] APs were composed using a parameterized AP profile where separate components control the initial upstroke (phase 0), the immediate fast repolarization and the AP plateau (phase 1 and 2, respectively) as well as the repolarization part (phase 3). In this way, APs were assigned individually to the cells of specific layers. The software enables the student to specify or modify the AP shape interactively, including the timing of depolarization and repolarization (Fig. 3).

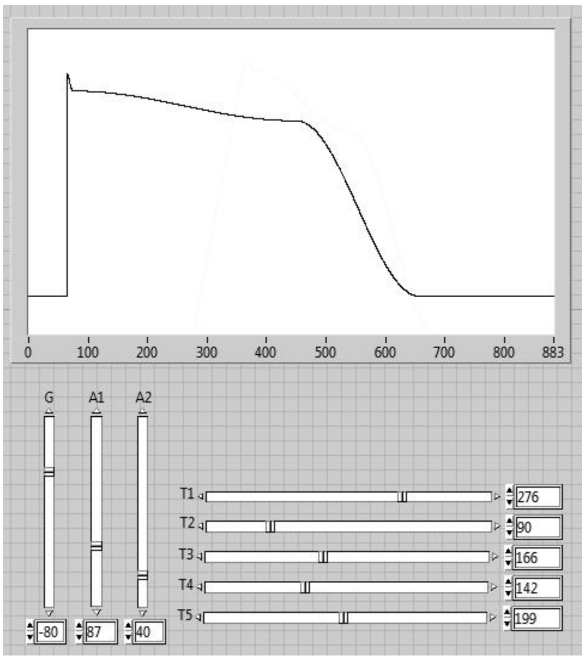

Fig. 3: Menu for interactive parametrization of APs. The scaling factors andtime constants relate to the different phases of the AP.

Differences between epicardial, mid-myocardial and endocardial cells are primary related to the AP duration as illustrated in Fig. 4.

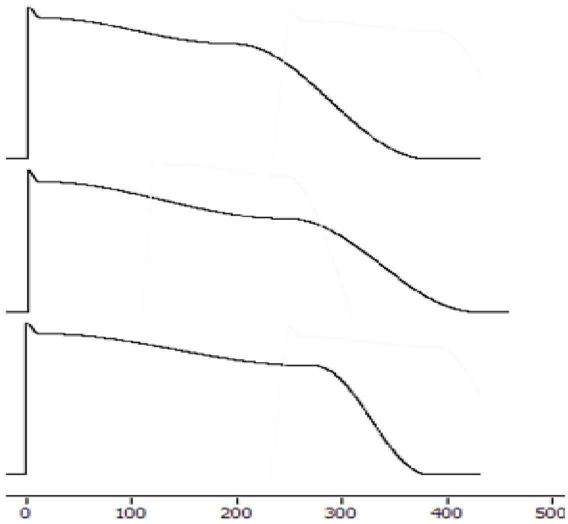

Fig. 4: Simulated APs assigned to epicardial (top) , mid-myocardial (middle) and endocardial (bottom) layers. The AP durations, given at 90 % repolarization (APD90) are 350 ms at the endocardium, 380 ms at the mid-myocardium, and 340 ms at the epicardium. The scale of amplitude for APs is arbitrary but normalized for all APs.

D. Simulation of Activation Sequence

The activation time (AT) represents delay between the start of myocardium excitation and activation of each individual element, and controls the activation sequence. The excitation starts at the endocardial layer and spreads through the mid-myocardium and the epicardium. Timing of activation may be changed interactively using a provided graphical user interface (GUI) as depited in Fig. 5.

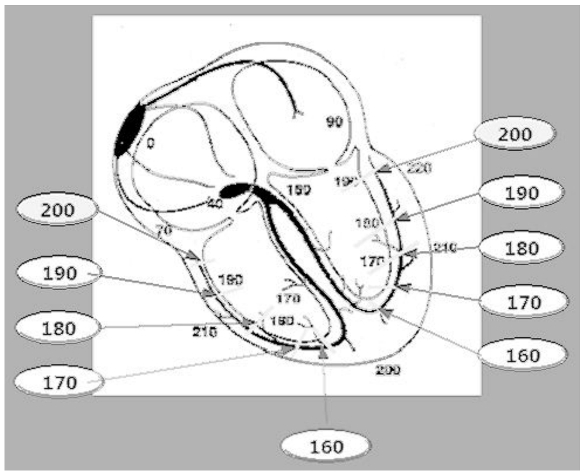

Fig. 5: GUI for interactive selection of activation times. The schematic drawing of a cross section of the heart represents the pathway of myocardial excitation starting at the endocardial layer and spreading through the mid-myocardium and the epicardium. Numbers indicate the activation time.

IV. PROJECT APPLICATIONS

A. Framwork

The subsequent projects are devoted to studying and understanding basic problems in cardiac electrophysiology related to (i) the estimation of transmembrane currents, (ii) the characterization of extracellular potentials, and (iii) the interpretation of the ECG on the body surface. The application of Cell2ECG requires knowledge of the physiology and anatomy of the heart, the understanding of cellular electrophysiology and a mathematical background for differential equations as well as numerical methods for solving them. After an introduction to the concept of Cell2ECG, students are required to reproduce the mathematical description of the equivalent source model as developed in (1)-(11). In contrast to other approaches [3-6], the numerical implementation of the source model is an essential step in the learning process. In order to verify the models, simulation results are compared against experimentally obtained data under various physiological conditions as provided by the database. For each project, a report is delivered consisting of derivations, physiological interpretation, figures, tables, programming code, results and discussion.

B. Estimation of the Transmembrane Current

Using (11), transmembrane current in an endocardial, mid-myocardial, and epicardial layer must to be determined. Specific aims include the investigation of the influence of the intracellular and extracellular resistance. A typical example of a simulated and an experimentally obtained transmembrane current is shown in Fig. 6.

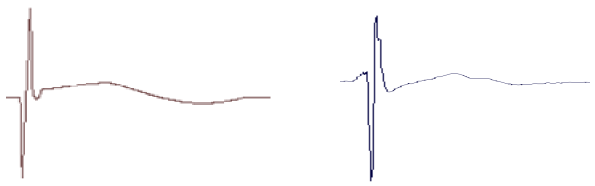

Fig. 6: A comparison of simulated (left) and experimentally obtained (right) transmembrane currents. Differences may be caused in part by the contributions of distant sources (far field effects). Scales arbitrary but normalized for both traces.

C. Estimation of Extracellular Potentials

The extracellular potential V(x,y) for a transmembrane current source, Im, is related to the distance r between the current source and the observation point [8]. In the two-dimensional case, the superposition principle for multiple linear current sources leads to

$$V(x,y) = \frac{Re}{\pi} \sum \frac{Im}{|r|} \quad (12)$$

where Re is the extracellular resistivity.

Besides assigning an AP, activation times need to be defined for each element. Specific aims include the investigation of the effect of the intracellular and extracellular resistance as well as the influence of the number of elements used for the simulation. Fig. 7 provides an example of a simulated and an experimentally obtained extracellular potential.

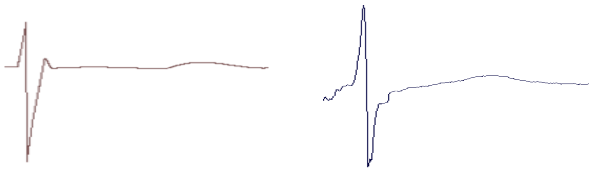

Fig. 7: A comparison of a simulated (left) and an experimentally obtained (right) extracellular potential. Significant differences may be due in part to the fact that the wavefront in the model is assumed to be planar and propagating with uniform conduction velocity. Scales arbitrary but normalized for both traces.

D. Simulation of the ECG

Extending the approach of Project 2, the simulation of extracellular potential will include current sources from all segments of the LV. For this purpose, APs and activation times are assigned and a representative current source is calculated for the center element of an endocardial, mid-myocardial,and epicardial layer in each segment. Assuming a homogeneous volume conductor, the ECG is obtained by the weighted sum of these representative current sources with reference to the distance between current source and observation point (12). Specific aims include the investigation of the relevance of the AP shape as well as the activation sequence. As Fig. 8 reveals, simulation leads to similar waveform morphologies observed in the experimentally obtained data.

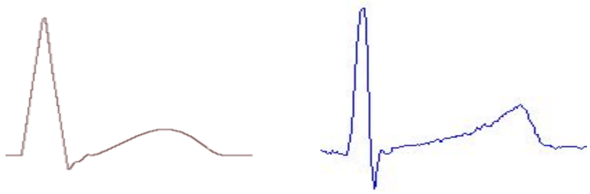

Fig. 8: A comparison of a simulated (left) and an experimentally obtained (right) ECG. The discrepancies were accounted for by variations in the AP shape and the activation sequence. Scales are arbitrary but normalized for both traces.

E. Effects of Cardiac Ischemia

In order to simulate the effects of epicardial ischemia on the ECG, the epicardial AP was modified as shown in the upper panel of Fig. 9. The severity of the ischemia can be modeled by an increase in the resting potential and a shortening of the duration of the AP plateau in the affected layer of a specific wall segment. The corresponding elevation of the middle part of the simulated ECG (lower panel) is related to the changes in the plateau of the epicardial AP. Similar effect can be demonstrated by modifying the endocardial AP.

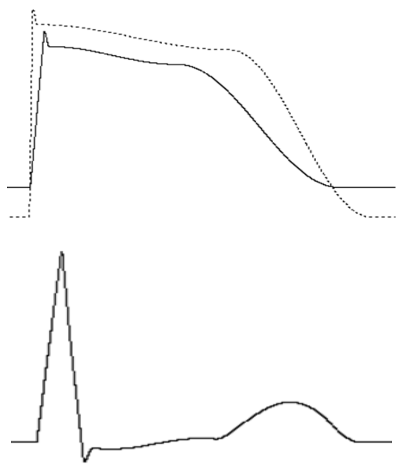

Fig. 9: Upper panel: Simulations of epicardial APs from normal (dotted line) and ischemic myocardium (solid line). Lower pabel: Simulated ECG corresponding to the ischemic epicardial AP. For reference see Fig. 8.

V. DISCUSSION

Cell2ECG provides a concept for an interactive simulation program that enables the user to study the relationship between the electric current sources of the heart and the resulting electrocardiographic signals on the body surface. A primary goal of the projects is for the student to gain proficiency in developing a mathematical description as well as a numerical implementation of the equivalent source model.

Comparison testing of Cell2ECG shows simulated and experimentally obtained data reveal quite similar waveforms. Furthermore, discrepancies were accounted for in the simple heart model due to the assumption of an infinite homogeneous volume conductor. A more accurate approach would have been to calculate the ECG from each point in the heart model. However, this would dramatically increase the complexity of the model and require a significant increase in the number of computations. This reduces the effectiveness of the simulation as a learning tool. At the designed level of complexity, it is hoped that the proposed projects will cultivate the student's interest in the analysis of physiological systems as well as in computational modeling, encouraging further study of more in-depth models.

In summary, Cell2ECG represents a simulation platform for electrical activities of cardiac cells, which provides a tool to examine the mechanisms underlying the genesis of the ECG under various physiological and pathophysiological conditions. It aims to serve as an educational tool and as a research tool as well, such as analysis of slow conduction in the infract border zone, simulating ECGs under ischemic circumstances, or during ectopic activation. The modular structure of Cell2ECG permits easy modification or expansion by adding more function to the defined menus, for example adding visualization of the activation sequence synchronously with the ECG waveform generation.

***Abstract*—Understanding global change is important for creating a sustainable environment, and is a key interest of the Earth systems science community. Here we present an educational tutorial that explores the relationship between sea level and global temperature using modern-day records and time-series analysis and the *Java-DSP Earth Systems Edition (J-DSP/ESE)* application. The objectives of the tutorial are to apply pre-processing steps based on signal type, perform spectral analysis and identify significant frequencies, perform coherency and cross-phase analysis between two records, and arrive at an informed understanding about the relationship between sea level and global temperature change. Preliminary student assessment indicates that students were comfortable using *J-DSP/ESE*, and quickly understood the signal processing concepts. The analysis reveals correlation between sea level variations and global temperature at inter-annual timescales related to the El Niño climatological phenomenon. In sum, the tutorial improved students' understanding of basic factors that influence global sustainability and habitability.**

Keywords—Earth signals, Java-DSP, multidisciplinary education, global sustainability, time series analysis.

I. Introduction

Global change science investigates the physical, chemical and biological processes that regulate the Earth's surface systems. A fundamental objective of the science is to understand the effects of anthropogenic activities on Earth systems. Primary among these are the consequences of elevated Earth surface temperatures on the global sea level. With rising Earth surface temperatures, the oceans are expected to experience thermal expansion and mass contributions from an ablating cryosphere. Quantifying the relationship between sea level and global warming is fundamental to forecasting future changes.

The Intergovernmental Panel on Climate Change (IPCC) [1] reported that over the latter half of the 20^{th} century ocean temperatures and sea level increased, both with significant interannual variability. Over the 20^{th} century there was an average sea level rise of 1.8 ± 0.5 mm/year, with evidence for acceleration to 3.1 ± 0.7 mm/year from 1993-2003 [2]. This rise is attributed to thermal expansion of the oceans and mass contributions from melting glaciers, the latter becoming the dominant source for sea level rise late in the century. Thus far, the polar ice sheets have not been considered by the IPCC to be major contributors to recent sea level rise.

Projecting forward with these estimates, sea levels will rise another 0.18 to 0.31 meters by the end of the 21^{st} century. However, the acceleration of global warming would mean that the rise could be greater, a 0.26 to 0.59 m rise by 2100 for "business as usual," and could even exceed 1 meter if polar ice sheets start to melt faster [3]. The new book, "Rising Sea Levels: Past, Present, Future" [4] explains the implications of sea level rise on modern society. The problem arises from the increased incidence of higher high tides and storm surges riding atop an elevated sea level. Thus, if sea level rises only 0.5 m, many of the world's largest cities, which are preferentially situated along coastlines, will be affected; a 5 m rise could affect ~670 million people, and a 10 m rise as many as 871 million. This is a significant change in society's habitable zone that needs to be anticipated by governments around the world, and ideally ameliorated through concerted reduction of anthropogenic activities and emissions contributing to global warming and climate change.

The tutorial presented here examines the global warming - sea level link through multivariate time series analysis of the global temperature and sea level records. While both global temperature and sea level have been increasing, it is not possible to ascribe causation based simply on linear trends. Numerical modeling is needed to demonstrate how added energy from global warming melts an ice sheet or thermally expands an ocean. Time-series analysis, such as that carried out in this tutorial, provides other, key empirical constraints. The global temperature and sea level records have strong inter-annual variations, which will allow the identification of lead and lags between the records, from which a determination of forcing and response time may be inferred.

II. CRITICAL SIGNALS OF GLOBAL CHANGE

2.1 The Global Temperature Record

The global temperature record consists of monthly-mean temperature data that are averaged over 5ºx5º (longitude, latitude) grids from more than 3000 stations. The data are preprocessed to remove the seasonal cycle and biases from stations at different elevations, and presented as a "temperature anomaly" record. Today there are now independent versions of the global temperature record; much of the contributing station data is the same, but the processing techniques and decisions are different [5,6]. The HadCrut3 temperature anomaly record [7] is used in this study (top curve in **Fig. 1**).

2.2 The Global Sea Level Record

Global sea level records are constructed from tidal gauge measurements and satellite altimetry [8,9]. Tidal gauges have been in operation since the early 1800's; sea level measurements from satellite altimetry have been available since 1992. The combined TOPEX-Jason 1 and 2 satellite altimeter record [9] with seasonal components removed is used in this study (middle curve in **Fig. 1**).

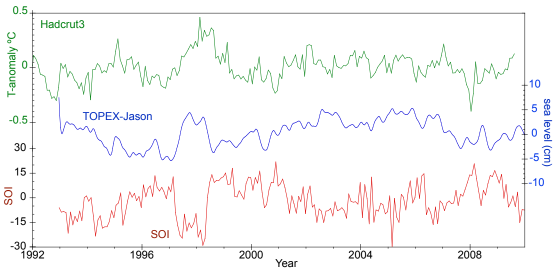

Fig. 1. Critical global change signals, 1993-2010. Top: the Hadcrut3 global temperature record, sampled at Δt=0.0833 years [7]. Center: the TOPEX-Jason satellite altimeter measurements of global sea level sampled at Δt=0.0272 years [9], low-pass Gauss-filtered over f=[0,4 cycles/year]. Bottom: the Southern Oscillation Index (SOI), sampled at Δt=0.0833 years [10].

2.3 The El Niño-Southern Oscillation

The El Niño/Southern Oscillation is a coupled ocean-atmosphere system in the tropical Pacific that generates interannual climate variability at the global scale, related to the Southern Oscillation and the atmospheric pressure difference between Tahiti and Darwin [10]. The variability carries over to both global temperature and sea level change [5,9] (compare the different curves in **Fig. 1**), but the phasing of the variations among the three processes is unknown, and is to be determined in this tutorial.

III. GLOBAL CHANGE ANALYSIS WITH J-DSP/ESE

3.1 The J-DSP/ESE standalone application

Java-Digital Signal Processing (J-DSP) is a web-based, platform-independent, visual programming environment that enables users to perform signal processing calculations and simulations. J-DSP was built from the ground up in Java to provide free and universal access to an array of signal processing functions that can be used for research and education. Signal manipulation functions appear in J-DSP as "blocks" that are brought into the simulation environment by a drag-n-drop process. Signal and data flow is established by linking the blocks. Original J-DSP functionality targeted engineering algorithms for signal processing, imaging, controls, time-frequency analysis and communications applications, and is currently used as an online Java-applet for undergraduate education [11].

A standalone version, *J-DSP/Earth Systems Edition (J-DSP/ESE)*, was developed with functions for input/output, interpolation, re-sampling, windowing, filter design, univariate and multivariate spectrum estimation, and time-frequency analysis, customized for the analysis of Earth signals. A full description of *J-DSP/ESE* appears in Ramamurthy et al. [12]; the application workspace is displayed in **Figure 2**. The application is free and available for download at (http://jdsp.engineering.asu.edu/jdsp_earth/index.html). Here *J-DSP/ESE* is used to perform univariate and multivariate time series analysis on the critical global change signals presented above.

3.2 Artificial test case

Figure 2 illustrates functions that are applied in this tutorial. Two test series of length 1000 with a uniform sample rate of Δt=1 are defined (t =nΔt, n=1,2,…,1000):

$$data1(t) = \sin(2\pi t/10)+n_1(t)$$
$$data2(t)= \cos(2\pi t/10)+n_2(t)$$

Simple periodograms (parameters set to single-frame, rectangular) of these time series are very similar, with a spectral peak at f = 0.1. Time-wise, data2 could be considered to lead data1 by a quarter-cycle, i.e., phased by 90º, consistent with the sine-cosine relationship. To examine this in the spectral domain single-frame coherency analysis is performed, with data1 input first ("top branch"), and indicates a peak at f = 0.1, where cross-phase registers -90º. Thus, in the J-DSP/ESE coherency function, negative cross-phase indicates that data2 leads data1.

Fig. 2. Workspace of J-DSP/ESE showing periodogram and coherency analysis of two test series data1 and data2.

3.3 Global change spectra

A first important step in comparing these critical global change signals is to characterize their spectra. This is accomplished with periodogram analysis. Here, the simple (single-frame) periodogram is used to calculate univariate spectra of the three records. All three records share a common trait, namely, large-magnitude inter-annual variations (i.e., cycles longer than 1 year); visual inspection of **Figure 1** suggests that many of the recorded variations are common among them. Thus, the frequency band f=[0,1 cycles/year] is expected to have most of the power in these records, and is the focus of this exercise.

The time interval 1992.96-2009.92 is examined, which is a common interval for all three records. The sample rates of the records are different (**Fig. 1**), and so are resampled to uniform Δt=0.02 years. Means and linear trends are subtracted. Each record is zero-padded to 8192 points prior to the periodogram estimation. Zero-padding is useful – even essential – when the record length is short (16.96 years here), and the frequencies of interest are low. The periodograms reveal multiple inter-annual frequencies in the three records (**Fig. 3**). Common among them are 1/(4 years); others may also reflect a common origin, e.g., 1/(3 years) and 1/(6 years) or 1/(7 years). The sea level spectrum has fewer higher frequency components, possibly indicating a filter response to forcing from temperature and/or the SOI. Multivariate methods must be applied to determine whether there are statistical relationships among the three records, as follows.

3.4 Coherency and cross phase spectra

To examine the correlation among the three records presented above, eight-frame, un-tapered coherency and cross-phase spectra are calculated (**Figs. 4-6**). For f=[0,1 cycles/year], coherency is elevated in all three analyses, indicating correlated inter-annual power.

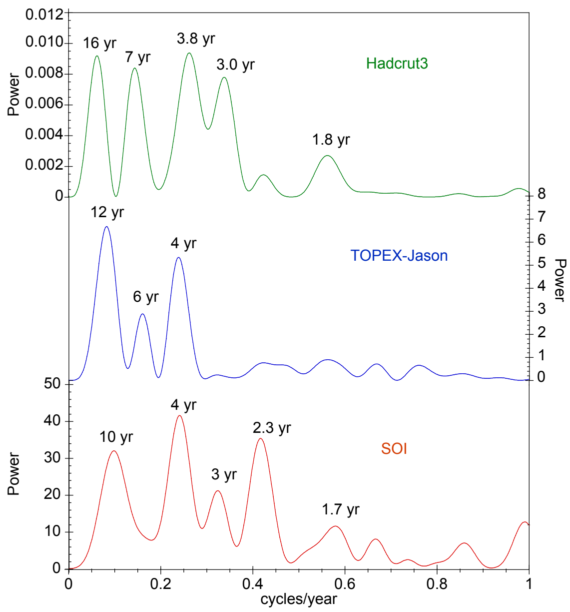

Fig. 3. Single-frame periodograms of the three records in **Figure 1**, for the time interval 1992.96-2009.92, and zero-padded to a 8192 point length (see text). Top: the Hadcrut3 global temperature record. Center: the TOPEX-Jason satellite altimeter measurements of global sea level. Bottom: the SOI index.

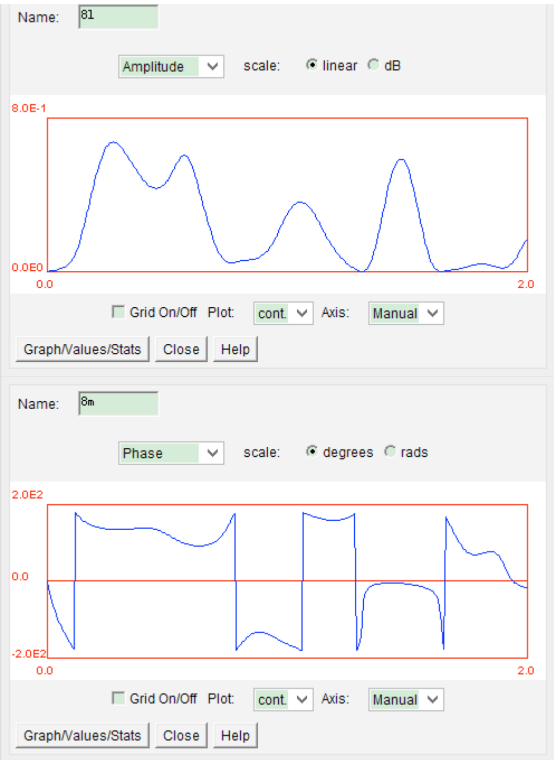

Fig. 4. Eight-frame coherency (top) and cross-phase (bottom) spectra for global temperature v. SOI for 1992.96-2009.92. The means and linear trends of the inputs have been estimated and removed. For f=[0,1/year] cross-phase decreases slightly from 180º, i.e., SOI leads global temperature.

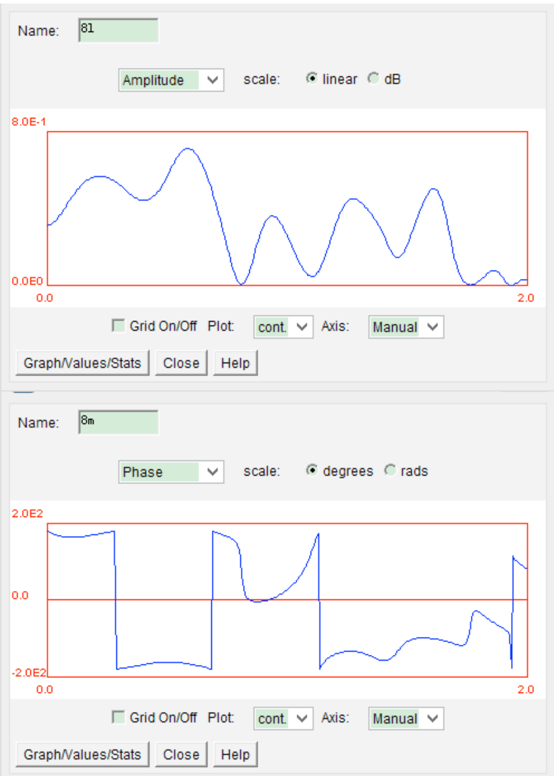

Fig. 5. Eight-frame coherency (top) and cross-phase (bottom) spectra for sea level v. SOI for 1992.96-2009.92. The means and linear trends of the inputs have been estimated and removed. For f=[0,1/year] cross-phase is 180º, i.e., SOI and sea level are out of phase.

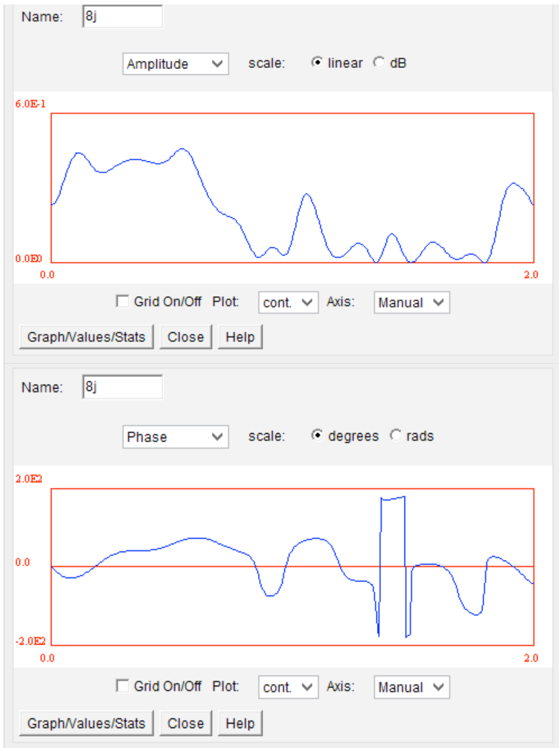

Fig. 6. Eight-frame coherency (top) and cross-phase (bottom) spectra for temperature v. sea level for 1992.96-2009.92. The means and linear trends of the inputs have been estimated and removed. For f=[0,1/year] cross-phase is positive, i.e., sea level leads global temperature.

The cross-phase spectra indicate that SOI and global temperature are out of phase, with the slightly decreasing phase indicating SOI leading temperature. SOI and global sea level are anti-phase-locked, and global sea level leads temperature. Additional measurements are required to determine the statistical significance of the coherency and cross phase. For example, is the measured global sea level lead over global temperature a significant result, or are the measurement uncertainties too large to rule out a zero-phase relationship? If it is determined that the lead is significant, then the more complicated question of why can be examined with confidence.

III. Tutorial Objectives and Assessment

The objectives of this tutorial are as follows:

1. Introduce concepts of time series, frequency, spectrum, and correlation.
2. Introduce common preprocessing steps and their benefits.
3. Perform periodogram analysis and identify significant frequencies.
4. Perform coherency and cross-phase analysis between two signals.
5. Analyze the relationship between El Niño, global temperature and sea level.

The overall objective is to increase student awareness of the response of the oceanic response to global warming, through hands-on manipulation of state-of-the-art global change data. The analyzed data reveal a dynamic and interactive Earth surface system that is rapidly evolving, and that poses profound

TABLE I. ASU WORKSHOP – CONCEPTUAL ASSESSMENT QUESTIONS WITH THE CORRECT ANSWERS

No.	Question	Type	Answer
1.	Consumption of energy by humans from a million years has increased:	Multiple-choice	100 fold
2.	The primary energy source in the USA is :	Multiple-choice	Fossil fuels
3.	The average human sitting burns:	Multiple-choice	100 watts
4.	Interannual variations of atmospheric carbon dioxide are characterized by:	Multiple-choice	Periodicities in the 3-5 year range
5.	Long term trend in the global temperature is:	Multiple-choice	Increasing but slowing in the past decade
6.	Global temperature variations have the following relationship with carbon dioxide variations	Multiple-choice	Carbon dioxide lags temperature
7.	Global sea level variations have the following relationship with global temperature variations	Multiple-choice	Sea level lags temperature
8.	At a frequency of 1 cycle/year, if the cross phase is 90 degrees, what is the lag between the two signals (Global temperature and carbon dioxide)?	Multiple-choice	3 months
9.	Over the past 30 years, what change has happened in the phase relationship between the global temperature and carbon dioxide variations?	Multiple-choice	The lag period has increased
10.	The phase relationship between the sea level and global temperature variations point to the possible following cause(s):	Multiple-choice	De-glaciation

TABLE II. ASU WORKSHOP – SUBJECTIVE ASSESSMENT QUESTIONS

No.	Question
1.	I understand the concept the use of coherency and cross-phase more clearly after performing the exercises.
2.	The user interface of J-DSP/ESE is intuitive and easy to use.
3.	I will be able to perform analysis of similar Earth systems datasets comfortably using the J-DSP/ESE version.
4.	How much time did you need to become comfortable in using the J-DSP/ESE version?

challenges to global sustainability and habitability.

We administered this tutorial at a workshop at Arizona State University in January 2012 to an audience of 14 electrical engineering graduate students with a background in signal processing, but not in Earth science. Prior to the tutorial, the students were introduced to key concepts behind 20^{th} century climate change. A pre-quiz conceptual assessment with seven questions was administered before the start of the workshop. At the end of the workshop, the participants answered a post-quiz conceptual questionnaire that consisted of the same seven pre-quiz questions plus three questions, and a subjective assessment questionnaire. The ten questions along with their correct answers are given in **Table I**. The questions in the subjective questionnaire are given in **Table II**. For each of the first three questions in the assessment questionnaire, the participants were asked to choose from the following responds: (a) Strongly agree, (b) Agree, (c) Neutral, (d) Disagree, and (e) Strongly disagree. For question 4, the possible four responds were (a) Less than 5 minutes, (b) Less than 10 minutes, (c) Less than 30 minutes and (d) More than 30 minutes.

The correction rates to the assessments and first three questions in the subjective questionnaire are summarized in **Figure 7**. The average performance in the assessments improved from 40% to 69%, as evaluated from the pre- and post-quiz results, which points to a successful use of the tutorials and J-DSP/ESE in interdisciplinary education. Furthermore, from the subjective assessment results, 85% of the participants agreed that *J-DSP/ESE* was easy to use and they were comfortable in understanding the concepts. Over 85% of the participants answered that they became comfortable using *J-DSP/ESE* in less than 10 minutes. From these assessment results, this tutorial along with the software, provided valuable information about global change to the non-specialist audience.

IV. CONCLUSIONS

This tutorial explores the relationship between critical global change signals related to global warming and sea level change. Students were asked to evaluate the frequency content of three records, global temperature, global sea level, and Southern Oscillation (SOI), and to assess correlations between the records. The strongest correlation was between global temperature and sea level change, that included frequencies associated with SOI variations. Sea level was shown to lead temperature variations. These results demonstrate couplings between major Earth surface processes that directly impact global sustainability and habitability of the Earth's coastal zones.

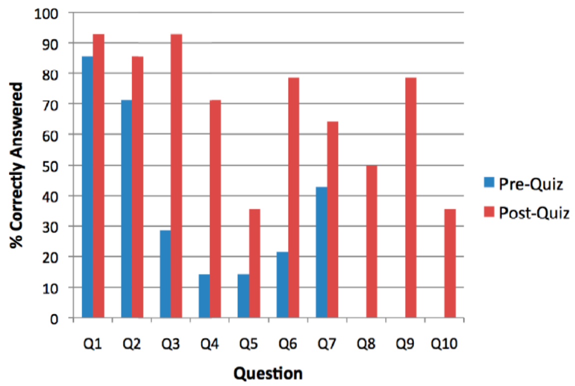

Fig. 7. Summary of the results in the technical assessment and first three questions of the subjective assessment.

This tutorial introduces students to basic concepts in global change and time series analysis. The new standalone application J-DSP/ESE was used to carry out sophisticated but simple exercises to elucidate the strong link between global temperature and sea level change. The plan is to build on this approach with alternative data, and to develop ways to statistically assess the measured dynamical interactions.

A Computer Science Course in Cyber Security and Forensics for a Multidisciplinary Audience

Wendy A. Lawrence-Fowler
Department of Computer Science
The University of Texas-Pan American
Edinburg, Texas
wfowler@utpa.edu

Abstract— **The preparation of a graduate level cyber security and forensics course in a computer science department that addresses theory, policy, and application for a multidisciplinary student audience can be daunting when the majority of students in the class do not have a computer science background. The course takes a holistic approach to broaden knowledge and deepen understanding of the domain of cyber security using cross disciplinary teams to gain understanding and experience taking theory to practice and practice to theory. A framework of understanding is built through the examination of the body of scholarly conceptual and technical works and hands on experience with hardware and software platforms and networks. Computer Science provides the theoretical underpinnings and technical details, methods, and tools to examine security concepts; Forensic Science provides the approach to critical analysis of digital evidence; and Behavioral Analysis provided a way to synthesize knowledge and scientific method to gain some understanding of criminal behavior as well as the breadth and economic impact of cybercrime. This approach resulted in students who gained technical proficiency and perspective and experience working with people with divergent backgrounds, abilities and knowledge sets.**

Keywords—cyber security, forensics, multidisciplinary learning, security education, information security training

I. INTRODUCTION

In the era of information, security is a common topic of discussion in public and private, large and small organizations. While information security is not a new field, the increasing number of security breaches and threats to personal, organizational, and national safety have created a focus on cyber security. This has created an increased demand for qualified security professionals in both the private and the public sector. Emerging fields of study and practice in cyber security computer forensics, network security, software security, and critical infrastructure protection are increasingly important areas of interest [1].

The U.S. government has recognized that "securing cyberspace is an extraordinarily difficult challenge that requires a coordinated and focused effort from our entire society – the federal government, state and local governments, the private sector and the American people" [2]. In addition to the National Initiative for Cybersecurity (NICE) at NIST, the U.S. Intelligence Community established the Intelligence Community Center of Excellence in National Security Studies Program (IC CAE) in 2005 to strategically meet the nation's demand for a competitive, knowledgeable and ethnically diverse pipeline of professionals to meet the United States' National Security Imperatives in the 21st Century. In 2007, The University of Texas – Pan American, a Hispanic Serving Institution, established an Intelligence Community Center of Academic Excellence (IC CAE) with funding from the Office of the Director of National Intelligence (ODNI). The purpose of the Center is to prepare students for careers in intelligence and security through advanced interdisciplinary studies using an approach that assures that the next generation of Intelligence Community professionals is prepared with the appropriate skills and breadth of knowledge to be leaders in the national security challenges in the global economy of the 21st century.

Recognizing the breadth of knowledge required to lead security initiatives and recognizing that solutions to the current challenges in security demand the integration of human and technical resources, the UTPA IC CAE uses a multi-disciplinary approach to achieve substantial synergies in combining knowledge from different disciplines to IC challenges in information assurance and analysis, risk assessment, management, leadership, and technology. Housed in the College of Social and Behavioral Sciences, the IC CAE leads the discourse on national security across the campus and identifies specific needs associated with bridging seemingly disparate disciplines.

The UPTA IC CAE created and manages an interdisciplinary Global Securities Studies and Leadership Program (GSSL) that involves significant outreach activities to expand the potential workforce pipeline and educate the general community about national security. Like the other MSI based Centers of Excellence, the UTPA GSSL program includes significant outreach efforts to attract individuals to the pipeline for security professionals. However, unlike many of the centers, the GSSL program introduced new courses,

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

new degree programs and a certificate program in Global Security Studies and Analysis to the UTPA curriculum. The GSSL programs also differ from programs offered by NSA Centers of Academic Excellence in Cyber Operations that tend to be deeply technical in a substantial number of topics. As of 2008, the GSSL program coordinates an undergraduate minor, a graduate certificate and a Master's degree in Interdisciplinary Studies (MAIS). With the exception of the new courses, the program design consists almost entirely of existing UTPA courses, taught by current faculty in established departments. Its near-universal reach across the university curriculum is ambitious because it articulates skill and knowledge sets that reside in many of UTPA's departments.

This paper discusses the challenges of delivering a Computer Science course in Cyber Security and Forensics as a part of the technical competency course sequence for the GSSL MAIS. The original course is designed as a masters level course in computer science that addresses theory, policy, and application. This course is modified to provide a computer science perspective on theory, policy and application to simultaneously meet the needs of a diverse multidisciplinary audience in three graduate programs: Computer Science, Information Technology, and Global Security Studies.

II. THE GLOBAL SECURITY STUDIES PROGRAM

A. Overview of Master's of Interdisciplinary Studies(MAIS)

The MAIS degree prepares students for careers in Intelligence and National Security through focus on advanced research, effective cross-discipline team communication, and critical analysis. Given that jobs in government or private industry often require multidisciplinary cooperation, the GSSL MAIS prepares students to work with people from different backgrounds, abilities, and knowledge bases. This approach assures that students have the opportunity to gain the perspective of and proficiency in multiple disciplines, preparing them for careers in national security.

The Intelligence Community has defined and organized 5 'Primary Critical Skill Sets/Competencies' based on categories of security employment that people will specialize in: 1) Information Technology Specialists, 2) Political/Economic Specialists, 3) Language Specialists, 4) Threat Specialists, and 5) Scientific/Technical Specialists [3]. The GSSL programs engage students and faculty in each of these five Primary Critical Skill Sets. In addition to the primary skill sets, a number of IC defined 'Specific General Competencies for Intelligence Professionals' areas are addressed in the program including analysis, analytical reasoning, critical thinking, communications (oral and written), research, developing rational conclusions and deriving alternative solutions from ambiguity and limited data sets[3].

B. MAIS Curriculum

The GSSL MAIS consists of 36 semester hours of study, including a 12 hour core sequence, a 15 hour concentration in interdisciplinary studies and a 9 hour technical competency sequence.

Through the core sequence the students learn how skill sets relate to the global context of intelligence and security work. The core courses address the competency skill areas including advanced research, problem solving, critical thinking, technical writing, and leadership. The core courses consist of Global Security, Open Source Research, Interdisciplinary Research and Analysis, and a practicum in Global Studies Security Studies. The interdisciplinary course sequence addresses critical competencies required to understand the globalization of communication, societies, cultures, governments, businesses, and technology. The required courses include Culture and Communication, International Management, Cross Cultural Psychology, Statistics and a graduate level elective.

The technology competency sequence provides students with the essentials of information technology and computer systems with a focus in information security. The course sequence consists of Information Security, Principles of Information Technology Systems, and Cyber Security and Forensics [3, 4]. The first course in the technology series is offered by the faculty in the Department of Computer Information Systems located in the College of Business. The second two courses are taught by faculty in the Department of Computer Science in the College of Engineering and Computer Science. All three of these courses existed in their respective departments with intended audiences other than the participants in the GSSL program prior to their identification as the technical competency sequence.

III. CYBER SECURITY AND FORENSICS COURSE

Using a variety of learning resources, the Cyber Security and Forensics course addresses a broad set of topics in cyber security and cyber forensics. The goal is to assure that students gain an understanding of the breadth and depth of what cyber security and cyber forensics mean in abstract terms and in the context of real systems. Through reading, lecture, discussion, and thought experiments [5] students learn about the underlying formalisms and technologies that address challenges and potential threats to confidentiality, integrity, and availability. Students learn aspects of cybercrime and ways in which to uncover, protect, exploit, and document digital evidence. Students are exposed to different types of tools, techniques, and procedures, as well as policy and legal issues.

The use of a hands-on-laboratory component reinforces formalisms and technologies introduced in lecture and discussion. Augmenting lecture and discussion based thought experiments, the labs support understanding through direct experience in applying knowledge in new situations [6,7,8]. Students develop skills in the reduction of theory to practice and abstraction of practice to theory.

A Blackboard instance of the course is used to manage learning resources, support communication, and the sharing of knowledge and perspectives on the discipline. Rather than assigning a textbook, the course uses a set of scholarly and technical works from academic, industrial, and government sources. Students have access to a variety of open source tools, commercial hardware and software products and a laboratory in which they are free to experiment.

A. Learning Objectives

Upon completion of the course, students are expected to (1) understand the basic theory and concepts of cyber security and privacy including policies, models, and mechanisms; (2) understand ethics, legal issues, and human factors associated with cyber security and forensics; (3) understand security vulnerabilities and be able to describe threats and risks; (4) be able to explain best practices in giving access to systems and networks and implement proper authentication techniques; (5) be familiar with cryptographic techniques, asymmetric key algorithms, and create certificates; (6) describe the requirements for a cyber forensic investigation and demonstrate an understanding of tools, techniques and procedures; and (7) be conversant in current security related issues in the fields of cyber security and cyber forensics.

B. Course Topics

The course begins with an overview of the security problem followed by an introduction of fundamental tools and techniques for addressing security. After providing a broad introduction to security, the course focus shifts to forensics.

Course topics include:

- Confidentiality, integrity and access policies (policy and metapolicy)
- Information flow and content (encoding and entropy)
- Cryptography and ciphers
- Network security
- Malicious logic, vulnerability analysis
- Strategic planning for security
- Law and legal issues
- Volatile and persistent data
- First responder activities
- Hacking: ethical and not

The discussion on strategic planning for security includes a presentation of requirements to create a security organization. This discussion, intentionally placed two thirds of the way through the semester, presents a scaffolding that provides a real-world context and supports the creation of connections between security topics. This discussion illustrates the real world application of all that has been covered to date and creates an opportunity to shift the course focus from security to forensics.

C. Laboratory Component

The laboratory component of the course gives students practical experience with the concepts introduced in lecture and discussion. Each lab is designed so that students gain experience working with real world tools and real world problems. A broad array of commercial hardware and software, and open source tools are provided to develop solutions for problem based challenges involving confidentiality, integrity, access, and trust. Students identify and disable network attacks. They find hidden information, and they conduct forensic investigations using a systematic approach to evidence identification, preservation, analysis, documentation, and presentation following acceptable legal procedures and laws of evidence[6].

Lab exercises are completed by interdisciplinary teams to encourage transfer of understanding and perspective across the spectrum of divergent bodies of knowledge held by course students and to address varying levels of comfort and skill in using technology. Lab exercises are designed to be completed in real world settings on either personal computers or in the Computer Sciences Advanced Studies Lab. While connected to the campus network for internet access, the Advanced Studies Lab is reconfigurable as need be for this course and the networking courses that share the facilities.

Lab exercises assigned during the course include:

- Controlling access to files and folders with special access to network shared folders in Windows and Unix/Linux environments
- Mining cache, cookies, and history for traces of activity and hidden value
- Mining programs and files: Registry tracks
- Network security: Identifying and disabling network attacks with Security Onion, Squil, Sqert, and Snorby
- Securing networks with software and hardware firewalls
- Public faces – Social media and the flow of information
- Imaging and analyzing storage devices with EnCase
- Imaging and analyzing storage devices and capturing volatile data with open source tools
- Steganography

Two additional lab exercises are available for students that are interested in testing their programming abilities. The first exercise involves creating a covert channel to pass one bit of data. The second exercise involves implementing a robust queue. They are given Bishop and Elliott's 2011 paper on robust programming as a resource for this exercise [9].

D. AssessmentTechniques Used

Formative and summative evaluations are given to both make adjustments to content delivery and to assess student learning. Students are given weekly assignments that include a set of readings and at minimum one deliverable. Deliverables vary by week, but in general consist of one or more of the following: 1) short responses to issue specific questions used to measure understanding of the lecture and reading assignments, 2) lab results along with self-assessment of success, and suggestions on improving the lab, 3) short essays on how a reading relates to past, current, or future experiences in global information security, 4) contribution to a course glossary by adding terms and definitions to build a broad and common lexicon for security, 5) identification of a resource and explanation of its value, 6) a reaction paper on a particular assigned reading. Every class begins with a background knowledge probe to assess student familiarity with terms and concepts. Thought exercises introduced during lectures provide a means to gather input on how well students comprehend the content of discussion and lecture. These experiments require higher order thinking: analysis, synthesis, and evaluation, providing the instructor with information about students learning and a self-assessment tool for students. All laboratory exercises include a request for feedback on the activity and most include a required opinion either on the tools, process, or the lab's value add to the learning experience. A relatively casual atmosphere in lab leads to conversation and additional opportunities to gather feedback about content delivery and student learning.

Two larger learning exercises serve as exams. The first exercise serves as a midterm. Students are given three questions: two questions that require students to research specific security models not previously presented in lecture and discuss their application. A third question serves as a thought exercise requiring critical thinking and synthesis. The second large exercise serves as a final. Students choose one of two challenges. In the first challenge students must build a forensic tool kit from existing open source resources and write a comprehensive user's guide on when, why and how to use each tool in acquisition, analysis and presentation during a forensic investigation. In challenge two, students read Cliff Stoll's book "The Cuckoo's Egg" and write a 7 to 10 page response to one of three prompts. Each of the prompts requires analysis, synthesis, critical and creative thinking.

IV. Discussion

Computers, the Internet, e-mail, wireless technology toys, and social networks are pervasive and a ubiquitous part of everyday life. The growth in digital details that are created, captured, and stored in more places than most people realize is exponential as is the growth rate of crimes in which cyber technology is the instrument of, the target of, or by its nature, the location where evidence is stored or recorded. The number of security breaches and threats to personal, organizational, and national safety and the increasing costs of security breaches have create a focus on cyber security[10,11,12] and a demand for qualified security professionals in both the private and the public sector[2,3]. Academic institutions respond by offering new undergraduate and graduate courses in cyber security [13] and forensics [6].

A. Background

The course that was chosen for the GSSL MAIS technology sequence to address cybersecurity was originally designed for graduate students in a computer science master's program. Students were expected to be familiar with networks, operating systems, data structures, programming languages, software application programming and hardware. The course takes a breadth first approach to introducing the fundamentals of computer security and forensics. Balancing lecture content with hands-on laboratory exercises, students have the opportunity to experience theoretical concepts and their implementation. Reflective learning exercises are designed to empower students to link prior knowledge with new knowledge and develop a deep understanding of the complexity of cyber security and forensics theory and practice.

B. Challenges

It is a challenging task to offer this graduate level Computer Science Security and Forensics course to graduate students in programs outside of computer science. Traditionally at UTPA, the course is an elective in the Master's of Computer Science and the Master's of Science in Information Technology (MSIT) programs. The course is taken after students have completed an advanced networking course.

However, with the inclusion of this course in the GSSL MAIS, the demographic profile of students taking the course changes radically. Less than 3% of the students have undergraduate degrees in computer science and are pursuing a Master's degree in Computer Science. The remaining 97% of the students' program affiliations are split between the MSIT and the MAIS. Of this group, only 8% have formal undergraduate training in information technology.

The new demographic includes students who have undergraduate degrees in accounting, computer science, criminal justice, early childhood education, economics, graphic design, information technology, political science, psychology, and sociology. The majority of MAIS students move directly from their undergraduate education to the graduate program. The majority of MSIT students are currently working as professionals in information technology and have extensive experience in either networking or management information technology systems. On occasion the class includes a Chief Security Officer from a banking institution or local government agency.

A prerequisite course, Principles of Information Technology Systems, provides leveling preparation for the concepts introduced in the class. However, 40% of the class has either not taken the leveling course or are completing it concurrently.

Recognizing that the essential body of knowledge for the domains of security and forensics are broadly distributed and include deep subdomains, the first challenge is to modify the course. A set of topics are defined using the IC CAE documents, the five Primary Critical Skill Sets [3], and the UTPA GSSL program goals and curriculum. An approach to the topics is developed that recognizes that security issues do not rest solely in the domains of Computer Science and Information Technology[14].

Competency in mathematics presents a second challenge. Given the nontechnical nature of most students' backgrounds, competency in mathematics clusters at the level of college algebra. This means that when using theoretical constructs to introduce security concepts such as confidentiality, integrity, and information theory, additional techniques must be implemented to facilitate the learning or building up of the formal concepts. Metaphors provide excellent support in understanding concept proofs. For example, a love triangle is useful in explaining a trusted relationship. A coin is used to demonstrate encoding. Translating the concepts into examples from everyday life allows students to transfer existing knowledge.

The diversity in students' program of study demands the establishment of a common vocabulary in security and forensics to support effective communication and to facilitate sharing of perspectives and knowledge across the disciplines. To address this third challenge, students use a forum to provide profiles, including their backgrounds and expertise. They create a wiki, submitting terms and definitions, to build a common lexicon. A second wiki serves as a repository for students contributed resource materials. These wikis create a framework for growing the Essential Body of Knowledge (EBT) [15] and support peer to peer learning where knowledge is transferred and created in a learning community. The diversity of academic training, perspectives and experience means that students are exposed to the breadth of knowledge that professionals should know to be conversant in the field. Students, at minimum, know the key concepts and terms to perform their work functions in security and they gain, at least, a basic familiarity with all of the key terms and concepts in the EBT [15].

Thought exercises are used throughout the lectures to provide an opportunity for students to think independently, discuss their thoughts in pairs, and share their ideas with the class. This think-pair-share approach also serves as the basis for work outside of class. Students reflect on concepts and present their thoughts on forums or in the form of short essays. These reflections serve as the basis for conversation and the opportunity to elaborate on ideas. This approach increases personal communication that is necessary to process, organize and retain ideas[16]. The approach takes advantage of the students' diverse knowledge base to expand individual perspectives on security and forensics topics.

There is also a great diversity among the students' skill levels in the use and the understanding of computing environments. Labs, originally designed to expose students to the concepts introduced in lecture and discussion are found to be too complex. The labs are modified so that students with minimal background in computing are able to complete the exercises and gain conceptual insight. In addition, early in the semester students are intentionally directed into interdisciplinary teams. Each team has at least one individual with a strong background in information technology or networking. The multi-disciplinary nature of the lab teams is leveraged to assure exposure to alternative viewpoints and process design. Due to the lack of programming skills among students in the course, two additional labs are available for deeper investigation by those individuals that are interested: (1) programming a covert channel and (2) programming a non-robust queue [9].

Among other challenges include faculty competency across the breadth of the course topics. Fortunately, there is strong interest and investment in information security at the institutional level. Taking advantage of the human capital resources in Privacy and Security and in the UTPA Division of Information Technology, subdomain experts in network security and forensic investigation provide lectures and lab instruction and guidance. The University's Chief Security Officer, along with recognized security experts from the health industry and intelligence community, discuss strategic planning for security.

C. Observations and Course Outcomes

As a collective, the mix of learning activities complements the course learning objectives. Aside from the lectures, classroom and lab based activities are modified to reinforce collaborative learning. The intent in building a common lexicon and resource base is to allow students to discover the breadth and depth of issues related to cyber security and forensics. They have the opportunity to both review and build on each other's work. It is evident in the questions and comments in the forums and the contributions to the wikis that students are expanding their knowledge base. Periodically in lecture, thought exercises are used to gain a feeling for student understanding. These typically involve a specific problem to solve that requires the application of a new concept. Using the think-pair-share approach allows the students in the different programs another opportunity to learn how individuals with different backgrounds might approach the same problem. Essays on readings often contain not only reflections on course content, but also reflections on classroom think-pair-share and lab discussions. In addition, student essays on content and its projection on their lives often include commentary on how their views or knowledge have changed.

Labs that proved too difficult to complete without a prerequisite computer science background are reworked such that they are too difficult for one person to complete working alone, but are easily completed when individuals work in teams. The casual lab environment and multidisciplinary teams expose students to different approaches to solve problems and they are encouraged to investigate, compare and evaluate multiple approaches. On many occasions student teams define competitions for themselves to develop the most efficient or effective solutions or processes. Students often stay well past the end of the lab to do self-initiated benchmarking or complete peer reviews.

There are a number of times throughout the semester that discussions lead to one or more members of the class taking responsibility for peer teaching. For example, a student who served as a data analyst in a combat zone shared his direct experiences with encryption and ciphers. On another occasion, one GSSL student who serves as the Chief Security Officer for a bank explained security policies and processes for internet transactions, a second student in the MSIT program explained a possible underlying implementation, and a third student from Computer Science provided an alternative approach. And on yet another occasion a GSSL and a MSIT student worked outside of class to implement and subsequently demonstrate to the class a virus that would bypass the firewalls set up during a lab exercise.

The students in the MAIS program tend to be very high verbal, while the students in the MSIT and MSCS programs tend to be computationally stronger. It is apparent from essays, presentations and final challenge submissions that the writing and course discussions throughout the semester help to improve students' verbal and written communication skills as well as their awareness. While this is evidenced as the course progresses, this improvement is most apparent in the choices made for the final learning challenge. Even though the class is fairly evenly split between GSSL and technology based graduate students and the MSIT and MSCS students are focused on the forensics toolkit project, in the end, the majority of the students choose to complete the challenge in which they read a book and respond to a prompt. In all of the responses, students thoroughly address the technological issues discussed in the book as well as provide critical analysis of the strengths and failings of the human systems.

Finally, based on the responses collected from the university's standard Student Evaluation of Teaching Form, students appreciate the opportunity not only to take on responsibility for their own learning, but are more fully engaged when presented with the challenge. The opportunity for collaborative learning empowers students to learn. The exposure to multiple perspectives on the same concepts through active and meaningful interaction is received well. They indicate an appreciation of the exposure to a wide range of experts from the field and the juxtaposition of policy and implementation in theory and practice. Students indicate that they feel the information learned in the class is important, the mix of activities are beneficial to learning and the overall quality of the course is very good to excellent.

V. Conclusion

This paper describes a Computer Science course in Cyber Security and Cyber Forensics offered at UTPA. The challenges of offering this course to a multidisciplinary audience lead to changes that leverage the diverse student knowledge base. During the course students learn, practice and gain understanding of concepts and develop the technical and leadership skills required of cyber security professionals. Hands-on lab exercises facilitate understanding of difficult concepts and procedures. Using both commercial and open source tools provides a rich environment. Using interdisciplinary teams facilitates the exchange of knowledge and understanding. Students see how complex the issues in cyber security and forensics are. Students gain an appreciation for true multidisciplinary nature of the field.

Acknowledgment

I would like to recognize Jennifer Garcia Avila for guiding us through EnCase, Ramon Herrera for providing expertise in network security Joe Voje for providing a strategic view for security, Dr. John Abraham for access to resource materials, Jeremy Miller in implementing many of the hands-on-labs and the UTPA IC CAE for coordinating the 2012 Cyber Security Symposium.
