EEG-based Comparisons of Performance on a Mental Rotation Task between Learning Styles and Gender

Elizabeth Hames and Mary Baker

Autumns Dawn NICE Lab
Lubbock, TX, U.S.A.

***Abstract*— Retention and diversity are central issues in engineering schools. Students' learning styles may hinder understanding of course material if presented in an incompatible way. While learning styles assessments are informative in determining the students' preferences in how they learn, there have been few studies that correlate student learning styles with cognitive and intellectual abilities. The goal of this study was to determine the relationship between students' learning styles, as determined by the Felder-Solomon Inventory of Learning Styles (ILS), and their cognitive abilities. This study uses functional electroencephalography (EEG) to evaluate the areas of neural activation in the brain while engineering students are performing a mental rotation task. Learning style preferences and mental rotation scores are correlated with the EEG activation. Learning styles differences were observed, primarily across gender. Most of these differences were in EEG patterns as opposed to actual task performance, indicating that individuals of different gender and learning style preference might be engaging different parts of the brain on a task while exhibiting similar performance on the task.**

Keywords—mental rotation; EEG; electroencephalography; learning styles

I. Introduction

A. Learning Styles Assessment

Learning styles assessments are often used in engineering education to determine the preferred learning styles of engineering students, and to provide insight into how students learn in different environments. The Felder Silverman Learning Styles Inventory (FSLSI) is a popular learning styles instrument designed specifically for assessing learning styles of engineering students. It consists of forty questions that measure learning style preferences across four scales: active-reflective; sensing-intuitive; sequential-global; and, visual verbal [1]. Active learners prefer to learn through hands-on activites, while reflective learners prefer to think things through first. Sensing learners are good with facts and methodologies, while intuitive learners are good at grasping new concepts and models. Sequential learners prefer to learn in logical steps, while global learners tend to learn in non-linear jumps. Finally, visual learners learn from what they see, compared to verbal learners who learn from "words" that they hear or read. According to the descriptions given in [1], no one is on one end of the scale all of the time – for example, even learners who are strong active learners will have some characteristics of reflective learners. The FSLSI has been shown to have consistence results across engineering groups as well as a test-retest capability up to eight months [2].

Learning styles inventories have been used in engineering education to aid in understanding issues such as recruitment and retention facing engineering schools, and to address ways to adjust educational environments and approaches to curriculum development to appeal to a wider, more diverse range of students. Attempts have been made to look at correlations of learning styles to performance on standard concept inventories in both Signals & Systems and Dynamics courses [3-4]. Similar attempts were made in [5] to correlate learning styles with longitudinal performance in Physics courses. Results have been inconsistent in these and other published studies looking at learning styles and performance assessments in subject specific areas. No studies have looked at the relationship between learning styles and EEG.

Understanding how to individualize learning is significant for engineering programs to expand student recruitment and retention. As new e-learning environments and technologies are coming on-line that can use adaptive technologies to vary the materials based on student responses, it becomes even more important to understand and quantify students' learning style preferences on a more fundamental level.

In this study, we looked at the relationships between student learning styles as measured by the FSLSI, and brain activity measured by electroencephalography (EEG) during a cognitive task (specifically, a mental rotation task) designed to engage different cognitive abilities. The goal was to determine whether students with different learning styles utilize different brain regions and networks when solving problems. In the course of evaluating the data, it became evident that gender was a significant contributing variable; hence, gender was added as a factor in the analysis of the relationships between brain activation as measured by EEG and learning styles. Ultimately, the results of studies such as this one can result in brain activation patterns being coupled with learning models and theories and with teaching practices to better engage students in the educational process.

B. Mental Rotation Overview

Three stimuli are commonly used in mental rotation: the 3D block stimulus, alphanumeric figures, and abstract objects [6]. There are various experimental designs for mental rotation. One such design is to compare rotated images to determine whether they are identical or mirror images [7-10]. Others use translation of objects (in [9-10]) or matching of rotated objects (in [11-12]). Presentation of mental rotation tasks can be either 2D or 3D, with many researchers describing significant gender differences in 3D rotation, but not in 2D [13]. Mental rotation involves visualizing the image, mentally rotating the image, making a comparison between the rotated image and the comparison image, making a "same or different" decision, and finally, sharing the decision [14]. The steps in mental rotation were also reported in [15], where the authors attempted to separate the processes involved in mental rotation (encoding, mental rotation proper and object matching) in a neuroimaging study. Reference [15] found that the right frontal lobe is responsible for encoding and comparison/decision making while the left parietal and left temporal regions are most involved in generation of images and their mental rotation. A number of cognitive domains are believed to be involved in the various stages of mental rotation, leading to many areas of brain activation [16]. Some cognitive domains, like visual processing and visual-spatial memory, are obvious. Others are not immediately obvious – motor and motor imagery processes are involved, as is executive planning. In some cases, verbal processing and verbal memory abilities are also related to performance on mental rotation tasks. The wide array of cognitive processes associated with mental rotation make it a good task to use for comparison across different learning styles.

From an educational standpoint, mental rotation is an interesting task for two key reasons: first, it has been shown that there are significant differences between male and female performance on mental rotation tasks in 3D [13]; and second, it is known that training programs can significantly improve mental rotation scores [13,17]. Mental rotation represents a common set of skills needed in engineering. As an example, in Electrical Engineering, students must perform mathematical operations such as cross products using the right hand rule. The right hand rule requires a visualization of a rotation vector in 3D space. Some students grasp this concept easily, while others struggle with the visualization aspects of it. Other fields of engineering also involve the use of 2D space to represent 3D objects. Even the basic sciences contain examples of the application of skills like those used in mental rotation tasks. Stoichiometry and the visualization of molecular bonds and structures; electromagnetic fields and antenna patterns; and many other examples from engineering, biology, chemistry, and physics require this skill to some degree. One can observe some students using their hands while others might talk or reason themselves through the problem. What is observed in the classroom is reflected in data obtained from neuroimaging studies: there are different cognitive approaches to the mental rotation problem that result in activation of different brain regions. These cognitive approaches might very well be related to learning preferences as well. For example, when considering learning styles, active learners might take a motor-oriented approach to the rotation task because they are more prone to want to work in a "hands on" manner, as opposed to reflective learners who might not engage the motor rotation processes in the brain. This would presumably result in different scores and reaction times between the two learning types as well as in the activation of different brain regions that are active during the task. Hence, the goal of this study was to understand the effect of learning styles on performance and brain function during a mental rotation task. The results of student performance and brain function as measured by EEG on Mental Rotation were compared with the FSILS to determine whether any relationships exist between learning style preferences and cognitive abilities, and whether these relationships are constant across gender.

II. Methods

A. Participant Selection and Setup

This study was approved by a Human Subjects Internal Review Board. Student participants were selected from within the Whitacre College of Engineering, primarily from the undergraduate population and distributed across departments, with Mechanical and Electrical Engineering majors having the greatest number of students in the study, combining to comprise almost 60% of the participants. Of the 51 participants, 19 were female and 33 were male. This reflected an over-representation of female students when compared to the College of Engineering demographics. As is standard in most neuroimaging studies, all particpants were given a handedness questionnaire: forty-four students were right handed, 1 was left handed, 3 were ambidextrous with a preference for right and 3 were ambidextrous with a preference for left.

Study participants were asked to complete the Felder Silverman Learning Styles Inventory (FSLSI) and their scores were recorded across all four scales. The mental rotation task was administered along with two other, unrelated tasks, using a computer based testing system, e-Prime, that presented the test questions and tracked scores and reaction times as participants responded using response pad buttons. Participants received an EEG while performing the task. The EEG was acquired using EGI 64-channel HydroCel Geodesic Sensor Nets at a sampling rate of 500 samples per second. The 64 channels on the net correspond to the standard EEG 10-20 electrode arrangement based on the diagram shown in Fig. 1.

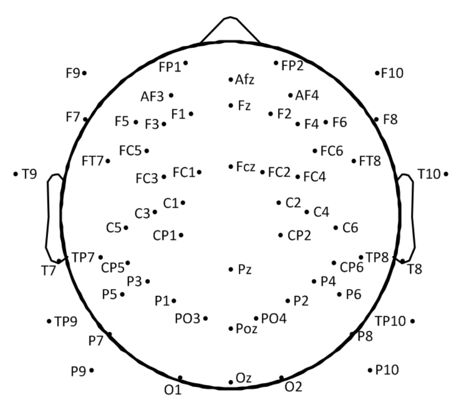

Fig. 1. EEG Channel Locations

The EEG was taken in a sound-proof, unlit room to eliminate artifactual signals. The task stimuli were presented on a 10.25" by 13.25" monitor. Participants were given a keypad with four buttons corresponding to four multiple choice answers for each question.

B. EEG

EEG measures scalp potentials using electrodes (or channels) placed on the head – in this case, using a "net" of electrodes. The scalp potentials represent the linear superposition of electric dipoles within the brain. It is important to be aware that when this paper refers to power in the left frontal region, this means power as measured by electrodes in the left frontal region – the actual signal sources can be distributed throughout other brain regions. EEG signals are commonly separated into five frequency bands for analysis: delta(1-5Hz), theta(5-8Hz), alpha(8-12Hz), beta(12-30Hz), and gamma(30-50Hz). Power levels in each frequency band are associated with different brain processes – conventional analysis focuses on alpha and beta bands for awake and alert adults; however, more recent research indicates that activity in other bands might be relevant to cognition as well.

The EEG data were pre-processed using EEGLAB [18]. The data were low pass and high pass filtered with cutoff frequencies of 50 and 0.5 Hz, respectively. Artifacts in the data due to eye blinks, muscle movement, and other spurious signals were removed using independent component analysis (ICA) as implemented in EEGLAB [19]. For each type of mental rotation question, the EEG was segmented in time to include 1-second segments (referred to as epochs) beginning with the time that the stimulus was presented, and ending after 6 1-second segments. Each epoch or segment was analyzed separately in order to capture the sub-processes of mental rotation described in [15]. To reduce the dataset sizes, the central channels (Afz, Fz, Fcz, Pz, Poz, and Oz) were removed and the remaining 54 channels were divided into 22 regions, 11 in each hemisphere, shown in Fig. 2.

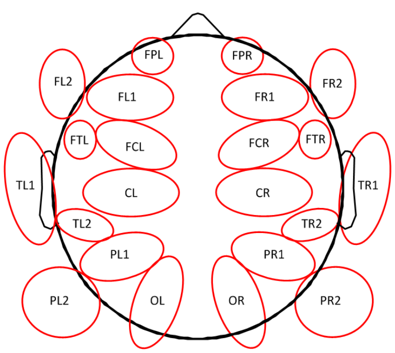

Fig. 2. EEG Regions; Notation: F – frontal, P – parietal, T – temporal, O – occipital, C – central, L – left, and R - right

After the data were epoched and sorted by task type, the frequency spectrum was determined in Matlab, and average power levels were determined for each of the aforementioned frequency bands. Note that the power levels used were for electrode locations, and while these are indicative of power in those immediate brain regions, it is possible that other sources from deep within the brain are contributing to the power at a given channel location.

C. Mental Rotation Task

The mental rotation task was designed similar to that used in [20], involving "3D" figures. The participant matches one of four figures with a top figure. The matching figure is either a rotated, mirrored, or identical version of the top figure. The baseline task (identical figure) was designed for an fMRI version of this test, not reported in this paper, and so were not considered. There are three kinds of rotations: rotation in the plane of the screen, depth of the screen, or a combination of both. There are a total of 48 stimuli for the task. The questions are arranged in a block format with alternating blocks of 3 depth, 3 plane, 3 combination, 3 mirror and 4 baseline tasks. In this paper, only the depth rotation, plane rotation, and mirror tasks will be analyzed. These three tasks, depth rotation, plane rotation, and mirror, will be referred to as D, P, and M, respectively. Fig. 3 shows examples of each of these three tasks.

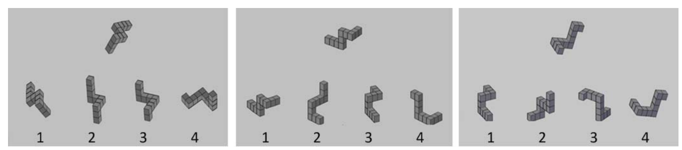

Fig. 3. Plane rotation(left), depth rotation(center), and mirror(right)

III. RESULTS

A. Learning Styles Results

The FSLSI assessment ranks participants in four cognitive domains using a scale from 11a to 11b, depicted in Fig. 4. For example, in the category of VIS/VRB, 9a-11a is strong preference towards visual, and 9b-11b is a strong preference towards verbal. Scores between 1a/b-3a/b indicate a fairly well balanced learning preference, and between 5a/b-7a/b indicate a moderate learning preference. Fig. 4 shows the distribution of FSLSI scores among the 51 participants for all 4 scales.

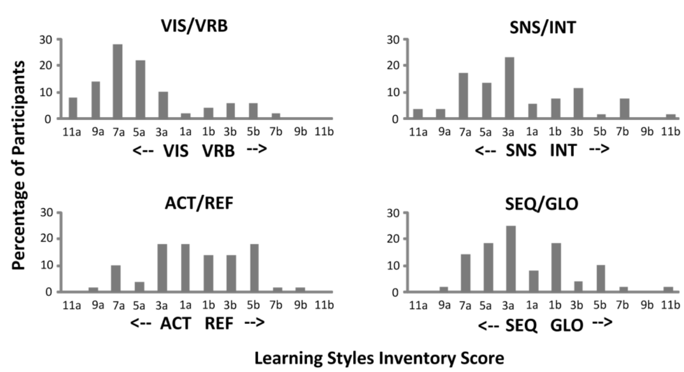

Fig. 4. Distribution of Learning Styles

The histograms presented in Fig. 4 do not indicate a smooth or even Gaussian distribution across the entire spectrum (ACT versus REF is closest to a normal distribution [2]), hence both correlations and t-test comparisons between groups with different learning styles are used in this study. The distributions look almost bimodal, with only the active-reflective scale appearing to peak near the center of the continuum.

Table I gives the distribution of learning styles broken down by gender, with the numbers shown as well as percentages given in parentheses. In general, the distributions between styles are similar across gender category with the exception of the sensing/intuitive scale, where the women participants show a much stronger skewing toward sensing as opposed to intuitive. The results are comparable to previous studies where engineering students are predominately active, sensing, sequential, and visual [2].

TABLE I.

Gender	ACT	SNS	SEQ	VIS
Male	18(55%)	20(61%)	21(63%)	28(84%)
Female	8(44%)	15(83%)	12(67%)	14(78%)
	REF	INT	GLO	VRB
Male	15(45%)	13(39%)	12(37%)	5(16%)
Female	10(56%)	3(17%)	6(33%)	4(22%)

In the following sections, participants' scores, response times, and EEG activation are correlated with their learning styles scores. Correlations were determined using both a continuous scale and a divided scale. For example, on the visual/verbal scale, the visual end of the scale (the "a" end) ranges from a weak score of 1 to a strong score of 11, as does the verbal end of the scale (the "b" end) For a divided scale, correlations were run for each end of the scale separately, with scores running from 1 to 11. For a continuous scale, correlations were run for both ends of the scale simultaneously, with scores running from -11 (visual end) to +11 (verbal end). This was done because, in some cases, the learning style distribution appears to be more continuous, while in other cases it appears to be more bimodal.

B. Mental Rotation Results

The average scores and response times for each of the three tasks, D, P, and M, are given in Table II, and are shown broken down into results for gender and learning styles groups. A statistical t-test was done to determine if scores or response times differed significantly across gender or group (M vs. F, ACT vs. REF, SEQ vs. GLO). Comparisons with statistically significant difference (as determined by the t-test with a p-value of .05) are indicated with asterisks in Table II.

TABLE II.

	Scores (% correct)									
Task	***M***	***F***	***ACT***	***REF***	***SNS***	***INT***	***SEQ***	***GLO***	***VIS***	***VRB***
D	79	70	74	78	74	80	73	80	75	80
P	64	56	63	60	60	65	61	62	62	58
M	63*	51*	63*	54*	57	63	55*	66*	60	51
	RT (seconds)									
Task	***M***	***F***	***ACT***	***REF***	***SNS***	***INT***	***SEQ***	***GLO***	***VIS***	***VRB***
D	6.0	6.4	5.9	6.4	6.3	5.8	6.2	6.0	6.1	6.2
P	7.7	7.8	7.5	8.0	7.9	7.4	7.9	7.3	7.6	8.2
M	7.3	7.9	7.6	7.4	7.8	7.0	7.7	7.1	7.7	6.8

Table II shows that female participants scored significantly lower on the mirror rotation task than males, while active and global learners scored significantly higher than referential and sequential learners, respectively. Across every group, scores decrease from depth rotation to plane rotation and mirror task, indicating these tasks are more difficult for all participants. Response times are also longer for plane rotation and mirror when compared to depth rotation.

Each learning styles group was further divided into male and female and a t-test was performed within a gender category for scores and response times. Plane rotation response times were significantly different ($p<.05$) between visual and verbal females with verbal females having a two second longer response time than visual females.

Scores and response times on the D, P, and M tasks were correlated with both divided and continuous LSI scales for males (M), females (F), and all male and female learning styles groups (i.e. ACT F, ACT M, REF F, REF M, etc.). The correlations that were statistically significant ($p<.05$) are shown in Table III. A positive or negative correlation is indicated by a plus or minus sign in parenthesis next to the passed correlation.

TABLE III.

Learning Styles Category	Correlation
SEQ M	M RT(-)
SNS/INT F	D RT(-)
REF F	D Score(+)
SEQ F	D Score(-)

There were very few correlations between learning styles and mental rotation scores or reaction times that were statistically significant. Sequential males have a negative correlation between mirror response time and their sequential score. This indicates that of the men studied, the more sequential they were, the faster they respond to the mirror task. Reflective and sequential females had opposite correlation results on the depth rotation task. Females with higher reflective LSI scores had higher depth rotation scores while females with higher sequential LSI scores had lower depth rotation scores. On a continuous SNS/INT LSI scale, females had a negative correlation with their response time on the depth rotation task. Females who were more intuitive as opposed to sensing had faster response times.

C. EEG Results

Comparisons between groups' EEG power were made using a t-test. The following groups were compared: males and females (M/F), ACT/REF learners, SEQ/GLO learners, SNS/INT learners, and VIS/VRB learners. Within the delta and theta bands, the only significant ($p<.01$) differences in EEG power were between males and females, occurring across every epoch and almost all channels. Due to the large number of differences observed in males and females for these two frequency bands, the data will not be presented in a table. The channels with statistical differences in EEG power between groups in the alpha, beta, and gamma bands are given in Table IV. If a channel passed as significant for more than one of the six epochs within a task, the percent difference between groups was averaged for every epoch it appeared.

TABLE IV.

Groups	Alpha			Beta			Gamma		
	Region	*Task*	*% Diff**	*Region*	*Task*	*% Diff**	*Region*	*Task*	*% Diff**
M/F	FL2	All	39	FPL	P, M	-20	FPL	All	-25
	PL2	M	32	FL2	All	24	FL2	D	27
				TL1	D	20	TR1	All	33
				PL2	D	29	PR2	All	24
				TR1	All	25	TL2	D	26
				PR2	All	22			
				PR2	D	19

SEQ/GLO				PL2	P	29	PR1	P	15
VIS/VRB							PL2	P, D	-45

*Percent difference is calculated by (Group1-Group2)/average(group1,group2)

Overall in this study, males and females had more statistical differences in EEG power on all tasks than all the learning styles groups. Electrode impedances were measured and reviewed to insure no differences among genders or outliers. There were no statistically significant differences in any impedances. Females had statistically higher power in the left pre-frontal channel on all tasks in the gamma and beta bands. Males had statistically higher power in the right temporal-parietal region on all tasks in the beta and gamma bands. Males also had higher power in the left frontal region on all tasks in the alpha, beta, and gamma band. Reflective learners had statistically higher power than active learners in the right temporal-parietal area on the M and P tasks for the gamma band. INT learners had statistically significantly higher power than sensing learners for the right frontal area on the P task. Sequential learners had statistically significant higher power than global learners on the P task for the left temporal region in the beta band and the right parietal region in the gamma band. Verbal learners had higher power than visual learners in the left temporal region on the P and D tasks in the gamma band.

D. Correlation with EEG Power

EEG average power in all five frequency bands across each task for males (M) and females (F) was correlated with two measurements: 1) LSI scores on the continuous and divided scales and 2) D, P, and M scores. Only the correlations that had statistical significance are reported (p<.01). A smaller p-value was used compared to the correlations between LSI scores and mental rotation scores because a very large number of correlations were significant. We will focus on the beta frequency band because it is commonly associated with an active cognitive state. The results for the beta frequency band are presented in Tables V(correlation with LSI scores) and VI (correlation with D, P, and M scores). A positive or negative correlation is indicated by a plus or minus sign in parenthesis next to the correlated LSI scale or correlated task (scores). The results from these correlations will be discussed in Section IV.

TABLE V.

IV. DISCUSSION

Differences between groups occur primarily across gender rather than across learning styles as indicated by both the correlations and t-tests. While observing differences across gender, it is important to remember that the prefrontal cortex develops slower in males that females, not maturing until the late 20's. This anatomical difference could influence results [21]. For this reason, the correlations between EEG power and LSI scores/mental rotation scores will be discussed separately for males and females.

A. Females

Correlations between EEG power in females and mental rotation scores occur predominantly in verbal and sensing learning styles. Female verbal learners exhibited a positive correlation for right frontal EEG power with mirror scores, but a negative correlation between right frontal power and the depth/plane rotation scores. Recall that in [15], right frontal power was associated with encoding on a rotation task. Verbal females who use encoding seem to benefit by it on the mirror task, but not the rotation tasks. Female verbal LSI scores were positively correlated with left frontal power across all tasks, but negatively correlated with left temporal power, indicating that female verbal learners are clearly engaging the verbal mediation process across all tasks. Their left frontal power correlated negatively with mirror scores. These correlations suggest that the verbal females in this study who attempt to verbally mitigate the mirror part of the task tend to have decreased mirror task scores.

Female active learners showed positive correlation with right frontal regions and depth rotation, opposite with what we discussed in verbal females. Active females also had a positive correlation with right temporal regions and plane rotation. They had no significant correlations with their active LSI scores and EEG power.

On the depth rotation task, sensing females had positive correlations between left parietal power and both their sensing LSI scores and depth rotation scores. The relationship between left parietal regions and depth rotation is expected, as the parietal region is associated with visual spatial processing tasks. Similar to active females, sensing females had a positive correlation with EEG power in right temporal regions and plane rotation. They also had a positive correlation with EEG power in right frontal regions and plane rotation, an opposite effect seen in verbal females.

Global females' plane rotation scores correlated positively with right frontal and temporal regions, similar to sensing and active females, but opposite to verbal females and global males. Across all tasks, global females had a positive correlation with left parietal power and their global LSI scores, indicating the global females were using visual spatial processes to perform the tasks. Only on the mirror task, global females had a positive correlation between their global LSI scores and left frontal power. This indicates that they may have switched strategy for this process to recruit verbal mediation processes.

B. Males

While females only had significant correlations between EEG power levels and their learning scales when the divided scale was used, males showed a different pattern, with EEG power correlating with scores on continuous sensing/intuitive and global/sequential scales. In both cases, EEG power in the right frontal regions was negatively correlated with LSI scale scores. In other words, the more intuitive and sequential the learning style in the studied males, the lower the EEG power in the right frontal lobe, used in the encoding stage of mental rotation.

In males, unlike females, correlations between EEG power and mental rotation scores occur predominantly in sequential and intuitive learning styles. Male sequential learners show positive correlations between plane rotation scores and EEG power in both left and right temporal, parietal, and occipital regions. This pattern of activity is consistent with the generation and rotating of images described in [15], with the exception that the activity is present on both sides of the brain, similar to the bilateral patterns of activation observed in [11] using fMRI studies of mental rotation tasks in math-gifted adolescent boys. Sequential male learners showed negative correlations between depth rotation and left frontal power, and between mirror rotation and right frontal and parietal powers, indicating that perhaps sequential male learners who score well in mirror and depth rotation do not utilize the frontal regions as strongly as do those with lower scores.

Intuitive males also had positive correlations between plane rotation and left and right frontal-central regions, showing once again the bilateral activity for plane rotation in those who score well in plane rotation tasks. Depth rotation was negatively correlated with the right parietal power, indicating that males who score lower on depth rotation do not use the right parietal regions as much as those who score higher.

Active, reflective, sequential, and verbal males all had negative correlations between their right frontal/right frontal temporal power and mirror scores. This means that males who used less right frontal power, associated with encoding, had lower scores on the mirror task than those who used more right frontal power.

V. CONCLUSIONS

When comparing EEG power between learning styles types and genders using the t-test, very few significant differences were observed. However, when comparing learning styles types using their significant correlations between EEG power and LSI scores/mental rotation scores, many differences were observed. There are two postulated reasons for the differences between the t-tests and correlations. First, the effect might be stronger on one end of the continuous LSI scale, hence passing correlations, but not t-tests. Second, LSI scales may not be truly independent. For example, verbal learners might be more skewed to also contain active qualities. Future work needs to include a study into the dependencies within learning styles.

As seen from the t-test results between groups on scores and response times, rotation scores and reaction times do not indicate a difference in performance, but t-tests for EEG power between groups indicate differences in brain activity. Correlations between EEG power and LSI scores/mental rotation scores also produced more significant correlations than the correlations between LSI scores and mental rotation scores. This indicates that even though performance may not correlate with learning styles, the students are using very different brain regions and cognitive strategies.

Plane, mirror, and depth rotation all result in very different correlations between EEG vs. LSI and between EEG vs. rotation scores, indicating that unique processes are going on for each type of rotation. Correlations between EEG vs. LSI and between EEG vs. rotation scores are also quite different across gender. This could translate into a couple of things: learning styles mean different things for different genders or mental rotation process is different across genders. Notice that within females, only one side of each learning scale showed significant correlations while the other exhibited no significant correlations. However, within males, both sides of each learning scale were present with significant correlations. Also, males had continuous scales show up as significant for correlations between LSI and power. The results of our study underscore that more is needed than just designing curriculum based on learning styles: gender is also significant in learning. When it comes to tasks that involve visual spatial processes, strategies that use verbal mediation and other skills may be significant, particularly in female students.

From a practical point of view, this study underscores the importance of engaging students in the engineering classroom through a variety of experiences. One example strategy would be to provide time for reflection after asking a question in class before soliciting student responses and to ask students to verbally describe how they reached an answer. Visual spatial processing might be enhanced through the use of actual or virtual 3D models – for example, bringing a bread-boarded circuit to class or showing a 3D computer aided design sketch rather than only sketching a circuit schematic on the board. It is important to consider using different means of delivering information in different ways in the classroom as well as to allow students to respond to that information in different ways (written answers, verbal answers, graphical illustrations).

This study is limited to engineering students. For this reason, the results should not be generalized to all male and female students, or even all STEM students. The study was intended to demonstrate that learning styles could be correlated with brain activation patterns and performance on cognitive tasks. Future studies involving a verbal task would provide additional information that might be of use in an educational setting.

Abstract— **This paper presents a research work on the detection of students who show signs of frustration in learning activities in the area of algorithms, to then assist them with proactive support actions. Our motivation for the development of this work comes from students' difficulty in learning the concepts and techniques for building algorithms, which constitutes one of the main factors for the high dropout rates of computing courses. With the intent of giving a contribution to the reduction of such evasion, this research highlights the importance of considering students' affective states, trying to motivate them to study and work out their difficulties, with the assistance of computer systems. For research validation purposes, a tool was built to: a) infer the student's affective state of frustration while solving exercises of algorithms; b) detect signs associated with frustration, to provide resources to support student learning. Case studies were conducted with students of algorithms at the Faculty of Technology Senac Pelotas, in 2011 and 2012. The rules generated by the data mining software used to identify students' affective state of frustration, as well as an analysis of students' performance are presented in this article.**

Keywords—Affective Computing; Teaching and Learning of Algorithms; Informatics Education.

I. INTRODUCTION

Algorithms is an essential subject for courses in the Computer Science field [1]. It is also known for the learning difficulties imposed upon the students, being considered by many authors as co-responsible for the high evasion rates in the courses within the field [2][3]. Among the activities conducted in algorithm classes we can highlight the preparation of exercises containing the required steps (statements) to solve a problem. These exercises can be implemented and tested within a programming environment, thereby creating a great number of interactions between the student and the computer.

It is possible to store the data from these interactions and provide the teacher with a set of indicators of the student's performance. On the basis of studies stressing the importance of considering affective aspects of the learning process [4][5], this research intends to investigate possible relationships between data from such interactions and a feeling of frustration that students may have when studying algorithms [6][7]. Since it is virtually impossible for a teacher to monitor the activities of everyone in classes with a large number of students, it is understood that providing a computer system with proactive actions supporting a learning process at the time when the student demonstrates frustration can be a major source of help for the student.

The field that focuses on the study of the detection and expression of affective states in computer systems is part of the area so-called Affective Computing. The expression was first used by Rosalind Picard in [8]. The author argues that a computer with emotional capabilities should be able to understand and express its own emotions, to recognize emotions in others, to control affection and use humor and emotions to encourage adaptation behaviors.

In order to implement Affective Computing techniques and methods in computer systems, one can try to associate a standard behavior to a certain affective state based on the detection of physiological or behavioral characteristics of the user [9][10]. The same holds true for the expression of emotions. It is possible to use affective agents to interact with the user by transmitting and inducing emotions based on facial expressions, gestures and looks. This is not a trivial process and different research is being developed in this field of study [11][12].

Within the context of Computer Science, courses of algorithms show a high fail and dropout rates [13]. This makes educational practices for the teaching of algorithms a target of countless studies seeking to minimize the difficulties of students [13][14]. Thus, this research seeks to contribute to the algorithm learning process, using Affective Computing methods to target specific support to students who feel frustrated when conducting their activities.

This document is organized as follows: sections 2 and 3 highlight aspects related to the teaching of algorithms and the Affective Computing field. Section 4 presents a tool built to validate this research, with emphasis on the resources to detect the affective state of frustration and help students who show this sign. Finally, some final considerations and and directions for future work are presented.

II. TEACHING ALGORITHMS

A. *Algorithms: Overview*

An algorithm is a path, a sequence of steps to be taken in order to reach the solution of a problem [15]. It should be noted that there are many ways that can lead to a satisfactory solution to a problem. Thus, a problem can be solved by different algorithms – all of them equally correct.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

The field of algorithms and its formalization in computer programs is an essential part in the field of computing. When implementing an algorithm, a student describes a set of statements following a specific syntax in order to solve a computer problem. Statement syntax means the set of rules regulating the usage of words and punctuation [16]. A text or graphic representation may be used in order to allow a student to organize and represent his or her strategy to solve the proposed problems.

The computation of the harmonic mean of a student's grade or the validation of a user's password are examples of exercises proposed in courses of algorithms. Thus, each exercise presents a new problem to the student and, along the semester, problems requiring the use of logical resources such as iteration, logical decisions, loops and data list handling (vectors) are proposed. It is often the case that, for each type of problem, the student is given a list of exercises for the understanding and practicing of algorithmic methods. However, one of the biggest problem for students is the difficulty to abstract and describe solutions to these problems using few and simple structures [17].

In short, solving problems by writing algorithms entails the need to understand the problem, to adopt a set of actions in a sequence of steps, to represent this set in a given language (or a flow chart) and then to convert it into a program, describing it according to a specific syntax. Since it is the student who runs and tests the program, he or she must check whether his or her algorithm has produced the expected and correct results. Recurrent errors identified in tests of programs written by the students may result in a feeling of frustration. This as well as other affective states, such as confusion, anger and anxiety may affect productivity, learning, social relations and the general well-being of the students [18]. In this context, it is important to detect this affective state in the student, so actions can be taken to help him or her tackle the subject [19].

Jenkins [20] notes that programming is a tough ability to master, being considered by most students as a "boring and difficult" task. The author stresses that some of the difficulties in learning algorithms are related to the nature of the required programming skills, while others concern the teaching and learning methods of some skills.

The relationship between the difficulties in learning algorithms and the feeling of frustration caused by these difficulties can be verified in several articles on the topic. Castro et al. [6] stress that students face a huge obstacle to apply their previous skills when they have their first contact with algorithms, which creates fear and frustration. The authors further point out that the consequences of this obstacle are constant fails, apathy, low self-esteem and dropouts, which ultimately encourages evasion. Sirotheau et al. [7] also claim that, for many computer science students, their first exposure to learning programming is usually frustrating. The reasons for the student's frustration are discussed in the authors' work, such as lack of a view of what is intended to be solved and need for abstraction of the operation of the chosen mechanisms. The authors add that the obstacles tend to lead to problematic situations such as high fail and evasion rates.

Helping students with learning difficulties is not an easy task, since matters connected to school failure are always complex and there is no ready recipe or miracle methods [21]. The supporting approach adopted by this research seeks to help students by combining methods focused on: i) using computer system for the purpose of supporting the student [22][14]; ii) considering the affective aspects of students in the process of teaching-learning algorithms [4][5]; and iii) adopting a special strategy for dealing with students displaying difficulties in learning the subject [21].

B. Related Works

Research related to teaching algorithms try to present alternatives in order to make programming a less arduous task for beginning students in Computer Science courses. Piteira and Costa [23] note that the works prepared to support the teaching and learning of computer programming are based on the development of tools and strategies intended to help with the major challenge of teaching algorithms.

Rodrigo and Baker [24] attempt to identify the student's frustration in the subject of algorithms by applying a mathematical formula drawn from the student's actions during the writing of programs using the BlueJ framework. The main difference between the authors' proposition and this research is that our work attempts to help the student at the time he or she begins to show signs of the affective state of frustration. Furthermore, it is believed that a tool using pseudocode may avoid a number of likely difficulties for a student beginning with the BlueJ framework which, for some authors, is better suited to teaching Object-Oriented Programming [25].

In another example investigates the factors leading to difficulties learning programming and discuss alternatives for teaching algorithms [14]. The authors conducted a study involving 182 students of the Multimedia University in Malaysia and proposed a solution based on learning games, which increased the students' interest in the Computer Programming I subject.

The game-based approach is usually interesting to motivate the students. However, it is understood that such method may at times deviate the student's view of the actual programming tasks. Our approach tries to ease the algorithm-building process by creating a tool that allows students to make the exercises by writing their programs in pseudocode. This tool includes features to capture the student's affective aspects in order to support learning when the student shows signs of frustration.

III. AFFECTIVE COMPUTING

Affective Computing, according to [8], is the field of Computer Science that investigates how to detect affective states of the user of a computer system, and how to express affective states accordingly. For Tao and Tan [26], Affective Computing tries to assign human abilities to computers, such as observation, interpretation and generation of affective behavior, thus improving the quality of human-computer communication.

Duo and Song [27] note that Affective Computing has attracted the attention of educators as it enables them to develop computer tools that are able to assess the affective states of students, thus allowing for the implementation of customizable educational strategies. Inferring the students' affective states may help to predict the evasion of certain individuals and the likelihood of poor school performance [28]. For the authors, Affective Computing may enable the assignment of human psychological features to a virtual learning environment, thus minimizing the possibility of leading the students to boredom and frustration.

According to Picard et al. [19], one of the relevant points of Affective Computing studies in the field of education is trying to correct an imbalance in the use of the computer as an educational tool that favors cognitive over affective aspects. Affection is interconnected with cognition and guides rational behavior, memory recovery and creativity, among other elements [4]. The term cognition refers to the set of mental processes that participate in the acquisition of knowledge, in the perception of the world (and ourselves) and how this world is represented [29].

Several discoveries have shown that affective states tend to affect various behaviors in subsequent tasks [30]. In education, identifying the affective states of students may enable actions to be taken in order to help them in their studies [8].

The work of neuroscientist Damasio [4] underscores the role of emotion and feeling for the individual. According to him: a) emotion exerts influence in mental processes; b) brain processes devoted to emotion are intrinsically connected to the processes devoted to reason; c) the mind cannot be separated from the body. The book is titled "Descartes' Error" because Descartes believed in the separation between body and mind – where the mind only needed the body to be able to operate, without any other connection between them. But Damasio believes exactly in the opposite, that body and mind are closely connected. The mind commands the entire body, but it is the sensations that the body sends to the mind, along with cognition, that induce it to operate that way.

A. Emotion Detection Methods

Pattern-recognition methods can be used to recognize emotions in a computer system. According to [30], users' data can be collected from physiological sources as well as from task performances, also named behavioral observations. The authors further state that there is plenty of room for the discovery of new methods and these are only a few of the possibilities.

Physiological methods use computers equipped with sensors capable of detecting physiological changes in users and then associate them to affective states. However, detecting changes and assigning them to the correct affective state are two different problems [31]. In this process, error interpretation may occur, both between people and between people and machines - as can be observed in [32]. The authors analyze aspects of a smile that may be related to a user's frustration or pleasure.

Another research example of the use of physiological methods for the detection of affective states employs four devices to collect data from users: a) facial expression detection systems on devices such as webcams; b) chair with posture analysis sensor; c) mouse pressure sensor; d) skin sensors.

A different approach to the detection of affective states is based on the observation of the user's behavior, by monitoring his/her actions when using a computer system. In education, the number of errors in questions about a topic, the time devoted to the solution of one exercise, the number of attempts to perform an activity correctly or the number of clicks on a help button can be used to infer information about a student. A computer model can then be used to find behavioral patterns and to relate each pattern to certain affective states. In other words, the events preceding the detected affective state are assessed.

Based on the understanding that a programming environment for learning algorithms can produce information that may be associated to the student's affective state of frustration, the detection based on the analysis of behavioral observation was the method chosen in this research. Furthermore, even though hardware sensors may be used in a laboratory environment, it is difficult to implement such strategy in a classroom or school laboratory when a large number of students is involved [34]. Other studies use sentiment analysis to extract subjective information from text material, such as users' opinion, judgment, or affective state [49][50]. This approach has not been considered here as our focus has been to support students in solving problems in algorithms, an activity that does not involve a lot of writing.

B. Frustration

Frustration is an emotional state resulting from the occurrence of an obstacle preventing the satisfaction of a need. Reynolds [36] searches for a definition of the term in Psychology, which regards frustration as a negative feeling that arises when an attempt to reach a goal is thwarted. On the other hand, Amsel [37] indicates that one of the main causes of frustration is associated to a delay in obtaining conditioned responses. There is also a number of writers on the topic that associate frustration with aggression [35].

Rosenzweig [38] states that frustration is a phenomenon originated by deprivation, dissatisfaction or conflict involving states preventing or creating obstacles to the consummation of an impulse or a need.

A research conducted by Moura [39] associates frustration with a feeling that arises in the individual when facing the demands required by the current globalized scenario. Such demands may be considered continuous sources of rebellion, hopelessness and depression in individuals. These feelings, which are considered universal or typical of human nature, may be associated with the concept of frustration.

Frustration is also traditionally understood from two standpoints: a) Firstly, frustration may be understood as the representation of an object preventing the fulfillment of a need, something outside the subject, i.e., an obstacle or an event; b) secondly, frustration is used as a term describing a negative feeling representing failure or sadness for not achieving something intended [39]. Thus, the phenomenon is understood under these two conceptual subdivisions: frustration as the object itself and frustration as a feeling.

In the field of education, Schank and Neaman [40] recognize that fear of failure is a significant barrier for learning. In this context, Kapoor et al. [9] believe that such failure may be treated in several ways: a) by minimizing the student's discouragement through the reduction of likely humiliations; b) by fostering the understanding that the consequences of failure will be minimal; and c) by providing motivation to overcome or divert the student's attention from failure's unpleasant aspects. The authors further stress that perseverance with failure may be turned into learning, but should not lead to intense frustration, which often results in the students' desire to quit their studies in order to avoid similar experiences.

As for computer systems dealing with the affective feeling of frustration, Hone [41] states that the purpose of creating systems responding to the user's frustration is to develop interventions to try to lessen it. Kappor et al. [9] follow the same line when they state that developing systems capable of detecting whether a student is frustrated may allow for positive intervention, with the purpose of helping students to use their frustration as a learning opportunity indicator.

C. Supporting Theories for the Proposed Model

The implementation of the proposed model for the detection of the student's frustration, as well as the use of behavioral variables, is supported by the following works:

a) Kapoor, Burleson and Picard [9]: in this research, while a student worked on a Tower of Hanoi exercise, his/her data was collected with the use of complex equipment. The purpose was to store a set of the user's affective expressions preceding the user's clicking on the "I'm Frustrated" button. Therefore, each new occurrence of this set of affective expressions was an indication that the user was frustrated;

b) Bercht [10] indicated that affective states could be detected by a computer system from several behavioral variables of the student..

Aligned with the ideas of Kapoor et al. [9], the research presented here seeks to record the students' actions while they perform certain activities, trying to associate the collected data with information about the students' affective states. However, our research employs data collected from the students' interaction in a programming environment as a way to identify situations that can lead them to the affective state of frustration. The advantages of this detection method are highlighted in section A of the next section.

IV. THE TOOL TO DETECT AFFECTIVE STATES

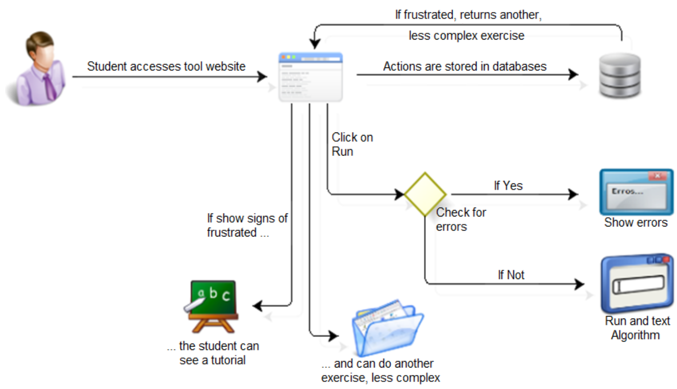
In order to validate this research, a tool has been developed for the purpose of capturing the student's behavioral variables while working on algorithm exercises. In the writing and testing of an algorithm, a student generates hundreds of even thousands of interactions with the computer. The system implemented stores these interactions, which may be later associated to the students' affective state of frustration.

Initially, apart from typical buttons of a programming environment, the tool also included the button "I'm Frustrated". The following actions have been captured by the tool: (a) the number of times the student compiled the program; (b) the total number of mistakes; (c) the amount of time between the beginning of the exercise and the last compilation of the program; (d) number of previous attempts without solving the problem; (e) number of compilations without syntax errors. When a student clicked on the "I'm Frustrated" button, the data collected is then associated to a situation that produced the student's affective state of frustration.

Systems of this nature, in which the user is required to inform his or her affective states, are used based on researches indicating that humans are more prone to inform negative feelings about themselves to computerized systems than to other humans [42] [43].

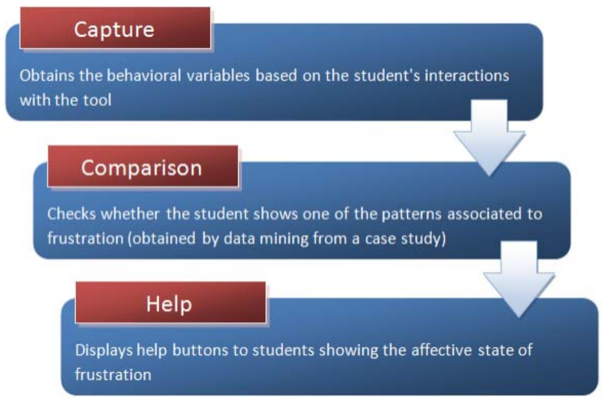
Later, once the variables associated to the student's affective state of frustration have been cataloged, the reference values are used to identify the students who presented signs of frustration and provide these students with educational supporting actions - as illustrated by figure 1.

Fig. 1: Tool operation



The importance of adding resources to respond to students in an affective manner is highlighted in [44][45]. Figure 2 presents the main actions performed by the tool.

Fig. 2: Actions performed by the tool



The assistance proposed by the system attempts to provide a different learning strategy to fill the cognitive gaps of a student who shows difficulties in solving the given problems, as proposed by [21].

As an analogy to the process developed in this work, one could relate it to a car's ability to detect the driver's fatigue. The system captures data assessing changes in the steering wheel and, on the basis of a behavioral pattern, it indicates possible fatigue of the driver. Sound and visual signs are displayed, suggesting the driver to stop.

A. Frustration Detection

In order to capture the behavioral variables associated to the student's affective state of frustration, three case studies were developed. The first one involved 58 students. The second had 14 students and the third one had 6 students, the latter a qualitative study used to assess the student's performance and participation. The number of records stored to keep track of students' interactions has been very high. In the first experiment, the button "Run" has been clicked 2197 times, generating a number even higher of records for the 58 participating students. These were the records used in this research.

The first study had the purpose of identifying patterns in the users' data relating their behavior when working with the system and their indicated state of frustration. The results obtained in this case study allowed the identification of:

a) The existence of situations showing the great difficulty of students when doing the exercises;

b) The fact that these extremely difficult situations can be captured by the tool;

c) Consistency between what the student revealed to the environment and the student's affective state of frustration, according to the difficulties found by the student when doing the exercises;

d) The possibility of associating the affective state of frustration to the student's behavioral variables while he or she used the programming environment.

The findings of the study led to the delineation of the next steps of the research.

The second step attempted to elicit from the collected data the rules that enabled the identification of the behavioral variables associated to the student's affective state of frustration. The WizRule Data Mining software has been used for this purpose, a software by WizSoft (www.wizsoft.com). Witten and Frank [46] state that, in the process of data mining, the patterns discovered must be meaningful so as to provide some advantage to the domain in which they are used. Fayyad [47] stresses this same idea by saying that data mining can potentially help users to identify useful and understandable patterns in large volumes of data.

The rules obtained from the second case study are shown in figure 3.

Fig. 3: Rules associated to the student's affective state of frustration

a) If **number_of_compilations_with_errors** *is* **High** *Then*
frustrated *is* **True**
Rule's probability: **0,800**

b) If **number_of_compilations_without_errors** *is* **High** *Then*
frustrated *is* **True**
Rule's probability: **1,000**

c) If **duration** *is* **High**
and **consecutive_programs_with_errors** *is* **High** *Then*
frustrated *is* **True**
Rule's probability: **1,000**

d) If **consecutive_programs_with_errors** *is* **High**
and **number_of_compilations_with_errors** *is* **High** *Then*
frustrated *is* **True**
Rule's probability: **1,000**

e) If **consecutive_programs_with_errors** *is* **High** *Then*
frustrated *is* **True**
Rule's probability: **0,750**

As it is possible to observe in the rules generated by the data mining process, the students indicated that they were frustrated in situations where: (a) they could not solve a problem due to syntax errors in their programs; (b) there were probable logical mistakes in the solution (occurence of several compilations without syntax errors); (c) the student spent a large amount trying to solve the exercise; (d) the students had difficulties in consecutive exercises.

The third case study attempted to check whether the generated rules were correct. In other words, if the tool was able to detect the times when the students were about to feel frustrated doing the exercises. Table I shows some of the students' comments obtained from questions included in the tool itself.

TABLE I. CONFIRMATION OF RULES ASSOCIATED TO FRUSTRATION

Yes / No	Comment
Yes	One error complicates the entire exercise
Yes	I can't understand the contents from the start
Yes	Compilation errors are time-consuming, making the search for the correct meaning tiring when writing the program
Yes	An algorithm is like mathematics, it has to be exercised. Of course some are easier than others, as the logic is clearer.

B. Learning Assistance

In order to support the learning process of students who showed signs of frustration when doing the algorithm exercises, the following features were added in the form of buttons displayed on the tool:

- The provision of a step-by-step tutorial with the solution of the exercise the student had difficulty doing.
- The recommendation of a new exercise previously added by the teacher, which was more linear in terms of the complexity level of the concepts exercised by that point of the subject.

Zabala [48] provides several examples that support the research methods employed in this research. He states that the different learning paces of students must be respected by providing different types and number of activities. In another moment the author states that it is appropriate "to use different strategies to represent the problems… among them the utilization of simpler problems, which encourages and strengthens the mastering of heuristic strategies".

Figure 4 shows the tool screen featuring the buttons "Tutorial with the Solution to This Exercise" and "Get Another, Less Complex Exercise". They are displayed at the time of the occurrence of one of the rules displayed in figure 3. They try to provide special treatment to a student experiencing difficulties doing an exercise. Thus, the idea is to turn the student's frustration into a learning opportunity, as proposed by [9].

Figure 5 shows the aid given to the student. He can see the development of the exercise in a step by step fashion, and he can then go back or forward depending on his pace of learning.

Fig. 4: Tool screen featuring buttons to help the student

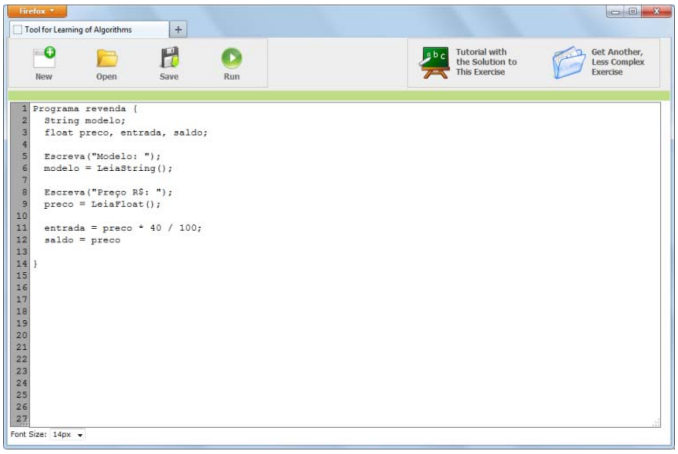


Fig. 5: Tutorial with the solution to exercise

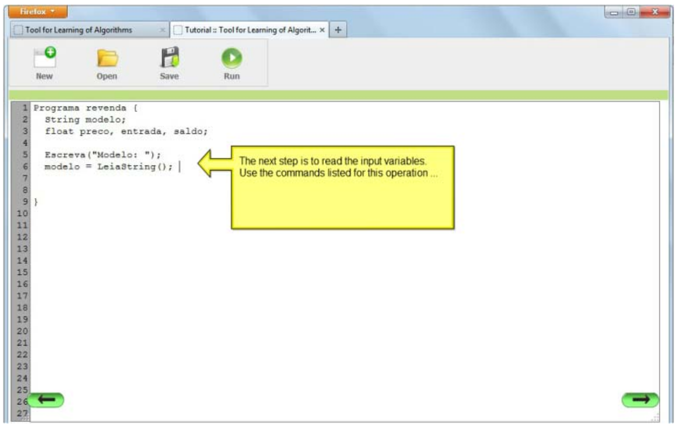
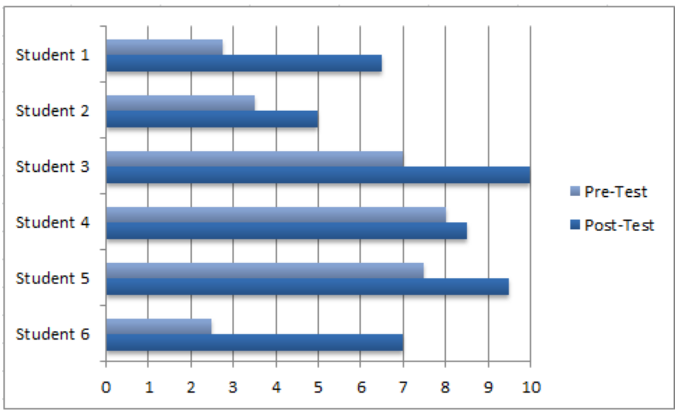


In order to assess the possible benefits of helping the students when they begin to show one of the behaviors associated to the affective state of frustration, a supplementary course on algorithms was offered to those who had difficulties in learning. The analysis was based on two evaluations conducted before and after the course. Each evaluation had 4 exercises. Figure 6 presents a chart with a comparison between the students' performance in pre and post-test.

Fig. 6: Chart depicting students' performance in pre and post-testing



It has been possible to observe during the workshop carried out with the students that they often used the resources that were made available to them, such as the tutorials and the offer of less complex exercises. Such tools have contributed with the good results the students obtained in the post-tests.

V. FINAL CONSIDERATIONS

The work developed in this study had the purpose of investigating how to detect and help students showing signs of frustration in their learning process of algorithms, from the discovery of behavioral patterns in the student's actions in a programming environment. The employment of Affective Computing methods attempted to help the teachers of the subject to focus their attention to students who may be displaying affective states which can negatively affect their learning process, as suggested by [19].

The purpose of this work has been to associate the behavioral variables produced by the students in a programming environment to the students' affective state of frustration. In order to validate the study, a tool converting pseudocode into computer programs was created in order to capture the student's actions. The development of case studies enabled the detection of a pattern to identify students who were likely to be feeling frustrated in the subject.

Another step tried to help these students by offering them a step-by-step tutorial with the resolution of the exercise in which they were showing some difficulty. A new and less complex exercise was also presented to the student. From the case studies conducted, the following conclusions were drawn:

- There is evidence that the behavioral variables produced by the students' interactions with the programming tool were associated with repeated coding errors and delays in completing the exercise. These actions were associated to the student's affective state of frustration.

- It was possible to help the students in their learning processes at the time when they showed one of these behaviors associated to frustration, by using a teaching method focused on their difficulties.

It should be further noted that this approach can be used both for in-class and distance-learning courses, especially in the first classes, where a larger number of dropouts is observed. For in-class courses, it especially contemplates shy students who may ultimately give up on the course without the teacher's perception, as they do not ask for help or demonstrate their difficulties. For distance-learning courses, the use of a tool to detect and help students showing signs of frustration may be important for teachers/tutors to perceive the students' actual difficulties. The recommendation of simpler exercises which are more appropriate to the student's level may be a good strategy to tackle such problem.

For future works, we are starting to investigate the integration of this approach with other research focused on addressing the students' motivational aspects. The development of a portal for learning algorithms is also planned, in order to make the tool built here available to algorithm teachers, including a set of exercises and tutorials.

Finally, another contribution of this research has been to show that it is possible to develop educational applications that make use Affective Computing methods to infer students affective states, without necessarily using complex equipment to capture physiological data.

***Abstract*—Previous studies suggested that the implementation of note-taking strategies impacted students' learning process and performance. Research also suggested that collaborative learning facilitates students to learn from different views of interpreting information. The objective of this study was to investigate students' metacognitive skills and social networks while using electronic and paper-based enhanced guided notes. Students' worked in groups of three or four to complete the EGN. The impact of the collaborative note-taking activities on the students' collaboration processes was examined using social network analysis. Our findings revealed that students' cognitive and metacognitive strategies between electronic and paper-based EGN groups were relatively similar. Our data analysis of students' social networks revealed two clusters of students, high and low groups that represented the level of students' connectivity in a collaborations network. The findings suggested that the high group outperformed students in the low group in the use of cognitive, monitoring, and regulating strategies. Implications of the use of collaborative note-taking in engineering classroom will be discussed.**

Keywords— collaborative note-taking; engineering college; enhanced guided notes

I. INTRODUCTION

A wide body of literature suggests that students learn best when they take an active role in learning through discussion, practicing, and applying concepts and ideas [1]; however, these activities are often impractical to conduct, particularly in large classes. In engineering education, most instructors present engineering concepts and teach engineering problem-solving skills by lecturing. Many of those lectures, especially in the general engineering courses, are delivered to large numbers of students in lecture halls. The major concern that most instructors have is about the effectiveness of the lectures in facilitating students' learning. According to some studies [2-4], students' attention during lectures declines after 10-15 minutes. Hartley and Davis [3] also found that the amount of notes written declined over the course of a lecture. Unless the students' attention is focused on what the instructor is saying, there is little chance that meaningful processing and note-taking will follow. As a result, some students fail to record the primary ideas; instead, they try to record all the information that they hear without critically judging the importance of the lecture content. In practice, maintaining attention and focus presents a considerable challenge for both instructor and students.

Compared to the traditional lecturing method practiced in most colleges, these new learning materials and strategies may offer students an enhanced learning experience that more effectively utilizes the lecture time. By combining the guided notes together with a collaborative note-taking process, students are encouraged to exercise metacognitive skills and participate in team activities. Metacognitive skills play a significant role in students' control of their cognition such as planning, monitoring, and regulating their own cognitive strategies. These activities help students to learn how to encode information received from the lecture and ultimately improve note-taking skills. It is the intent of this study to implement a new type of note-taking activity that not only helps engineering students to actively engage in learning during lectures but also helps them become better at note-taking. Although many studies have revealed a positive correlation between collaborative learning and student performance, few studies have investigated students' profiles on the collaborative note-taking activity and its relationship with metacognitive strategies and social networks. The main objective of this study was to investigate students' metacognitive skills and social networks while learning using electronic and paper-based EGN.

II. RELEVANT LITERATURE REVIEW

A. Standard versus Enhanced Guided Notes

Standard guided notes have been used in classrooms for quite some time, and multiple studies have been conducted to evaluate their effectiveness. The guided notes consist of incomplete information with blank spaces available for student notes. They may consist of concepts, diagrams, problems, and conclusions. Previous studies revealed that students who used a guided note-taking method performed better on conceptual tests and increased their attention level during lectures [5-7]. Kiewra argued that this effectiveness is associated with the increased encoding required by the students as they strive to complete the missing details [8].

Compared to standard guided notes, enhanced guided notes (EGN) contain more than blank spaces in which students need to provide detail information. An example of part of the EGN is provided at the Appendix. The EGN of the current study, based upon lessons learned from previous research [5], included two new components that are not present in standard guided notes: (1) questions that prompt students to assess their metacognitive knowledge throughout the guided notes [9], and (2) the notes will be further enhanced through the inclusion of outside class activities. This study added additional note-taking activities with a metacognitive knowledge component to the standard guided notes. Metacognition is a fundamental tool that enables learners to control their own cognition [10]. This leads learners to learn better [11]. By imposing note-sharing with others in the class and prompting metacognition of this collaborative process, we will further enhance the students' metacognition. Lehrl and Fischer connected the information processing theory to the social constructivist theory introduced by Vygotsky, which suggested that learning occurs when students actively construct their knowledge based upon social interaction [12]. In educational practice, these interactions should assist students to become actively aware of their knowledge.

B. Collaborative Note-Taking and Social Network Analysis

The collaborative note-taking was added to our EGN for three reasons: (1) to help students explore other essential information that may not be included in the guided notes; (2) to become familiar with different views of interpreting information from other students; and (3) to expose students to alternative note-taking strategies. The first reason for including collaborative note-taking is that for each topic, there are aspects of the course materials that are not covered during the lecture. The materials may be part of the course materials, but insufficient time is available for detailed coverage during lectures. The second reason is to help students to become familiar with different views and clarify information with their classmates. When the faculty is unavailable, access to information occurs through the social networks. Moreover, the collaborative note-taking implemented electronically will give new learning experiences to students.

The impacts of the collaborative online note-taking activities on the students' collaboration processes can be examined using social network analysis techniques. Marin and Wellman [13] described social network as "a set of socially relevant nodes connected by one or more relations" (p. 11). In this study, nodes refer to students who work together with their peers. In addition to mapping the networks, centrality metrics will be used to capture positional information for each individual in a collaborations network. We will examine individual student position within the classroom using In-degree Centrality to examine the students' direct connectivity to other players (a measurement of a group leadership role) [14-16].

C. Metacognition in a Self-Regulated Learning Framework

Extensive research has been conducted to evaluate the importance of metacognition in learning, especially in problem-solving ability [17-19]. Flavell [21], who coined the term *metacognition* categorized it as metacognitive knowledge and metacognitive experience. He described metacognitive knowledge as "one's knowledge concerning one's own cognitive processes and products or anything related to them" (p. 232). He also identifies three different types of metacognitive knowledge: person (the knowledge a person has about him or herself and others as cognitive processors); task (the knowledge a person has about the information and resources they need to undertake a task); and strategy (knowledge regarding the strategies which are likely to be effective in achieving goals and undertaking tasks) [22]. In another research, Paris and Winograd [23] offered a more comprehensive view in which metacognition can be observed through two essential features: cognitive self-appraisal (CSA) and cognitive self-management (CSM). Lawanto & Johnson [24] noted that CSA and CSM are distinct, easy to identify, and position the learner as the central part of the metacognition issue. CSA refers to learners' personal judgments about their ability to meet a cognitive goal; CSM refers to learners' abilities to make necessary adjustments and revisions during their work.

The association between cognitive and metacognitive strategies can be captured by a self-regulated learning framework. According to Pintrich [25], self-regulated learning is ''an active, constructive process whereby learners set goals for learning and then attempt to monitor, regulate, and control their cognition, motivation, and behavior, guided and constrained by their goals and the contextual features in the environment'' (p. 453). In addition, Zimmerman [26] stated that self-regulated learners are "metacognitively, motivationally, and behaviorally active participants in their own learning process" (p. 329). While many theoretical perspectives of metacognition and self-regulated learning have been proposed, we chose Butler and Cartier's model of self-regulation [27-30] because it defines the interplay between metacognitive knowledge and metacognitive control, conceptualized as cycles of "self-regulation in action," within a particular learning activity.

Butler and Cartier's SRL model consists of eight major features (i.e., SRL features) that interact with each other: layers of context, what individuals bring, mediating variables, task interpretation, personal objectives, SRL processes, cognitive strategies, and performance criteria. The current study focused on two major features of the SRL model: SRL processes and cognitive strategies; SRL processes represent students' metacognitive strategies. Students manage their engagement in academic work by using the sixth feature in the Butler and Cartier model: planning, monitoring, evaluating, adjusting approaches to learning. Students prepare their learning activity, select strategies for task completion, self-monitor progress, and adjust goals, plans, or strategies based upon self-perceptions of progress or feedback and performance. These strategies are iterative and dynamic endeavors. The seventh feature, cognitive strategies, refers to students' cognitive activities as they engage in learning, as planned, monitored, and adjusted through self-regulating strategies.

III. THE STUDY

A. The Participants and Context of the Course

Sixty-six engineering students enrolled in the Fundamental Electronics for Engineers course participated in this study. The electronic group was given an iPad 2™ tablet for shared note-taking. The selected students were given an opportunity to accept or reject the offer. This process took several iterations until all available iPads were distributed. Some additional students who had their own electronic devices also chose to participate. While 32 students used electronic devices, 34 students used paper-based EGN to take notes. Two formats of EGN were provided: electronic (iPad) and paper-based EGN. Students' worked in groups of three or four to complete the EGN. Electronic group students were required to download blank EGN through a repository server. After taking and reviewing notes in classroom, the students were asked to submit their EGN into the repository server. They were also suggested to review both their own and peers' EGN. On the other hand, the paper-based group students were asked to complete their EGN by discussing it with their group. After completing the EGN, they submitted one set of EGN that represented their group for each topic.

The course covered the study and application of direct DC/AC and digital concepts including circuit fundamentals, theorems, laws, analysis, components, digital design fundamentals, and combinational circuits design, equipment, and measuring devices. The use of these guided notes was intended to replace the one-way communication that was typical of class meetings.

B. Instrumentation

A self-regulated learning survey instrument developed using Butler and Cartier's SRL model was used to capture students' cognitive and metacognitive strategies. The SRL survey was adapted from the Inquiry Learning Questionnaire (ILQ) by Butler and Cartier based on their theoretical model [27-30]. Students were asked to rate themselves on a 4-point Likert scale (1 = *almost never*, 2 = *sometimes*, 3 = *often*, 4 = *almost always*). Four subscales were developed to capture students' cognitive and metacognitive skills at the beginning and end of the semester. The subscales were planning, monitoring, regulating, and cognitive strategies. Subscales of the questionnaire had Cronbach's Alpha scores ranging from .637 to .870 (see Table I for samples of the SRL questionnaire items). Furthermore, online social networking surveys were conducted twice, at the beginning and end of the semester. To map the networks, in-degree centrality metrics were used to capture positional information for each individual in a collaborations network.

TABLE IA: PLANNING STRATEGIES

No	**Before I begin the activity of learning and solving math, science, or engineering problems involving new concepts, I start by…**
1	planning my time
2	choosing a method for completing the problems
3	creating a strategy
4	checking the scope of the activity

TABLE IB: MONITORING STRATEGIES

No	**When learning and solving math, science, or engineering problems involving new concepts, I…**
1	judge the quality of my work
2	check now and then to see of my work is going well
3	check to make sure I have completed everything required for the activity
4	identify what I do and don't understand
5	check whether I can describe the main topic of the subject
6	check that I have found all the important concept
7	check what I can remember from what I learned
8	keep track how much time I have to finish my work
9	ask myself whether my methods for solving problems are good
10	ask myself whether I will get a good grade
11	check to make sure I come up with a n answer that makes sense to me

TABLE IC: REGULATING STRATEGIES

No	**When I have difficulties learning and solving math, science, or engineering problems involving new concepts, I…**
1	check to make sure I have completed everything required for the activity
2	review the difficult concepts again
3	try to make links between concepts
4	make links between concepts I am learning and problem I solved
5	try to memorize concepts
6	try to use better methods for working

TABLE ID: COGNITIVE STRATEGIES

No	**While I am learning and solving math, science, or engineering problems involving new concepts, I…**
1	pay attention to underlined or bolded words in learning resources, if there are any
2	pay attention to important concepts
3	take notes on the important concepts
4	think about what I already know about the subject
5	draw conclusions from what I have learned
6	think of related examples
7	think of how I can apply the new learned concepts to solve a problem or respond to questions
8	find links between concepts

C. Data Collection and Analysis

Students were asked to complete a self-regulated learning questionnaire at the end of the semester. Data from the questionnaire were analyzed using descriptive statistics to investigate students' cognitive and metacognitive skill profiles. We also conducted a non-parametric statistical test (i.e., Mann-Whitney) to investigate whether the groups had different levels of cognitive and metacognitive skills at the end of the semester.

Furthermore, the impact of the collaborative note-taking activities on the students' collaboration processes was examined using social network analysis. Online social networking surveys were conducted at the end of the semester. The data were gathered using a social-networking survey based on those described by Schreuders and Mannon [31] and Cross and Parkers [32]. To map the networks, in-degree centrality metrics were used to capture positional information for each individual in a collaborations network. Node-XL application was used to visualize the networks. A cluster analysis was conducted to investigate whether there was a variation on level of students' direct connectivity to other students in the network.

IV. Findings

The objective of this study was to investigate the impact of the collaborative note-taking on students' cognitive-metacognitive skills and social networks while using electronic and paper-based enhanced guided notes. According to the study objective, the research questions guiding the current study included: (1) Was there any difference between electronic and paper-based EGN groups regarding their cognitive and metacognitive strategies and social networks?; and (2) How did students' social networks relate to their cognitive and metacognitive strategies?

A. Was There Any Difference Between Electronic and Paper-Based EGN Groups Regarding Their Cognitive and Metacognitive Strategies and Social Networks?

1) Cognitive and Metacognitive Strategies in Electronic and Paper-Based EGN Groups

The mean value of each SRL feature was used to describe students' SRL profiles that belonged to the groups of students. Descriptive statistics of groups' cognitive and metacognitive strategies while learning electric circuit concepts using electronic and paper-based EGN are shown in Table II below.

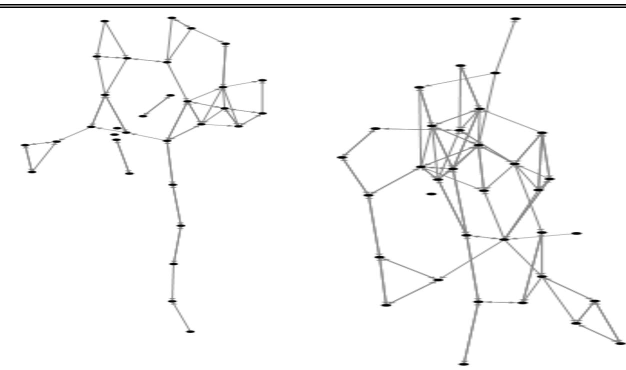
TABLE II: Mean Scores and Standard Deviations of Cognitive and Metacognitive Strategies between Electronic and Paper-based Groups

Feature	Electronic EGN Group (n = 32)	Paper-based EGN Group (n = 34)
	***M* (*SD*)**	***M* (*SD*)**
Planning Strategies	2.52 (.50)	2.61 (.51)
Monitoring Strategies	3.08 (.38)	3.06 (.50)
Regulating Strategies	2.92 (.41)	3.06 (.49)
Cognitive Strategies	3.14 (.35)	3.21 (.48)

From the descriptive statistics, we found students' cognitive and metacognitive strategies between electronic and paper-based EGN groups were relatively similar. Although overall there was no significant difference found between both groups, our findings suggested differences in the questionnaire-item level specifically on planning, monitoring, and regulating strategies. We found that the paper-based EGN group outperformed the electronic group on items such as "creating a strategy" (PS: Z = -1.865, p =.031), "review the difficult concepts again" (REG: Z = -1.814; p = .035) and "try to use better methods for working" (REG: Z = 2.156; p = .015). On the other hand, the electronic group outperformed the paper-based EGN group on "ask myself whether I will get a good grade" (MON: Z = -2.080, p = .019). These findings suggested that overall both groups had a similar level of SRL skills after using enhanced guided notes, either electronic or paper-based EGN.

2) Students' Social Networks Between Electronic and Paper-Based EGN Groups

An analysis of in-degree centrality showed that the paper-based group had more connections among the students than did the electronic group (see Figure 1). We found from Chi-square tests conducted that the difference in the total number of connections between both groups was significant ($\chi 2$ = 8.100, df = 1, p = .004).

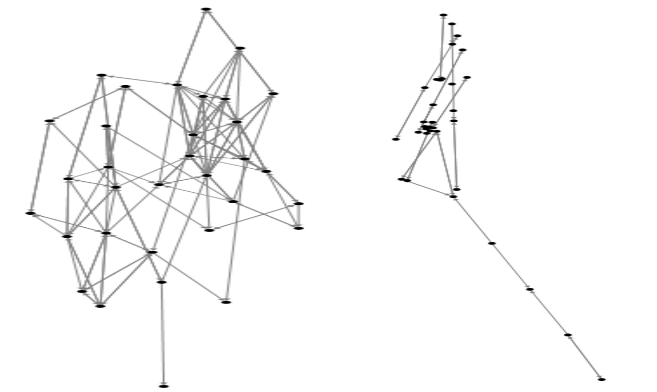


Electronic group (Total connections: 62)	Paper-based group (Total connections: 98)

Fig. 1. In-degree centrality graphs between both groups at the end of the semester

B. How Did Students' Networks Relate to Their Cognitive and Metacognitive Strategies?

We further examined students' social networks to evaluate whether the level of social networking reflected students' competence. A cluster analysis was conducted to examine the different social networking levels among the students. In-degree centrality, which examines the students' direct connectivity to other class members (a measurement of a student leadership role) [14-15], was used as a parameter to conduct the cluster analysis. Our analysis found two clusters: high and low levels of social networking. An analysis of in-degree centrality found that the high level of direct connectivity group had more connections among the students than did the low level of direct connectivity group (see Figure 2). We found from Chi-square tests conducted that the difference in the total number of segments per student between both groups was significant ($\chi 2 = 71.122$, $df = 1$, $p = .000$).



High level of direct connectivity (Total connections: 136)	Low level of direct connectivity (Total connections: 28)

Fig. 2. In-degree centrality between high and low levels of direct connectivity

Descriptive statistics of the groups' cognitive and metacognitive strategies between high and low levels of direct connectivity are shown in Table III below. Significant differences were found between both groups on cognitive (Z = -1.967, p = .024), monitoring (Z = -1.861, p = .031), and regulating strategies (Z = -2.160, p = .015).

TABLE III: MEAN SCORES AND STANDARD DEVIATIONS OF COGNITIVE AND METACOGNITIVE STRATEGIES BETWEEN HIGH AND LOW LEVELS OF DIRECT CONNECTIVITY

Feature	High Level of Connectivity (n = 33)	Low Level of Connectivity (n = 33)
	***M* (*SD*)**	***M* (*SD*)**
Planning Strategies	2.73 (.55)	2.57 (.48)
Monitoring Strategies*	3.18 (.42)	2.96 (.44)
Regulating Strategies*	3.11 (.44)	2.80 (.43)
Cognitive Strategies*	3.30 (.44)	3.05 (.36)

Our findings also suggested differences in the questionnaire item level on monitoring, regulating, and cognitive strategies. We found that the high level of direct connectivity group outperformed the low level of direct connectivity group on cognitive strategy items including "pay attention to important concepts" (CS: Z = -1.865, p < .05), "think of how I can apply the new learned concepts to solve a problem or respond to questions" (CS: Z = -1.814; p < .05) and "find links between concepts" (CS: Z = -2.156; p < .05). The high level group also outperformed the low level group on monitoring strategies: "check now and then to see if my work is going well" (MON: Z = -1.890, p < .05), "check whether I can describe the main topic of the subject" (MON: Z = -2.463, p < .01), "check what I can remember from what I learned" (MON: Z = -1.982, p < .05), "check to make sure I come up with an answer that makes sense to me" (MON: Z = -1.856, p < .05), and regulating strategies: "review the difficult concepts again" (REG: Z = -2.013, p < .05), "try to make links between concepts" (REG: Z = -2.352, p < .05), "try to memorize concepts" (REG: Z = -2.478, p < .05), and "try to use better methods for working" (REG: Z = -1.890, p < .01).

V. CONCLUSIONS

This paper provides insights into shared note-taking activity using metacognitive and social network perspectives. In the current study, electronic and paper-based enhanced guided notes were used to implement collaborative note-taking activity in the Fundamental Electronics for Engineers course. Our evaluation of students' metacognitive skills between electronic and paper-based EGN groups showed that their skills were relatively similar. Although overall there was no significant SRL difference between both groups, our findings suggested differences in the questionnaire-item levels on planning, monitoring, and regulating strategies.

An evaluation of students' social networks revealed that the paper-based group had more connections among the students than did the electronic group. Furthermore, social network analysis was also conducted to investigate whether the level of social networking reflected students' competence. A cluster analysis revealed two clusters: a high and low level of social networking. Our findings showed that the high level of direct connectivity group outperformed the low level group on cognitive, monitoring, and regulating strategies.

VI. IMPLICATIONS

Several implications resulted from the current study: *First*, educators may offer the use of electronic and paper-based EGN based on students' preference for a collaborative note-taking activity. Our evaluation found that groups who were willing to utilize both electronic and paper-based media had similar self-regulated learning skills. Data analysis revealed significant differences only on a few items. Specific improvements on the electronic EGN need to be conducted to improve the use of the guided notes. *Second*, the nature of collaboration between electronic and paper-based EGN groups may explain why students in paper group had more connections on their social networks. Electronic group students had direct access to their peers' EGN through a repository server. They were asked to review their peers' EGN to complete their own notes. Electronic students could complete the task required by their teacher although they did not meet face-to-face during the semester. It might limit these students' collaborative activities with other students in the class. On the other hand, paper-based group were asked to have a face-to-face collaboration with their peers to complete their EGN. This activity might provide paper-based students more chances to collaborate with their classmates than electronic group. It may be helpful to obtain more detailed information about the way both groups communicate and learn with their team members. The teacher may encourage both groups to set up regular communication with their peers either using recorded asynchronous online discussion or face to face meetings.

As suggested by the findings, students who have more direct connectivity on their social networks showed a higher level of metacognitive skills compare to their peers who had less direct connectivity. Also, according to the findings, teachers may collect students' social networks information at the middle of semester to rearrange team membership or suggest different collaborative activities based on social network analysis.

Two directions are proposed for the improvement of future work. *First*, because some of our findings were suggestive and this study included a limited number of participants, any interpretation should be done with caution, and future work in this area is highly recommended. Studies should be conducted with a larger sample size to determine generalizability of the findings. *Second*, future research should compare collaborative and non-collaborative note-taking activities using an experimental research design to better understand students' metacognitive skills in a collaborative setting while using enhanced guided notes. A longitudinal study may be useful to see how the intervention of a collaborative note-taking activity using enhanced guided notes impacts the next level of classes.

***Abstract*—We collected qualitative data to examine how engineering students' previous experiences, present academic course work, and future goals create cognitive pathways to a career in engineering. Using future time perspective theory as our literature base, we conceptualize cognitive pathways as relationships or links between reconstructed-past, present-active, and imagined-future events that lead to a career in engineering. Our goal is to begin to develop evidence for cognitive linkages between past, present, and future that motivate students to pursue careers in engineering. To gather the data, 21 students were interviewed after they completed a timeline of their lives, consisting of their developmental experiences, present academic work, and their imagined future. We used purposive sampling to recruit participants who are strong engineering students to provide preliminary evidence for what ideal cognitive pathways might look like. The data are being collected as part of a funded "seed" project to conduct exploratory work that can ultimately lead to a well-designed larger project. Here, we present some preliminary results of our analysis, including example case study of a participant timeline. The results are primarily descriptive, and provide a glimpse into our analytic techniques and mixed method approach to the data.**

Keywords—future time perspective, engineering education, growth modeling

I. Introduction

Elan Vital is a philosophical concept originally coined to describe the complexity and self-organizing nature of organisms as they evolve [1]. Translated commonly as "vital impetus," it has been used a number of ways across a wide variety of disciplines. One area where the concept gained a strong foothold is in the study of how people think about time. Minkowski, an early phenomenological psychiatrist who studied among other things schizophrenia, co-opted the phrase to describe the cogency of a person's spatial temporal representation of time [2]. Rappaport, an admirer of Minkowski's work, adopted the principle to advance the study of time perspective, or how a person's spatial temporal representation of time is related to success and overall well-being [3]. For Rappaport, *Elan Vital* is akin to a river of perceived time, where a person's reconstructed past, present experiences, and imagined future flow together seamlessly as one long connected stream. In a nut shell, Rappaport proposed that *Elan Vital* – as defined by a person's perception of time – was central to mental health and well-being. Using a timeline technique he developed, called the Rappaport Time Line (RTL), he spent the majority of his career documenting disturbances in *Elan Vital* in his patients. He found that the ways in which people cognitively represent time along spatial temporal dimensions and how they experience time in certain contexts was related to their mental health and personal success.

II. Project Purpose and Analysis

In the current project, we have attempted to examine *Elan Vital* in a sample of engineering students. We hypothesized that, similar to Rappaport's body of work, successful engineering students would possess *Elan Vital*, and that we could find evidence of cogent cognitive pathways, sprung from developmental experiences and leading to present behaviors and an imagined future, using Rappaport's RTL technique. We used purposeful sampling techniques to recruit senior engineering students who described themselves as hardworking and successful students. All of the students in the initial sample had achieved high GPA's, were involved in an internship in the immediate area, and were graduating at the end of the semester they participated in the study. We focused on mechanical engineering students with interests in energy, and offered them a small incentive to participate in our study. We asked participants to complete a personal timeline of their lives (using Rappaport's protocol), followed by a forty five minute interview where they were asked to describe their timeline and the events they included. All participants were read the following prompt:

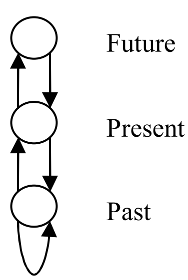
> Imagine this piece of paper represents your entire life, past, present, and future. Please mark any significant life experiences on it. You can organize it however you like. Please include events that have happened, those that are happening, and those that will happen, and indicate an age for each experience. Please include any events, not just those related to engineering.

Then, they were left alone for fifteen or twenty minutes to complete the task. Afterwards, the researcher engaged the participant in a semi-structured interview where the student was asked questions about the various events in their timeline and how they eventually chose to pursue a career in engineering.

We have begun our analysis of the data by focusing on the timelines created by the participants. Specifically, we have documented how far into the past and the future their individual timelines extend, as well as the number and the types of events they identified. We have begun to code the events in the timelines using a protocol we developed in a previous, related study [4]. We have proceeded on a case by case basis, identifying past and future events related to a career in engineering and calculating past and future extension. To produce evidence for *Elan Vital*, we have developed some preliminary differential equations to simulate whether the predicted growth in the number of events in their future in engineering matches the shape of the growth described in the developmental future time perspective literature.

Willy Lens, a future time perspective researcher, using a similar timeline technique, studied how far into the imagined future people tend to extend their future goals [5]. Studying people from across the developmental and social economic spectrum, he found a very stable "inverted U" shaped pattern, where the amount of future time and number of future events one thinks about on a regular basis increases slowly into adulthood and then drops radically. Using the number of engineering events students described in their timelines and the dimensions of their spatial-temporal representations of time, we simulated the growth of engineering student's future engineering events, as well as the predicted growth of their present and past constructions.

For our preliminary growth models of an individual cognitive system, let *dx/dt* represent the growth of events in cognitive space (i.e. past, present, and future); let X equal the number of engineering events listed in the past, present and future, respectively, on the timeline; let b equal the growth rate of the cognitive space (set equal to 1); and let a equal the cognitive limitation placed on engineering events (calculated by subtracting the proportion of the past, present and future devoted to engineering events from 1). We modeled the variables as a complex system, so that future *dx/dt* was determined by the present *dx/dt* and the present *dx/dt* was determined by the past *dx/dt*:



These are the same types of models used to analyze food webs, population growth, and other types of complex systems where system components are interrelated [6].

For our model, we defined three trophic levels, past, present, and future, with past ($X1$) as the primary tropic level and so on:

$$dx_1/dt = X1(b_1 - a_{11}X1 - a_{12}X2)$$

$$dx_2/dt = X2(-b_2 + a_{21}X1 - a_{23}X3)$$

$$dx_3/dt = X3(-b_3 + a_{32}X2)$$

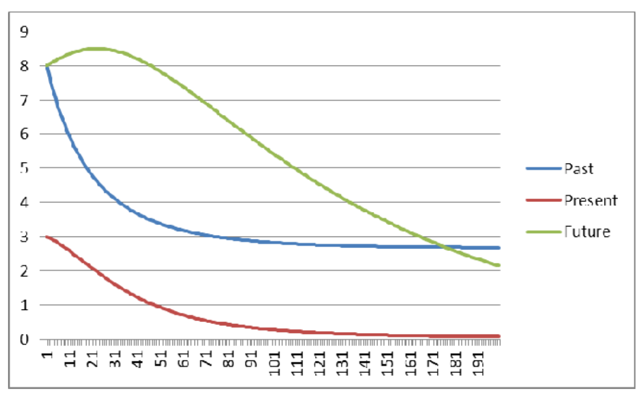
To model our simple three component system for each individual, we used the fill in function of a basic spread sheet and set a very small, arbitrary incremental time step of Δt = .01. In the first row of the first three columns of our spread sheet we entered the initial values for $X1$, $X2$, and $X3$, or the number of engineering events recorded on the timeline for the past, the present, and the future. These acted as our start values. In the second row of cells, we entered our equations, with X+(.01) as a multiplier of the initial X value at all three trophic levels to stimulate growth. The equations were entered for each participant into the spread sheet as such (example model from the study),

=A1+(0.01)*A1*(1-(0.36*A1)-(0.5*B1))

=B2+(0.01)*B2*(-1+(0.36*A1)-(0.38*C1))

=C1+(0.01)*C1*(-1+(0.5*B1))

and then the fill down function was used to simulate growth for 200 iterations of the system. In this example, the participant listed 8 past engineering events, 3 present engineering events, and 8 future engineering events. These were his start values. From the timeline, we determined that 36% of his spatial temporal past was devoted to events not related to his engineering career, 38% of his spatial temporal future was devoted to events other than those related to his engineering career, and 50% of his present events were related to something other than his engineering career. These were entered as cognitive limitations. In our simulation, we were looking to see if, given the individual constraints, the changes in the number of future events overtime matched the "inverted U" shape. In this example, the shape of his projected number of future events matched the shape of the extension describe by Lens et al.



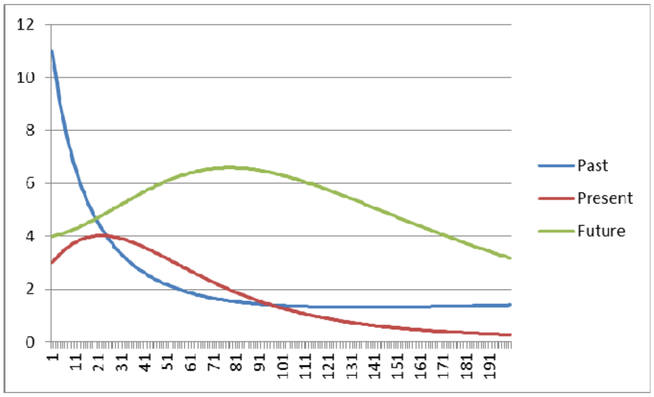
For a comparison, we ran a simulation for a student who was more past oriented. This student listed 14 past events related to her engineering degree, but only 1 in the present and four in the future. However, only 25% of her future events were related to something other than engineering, suggesting an intense focus despite her past orientation. Her model was as follows:

=A1+(0.01)*A1*(1-(0.5*A1)-(0.5*B1))

=B1+(0.01)*B1*(-1+(0.5*A1)-(0.25*C1))

=C1+(0.01)*C1*(-1+(0.5*B1))

And produced the following line graph:



Again, given the characteristics of her timeline, we can see that her projected number of future events, reflective of her extension into her imagined future as an engineer, produces the inverted U shape described by Lens et al. and perhaps she is likely to increase her focus on the future over time as described by future time perspective researchers.

As described by Rappaport, those students who listed positive engineering events in the past and future, and devoted a large portion of their cognitive space to engineering related events produced simulations that matched the "inverted U" shaped described by Lens et al. We believe that these findings can be viewed as very preliminary, but interesting evidence for the power of *Elan Vital* to maintain engineering students' focus on achieving future goals and persisting in the field. Future simulations based on participants with different timeline characteristics will help us to continue to make progress in these types of analyses.

III. Discussion

Our preliminary results suggest that students who possess *Elan Vital* in their timelines may have a better chance of continuing along a typical developmental path when it comes to setting and attaining future goals in an engineering career. Perturbations to the cognitive system, perhaps in the form of counseling or advising, that may help a student to develop a cogent pathway to engineering by reconstructing the past experiences that were important to their development, and using them to construct a cogent pathway into the imagined future, may be an important tool for retaining engineering students through to graduation. In our presentation, we will provide further information about our simulated models, as well as evidence from the narratives and timelines to support our claims.

Abstract—Previous studies on student misconceptions of science and engineering concepts focused on repairing and correcting misconceptions after they have formed. However, it may be too difficult or too late to correct and repair such misconceptions by the time misconceptions have been formed or identified in engineering students. This work-in-progress focuses on a different approach towards treating persistent misconceptions, switching from correcting and repairing persistent misconceptions to preventing those misconceptions from forming.

Keywords—misconception; preventing misconception; conceptual change

I. INTRODUCTION

Misconceptions refer to students' personal conceptions that are different from accepted scientific conceptions [1], [4]. Students come to class with a variety of experience, existing ideas or explanations about some science and engineering concepts that can differ from what is generally accepted by scientists [1], [5]. Reference [6] stated that misconceptions are more than misunderstandings about a concept. Misconceptions are "part of a larger knowledge system that involves many interrelated concepts" (p. 437) and are "extensions of effective knowledge required to function productively within a specific context" (p. 438). Thus the development of misconceptions can be sequential in that once a misconception has been formed it may be further enforced and built upon [7], [8].

There are different kinds of misconceptions. Some misconceptions are due to simple confusion or misunderstanding; some are due to a lack of information or knowledge [9]. These types of misconceptions are relatively easier to treat at the time when they are spotted. However, there are fundamental misconceptions such as diffusion process, which differ from other observable and macro level processes, for instance blood circulation. These misconceptions are due to the differences in the way that some small-scale engineering processes differ from other observable and macro level processes, which are persistent against instruction and remediation [10]. Such misconceptions may also get reinforced through formal instruction or coursework [8]. Effective strategies must be identified and designed to eliminate or prevent misconceptions in order for meaningful learning to occur [1], [11].

II. A SYNERGISTIC APPROACH TO PREVENT PERSISTENT MISCONCEPTIONS

This work-in-progress reports a synergistic approach that utilizes effective instructional design (ID) and the development of mental representations of complex concepts and phenomena in thermo-fluid sciences to help prevent misconceptions. ID is a systematic process to design and develop instruction and learning activities by addressing five "Ws" and one "H", which are why, who, what, where, when, and how to teach [12]. The development of mental representations refers to helping students develop a cognitive mental framework of two scientific processes (emerging and sequential processes) [9] and small-scale complex and difficult concepts. We have carefully analyzed five "Ws" and one "H" of the ID process in this particular context as the foundation of the synergistic approach.

Why? (1) Persistent misconceptions exist among junior and senior engineering students after they have taken related college-level [13] and (2) remedy strategies seemed to be ineffective in repairing some misconceptions of difficult concepts [8], [7]. The prevalent and persistent nature of misconceptions of core engineering concepts presents an issue not only for students' overall learning outcome, but also their retention in engineering majors. Therefore, new effort needs to be targeted towards how to prevent students from forming persistent misconceptions.

Who? We choose to work with first-year engineering students due to (1) the learning impediment or possibility that formal instruction actually reinforces misconceptions [14], [7] and (2) enormous amount of time and resources that have been spent on repairing misconceptions but persistent and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

robust misconceptions still prevail among undergraduate engineering students.

What? Thermo-fluid sciences was selected as the subject domain because misconceptions of such concepts are (1) prevalent among undergraduate engineering students [13]; and (2) persistent against and robust to instruction and remedy interventions [15], [8], [10]. Therefore, thermo-fluid sciences is a good subject candidate for exploration of the proposed synergistic approach to research.

Where? Computer-based learning modules hosted in Moodle (a learning management system) that is very accessible provided to participants. A designated classroom for participants who desire to interact with subject experts while studying learning modules will also be provided to accommodate multiple learning pathways and different learning preferences.

When? Ideally, it seems that in order to prevent persistent misconceptions among undergraduate engineering students and the learning impediment, it is necessary to work with students prior to any instruction on difficult concepts, especially for particularly challenging concepts such as those in heat transfer [16], [8]. Thus, we work with first-year engineering students who have completed basic college-level science and math courses but prior to taking any course related to thermo-fluid sciences.

How (How are we going to teach the What to Who?)? The How includes the selection of instructional strategies, tools, and organization of learning activities to ensure/enhance learning outcomes and experience. After reviewing various strategies for treating misconceptions, we selected and designed three instructional strategies for the design and development of learning materials and learning activities. First, we selected the interactive learning strategy for "teaching" our subject content to bring better learning outcomes [17]. Interactive learning activities in this project refer to student actions with learning materials and technology tools through interactive reflection and inquiry prompts to promote conceptual understanding [18]. Interactive reflection and inquiry prompts ask students to reflect on their learning and describe in their own words about the subject content, providing an opportunity not only for deep understanding but also guided-construction of new knowledge [17].

Second, we will train students in forming mental representations of scientific processes (SPs) (domain-general training) [10], [19]. We will train students on sequential and emergent processes (domain-general training) that have distinct underlying mechanisms in terms of overall interactions among their constituent elements. The domain-general training on two SPs will help students form a cognitive mental structure of emergent processes and provide a special anchor for assimilating and encoding new information while learning difficult concepts [10], [19]. Third, difficult thermo-fluid concepts and phenomena will be explained and described in the language of two scientific processes (SPs) (emergent and sequential processes), especially emergent processes. This strategy is a domain-specific approach and one step further of the domain general training on two SPs. Our "mapping" of difficult concepts with properties of emergent and sequential processes reflects a new effort on learning difficult engineering concepts with the development of students' mental representations of two SPs to prevent misconceptions. The "mapping" further places students in the context of the emergent processes framework to understand difficult concepts as proposed by the National Research Council study of How People Learn [20]. Last but not least, computer simulations will be designed or selected for difficult concepts/phenomena and also help "teach" our subject content. Computer simulations allow students' manipulations of abstract engineering phenomena at small-scale levels and provide them an opportunity to study complex phenomena that are not possible with other tools [21].

Currently, the project training materials including computer simulations for difficult engineering concepts are under development. A group of first year engineering students will be recruited to receive the training in an experimental study after they finish necessary courses in physics, chemistry, biology, and math. The same group of students will be recruited again for a follow up study after they have completed relevant coursework in thermodynamics, fluid mechanics and/or heat transfer. If participants in the experimental group perform better in the follow-up post-test, we can infer they did not have to repair as many misconceptions and the synergistic approach achieved the purpose of preventing persistent misconceptions of difficult engineering concepts.

ACKNOWLEDGEMENT

We thank the National Science Foundation (NSF) for supporting this study (EEC-1232761). Any opinions, findings, and conclusions or recommendations expressed in this material do not necessarily reflect the views of the NSF.

Creating an intrinsic-motivation-driven course design method

***Abstract*— The low-cost intrinsic motivation (IM) course conversion project is an effort to create a new system of course design that focuses on creating scalable and sustainable courses that emphasize promoting students' IM to learn. Unlike many course design methods such as idea-based learning, project- or problem-driven learning, or "flipped" classrooms, which first ask, "How do we help students learn X better," we ask "how do we foster intrinsically-motivated learners who want to learn X?" While this course design method still uses theories of cognition to design course structures, it uses motivational constructs such as purpose, autonomy, relatedness, and competence as the primary design considerations of a course. Secondarily, the course design method considers and documents the financial, time, political, and psychological costs of course design. In this paper, we present a preliminary attempt to formalize this IM-driven course design method as well as a system for evaluating the short- and long-term costs of implementing a specific course design.**

Keywords—intrinsic motivation; course design; learning theory; engagement

I. INTRODUCTION

While course design has historically favored the cognitive outcomes of learning, there is a growing understanding in educational theory that the affective or motivational outcomes of learning moderate the cognitive outcomes as motivational constructs such as self-efficacy beliefs can accelerate how students learn challenging course material and help them persist in learning activities when they fail [1-5]. Concurrently, research on why instructors do not adopt effective teaching practices often cite that instructors are unwilling to overcome the time and financial costs needed to learn and implement new teaching techniques [4, 5]. Further, many instructors who attempt to adopt new teaching methods are often discouraged by students' initial apathy or even hostility toward new teaching methods [4]. In this paper, we present a course design method called the low-cost intrinsic motivation course conversions that maximizes learning by focusing on both student and instructor motivation [6]. While content and techniques are still important, they play complementary or secondary roles to the goal of fostering motivated learners and designing courses that instructors are motivated to teach.

The paper begins with brief backgrounds on motivational theory and course design methods followed by a description of the course design method. The method has three stages: evaluate the current course, create structured spaciousness, and manage the cost of the design. The paper concludes by applying the method to a sophomore level computer engineering course. By creating purpose-rich assessments that provided students with autonomy over their learning objectives, the revised course provided better support for students' intrinsic motivations to learn and increased performance on standard cognitive learning outcomes as compared to an active learning focused design [6].

II. A PRIMER ON MOTIVATIONAL CONSTRUCTS

While any motivation theory can help an instructor better motivate students, we chose Self-Determination Theory (SDT) and its emphasis on psychological needs. SDT describes how the satisfaction of certain psychological needs can shape the orientation and amount of an individual's motivation in a situation or context [7]. This sole focus on needs provides a condense set of constructs that can serve as the quality criteria for a course design method. The orientation of motivation affects the amount and quality of learning and ranges on a continuum from amotivation through extrinsic motivation (receiving rewards such as grades, complying with rules) to intrinsic motivation (deriving from the inherent value of an activity) [2,7]. Table 1 presents four motivational orientations to simplify SDT to a digestible and memorable continuum: amotivation, external regulation, identified regulation, and intrinsic motivation.

TABLE I. FOUR MOTIVATIONAL ORIENTATIONS FROM SELF-DETERMINATION THEORY

Motivational Orientation	Simplified Description
Amotivation	Disengagement from an activity or context (e.g., "I'm not good at math.")
External Regulation	Engagement is regulated by the threat of punishment or promise of reward (e.g., "I need an A.")
Identified Regulation	Engagement is regulated by a desire to achieve internalized values or goals. (e.g., "I hate proofs, but they help me understand the concepts.")
Intrinsic Motivation	Engagement satisfies intrinsic psychological needs. (e.g., "I love solving proofs because I enjoy figuring out why things work.")

Students tend to learn more when they are intrinsically motivated to learn [1,2]. We can support students' motivation

generally and shift them towards an intrinsic orientation by supporting their senses of Purpose (what I do matters), Autonomy (I am in control), Relatedness (others care about me), and Competence (I can be effective) [7] (PARC needs).

The type of motivation also has a hierarchical structure that varies by time scale or domain [8]. Motivation can be situational (e.g., a homework assignment or a group meeting), contextual (e.g., a semester-long project, a course, or learning engineering), or global (e.g., a person's default motivational orientation). A person's motivational orientation may vary across these three levels in every situation and over time [8]. For example, a student may globally use identified regulation with the goal of self-betterment, but contextually be intrinsically motivated to write a simulation program, but situationally be externally regulated by a deadline simultaneously. As students experience more situations in engineering courses that intrinsically motivate them to learn, these situational motivations can lead to a contextual intrinsic motivation to learn engineering [9]. Conversely, students who are initially intrinsically motivated to learn may become amotivated as they experience amotivating situations [9].

III. Brief Background on Course Design

Research has documented five main categories of course design methods [10]. These course design methods often focus on desired cognitive learning outcomes, careful sequencing of learning activities for optimal learning, or departmental pressures and mandates [10]. Backwards course design, and its successor idea-based learning, was the first course design method and was cognitively focused [11-13]. In idea-based learning, a designer's first objective is to identify a small number of "big ideas" or central concepts that connect the course content (e.g., force and energy in mechanics or equilibrium in fluid mechanics) [11]. These central concepts are broken down into enduring understandings: canonical examples that critically inform how students will think about the concepts [11-12]. Students' enduring understandings are then supported by situational learning activities. The course designer's goal is to create a series of learning activities that spiral around these central concepts by stepping through the enduring understandings with the goal of helping students develop an integrated conceptual framework of the material that leads to deeper learning [11].

Course design methods such as the "flipped classroom" or just-in-time teaching are structured around the cognitive principles of providing rapid feedback; repeated, spaced exposures to content; and opportunities to actively manipulate concepts [14]. A designer may not change the order of topics or the course content, but the method of content delivery is modified so that students are exposed to content outside the classroom and actively engage with content in the classroom.

Course design methods such as problem-based learning and inquiry-based learning focus on a mixture of cognitive and affective outcomes in their design principles [15-17]. A primary critique of traditional course design strategies is that the cognitive skills needed to succeed in the traditional classroom are not the skills needed in authentic tasks in industry or the "real world" [15]. Problem-based and inquiry-based methods in contrast promote the cognitive skills of critical, analytical, or metacognitive thinking by requiring students to engage with more "authentic" learning environments [16]. A secondary goal is that students will be more motivated to learn as they engage in problems that they encounter in the real world with their peers (i.e., increased senses of purpose and relatedness) [15].

Although each of these research-based course design methods can improve students' motivation to learn, most instructors who implement these methods have at best only their intuitions about how to better motivate their students. In other words, the course is designed first to promote certain cognitive outcomes, and promoting students' motivations to learn is considered as a matter for troubleshooting student resistance or amotivation [18]. For example in Hansen's recent book on idea-based learning, students' motivations are only briefly mentioned as part of the development of learners as they become more mature in their learning. [11].

IV. The IM-Course Design Method

The philosophy of the IM-course design method is captured by a central image of structured spaciousness. This image is composed of two complementary palettes that may need to be held in tension. First, the structure of instruction provides objectives that communicate the purpose of instruction and instill the confidence in learners to succeed. Spaciousness conveys a sense of freedom or self-determination, but also the time and place for the cultivation of community and relatedness. With this central image, we present a general framework for creating structured spaciousness.

Following the principle of creating structured spaciousness, this course design method intends to provide structures that guide and embolden the course designer, yet provide spaciousness so that the course design method is not prescriptive. We provide examples as illustrations of the principles rather than as masters to be copied. A course design will be most effective only when the instructors also possess the senses of purpose, autonomy, relatedness, and competence about their courses that undergird their motivation to teach.

The design method is iterative and has three primary steps: A) Evaluate the current course design's support of students' intrinsic motivation, B) create structured spaciousness by generating potential modifications to improve the course design's support of intrinsic motivation, and C) manage the cost of the proposed modifications to inform decisions about which modifications to adopt. After managing the costs, the designer should evaluate the course conversion to determine if the design objectives were met. If not, then additional iterations may be needed.

A. Evaluate the current course design

An evaluation of a course's existing design can provide a point of reference for reimagining the course and assessing the costs of any revisions. To perform this evaluation, the course designer must consider how students in the course would experience the course and how it meets their psychological

PARC needs. For example, the designer could rate the course as providing low, moderate, or high levels of support for each need (see Table 2). After evaluating the course, the designer can use the evaluation to identify opportunities to improve the course's effect on students' motivations to learn. For example, a designer might rate the purpose of the course as low because the homework assignments lack meaningful contexts that connect with students' interests, so the designer might create assignments based on students' expressed interests in taking the course or replace homework with projects.

TABLE II. COURSE EVALUATION GRID: BASED ON SUPPORT OF PSYCHOLOGICAL (PARC) NEEDS FOR MOTIVATION

	Rate the course's support of each need		
Purpose	*Low*	*Moderate*	*High*
I believe that this course is a valuable part of my education			
I find the course's learning objectives to be compelling, useful, and comprehensible			
The course material captures my interest and is relevant to my life			
Autonomy	*Low*	*Moderate*	*High*
I have control over learning goals and content			
I get to develop and use my own learning strategies			
I get to choose deliverables, resources, due dates, teammates, or specify course policies			
Relatedness	*Low*	*Moderate*	*High*
I get to work collaboratively with my peers			
I feel connected to my instructors			
My work has positive impacts on people outside the classroom			
Competence	*Low*	*Moderate*	*High*
I believe I can be successful and achieve the learning goals			
I can engage in challenging and meaningful goals			
I get positive formative feedback on my learning process, not just my performance			

The designer must also evaluate the costs that are incurred by teaching the course in its original form. A more detailed description of cost analysis is provided in the section on cost management. The goal of an IM course conversion, though, is to either maintain or lower the costs required to teach the course. This goal cannot be achieved without careful accounting of the costs of teaching the current course. Identifying high cost components of a course can similarly reveal opportunities for improvement in the course design.

B. *Create structured spaciousness*

Based on the analysis of the original course design, the designer should generate a list of potential modifications for the base course design. These modifications could be major or minor, but at this point in the design process the goal should be focused on imagining idealistic designs regardless of their feasibility. While the designer's ideals may not be realizable, identifying these ideals is critical for creating a sense of aspiration or stronger sense of purpose in the design process. This stronger sense of purpose is critical during the cost negotiation phase which requires critical evaluation of the ideas and a priority structure for decision making. For example, in one course, the designer wanted to focus on developing students' collaborative problem solving skills, but was required to administer a final examination. While the ideal summative feedback was identified to be a final project completed in teams, this option became untenable. However, the identification of this ideal informed the structure of the final examination, which became more design focused and required students to create smaller components of a bigger system as if they were working in teams.

Further, the designer is also encouraged to borrow or use principles of course design from other course design methods. However, the evaluation of these methods will be based on motivational rather than cognitive outcomes. For example, the designer can use problem-based learning techniques to better support students' sense of purpose.

To facilitate ideation around modifications, we use our image of structured spaciousness to guide the ideation process.

1) *Identify a strategic core (Creating structure)*

From both the motivational and cognitive perspectives [11], the designer needs to determine a narrow strategic core of goals, outcomes, and/or objectives of the course. From the perspective of IM course design, the focus for identifying a strategic core is primarily to enhance the students' sense of purpose in taking the course. In other words, the focus is on *why* certain concepts and skills are important and not simply on what should be on the list of possibly important concepts or skills. Identifying a strategic core secondarily provides a decision-making framework for determining which activities or content are negotiable or non-negotiable for the students. Without a strategic core, the course can easily become bloated, overwhelming students with excess content. Alternatively, the purpose of the course can become diluted, and students fail to understand why the course is valuable or important.

A narrowly defined strategic core can also improve students' sense of competence by creating a manageable list of course goals. If the designer can reduce the course goals to two or three strategic objectives, students can develop a better sense of what they need to master to be successful, which in turn can increase their sense of competence. Further, a strategic core can reveal what assessment activities to include in the course and provide stronger rationales for them, thereby helping students feel that they are receiving the feedback that they need to succeed.

The identification of a strategic core can lead in many directions that depend on how the course fits within its broader curriculum; a first-year course which serves as the gateway to the discipline will have a different type of core from an upper-level technical course. For gateway courses, the purpose of the course may lean more towards helping students understand the value and nature of the discipline or helping the students to better understand the expectations of the discipline. For technical courses, promoting purpose and competence can often be achieved by narrowing the focus of the course to a few core concepts or skills that will be critical to the students' later success. Purpose can also be promoted by providing opportunities that intersect with students' broader interests or that demonstrate the usefulness of the course material.

As mentioned earlier, we encourage designers to identify the ideal forms of feedback and assessment that they believe would best support students' sense of competence and reinforce the purpose of the course. A discussion of feedback methods is beyond the scope of this paper, but there is an abundance of literature on effective feedback techniques (e.g., [19]). For example, the use of rubrics can support purpose and competence by specifying what students are expected to do and learn [20].

As an example of redefining the strategic core, a sophomore-level technical course was originally defined by a week-by-week list of topics that was incomprehensible to the incoming student and lacked a week-to-week cohesion between the topics. This lack of cohesion diluted the purpose of the course and many students delayed taking the course for as long as possible because they did not understand why the course was useful. To refine this course, we identified the conceptual core "big ideas" as prescribed by idea-based learning [21]. Identifying the core big ideas empowered the instructors to cut the number of topics covered by the course in half and to provide a greater sense of purpose to the course. The course objectives now consist of three core big ideas and choices for students to explore how those big ideas are used in practice. In accordance, course assignments and feedback changed to help students better achieve mastery of these three big ideas. For example, the instructors and teaching assistants (TAs) now create a menu of short projects that demonstrate how the core concepts apply to different sub-disciplines [6, 22]. Students complete these projects during the first five weeks of the semester. The instructors and TAs each become a supervisor for the project that they find to be most interesting (e.g., a TA researching sensors would likely choose to supervise projects related to sensors). Similarly, the students choose one project that they find most interesting. By pairing students with instructors based on interests, we found that the instructors and TAs were more eager to provide feedback to the student project teams, improving course performance and the course climate's support of the students' intrinsic motivation to learn [6, 22].

Identifying a strategic core may provide a tertiary benefit by lowering the psychological tolls assessed when engaging instructors who are normally resistant to pedagogical change or reform. For many instructors, their sense of competence may be based on their sense of expertise and knowledge of the course material. If a reformer begins the conversation about change with an instructor by addressing pedagogy first rather than content, the reformer is situated as the expert rather than the instructor. This power structure can be demotivating for the instructor who may seek to maintain their sense of competence in content rather than engage in their lack of competence in pedagogy. With careful engagement about the content, these instructors gain increased autonomy to make changes and reconsider the structure of a course, thereby increasing their motivation for change. The reformer's goal is then to nudge and guide the application of the instructor's motivation.

2) Designing supportive spaciousness

From the perspective of SDT, an instructor's level of autonomy supportiveness is the most critical aspect of promoting students' intrinsic motivation to learn [23-26]. Autonomy supportiveness can be derived situationally from the instructor's attitudes and actions during instruction or contextually from the course design and the cumulative effect of the instructor's attitudes and actions [24]. Different course designs can facilitate or discourage an instructor's use of autonomy-supportive behaviors [24-26], so the designer must carefully construct spaciousness in the course to facilitate the instructors' use of autonomy-supportive behaviors. Designers can create this spaciousness in the course design by intentionally giving students control over course policies, choices in content coverage or deliverables, or using inquiry-based course designs that are driven by students' questions.

In conjunction with creating spacious course structures, instructors must also consider how they interact with students and reformers must help instructors identify and value autonomy-supportive behaviors. For example, autonomy-supportive instructors spend more time listening, articulate fewer directives, ask more questions about what the student wants, verbalize fewer solutions to problems, make more empathetic statements, and offer greater support for students' internalization of learning goals (e.g., providing more rationale for why an assignment should be accomplished or for the value of the learning goals) [25-26].

Similarly, the designer can use their initial evaluation of the course to reveal opportunities to promote students' sense relatedness. For example, students' sense of relatedness with their peers can be promoted through the use of team-based learning techniques. While a review of effective team-based learning techniques is beyond the scope of this paper, instructors can use the principles of SDT to provide some guidance on how to promote positive team environments. For example, instructors need to help students develop their sense of purpose in their teams. Instructors can help students internalize the importance of learning in teams, help structure teams around a common interest or purpose, or help students identify complementary roles in their teams in order to create good teams which in turn promote students' sense of relatedness. Since relatedness can take time to form, the designer must craft the space for this relatedness to grow.

C. Manage the costs of potential course designs

In order to evaluate the cost of an innovation or to determine how to best minimize the costs of an innovation, there needs to be an accounting of the resources available to, and costs incurred by, the course.

1) Costs of reform and course design

In our efforts to reform courses, we have identified four major costs that act as barriers to change for instructors: time sinks, financial costs, psychological tolls, and political taxes. While the barriers of time, money, and politics (tenure and promotion) are often well documented [5], the psychological tolls are rarely formally discussed in the literature.

Time sinks (e.g., grading, lecture preparation, course management, etc.) reduce the likelihood that a future instructor will adopt a similar teaching method. Financial costs can constrain the design and analysis tools available to students or restrict hiring additional teaching assistants. Political taxes can restrict what types of innovations will be acceptable to a department. Finally, psychological tolls can reduce an instructor's willingness to try new techniques. The psychological tolls of an innovation are particularly critical to address since they are also best addressed by understanding motivation and other affective orientations of the instructors. By addressing an instructors' understanding of their own motivation, it may help them better understand how to address their students' motivations. The remainder of this subsection is anecdotal from our experiences in executing education reform, but also develops from critical reflection of theory in practice.

To better understand the nature of psychological tolls, let's discuss common barriers to adoption from the perspective of the needs outlined by SDT.

Purpose-barriers: Many instructors refuse to adopt new pedagogies, because the effort required to make the change does not fit within their value system. Perhaps the instructor does not believe that teaching is valued. Perhaps the instructor does not value the proposed outcomes of the teaching method. Perhaps the instructor does not believe that a teaching method is so much better that it justifies the increased financial or time costs. Instructors with this barrier may benefit from journal articles and cognitive arguments, but they may also need to believe that a specific teaching method is beneficial to themselves and not just the students. Discussions of cost-benefit analysis or appeals to intellectual stimulation may prove more successful than evidence of effectiveness.

Autonomy-barriers: Many instructors are threatened by giving students autonomy because they then feel a loss of control and a loss of their own autonomy. In the presence of this loss of control, many instructors may perceive a course as a failure despite its successes. For example, letting students wrestle with core concepts in groups without direct supervision (high autonomy for students) can feel like a failure if the students do not get the right answer during that group work. For many instructors, they feel that instruction has only been successful if the students report the right answer with affirmation from an expert (low autonomy for students). This desire for control can persuade many instructors that many active learning or inquiry-based learning techniques are ineffective, despite any evidence to the contrary. The concept of structure spaciousness may be valuable in helping instructors redefine their sense of control and autonomy. Instructors can feel a greater sense of autonomy when they better understand where and when they are choosing to delegate control to their students and what types of control benefit learning.

Competence-barriers: When attempting to use a new teaching method, an instructor's sense of competence can easily be lowered by the unfamiliar. Early failures in attempts with new teaching methods can further lower the sense of competency. An instructor who has tried and failed may not need to be convinced of the efficacy of a method, but rather may need better support structures, mentoring, or simply a positive experience with a pedagogy.

Relatedness-barriers: Students often resist pedagogies that differ too much from their expectations and create an adversarial environment. Instructors can easily be deterred by negative student feedback as it can erode their sense of relatedness with their students. Instructors can also feel a depleted sense of relatedness if they are isolated in their attempts to adopt new pedagogies. Without a community of supportive colleagues, the aforementioned losses of competence or autonomy cannot be offset by a strong sense of communal values and support. This barrier can be addressed by fostering supportive instructor communities or bolstering an instructor's sense of competence so that criticisms are not as damaging.

Knowing how to address an instructor's concerns and objections requires careful noticing of, listening to, and questioning of assumptions, experiences, and beliefs. Alternatively, instructors must critically reflect on their objections to better understand how their motivations may be directing their cognitive decisions and processes.

Finally, costs can be short-term or long-term. For example, generation of video lectures might be a high short-term cost of video production and have low long-term costs of hosting the videos. In contrast, assigning written homework assignments from a textbook might have a low short-term cost of selecting problems and incur a high long-term cost of grading. High short-term costs can block initial adoption of a pedagogy, and high long-term costs can block the sustainability of a pedagogy after initial champions stop paying for those costs.

2) Resource identification and generation

The course designer needs to identify what resources are available to the course and how those resources are being used in order to develop a strategy for how to offset the long-term and short-term costs of an innovation. A low-cost IM course conversion creates change to the course through a mechanism of deliberate cost-swapping.

It is best to invest in short-term costs when those short-term costs can lower the long-term costs of teaching a course. For example, investing in the creation of video lectures, online grading systems, and problem solving activities for a flipped classroom has a high short term cost, but it can potentially lower long-term costs as the entire course becomes scripted, the instructors no longer need to prepare lectures, and fewer assignments need to be manually graded.

Cost swapping can also take the form of exchanging costs of the same type. For example, changing course content or using drastically different pedagogies from a departmental norm can incur high political taxes and resistance. To offset this tax, our reform efforts tend to focus on the large enrollment required courses that few, if any, instructors want to teach. While some political systems might dislike our pedagogies, other political systems gratefully accept our help with these understaffed and poorly rated courses.

Finally, course designers should also consider how any high costs can be distributed among the students. Students can contribute to an IM course conversion by deciding content (e.g., finding interesting real-world examples), creating course materials (e.g., homework assignments, video lectures, etc.), content delivery (e.g., collaborative creation of wikis), and formative and summative assessment (e.g., peer review) [27]. By carefully distributing some of the cost of reform among the students, the course design can further support students' purpose, autonomy, relatedness, and competence, fostering their intrinsic motivation to learn [27]. In perhaps a best possible scenario, intrinsically motivated students can become the engine that drives education reform rather than the instructors. We have seen hints of this new engine forming in our efforts as students who experienced an IM course conversion have returned to help teach the course for free as peer mentors, others have filmed video lectures, and still others are developing online auto-grading tools.

As the designer manages the costs of different course modifications, the modifications will change and present new costs or new resources. Consequently, the evaluation and decision process must necessarily be iterative. After the design, costs, and resources of the modifications stabilizes, the designers should evaluate and compare the costs and IM support of the different proposed modifications. The final course design should reflect a balance between strong support of students' IM to learn, yet with low costs to the instructors and institution.

V. An Example IM Course Conversion Process

In this section, we conclude by providing an example of how this course design method was used to perform a low-cost IM course conversion on a large enrollment course that focused on technical computer engineering skills during the sophomore year.

Every semester, the course enrolled 200-250 students. The students would attend two lectures and one discussion section (~30 students per section) per week. Prior to the course conversion, students would complete a weekly battery of online homework problems and then a written homework problem set. Students would also complete seven prescriptive laboratory exercises over the semester and two or three midterm examinations depending on instructor preference. The course culminated with a comprehensive final examination.

A. Evaluating the current course design

The initial evaluation of the course revealed that the weekly homework problem sets created one of the greatest hindrances to students' motivation to learn and highest costs to the course.

1) Evaluating support of PARC needs

Written homework problem sets typically contained four to eight problems assigned after a week of instruction on the topics. Students were given a week to complete the assignment, and then students would receive their graded problem sets at least a week after turning it in. The problem sets often used rote, context-less problems (low purpose). All students completed the same assignments (low autonomy). Students were required to submit their assignments independently (low relatedness). Because it would take on average of three weeks for students to receive feedback, student rarely read the TA's comments and the feedback did not provide students with feedback on how to adjust their learning strategies (low competence). Finally, the large enrollment and impersonal nature of the problem sets led to rampant cheating (low relatedness and competence).

2) Evaluating course costs

The course employed a cohort of TAs to help with the course for a total of 80 hours per week of which an estimated 64 of those hours were spent grading. The remaining TA hours were divided between instructing discussion sections, office hours, and staff meetings. Due to this high grading load, the course also needed to hire undergraduate graders to lighten the grading load on the TAs so that they could engage in their other course duties. New problem sets were written each semester in an attempt to combat cheating.

B. Creating structured spaciousness

Because grading consumed so many resources and students were not receiving effective feedback, we focused on changing the mechanism for feedback on the homework assignments. We created a construct called the weekly consultation meeting. The weekly consultation meeting took place the week after students were introduced to the course material, shortening the feedback cycle (high competence). During the weekly consultation meeting, the TAs met with teams of five students for an hour to discuss the homework assignment (high relatedness) and address students' personal difficulties (high competence). Students received 50% of the homework grade for bringing a completed homework assignment and could earn the remaining 50% by contributing meaningfully to the group discussion about the assignment (high relatedness). Further, we added a menu of challenge problems to the homework assignments which were based on various real-world design problems that highlighted how the course material was relevant (moderate purpose). Students picked one challenge problem from the menu to solve based on their interests (moderate autonomy).

As a byproduct, the emphasis on oral discussion of the problem sets virtually eliminated the cheating problem in the course as writing down the correct answer was no longer sufficient for full credit. Rather than coming to the consultation meetings with copied answers, students would come with targeted questions.

C. Managing the costs of potential course designs

We made this modification low cost by swapping the time intensive process of grading for a similarly time intensive process of weekly consultation meetings. With 250 students in the course and five student teams, the TAs needed to spend 50 hours per week providing feedback to students on their homework assignments. With this reduction from 64 hours of grading, we also no longer needed to hire an undergraduate grader to support the course, and thus reduced the financial cost of the course as well. Changing the TAs' duties also incurred low political taxes and psychological tolls. Since most TAs had never taught with different pedagogies, they did not resist the new grading paradigm.

We also maintained a lower time cost to the modification by not requiring the primary course instructors to change their preferred lecture delivery methods. Further, allowing the instructors to continue teaching with familiar methods also reduced the political tax and psychological toll of the innovation.

Iterations on the design method revealed additional opportunities to increase students' sense of purpose and autonomy in the course. The weekly consultation meetings created the time and place to infuse student-led project-based learning in the course. Since students had weekly team meetings with course staff, they could work with these same teams on extended, purpose-driven projects in lieu of midterm examinations. At the beginning of the semester, students were given a choice of projects to complete and were organized into teams based on their expressed interest in different projects (high purpose, high autonomy, and high relatedness). This switch to projects created a new short-term cost of creating rubrics and project ideas, and this cost was swapped with the long-term cost of writing and grading examinations.

As we demonstrate in other publications [6, 22], this deliberate cost swapping method created a low-cost innovation which better supported students' intrinsic motivation to learn as indicated by the Learning Climate Questionnaire. Climate scores rose from five points out of seven on a Likert scale to six points [22]. The course conversion additionally improved students' cognitive outcomes and conceptual learning as students' learning gains as indicated by a concept inventory revealed that students' conceptual understanding improved to 50% learning gains as compared to 25% learning gains in previous offerings of the course [22].

Expectations and Realities for Community College Engineering Transfers at a Large University

Dr. Mary R. Anderson-Rowland
Arizona State University
mary.anderson@asu.edu

Abstract—**This paper is focused on identifying the factors that worry potential and new transfer students in engineering. Special efforts to help students transfer smoothly into engineering and computer science have been in place since 2002 at Arizona State University (ASU) through an Academic Success and Professional Development class and a Motivated Engineering Transfer Student (METS) Center. During this time, we have become aware that transfer students come to a university with certain expectations and preconceived ideas, some which are true and some which are not. In addition, many transfer students are not aware of some of the realities they will face as a transfer. In order to check on what the actual expectations and realities are for transfer students, we surveyed 120 transfer students who were enrolled in the Academic Success Class during Fall 2012. The top six expectations were reality over which the transfer students had little control: higher tuition, some very large classes, expensive parking, a large campus, a long commute, and difficulty in parking. These expectations were followed closely by several factors to which the students had some control: GPA shock, a faster pace of classes, feeling like a freshman all over again, and not knowing where resources are. The top four expectations upon transferring were the same as the top four realities, although in a different order. For half of the students, the fifth most prevalent reality was that the METS Center helped in their transfer. The next most frequent realities were that the pace of classes was faster and that classes had more assigned homework than they had at the community college. We also examined gender differences. We detail what we are doing to help transfer students with these realities.**

We will use the data in this paper to inform potential and new transfer students and to help them plan for success. Even though much of this knowledge may be well known, a new transfer often does not believe that the challenges will affect him. By using the results of this study, at this university, the facts are more believable. We encourage others working with transfer students to become familiar with the expectations and realities of their own transfer students in order to help them be successful.

Keywords-intentional advising, recruitment, retention, survey, transfer expectations, transfer shock

I. INTRODUCTION

Two major factors are responsible for the recent increased interest in community colleges as a source for more engineers in the U.S. First, due to economic, health, and environmental concerns, President Obama has called for an increase in at least 10,000 engineering graduates per year in the US. [1] Secondly, due to the recent economic down turn, it is more difficult for students to be able to afford the rising tuition of both private and public universities. The community college then is a largely untapped resource for additional engineering students, especially for females and underrepresented minority students, and also offers a much more affordable education for the first two years of college.

In order to graduate more transfer engineering students from four-year institutions, we need to have more students at the two-year institutions choose engineering and the right policies and programs need to be in place. [2] Students at the community college (CC) need to be encouraged, motivated, mentored, and supported to choose an engineering degree and to transfer to a four-year college. Often both academic and financial support are needed. We can begin to understand how difficult this task is for engineering when we consider that for all majors, nearly 60% of students entering four-year institutions earn a bachelor's degree in six years, but only 31 percent of public CC students go on to complete either an associate or a bachelor's degree in six years according to U.S. Education Department data. The U.S. Education Department further reports that only 26% of U.S. CC students transfer to four-year institutions.[2] This percentage is even smaller for underrepresented students.

Getting CC students to be aware of engineering and to consider it as a major is a topic all in itself. We were surprised to learn several years ago when we first started to visit five non-metropolitan CCs, that we were the first engineering faculty and staff to set foot on their campus and talk to students about the excitement and opportunities available in an engineering career. We know that a captive audience in a classroom is the best way to communicate with non-metropolitan CC students. We continue to do research on the best ways to interest more students in engineering. [3-5]The literature on "promising practices for community college student success" include many good programs that work both at the CC and at the four-year transfer institution. [6] For example, while the CC needs to have an emphasis on the first year experience, the four year institutions need to have an emphasis on the first transfer semester (as well as their first year native students).

In this paper we want to identify the particular factors that concern potential transfer students and the actual realities that they face after they transfer to Arizona State University (ASU) in engineering and computer science. Henceforth, unless otherwise noted, the term "engineering" shall include computer science.

There are many policies and programs that can ease the transfer process in general for community college students. A first step is having a transfer equivalency guide so that students at a CC will know which courses will transfer to a particular four-year college. The state of Arizona has a state-wide equivalency guide between its three universities and 21 CCs. In addition, an engineering student needs to know which CC courses will count toward their particular major at their intended transfer university. "METS (Motivated Engineering Transfer Students) Pathways" will soon be in place to do just this at Arizona State University and five targeted Arizona non-metropolitan CCs who have been partnering for the past four years.[6]

A second step in this process for potential transfer students is for there to be a supportive, academic environment at the CC to be encouraging the CC students, to answer their questions, to help make sure that they are making timely steps toward transfer. There several good sources of material on how to best do this including "A Matter of Degrees: Promising Practices for Community College Student Success" which discusses the planning for success, initiating success, and sustaining success.[7] CCs and universities need to have knowledgeable advisors to assist with transfer and orientation sessions at both institutions and should include information on transfers. [8]

The third step is the actual transfer and first semester at the four-year school. This process is so well known for being difficult that it has its own name: "transfer shock." The term "transfer shock" was coined by John R. Hills of the University System of Georgia in 1965. [9] The term grew out of the discussions on whether a community college transfer student does as well as a native student in their studies. The term generally refers to GPA shock and the fact that, in general, transfer students suffer about .5 grade drop during their first semester of transfer relative to their average GPA at the CC. Forty-five years later, the term is still active. However, new transfer students generally go through many "shocking" things when they transfer in addition to a drop in grades. [10]

There are several things that the four-year school can do to ease the transition. We make visits to the CCs and encourage the CC students to start talking to the academic advisors at ASU long before they actually transfer. Sometimes taking a course the summer before the fall transfer can save a semester later in a series of courses that need to be taken. Potential transfer students are encouraged to apply by January if they expect to transfer in the fall or the spring semester after, in order to be eligible for scholarships which have a February 1 deadline. A time flow chart is given to the students with important check points in a transfer, as well as contact numbers for ASU advisors and financial aid. Students are warned to not take all of their courses on two days so they can work the other three. The students are offered the assistance of an ASU mentor, but few students take advantage of this support. Potential transfer students are invited to come to a transfer orientation in the METS Center to meet the staff, have a tour of the engineering buildings, and to meet and talk with students who have transferred from their CC. It is helpful for a potential student to know that others have transferred from their CC and are doing well.

A fourth step for a successful transfer student is to have a continuing supportive and encouraging environment with available help for problems they may encounter and need assistance with. This step is covered with our academic scholarship programs and a two semester hour credit class, Academic Success and Professional Development. This program has been explained in other papers. [11-14] Donna O. Johnson's "4.0 Plan" is used for academic support. [15] Our program follows Tinto's four major components needed for college retention: high expectations, support (academic, social, and, perhaps, financial), assessment with frequent feedback, and involvement. [16]

Special efforts to help students transfer smoothly into engineering in the Ira A. Fulton Schools of Engineering have been in place since 2002 at ASU. Visiting the CCs; hosting open houses for potential transfer students; providing a METS Center for transfer students to study, network, use a computer, have free printing, and ask questions; and offering an Academic Success and Professional Development course are all done to smooth the transition process. After transfer, the students are given tools and encouragement to help them graduate and go right on to graduate school. The program has been successful: 95% of upper division transfer scholarship students graduate (vs. 70% for men and 64% for women upper division transfers, in general) and over 50% go to graduate school versus less than 20% in the nation.

This paper is focused on identifying the factors that worry potential and new transfer students in engineering. We surveyed the 133 transfer students enrolled in the fall 2012 FSE 394 Class, "Academic Success and Professional Development. The class had one hour credit which counted in the GPA, but not the program of study. An on-line survey asked the students questions about their anticipated fears regarding their ASU transfer, as well as their actual problems encountered after transfer. By analyzing these responses, we try will try to improve ways in which we can help solve some of the angst or at least warn the students and give help for dealing with the challenges. Hopefully by knowing that this is recent data at ASU, the students will understand that they may face the same problems.

II. THE SURVEY

During the fall 2012 semester, 120 of the 133 (90%) transfer students in the FSE 394 Academic Success and Professional Development class completed an on-line survey. This survey is similar to a survey given in 2007 [13] and the same as a survey given in 2010 [14]. These surveys were to smaller groups of transfer students. We wanted to know if a larger group of transfer students would give a different picture of transfer or if there were any noticeable changes in the perception of the transfer process during the past few years. The students were asked what their expectations and fears were upon transferring and what the reality was of their first semester at ASU. The students were asked to check all answers that applied in each case and to add any other situations that applied.

The expectation results of the survey are given in Table I. The percentages of females and males citing each expectation were compared for statistical significance. There were four differences between the females and the males with regard to their expectations. The most pronounced difference was that females expected more than males that the class pace would be much faster (p=.042). There are two areas which show a slight difference. The long commute was more worrisome to females than males (p=.092) and the females were also more concerned than males about the difficulty of parking (p=.092). A slight difference (p=.145) in genders is noted with respect to tuition. A higher percentage of males than females noted that transferring would mean a higher tuition.

Next we look at the realities of the first semester transfer to ASU. These results are shown by gender in Table II. By the percentages of either female or male students reporting, we can see that many of the expectations of transfer became reality. Eight areas were named as realities for over 50% of the females, while only four of the areas were selected by over 50% of the males. If we consider the top eight realities percentage-wise for each gender, we see that the females and males agree on the top four realities and seven of the first eight, although not exactly in the same order. The expections are that the females ranked "overwhelmed with classes/logistics" as tied for number 6, while the males ranked this 13th. On the other hand, males ranked "pace of classes is much faster" 5th, while females ranked it tied for 10th.

There were four areas which were statistically more significant (p<.05) for females than males These areas are: overwhelmed with classes and logistics, classes are harder than expected, lonely (don't know anyone in class), and too many credits hours or too much work. There are four additional areas where the genders differed percentage-wise by .05<p.10. One transfer reality, "worked too much to do well academically" was more prevalent for males (p=.063). The other three areas were more prevalent for females: all of the easy classes taken (p=.057), did not spend much time on campus (p=.066), and easy classes taken, upper division classes are harder (p=.083). Two additional areas are slightly significant with .10<p<.15. One, "hard to get into study groups" (p=.111) was more worrisome for females. The second, "higher tuition" was mentioned by more males (p=.145).

Table I. Expectations of Transferring to ASU

Expectations of Transfer to ASU				
Reason	Females %/Rank n = 24		Males %/Rank n = 96	
**Expensive parking	75	1	56	3
Some classes very large	71	2	57	2
Higher tuition	67	4	82	1
**Long commute	67	4	47	6
*ASU large	67	4	49	4.5
*Class pace much faster	63	6.5	45	8
Difficulty parking	63	6.5	46	7
Transfer GPA may drop	50	8	49	4.5
Lonely (don't know anyone)	38	9	31	10
Easy classes all taken	33	10.5	23	12
Resources locations unknown	33	10.5	28	11
*More assigned HW	29	12	22	13
Feel like freshman again	25	13	39	9
Had friend who would help	4	14	4	14

*** p<.05, **.05<p<.11, *.11<p<..17

Additional expectations:

- Female: Thought I would be disoriented
- Female: Teachers don't care as much and office hours are terrible
- Female: More PPT slides
- Female: Less professor extemporaneous lectures
- Female: Isolated and I would fail all my classes with no one to study with
- Female: Had a friend who would help me

- Male: I may not have the focus or motivation as other University students
- Male: Not finding a good apartment
- Male: Paying tuition

Table II. Realities of Transfer to ASU

Reason	Female Rank/% n = 24		Male Rank/% n = 96	
***Higher tuition	2	67	1	82.8
Expensive parking	2	67	3	57.5
Some classes very large	2	67	2	58.6
ASU is large	4.5	63	4	55.2
METS Center helped	4.5	63	6	47.1
Long commute	6	58	8	41.4
*Ovewrwhelmed with classes/logistics	7.5	54	13	28.7
Difficulty parking	7.5	54	7	42.5
Pace of classes is much faster	9.5	50	5	48.3
Classes have more assigned HW	9.5	50	10	37.9
Classes are harder than expected	12	46	12	33.3
Hard to get into study groups	12	46	15.5	24.1
Lonely (don't know anyone in class)	12	46	18	19.5
**Too many credit hours/too much work	14.5	42	22	13.8
***Easy classses taken, UD classes harder	14.5	42	19	18.4
Did not spend much time on campus	18	38	20	17.2
Had a friend/mentor	18	38	15.5	24.1
Transfer GPA may drop	18	38	9	39.1
**All easy classes taken	18	38	19	18.4
Hard to get to know professors	18	38	11	35.6
Feel like a freshman	21	33	15.5	24.1
Don't know where resources are	22	29	15.5	24.1
Lost	23.5	17	23.5	12.6
No problems	23.5	17	25	4.6
Worked too much to do well academically	25	8	21	16.1

***p<.05, **.05<p<.10, *.10<p<..18

Additional realities noted by the students:

- Female: I am looking forward to doing better. I learned how to network with other students. I met a lot of students at METS
- Female: It's not as bad as I thought
- Female: Tenured profs love PowerPoint
- Male: Family related
- Male: I did really well
- Male: Many resources don't really help
- Male: Requires much more responsibility on the part of the student in order to succeed. Teachers do not baby you through a course.

These comments are thoughtful reactions to transferring and will be included in the next survey. More research is needed to understand what "resources" did not help.

III. Analysis

Top expectations and realities for transferring from a CC to a university were the same, in general, for both females and males. However, since inequities for women are often slight, we look at the main differences in transfer expectations and realities for females and males. Table III gives the main differences and their significant value.

Table III. Significant transfer expectation differences by gender

Expectation	P-value	Fisher exact
**Expensive parking	.066	.108
**Long commute	.069	.110
*ASU is large	.104	.170
*Pace of classes is much faster	.111	.170
*Classes have more homework	.115	.121

*** p<.05, **.05<p<.11, *.11<p<..17

In all five of the significant transfer expectation differences by gender, a higher percentage of females expected to encounter the event than did percentage of males. Expensive parking was expected by 75% of the females and only 56% of the males. The long commute was expected by 67% of the females and 47% of the males. The class pace was expected to be much faster by 63% of the females and only 45% of the males. A higher percentage of females (29%) than males (22%) expected the university classes to have more homework. We are using .11<p<.17 to note that this characteristic may indicate a trend that females have more concerns in these areas than males. However this higher expectation could also mean that females are more prepared to encounter these events at ASU.

Table IV lists the primary differences by gender in regard to the realities that the students faced after they had transferred to ASU. All of the significant differences are due to the females noting an event at a higher percentage than males, except for the first reality, higher tuition. In this case, 90% of the males noted the higher tuition, but only 67% of the females.

Table IV. Significant transfer reality differences by gender

Reality	P-value	Fisher exact
***Higher tuition	.023	.009
*** UD classes are harder	.044	.034
**Took too many credit hours to do well or due to work	.070	.067
**All of the easy classes already taken (non-engr.)	.078	.059
*Overwhelmed with classes/logistics	.167	.174

***p<.05, **.05<p<.10, *.10<p<..18

Forty-two percent of the females found that upper division classes are harder than lower division classes, while this was true for only 25% of the males. Similarly, 42% of the females said that they were taking too many credits relative to their work load, while only 22% of the males said so. A higher percentage of females (38%) noted that all of their easy (non-engineering-related) classes had been taken relative to only 24% of the males. While 39% of the males were overwhelmed with classes and logistics, 54% of the females were overwhelmed. These differences may be some indication that female transfer students have a more difficult time adjusting to the transfer.

It is interesting to also check if any of the realities were either more or less a factor for students than the expected. If we use a pairwise test to see if the number of females who selected an event as expected is the same as the number of females who selected that event as reality, there is no significant difference as a whole. There are, however, a few differences that are worth noting. On the other hand, with a p-value = .012, there is a difference between the percentages of men selecting the events as expected or as reality. We note the major differences in Table V.

Table V. Noted differences between expectation and reality

Event	Expectation #	Reality #
Females: Have a friend/mentor	1	9
More assigned homework	7	12
GPA may drop for transfer	12	9
Pace of classes is much faster	15	12
Males: Had a friend/mentor	4	29
More assigned homework	21	43
ASU is large	47	64
Pace of classes is much faster	43	52

Interestingly, the females and males share three events where reality seemed to be somewhat different than expectations. The largest difference for all of the students was that more of the students had a friend/mentor to help them than had expected to have one. More females and males found that there was much more homework assigned in classes at the university than had expected this before transferring. More females expected there to be a drop in their GPA than actually experienced this. More males found ASU to be very large than had anticipated this as a factor before they transferred. Both females and males found the reality of the pace of ASU classes to be somewhat different than they expected, however less females found this to be a reality, while more males found it to be so. Perhaps females had a more realistic view of university classes or had overestimated the actual pace of the classes before they transferred.

IV. DISCUSSION

Six of the top 8 expectations/fears of transfer by both females and males are all realties of the largest university in the nation with over 73,000 students and the largest single campus in the nation with over 53,000 students. These items are: higher tuition, expensive parking, large classes, a large campus, a long commute, and difficulty parking. It is a fact that the tuition at CCs is much lower than the tuition at four-year schools and universities. There is a wide range of tuitions among public and private institutions. ASU, as a public Research I university, actually has one of the lower tuitions in the nation and has been touted as a good bargain for schooling. However, Arizona is a leading state in the nation for a low percentage of families being able to afford tuition for their children. [17] An estimated over 90% of the transfer students that come to ASU have unmet financial need. We are well aware of this and realize that transfer students often are attending ASU on a combination of scholarships, grants, and loans. In order to help with this, our program has $4,000 scholarships which, at the present time, pay for about 40% of the tuition. We also encourage students to do internships and paid research positions as a way to help finance their education, as well as assist their academic and professional development.

We work with the students on resumes, elevator speeches, how to work a career fair, interviews, portfolios, and a research paper. We alert the students to the career fairs held at ASU, the informational sessions held by companies on campus, notices of possible internships or research opportunities such as the NSF Research Experience for Undergraduates, and having industry speakers with graduate engineering degrees come and speak in the Academic Success and Professional Development Class.

Although paying for an undergraduate education is difficult for most of the transfer students, still, from day one, we encourage them to go directly to graduate school. Industry is becoming more and more high tech and there are many high tech industries in Arizona which are interested in hiring engineers with a Master's or PhD degree. The students in the program hear from a panel of graduate students who have gone through the program. The graduate students in the program encourage the undergraduate students and give them confidence that they, too, can do graduate school. The graduate students also explain that they did not feel that confident about their field with a Bachelor's degree, but during the Master's program they did become more confident in their field. We want the students to find an area in which they are interested and excited and to do research in that area. If a student knows what they are interested in, they can better choose the companies for whom they would like to work. If the new engineer does not choose their area of interest, someone else will choose for them.

The next set of transfer realities include mostly items for which little can be done to change the situation: ASU is large, parking is expensive, some classes are very large, parking is difficult, and the commute may be long. ASU is large and some classes are large, although the higher the level of class, the smaller the size will tend to be. We have tried to make the campus seem smaller by having a METS Center where the students can gather, network, study, use a computer, and work in a study group. In addition, there are always two or three transfer students working in the Center who are available as informal counselors. A Center Director with a Master's degree in engineering and an MBA is also available to help students. We also keep the meetings of the Academic Success and Professional Development class smaller than 30 so the students can network, learn that others are having problems and learning how to overcome them, find study group partners, and become acquainted with other engineering students. Parking difficulty, parking prices, and a long commute are items that we cannot change. Since students at the community college usually have adequate and either free or low cost parking, the parking situation at a large university is a challenge. The long commute may be due to the students who continue to live where they did when they went to the community college. Further investigations needs to be done to see if there is a correlation between those students that have a long commute and those students who have dependents and were not able to easily more nearer to the campus.

The METS Center was included in the top eight transfer realities for both females and males as helpful with their transfer. We are glad that the students are finding that the Center is of help since that is the major reason for the Center's existence. The "pace of classes is much faster" and "overwhelmed with classes/logistics" are addressed with the 4.0 Plan. [15]The time management part of the 4.0 Plan should help with classes and logistics, while the 4.0 Plan for learning, should help the student with a faster paced course since the student will have read the material before class.

The rest of the transfer realities fall into five broad categories: academics, feeling like a freshman all over again with a GPA of 0.0, not knowing where resources are, being lonely or finding it hard to get into a study group, and working too much. Using the 4.0 Plan with our Academic Success Plan has made a big difference for scholarship students. In the Fall of 2010 we tested the effect of the 4.0 Plan and found that the new scholarship transfer students with the 4.0 Plan did not suffer any GPA transfer shock. There was no statistical difference in their first semester transfer GPA and their GPA when they left the CC. On the other hand, the other transfer students in their first semester in engineering averaged about a .45 grade drop.

Having successful transfer students available at all times in the METS Center provides transfer students with a resource: someone who can answer their questions or find someone who can. An example is a new transfer student bemoaning the fact that knowledge of MATLAB is required in a course they are taking and they have never had MATLAB. A METS Center staff could tell the student where to find a good tutorial for MATLAB online that can easily be done in a few hours. Of course, the transfer student in trouble has to ask for help. We try to anticipate a lot of the questions and give answers in the FSE 394 class and we also have over 100 critical questions and answers on line on our website www.mets.engineering.asu.edu. Also to help students academically, we have a free tutoring program available upon request. If a student needs help with tutoring, we try to find a volunteer tutor to help them. Two additional tutoring sites exist for engineering students.

We urge students to spend as much time on campus as possible and to either create or join a study group for each class. Study groups usually meet on campus and so spending more time on campus and being in a study group go together. We encourage students to find someone else in the Academic Success class for a study group so they are working with someone else who wants to achieve. A tip for students working into the early evening is to stay at work for an extra hour or two and to finish the homework so that when they return home, the homework is finished and the student can spend time with their family or doing other things. It is difficult to come home from work, relax, and then start homework.

We know that it is easy to feel lost or lonely on a large campus. We encourage our students to study in the METS Center and to get to know other students at the same time. We also encourage the students to join two student organizations: one in their major such as IEEE or ASME, and another such as the Society of Women Engineers, the American Indian Science and Engineering Society, the National Society of Black Engineers, or the Society of Hispanic Professional Engineers. The students are encouraged to slowly become involved in the organizations and to later take a leadership role. Industry wants to hire engineers who are not only good students academically, but also students, who are leaders, can work in teams, and like to work with others.

Working too much is a continual problem with transfer students and seems to be increasing in the past couple of years. Some students worked full-time and attended a CC full-time and were able to do so with over a 3.0 GPA. However, this does not work at the university. The students are warned that if they want to be a full-time student, they should work no more than 20 hours per week. However, each semester there are students who believe that this rule does not apply to them and they will be able to pull this load and still do well academically. Unforeseen increases in the workload per week can "wreck havoc" on a student's academic program. For example, a student who was working 20-30 hours per week was suddenly told that he must work 40 hours per week because another employee quit and product needs to get out the door. The student was responsible for a family with children and had to work. Soon the student, working full-time, dropped out of school rather than risk very low grades. Loans are a possibility for some students and students in the success class are students are told that there are two good reasons for a loan: to buy a house and to invest in their engineering education. Some students are not willing to go into any type of debt and some students are already up to their loan limit. In over 11 years of doing these programs, the author has seen only one student who has been able to work full-time (in an engineering position), be a student full-time, and do well academically. The female student is married, but has no children. She claims that it was difficult to do at first, but that now she has her schedule set to accomplish this. It is not easy.

V. CONCLUSIONS

In the surveys that have been done with transfer students for over 10 years, this is the first time that any gender differences were noted. Perhaps part of this was due to the fact that the numbers were small and it was difficult to make any conclusions. Although in general, the top expectations and realities of transfer were the same for both genders, several differences did emerge.

Females seemed to expect more challenges upon transfer than males. Only three challenges were identified by more than 50% of the males: higher tuition, large classes, and expensive parking. Eight challenges were identified by more than 50% of the females. The additional five challenges were: a long commute, pace of classes is much faster, ASU is large, difficulty parking, and their GPA may drop.

Females appear to experience more challenges upon transfer than men. There was one area that was statistically significant at $p<.05$: upper division classes were harder than expected. Three areas worth considering as troublesome for females is having a combination of too many credit hours and too much work, being over whelmed with classes and logistics, and that most of the easy non-engineering courses have already been taken, .making the rest of the classes harder. The additional work of the females may have involved family responsibilities. In general, the females had more commute time than the males, which could account for some of the overwhelming with classes and logistics.

These additional females concerns are all items for which help can be given by proper course selection, following the 4.0 Plan, being in a study group, being involved in student organizations, and perhaps reducing the work load. We urge others to survey their transfer students to see if there are areas of concern for which the university can help ease the challenges, including transfer shock.

Additional study will be done to discern if there is a difference between transfer students from non-metropolitan CCs and transfers from metropolitan CCs. We will also investigate if there is a difference in the perception of transfer by students who hold the $4K scholarship and those students who do not.

Thanks go to Mr. Carlos Flores who set up the survey online and assisted with the data analysis.

***Abstract*—Sixty-one sophomores were interviewed at six large public institutions to learn why they chose their institution and their engineering major. The institutions were categorized as either requiring a first-year engineering (FYE) program or allowing students to matriculate directly into a major. At these institutions, the first-year experience either required a common introduction to engineering course, required introduction to engineering courses that were not common to all majors or included an optional introduction to engineering course. The impact of the matriculation mode on selection of the institution and the presence or absence of a required first year course are studied. We find that cost of attendance is far more important than matriculation mode for most students choosing their institutions. Required and optional first-year courses, when taken, do tend to help students either affirm their prior choice of major or select an engineering major that suits their interests.**

Keywords—institution selection, major selection, first year programs, introduction to engineering courses

I. Introduction

A. Background

A taxonomy has been created that categorizes the 390 ABET accredited undergraduate engineering programs into nine distinct categories based on 1) whether students are admitted directly to an engineering major concurrent with institutional admission or whether they must pass certain academic hurdles before being admitted to an engineering major and 2) whether an introduction to engineering course is required or optional in the first term of enrollment for all majors [1]. Related work was undertaken using the Multiple Institution Database for Investigating Engineering Longitudinal Development. MIDFIELD contains student record data for 977,950 unique students, 106,000 of whom entered the college of engineering as first-time-in-college (FTIC) students (not transfers) at eleven public institutions in the U.S. from 1987/88 to 2009/10 academic years for whom there were at least eight semesters of data. This work has shown that students who are required to take a common introduction to engineering (CITE) course in their first term of enrollment are more likely to graduate in engineering and in the first engineering major that they declare than students who are not required to take a CITE course. This phenomenon occurs whether they matriculate directly into their engineering major or wait, either by their own choice or institutional requirements, to choose a major [2].

MIDFIELD institutions fall into three of the nine categories identified in the taxonomy – Direct Matriculation-all with a required introduction to engineering course in the first term for all students (DMa), First-Year Engineering (FYE), and Direct Matriculation-partial where an introduction to engineering course is required in the first term for some, but not all, majors (DMp). Those three categories encompass 64% of all undergraduate engineering institutions in the U.S. and 81% of the engineering students. The dynamics of selecting an engineering major at or after matriculation are particularly important in light of the fact that very few students switch into engineering after matriculating into non-engineering majors [3]. Combining recent findings that introductory engineering courses appear to improve persistence and reduce the number of times a student changes majors [2] with other work that indicates that each time a student changes majors results in a concomitant delay in the time to graduation [4] accentuates the need to understand the process of selecting a specific engineering major. Although previous research has studied the fraction of students selecting different majors within engineering [5], those studies have been mostly quantitative. The present study adds a qualitative component to the literature on this critical issue.

B. Selecting an institution, engineering, and a specific major

Institutional choice has been studied extensively and in detail, and continues to be studied given the likelihood that generational differences change the dynamics of institutional choice. Recent work disaggregates traditional students [6] from non-traditional students [7], since the two groups use different criteria to make their selection. Earlier work summarizes a range of factors that influence why students choose engineering [8]. The selection of a specific engineering major is less studied, but prior research provides some important clues that the design of an institution's first year of engineering influences this decision [2], [5].

C. The current study

MIDFIELD is not only a database, but also a long-lasting, diverse partnership of researchers and data providers. To shed light on why students choose engineering and their particular engineering major, 61 sophomore students who entered as FTIC students were interviewed at six of the MIDFIELD partner institutions. Half of these schools require students to take a CITE course and the other half offer introduction to engineering courses but either do not require all students to take them or do not require all students to take the same course. In the taxonomy that has been developed, two of the schools are FYE, two are DMa, and two are DMp [1]. Table 1 shows the matriculation model and presence of a common introduction to engineering course at the study institutions. Pseudonyms are used for the institutions to protect the confidentiality of the students who were interviewed. Note that at F-State, although all majors require an introduction to engineering course, they do not all require the same one and there are many options from which students may choose.

TABLE I. MATRICULATION MODEL AND CITE STATUS OF STUDY INSTITUTIONS.

Institution	Matriculation Model	CITE
A-State	FYE	Yes
B-State	DMa	Yes
C-State	FYE	Yes
D-State	DMp	No
E-State	DMp	No
F-State	DMa	No

Our research questions were:

1. Why did students choose their institution?
2. Did the matriculation model of the institution affect the students' decision to choose that institution?
3. Why did students choose their engineering major?
4. Did an introduction to engineering course, if taken, affect the students' choice of major?

This material is based upon work supported by the National Science Foundation (NSF) under Grants 1025171. The opinions expressed in this article are those of the authors and do not necessarily reflect the views of the NSF.

II. METHODS

A. Gathering information on the matriculation process

A person in the engineering college on each campus with access to email lists of second year students was asked to send an email to students in their second year. The list was restricted to those officially majoring in civil, chemical, computer, electrical, mechanical, and industrial engineering as well as those who were still officially in an FYE program or who were in an engineering undecided or unmatriculated category. Unmatriculated students have expressed a major preference but have not yet met the requirements to matriculate in their major of choice. The email invited students to click a link that would take them to a qualification survey on Survey Monkey™ [9] which asked for contact, demographic, GPA, major, and scheduling availability information. At each campus, 8-12 students were selected to be interviewed with an additional 8-12 students chosen as alternates. The selection criteria were the following:

- At least 3 majors represented plus FYE/undecided/unmatriculated
- At least 2 women
- At least 2 underrepresented minorities
- At least 2 excellent students (>3.5 GPA)
- At least 1 fair student (<2.5 GPA)

Selected students were interviewed in the Fall of 2011, Spring of 2012, Fall of 2012, and Spring of 2013. Students were generally first or second semester sophomores The interviews were semi-structured in nature, using predetermined questions but allowing the interviewer to follow up where appropriate. Students were asked about their decision to attend their school; why they chose engineering in general and their particular major; the influence of the matriculation model at their school (FYE or DM) on their choice of school and of major; the influence of the first year in general on their choice of major; other influencers of their choice of major; planned major for those still in FYE or undecided; and reasons for remaining in FYE or undecided, if applicable. Students who completed the interview were paid $20 for their participation. We then engaged in open coding of the interview transcripts to identify themes related to our research goals.

B. Interview Sample

Table 2 shows the sex, race, and major of the study sample at the time of the interview. The interviewed population was 37% female and 40% non-White, oversampling female and non-white students relative to their population at the institutions and in the selected majors. Females comprise just less than 20% of students in the selected majors and Whites make up 79% of that population. We oversampled women and minorities to make it possible to draw inferences based on gender and race within the relatively small population of interviewees. The interviewed population likewise somewhat oversamples the number of students in industrial, mechanical, civil, and chemical engineering at the third and fourth semester in MIDFIELD and underrepresents computer, electrical, first year, and undecided engineering.

TABLE II. SEX, RACE, AND MAJOR OF STUDY SAMPLE

Race/Sex	CE	CHE	CPE	ECE	EE	FYE	IE	ME	NON	UNE	Total
White Male	3	4	1	1	3	2	2	7		2	25
White Female	3	3				1	1	3	1		12
Asian Male		1	1		1			1		2	6
Hispanic Female		2						3			5
Black Male		1				1	1			1	4
Asian Female					1		2				3
Hispanic Male	1	1					1				3
Black Female	1						1				2
Other Male					1						1
All Male	4	7	2	1	5	3	4	8	0	5	39
All Female	4	5	0	0	1	1	4	6	1	0	22
Grand Total	8	12	2	1	6	4	8	14	1	5	61

III. FINDINGS

The initial analysis has illuminated themes about why students selected their institutions and engineering majors. Quotations have been modified to improve readability by deleting verbal crutches, such as "um" and "you know" and false starts. As indicated earlier, we have assigned pseudonyms to the MIDFIELD schools (A-State, B-State, C-State, D-State, E-State, and F-State) and some of the competing institutions (e.g., University of A) to which students also applied to enhance readability while maintaining institutional confidentiality. Each letter represents a different state so A-State and University of A are in the same state, as is Private A. A school with a national reputation is called Famous Tech. Other pseudonyms are used for regional institutions to reflect geography and whether they are public or private. Speakers are identified by their institution (A, B, C, D, E, or F) and the order in which they were interviewed.

A. Why students choose their institution

MIDFIELD schools are all public and generally much larger than schools that offer ABET accredited engineering programs in the U.S [10]. Together, MIDFIELD schools confer more than 10% of all U.S. engineering bachelor degrees. Because many MIDFIELD schools are also the flagship engineering institution in their state, students often choose to attend these schools because of a combination of their engineering reputation, proximity, and in-state tuition.

I only considered in-state schools. …[B]eforehand I did my research on the college of engineering of those schools…and as far as University of East D, I mean I heard a lot of good things about their college of engineering, [but] I ultimately chose D-State really because of the prestige I would have to say, and its proximity to my hometown. (D4)

Due to its roots as a coalition of southeastern engineering colleges, many students applied to multiple MIDFIELD schools, but most still chose the one in their home state, although reputation, specific programs, or campus characteristics did occasionally cause students to cross state lines in spite of having to pay out-of-state tuition.

I figured there wasn't anything that C-State had offered that D-State couldn't offer that was worth that amount of money. (D2)

[Me] and my mom had a really long conversation about [giving up an in-state merit-based scholarship]. It was between, basically because Famous Tech was out of the question, D-State and E-State and we felt like E-State would give me a better degree… After you get your degree and when you get a job, and how much you'll be able to make, it's more – it's better at E-State than it would be at D-State, and especially for my major as well, engineering. Because we specialize in engineering here at E-State. (E9)

For the MIDFIELD schools that are in states that offer statewide scholarships to highly qualified students, the availability of that scholarship to pay tuition is additional incentive. Occasionally parents or students themselves will limit their choices to in-state schools when applying because of a combination of the scholarships and in-state tuition.

The only other school I considered was University of E because my sister went to [a private school] and that was $40,000 a year. And so my parents were in a good economic standing at that point. And then the economy went all bad and stuff, and they were kind of like "We don't want to do the whole $40,000 a year school." So I lived in State E. I live about 15 minutes away. (E2)

Well, I wanted to do chem engineering and my dad told me I needed to stay in state and there are only two schools that are public that offer it – University of C and C-State. I don't really care for University of C so C-State was it. (C11)

More often, in spite of considering schools out of state or private institutions, the student will choose the MIDFIELD school in state because of the cost.

And then Private A did not have a chemical engineering program and Private Tech was too expensive so I came here…There are only four [engineering] schools in State A, I found out. A-State is the closest, basically…[and] a lot more reasonably priced…A-State is probably the best reputation to cost. So, good education for not 2-1/2 times the amount of money. (A3)

B. Impact of Matriculation Model on Institution Selection

The vast majority of the students interviewed did not know at the time they were applying what the matriculation model of their school was. For most of those who were aware of the model, either at the time they applied or sometime after, the matriculation model did not affect their decision to choose that institution – cost was a much more important consideration. Of the 20 students interviewed at FYE institutions, six indicated that they knew in advance about the FYE model and it was attractive to them because they liked the structure, liked having time to decide, and were afraid of getting stuck in a major that was a poor fit.

When I first heard about it, I [thought] it must be very organized, very structured. They want all students to have a basic foundation. I really wanted to do it. (A6)

[The FYE program] is why I chose A-State over Nearby State U. Because Nearby State, when you first go in, you go in as a ME…So here it gave me a chance to see them all before I got into it. So I would say that was – I guess that it was a big factor but that's why I didn't apply to Nearby State. (A9)

[The FYE program] was something I was interested in…because I thought I wanted to do mechanical engineering because I did First Lego Robotics [sic] all through elementary school and then coached it in high school. But I didn't want to get stuck in something if that wasn't what I was really interested in. (C4)

The students at the two DMa institutions had different perspectives on the effect of the matriculation model on their choice because B-State has a common introduction to engineering (CITE) set of courses, the passing of which are required to advance in the declared major, while F-State, though requiring all students to take some form of introduction to engineering, has a variety of those courses from which students could choose. Students at B-State were generally unaffected by the matriculation model when they were choosing schools. In contrast three of the 10 students interviewed at F-State indicated that it was important to them to be able to choose their major up front so that they could get right into their major studies. One student who had also applied to C-State indicated that he would have preferred the FYE model but other attributes of F-State made it more attractive.

I was pretty set on chemical engineering coming in. My parents tried to persuade me out of it; they're both chemical engineers. And, I was pretty determined about it. So I think that was – it was nice to be in the program to start with and not know that I had to, you know, apply my sophomore year. And what if I didn't get in? (F4)

C. Why students choose their major

The different engineering disciplines attract students for different reasons. Civil engineers like infrastructure, including roads and water systems. Students who switched to civil from environmental engineering indicated that they did so in many cases because of the lower chemistry requirements. The reasons students most often cite for choosing chemical engineering is an aptitude for chemistry and math and often a dislike for physics. Chemical engineering students also mentioned earning potential more than other majors and an initial desire to attend medical school. Many of the students who chose electrical and/or computer engineering were exposed to it through robotics competitions in high school. Six of the nine students in these majors reported having a family member who is an engineer, the highest percentage of any of the majors. Industrial was the major chosen most often by students who entered undecided or from another discipline. Two switched to industrial engineering from biology, one from a smaller engineering discipline, and one from undecided engineering. Mechanical engineering students cite the breadth of the field as a key reason for choosing it. More students in this discipline indicated that they enjoy working with their hands than students in other fields. These students also tend to prefer physics to chemistry.

Many students decided on their engineering major in high school or even earlier. Others, believing that their aptitude for math and science made engineering a good choice for them, were less sure of their specific major when they entered the university. FYE programs are designed to force students to wait to declare a major until they have been exposed to their options in engineering. Other students entered their institutions with an undecided engineering major, voluntarily taking extra time to decide. Students at DMa and DMp institutions are free to declare a major when they enter the institution, and the majority do so. However, of the students interviewed, only a third (12/36) were in the same major at the time of the interview during their sophomore year as they declared when they entered the institution. Some of these students changed majors the summer before their first year or immediately on arrival after further research between the time they were accepted and the time they enrolled. More often, however, there was something about the first-year experience, particularly introductory courses, that had an effect on the students' sophomore major.

People who entered undeclared were much more likely to be female and non-White – of 10 who entered undeclared, 4 were female and three of those were Hispanic. Of the six men, 3 were Asian, 2 White, and one Hispanic. All of those who were still undeclared at the time of the interview were male which may indicate that the undeclared time period is more helpful for placing women in majors than men. The four students who remained in an undeclared engineering status, were academically capable, with three of them reporting GPAs in excess of 3.0. The fourth faced a personal situation that caused his grades to suffer and was not allowed to declare a major until his grades improved. The other three indicated that they were having difficulty selecting a good fit or "wanted to be sure" before committing. They seemed to find multiple disciplines attractive and were having a difficult time making a decision.

I'm leaning towards materials. It's funny because for the longest time, I was like going back and forth between a lot of different fields. [P]eople I talked to they would get confused 'cause you know one day I said I'm going to do this, and then like a few weeks later I said I wanted to do that. But, yeah, I think going to the Introduction to Engineering, that one class where they showed – they demonstrate all of the engineering fields, I think that was really helpful. It gave me an idea rather than going to the website and reading what a field is all about, but then you know to actually have professors or Teacher's Assistants actually – they gave demonstrations and stuff rather than just giving you a lecture of what it's about. I think that was really helpful. But, even after completing that course it seemed like I still didn't have a very solid idea of what field I wanted to take. But it gave – at least it gave me like a better *idea. 'Cause like I think my real problem is that I could see myself in all of the fields, to be honest. And, to narrow it down to one field, it would be kind of a daunting task. But, I think I'll make a solid decision soon. I'm confident that it will be happening. (D4)*

Unlike most of those who still remained undeclared, the four students remaining in FYE had not declared an engineering major due to failing or never taking the required courses to declare a major.

Seven students were interviewed who began their studies in non-engineering disciplines (a few more applied to other disciplines, but changed to engineering before enrolling). Five came from other STEM disciplines – math, biochemistry, biology (2), and zoology and they chose civil, chemical, mechanical, and industrial (2). The biology and zoology majors had initially considered medicine but found that they did not enjoy those majors and decided to switch to engineering. All three were at DMp schools, as was the biochemistry major, which made switching relatively easy. The math major was at an FYE school and therefore was required to switch from math to FYE and complete the requirements before ultimately choosing the civil engineering major.

Two students came from arts and sciences undecided into engineering. One did so strategically because he was advised it would be easier to get into arts and sciences undecided than into the engineering school. He met the requirements and chose mechanical engineering. Another applied to engineering but was offered a path to engineering through arts and sciences undecided and was still in FYE at the time of the interview because he needed to complete the introduction to engineering sequence.

D. Effect of an Introductory Class on Major Selection

At the three schools where a CITE sequence was required, many of the students found the portion of the introductory course where the different disciplines were introduced to be either confirmatory of the major they were sure they wanted or it helped them find a discipline that better suited their interests and skills than what they thought they wanted.

The first year classes definitely solidified it because of the parts of the class that had to do with mechanical engineer[ing], those were my favorite parts because I knew we did electrical, computer engineering and those are the parts I didn't like, but once we got into mechanical, I enjoyed the classes. (C2)

Well, that first engineering [course] we do seminars, so they have all the colleges come in and give us a little spiel about each other. So that was when I really saw what mechanical could be for me and then what IE wasn't. So it kind of opened my eyes to if I chose mechanical, I didn't have to get stuck designing a screw or something like that. I could do multiple things with it. (A9)

I just declared [civil engineering] over winter break. It was in our first semester we learned about all the different engineering things and we went to information sessions and I think that civil interested me the most in what I wanted to do. And also…I saw helpful and nice and enthusiastic staff that it made me kind of excited. (C1)

One student, in addition to confirming his desire to major in electrical engineering added a second major in computer science based on an information session in Engineering I.

I decided on…the electrical engineering major in high school during the design class. But then, I decided on the CS major during the general engineering class we had. We had to go to information sessions. And I was always interested in computer science and I thought about getting a minor in it. But I decided I want a double major during that class, during the presentation because there are just so many more advantages to majoring than simply minoring that I learned during that presentation. (C5)

Of the non-CITE schools, D-State and E-State do not require any introduction to engineering course, but offer them for students who wish to take them. Half the students at D-State chose to take either an introduction to a discipline course or an engineering survey course, the latter being highly recommended for undecided students. One of those students took both. The undecided students who took the engineering survey course found it very helpful for choosing a major.

I took this class called Intro to Engineering where basically they take you to every department of engineering and basically tell you what it's all about. And that was when I discovered industrial engineering….[F]or me it was kind of funny because every week they'll take you to a different department. So industrial engineering was the second segment I went to. So I go there, I learn more about it, and I like automatically fall in love with it. But then there's still the rest of the class, so week after week, after week, it was just kind of like, I don't like this, I don't like this, I don't want to do this with the other majors. So, I think for me it just had a big impact because it really helps me see what it was I was interested in. (D2)

The only student to take it at D-State who was not undecided found, much like students at the CITE schools, that it reaffirmed his interest in civil engineering.

[Intro to Engineering] reaffirmed that I wanted to do civil. So, civil was the most interesting. And then, the other ones, they were interesting [but] I just couldn't see myself doing them. (D7)

F-State requires all students to take at least one introduction to engineering course, but there are a variety from which to choose including introductions to the specific disciplines, an engineering projects course, and an engineering survey course. Half of the 10 students interviewed took the projects course and nine of the 10 took introduction to a major. The introduction to the discipline courses offered students the opportunity to learn from speakers and projects what the career path would be in that discipline and tended to make the students more sure of their choice.

I learned more about what chemical engineering was [in Intro to Chemical Engineering]. I wanted to understand what really chemical engineering was. And, going out and seeing research in the different labs, factories, or research areas it made [me] more interested to know that it's something similar *to what I've been dreaming of in a way. Because I always wanted to work in a lab. …And, when I saw that there was a lot of actual things like that, a lot of jobs that you can do with especially here in State F, that really made me interested in continuing this major. And as well as we wrote a research paper on a choice of medications. And, I researched Ibuprofen and … I found that really interesting and knowing that this is something that I can also do in the long run, this is another option that I can get into or maybe one day find a drug that will somehow help others. But other than [that], it was more of just understanding what chemical engineering was about. …And professional speakers that came to speak with us, I feel like they were the people that encouraged me the most to continue because I wasn't doing really great in my classes GPA-wise and they had told me that grades didn't really matter. At a point they do, but it was more about what you did in college, and the outside things that you did for the college, or for yourself that count the most. And, when I heard that I mean it made me feel more willing to continue even though I was struggling. …And, that to me was what made me continue doing chemical engineering as well, and inspired me. And that's what I really liked about the class the most. (F9)*

One student knew that her career goal was to work with water systems, but after one day in introduction to environmental engineering, realized that the civil engineering major was more suited to her goal and immediately switched to the civil engineering major and the introduction to civil engineering class. Introduction to mechanical allowed students to work in a machine shop with hands-on projects and confirmed their desire for that major when they were not completely sure that was what they wanted to do when they arrived.

I took an Intro to Mechanical Engineering class and it was just, using a lathe or a mill and we made like this bottle opener out of a puck of aluminum. And so that was really cool because it was really hands-on and it was just cool to see what you could do....And you know, in a couple of weeks we made this cool little simple thing, and it's like well imagine what you could do with you know four years and then after that. And so that was probably a deciding factor too. (F3)

IV. Conclusions and Limitations

A. Conclusions

In this paper we have asked why students chose their institution and their particular engineering major and what the effects of the institution's matriculation model and related common introduction to engineering courses were on that choice. We find that, for the most part, students were unaware of the matriculation model when they applied to their institution or, if they were aware, that it was not influential on their choice. Cost of attendance was a much more important factor and tended to influence students to choose engineering schools in their home state. The presence of statewide scholarship programs was another influential factor for students staying in-state in the states that have such programs, but had little impact on the decision to major in engineering, as has been found elsewhere [11].

There is relatively little prior research on why students choose between engineering majors. Most research to date has focused on why students choose engineering as a whole or on single disciplines (e.g., [12], [13]). This study has shown that many students choose engineering or a particular discipline because of experiences before entering college, but that the first-year experience in an engineering program, particularly an introduction to engineering course that includes a survey of available disciplines, affects them by either confirming their prior notions of the suitability of a particular major or giving them the information needed to make an informed choice of a different engineering major.

Many students decided to major in engineering during high school and some settled on a major at that time. Still, the majority of those interviewed who were allowed to declare a major when they entered their institution, changed majors. Women were more likely to come into engineering as undeclared, even when they could make a choice, but once they had the information they needed, they declared a major; some of the men appeared to have more difficulty making up their minds.

Students who enter engineering majors from outside of engineering are relatively rare [3]. In this study, most of those that did came from other STEM majors, which Ohland et al. found was the more likely path for that small group. A couple came from arts and sciences undecided either by their own choice or the institution's, demonstrating that the pathway is viable for students who may need to prove themselves to the colleges of engineering to be admitted.

B. Limitations

The criteria set forth for selecting students to be interviewed lead to an inherent selection bias which means that quantification of the findings may not necessarily be representative of sophomores as a whole. Smaller majors were purposely excluded to determine if there were any commonalities among the larger majors.

V. Acknowledgement

The authors would like to thank Sandi Bramblett, Richard Layton, Kay Leager, Donna Llewellyn, Deborah Mayhew, Erin Shealy, Mary Steiner, and Bevlee Watford for their assistance.

***Abstract*—This paper describes a comprehensive academic success and professional development (ASAP) framework that has been developed within Arizona State University's (ASU's) Ira Fulton School of Engineering over the past decade. Centered around an ASAP class offered each semester, with need-based scholarships serving as incentives/facilitators, the success of the program has been tremendous – with retention and graduation rates for participating scholars exceeding their counterparts at ASU and at other universities across the nation. Program activities, lessons learned and strategies moving forward are discussed within the paper.**

Keywords*—*academic success and professional development (ASAP); engineering scholarship programs; research projects; life-long learning; graduate school; student-centered mentoring

I. Introduction: Motivation And Summary

Motivation: Issues and Challenges Facing the Nation. As the rate of technological progress continues to soar, the need for highly trained engineers has never been greater. To meet anticipated future technical demands, the nation requires many more engineers. Traditionally, this demand has been addressed, in part, by recruiting talent from around the world. While this approach is expected to remain a critical component of the nation's strategy, it's now widely accepted that the nation must recruit and develop talent from within. This is because a highly trained engineering workforce is essential to fuel innovation, remain economically competitive, and ensure national security. Moreover, it's not healthy for large portions of the population (e.g. women/underrepresented minorities) to be left out of areas of national importance.

Summary. In an effort to address the above, exacerbated by an alarming disinterest in STEM and falling math-science scores, we describe a comprehensive framework for significantly increasing the number of highly trained engineers entering the STEM workforce. This framework has been developed over the past decade at Arizona State University's Fulton School of Engineering. Central to the framework is an Academic Success and Professional Development (ASAP) class that has been offered to lower-division, upper-division, and graduate students participating in one of our NSF funded (CSEMS, S-STEM, STEP) scholarship programs [1]-[18].
The main purpose of the ASAP class – offered each semester – is to expose our selected scholars to time-tested student-centered instructor-driven methods/techniques to help students (1) succeed academically, (2) discover, develop, and nurture their technical passions, and (3) develop essential skills to prepare them for life-long-learning and to enter a highly competitive global STEM workforce which offers a wide range of exciting career opportunities.

While we have strived to provide leadership with respect to nationally practiced ASAP activities, we certainly have built and continue to build upon the successes of others [19]-[37].

The remainder of the paper is organized as follows: Section II describes ASU's institutional setting. Section III provides an overview of ASU's ASAP program. Section IV provides an overview of the student-centered activities covered in the associated ASAP class. Section V provides a summary of Program Results. Section VI provides strategies moving forward. Finally, Section VII summarizes the paper and provides directions for future work.

II. Institutional Setting

The following summarizes ASU's institutional setting:

- ASU is the largest public university in the nation (with over 72K on all of its campuses; over 60K on the Main Tempe campus)
- ASU is a Carnegie Research I University
- Fall 2012 engineering enrollment exceeded 8,700
- This included 1,500 first-time freshmen and 2,800 graduate students
- Research expenditures for FY 2012 was \$77.6M
- 235 tenured or tenure-track faculty
- ASU is situated within the Phoenix metropolitan area. As such, it is surrounded by a very broad industrial engineering-centric base – one which offers ASU's engineering students many great opportunities; e.g. internships, mentoring, jobs, etc.

This work has been supported, in part by NSF S-STEM grants: 0728695, 0807134, 1060226, NSF STEP grant: 0856834, and by a 2012 grant from Women & Philanthropy. See references [1]-[18].

III. OVERVIEW OF ASU'S ASAP PROGRAM

A. Students Served By ASAP Program

ASU's ASAP program serves students across the Ira Fulton School of Engineering. (In this paper, when we write engineering, we mean it to include computer science as well as computer systems engineering.) Our program directly serves freshmen through seniors as well as first and second year graduate students.

Recently, over 30 lower-division students (freshmen and sophomores) and over 80 upper-division students (juniors, seniors, first and second year graduate students) receive our full $4K scholarship (per year). Per NSF requirements, these students are <u>academically-qualified and financially-needy</u> (as determined by their submitted FAFSA form). The above includes transfer students as well as traditional students. Another 30 or so students, receive $300 incentives to take the ASAP class. As word of our program has spread, many students have decided to take our ASAP class. With ASU institutionalizing a version of our ASAP class for transfer students, we expect this trend to continue. While we have served up to 200 students in a year, we are certainly not able to support all of ASU's academically-qualified financially-needy students that wish to become engineers.

Finally, it is important to note that over 60% of our scholars are women or underrepresented minorities.

Recruitment of ASAP Students. We aggressively recruit our scholars from community colleges and high schools across the state of Arizona as well as from within ASU. Freshmen are specifically recruited via ASU's Presidential Award winning Joaquin Bustoz Math-Science Honors Program (Cynthia Romero, Senior Coordinator). Periodic visits are made to and from rural community colleges (CCs) situated far from ASU (3-4 hour drive, one way). An NSF STEP grant supports this activity with partnering CCs: Arizona Western College, Central Arizona College, Cochise College, Eastern Arizona College, Mohave College. We visit each of these schools each semester. We hold sessions with students (typically 20-30 at a time) to discuss the many exciting opportunities that an engineering career can offer. After our visit to the partnering CC, they visit ASU (typically with 10-15 students). The students spend a full day on the ASU campus – having planned seminars on transfer issues, financial aid, as well as engineering opportunities. The students get a chance to visit labs, meet with professors, and meet with students that made the transition from their CC.

B. ASAP Faculty, Staff, and Support

The authors (Drs. Rodriguez and Anderson-Rowland) run ASU's ASAP Program. Both have an extensive background with respect to managing ASAP programs [1]-[18]. Both have managed NSF S-STEM, CSEM, STEP and other grants (e.g. Women & Philanthropy). Both have received numerous awards for mentoring, education and research.

Participating scholars/students use two (2) facilities:

(1) METS (Motivated Engineering Transfer Students) Center

(2) Intelligent Embedded Systems Laboratory (IeSL)

Over 400 students use the METS Center each year. The METS Center Director, Anita Grierson has an MS in Mechanical Engineering as well as an MBA. She helps administer the upper-division program as well as providing one-on-one mentoring to participating ASAP scholars.

The METS Center is staffed by former ASAP scholars. These students further provide assistance to participating ASAP scholars/students. Ideas from [33]-[34] provide the foundation for "students-helping-students."

Both facilities (particularly the METS Center) serve as a home away from home for the students. The *IeSL* provides a place for students to work on projects at any time day or night ("24-7").

Cynthia Romero (Senior Coordinator, Joaquin Bustoz Math-Science Honors Program) has assisted Dr. Rodriguez in administering the lower-division program.

C. Guiding Principles

Our ASAP program is based on the following guiding principles:

(1) <u>*Financial Support*</u>. Many students need financial support. Without it, they cannot focus on their studies. Without it, many are forced to take on low paying time-consuming jobs that detract from more scholarly academic pursuits.
(2) <u>*Mentoring*</u>. Student-centered mentoring by program faculty is critical. Many of the students, particularly women and underrepresented minorities have lacked role models. Even some of the very best students lack essential role models as well as critical technical/career perspective and confidence.
(3) <u>*ASAP Activities*</u>. Students require assistance with their academics as well as professional development.
(4) <u>*Life-Long Learning and Global Economy*</u>. Students must understand the importance of life-long learning and the increasingly competitive global economy.
(5) <u>*Participating in Ongoing Technological Revolution*</u>. Students must be encouraged (and shown how) to

participate in the ongoing and increasingly accelerating technological revolution.

Financial support run our program (i.e. provide scholarships, pay staff) has been provided by NSF as well as other organizations/companies. (2)-(5) are directly addressed within our ASAP class.

In an effort to further articulate our educational philosophy, we find it useful to cite the work of Vincent Tinto, a well-known Distinguished Professor of Education (Syracuse University). He has been concerned with the retention of college students since the 1970's [35]. His most cited work is [36]. His most recent book [37] carefully delineates what students need in order to stay in college and graduate. His four main principles are as follows:

(1) *Expectations.* High expectations are an essential (necessary) condition for student success.
(2) *Support.* Without academic, social, and in some cases, financial support, many students, especially those who enter college academically underprepared, struggle to succeed.
(3) *Assessment and Feedback.* Students are more likely to succeed in institutions that assess their performance and provide frequent feedback in ways that enable students, faculty, and staff alike to adjust their behaviors to better promote student success.
(4) *Involvement (Engagement).* The more students are academically and socially engaged with faculty, staff, and peers, the more likely they are to succeed in college.

Our ASAP program has been aligned with these four principles since its in 2000.

Web Sites. Our program is supported by the following web sites – sites that are still under development:

http://aar.faculty.asu.edu/lapdp.html

http://mets.engineering.asu.edu/

The latter site has been designed to specifically address the needs of transfer students from CCs. Such students often suffer a GPA transfer shock when transferring from a CC to a 4 year school. This is not the case for transfer students participating in our ASAP program.

IV. Overview of ASAP Class Activities

The ASAP class is a two (2) credit class. Program scholars are required to take the class each semester that they are on scholarship. The class is taught at two (2) levels:

- Lower division – including freshmen, sophomores, and transfers from community colleges (CCs) as well as transfers from other 4 year institutions;

- Upper-division – including traditional juniors and seniors as well as transfers from CCs, transfers from other 4 year institutions, and first and second year graduate students.

Several sections are offered in order to accommodate student schedules and to keep the class size below around 30. The classes are jointly taught by the authors – with Dr. Rodriguez assuming primary responsibility for the lower-division students and Dr. Anderson-Rowland assuming primary responsibility for the upper-division students.

ASAP class activities include:

(1) Donna O'Sullivan's Guaranteed 4.0 Learning System (http://www.guaranteed4.com/);

- This learning system addresses critical academic skills such as time-management, effective and efficient study habits, note-taking, test preparation, etc.

(2) Importance of projects to discover, nurture, and develop ones technical passions;

- The idea here is that students who discover, nurture, and develop their technical passions are much more likely to remain motivated, focused, enthusiastic, and engaged – feeling empowered by the fact that they can "see the light at the end of the tunnel;" i.e. understanding what possibilities await them when they complete their BSE.

(3) Applying for a project, research experience, internship, graduate school, scholarship/fellowship, job;

- In addition to shedding light on the various paths that students can choose, we show them how to navigate each of the paths. A critical issue here is being able to demonstrate why the path is worth taking and, more importantly, that the student is capable of getting on the path and successfully completing it. Often, some of the best students lack critical perspective and confidence.

(4) Critical questions that students need answers to;

- It is well understood that students will have to answer or get answers to many critical questions as they progress academically and professionally. To assist students with this, we have compiled a list of 139 questions at:

  http://aar.faculty.asu.edu/critical_questions.pdf

  These questions – which are still under development – currently address each of the following 15 topics (NOTE: Numbers in parentheses indicate the number of questions currently in that group):

  I: BS in Engineering (5)

  II: Why Engineering (8)

- This includes pointing out exciting growth areas within engineering –areas that have been deemed as areas of national importance:

  http://aar.faculty.asu.edu/growth.html

III: Choosing an Engineering Discipline (13)

- This includes explaining what is “traditionally done in each of the engineering disciplines” as well as showing students the breadth of each discipline.
- Students, for example, traditionally associate aerospace engineering with “traditional” topics such as aircraft, spacecraft, propulsion systems, and (possibly) automobile design. Aerospace engineers, however, can work alongside physicians – utilizing their CFD (computational fluid dynamics) knowledge – to develop new cutting-edge sensors to detect and map out the progression of cardiovascular disease and obstructions throughout the body – a very significant contribution that traditionally is not associated with aerospace engineers!
- Traditionally, students have a tendency of viewing their chosen engineering field very narrowly. As systems become more complex, multidisciplinary engineering teams will be called upon to solve the problems at hand. As such, traditional disciplines are increasingly growing with respect to the problems they can address.

IV: Financing My BS in Engineering (8)

V: Why Pursue a BS in Engineering at ASU? (27)

- This topic has many questions so that students can become familiar with the many resources that ASU provides. The following document provides some details:

  http://aar.faculty.asu.edu/AAR_WHY-ASU-ENGINEERING_10_5_11.pdf

VI: Importance of a Mentor (6)

- We believe that one-on-one mentoring is the next critical factor contributing to student success – after financial support, personal commitment, and having a technical interest. Mentors help students answer all kinds of questions (see above). We work hard to connect students with mentors in their fields – a community of mentors. The following is a primer on finding a mentor:

http://aar.faculty.asu.edu/AAR_Finding_a_Mentor.pdf

VII: Importance of Research: Figuring Out What I Want to Do (14)

- We believe this to be one of the most important topics addressed in the class. We use research/projects as a vehicle by which students discover, nurture, and develop their technical passions. See (2) above. The following primer helps students get involved in research:

  http://aar.faculty.asu.edu/AAR_Getting_Involved_In_Research.pdf

- Here, it is important to convey the many exciting areas that exist for students to work in – areas of national importance; some representing grand engineering challenges. See (9) below.

VIII: Important Skills (16)

- Important skills include: problem solving skills, information gathering/research, data analysis, programming, modeling, simulation, virtual prototyping, writing, public speaking (may include multi-lingual to interact with customers abroad), interviewing, etc.

IX: Leadership, Service, and Professional Networking (8)

- Companies want individuals that can work independently as well as in groups. They particularly want individuals that can lead groups of people. For this reason, the following is relevant: special projects, student/professional organizations, community service, tutoring, going to conferences, etc.

X: Importance of Graduate School (5)

- The importance of graduate school is even addressed for incoming freshman. The following document describes writing a statement of purpose – something students must do for many activities; e.g. graduate school, scholarships, fellowships:

  http://aar.faculty.asu.edu/AAR_WRITING-A-STATEMENT-OF-PURPOSE-10_14_11.pdf

  Over 50% of our upper-division scholars go on directly to graduate school - more than twice the national average.

XI: Financing My MS/PhD in Engineering (4)

- For most students, if the finances do not work out, everything suffers. All of our scholars are financially needy (as determined by the FAFSA form). For many of our students, the $4K scholarship allows them to focus on their studies rather than taking a low paying time-consuming job that severely detracts from studying and other scholarly activities.
- Given this, the financial support we offer to our scholars is very critical. To sustain our program long term, we hope to build a partnership between the federal government, the state, and industry. This will be discussed further below when we discuss strategies moving forward.

XII: The MS Thesis (6)

- Many of our students use the project mechanism that we strongly encourage as a vehicle for establishing a foundation for their senior design project, their undergraduate honor’s thesis (required by ASU’s Barrett Honors College) or even their MS thesis.

XIII: Getting a PhD (8)

- Several of our students started as freshman, selected a topic (e.g. policy making with respect to energy and global warming), and are now working on their PhD on the topic they chose as freshman! This is very inspiring to us. We know that with proper support (financial and otherwise), we can get many students to follow suit.

XIV: Starting a Company (6)

- Here, the goal is to get students to think outside the box and to fundamentally encourage a small company entrepreneurial spirit driven by independent thinking and getting a product to market. Several of our scholars have started companies while students.

XV: Choosing a Job and Job Advancement (5)

(5) Importance of a mentor to help students answer critical questions;

- In addition to explaining the importance of mentors, we help the students find mentors (see VI above).

(6) Importance of life-long-learning in an increasingly competitive global economy;

- Since the inception of the program in 2000, Dr. Rodriguez has addressed the significance of the global economy, increasing competition, and the associated need for life-long learning. The Great Recession has made these topics far less abstract for our students. We have seen how freshman very quickly accept the "need to aggressively take control of one's career immediately" and that their futures depend on it.

(7) Importance of graduate school and the many opportunities that an advanced graduate degree opens;

- Graduate school is another critical theme that we expose all of our students to – even freshman. We want them to go to graduate school, not because of the extra salary they will earn, but because of the significantly increased opportunities that will be afforded to them; e.g. increased technical challenges that permit them to work on the "coolest of problems," work schedule flexibility, and much more.

(8) Exciting engineering career opportunities;

- In an effort to convey the many exciting career opportunities that lie before the students, we often bring in speakers from industry. This has included former program participants that have gone on to obtain their MS in engineering and assume challenging positions in industry (e.g. designing hypersonic vehicles at NASA, working on multi-core microprocessor work/heat management algorithms at Intel). Graduate students are also recruited as speakers (e.g. design of micro-air vehicles). Sometimes we have panels of students.

(9) Choosing a technical area – areas of National importance;

- Choosing a technical area is very challenging for most students. Reasons that students give for this are as follows: (i) "too much to choose from," (ii) "do not know enough to choose." Our feeling on this is that the students are partially correct. There is a great deal to choose from and the students often lack critical background. Despite this, we urge the students to start the learning process as soon as possible so they can discover, nurture, and develop technical passions to sustain them as they move forward. We tell them to start selecting as soon as possible – so that they can control their destiny. The consequences of not choosing is that someone else (typically a recruiter from a company) will be making the final choice on what the students will work on. We advise the students to plan ahead, to set job goals, to work the plan, and to pursue the job goals. This is part of the career plan. See (11) below. The alternative is to submit themselves to the randomness of the interviewing process. We have found that this can lead to severe "job disillusionment;" i.e. a misalignment between expectations and reality.
- We work hard to point out cutting-edge areas - areas that have been deemed areas of national importance; e.g. electric vehicle technologies (e.g. batteries), green biofuels, efficient solar cells, cognitive radio for maximizing spectral capacity (bandwidth) in communications, content-rich mobile libraries, early disease diagnosis, DNA sequencing, immersive teaching software, online learning for all, advanced super computers, advanced transportation systems (e.g. high speed rail, reusable hypersonic vehicles), vaccines for every flu strain, advanced prosthetics and robotic systems, personalized medicine, real-time language translation, regenerative medicine (organ growth), air traffic control, advanced armor, smart robust energy grid, nanotechnology.

  http://aar.faculty.asu.edu/growth.html

  Students have worked on projects in most of these areas.

(10) Importance of multidisciplinary thinking;

- As stated above, we try to show students how traditional fields overlap with one another – particularly to solve cutting-edge problems whose solutions lie at the boundaries of multiple disciplines.

(11) Developing a comprehensive career plan;

- Believing in the old adage:

  "plan your work and work your plan,"

we get our students to develop a comprehensive (10-15 year) career plan:

http://aar.faculty.asu.edu/AAR_COMPREHENSIVE-CAREER-PLAN-10_17_11.pdf

Such a plan forces students to think about future classes, summer classes, summer internships, special projects, and what they want to do with their future!

(12) Writing a technical proposal, paper, presentation, and statement of purpose.

- Each of these helps students learn how to present their work. The following documents assist students with these assignments:

  http://aar.faculty.asu.edu/AAR_RESEARCH-PROPOSAL-GUIDELINES-10_14_11.pdf

  http://aar.faculty.asu.edu/AAR_Writing_a_Technical_Paper.pdf

  http://aar.faculty.asu.edu/AAR_WRITING-A-STATEMENT-OF-PURPOSE-10_14_11.pdf

From semester to semester, we try to get students in the ASAP class to significantly improve upon what they did in the previous semester. As such, the ASAP class and the guidance we provide are very student-centered. ASAP program faculty maintain an open-door policy for program students.

V. Overview of ASAP Program Results

Some of our ASAP program results are summarized below:

- Over 85% of our scholars graduate with an engineering degree (includes computer science, not construction) - (ASU: < 50%).
- Over 50% of our lower-division scholars participate in paid REUs/internships.
- Over 90% of our upper-division scholars graduate (ASU: Male - 70%, Females - 65%).
- Over 50% of our upper-division graduates go directly on to graduate school (> twice national average).
- Over 60% of our scholars are women and/or underrepresented minorities.

Many of our scholars have gone on to win prestigious scholarships (e.g. SMART, Goldwater), fellowships (e.g. NSF, GEM, NASA), and attend top engineering programs.

The activities conducted within our ASAP class have evolved over the past decade. They have been tested and they have been found to be very successful.

A very critical issue that we continue to face is that we do not have enough financial resources to address all of the academically qualified financially needy students at ASU. This issue has been exacerbated by the recent Great Recession as well as the ongoing sequestration. Ideas for addressing this financial/sustainability issue are discussed below.

VI. Strategies Moving Forward

Recently, the ASU Fulton School of Engineering has agreed to offer a class for transfer students which adopts some of the ideas addressed within our ASAP class. We will continue to work with them in order to further institutionalize our ASAP concepts.

Moving forward, we will continue to modify/improve our ASAP classes; e.g. to offer more challenging opportunities for one-on-one student-centered mentor-guided projects. This is precisely what ASU's Fulton Undergraduate Research Initiative (FURI) attempts to do:

http://more.engineering.asu.edu/furi/program-requirements/

A critical issue here, is having financial support for academically-qualified financially-needy students. Without the financial support, we may lose very capable students to low-paying time-consuming jobs that detract from more fruitful academic and scholarly activities. As stated earlier, this is also the case for our ASAP activities.

To address this critical financial issue, we plan to move forward with strategies that permit us to maximally expand our ASAP activities to non-scholarship students. This is approach, while welcomed by the federal government (NSF) and state governments (many operating with unsustainable debt because of future outlays; e.g. benefits), is very difficult. In view of this, we plan to expand providing small ($300) incentives for students to pursue our ASAP activities. We also plan to seek a partnership that involves federal government, the state government, and industry. This model, we think is suitable for America. The German model of government directly funding high school students interested in engineering, is probably politically untenable in the U.S. – at least until the current debt crisis is substantively addressed.

VII. Summary And Conclusions

Within this paper, we have presented a comprehensive framework for significantly increasing the number of individuals entering the engineering profession. The framework is based on a 2 credit ASAP class that students take each semester. While we have seen our ASAP concepts being adopted across the nation, financial sustainability of a scholarship program to attract academically-qualified financially-needy students requires a new approach in order to be scalable. Toward this end, we have proposed a partnership between the federal government, the state, industry, and the student. We believe that such an approach will permit the nation to produce the engineers it needs without unduly relying on external engineering talent.

Acknowledgments

We would like to acknowledge the hard work of Anita Grierson (Director, METS Center), Cynthia Romero (Senior Coordinator for Joaquin Bustoz Math-Science Honors Program), the many ASU professors that have served as mentors to our scholars/students, our very dedicated community college NSF STEP grant partners (Rakesh Pangasa – Arizona Western; Clark Vangilder – Central Arizona; Bubba Hall, JoAnn Deakin, Fend Yang – Cochise College; Jack Bailey, Phil McBride – Eastern Arizona College; Michael Butcher, John Saber, Mike Rourke – Mohave College), and the members of our external and industrial advisory boards.

***Abstract* - This paper addresses an accelerated track for military veterans into bachelor's degrees in engineering. It is an update on a project that was first reported at FIE 2011. An initial thorough evaluation of the veterans' training, experiences, and expertise has been conducted with the option of granting academic credit where appropriate. Therefore, it is important to have contact with the military veteran prior to their arriving on campus to begin their schooling. Current policies give little credit for military experience or training. The development of on-line pre and post assessments and subject based tutorials are being used to accelerate the veteran's entry into the traditional math sequence. Veterans may have a base of technical knowledge acquired through the technical nature of their service posts. Assigning them to introductory level courses with traditional freshman and sophomore students does not respect their technical expertise nor challenge their capabilities and accustomed pace.**

Keywords – Veterans; accelerated programs; electric energy systems

I. MOTIVATION

This work-in-progress paper is an update on a project that was first reported at FIE 2011. It addresses curricular issues involved in integrating post-9/11 veterans into the engineering workforce. A 2009 NSF Workshop on Enhancing the Post-9/11 Veterans Educational Benefit [1] indicates that new, more generous veterans' educational benefits create an opportunity to expand the technical workforce while benefitting those who have served our country. The workshop further indicates that the veterans include a diverse and qualified pool of future talent for the nation's engineering and science employers.

The main aspect of this project is an accelerated track for veterans into engineering bachelor's degrees in engineering for those with no bachelor's degree or with a non-technical degree. The initial technical focus will be in the renewable energy and energy distribution systems areas.

A focus group of veterans already in the electrical and computer engineering department identified transfer credit for military experience and in-state tuition availability as the most important issues that affect their success.

II. ACCELERATED BACHELOR'S DEGREE

This paper addresses an accelerated track for military veterans into bachelor's degrees in engineering. It is important to have contact with the military veteran prior to their arriving on campus to begin their schooling.

An initial thorough evaluation of the veterans' training, experiences, and expertise was conducted with the option of granting academic credit where appropriate. A need currently exists for increased academic recognition of military experience to increase the opportunity for student veterans to complete a degree in a timely fashion [2]. One issue with the use of military credit is that most of the academic credit is ungraded. A possible avenue to overcome these rules is the use of advanced placement exams (where they exist) and university generated quiz-out exams. Other resources such as the American Council on Education [3] directory and university credits for community college work also provide a resource to determine class equivalency.

Required courses identified for consideration of assigning experiential credit include the following: professional and leadership development courses, a social science/humanities elective and one technical elective. The program also includes development of on-line pre-assessments and linked subject based tutorials to accelerate the veteran's entry into the traditional math sequence beginning with Calculus I or higher. Lastly, the same concept of online pre-assessment and tutorials followed by a proctored final assessment is also being developed for entry level engineering courses. In the field of electrical engineering the course to be used for evaluation is Circuit Theory I and therefore its prerequisite, Introduction to Electrical Engineering. These courses present basic concepts in electrical theory, engineering applications and an introduction to circuits laboratory. As in mathematics, veterans would complete an on-line pre-test with linked subject based tutorials ahead of enrolling in the program. Then the veteran would have the option of completing a one-time proctored post-test for course credit (C or better). This approach leverages the veterans' existing technical knowledge acquired through the technical nature of their service posts and accelerates their entry to follow-on technical courses.

By taking full advantage of the program's structure of (1) advising and assessing of military experience, (2) the mathematics refreshers and (3) the post-assessments for entry level engineering course credit a veteran would be able to earn as many as 13 of the 129 credits required for a Bachelor of Science in Electrical Engineering, which is

This work is partially funded by the National Science Foundation Division of Engineering Education and Centers projects 1037640 and 1135742.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

approximately equivalent to one semester on campus. This is in addition to the six hours of prerequisite mathematics courses that can be bypassed by proper review and performance on the mathematics placement exam. Student success in the post-test for credit and academic success (C or better) in subsequent courses will be the primary evaluation metric. The evaluation of this metric will take place when a statistically significant number of students have had access to the accelerated option and are enrolled in the program.

Additional on-line training will focus on areas related to common computer application programs such as MatLab, P-Spice, and Verilog (used in introductory course taken by all electrical engineering students).

III. Technical Focus

Energy has been identified as a critical area where there is a large projected shortage of trained technical personnel. A 2008 NSF Workshop on the Future Power Engineering Workforce [4] indicated "a serious need is emerging for more power and energy engineers to: a) replace retiring engineers so that critical expertise is maintained; b) meet rising infrastructure construction needs; c) modernize the grid as communications, computing, and electric energy technologies converge; d) help stem the tide of electric equipment manufacturing moving off-shore, and; e) solve arising engineering challenges, such as the development of advanced power electronics and energy conversion systems, new generation and storage technologies, and the integration of those technologies into the grid.." The IEEE Power and Energy Society [5] has also indicated that "Immediate action must be taken to avoid letting a growing shortage of well-qualified electric power engineers slow progress in meeting critical national objectives."

In 2008 an industry consortium called the Kansas State University Electrical Power Affiliates Program (EPAP) was formed. EPAP is a consortium of industry leaders committed to the continued excellence of engineering education in the area of electrical power and energy systems. The program can be leveraged to help with various aspects of this proposed work, including the recruitment seminar, internships, and research projects. [6,7]

The energy systems emphasis builds on the existing expertise of the faculty at Kansas State University. Energy systems is one of the five areas of specialization in the electrical engineering program and attracts about 50 percent of the undergraduate students. In addition, the department offers a master's degree with an energy systems emphasis. This master's program has been offered via distance education since 1992, and has approximately 25 off-campus students per semester.

Another aspect of this project is the inclusion of summer internships for participants. These will be provided by members of EPAP and by funded research projects at the university.

IV. KSU and the Military Environment

Kansas State University is near a major U.S. military installation, Fort Riley, and has more than 60 years of experience providing educational opportunities to military personnel and their families. The university provides academics, activities, services and support for military families. Kansas State University has been ranked among the most military-friendly universities in the country by *Military Advanced Education* magazine and by *G.I. Jobs* magazine. Fort Riley is a 15 minute drive from campus. In addition courses are offered on post and via the Internet.

A model partnership between Kansas State and Fort Riley was recently renewed. The agreement was designed to serve as a model military-to-university-community partnership. The agreement sets the following objectives: enhancing each institution's ability to accomplish its mission through collaboration; enhancing the professional and personal quality of life for each institution's constituent communities; creating new and innovative opportunities and programs that add great value to each institution through partnership; and increasing capacity at each institution to steward, manage and sustain major resources through collaboration, innovation and partnership.

Programs between Kansas State University and the First Infantry Division and Fort Riley today aim to create new relationships; offer a diverse experience and perspective; build a stronger academic-military community; improve quality of life; and enhance education and professional development. Increasing the attractiveness of Kansas State University's engineering programs to veterans through the acceleration of degree completion times will add to the partnership between Kansas State and the U.S. military.

V. Future Plans

The major activity will be the continuation of tutorial development. The creation of accelerated courses specifically for veterans enrolled in the program will be another aspect used to accelerate degree completion.

The TIES Program: A Transfer Initiative for Engineering Students

Jill Auerbach and Douglas B. Williams
School of Electrical & Computer Engineering
Georgia Institute of Technology
Atlanta, GA 30332-0250
USA

***Abstract*—Strategies to recruit and retain underrepresented students in the STEM fields are as diverse as the students they seek to engage. The community college pipeline is well recognized as a source for both nontraditional and underrepresented students for engineering programs. The Transfer Initiative for Engineering Scholars (TIES) addresses the unique needs of this cohort who transfer as juniors from the community college environment. TIES is currently in the fourth year of receiving funding from NSF's S-STEM program and providing financial support to eligible students in an environment committed to smooth transitions, multiple options for student support services, community building with peers and faculty, leadership development, and mentor relationships. Many of the support activities build upon previously existing retention programs, but new components, such as leadership seminars, community building, and industry mentoring, were developed specifically for TIES participants. Among the several components of the program, those that contribute to a supportive community environment were seen by the students as extremely important for a successful transition to Georgia Tech's undergraduate electrical engineering and computer engineering programs.**

Keywords—transfer initiative; community college pipeline

I. Introduction

The overall objective of the TIES program is to increase access to Georgia Tech's School of Electrical and Computer Engineering (ECE) for students transferring from community college who demonstrate financial need. The program is designed to enhance their ability to graduate with the strong academic records that afford students rich opportunities for career and/or future education choices. This objective is achieved through the following goals:

- Increase the number of competitive community college transfer applicants applying to Georgia Tech;
- Award TIES scholarships to newly admitted students with financial need and academic commitment;
- Implement strategies to minimize the challenges of transferring from two-year to four-year institutions, and retain and successfully graduate TIES scholars;
- Provide opportunities to expose TIES scholars to experiences that will enhance their options for post-graduation opportunities; and
- Structure the TIES enrichment program so that other transfer students can benefit from the activities.

The special challenges faced by students who take this "non-traditional path" to engineering are formidable for even the most academically talented students. Using a management and support team that has had success with a variety of outreach and retention efforts, TIES has built and expanded upon these strategies to offer multiple novel support program options specifically for non-traditional junior-level transfers. Several program elements, such as active involvement with a cohesive student cohort and mentoring activities focused on research and career development, help to keep students motivated to succeed without premature feelings of defeat.

II. Program Framework

A noteworthy feature of TIES is that the program is implemented at the departmental level and builds upon the conceptual framework of student persistence developed by Vincent Tinto [1,2]. According to Tinto, when students enter the college or university environment, they bring with them attributes that will influence their academic goals and commitments. Once in college, other factors associated with the institutional experience, which consists of both academic and social factors, will also influence student persistence. The likelihood that students will persist is driven by the extent to which students are integrated, both academically and socially, into the college environment. Tinto's model remains essential to understanding the complex nature of student retention and is the conceptual framework for the extensive body of research that examines the effectiveness of various strategies used to engage students successfully [3,4].

Retention of students who transfer from the community college to research institution environment presents particular challenges. Institutional impact on community college students who do transfer has been established in the context of Tinto's model. Moreover, both the community college and the university are responsible for identifying the challenges of transferring and offering strategies to address those challenges [5]. Orientation sessions that target transfer students specifically for early help with services such as advising are important for the initial transition, but Townsend and Wilson provide evidence that formal orientations may need to provide

This material is based upon work supported by the National Science Foundation under Grant Number 0849984.

more "hand holding" [6]. Furthermore, Townsend and Wilson suggest that resources expended by universities to increase academic engagement are disproportionately targeted at first-time freshman students. Even undergraduate research, which typically is geared for juniors and seniors, is more likely a feature of the non-transfer student academic experience. According to a 2010 study of 404 institutions by the Institute for Excellence, 12.1% of transfer students participate in undergraduate research, compared to 34.0% of seniors [7]. Not only is undergraduate research regarded as an effective way to achieve academic engagement and, thus, positively impact retention, findings from a recent study suggest that undergraduate research may help underrepresented minority students more fully integrate into the institution [8].

While retention models have evolved to reflect larger societal changes and research identifies effective intervention actions, Tinto points out that effective implementation remains a major challenge [9]. Thus, program elements from two existing, successful School of ECE programs contributed to the successful implementation of the TIES program. One of those program components centers on undergraduate research and engagement with other students, including graduate students. Another major program component ensures regular contact with faculty, which Tinto argues is critical to successful institutional retention programs.

III. BUILDING ON PAST ACTIVITIES

A. Partners in Transitioning to Tech

Partners in Transitioning to Tech (PITT), a retention program aimed at dual degree transfer students from historically black colleges majoring in ECE, was first implemented in 2004 with seed funding for five-years from Georgia Tech's College of Engineering. Like most community college transfers, dual degree students transfer in at the junior level. Of the several program elements used for PITT's nontraditional student cohort, two were identified by participants as particularly helpful [10]. First was the use of "Super TAs," who were ECE majors with dedicated time each month for PITT students. The Super TAs had a variety of roles, such as mentor, tutor, and friend, and, moreover, they regularly checked-in with students to show interest and concern, often heading off problems before they became serious. Second was the practice of holding small group course planning and advisement sessions run by the PITT faculty program directors. The small group dynamic encouraged interaction among students, sharing advice regarding courses, instructors, and study strategies. Having these same faculty advisors facilitate these sessions helped create a sense of ease with faculty, an environment that many of the students had at their previous home institutions. Both of these program components have been highly successful for the TIES program.

B. Opportunity Research Scholars

Opportunity Research Scholars (ORS) is a highly successful, innovative program designed to increase retention and promote the academic success of ECE students [11]. The model for ORS is based on studies on student retention and success that consistently confirm the relationship between student "engagement" and academic success. As a team-based undergraduate research program, 3-4 undergraduate students are matched with a PhD student mentor and work on specific research projects, attend monthly workshops, complete technical communication assignments, and interact with faculty in the research laboratories. The effectiveness of this program to fully "engage" traditional students in the academic environment was the impetus to adapt the program for community college transfer students.

ORS provides two options for TIES scholars. The greater time commitment involves joining a research group, which requires weekly hours in the lab, developing a research poster, and presenting at department competitions. TIES scholars, in good academic standing, may apply for an ORS slot during their second semester at Georgia Tech. The academic progress of TIES scholars who do participate in ORS is closely monitored to ensure that the demands of the research experience do not conflict with progress toward degree. The alternative is to participate only in the monthly workshop series. These workshops are designed specifically for electrical and computer engineering students tend to be interactive, and engage students with their peers in the school. Examples of monthly workshops include:

- A Glimpse into Industry: Working in industry and life after graduation (past presenters include representatives from Rockwell Collins and Texas Instruments)
- Developing a Scientific Research Poster: Conducted through ECE's Undergraduate Professional Communication Program.
- Georgia Tech Research Option Program: Conducted by ECE faculty members, this interactive discussion focuses on research for credit, Georgia Tech's Research Option, and other options for maximizing the research experience.

Since undergraduate research is a successful strategy for increasing student retention, keeping students motivated to do well in school, and helping students understand how coursework translates to real world application, ORS has been a valuable option for TIES scholars.

IV. PROJECT STATUS

These ECE programs constitute the basis for many of the strategies that have been used for the TIES scholars. Eligible students have been invited to apply for participation in ORS, and many of the successes and lessons from PITT form the foundation of the TIES support system.

At the end of the fourth year, 31 students have participated in the TIES program. From that group, 21 have successfully graduated, 8 students remain active and in good academic standing and 2 students have not been retained at the institution. At the end of the third year, the decision was made to close enrollment for the TIES scholarship in order to reserve enough funding for all 29 students retained in TIES to graduate. Of these 29 students, 27 students regularly attended TIES functions and utilized the support services offered through the program. Non-scholarship students who have also transferred from community colleges are invited to TIES programming, although few attend. Some TIES students were non-scholarship eligible for specific semesters because they fell below the required minimum course credits. These students however remained active in the program during those semesters as part of the TIES community.

Given that a major purpose of TIES is to minimize the challenges of transferring from two-year to four-year institutions in order to retain and graduate students, building a support system among students was a top priority. In the first year of the program, this process was challenging because of the lack of a critical mass of students. Only four TIES scholars were in the program for the first semester. To compensate, the TIES program staff met frequently with the students to establish a connection between them and the program directors. This first group of students formed a tight-knit group and a solid foundation for the next year when the program increased to 20 active TIES scholars.

The community-building activities fall into three basic categories:

- Informal meetings with TIES program staff
- Workshops conducted by non-TIES staff
- Events hosted by the department's undergraduate research program (ORS)

The informal meetings with TIES program staff have consistently been successful in terms of creating connections both among the students and with TIES staff. These meetings, held at the beginning and mid-point of the semester, focus on individual student questions. The culture during the meetings is very informal and interactive, where students answer each other's questions and offer advice. During the meetings, TIES staff responds to student questions regarding course planning and selection, as other students feel comfortable chiming in about their own experiences. Study partners and tutoring have resulted from the interactions at these gatherings. The supportive atmosphere has also encouraged students to take advantage of the open-door policy of the TIES staff, which contributes to an overall comfort-level within the Georgia Tech environment. Each semester, a growing number of TIES students take advantage of the opportunity to meet one-on-one with TIES staff – an offer that is reinforced during the meetings.

The workshops conducted by non-TIES staff have been well attended and appreciated, based on feedback from the TIES students. While these sessions may not be as effective for community building as the informal meetings, they provide students with critical information and materials in a small group setting. Each year, workshops are offered that focus on career-related topics, which have been extremely well received by the TIES students. Even though all of these workshop topics can be found in other venues at Georgia Tech, the TIES students appear to benefit more from the dedicated events. For students who are relatively new to Georgia Tech and who enter as juniors, the larger workshops held in lecture halls can be intimidating.

Taken together, these program components are intended to enhance options for post-graduation opportunities and promote graduate school attendance. Based on survey data from the 2012-13 TIES cohort of 19 students receiving TIES funding who were asked if their plans or goals for after graduation had changed since transferring to Georgia Tech, eight reported that their plans had changed and that they now plan to go to graduate school. In addition two students said that they had always planned to attend graduate school. While these data do not show that TIES actually caused the change, the programming is geared at retaining these students and creating a positive academic experience. The survey data thus far confirm that these goals have been achieved.

Investigating How Service-Learning Alumni Construct their Engineering Selves

James L. Huff[1,2], Carla B. Zoltowski[2],William C. Oakes[1,2], and Brent K. Jesiek[1]
School of Engineering Education[1] and Engineering Projects in Community Service (EPICS)[2]
Purdue University
West Lafayette, IN, USA

Abstract– **Prior research has demonstrated that traditional academic pathways tend to provide engineering students with a predominantly technical sense of professional identity. We respond to this research by investigating how a non-traditional pathway, marked by a large service-learning program, engenders a sense of engineering identity. We approach this investigation using a thematic analysis and are currently developing themes related to how alumni/ae of this program construct their engineering selves. We are currently in the early stages of analysis and will present the elaborated themes at the conference.**

Keywords- engineering identity, non-traditional pathways, mixed methods, sociotechnical

I. Overview

Leading voices in the engineering community, such as ABET [1], the NAE [2], the ASCE [3], and the ASME [4], have established criteria that articulate the desired characteristics of an engineer. However, such visions of engineers do not always align with the reality of how engineering is understood and practiced, as demonstrated by several key findings from engineering studies and engineering education literature (e.g., [5-12]). Indeed, many studies reveal that professionals tend to construe their engineering identity as one that is purely technical, even if most workplace activity is non-technical in character. Additionally, they suggest that the academic pathways and undergraduate experiences of pre-professional engineers play a substantial role in constructing how they understand their engineering abilities and identities [6-12], even if this role is unintended [10].

This particular study extends prior research by investigating how alumni/ae of Engineering Projects in Community Service (EPICS), a multidisciplinary, service-learning program, make sense of their engineering identities and then connect these identity constructions to their undergraduate experiences. Unlike the earlier cited studies, this investigation examines sense-making in professionals with *non-traditional* academic pathways, specifically participation in EPICS.

II. Conceptual Framework

We place this particular investigation among other core theoretical concepts found in other studies. We especially attend to how the participants in our study understand technical and non-technical characteristics of their engineering ability and identity. Previous social science research on engineers, including those already cited, have responded to examining how engineers understand technical and non-technical nature of their work. Notably, Faulkner has posited that a social/technical dualism, or "a strong sense of the technical which specifically excludes the social", permeates "engineering professional training, identities, and practice" (p. 764 in [5]). Other engineering studies research provides further evidence for this social/technical dualism (e.g., [11, 14]), although some studies have found that this dualism may be somewhat more nuanced than originally understood by Faulkner ([9, 13]).

Additionally, we attend to the intentional and unintentional role of engineering education in *professionally socializing* the participants of this study. In other words, we especially examine how the experiences of engineering education, including EPICS, have influenced the participants' thinking about "what it means to be a 'good' engineer" [11]. Although sociological studies, including those done on engineers, name this dimension of education as *professional socialization* (e.g., [5, 11], several investigations of engineering education have recognized how undergraduate engineering degree programs play a critical role in the ways that their students construct understandings of their "engineering selves" (p. 117 in [12]; see also [8, 15-18]).

III. Methods

This study is part of a larger embedded, mixed-methods investigation [19, 20], specifically QUAL(quan), which probed how EPICS alumni/ae relate their experiences in the program to their professional preparation (for more on this study and EPICS itself, see [21-23]). In this larger study, a diverse range of participants (n = 27) were purposefully sampled from respondents to a previous survey (n = 523). We conducted semi-structured, in-depth interviews with these 27 participants via Skype and telephone calls. The interview protocol was informed by both the individual survey responses the objectives of our larger investigation.

Though the explicit focus of the larger study was on their experiences in EPICS, as we analyzed the transcripts we were surprised to discover the richness in how interview participants articulated their own engineering identities and abilities. While such discussion might be expected from participants that practiced engineering (n = 18), we found that even participants with non-engineering occupational roles (n = 9) had profound ways of discussing how they identified as engineers. Participants often connected these descriptions of their engineering identities to EPICS and other experiences.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Consequently, we are conducting a separate analysis of the transcripts with the objective of thematically organizing the participants' articulations of how they understand their engineering selves. The methodology of this particular investigation is considerably influenced by how Braun & Clark describe *thematic analysis* [24]. That is, we are following a systematic process that involves multiple iterations of studying the participants' interview transcripts in order to organize thematic descriptions of how service-learning alums understand their engineering selves. As we have described elsewhere [22], we have analyzed the transcripts for in-depth understanding of *individual* participants' accounts as well as thematic patterns that describe the *collective* set of accounts.

IV. Preliminary Analysis

Although we are in the early stages of organizing and describing patterns of how study participants describe their engineering selves, we have already seen some broad themes in their accounts. More specifically, we note that the participants employ a variety of strategies for reconciling technical and non-technical characteristics of their practice and identities. They often distinguished between technical and non-technical characteristics of their professional identities, practice, or training. Such perspectives did not completely align with Faulkner's social/technical dualism [5], at least in the purest sense. Even among those alums that demonstrate some evidence of such dualistic thinking, they seem to at least consciously value the non-technical dimensions of their work.

Additionally, we recognize through their accounts that EPICS and other undergraduate experiences played a critical role in helping them understand what it was to *be* or *become* an engineer. This socialization effect of their education seems so pervasive that even some participants *without* engineering jobs discussed how they saw themselves as engineers. With some exceptions, participants typically expressed how EPICS interacted with other undergraduate experiences to show them "what it means to be a 'good' engineer" [11].

At the conference session, we will elaborate on these themes to further describe how EPICS alums make sense of their engineering selves. We will also discuss how these identity constructions connect to their experiences in EPICS and other undergraduate experiences and what these findings suggest for future engineering education research and practice.

Lesbian, Gay, Bisexual, and Transgender Students in Engineering: Climate and Perceptions

Kathryn F. Trenshaw[1], Ashley Hetrick[2], Ramona F. Oswald[3], Sharra L. Vostral[4,5], and Michael C. Loui[6]
[1]Chemical & Biomolecular Engineering, [2]English, [3]Human & Community Development, [4]Gender & Women's Studies, [5]History, [6]Electrical and Computer Engineering
University of Illinois at Urbana-Champaign
Urbana, Illinois

***Abstract*—Few studies of the climate in engineering for lesbian, gay, bisexual and transgender (LGBT) students have been conducted. According to these studies, LGBT students are often forced to cope with hostile climates in engineering. To address the question of how LGBT students experience the climate in engineering, we interviewed a total of 16 students at two institutions in the Midwest. We analyzed the interview transcripts using open coding based on a combination of Meyer's Minority Stress Theory and Tinto's Theory of Student Departure. Preliminary results indicate that LGBT students experience more situations of exclusion within engineering than in other areas of their campuses. Based on their experiences, students advocate increased visibility for LGBT students in engineering and a mentoring program to provide support from engineering faculty and graduate students who also identify as LGBT.**

Keywords*—LGBT, engineering, undergraduate, climate study, student interviews, mentoring program

I. Background and Significance

"While much is known about the experiences of women and racial/ethnic minorities in male-dominated fields such as engineering, the experience of lesbian, gay, and bisexual (LGB) indentifying individuals remains unstudied" [1]. Cech and Waidzunas [1] broke new ground in 2011 with the first study to specifically investigate the experiences of LGBT students in engineering. Interviewed LGBT students reported feeling "tolerated" rather than seeing engineering as tolerant or accepting. They were forced to employ a variety of emotionally exhausting coping mechanisms to persist in their engineering programs.

While Cech and Waidzunas were the first and only scholars to consider LGBT students in engineering [1], others have studied LGBT college students in general. In the typical college classroom, a significant percentage of students are LGBT with reported proportions up to ten percent [2]. Surveyed LGBT students report experiencing verbal and physical abuse, mainly from other students [3][4], and are at higher risk of encountering sexual prejudice in male dominated majors [5]. There is a need, in both engineering and LGBT research, to address the issues raised by Cech and Waidzunas and to better understand the unique difficulties faced by LGBT students in engineering.

This study builds on the work of Cech and Waidzunas by expanding on the experiences of LGB students in engineering at two different institutions as well as including the perspective of a transgender student, making it truly a study of LGBT students in engineering.

II. Methods

Interviews were carried out at two different institutions, Lavender University and Teal University (pseudonyms). Of the 16 undergraduate students interviewed, three self-identified as lesbian, 10 as gay, two as bisexual, and one as transgender (specifically genderfluid).

A. Lavender University

Near the beginning of the Fall 2012 semester, we interviewed 13 LGBT undergraduates in engineering at Lavender University, a rural, public institution in the Midwest. Interviews were semi-structured and focused on several themes, including overall campus climate, the climate in engineering, interactions with others related to LGBT issues, and recommendations for improving the climate in engineering. These themes were based on interview protocols used previously by Cech and Waidzunas [1]. Interview transcripts from Lavender University were coded using open coding based on a combination of Meyer's Minority Stress Theory [6] and Tinto's Theory of Student Departure [7]. Minority Stress Theory emphasizes the unique stresses minority individuals face stemming from the conflict between their own values and those of the dominant culture around them [6]. These stresses reduce the sense of social integration students feel within the academic culture around them, resulting in a lack of overall academic integration and possibly the decision to drop out of college [7]. Analysis is currently ongoing to fully develop themes.

B. Teal University

Near the middle of the Spring 2013 semester, we interviewed three LGBT undergraduates in engineering at Teal University, an urban, private institution in the Midwest. In addition to the content of the Lavender University interviews, Teal University interviews included themes of family background and high school experiences. Open coding of the Teal University interview transcripts is currently ongoing.

III. Preliminary Findings

We developed four preliminary themes from the Lavender University interviews which include the minority stresses

978-1-4673-5261-1/13/$31.00

expressed by interviewees and suggested interventions to improve their academic integration: 1) engineering is heteronormative, 2) engineering is forgotten by the LGBT community, 3) engineering is exclusionary, and 4) LGBT engineering students need support. The lack of engagement between engineering and the larger LGBT community leaves students caught in the middle with few places to turn for support, either academic or personal.

A. Engineering is Heteronormative

The interviewees perceived engineering as heteronormative both from a lack of conversation about diversity in their courses and from a lack of personal life discussions between engineering students in general. This focus on strictly technical activities and "taboo" against sharing personal stories in engineering indicated to LGBT students that their perspectives were not desired or valued within the normative expectations of heterosexual engineers. Representative quotations from interviewees are below (names replaced by pseudonyms):

> I think that [Lavender University] as a whole is very, very open minded and accepting, but I think in the [engineering school] it's a little bit different just because it's totally a straight male dominated world. … I don't feel necessarily discriminated against, but I don't feel like overly accepted either … [Elsewhere on campus] we're constantly bombarded with, "Keep an open mind. Be accepting," which I think is totally great, obviously, but I don't necessarily hear that message in the College of Engineering. – William

> I wanna talk about my girlfriend without having to blurt it out and like I want it to just be okay. I want to know [engineers are] okay with it because even though it doesn't define me, it's part of who I am, so it's just easier. – Mary

> My professor … whenever he's describing charges of atoms, positive and negative … he's always like, "The girl will be here and the guy will be here and you are very attracted to the girl," and he's asking all the guys … and I'm just thinking, "Well, I mean, yeah, most of these guys are, but I'm not going to be! This example doesn't pertain to me!" – Josh

B. Engineering is Forgotten by the LGBT Community

LGBT students in engineering perceived a lack of support from the general LGBT community on campus specifically for engineering. Engineering buildings often lacked visibility for LGBT organizations or events as if they had been neglected deliberately. Some non-engineers in the LGBT community also expressed surprise or confusion upon discovering that LGBT students were pursuing engineering majors. Representative quotations from interviewees are shown below:

> We should post more fliers and stuff around the actual engineering buildings…. There are people who are in that building … who might want to join the group … but they just don't have the access to it on their own because they're not searching or some reason like that and it would be good if it was available for them to see. – Josh

> [Non-engineers in the LGBT community], typically they say, "[Engineering] doesn't really seem like a field that you'd be interested in," like "you" connotation with, "because you're gay." – Josh

C. Engineering is Exclusionary

Fundamental aspects of engineering as a discipline, such as male dominated majors, frequent team projects, packed academic schedules, and constant competition create an indirectly exclusionary climate for LGBT students. LGBT students described anxiety with disclosing in mostly male engineering teams because of the reactions of their teammates, but lacked the free time outside of class to pursue other activities or find community outside engineering. Situations of exclusion were described most often within the engineering classroom or during casual conversation with other engineering students. Representative quotations from interviewees are shown below:

> I'll just not disclose [my sexual identity] if I have a group thing just because things tend to go a lot smoother if I don't bring something like that up. – Alan

> I think I'd like to go to some of the [LGBT student organization] stuff, but, yeah, that's it. I really haven't had time to do anything else. – Sarah

D. LGBT Engineering Students Need Support

To improve the climate in engineering for LGBT students, the interviewees commonly recommended increased visibility of LGBT organizations on the engineering campus as well as incorporation of LGBT issues into engineering courses. Every interviewed student responded positively to the idea of implementing of a mentoring program for LGBT students in engineering with LGBT faculty and graduate students or allies. In general, the interviewees' suggestions would increase visibility and support for LGBT students in engineering.

IV. FUTURE DIRECTIONS

To further explore the climate for LGBT students in engineering at Midwestern institutions, we will finish analysis of interviews at both Lavender and Teal University and triangulate with secondary data from climate surveys taken in 2011 at a rural, public institution, an urban, public institution, and a rural, public institution without an engineering program. We will also compare the climates of rural and urban institutions. This analysis is currently ongoing.

Since interviewees responded positively to providing an LGBT mentoring program in engineering, we hope to start such a program at one of the institutions studied with interested LGBT faculty and graduate student mentors during the Fall 2013 semester.

While these exploratory interviews give a window into the climate experienced by LGBT students in engineering at two Midwestern institutions, we hope to extend the study nationwide to reveal the similarities and differences in the climate in engineering for LGBT students in various regions across the country. Collaborations with institutions on the East Coast are currently underway.

ACKNOWLEDGMENT

***Abstract*—This paper describes a multi-device Learning Management System based on Moodle with alternative interfaces providing accessibility for people with disabilities. The software architecture built over Moodle is described as well as the interface created to offer access through a TV. An initial user focus group has been used to test and get feedback for further developments of the system.**

Keywords——Adapted Interfaces; Educational Environment; e-learning; accessibility; disabled people

I. Introduction

In parallel to the technological advances in the world of the Internet and the Web we have witnessed a quantitative and qualitative increase in the amount of educational content and supporting platforms for distance learning and e-learning. E-learning environments are usually based on a desktop or laptop to support users' interactions, so the introduction of mobile devices like smartphones or tablets provides the missing element to foster enriching ubiquitous learning, that is, the possibility to learn everywhere anytime. Besides, some of these paradigms support group interaction, thus facilitating collaborative learning among peers or between learners and educators. This represents an ultimate contribution to bring education closer to the citizen, regardless of their initial education level or their intellectual and physical abilities. Specifically, groups of people with some degree of dependence and people with disabilities in particular, would dramatically benefit from these new technologies to increase their training and education opportunities. For example, elder people or wheelchair users may encounter difficulties to access conventional educational facilities.

The Foundation Vodafone-CERMI/Spain Observatory 2011, through its report on the current state of accessibility in Information and Communication Technologies (ICT) [1] stresses the need to implement strategies to promote the digital inclusion of people with disabilities, focusing on overcoming barriers and promoting their skills and motivation, as people with disabilities still face many barriers to the use of ICT products and services, which in turn are essential elements of social and economic life.

Nevertheless, technological solutions to provide distance education to these groups are still inadequate, so the aim of the research work discussed in this paper is to provide a supervised learning and self-adaptable environment for people with disabilities, focusing on the specific training-related needs of our target group, who in many cases also need direct and continuous assistance by a teacher or relative. Therefore, two main aspects guided the development of this platform, namely (1) the need for adapted peripheral and control devices, and (2) the need to create an environment in which several people can interact at the same learning scenario.

First, we have analyzed the daily behavior of our target group with the aim of e-learning to move closer to them and not the other way around. Recent studies [2][3] show that a high percentage of people with special needs spend many hours at home, in the company of family members and/or caregivers in physical spaces typically known as living rooms or TV rooms. That is the reason why this device will be used as the central element around which to build our proposal. Note that the TV set is the electronic appliance with the greatest presence in homes around the developed world, and with which target users are more familiar. In addition, we introduce the Home Theatre Personal Computer as the binding element between the TV world and the Internet. The hardware platform eventually developed will also integrate different control devices and peripherals tailored to these groups, ranging from gesture-based remotes to touch screens in smartphones and tablet computers.

On the other side, we have tried to adapt available e-learning services rather than to develop new ones from scratch. The real challenge lies in providing convenient access to these tools, that is, to adapt them to be used by an individual with some degree of disability. For this reason, we developed a Moodle client specifically tailored to a TV environment, as it is one of the most popular and widespread Learning Management System (LMS), with over 72,000 instances in 223 countries worldwide [4]. This makes it possible to reuse the management engine in any existing Moodle instance, and therefore to gain access to wealth of pre-existing content and courses. This adapted LMS is completed with a self-configurable environment based on the target users' profiles, which include an accessible TV viewer application to gain access to resources such us Wikipedia, YouTube, email, social

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

network platforms, and a portfolio of educational, rehabilitation, and cognitive training games specifically tailored to people with special needs.

The rest of the paper is organized as follows: the next section discusses the technological proposal selected to provide our target holistic educational environment for people with disabilities. Then, Section III introduces the platform developed from the target user's perspective, that is, the TV-integrated Moodle client and its functionalities, together with the collection of interfacing and control devices that provide full accessibility to the platform. Section IV outlines the pilot carried out with real users intended to assess the usability and usefulness of this proposal. Finally, we provide some conclusions on the design, development and testing of the developed system.

II. Technological proposal

Typically, people with disabilities require devices specifically adapted to their particular needs. They are even part of their personal spaces. In many cases, the adaptation of these devices has a much higher cost than the one these individuals can afford. As a consequence, in many cases performing certain common daily tasks or activities is not possible to all.

In the world of education, and more specifically in the world of distance learning, the above mentioned adaptation requirement is still present. People with mobility impairments, people with cerebral palsy, the visually impaired or the Deaf will definitely have different needs when facing the adaptation of an LMS.

There are some initiatives for the development of platforms following accessibility standards set by the World Wide Web Consortium (W3C). In these cases, the accessibility issues are focused on the platform itself, and not on providing a suitable access model to the platform. Thus, although the platform may meet W3C the accessibility requirements, if users with certain limitations (e.g. mobility impaired users) cannot interact with it, the platform is no longer universally accessible in a strict sense.

On the other hand, if we focus on the content hosted by any distance learning platform and the functionality provided to interact with that content, we can see a tool with enormous potential to support most educational scenarios.

According to this premise, this project extends the access mode of an LMS so that for it to be accessible not only through its default interface (i.e., a web browser), but also through any other device capable of processing the information provided by web services.

Another important feature of the proposed model of operation is the graphical user interface not being unique and not being dependent on the specific LMS, but on the eventual device utilized to display the data obtained via web services. Therefore, the client device is the one responsible for graphical user interfacing, that is, to provide the same content in an accessible way according to the specific characteristics of individual target users.

Among the LMSs currently available, Moodle 2.0 has been chosen for this project. This decision is based on three main reasons:

- Its enormous popularity.
- Not being a particularly accessible LMS. A side objective of this research is to study how a non-accessible platform can be converted into an accessible one.
- The specific version chosen supports web services. Web services support the communication among software applications and components thereof in a standard way, independent of the select programming language or software development platform, both at client and server sides.

An important point to consider is that the support for web services offered by this platform is intended primarily for platform administration (e.g., user management). For this, Moodle 2.0 provides support for creating applications via Remote call Procedure based on Extensible Markup Language) XML-RPC, Action message Format (AMF), Representational state transfer (REST) or Simple Object Access Protocol (SOAP). In our case, we will rely on the XML-RPC technology to extend the functionality of the platform. This decision is based on its dynamic characteristics to support the introduction of new parameters for already existing functions. With this, new functions are not needed in the client side to interact with new features introduced at the server.

Fig. 1 illustrates the internal workings of web services in Moodle. As depicted by the figure, have defined an intermediate layer within the Moodle's core to serve as a middleware between requests from the web service layer and each of the modules that provide LMS features, including user management, course management, questionnaire management, or multimedia content management.

A. User authentication

The authentication requirements of the developed platform go beyond the Moodle authentication model. The need to provide additional services to those provided by the LMS requires a centralized authentication service. All services defined in the platform, including tele-education, should interact with this centralized authentication service to check users' credentials.

Authentication is also based on the web services architecture [5]. This architectural model enables the platform to be fully scalable, supporting the introduction of new services in a fast and flexible way.

For user authentication, SOAP was the selected web services technology. In a user authentication system, security is a most relevant aspect. This technology supports channel encryption (SSL) through WS-Security [6]. With this, all communications with the authentication service will always be encrypted, thus adding a layer of security to the transmission of user-password pairs.

Fig. 2 depicts the flowchart for user authentication. To provide greater security to information exchange, the user-password pair is sent only once. Upon receipt of both elements, user and password, the authentication service verifies that these credentials are correct and generates a session token to be returned to the user. This token is unique for each user currently logged in the platform. When users interact with any of the services defined, they send their session token, and the service requested will be responsible for validating the token with the authentication service. This operation mode supports all users to be collected in a single centralized service, which in turn facilitates user administration and efficient access of each user to each of the services offered.

To access the features provided by Moodle from the new adapted client devices, an additional software layer has been added to the server including different web services to support (adapted) access to the main features of the LMS (cf., Fig. 1). The process for invoking this new layer of services is as follows:

1) Once the user has been authenticated, the client application gets the corresponding session token for that user.
2) The authentication service interacts with Moodle's back-end to report about the new user. Moodle creates an association between the user and the session token.
3) The client application includes the session token in all requests performed to Moodle's web services.
4) The new web service layer checks that the received token is valid, and identifies the accessing user.
5) Moodle returns through web services all the information requested through the client application.

As can be inferred from the description above, information kept by Moodle is no transferred directly to the user, but it is packed to be sent through XML-RPC protocol to the client application. This application will display the information once conditioned according to the specific user's profile, and will collect user actions and send them back to Moodle for her to browse across the desired educational content.

B. Communication

In a system of this kind, communications are an essential part of it. When we talk about communication, we are referring to the ability of the system in establishing a communication channel among users.

To implement the initial idea to provide a system capable of adapting to different client devices requires establishing a versatile and extensible communication service. Presently, a communications protocol both popular and having the required functionality is the Extensible Messaging and Presence Protocol (XMPP) [7]. Among other popular services on the Internet, this protocol is used by both Google (i.e., GTalk) and Facebook messaging services. Its potential to be adapted to the particular needs of most messaging projects makes it a very interesting solution for almost any messaging or conference service. Another major advantage of this protocol is its support for user presence control. This feature facilitates not just knowing when a user signs in and off a system, but also identifying the actual device that completed the connection. Thus, applications using this protocol will be able to route all messages in a simple way to the actual (mobile) device where the user is located.

The platform discussed in this paper uses an Openfire [8] communications server, distributed under the General Public License (GPL). With it, the platform is fully autonomous to manage all communications required by users without having to resort to third-party communication and presence control services.

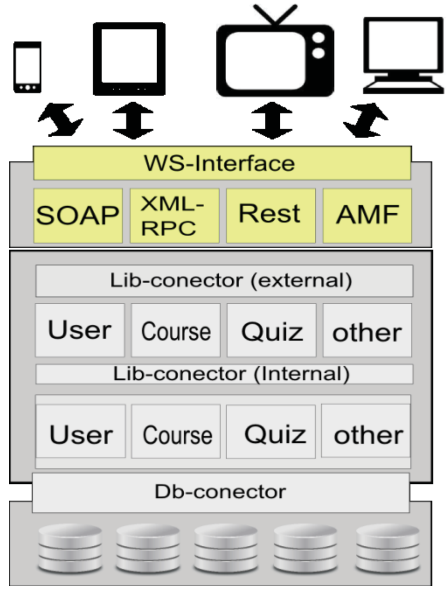

Fig. 1. Web services developed at Moodle

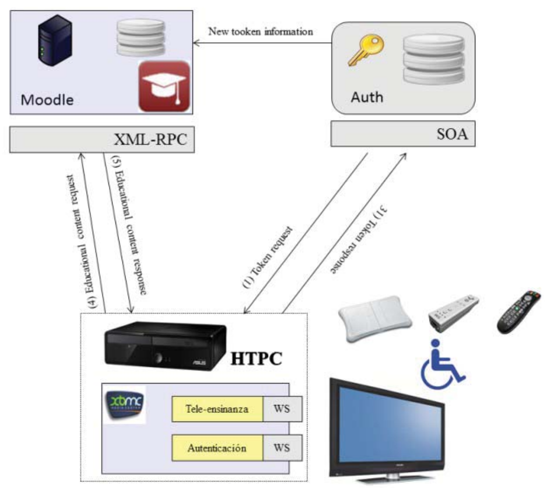

Fig. 2. T-learning system's architecture

Communications become a means through which both students and teachers can easily stay in touch. For example, a student may ask a question through the chat facility using her adapted device, and teachers may answer it via any instant messaging program that supports XMPP protocol.

III. Holistic Educational Platform

The aim of the platform discussed here is to implement a tele-education system accessible through different devices to facilitate and / or provide access to any individual independently of her personal dependence situation. In this section we outline the adaptations performed to Moodle to be used from a television environment based on a Home Theater Personal Computer (HTPC). The implementation of this client environment has did not only addressed the technical developments needed to use a Moodle front-end from this environment, but also, and above all, to facilitate its usage by people with a broad range of disabilities. For that, various interaction mechanisms have also been integrated.

As discussed above, the design of this system is based on a client using an HTPC. This device implements all the business logic required to interact with Moodle and to display educational content on a TV screen. All information transmitted between Moodle and the client is packed into XML-RPC frames to be processed and conditioned to be shown on the TV.

It is important to recall at this point that the client application will be in permanent contact with the web services developed at the server side to post back all the actions performed by the user. In the case of the previous figure, when the user answers a question in the questionnaire, the client application will send this information to Moodle, so that it can perform the same operations as if the accessing client were following the course from the standard web browser interface. Insofar Moodle is concerned, the student will be following the course in exactly the same way as if she were accessing it from any web browser. Thus, all features available in Moodle (e.g., to track user actions across courses) are still available for courses followed through adapted client devices.

A. TV-integrated functionalities

Once signed in, the student has access to both Moodle courses and the communication facilities introduced above. Through the communication service, students may establish communication with the teacher directly from their TVs and the adapted control devices adapted discussed below. Thus, as students progress along their courses direct assistance from teachers or peers in their address books can be obtained in a much more agile way.

To carry out the courses in which a given student is enrolled, the client application communicates with Moodle through the implemented web services according to the communication mechanism discussed in Sect. II. All information received by the client, (e.g., the lessons in a course or specific educational resources) are displayed on the TV screen in a way accessible to the user's needs. In turn, the student will use the TV remote or any other adapted control device to navigate through the options displayed on screen and interact with them. Each of these actions will be captured and sent back to Moodle for it to perform the required operations to support course interactions. Among the actions a user may perform are:

1) Access to the course list: a student may access all courses in which he is currently enrolled.

2) Access to a specific course: a student may follow any of these courses.

3) Score/marks visualization: a student may view the scores and marks obtained on her courses.

4) *Testing:* a student may complete any evaluation questionnaire associated to any of her courses.

Note that all Moodle logic related to course access is implemented in the new scenario. For example, course completion criteria are strictly followed by this platform. As discussed above, the developed web services act as a middleware to isolate the underlying Moodle business logic while allowing a user to follow a course from any supported client device. In other words, the client is responsible for establishing and maintaining the exchange of information between the user and Moodle, while Moodle is responsible for all the business logic of the courses. For example, when a teacher establishes that a course has certain completeness conditions, these conditions will still be present no matter the actual access device or student profile. If certain conditions are defined for evaluation questionnaires, these conditions will be followed by all client instances. As in the standard Web version, the student receives information on the completion conditions when accessing a questionnaire (e.g., number of remaining attempts, evaluation methods, scores obtained in previous attempts, etc.), the only difference being that this information and the actions triggered thereof are handled in a way adapted to each specific student.

Fig. 3. Control Platform through several dispositives

Fig. 4. Control Platform through Kinect

B. TV Adaptation

One of the advantages discussed earlier corresponds to the possibility for users to access and interact with Moodle courses using adapted devices according to their personal requirements and needs. To provide fully adapted control to different types of users with different disabilities several control peripherals were integrated. We enumerate below the ones currently available.

1) Conventional remote (cf. Fig. 3).
2) Nintendo's WiiMotes [9] (cf. Fig. 3).
3) Microsoft's Kinect [10] (cf. Fig. 4).
4) Tablet and smart-phones (cf. Fig. 3).
5) Additional devices connected by USB, infrared, WiFi or Bluetooth.

IV. Holistic Educational Platform Validation

The platform presented in this paper has been validated, from a technical and functional the standpoint, through a pilot project with real users (cf. Fig. 5) with disabilities. This pilot was performed with the collaboration of the Galician Confederation of People with Disabilities (COGAMI) [11], an organization with more than 20,000 associated people with different types of disabilities. This collaboration was orchestrated as part of a research project funded by the department responsible for social policies at the autonomous government of Galicia (Spain).

Fig. 5. User at home

This association, COGAMI, is a confederation created in 1990 with the aim of strengthening the member associations and to provide solutions to the isolation in which most people with disabilities in Galicia lived. Collaboration with COGAMI arises from the adequacy of the developed system to the profile of this confederation's users. COGAMI's fundamental mission is to achieve full inclusion of people with disabilities in all areas of society, through the defense and promotion of their rights, and fostering through partnerships and coordination with other stakeholders the delivery of services meeting their needs and expectations. Therefore, they proposed University of Vigo in Spain and the researchers involved in this project to provide technological solutions as the ones presented in this article.

Among the most important services provided by COGAMI, are the ones related to training and employment promotion. The testing of the platform discussed in this paper was performed in this scenario. COGAMI already had some expertise on computer-mediated education, as it has already been utilizing a PC-based e-learning platform named Delphi.

For the realization of the pilot project, COGAMI selected 15 users, with degrees of disability between 33% and 95%, with more than half of participants (53.33%) experiencing an average degree of disability around 70%. Note that all pilot participants were familiar with the use of tele-education systems in traditional environments (Web and PC-based Delphi).

A. Results

We discuss below the main results of the validation of the use of the platform by the users selected. In relation to the methodology implemented for the pilot experience, it was organized along two phases. First, COGAMI staff made a presentation of the platform at each participant user's premises. This presentation consisted on a single brief introductory training session lasting 15 minutes. Then, at the beginning of the training course through the platform, users were given two questionnaires [12] together with specific instructions to complete them. The first questionnaire had a series of questions about participants' previous experiences with PC platform and the TV, which was intended to be complete prior to interacting with the platform. The second questionnaire, intended to be completed after the completion of the course through the platform, focused on evaluating the usability of the system, the different services offered, and the course content.

4) Results on content assessment.

User feedback was collected on the degree of accessibility of content and its presentation through the Moodle client for the TV set. Questions tackled the readability of textual content, the display of different types of multimedia content, the information provided to track courses, the quality of video assets, and accessibility and ease of use of self-assessment instruments (i.e., adapted Moodle questionnaires).

Regarding the participants' responses to these five items, we would like to point out that results show an average user satisfaction level above 70% in relation to reading and watching course content on the TV set, and in relation to the quality of the information (cf. Fig. 6).

5) Results on platform assessment.

At the technical level, and specifically regarding its degree of usability, the questionnaire included questions designed to assess general usability and accessibility aspects of the platform. These questions were proposed by COGAMI, an institution that collects ample experience on providing services to people with disability, and they addressed the control peripherals used, the information provided on the use of the platform's features, the quality of the content displayed on the TV screen, whether it was possible to intuitively understand the use of the platform, the communication channels with the caregivers and relatives, the degree of interactivity offered by the platform, and its overall accessibility. Fig. 7 provides some figures about the users' feedback on these aspects. In general, feedback from users was completely satisfactory, as most aspects achieved a 100% degree of perceived usability and accessibility, beyond our initial expectations when designing the pilot.

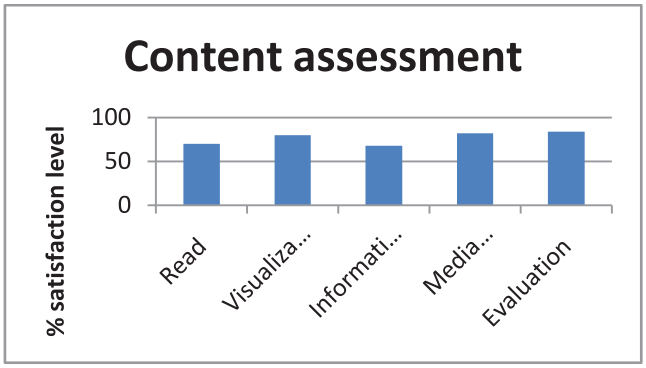

Fig. 6. Main Results on content assessment

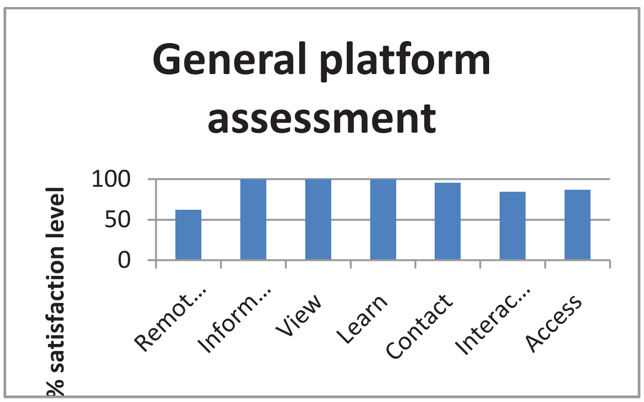

Fig. 7. Main Results on platform assessment

One of the outcomes that deserve special attention, as it was the aspect getting lower user scores (i.e, satisfaction levels), is the feedback on the remote control used to control the platform. Both the conventional TV remote and the Wiimote were not perceived in many cases as the most suitable solution for people with a very high degree of disability. However, as the open nature of the HTPC supports the integration of any input device with a USB connection, it would be possible to integrate specific custom devices to access to the platform. Nevertheless, the achieved average satisfaction rate was around 60%, which in any case is higher than the average satisfaction rate of other solutions.

V. CONCLUSION

This paper discussed an e-learning platform designed for the whole family, and especially adapted for people with some degree of disability or dependence. It described the technological solution adopted, based on open systems, and more specifically on the Moodle LMS and the HTPC platform, facilitating its maintenance and future upgrades sustainable development. The paper also introduced the architectural solution addressing the integration of different control systems and devices that complete the final accessible platform. Then, we have described the development and integration of a Moodle client tailored to a TV environment and how access to the services offered by this LMS is provided through a TV appliance. This adaptation is performed considering that our target audience may include people with disabilities or experiencing some degree of dependence (e.g., the elder), so both the graphical and integrated control peripherals have been integrated taking into account the general requirement of universal accessibility.

Besides, this work included its validation with actual users with disabilities through a pilot project whose results are fairly satisfactory. For example, content accessibility, platform's simplicity and ease of use, or the ability to interact with others have been perceived as very positive. However, the developed platform is still open to further improvements. More specifically, the pilot process served to identify the need to improve the integrated control peripherals by paying particular attention to the possibilities offered by tablets and smartphones, the need to improve the navigation sequences in courses, and the need to pay additional attention to course content accessibility. However, results demonstrate the feasibility of this approach for the education and training of people with disabilities based on an open t-learning environment, which offers new possibilities to provide education to these collectives, and therefore to achieve their complete integration into society and the workplace.

Finally, the research team is presently focused on the improvement of the discussed platform with the integration of new multimedia solutions, the improvement of the features presently available at the TV client to foster social learning (e.g., blogs, tools for local and remote collaboration, etc.), the development of new adapted content, the integration of additional control peripherals for people with very severe motor disabilities, and to develop a new pilot project targeted to assess the introduction of this platform for the training of persons with disabilities in the framework of employment promotion, which is a most relevant aspect to be tackled according to our partner associations.

ACKNOWLEDGEMENTS

Online Course Advising: Differences in Student Response by Gender and Ethnicity

Rui (Celia) Pan, Joyce B. Main and Matthew D. Pistilli
Purdue University
panr@purdue.edu, jmain@purdue.edu, mpistill@purdue.edu

***Abstract*—Previous research suggests that effective academic advising can lead to better academic outcomes among undergraduate students. This study examines patterns between the use of an online advising tool, Course Signals, and course performance among students in engineering and technology. The number of advising interventions distributed through Course Signals tends to be positively associated with improved student course performance, particularly among female students. Findings suggest that online advising has the potential to be an effective method to improve student academic performance.**

Keywords—online advising; course performance; gender

I. INTRODUCTION

Although the participation of women and minorities in engineering has increased over time, they still constitute a lower share of engineering undergraduates. Women in engineering earned only 18% of the engineering bachelor's degrees in 2010 [1]. Meanwhile, among those who received bachelor's degrees in science and engineering in 2009, 10% were Asian/Pacific Islanders, 8% African Americans, 9% Hispanic, and 0.7% American Indian/Alaska Native [2]. As the United States faces a shortage of high-tech workers, attracting more women and minorities into engineering would help fill the gap [3]. Therefore, developing strategies to effectively recruit and retain female and minority students is one of the top priorities for engineering educators.

One potential solution to improve student retention in engineering is academic advising. Previous research indicates that high quality academic advising is a key factor in engineering students' academic success and retention [4-5]. Engineering programs are encouraged to "evaluate student performance, advise students regarding curricular and career matters, and monitor students' progress to foster their success in achieving program outcomes" (p.1) [6]. Research also suggests that women may be more responsive to advising interventions and signals that grades may provide [7-8]. Many computer tools and systems have been invented to facilitate the advising process [9]. Among these tools is Course Signals, which uses real-time data pertaining to student performance and other indicators to provide up-to-date feedback to students. Course Signals can also be used to deliver advising interventions aimed at promoting more effective study strategies and other changes that can lead to better outcomes [10].

In this study, we ask: is the frequency of advising interventions delivered through Course Signals associated with improved academic performance? Are there variations in student response to Course Signals by gender or race/ethnicity?

II. LITERATURE REVIEW

A. Advising

Successful academic advising requires an investment of time and effort from both advisor and advisee. In order to assist and facilitate the advising process, various computer tools have been invented to provide student information, academic records and advising resources to both advisors and students in a timely manner [9]. Some advanced tools can further process information and offer basic suggestions to students, such as selection of potential courses [9]. Research shows that these tools can provide effective assistance to advisors and students, especially at the beginning of the semester, when students need help to register courses [11-12], and at the end of the semester when advisors need students' grade point averages (GPA) to identify students who may have some difficulty with course progress [13].

While these methods and tools can help students with course selection and overall academic progress, there are also online advising systems that provide real-time feedback regarding course performance. Campbell, Collins, Finnegan & Gage (2006) proposed the idea of developing an early warning system to identify students who were at risk to provide interventions in time to improve student performance during the course [14]. Similar systems have been developed and utilized in advising engineering students at several institutions. These early warning systems allow instructors to recognize and advise students who have difficulty in their courses and help those students improve their performance [15-17]. For example, at Iowa State University, first year math, chemistry and engineering instructors can inform students and advisors on students' class performance within the first four to six weeks by using an early warning system [15]. This system enables advisors to recognize and advise students who are not performing well in class, but have not yet sought advising help [15]. The early warning system used in Rochester Institute of Technology has similar functions, as it allows faculty members to send emails to students who have difficulty in their courses [16].

Although many advising tools and systems have been implemented, there are limited studies on the impact of advising on engineering students' academic performance. Existing studies on advising suggest that advising can improve students' performance. For example, Morehead and Johnson (1964) found male electrical engineering freshmen who received increased informal advising contact had a significantly higher GPA than those who were in the regular advising program [18]. Goodwin et al (2010) examined the impact of an early warning system, which was implemented in first year math, chemistry and engineering courses. In their study, engineering students who entered college as undeclared engineering major in those courses were contacted by their advisors once they received warnings while students who entered as declared were not contacted by advisors when they received warnings. The analysis showed that students who received warnings and advising had better performance, compared with those who only received warnings [15].

While literature indicates that advising helps students improve their academic performance, it is not established whether there are differences in student response to online advising by gender or race/ethnicity. Previous studies on gender issues suggest that women may be more sensitive to grades. For example, research in economics shows that female students who receive an "A" in their first economics class are more likely to choose economics as their major [7]. In physics, Ost (2010) also discovered that women were more sensitive to grades; "For females a one point increase in GPA in physical science courses improves the probability of persistence by 13.4% whereas the corresponding figure for males is only 10.7%. Similarly, a one point increase in overall GPA (holding constant science GPA) leads to a much steeper decline in persistence for females than for males" (p. 932) [8].

Research on engineering and science students further suggests that female and male students respond to classroom technology or educational strategies in different ways. For instance, King and Joshi (2008) investigated the use and effectiveness of personal response systems (clickers) in chemistry and found that female students participated more actively than male students when given the clickers [19]. Kang et al. (2012) also examined gender differences in learning biology using two types of pedagogy: traditional lecture and narrative case studies with use of clickers. They found that while women performed better or similarly in classes that utilized narrative case studies with clickers compared to traditional lecture classes, men performed better in lecture classes [20].

Strategies, such as increased mentoring and academic support, have been used to increase the academic success and retention of underrepresented students [21]. For example, underrepresented students who received additional visualization specific instructions in an engineering graphics course were more likely to persist and have higher overall GPA compared to students who did not receive the additional support [22]. It is unclear, however, whether minority students respond to those strategies differently from their white counterparts.

B. Course Signals

One advising system that incorporates the main features of an early warning system is Course Signals. A predictive algorithm is applied to estimate students' risk statuses based on factors, such as student course effort, academic performance, prior academic history, and demographic characteristics [10]. The result is then translated into a red, yellow, or green signal, which is displayed on the student's course homepage to provide the student with up-to-date feedback on his/her course performance [10]. In Course Signals, "a red light indicates a high likelihood of being unsuccessful; yellow indicates a potential problem of succeeding; and a green signal demonstrates a high likelihood of succeeding in the course" (p2) [10].

Course Signals provides instructors two ways to communicate with students about their risk status in the course: a signal and an intervention message [23]. Instructors are encouraged to reveal the signals and send personalized intervention messages to students on a regular basis in order to advise students on their progress in the course [24]. While we have data on the number of advising interventions sent by each course instructor in the sample, we do not have information on the type of messages or advising instructions sent.

Since advising is one of the major factors that affect female and minority students' satisfaction and success in studying engineering [25-26], we explore the impact of Course Signals on student course performance with a focus on potential differences by gender and ethnicity/race. Our aim is to determine whether more frequent use of Course Signals is associated with improved course performance among engineering and technology students, and if there are variations in student response by gender or race/ethnicity.

III. DATA

A. Sample

The sample includes engineering and technology students from a large research university in the Midwest who were enrolled in a course utilizing Course Signals. The sample was limited to four courses with large enrollments (n > 90) offered in 2009 and 2010. Among those four courses, the Course Signals intervention was applied twice in two of the courses and three times in the remaining two courses. The data include demographic information, such as gender, race/ethnicity, citizenship, and declared major, as well as Course Signals information. Course Signals information includes the number of interventions (signals) provided to students and the color of the signals.

In total, 951 cases were analyzed (Table I). The sample includes 808 men, 143 women, and 234 international students. Among the U.S. citizens, 582 are Caucasian whereas 135 are Black or African American, Hispanic/Latino, Asian American, Pacific Islander, Native Hawaiian, or American Indian or Alaska Native. Of the sample, 619 students were majoring in engineering and 332 were majoring in technology. The lower percentages of women and minorities in the sample are consistent with the overall university student composition. In Fall 2012, only 21.4% of engineering undergraduates were female, 15.1% of technology undergraduates were female [27], and 13.7% of the total undergraduates were minorities [28].

In the rest of our paper, we refer to the 582 domestic Caucasian students as the Caucasian group and we categorize the 135 U.S. citizens who are Black or African American, Hispanic/Latino, Asian American, Pacific Islander, Native Hawaiian, or American Indian or Alaska Native as the minorities group.

B. Distribution of First Signal

Table II provides the distribution of first signal across demographic characteristics. Among engineering and technology students, 55% of male students and 50% of female students received green initial signals. A higher percentage of international students (68%) received green initial signals, compared to domestic students.

IV. METHODS AND FINDINGS

We divided students into three groups based on the color of the first signal that the student received: 1) red, 2) yellow, and 3) green. We categorized students based on their initial signals because although all students received interventions from Course Signals, the magnitude for improvement differs among the three groups. For instance, students whose initial signals are yellow could improve their performance to green, stay at yellow, or decrease in performance to red, whereas students who receive initial green signals can only receive the same signal or lower.

Within each group, we conducted Chi-square test or Fisher's exact test on male, female, domestic (Caucasian or minority), and international students separately to determine whether there is an association between students' performance and the number of signals given. We further compared the test results between student groups to identify differences by gender or ethnicity/race.

A. Analysis of Students Whose Initial Signals Are Red

For students whose initial signals are red, their final signals can either remain the same or turn yellow or green indicating an improvement in course performance. We categorized students who remained red in their final signal into a "same" group and those who received yellow or green final signals into an "improvement" group (Table III).

We used Chi-square test to test whether there is an association between students' performance and the number of signals given to students by gender and race/ethnicity. For groups with sample sizes less than five, we used Fisher's exact test. The second column in Table VI shows that all p values are greater than 0.05 demonstrating there is no significant association between students' performance and the number of signals given.

B. Analysis of Students Whose Initial Signals Are Yellow

We categorized students with initial yellow signals into an "improvement" group if their final signal was green. We put students into a "same" group if their final signal stayed yellow and into a "deceased performance" group if their final signal turned red.

In general, students who received three Course Signals interventions were more likely to improve their performance compared to students who received two Course Signals interventions (Table IV). We used Chi-square test or Fisher's exact test to further test whether there is an association between students' performance and the number of signals given to males, females, Caucasians, minorities and internationals separately. The results (Table VI, third column) show that an association exists in each group, except among international students. Based on the statistics in both Table VI and Table IV, an additional intervention appears to be associated with improvements in course performance. Compared to students who received two signals, a higher percentage of students who received three signals demonstrated a decrease in performance.

C. Analysis of Students Whose Initial Signals Are Green

For students whose initial signals are green, their final signals will either remain the same indicating maintenance of good performance or become red or yellow indicating a decrease in course performance. For those who remained green in their final signals, we put them into a "same" group. Otherwise, they were categorized as "decreased performance" (Table V).

TABLE I. DESCRIPTIVE STATISTICS OF SAMPLE

	Percentage	Sample size
Female	15.04%	143
Male	84.96%	808
International	24.61%	234
Caucasian	61.20%	582
Minorities	14.20%	135
Engineering students	65.09%	619
Technology students	34.91%	332
Total	100%	951

TABLE II. DISTRIBUTION OF FIRST SIGNAL BY DEMOGRAPHIC CHARACTERISTICS

	Initial signal=green Percentage (sample size)	Initial signal=yellow Percentage (sample size)	Initial signal=red Percentage (sample size)	Total
Male	55% (442)	25% (198)	21% (168)	808
Female	50% (71)	34% (48)	17% (24)	143
International	68% (158)	24% (55)	9% (21)	234
Caucasian	51% (294)	25% (146)	24% (142)	582
Minorities	45% (61)	33% (45)	21% (29)	135

Again we used a Chi-square test or Fisher's exact test, and found an association between number of interventions and course performance among female students (Table VI, fourth column). Among female students who received two signals, 71% remained green in their final signals whereas 92% of students receiving three signals maintained a green signal throughout the course.

TABLE III. ANALYSIS OF STUDENTS WITH RED INITIAL SIGNALS

Two Signals				Three Signals			
Group	Improvement Percentage (sample size)	Same Percentage (sample size)	Total	Group	Improvement Percentage (sample size)	Same Percentage (sample size)	Total
Male	73% (101)	27% (37)	138	Male	67% (20)	33% (10)	30
Female	74% (14)	26% (5)	19	Female	80% (4)	20% (1)	5
International	67% (10)	33% (5)	15	International	50% (3)	50% (3)	6
Caucasian	74% (87)	26% (31)	118	Caucasian	71% (17)	29% (7)	24
Minorities	75% (18)	25% (6)	24	Minorities	80% (4)	20% (1)	5

Caucasian	0.7702	<0.0001	0.2176
Minorities	1.0000	0.0314	0.4345

V. DISCUSSION

In this study, we investigate whether more frequent use of Course Signals is associated with better academic performance among engineering and technology students, and if there are variations in student response by gender or race/ethnicity. In general we find that among students who have average performance (yellow signal) at the beginning of the course, receiving an additional Course Signals intervention is associated with improved course performance. This additional intervention also appears to be associated with positive academic performance among female students suggesting that women may be more responsive to advising delivered through Course Signals. This is consistent with previous literature indicating that women are more sensitive to grades and that men and women respond to educational technology in different ways [7-8, 19-20].

Although the data suggest that additional interventions are associated with improved course performance, caution should be applied in interpreting these findings. These analyses are primarily descriptive, and not causal. There are several limitations to the study including the small sample size and the variations between the courses. While all instructors utilized Course Signals, there may be differences in their pedagogical approaches and grading practices that could explain differences in the magnitude of changes in student course performance. For example, an unexpected result is that a higher percentage of male, female, and Caucasian students who were given three interventions exhibited decreased performance compared to students who received two interventions. This difference in response could stem from differences in grading practices or the type of final exams given by the instructors in the two groups.

To address these limitations, we will expand our sample size and include a control group that would enable a causal analysis. The control group would be comprised of the same courses taught by the same instructors without the application of Course Signals.

VI. CONCLUSION

This study suggests that Course Signals, an online advising tool, has the potential to help students improve or maintain their level of academic performance. The results are consistent with the general conception that academic advising can promote students' academic success. Among students who have average performance at the beginning of the course, a higher percentage of students receiving three signals instead of two demonstrated improvements in course performance. In particular, Course Signals may have a positive impact on female students' academic performance. Among female students who were likely to succeed at the beginning of the course (green signal), a higher percentage maintained the green signal compared to those who received two signals. These findings suggest that advising delivered through online methods also have the potential to help students achieve better academic outcomes.

***Abstract*— Student diversity in higher education tends to focus on gender, ethnicity/race, and socio-economic status. However, these factors do not address cognitive diversity. Cognitive diversity, within the context of this study, refers to the varying ability of brain functions such as reasoning and memory, excluding persons with a developmental disability. Students with learning disabilities (LD), specifically dyslexia, contribute to this cognitive diversity. This study aims to initiate scholarly research on academic success factors for First-Year Engineering (FYE) students with dyslexia. FYE student performances on the Purdue Spatial Visualization Test-Rotations (PSVT-R) and Student Attitudinal Success Instrument (SASI) have been found to be predictors of academic success in engineering. A preliminary analysis of entering FYE student performance on the PSVT-R and SASI is conducted for three populations: students with dyslexia, students with a LD, and students without a LD. The anticipated findings will support the inclusion of cognitive ability, with an emphasis on LD and dyslexia, in FYE engineering diversity programs.**

Keywords*— *dyslexia, learning disabilities, spatial-visualization abilities, first-year engineering, academic success

I. Introduction

This work-in-progress (WIP) paper presents preliminary findings from a quantitative study designed to investigate critical factors influencing academic success of engineering students with dyslexia. "Dyslexia is a specific learning disability that is neurological in origin. It is characterized by difficulties with accurate and/or fluent word recognition and by poor spelling and decoding abilities. These difficulties typically result from a deficit in the phonological component of language that is often unexpected in relation to other cognitive abilities and the provision of effective classroom instruction. Secondary consequences may include problems in reading comprehension and reduced reading experience that can impede growth of vocabulary and background knowledge" [1]. This study examines spatial abilities and attitudes toward formal learning experiences. Comparisons are made between First-Year Engineering (FYE) students with dyslexia, a learning disability (LD), and students without a LD on the Purdue Spatial Visualization Test-Rotations (PSVT-R) and the Student Attitudinal Success Instrument (SASI). The PSVT-R is amongst the most common instruments for assessing visual spatial skills of engineering students [2]. It requires the student to visually rotate a solid to the correct position [3]. The SASI is a 161-item survey that is composed of 13 specific attitudinal and affective constructs, which have evidence of validity and reliability for engineering students [4]. The SASI is used to assess these constructs prior to the first year of engineering study and assists with retention programs and efforts at the first-year level.

II. Dyslexia & Engineering

A. *Disabilities in Engineering*

The National Academy of Engineering (NAE) has released several reports stating the U.S. must increase the diversity of engineers to meet the competitive need in the field [5][6]. Yet, this characterization of engineering diversity must be furthered to explicitly identify persons with different cognitive abilities such as a LD. The National Science Foundation (NSF) Committee on Equal Opportunities in Science and Engineering (CEOSE) supports the advancement of people with disabilities in STEM disciplines with the purpose of supporting diversity, however, LDs are not a major focus and data is not readily available. LDs are a major component of cognitive diversity, the varying ability of brain functions, such as reasoning, memory, and perception [7][8][9], and must be included in this national dialogue. The CEOSE has recently noted a need to regularly collect data on disabilities in STEM and requested that the National Center for Science and Engineering Statistics (NCSES) move forward with this recommendation [10].

B. *Students with Dyslexia: Self Perception*

Currently, there is minimal research explicitly investigating undergraduate engineering students with dyslexia. Research has found that history of academic achievement and stress impacts the self-perceptions of students with a LD or dyslexia in higher education [11][12]. These stress factors also persist in students that have both dyslexia and gifted abilities, referred to as twice-exceptional [13]. Twice-exceptional students with dyslexia are often identified late in their academic career; these students may be of particular interest to engineering. For example, competitive

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

engineering programs admit highly ranked students. If the admitted students are unidentified twice-exceptional persons with dyslexia and encounter challenges in their curriculum, anxiety and stress may be induced. Students with positive self-perceptions, supportive institutions, and a personal support network have success in higher education [14][15]. Students with LD and dyslexia in higher education attribute their success to motivation, planning, and organization. Lastly, a study of factors impacting retention found that belonging, involvement, purpose, self-determination, modeling inclusive behavior, and universal design for learning (UDL – which includes curricular and co-curricular components) were all key to retaining students [16].

C. Dyslxic Spatial and Visualization Abilities

In dyslexia research, spatial visualization ability debates have pivoted around the hypothesis of a "gift" [17][18] or a deficit [19][20]. Conflicting evidence has been presented for both [17]. The different neurological connections in the brain have led investigators to consider how those connections impact spatial visualization abilities and visual motion [21]. Studies have indicated that people with dyslexia have deficits in spatial visualization and detection of stimuli (motion) in a number of different tasks [21][22], others indicate that their was no differences between controls and persons with dyslexia in visual spatial tasks [21], and other studies suggest further spatial and visualization investigations must be conducted [19][18].

D. Research Questions

1. How do entering FYE students with dyslexia, with a LD, and without a LD perform comparatively on the PSVT-R?
2. How do entering FYE students with dyslexia, with a LD, and without a LD answer the SASI?

III. Methods

The PSVT-R and SASI was administered to all incoming FYE students at a large Midwestern public university; data was collected for fall 2010, 2011, and 2012. A matching comparison group was used for the initial statistical analysis to examine the data. From the SASI, three constructs predictive of academic success were selected: leadership, self- efficacy, and expectancy value. These constructs were selected based on key findings for student success in the dyslexia literature. It is hypothesized that students with dyslexia will perform differently than students without a LD.

IV. Preliminary findings

Institutional Review Board (IRB) approval is underway to access the necessary secondary data for this study. Data has previously been collected for entering FYE student performance on the PSVT-R and SASI. The authors have the support from the university disability offices and are seeking approval from the IRB to identify particularly students with dyslexia and LD for the analysis. Findings will be presented in a tabular format with the resulting statistical analysis based on tests of normality to determine if there is a significant difference in performance on the PSVT-R and responses on the SASI.

Factors Influencing Participants' Selection of Individual REU Sites

D. R. Economy, J. P. Martin, M. S. Kennedy
Clemson University
Clemson, SC, USA
deconom@clemson.edu, martin1@clemson.edu, mskenne@clemson.edu

Abstract*—This study seeks to elucidate factors influencing undergraduate engineering student intent to participate in research assistantships offered through National Science Foundation (NSF) research experiences for undergraduates (REU) site programs. Understanding participant decision criteria could increase targeting of specific student populations, improve program outcomes, and increase efficiency of site directors. This ongoing study builds off previous work by the NSF [1] on REU programs to answer the following questions: (1) are participant selection criteria uniform for all STEM REU programs or do they vary by program primary discipline, (2) do additional factors not previously considered, such as geography and other offers they receive, significantly impact REU selection, and (3) do factors significantly vary by each successive student cohort. To collect data, a survey was sent to REU participants through nine participating National Science Foundation (NSF) site administrators. Geographic distributions of applications were classified based on distance and spread with respect to hometown and indicated applicant divisions. Initial results showed that twenty five percent of these participants were offered multiple positions and seven percent of respondents declined another offer before accepting their current position.

***Keywords*—Research Experiences for Undergraduates; Student Selection; Student Decision Making; Summer Programs**

I. Introduction

Significant funding is being allocated for undergraduate research programs with the expectation that these programs will help increase the number of students applying to, and succeeding in, science, technology, engineering, and mathematics (STEM) graduate programs [2]. Research opportunities for undergraduates promote the development of student scientific research identity (i.e. becoming a scientist/researcher) [3] and also help students confirm or realize graduate education aspirations [4,5,6]. One prevalent type of these undergraduate research programs are the National Science Foundation (NSF) Research Experiences for Undergraduates (REU) sites, where student participants are recruited to academic research institutions for typically ten week mentored projects.

Initial studies of NSF REU site programs have sought to understand the factors that motivate undergraduates to apply for and select individual sites [1]. Although a previous report identified some influencing factors for NSF REU participants [1], more work is needed to identify: ***(1) if these factors are domain specific [such as materials science and engineering (MSE)] or if they are uniform for all STEM REU programs, (2) if additional factors, such as geography, are significant for impacting REU selection, and (3) if the importance of previously identified factors vary with each new student cohort.*** In this study, particpants within 2012 summer NSF REU sites were surveyed to help elucidate these aims. Another survey to be conducted of participating REU programs in the summer of 2013 will increase the number of respondents and investigate possible causal relationships for identified trends.

II. Methods

Feedback was solicited from participants within nine REU programs at eight different institutions within the U.S. A voluntary online survey was distributed via email to the REU participants through their site administrators. This survey included fourteen items to identify the aspects which students consider important when selecting research programs. It also included questions to ascertain the geographical location of where they graduated high school (hometown) and their current educational institution, which (and how many) REUs they applied to, as well as the other types of activities they pursued in addition to the REU program for summer work, and general demographic data (gender, class standing, # of years at current institution). The data collection instrument for this study was approved by each institution's Institutional Review Board.

Once results were collected, responses were stripped of any potential identifying information and specific institutional references were converted to classifications by the Carnegie Foundation for the Advancement of Teaching [7] and ZIP codes for anonymity. Statistical analysis was performed using Pearson's chi-squared tests and t-tests in order to identify statistical significance of trends observed from the survey.

III. Preliminary Results and Discussion

The REU sites participating were primarily classified as having very high and high activity research universities (RU/VH and RU/H) accounting for 44% and 40% of responses respectively; 16% of students attended an REU at an engineering special focus institution (SFI/Eng). A total of 61 participants responded with expected demographics (54%

Funding for this research was supplied by the National Science Foundation, DMR Award #1062873.

female, 44% male, 2% undisclosed gender, 58% rising seniors, 32% rising juniors, and 10% rising sophomores.)

A summary of factors identified by participants to their acceptance of a REU site offer is shown in Table 1. A majority of participants considered the stipend a influence (69 %), with smaller, but still significant, responses for research project focus, date of offer and housing/meal package. Factors selected by the smallest number of participants included the REU site application deadline, the distance of the REU site from the participant's hometown (close or far), and advice from advisors/professors. Eight percent of students noted other factors, such as that the participant only submitted a single REU application. The response frequencies for each decision making factor are noted in Table I.

TABLE I. STUDENT RESPONSE OF IMPORTANT FACTORS FOR ACCEPTING REU OFFER

Aspect	% Response
Stipend	69 %
Research Project Focus	64 %
Date of Offer	61 %
Housing/Meal Package	43 %
Activities Outside of Lab	38 %
Advice or Suggestions	34 %
Close to Home	26 %
Far from Home	22 %
Deadline of Application	20 %
Other	8 %

Comparing the results of this study with a previously published report [6] discussing selection criteria for REU participants notes interesting deviations. Two of the top three aspects noted in Table I (stipend and date of offer) were ranked much lower in the previous study [1]. This could be the result of a transition in student interest with more recent cohorts [8]. However, considering the limited sample size in this study, more data is needed to further confirm this finding. Additionally, the other report employed a Likert-like scale to note student importance, while our initial survey included a binary value of whether respondents considered the aspect important of not. Further scale development in successive survey iterations is desired.

The majority of students applied to two or less REUs, as seen in Fig. 1. Responses indicate that these students applied primarily to NSF sponsored REU programs as 62.3% of students did not apply for non-NSF REU positions and 52.5% of students did not apply for internships. Even though most students did not apply to many REU programs, 25% of students surveyed received two offers.

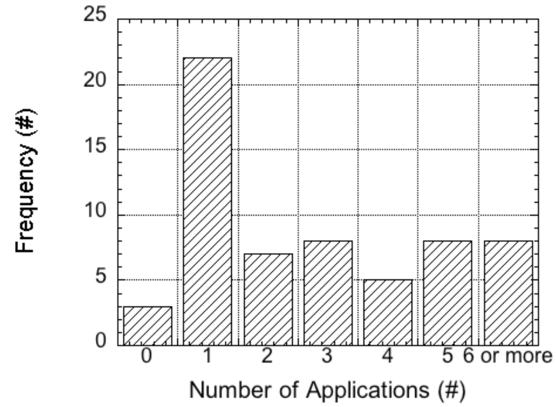

Fig. 1. Number of REU programs applied to per student applicant. The majority of students apply to 2 or less programs.

When decision factors are considered with respect to student demographics, some trends arise. The female students polled were significantly more interested in the housing/meal package (55% for females vs. 30% for males, χ^2 test, p-value: 0.068). Also, students that received two offers indicated that the date of the offer was especially important (93% for dual offers vs. 51% for single offers, χ^2 test, p-value: 0.003) and less likely to consider staying close to home important (7% for dual offers vs. 33% for single offers, χ^2 test, p-value: 0.053). When impact of Carnegie classification of REU site is considered, it appears to have affect whether students consider the application deadline to be important. Half of students responding from SFI/Eng REUs noting the importance of the deadline compared with 18% of RU/VH students and 12% of RU/H students. This could be due to the overall reputation of the schools associated, as SFI/Eng schools are by definition smaller and less research oriented than the others.

While some trends had statistical significance and could be reported, the analysis of demographic influence was limited by current sample size (61 survey responses). χ^2 tests showed that all other factors considered with respect to demographics (gender, class standing, REU institution type, and offers received) were not significant. Further work will include further development of the data measures and also an increase in the sample size to enable statistical significance.

Fig. 2 shows the distribution of distances between students' current institution and the REU that they attended. It can be seen that many students attend REU programs at their home institution and most remain within 500 miles. However, there is still a significant amount of students that travel farther distances, some even over 2500 miles. T-tests were used to determine that there was no significant deviation between the distances of schools that students applied to (total applications) compared with the REU site that they eventually chose. Similar trends were noted when viewing distance with respect to student hometown as well.

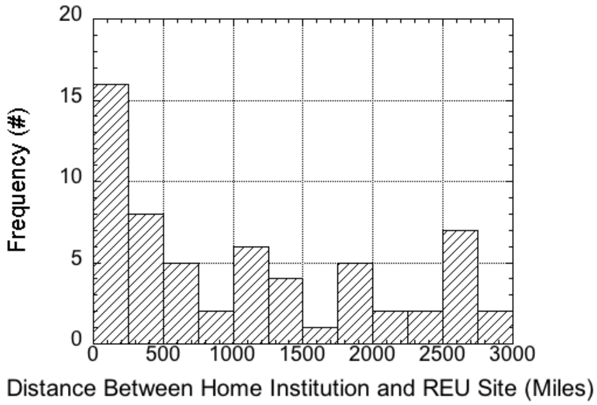

Fig. 2. Distance between the participant's home institution and the selected REU site. Some participants took part in REU programs at their home institution.

Analysis of geographic application distribution is underway to classify qualitative trends seen in student responses. Fig. 3 shows a representative participant application distribution created using the ggplot2 package in R [9,10]. Fig. 3 was created from representative data but modified in order to prevent identification of the individual. Initial classification suggests that there are multiple student application profiles such as: students who went far away from home for their education and applied to many long distance REUs, students who stayed close to home for their education and applied to many long distance REUs, students who went far away from home for their education and then applied to only that institution for an REU, and students who went far away from home for their education and then applied to a single REU that was not close to their home or their institution among other less common scenarios. Current efforts are underway to refine classification scheme and obtain inter-rater reliability measurements through the use of Fleiss' kappa calculations.

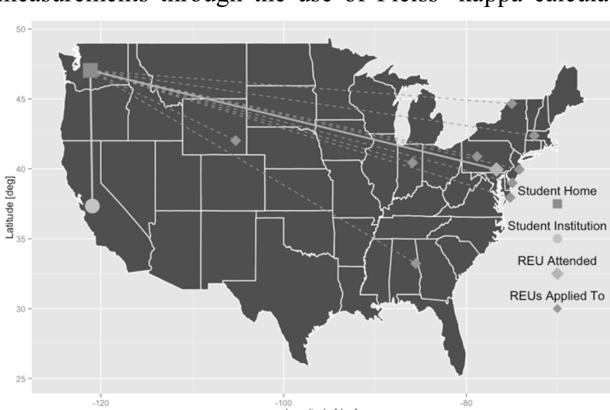

Fig. 3. Example distribution of potential application distribution to many REU programs across the USA.

IV. Conclusions and Future Work

Preliminary data from this ongoing study shows that recent REU participants consider stipend, research project focus, and date of offer to be the most important factors that influence their choice of summer program. However, when students received multiple offers, the date of offer was the primary factor. Students with multiple offers indicated that REU site location was less important than students with a single offer. When comparing with a previous report [6], it can be seen that there has been a shift from the identified motivating factors, this could be due to relatively small sample size (n = 61), or it could be due to varying student opinions in more recent cohorts [8]. Initial analysis has shown that there is no significant difference between the distance to institutions that students apply to when compared with the REU program that they finally select.

Acknowledgments

The authors would like to thank Mr. A. Cruickshank and Mr. B. Schultz (Department of Materials Science and Engineering, Clemson University), as well as Dr. G. Potvin (Department of Engineering and Science Education, Clemson University) for helpful discussions.

Context and Consistency in Students' Approaches to Solving Problems in Engineering Statics

Jeffrey L. Newcomer

Jeff.Newcomer@wwu.edu

***Abstract*—This paper examines students' responses to conceptually identical equilibrium and equivalence concept questions given in slightly different contexts, two as part of a final exam requiring explanation and the other two as part of a concept inventory. Since equivalence questions are essentially equilibrium questions from a different perspective, students were asked to apply the same concepts from two different perspectives and in two different contexts. Ideally student responses would be independent of context, but examination of students' answer selections and explanations indicates that approximately 2 in 3 students are consistent in their answers for equilibrium or equivalence questions in different contexts, but only approximately 1 in 3 students is consistent for both types of questions in both contexts. This paper builds off of previous studies of students' responses to Engineering Statics concept questions, explains the questions and methodology used in the study, and presents the results of the study.**

Keywords— Statics, Specific difficulties, Misconceptions

I. INTRODUCTION

How well do students transfer understanding from one context to another? If one asks what an expert would recognize as the same question in a different way or with additional requirements how often do students approach similar problems the same way? The traditional literature on transfer defines transfer as the ability to apply a skill learned in one context successfully in a different context. More recent work on transfer has focused more on the ability to use knowledge gained in one context to be able to learn in a new context, or the preparation for future learning (PFL), and focuses more on the student's perspective than the researcher or expert's perspective, also known as actor-oriented transfer [1]-[9]. Not all transfer, however, is related to novel situations. Sometimes the problem is only different in the details, but not in the structure or underlying model. To differentiate between these two types of transfer, Rebello et al. refer to situations where a pre-existing knowledge structure can be applied as horizontal transfer, and situations where the mental model must be created rather than referenced as vertical transfer [8]. Much of what students do on traditional end of class exercises such as final exams is an attempt to confirm students' horizontal transfer. The underlying hope is that students with sufficient horizontal transfer have a good PFL foundation and will eventually be able to apply their knowledge successfully in vertical transfer situations. Given the uncertainty that surrounds real-world engineering problems, the PFL foundation is critical to success and safety once the student becomes a practicing engineer.

In Engineering Statics equilibrium and equivalence are fundamental concepts that require students to apply the same methods. In both cases students must consider linear and rotational acceleration (or lack thereof) in order to guarantee that conditions are satisfied; in essence an equivalence problem is an equilibrium problem from a different perspective, so the tools and methods for solving equilibrium and equivalence problems are the same. From the perspective of transfer, for an expert equilibrium and equivalence problems represent horizontal transfer, but that may not be the case for students at the end of Statics. Many studies have shown that students either conflate linear and rotational acceleration or consider only one of them in many cases [10]-[17]. Previous work has also shown that students are not consistent in their approaches to equilibrium and equivalence problems when responses on those two types of questions are compared to each other [16].

One of the questions left open by previous studies is how much variation there is in students' responses to questions when the same type of question is asked in a different context. To test this notion of consistent student responses, three groups of students at Western Washington University (WWU) were asked to solve and explain a concept question on the final exam, a traditional on-paper exercise, and then asked to answer but not explain a conceptually identical question as part of the Concept Assessment Tool for Statics (CATS) concept inventory (formerly known as the Statics Concept Inventory or SCI), an on-line multiple choice assessment, for both an equilibrium question and an equivalence question [18]. The comparison of students' performance on the two equilibrium questions is an assessment of students' horizontal transfer, as is the comparison of the two equivalence questions. If the students have a stable model for both equilibrium and equivalence, then they should exhibit consistency on those questions on CATS and the final exam. Comparison of students' performance on the equilibrium and equivalence questions to each other represents a situation that is horizontal transfer to the expert, but might have some elements of vertical transfer for the students. A decline in performance across the two types of problems is an indicator that students do not recognize that equilibrium and equivalence problems represent the application

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

of the same concepts even though the problems are phrased differently. Ideally context, here meaning both the different formats and the different phrasings, would not have significant influence on students' responses, and students would be consistent in their responses, whether those responses are correct or exhibit specific difficulties.

The term 'misconception' is commonly used in engineering education to describe an incorrect understanding that must be unseated and replaced with a correct understanding, but there is an alternative theory in Physics Education Research that student difficulties are influenced by context if not outright context dependent [19]-[24]. In this view students' incoming understanding is made up of bits of loosely connected knowledge referred to as phenomenological primitives (p-prims) [19]-[23] or facets of thinking [24]. These p-prims, or knowledge elements, are triggered by context; while they may individually be correct in some circumstances, they may be applied in the wrong circumstances or combined improperly to form incorrect conclusions. According to this view, students do not need to have misconceptions unseated; instead they must learn which elements are correct in which contexts. These elements provide building blocks for reaching the desired mode of thinking. In this terminology, instead of misconceptions, students exhibit "specific difficulties" [25] – some more commonly than others. In order to design effective instructional material and techniques, one should take students' specific difficulties into account [26],[27].

One could argue that these two perspectives are not mutually exclusive. A student can have a fundamental misconception regarding a certain type of situation or problem, and this should manifest itself in a consistently incorrect approach to that situation or problem. If, however, the student has an inconsistent approach or unstable model, then it is possible that there is something discernable about the context that may be influencing the student's approach. This situation highlights some of the challenges that engineering education faces as we begin to acknowledge the contextual influence of students' specific difficulties.

A. Inconsistency

Since inconsistency is an important component of this study, it is necessary to be specific about how student consistency and inconsistency are defined. Quite simply, consistency is defined as using the same approach to the same type of problem in different situations, and inconsistency therefore is a lack of consistency. When looking at consistency in the context of assessing equilibrium questions, there are four ways in which a student could display consistent behavior: 1) always assess force and moment equilibrium; 2) always assess force, but never assess moment equilibrium; 3) never assess force, but always assess moment equilibrium; and 4) never assess force or moment equilibrium. Of the four it is obvious that the first is the desired behavior, but the other three also represent a consistent, if incorrect, approach. All other behaviors for assessing equilibrium on multiple problems are therefore labeled as inconsistent. The four consistent approaches represent good horizontal transfer, although the three consistent but incorrect approaches may be the sign of a misconception, and while the horizontal transfer may be good, these outcomes do not indicate good preparation for future learning. The inconsistent approaches not only are a sign of poor horizontal transfer, but also are indications that something in the context of the problem may be influencing a student's approaches to these problems.

Because the questions used in this study have also been used in previous studies [11]-[16], the correlations between students' answer selections and specific difficulties are known for these problems. Unfortunately, however, because the current version of CATS, run through the ciHUB, does not provide which incorrect answer a student has selected when the answer is incorrect, that information was not available for the spring 2012 group of students in this study. As a result, a simpler and slightly less informative definition of inconsistency needs to be used. For the purposes of this study, consistency is defined as answering the conceptually identical problems given in different contexts both correctly or both incorrectly. Unfortunately this conflates those students who are consistent and incorrect, and therefore may have a misconception, with those students who are inconsistent and incorrect, and may be influenced by context. What is important to note then is that results given here represent the best case scenario or upper bound of student consistency. While correct answers in both contexts are truly a sign of consistency, incorrect answers in both contexts might not be, because a student may select different incorrect answers in the different contexts, and those answer selections correlate to different specific difficulties.

Given that some of the information that would be desirable to have to discern what specific difficulties students are displaying is not available, there is still useful information in the conservative estimate that is available. There is also a clear correlation between doing poorly on the equilibrium and equivalence sections of CATS, especially the equivalence section, and making errors on traditional statics problems [28],[29]. As such, in addition to the consistency issue being examined here, the incorrect answers on these concept questions, whether consistent or not, are indicators of a likelihood that those students will also make more errors on traditional statics problems.

B. Statics at WWU

This study is based upon student response to concept questions given in Statics classes at WWU during the spring 2010, 2011, and 2012 academic terms. During this period 130 students were enrolled in these Statics classes, but not every student completed every assignment, so the analysis is based upon 109 student responses to the four concept questions. The Statics course at WWU, which has a pre-requisite of one quarter of physics (mechanics), is organized around six topics: free body diagrams, equilibrium, equivalence, separation of rigid bodies, friction, and linear algebra solution techniques, without differentiation between two vs. three dimensional cases, concurrent vs. non-concurrent force systems, and single bodies vs. frames and trusses [30]. These situations are all addressed in the course, but not in the order of traditional textbooks. Otherwise the course is a standard lecture-based course with homework, midterms, projects, a final exam, a limited number of think-pair-share exercises, and weekly Warm Up exercises for the first eight weeks of the quarter [31]. During this period students in Statics at WWU also were asked

(2010 and 2011) or required (2012), depending upon the term, to enroll in the OLI Statics class, which was used in lieu of a textbook [32]. The 2010 students had a lower average on the final exam than the 2011 and 2012 students, who had virtually identical average scores. The 2011 students had a lower average on CATS than the 2010 or 2012 students.

The final exam for the Statics class at WWU contains two concept questions derived from CATS questions in addition to five traditional problems. For the concept questions students are required to explain why the answer they have selected is correct or why the other answers are incorrect. This structure allows the instructor some insight into students' thinking on these questions.

II. The Questions

This study is based upon two pairs of conceptual questions. Each pair includes one question on CATS and one question on the final exam that is a modified version of the question from CATS. Figures 1 and 2 show the CATS and final exam versions of the equilibrium questions respectively.

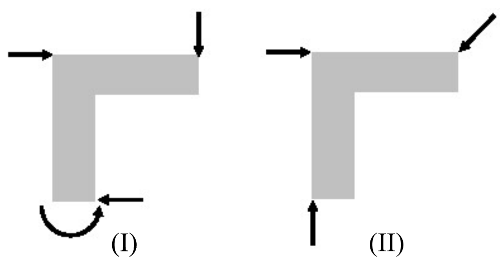

Fig. 1. CATS Version of the Equilibrium Question

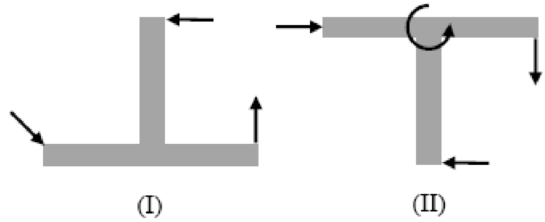

Fig. 2. Final Exam Version of the Equilibrium Question

The equilibrium questions ask students to consider the two bodies shown in Figures 1 and 2, and in both cases to determine which of the following statements is correct:

(a) I could be in equilibrium; II could be in equilibrium.
(b) I could never be in equilibrium; II could never be in equilibrium.
(c) I could be in equilibrium; II could never be in equilibrium.
(d) I could never be in equilibrium; II could be in equilibrium.
(e) Cannot say without more information.

The correct answer is (b); it is not possible for either system to be in equilibrium. One body has an unbalanced vertical force, which means force equilibrium is impossible; the other body has balanced linear forces, but they are arranged in a manner that guarantees an unbalanced moment. This is the most difficult question on CATS. Student responses to it have been extensively studied [11]-[13],[15], and those papers provide extra information, including what specific difficulties are associated with which answers.

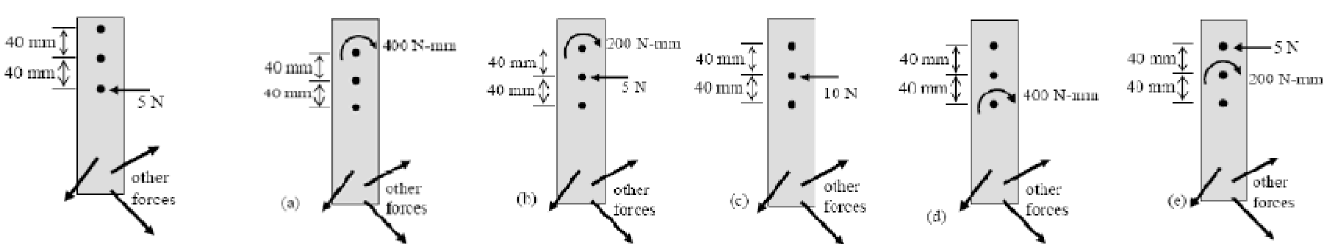

Fig. 3. Original System (left) and Answers for CATS Version of the Equivalence Question

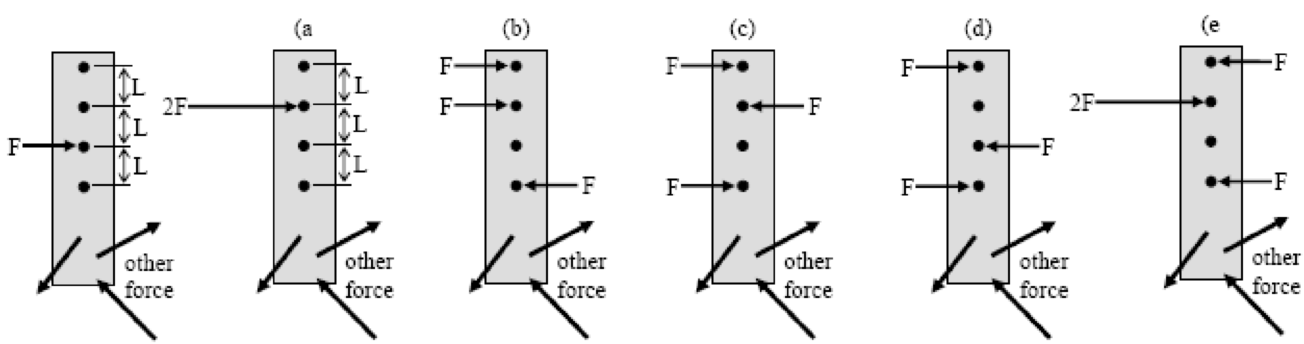

Fig. 4. Original System (left) and Answers for Final Exam Version of the Equivalence Question

The equivalence questions ask students to find an equivalent system to the one shown on the left-hand side of Figures 3 and 4. The question states that the body is subject to "other forces" on its lower portion, and it is kept in equilibrium by the additional force near the top. Students are then asked which of the other five systems shown would be able to maintain equilibrium if the "other forces" remain the same. For the CATS question, the correct answer is (b). Only systems (b) and (e) maintain force equilibrium, and of those two only system (b) maintains moment equilibrium. However, answer (a)-(d) all appear to maintain moment equilibrium if one only considers the top point. For the final exam question the correct answer is (c). Only systems (b)-(d) maintain force equilibrium, and of those three only system (c) also maintains moment equilibrium.

One of the observations from studying student explanations to the CATS problem in Figure 3 is that students who exhibit specific difficulties on this problem are much more likely to ignore force equilibrium than moment equilibrium. As a result of this observation, the final exam problem in Figure 4 was designed to be conceptually equivalent, but to not include any applied couples to see if that made any difference in students' approaches to the problem. It does, but only in a limited way. Students are still more likely to ignore force equilibrium than moment equilibrium when completing the problem shown in Figure 4, but they are also more likely to ignore moment equilibrium than with the problem in Figure 3. The question in Figure 4 does not, however, appear to be easier in the context of the final exam than the one in Figure 3. When the version in Figure 3 was used on the final exam for three classes in 2006 and 2007, the rate of correct responses was 73% (n = 140). When the version in Figure 4 was used in 2010, 2011, and 2012, the rate of correct responses was 64% (n = 129).

Table I gives the correct response rate for each of the four questions for the 109 students who completed all four questions. In both cases the rate of correct responses is higher for the final exam question, which also requires an explanation to accompany the multiple choice selection. What is interesting, however, is that the success rate is very similar for the equilibrium question, but notably higher for the equivalence question. The 2006 and 2007 students mentioned above had a correct response rate on the equilibrium question of only 45%. Those students did not take CATS, so there are no comparable data for the correct response rates on the CATS questions.

TABLE I. RATE OF CORRECT RESPONSES

Question	n	Rate of Correct Responses
CATS Equilibrirum	109	58%
Final Exam Equilibrium	109	61%
CATS Equivalence	109	44%
Final Exam Equivalence	109	64%

While there is nothing impressive about these results based on the numbers alone, the national averages on CATS for correct responses are 16% for the equilibrium question and 35% for the equivalence question [16].

III. CONSISTENCY ANALYSIS

Four aspects of consistency were considered for these student responses: 1) consistency on the equilibrium question, 2) consistency on the equivalence question, 3) consistency on all four questions, and 4) incorrect answer consistency on the equilibrium question for students in the 2010 and 2011 sections. Table II summarizes the results of the first three; the fourth is discussed below.

TABLE II. RATES OF CONSISTENCY IN RESPONSES

Question Type	n	Consistent		Inconsistent
		Correct	*Incorrect*	
1) Equilibrium	109	45.0%	25.7%	29.3%
2) Equilvalence	109	34.9%	26.6%	38.6%
3) Both	109	23.9%	9.2%	66.9%

The first two items, equilibrium and equivalence only, are the horizontal transfer situations. The distributions for the two based upon consistency v. inconsistency are not statistically different. The results are not horribly encouraging, with almost one-third of students not displaying good horizontal transfer for equilibrium, and over one-third not doing so for equivalence. When compared to other studies, however, these results are not as bad as it might seem at first, as evidence of horizontal transfer is often hard to find. In Rebello et al., for example, the researchers found no evidence of horizontal transfer from trigonometry to Physics [8].

It is also worth noting that for both the equilibrium question set and the equivalence question set that more than one-third of the students who displayed consistency were consistently wrong, which one could argue is worse than being inconsistent, and may indicate students with misconceptions. This is a virtually identical result to what was found in a study of students' consistency of assessing both force and moment equilibrium on these questions when students provided explanations to their answers [16]. In that study almost 36% of students who were consistent either selected incorrect answers or supplied incorrect explanations to these concept questions.

The third item, consideration of consistency on both equilibrium and equivalence, is a horizontal transfer situation from the perspective of the expert, but may not yet be for the students. As the data show, the consistency rate in this situation drops to roughly one-third of the students, although the rate of correct responses among the students who were consistent rises to slightly over 70%. The differences between this distribution and the first two are statistically significant ($p < 0.001$). This is an indication that students do not have strong or stable models that acknowledge equilibrium and equivalence as the same type of problem with different phrasing. These findings are also consistent with previous studies of these questions [16].

The fourth and final item, the consistency rate among those with incorrect answers can only be inferred from the student in the 2010 and 2011 classes (n = 59). Examining the incorrect answer consistency for those students for whom such information is available makes things worse. Of the 20 students who were in the 2010 and 2011 sections of statics who were consistently incorrect only 13 of them selected same answers for the equilibrium question on both the final exam and CATS. While these numbers are too small to draw any firm conclusions, it does clearly indicate that the fraction of students who are consistent while being incorrect is inflated, because their incorrect answers change with context, and on the equilibrium question each of the answers is strongly indicative of what the student actually assessed while completing the problem. If one infers that the roughly one-third of the incorrect responders are also inconsistent in all situations, the differences between the distribution for the consideration of all four questions (item 3) and the separate equilibrium and equivalence distributions (items 1 and 2) are still statistically significant ($p < 0.001$), so the implications regarding transfer remain.

A. Implications and Possible Explanations

The bottom line problem is fairly obvious, at the end of Statics, fewer than 25% of the students included in this study were able to answer four conceptually similar questions correctly, and fewer than 50% were able to answer three of the four correctly. Moreover, the national data cited in a previous study had fewer than 10% of students answering just the two CATS questions correctly [16]. This is clearly an issue that needs to be addressed.

What underlies the poor performance, however, is both less clear and integral to addressing the problem: student responses to conceptually identical problems vary with context. The immediate conclusion that can be drawn from this is that the misconception model of an incorrect understanding that must be unseated and replaced with a correct understanding is not valid for the majority of students. That is not to say that it is always invalid, but it not the proper approach to addressing students' ability to assess equilibrium at the conceptual level, whether those problems are presented directly or as equivalence problems.

The questions then become: What are the p-prims or facets of knowledge that students are using to build their approaches to equilibrium problems? What cues serve as triggers to get students to take a specific approach in a given context? The former question is not answerable from this study, but it was hoped that this study could shed some light on the latter question. Two of the possibilities that were raised earlier were 1) that including a couple symbol in the problem is more likely to invoke consideration of moment equilibrium and 2) that including numbers in the problem invokes a different approach to the problem [16]. Based upon studies of the CATS equilibrium question, the former seems to be true for students entering Statics, but does not appear to be true for many students at the end of Statics [11]-[15].

These potential cues were the impetus for the creation of the alternative version of the equivalence question used on the final exam (Fig. 4), which contains neither couple symbols nor numbers. Based upon students justifications of their answer selection, there is nothing to indicate that the lack of numbers made a difference, but there is some indication that the couple symbol may have made a difference. The rate of consideration of force equilibrium was identical for the 2006 and 2007 classes, who answered the problem in Figure 3 on their final exam, to students in the 2010, 2011, and 2012 sections, who answered the problem in Figure 4 [16]. There was, however, an 18% decline in the rate of consideration of moment equilibrium for the 2010, 2011, and 2012 group compared to the 2006 and 2007 group, and that difference is statistically significant ($p < 0.001$). This difference is reason to believe that the couple symbol does induce some students to consider moment equilibrium when they might not otherwise, but that does not appear to be true for the majority of students.

The equilibrium question responses may serve as a guide to strengthen the inference that the couple symbol is a cue. The students in the 2010, 2011, and 2012 group were slightly more likely to consider force equilibrium and significantly more likely to consider moment equilibrium on the equilibrium question than students in the 2006 and 2007 group. Since both groups of students answered what is essentially the same equilibrium question, including a couple symbol, one could surmise that the more recent group was more predisposed to consider moment equilibrium, so the fact that their rate of consideration of moment equilibrium on the equivalence question declined relative to the other group might be an indication that the couple symbol is a stronger cue for the consideration of moment equilibrium than the 18% decline implies. This is, however, not a provable supposition with these data.

These data also do not give a clear indication if the format is a factor. Students did significantly better on the equivalence problem on the final exam than on CATS, but had roughly equal performance on the equilibrium problem. The two obvious potential differences are that requiring an explanation for the answer on the final exam invokes deeper thinking on the part of the students, and that they are more motivated to do well on the final exam than on CATS. Testing whether the first one is an issue or not would require a different study, say with think-aloud reasoning on the part of the students. The second one, motivation, probably is not testable. It is true that the final exam question had slightly more potential to influence the course grade, but none of the in this study problems had a significant impact on the overall course grade. So while the data in this study show effectively that context influences students' reactions and/or approaches to problems, that transfer between equilibrium and equivalence is poor, and that the couple symbol is likely a cue for consideration of moment equilibrium for some students, but it does not shed much light on why these things are true or what the building blocks that students use for equilibrium analysis may be. That is a topic for continued exploration.

B. Future Work

The remaining tasks in this area are twofold: 1) continue to work to determine what p-prims or facets of knowledge are serving as the building blocks for student responses, and also what cues or contexts incite what modes of thinking, and 2) continue to work to develop exercises that will help reduce the contextual nature of students' responses to equilibrium questions. Simply stated, more input is needed by more researchers in this area. A deeper understanding of how students develop appropriate approaches to concepts such as assessment of equilibrium might help shed more light on how students approach more complex concepts in higher level classes.

In addition to continuing to study and develop tools to improve performance on equilibrium problems, it would be interesting to study some of the other conceptual areas of Statics in more depth to determine if student performance in those areas is also strongly influenced by context. There is no magic solution to get students to pick up concepts like equilibrium quickly and efficiently, but there may be approaches that improve the rates of learning and retention, and it may be easier to shed some light on them by broadening the scope of Statics concepts under consideration.

IV. Conclusions

This paper has examined student responses to two equilibrium and equivalence questions in two different contexts, a final exam with an explanation required and a concept inventory (CATS), to show that student approaches to equilibrium are inconsistent. The students in question completed conceptually identical equilibrium questions and equivalence questions in the two different contexts. Consistency on these pairs is an indication of good horizontal transfer. Furthermore, an equivalence question is essentially an equilibrium question from a different perspective, so in essence these students completed four different equilibrium questions with two forms of presentation in two different contexts. Consistency of all four questions is an example of horizontal transfer to an expert, but may not be so yet to the students.

Transfer on the same type of question in different contexts was relatively good based upon consistency, but was poor from the one type of question to the other. Examination of students' responses showed that roughly two-thirds of students were consistent in their approach to the same type of problem in different contexts, the final exam and CATS, but only about one-third of students were consistent in their treatment of all four problems, and roughly one-quarter of those students who were consistent were consistently incorrect. The conclusion of this study is that when it comes to equilibrium most students do not have deep-seated misconceptions that must be corrected, although some might, but that most students who are giving incorrect answers are reacting to context, including in some cases the symbol for an applied couple. Engineering education research needs to consider different models of student behavior when confronting students' specific difficulties in the area of assessment of equilibrium.

When a testbed does more than testing

The Internet-Scale Event Attack and Generation Environment (ISEAGE) – providing learning and synthesizing experiences for cyber security students.

jrursch@iastate.edu, dougj@iastate.edu

Abstract— The importance of laboratory exercises for students is recognized unilaterally by engineering and technology programs. As engineering educators whose academic focus is information assurance and cyber security, we believe students in cyber security need the same type of access to hands on opportunities as their counter parts in hardware design or circuit design. Students should be able to configure and run their own networks, as well as explore the vulnerabilities, exploits, and remediatios needed in a cyber security professional's tool kit. Further, they need exposure to working in the complexity of the Internet. While some might argue that simulation software could be a solution, it often lacks realism. In this paper we show how our institution goes beyond the providing the standard, formalized laboratory activities for our cyber security students by developing a unique, highly configurable testbed called Internet-Scale Event and Attack Generation Environment (ISEAGE – pronounced "ice age") that allows us to imitate the Internet. ISEAGE provides a controlled environment that allows real attacks to be played out against the students' networks and demonstrates to them real world security concepts.

This paper provides an overview of how the ISEAGE security testbed functions, as well as illustrates how ISEAGE provides our students five different types of opportunities for real world experience: support of formalized classroom work; cyber defense competitions for high school, community college and four year students; inquiry-based learning in a playground environment for high school, as well as college students; testing environment for network devices such as firewalls, data loss protection, intrusion detection; research environment for senior and graduate student work.

Keywords—testbed, information assurance education, cyber security, laboratory exercises.

I. Introduction

Engineering and technology programs across the United States recognize the importance of laboratory exercises (or hands on experiences) for their students to truly synthesize concepts. As engineering educators whose academic focus is information assurance and cyber security, we want to provide our students with the most realistic of laboratory experiences to help them hone their skills and develop the depth of thinking needed in this complex and every changing world we live in. Students in cyber security need the same type of access to hands on opportunities as their counter parts in hardware design or circuit design. They should be able to configure and run their own networks, as well as explore the vulnerabilities, exploits, and remediations. However, putting students in labs full of physical equipment can be expensive to do, even with virtualization. And, if given an unending supply of servers, hard disk and RAM to create local networks, it is still a challenge to mimic the complexity of the Internet. Others might argue that simulation software could be a solution, but it often lacks realism. So, we are presented with a hard problem. How do we create a realistic Internet for cyber security students to use?

In this paper, we show how our institution goes beyond the providing the standard, formalized laboratory activities for our cyber security students. We have developed a unique, highly configurable testbed called Internet-Scale Event and Attack Generation Environment (ISEAGE – pronounced "ice age") that allows us to imitate the Internet. ISEAGE provides a controlled environment that allows real attacks to be played out against the students' networks and demonstrates real world security concepts. The ISEAGE security testbed has an air gap proxy server through which students can connect to the Internet to download operating systems and patches or search for additional information about configuration problems, but no other traffic can escape. While ISEAGE can follow all TCP/IP protocols, it also allows manipulation of those protocols and traffic capture to demonstrate specific types of attacks such as Distributed Denial of Service.

This paper will provide an overview of how the ISEAGE security testbed was developed and functions, as well as future work underway with the testbed. However, the major focus of the paper is to illustrate how ISEAGE provides the environment so that our students have five different types of opportunities for real world experience. It is divided into four sections. Section II provides a technical overview of ISEAGE and how it is configured. Section III enumerates the five different types of experiences our students are provided by the ISEAGE security testbed: A) support of formalized classroom work; B) cyber defense competitions for high school, community college and four year students; C) inquiry-based learning in a playground environment for high school, as well as college students; D) testing environment for network

The ISEASGE security testbed was developed through Department of Justice funding.

devices such as firewalls, data loss protection, intrusion detection; E) research environment for senior and graduate student work. Section IV provides the conclusions and future work.

II. Overview of ISEAGE

There have been several successful network testbeds, the most widely recognized name in this area is DeterLabs [1], but ISEAGE is designed specifically for use in security research and offers several advantages over a conventional network testbed. It has four unique features as part of its highly reconfigurable architecture which allows for very small or very large network testing and rapid setup. Each of ISEAGE's features (architecture, tool set, data collection availability, and scalability) are described in the following sections.

A. Architecture

As shown in Fig. 1, the core of the ISEAGE security testbed is a routable IP network that supports the traffic to and from the networks and systems under test. Because of ISEAGE's internal programming, called ISEFlow, the architecture simulates the cloud environment of the Internet with multihops, but the traffic all stays contained within the security testbed. However, ISEFlow makes traffic appear as if it has routed through the Internet. ISEAGE is unlike conventional testbeds where each router represented by either a real router or a software router running on a computer. ISEFlow creates the external subnets as well as a large number of internal networks without needing to instantiate a separate router for each network. This internal cloud network represents a cluster of routers. If an external computer performed a traceroute to a server in a different network, it would see a number of hops between itself and server as if there were real routers between it and the server. The TTL field in the IP header would also indicate the traffic traversed multiple routers just as it would if it were traveling via the Internet.

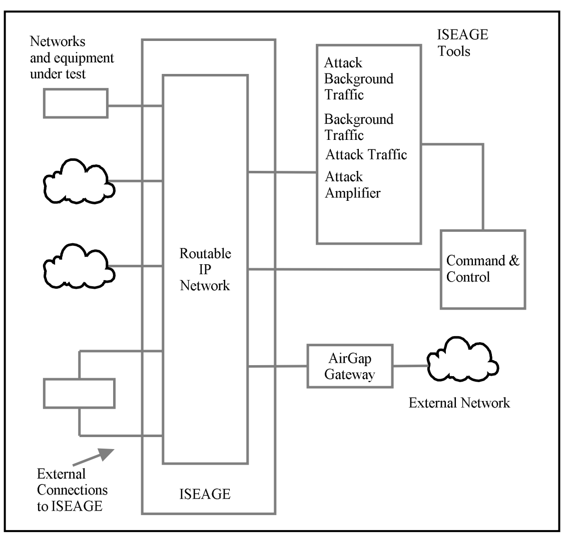

Figure 1. ISEAGE Architecture

As is also shown in Fig. 1, the networks and equipment under test are directly connected into the ISEAGE's routable network. Generally, this equipment is considered to be servers and end user machines. These types of devices are end points and view ISEAGE as an Internet connection. However, there is also the ability to connect external devices to insert additional routing infrastructure. These types of devices can use the data flow through ISEAGE and can be used to test routers, firewalls and other devices that interconnect multiple networks.

As was discussed in the introduction, the ISEAGE security testbed was created to allow work conducted in a secure environment. As shown in Fig. 1, there is a separate command and control network for configuring both the ISEAGE routable network and the networks and equipment under test. Further, Fig. 1 also shows the air gap proxy which is the only egress point for traffic leaving the ISEAGE security testbed. It allows web and ftp traffic to pass out of the networks attached to it, but restricts all other traffic. This configuration provides an isolated network environment in which the networks can run. It was intentionally developed to avoid the inevitable misconfiguration or unwanted attacks on the real world network by a student learning about or incorrectly configuring a device. Finally, the tool repository is shown in Fig. 1 and is discussed in Section B below.

ISEAGE is highly configurable and highly scalable. The authors have copies running on computers ranging in size from modest laptops to multi-machine installations. One of ISEAGE's unique features is the ability to have an unlimited number of routers connected. The only limitation is the size of the computer or server on which the framework is running. ISEAGE is currently built on ESXi servers allowing for the quick addition of additional resources for any project.

As a simple network configuration example for this paper, Fig. 2 is provided. For the sake of this discussion, it will be assumed the entire ISEAGE testbed is installed on one ESXi server. However, there are many different configurations that could occur in ISEAGE, depending upon the complexity required. Fig. 2 shows the network using five copies of ISEFlow which is depicted as a red box. Again, the number of ISEFlows can vary with the complexity of the installation. In this simple configuration between one and three routers are configured in each ISEFlow. Each of the numbered routers within the ISEFlow has an ingress and an egress address in public IP space. Again, because the traffic doesn't escape the ISEAGE security testbed, ISEAGE can use public IP address space.

The red boxes labeled B1, B2, and B3 are the ISEFlows that allow systems to be attached into the ISEAGE network. Outside of the red boxes at the top of Fig. 2 are five additional IP address ranges. Again, these are in the public space. The systems under test use these additional IP ranges. The devices are either attached as endpoints and view ISEAGE as an Internet connection or they are inline devices that use ISEAGE to test the data flow through multiple networks. In either case, the systems under test point their outbound traffic to the outermost router interface in the ISEFlow configuration to which they are attached. When traffic leaves the devices of interest, the cluster of routers in ISEFlow will alter the traffic as if the traffic traversed each router in turn.

The red box labeled B4 exists to connect the ISEAGE network to the real outside Internet through an air gap proxy that allows only web and ftp traffic out. Air Gap 1 also functions as an internal DNS server so all systems under test can have name resolution. The red box labeled B5 is a data collection port and can record all traffic in the ISEAGE network. The green box labeled Backplane allows ISEFlows to communicate with each other.

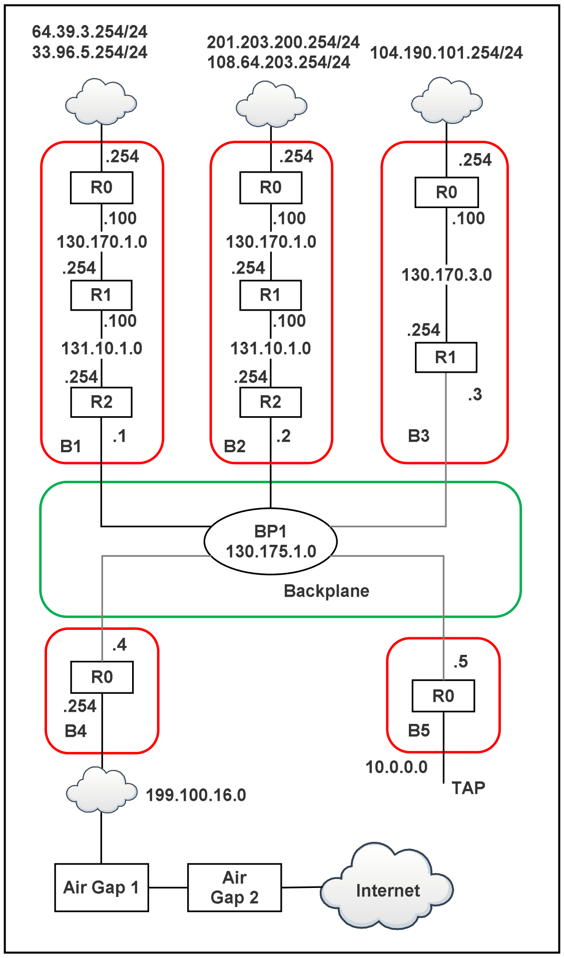

Figure 2. Simple network

B. *Tool Set*

There are multiple tools designed to support ISEAGE. The tools use a common command and control protocol to allow easy integration into the ISEAGE command and control network. Below is a brief description of the tool set.

1) Attack Amplifier & Condenser

The attack amplifier is used to convert an attack launched from a single computer into an attack that appears to be launched from multiple computers. This tool allows researchers to study distributed and flooding based attacks. With this tool researchers can create attacks that appear to come from thousands or even tens of thousands of computers.

The attack condenser works with the attack amplifier. Often distributed attacks create a large number of responses back to the attacker or responses that have been redirected to another target. The attack condenser will take the responses and condense them into a small number of responses. It can also be configured to respond to the messages. For example, if there is a redirected distributed attack pointed to a machine, the attack condenser can become that machine and absorb the attack and respond when necessary.

2) Packet Changer/Responder

The packet changer/responder can be used to modify packets in real-time as they flow through the network. This tool can be used to create man-in-middle attacks or can be used to generate traffic in response to certain incoming packets.

3) Attack Collector/Watcher/Replayer

These three tools are used to collect information to be replayed within the virtual internet. The attack collector is a honey pot / honey net that is used to collect host based attacks. The attack watcher is an intrusion detection system that captures network attacks. The attack replayer replays the attack inside the virtual internet. The attack collector and watcher are connected to remote sites via the internet using encrypted connections.

4) Attack Tool Repository

An extensive library of attack tools is maintained. The library allows the launch of a wide array of attacks. By feeding the attacks through the tools described above the testbed network allows examination of and design of mechanisms for defense against real attacks

5) Traffic Collector/Replayer

This tool captures traffic patterns from the actual Internet at particular locations so they can be replayed with ISEAGE. The collector captures traffic patterns only; it does not capture the data. The replayer then reconstructs traffic from the captured data to recreate as close as possible the background traffic seen at a given location on the actual Internet.

C. *Data Collection Point*

Another interesting feature of ISEAGE is its ability to capture all traffic through what is called a tap port. This is very useful when teaching about intrusions or when wanting a log of all network traffic during a research experiment.

D. *Scalability*

In addition to the full scale ISEAGE testbed several smaller versions have been developed. ISEAGE is capable of running on a single machine running virtualization. These smaller versions of ISEAGE are used in most of the setting discussed in this paper. The full scale ISEAGE is used primarily for research and device testing. The smallest version of ISEAGE runs on a laptop. The only limiting factor for the number of routers and nodes that can be used in the ISEAGE testbed is the size of the hardware on which ISEAGE is installed.

III. ISEAGE USES

There are five different uses of the ISEAGE security testbed in which student can gain valuable, real world experience with networks and security. The first three listed below (classroom, cyber defense, and playground) are very similar, but have distinct differences based upon who builds the network that is being tested and who does the testing.

A. ISEAGE in the Classroom

The ISEAGE security testbed is used to support several classes at Iowa State University (ISU). Two of them are discussed in this paper: an undergraduate introduction to networking and graduate level capstone course. Both of these courses use the ISEAGE architecture as a connection to the Internet. Both courses allow the students to build networks by setting up servers and running services on them. However, the undergraduate course focuses on teaching basic principles such as IP address space, network connectivity, and simple protocols. This course was not taught in the engineering college, but in the business college as part of the Management Information Systems (MIS) program. The hands on activities include designing and configuring a mail server, a domain name service (DNS), a firewall, and a web server using their assigned public IP address and domain name in the ISEAGE testbed. They also had to use Windows Server 2008 as their operating system. The course was taught in the traditional lecture manner with students needing to complete the hands on exercises on a computer on their own time; no lab was associated with this course. Students self-selected into teams of four to five to complete the project. The course included a project planning phase, an implementation phase, and an evaluation phase for each team of students.

The graduate course is an information assurance course capstone course developed at ISU to enable distance education students to complete the requirements for a Master's of Engineering in Information Assurance without setting foot on campus [2]. This course is entirely lab-based and is comprised of three parts: the planning and implementing phase (six weeks); the defending and attacking phase (four weeks); and the infrastructure assessing phase (five weeks).

While the undergraduate course had the planning and assessment phases, the graduate course was more rigorous and included an attack and defend phase. Here individual students create their own networks instead of working as a team. They adhered to a provided scenario or story line of what services have to be run. The students could select any operating system as long as it was open source, had a demonstration period that lasts throughout the semester, or was site-licensed by ISU. Additionally, the graduate students had to produce their own preliminary network plan that included a diagram of their network, as well as the rationale for selecting the operating systems and applications used. Again, the graduate students were assign public IP addresses and domain names in the ISEAGE testbed which they had to implement.

During the attack and defend phase each graduate student tries to identify vulnerabilities and weaknesses in his classmates' networks. Students are allowed to exploit these vulnerabilities on others' networks, as well as capture predefined flags or planting flags. Students must document their discoveries and activities as part of their final report. Additionally, while they are trying to exploit others' networks, they must defend their own networks and protect their flags.

In summary, in the MIS class the students build their own networks as teams using a Microsoft environment, but the networks were only tested by the faculty member to verify the systems were working. In the graduate course, a single student built his entire network using any operating system and then attacked other students' networks. In both cases the requirements for building the network were specified ahead of time and did not change during the semester.

B. ISEAGE as a Cyber Defense Environment

The goal of a cyber defense competition (CDC) is to have students design, and configure a set of servers and a network in a secure manner and in a relatively short, one-month period of time [3, 4]. Then, the students attend a two-day competition to defend their network from attackers. During the two-day competition, their goal is to prevent, if possible, any security violations or attacks on their network, as well as report and correct any problems that arise. They also must maintain full functionality of their systems for the end users. Students in ISU competitions are required to configure their networks as described by a scenario that details the services that they have to implement in a short story format, as well as their network address space. They are told they are the IT support staff for a company or school and have to implement services such as email, web mail, remote programming, file sharing, and web hosting. They are also told they are responsible for their own Domain Name Service (DNS) and it would be wise to implement a firewall to help protect their networks. They are also given some service, generally a web server, that is a legacy installation which must be supported in a present state. The legacy system provides some inherent security vulnerabilities that they have to protect against. Teams also have to protect flags from being captured by the attackers. These flags are encrypted files which contain a unique string and are required to be stored in a specific directory location on specific servers the teams are running. In our competitions, these student teams are known as the Blue Team. Depending upon the competition, the Blue Team may be comprised of high school students, community college students, four-year institution students or IT professionals/faculty members.

In addition to defending their network, the students also participate in numerous activities (called anomalies) throughout the competition which are designed to keep them engaged and slightly off balance just as real IT staffs get engaged in new projects and may overlook intrusions or security risks in new implementations. The people who activate these anomalies are the Green Team. This team of people are assigned to play the role of end users of the teams' networks. They can request changes to be made to the Blue Teams' networks throughout the competition. Some of these Green Team requests may run counter to the goal of having secure systems or may be to have the teams install some of the latest software that opens holes in their servers. The Blue Team must then decide how, or if, to implement the request on their network and how to implement it security.

The Green Team members are recruited from undergraduate student population, less technical corporate partners, and ISU faculty across campus. This wide variety of computer skill levels provides true tests of usability for the

Blue Teams. The addition of the Green Team is what helps keep the students focused on providing a useable network, as well as a secure one. Generally, the anomalies occur with a frequency of every 60 to 90 minutes during the competition. However, during the cyber defense competition an anomaly may be developed based upon a common characteristic found in the networks.

The group who tests each Blue Team network for vulnerabilities and plays the role of attackers in the competition are IT professionals, as well as Computer Engineering faculty and graduate students specializing in Information Assurance (IA), and are called the Red Team. The Red Team is led by an ISU IA faculty member and/or a member of industry who specializes in penetration testing. Since the competitions occur over a Friday and Saturday, their job is to conduct reconnaissance work on Friday and early Saturday morning when the teams are still setting up to determine what kinds of networks the teams are running or to carry out social engineering. Then, at the designated time on Saturday morning, the Red Team begins active network scans and active penetration testing against the Blue Teams' networks. Once vulnerabilities are found, the Red Team may act on those to gain access to the servers of interest. First, they must capture the flag on that server to prove that they have access to the box. Then, once they have the flag, they can reconfigure it, install additional software on it, install a virus on it or take any variety of steps that an attacker might take on a production server. The Blue Teams may recognize the Red Team's advances and may take actions to stop them or recover from them, as well as report the breach. However, the Blue Team may not attack or block the Red Team in an effort to protect their systems.

All competitions need a group to oversee the event and keep everyone in the competition honest. The White Team performs the role of adjudicator, as well as records scores for the Blue Teams given by the Green Team and Red Team on usability and security, respectively. The White Team also reads the security reports and scores them for accuracy and countermeasures. The White Team leader is usually an upper level undergraduate student or a graduate student.

In summary, for the CDC the Blue Team built their network and defended it, but the Red Team was the group doing the attacking. Also, the requirements for the network was constantly changing based upon the Green Team anomalies.

C. ISEAGE as a Playground Environment

Although taking a one semester class that uses ISEAGE allows students some valuable experience to build and protect networks, the pitfall is that the course only runs one semester. Then the equipment is reset and the networks that the students build are put back to original clean state. As part of the course evaluations, we discovered that it would be useful to allow students access to a centralized virtual lab year round so students could practice skills in an ungraded and experimental environment. Therefore a centralized virtual lab called the playground was created which is available throughout the year for students to build and experiment with different operating systems and security measures.

In the case of the playground, there are no requirements made of the students wanting to work in it. They are not given any network specifications or required to complete any reports. They are given open access to perform inquiry-based learning in their own time and speed. The systems that are under test would be the systems that they build and there is no one attacking them, but they could complete their own penetration testing as part of the inquiry-based learning.

D. ISEAGE as a Testing Environment

ISEAGE has been used to test data loss prevention devices for a major networking trade magazine and new testing series of different products is scheduled. Generally, the projects are the testing of commercial-off-the-shelf (COTS) products in a controlled environment. As part of each testing process the methodology and the metrics have to be developed. Here the student work is in development of the test metrics, performance of the tests, and the evaluation and results documentation.

The first three examples listed above (A-C) engaged students with creating and implementing networks of their own design. In this case, the network that is being developed in the ISEAGE testbed is focused on data flows being pushed through or to external devices connected into the testbed. There is more standardization of the network configuration. The creativity and learning comes from the development of metrics and the evaluation of the test results.

E. ISEAGE as a Research Environment

The ISEAGE security testbed was designed to provide an environment to conduct state of the art research in computer security and security tool development. ISEAGE is currently being used in several projects related to the modeling of critical infrastructures. Two projects are discussed in this paper. First, the ISEAGE security testbed is being used to model the State of Iowa cyber infrastructure with the goal of being able to determine interdependencies between systems and any weakness in the system. Additionally, "what –if" scenarios are developed to help the state develop contingency plans in case of a cyber attack. Once deployed, the State of Iowa will not only be able to test the infrastructure, but will be able to use ISEAGE to provide training of the staff and to try out new protection systems in a controlled environment.

The second project using the ISEAGE testbed is focused on the development a meta framework that allows modeling of critical infrastructure and assets with physical data which can be used for training, preparedness, and real-time reaction. This unified model is the Critical Infrastructure Modeling and Response Environment (CIMoRE) [pronounced "see more"] which represents a new paradigm for disaster planning and response. CIMoRE accounts for all critical infrastructure components such as roads, bridges, rail systems, water treatment facilities, power grids and telephone systems, cyber networks, as well as their interdependencies, in its single, unified framework. Because it is built upon the ISEAGE testbed, CIMoRE provides for a varying level of complexity in the inclusion or exclusion of critical infrastructure components. CIMoRE gives emergency planners and disaster responders the opportunity to view the physical locations of the critical infrastructure components, assess their interconnectedness, identify their failing health state, determine and avoid congestion, visually play out mitigation options, document analysis decisions and record the recovery of the critical components.

IV. Conclusions and Future Work

The use of the ISEAGE security testbed has provided the environment so that students have five different types of opportunities for real world experience: support of formalized classroom work; cyber defense competitions for high school, community college and four year students; inquiry-based learning in a playground environment for high school, as well as college students; testing environment for network devices such as firewalls, data loss protection, intrusion detection; research environment for senior and graduate student work.

The extension of the ISEAGE security testbed from graduate level research into the mainstream of undergraduate and graduate education has proven to be an outstanding way for college students to solidify concepts and gain real world skills in information assurance and network security. Undergraduate and graduate experiences, both in the classroom and out of the classroom, have become an integral part of much larger ISEAGE research project. While originally developed as a testbed for security research, the extension of ISEAGE's reach into general IA student education has been valuable.

By using the ISEAGE testbed, we provide our cyber security students with multiple opportunities to create and evaluate throughout their academic career. In addition to providing more numerous opportunities to participate in higher order thinking skills, ISEAGE also provides a wider array of activities with which to engage.

The ISEAGE security testbed is a continual work-in-progress. Currently a lab extender is under development to extend the ISEAGE closed infrastructure across the actual Internet, by placing a lab extender in a remote location connected via the Internet to a lab extender connected to the ISEAGE. The extender will use compression and special protocols to increase the effective bandwidth between two extenders. The lab extender can be used to provide remote testing of infrastructure components. The lab extender will also be used to setup remote virtual Internets for collaboration on research projects with other universities, agencies or businesses.

The authors are in the process of releasing the ISEAGE security testbed to other academic institutions. At the time of writing, we have two institutions using ISEAGE in their classrooms. One community college is using ISEAGE for a CDC-type activity for their own students in a network security course. The other is a state university that will be using ISEAGE to teach two introductory networking classes. These introductory networking classes will be patterned after the course taught in MIS at ISU and described above. The authors plan to distribute to additional institutions that have asked for similar configurations over the next several months.

Integrating Control Concepts in an Embedded Systems Design Course

Manuel Jimenez, Gerson Beauchamp, Reinaldo Mulero, Maria Gonzalez
Department of Electrical and Computer Engineering
University of Puerto Rico at Mayaguez
Mayaguez, PR 00681–9000

***Abstract*—This paper describes a project experience in a microprocessor interfacing course, where computer engineering (CE) and electrical engineering (EE) students were joined to develop a project designing and implementing a Digital Controller for a Three Degree of Freedom Helicopter (3DOFH). This is a highly non-linear problem brought in by the EE students from the Process Instrumentation and Control Laboratory (PICL). Besides serving as the course project for the students, the motivation for taking such a project was to create a base platform using embedded microprocessors where control students could acquire signal conditioning and embedded software design skills in a more realistic platform than that provided by virtual instrument environments. This paper describes the course setting, design approach, and experience gained by the students, establishing a collaboration modality that could be emulated to bring multidisciplinary projects into traditional courses.**

I. Introduction

In a typical embedded system design course, students are expected to successfully apply learned concepts through a design project. The Microprocessor Interfacing (MI) course at UPRM is a technical elective for Computer Engineering (CE) and Electrical Engineering (EE) majors with such characteristics. In this course, students learn how to solve engineering problems by designing, testing, and implementing embedded systems prototypes to meet the quality and requirements of a real life problem. A key aspect of projects is to induce students to interact with other disciplines outside the traditional scope of EE/CE courses while learning about interfacing and embedded systems design.

This paper describes the experience of joining, through a microprocessor interfacing project, students from electrical engineering (EE) specializing in control with peers in computer engineering (CE) specializing in software. In our program, these areas run in parallel, with control EE students rarely taking the interfacing course and virtually no CE students taking control courses. The problem they chose to solve as project consisted of designing and implementing a digital controller for a Three Degree of Freedom Helicopter (3DOFH). This is a highly non-linear problem assigned to EE control students in the Linear Systems Analysis course. In that course, students solve the problem mathematically and verify its characteristics via a virtual instrumentation environment. The motivation for taking such a project was to create a base platform using embedded microprocessors where control students could acquire signal conditioning and embedded hardware and software design skills in a more realistic platform than that provided by virtual instrument environments.

Several works in recent literature have reported diverse experiences with either educational objectives or aiming at resolving specific application problems dealing with control system models and their implementation on specific hardware controllers [1], [2], [3]. Although these and other similar articles provide insight into the design of control systems, none of them focuses on the interdisciplinary experience and cross learning achievable by joining educational and implementation objectives in a classroom experience.

The rest of this document describes the educational setting and course structure where this experience took place. Next we provide details into the design of both the embedded system hardware and software components and their integration. Moreover, we discuss the control system design process. The last sections summarize the most important project outcomes, analyzing the lessons learned in this experience by both, students and instructors.

II. Educational Setting

A. Program Structure

The Microprocessor Interfacing (MI) course is currently offered as a technical elective for both computer and electrical engineering majors. Both programs are five-year long with about 165 credit-hours each. Each program requires students taking at least eighteen credits-hours in technical electives. These elective courses define their emphasis areas.

In the computer engineering (CE) program the emphasis areas include hardware & embedded systems (HWES), digital signal processing (DSP), and software & computing (SWCS). In the electrical engineering program (EE) students choose their electives in one of five areas that include electronics, control, power systems, electromagnetics, or communications.

The MI course is a valid technical elective for both programs, but is mainly taken by CE majors who declare their emphasis area in HWES and EE majors concentrating in electronics. Some students from either program in areas other than HWES or electronics also take this course in preparation for their senior design experience course, particularly when they plan to develop projects that will use embedded systems techniques.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Students enrolled in the MI course are either in their last sophomore term or in their first semester as seniors. The course has as prerequisites the first course in Microprocessors, which is a core in both programs. Students are also required to have completed a course in programming languages and in digital electronics. These requisites ensure that students taking MI have fundamental knowledge in programming in both assembly and high-level languages, microprocessor-based systems, and understand the electronic structure of digital gates and drivers.

The MI course is offered in both spring and fall terms, with an enrollment of 20 to 30 students per term, typically distributed as 75% to 80% CE students and the rest are EEs.

B. Course Structure

The interfacing course has as an objective making students proficient in specifying, designing, and prototyping microprocessor-based embedded system. To achieve this objective, the course takes students through a tri-folded approach that combines classroom lectures, structured laboratory exercises, and a semester-long project.

1) Classroom Activities: As part of the classroom activities, students learn the fundamentals of how to develop microprocessor-based embedded applications. Discussed subjects include the architecture of embedded systems, design constraints, embedded systems life-cycle, interfacing and configuration of embedded peripherals, signal styles in traditional and serial buses, hardware prototyping techniques, embedded software design techniques, and concepts of real-time systems.

2) Laboratory Activities: In the laboratory, students work in teams of two or three members on a set of six pre-defined exercises. These exercises are completed before they delve into implementing hardware for their projects in synchronization with the subjects discussed in the classroom. The objective of these laboratories is for students to become familiar with the specific microprocessor they will use for their projects. The laboratory topics include the usage of processor's specific hardware and software development tools, using laboratory instrumentation, and exercises using embedded support peripherals that include general-purpose I/Os, interrupts, timers, low-power modes, serial interfaces, and data converters.

C. The Course Project

The project consists of a student proposed problem to be solved as an embedded system application. Students, working in teams of three or four members, submit a project proposal in the third week of classes. Proposals are structured following a set of guidelines published in the course web site. All problems proposed for the project must include four components in their solution, listed as follows:

a. **Microprocessor-based** meaning the solution must use a microprocessor performing non-trivial tasks.
b. **Communication** implying the system ability to communicate with another system.
c. **User Interface** allowing humans to somehow interact with the designed system.
d. **Control scheme** each system must have some form of control scheme within the application context.

Proposals are evaluated by the instructor and returned to the student with comments aimed at making the project feasible to be completed within the semester. Thereafter, in four additional stages, students go through the process of progressively developing a solution by a) developing an architectural design and software macro-model, b) a circuit design and software plan, c) implementing a building-block-level prototype and firmware, and d) system integration and application software.

For the architectural design stage, students use the problem specifications described in their proposals to develop a block-level diagram of their solutions and describing their hardware and functional descriptions. In this stage students also decide the processor to be used for their project, based on the system requirements. At this point, the architectural description is partitioned among group member, allowing each student in the group to contribute in the hardware and software design components of the project.

The circuit design stage assigns specific hardware and/or components to the functional blocks forming the system architecture to produce a schematic diagram of the system. This stage incorporates electrical and timing calculations to assess the correctness of the hardware design. A software plan based on the functional description of the previous stage is also developed.

Using commercial off-the-shelf components and a development kit of the selected processor, students develop working prototypes of each functional block in their designs and their firmware and provide the instructor a demonstration of the level of progress achieved so far.

The last stage is devoted to system integration and software application integration. All functional component prototypes are integrated according to the architectural design earlier developed. The application software developed for the system is also installed. The functional prototype is transferred to a printed circuit board, packaged, and a working demonstration provided to the instructor.

D. Course Evaluation

The course evaluation reflects the organization of activities as students receive credit for exams related to classroom lectures, performed labs, and project related activities.

Students complete one mid-term and one final exam mostly covering the material discussed in the classroom. Both are written tests, designed to assess the individual student proficiency in concepts and design criteria.

For the laboratory work, each lab session includes two or three exercises in interfacing and programming related to the discussed subject and completed by the students over a period of a week.

Each project stage is documented in a progress report discussed with the instructor in a group fashion. Students also take an individual oral examination after completing their prototype. This evaluation assesses the individual level of proficiency achieved by each group member in terms of the completed project.

At the end of the semester, students prepare a comprehensive written report of their project, documenting all stages of their designs and their prototypes. They also offer an oral presentation in front of their classmates about their project. This presentation is open to the academic community as well, and includes a live demonstration of their working prototypes. Some teams have used their projects to enter and successfully compete in local and national design contests.

III. The 3DOFH System

The integrative experience reported in this paper is based on the work developed by a mixed group of EE and CE students who took the MI course and proposed as project designing and prototyping an embedded system for the digital control of a Three Degree of Freedom Helicopter (3DOFH). The 3DOFH is a highly non-linear mechanical system emulating a stationary helicopter with two vertical propellers capable of rotating the structure in three different axes providing elevation (ε), jaw travel (φ), and pitch (θ) (see Figure 1).

The mechanical assembly is composed of a leveled arm mounted on a rotating base. At one end of the leveled arm is the helicopter part containing the two DC motors and propellers. By individually controlling the amount of power being sent to the DC motors, the horizontal arm can rotate around its center axis. This action produces a pitch angle θ proportional to the thrust vector forces developed by the voltage applied to the motors.

Since the DC motors alone cannot produce sufficient thrust to elevate the level arm, a counter weight is located in the opposite side of the helicopter to help these forces in the elevation (ε). With the right amount of pitch (θ) in the helicopter part, the system is able to rotate in the base part producing a travel angle (φ). The system has an three optical encoders to measure each angle: elevation, pitch, and travel. The objective of this system is to maintain a desired position and respond to disturbances with a desired control characteristics.

The system operates by establishing a set-point ($\varepsilon, \varphi, \theta$) via either a keypad or joystick. Once the set-point is reached, it must be kept in that position by the digital controller even in the presence of external perturbations and the inherent system noise. Figure 1 shows a conceptual diagram of the 3DOFH system denoting the motors, encoders, relative element positions and the controller.

The 3DOFH problem is traditionally assigned to EE control students in the Process Instrumentation and Control Laboratory (PICL). Its purpose is to provide students with an experience in the usage of linear state-space control systems. A custom designed platform is provided in the PCIL that incorporates the motors and sensors as shown in Figure 1.

For their PCIL project, control students linearize the system and proceed to implement it via a data acquisition card interface connected to a personal computer running a MATLAB/Simulink program. This virtual instrument setup runs on an ideal software environment where real world

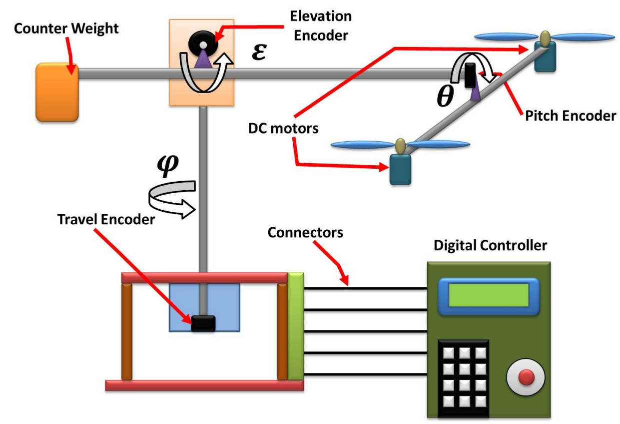

Fig. 1. Conceptual diagram for a 3DOFH system.

limitations and disturbances are not present. When using this approach, important details about sensors, motor interfaces, signal conditioning, and driver requirements are hidden from the students. This approach, although beneficial for novice control students, may limit the ability of advanced students to implement control system solutions in actual scenarios like those found in courses like the capstone design experience or in industry practice [4].

IV. The 3DOFH as an MI Project

The 3DOFH as an MI project represented an excellent scenario to bring out the hidden details in the implementation of a digital control system, while combining elements from electrical and computer engineering disciplines. With EE students bringing their background in control systems and CE students providing their expertise in digital hardware and software design for the same problem made for a convenient interdisciplinary experience.

To develop a successful solution, the students from both areas needed to work as team and acquire technical knowledge from each other's disciplines. The computer engineering students had to learn the basics of a closed-loop control systems, concepts of negative feedback, and compensator design. This basic understanding was necessary for the CE student to develop the appropriate embedded software to configure the microcontroller (MCU) peripherals.

The next sections describe the approach followed to implement the 3DOFH system as an embedded systems application. The description sheds light into how the concepts from both disciplines interbreed to produce a working solution to the problem.

A. Design Approach

The design of the digital controller for the 3DOFH project was partitioned into three main tasks. The first task was devoted to the hardware structure of the digital controller. As part of this task, a system block diagram was created, defining the controller architecture, a suitable processor selected, and the interfaces necessary for connecting the sensors and the MCU were designed. This stage also included the user interface hardware and the power supply system.

The second task consisted in the control system design. Here, the mathematical model of the system was obtained and the LQR compensator was designed. In the third task the embedded software was designed. Here, the algorithms for all MCU peripherals including timers, pulse-width modulation (PWM) modules, analog-to-digital converters (ADC), and quadrature encoder peripherals (QEP) were configured, and integrated with the Control Algorithm to yield a complete implementation. Below we provide additional details about each of these tasks.

B. Digital Controller

The digital controller module is the most important block of the system. It serves two fundamental purposes: first, it implements a control algorithm based on linear state-space design to reach and keep a given set-point. To this end the module incorporates signal conditioning circuitry, a dual motor driver, and a power supply subcircuit. The second controller function is to provide for a user interface that allows for configuring the controller parameters and directly interacting with the 3DOFH. The user interface integrates an LCD, a 4x3 keypad, and an analog, two-axis joystick. Figure 2 shows a block diagram illustrating the hardware components of the digital controller.

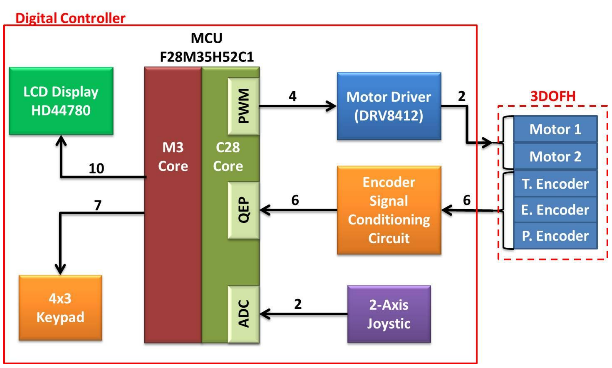

Fig. 2. Block diagram for the 3DOFH digital controller.

At the heart of the controller is Texas Instruments C2000 MCU. In particular, a Concerto F28M35H52C1 MCU was used [5]. The F28M35x Concerto MCU was a convenient selection as it provides a dual-core architecture incorporating an Arm Cortex M3 core operating as subsystem master, and a TMS320C28x core serving as subsystem control. The M3 core in the 3DOFH system was configured to partially control the user interface functions via the keypad and display modules.

The C28 core was devoted to all control functions, including monitoring the quadrature encoder peripheral (QEP) and managing the motor drivers through PWM signals. In addition, the C28 was in charge of sampling the analog signals from the joystick.

The motor driver on the right of the diagram (DRV8412) implements a dual H-Bridge driver to handle the two DC motors, receiving and amplifying the PWM signals sent from the MCU. The encoder-signal condition circuit (ESCC) attenuates the quadrature signals received from each of the encoders mounted in the axes of the 3DOFH assembly. The power circuit, not illustrated in the controller diagram, provides and distributes power to each of the components of the digital controller.

Communication between the M3 and C28 cores occurred through a dual-ported, shared memory block embedded in the C2000 chip.

The controller operation allows an user to either operate the system with a set default gains hardcoded in the controller's firmware or to specify via the user interface, a custom set of values defining a linear state-space design compensator.

C. Control System Design

The mathematical model of the three-degree of freedom helicopter (3DOFH) is based on the work by Ishitobi and Nishi [6]. The model is obtained from the sum of forces and momentums of the 3DOFH that results on a set of nonlinear state equations that describe the system behavior as shown below.

$$\ddot{\varepsilon} = \rho_1 \cos(\varepsilon) + \rho_2 \sin(\varepsilon) + \rho_4 (V_f + V_b)\cos(\theta) \quad (1)$$
$$\ddot{\theta} = \rho_5 \cos(\theta) + \rho_6 \sin(\theta) + \rho_8 (V_f - V_b) \quad (2)$$
$$\ddot{\varphi} = \rho_{10} (V_f + V_b)\sin(\theta) \quad (3)$$

This set of equations describes the system behavior in terms of angular positions (ε, θ, and φ) and the motor voltage inputs V_f and V_b. The terms "ρ_i" are parameters related to the mechanical properties of the system.

To design the controller, the system state equations were linearized to obtain a state-space representation of the form

$$\dot{\mathbf{x}}(t) = \mathbf{A}\mathbf{x}(t) + \mathbf{B}\mathbf{u}(t) \quad (4)$$
$$\mathbf{y}(t) = \mathbf{C}\mathbf{x}(t), \quad (5)$$

where $\mathbf{x}(t) = [x_1, x_2, x_3, x_4, x_5, x_6, x_7, x_8]^T$ is the state vector, $\dot{\mathbf{x}}(t)$ is the derivative of $\mathbf{x}(t)$, $\mathbf{u}(t) = [u_1, u_2]^T$ is the input vector, $\mathbf{y}(t) = [x_1, x_2, x_3]^T$ is the output vector, and **A**, **B** and **C** are constant matrices of appropriate dimensions. The 3DOFH state variables were assigned as follows:

TABLE I
STATE VARIABLE ASSIGNMENTS.

$x_1 = \varepsilon$	$x_4 = \dot{\varepsilon} = \dot{x}_1$	$x_7 = \int \varepsilon = \int x_1$
$x_2 = \theta$	$x_5 = \dot{\theta} = \dot{x}_2$	$x_8 = \int \varphi = \int x_2$
$x_3 = \varphi$	$x_6 = \dot{\varphi} = \dot{x}_3$	$u_1 = V_f$, $u_2 = V_b$

Notice that two additional state variables, x_7 and x_8, were added as the integrals of x_1 and x_3. This state augmentation was performed to eliminate the steady-state error in elevation and travel. The system was linearized by applying the

Jacobians to (1), (2), and (3). The resulting linear state-space constant matrices in the continuous-time domain were:

$$\mathbf{A} = \begin{bmatrix} 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ \rho_2 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \rho_6 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \frac{-\rho_{10}\rho_1}{\rho_4} & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

$$\mathbf{B} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \\ \rho_4 & \rho_4 \\ \rho_8 & -\rho_8 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix} \quad \mathbf{C} = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

Matlab$^{(R)}$ was used to design the state-space feedback gains for the system. The linear state-space system was first discretized with a sampling period of T = 1ms. The feedback gains were designed using the Linear Quadratic Regulator (LQR). The LQR is an optimal control regulator that minimizes control effort and state-variable energy while resulting in a stable closed-loop system [7]. The performance index to be minimized was:

$$J = \int_0^{\inf} (x^T(t)Qx(t) + u^T(t)Ru(t))dt, \quad (6)$$

where Q is a positive semi-definite matrix and R is a positive definite matrix. These are weighting matrices for the state and input vectors respectively. During the design of the LQR, matrices Q and R were systematically modified to obtain the best step response from a simulation. These matrices were modified to shift the weights of the compensator to emphasize the control of specific state variables. The resulting controller was implemented in the form of a difference equation

$$\mathbf{u}(kT) = K[\mathbf{r}(kT) - \mathbf{x}(kT)] \quad (7)$$

In equation (7), $u(kT)$ is the input vector, K is the controller gain vector, $r(kT)$ is the system reference vector (joystick), and $x(kT)$ is the state-variable vector. Notice that (7) is written in the discrete-time domain with sampling period T. Figure 3 shows the control system block diagram. The 3DOFH is represented in a linear state-space format in the continuous-time domain. The outputs of the system are sampled by the QEP and discretized. Numerical differentiation was used to estimate the velocities and numerical integration is performed to obtain the state-variable integrals. These values are compared with the reference values sampled by the ADC and the error signal produced is fed to the controller gain matrix. The resulting input signals are used to adjust the duty cycle of the PWM peripheral to control the DC motors.

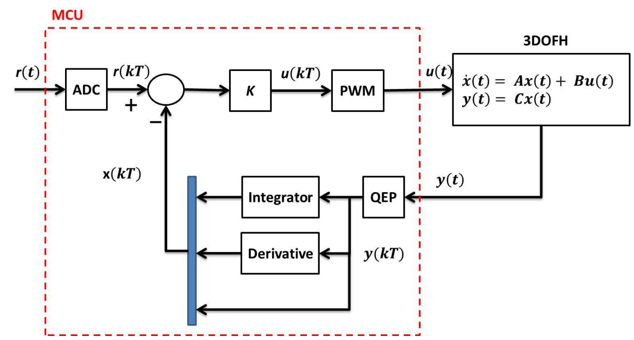

Fig. 3. Closed-loop linear state-space diagram.

D. Embedded Software Design

The embedded software was written in C-language using Texas Instruments' Code Composer Studio Integrated Development Environment (CCS-IDE). Although each MCU core can be individually programmed, the master M3 core needs to be programmed first to enable and make available the slave C28 core and its assigned peripherals.

Figure 4 shows a high-level flowchart of the system software organization. The system boots with the master M3 core, which in turn boots and initializes the slave C28 core. With both cores initialized all system peripherals required by the application can be configured. Next, the program, still running in the master core, waits for the user to select the controller configuration parameters. In the last stage, the control and user interface algorithms begin execution in their respective cores and remain running until the system is powered-off.

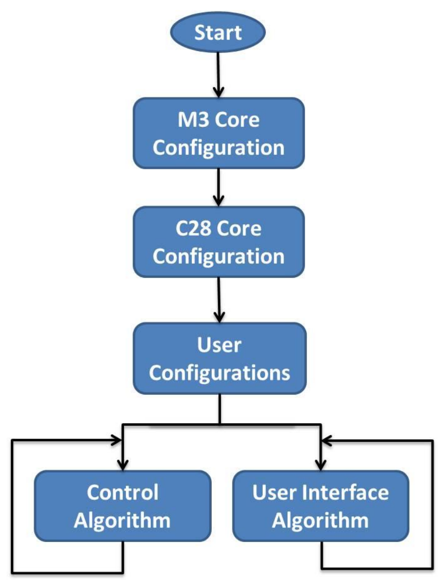

Fig. 4. Top-level flowchart of system software organization.

The M3 core plays its role as master by booting the slave C28 core and controlling the user interface.

The C28 slave core exerts control over the PWM channels, ADC, and QEP inputs, and running the control algorithms.

Two PWM channels were enabled, one per motor, each with its own 16-bit timer running at the C28 clock frequency. The average DC voltage applied to the motors was controlled by the duty cycle of their corresponding PWM outputs.

The optical encoder's outputs were managed through three on-chip quadrature encoder peripherals (QEPs). These allowed for updating the position counters without CPU intervention. The optical encoders in the 3DOFH have a resolution of 4096 counts per revolution. The QEP multiplies this value by four, resulting in a a total resolution of 16384 counts per revolution. The QEP counter was configured to initialize at 8,192, requiring the system to be pre-positioned in a balanced state at start to allow for initiating the control algorithm with a small, self correctable error.

The joystick, also managed via the C28 core, provides two analog outputs for jaw and elevation. These outputs are interpreted via the on-chip analog-to-digital converter only after a user, in the configuration process, enables the joystick to specify the system set point.

V. Project Outcomes

The students were successful in designing a controller, hardware, and software for a 3DOFH system and producing a working prototype of their design. The digital controller had all the features that were proposed for the system and its interfaces established the desired functionality. The user interface module effectively allowed for selecting between predefined or custom entered configurations and the joystick provided for smooth set-point selection establishing the pitch, jaw, and travel position of the system. While in operation, the user interface also provided real-time feedback of the 3DOFH angular position.

Stability was shown to be excellent for such a mechanical system, with a settling time less than 4s and less than 20% overshoot in response to a 90° step input in the travel angle. In lab performed tests the system was observed to reach steady-state in less than three seconds when strong disturbances were applied. The steady state error was also acceptable, about 0.09 radians as observed in the angular position feedback displayed on the LCD.

VI. Lessons Learned

Through the implementation of a three-degree of freedom helicopter project we were able to join computer and electrical engineering students from divergent areas in a cross-fertilizing classroom experience. EE students learned about software design, embedded systems and architectures, interfacing techniques, and multi-core systems. Computer engineering students in turn, learned about closed-loop system, digital control, linearization, system stability, and compensation.

They all were able to run a project from system conception through to prototype demonstration, passing through stages that included architectural design, circuit design, mathematical modeling, hardware/software integration, circuit and mechanical assembly, and technical documentation.

The experience provided a platform where control students could explore the details hidden in classical virtual instrument implementations. Computer engineering students developed a wider vision of the scope of applications that can be developed using their electronics and software background combined with knowledge from other fields.

From the instructors side, we interpret this experience as one paving the way to establish a set of experimental platforms to train control students on the details of implementing digital control systems using real life constraints. We expect to use this experience with computer engineering students to foster cross-disciplinary applications where embedded techniques provide solutions to complex, real-life problems.

VII. Conclusion

The outcomes from this experience showed us that it is possible to combine in a learning experience concepts and practice of traditional control system with those from an embedded system design course, enhancing the learning experiences of both EE and CE students. CE students learned how to implement digital closed-loop control systems on an embedded processor with a net learning gain beyond that obtained through the traditional open-loop systems they typically implement in their projects. For EE students, this experience allowed them to design and implement digital embedded controllers where real world limitations are present, delve into the software and hardware design strategies, signal conditioning, communication issues of an actual embedded implementation instead of the classical virtual instrument environment used in most control systems courses.

Acknowledgment

The authors would like to thank Texas Instruments Inc. for their support to this project by providing the C2000 evaluation kits, CCS-IDE, and several of the interface chips used for the prototype implementation.

***Abstract*—In November of 2010, Microsoft released the Kinect sensor for the Xbox 360 video game console. This device—similar to a webcam—allows an individual to interact with an Xbox 360 or a computer in three-dimensional space using an infrared depth-finding camera and a standard RGB camera. As of January of 2012, over 24 million units have been sold. Using a combination of custom and open-source software, we were able to develop a means for students to visualize and interact with the data allowing us to introduce the concepts and skills used in the field of Electrical and Computer Engineering. The unique technological application, visual appeal of the output, and the widespread ubiquity of the device make this an ideal platform for raising interest in the field of Electrical and Computer Engineering among high school students.**

In order to understand the appeal of the Kinect, a working knowledge of the technical details of the device is useful. The novelty and appeal of the Kinect sensor lies in its infrared camera, which is comprised of two distinct devices. An infrared projector sends out a 640x480 grid of infrared beams, and an infrared detector is used to measure how long the reflection of each beam takes to return to the sensor. This data set is known as a "point cloud". This point cloud is a three-dimensional vector comprised of data points between 40 and 2000, which correspond to distance from the device of each beam. The data in this array can then be parsed to construct a 3d image. The Kinect's infrared camera operates at 30Hz, or 30 samples per second, so the device is able to deliver a frame rate that is sufficient to create the illusion of motion. This allows for the development of applications that give the user a sense of interacting in real time with the image on the screen. The unique visual appeal, novelty of interaction, and relatively easy-to-understand theory of operation make the Kinect an attractive platform for recruitment and outreach.

Using the Kinect, a recruiter is able to quickly and effectively demonstrate a range of concepts involving hardware, software, and the design process on a platform that students are familiar with and find appealing. In a short window of time they are able to show examples and explain the fundamental principles of the system while providing tangible, meaningful, and enjoyable interactivity with the device itself. This level of approachability and familiarity is rare among highly-technical fields, and provides an excellent catalyst to develop interest in Electrical and Computer Engineering education.

Keywords—Kinect; engineering; outreach; education; Processing; natural interaction; embedded systems; Xbox 360

I. Introduction

As referenced in a prior paper from our department [1], the University of Oklahoma's Electrical and Computer Engineering department (OU-ECE) suffered a sharp decline in undergraduate enrollment from 2004 to 2008, during which enrollment numbers dropped from 387 in 2004 to 246 in 2008. In order to rectify this, action was taken to form a student-driven recruiting effort that emphasized hands-on, demonstrative outreach communicated in a peer dynamic [2]. This recruiting and outreach program was immensely successful, as evidenced by the undergraduate enrollment rising to 399 students in 2012. During this time a number of unique innovations in OU-ECE outreach were produced. While many successful hands-on demonstrations were born out of this program, a key omission was identified in the explanation and demonstration of embedded real-time systems and their application. In order to rectify this, several demonstrations were developed around the Microsoft Xbox 360 Kinect sensor. This paper aims to provide an overview of the Kinect platform, discuss the technical details of the Kinect and our application, analyze the perceived benefits of our approach, discuss the results seen thus far, and introduce some possible ways to expand the platform to increase its effectiveness.

II. Device Overview

In November of 2010, Microsoft released the Kinect sensor for the Xbox 360 video game console [3]. This device—similar to a webcam—allows an individual to interact with an Xbox 360 or a computer in 3-dimensional space using an infrared depth-finding camera and a standard RGB camera.

This device has become immensely popular, and as of January of 2012, over 24 million units have been sold [4]. There are currently over 150 games available for the Xbox that utilize the Kinect sensor, and Microsoft is currently focusing on integrating it in to the Windows environment. While Microsoft has popularized the device, the actual technology was developed by an Israel-based company named PrimeSense. PrimeSense offers a range of 3d imaging solutions; all characterized by their system-on-a-chip (SoC) design and the open-source software solutions that accompany the device.

III. Hardware Overview

From the perspective of an end-user the Kinect is similar to a standard webcam, but the technology behind the device is distinct from other commercially available cameras. The device is, in fact, two distinct devices—an infrared camera and a standard RGB camera—that are processed into a single dataset by PrimeSense's SoC. The layout of the device is shown in Fig. 1.

The Kinect's 3-dimensional imaging is accomplished by the infrared camera, which itself is comprised of two distinct parts that are managed by the SoC. The Kinect contains an infrared projector that emits a 640x480 grid of infrared beams. This grid leaves the Kinect in a conical projection and is reflected off of the environment. The Kinect then uses an infrared detector to calculate the length of time it takes each beam to return to the device. The SoC then uses that measurement to extrapolate the distance from the device at each point, and returns a three-dimensional vector to the host machine that is comprised of data points between 40 and 2000. These data points correlate directly to the number of millimeters away the person or object is from the device. This concept is illustrated In Fig. 2. In addition to creating this vector, the SoC also collects and correlates data from the RGB camera, allowing the device to determine with reasonable accuracy what color is present at each point in the cloud.

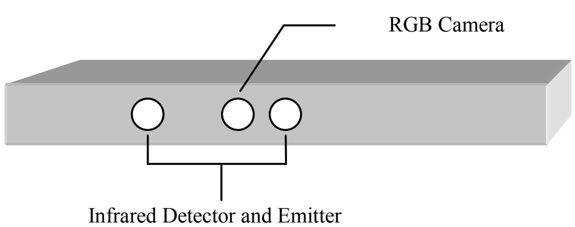

Figure 1 - Physical Layout of the Kinect

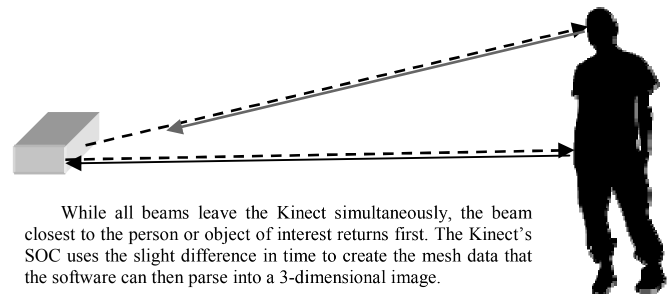

Figure 2 - Kinect Time Delay

Another key aspect of the Kinect's functionality is that it operates at 30 Hz, or 30 samples per second. This allows the device to deliver a frame rate that is sufficient to create the illusion of motion, and allows for the development of applications that give the user a sense of interacting in real time with the image on the screen.

While no single component of the Kinect is necessarily revolutionary, the combination of the components in to a complete system allows for an embedded system capable of real-time data acquisition, and enables powerful applications that are relatively simple to develop.

IV. Software Overview

By supplying the software to access the data from the Kinect in an open source fashion, PrimeSense has successfully fostered a large developer community around the Kinect. The PrimeSense Software Development Kit consists of two essential software solutions that facilitate development with the Kinect. The first is Open Natural Interaction (OpenNI), which provides an open-source API framework for development. Specifically, the OpenNI APIs allow access to voice command recognition, hand gestures, and body motion tracking [5]. The second software solution is Natural Interface Technology for End-User (NiTE). This software acts as a simple way to use the OpenNI framework with minimal CPU load [6]. NiTE provides the tools to quickly and easily turn the data from the Kinect device in to usable information about the depth, color, IR and audio data received from the hardware [6].

When choosing the development environment there were several key features that were important to us, both as developers and recruiters. In order for it to be an effective tool for distilling the core concepts, a simple interface and a robust development environment were vital. To this end, the demonstrations were developed in the open-source development environment "Processing" [7]. This environment vastly facilitates simple, rapid development, and contains many features that are a natural fit for the Kinect. By design, "Processing" is natively capable of generating robust, visually appealing displays using intuitive commands, and has a clean, simple user interface that lends itself to being incorporated in to the demonstrations. Another key component of our choice of development environment was the SimpleOpenNI wrapper for "Processing" that allows for even simpler access to the core features of OpenNI. An overview of the development hierarchy is provided in Figure 3.

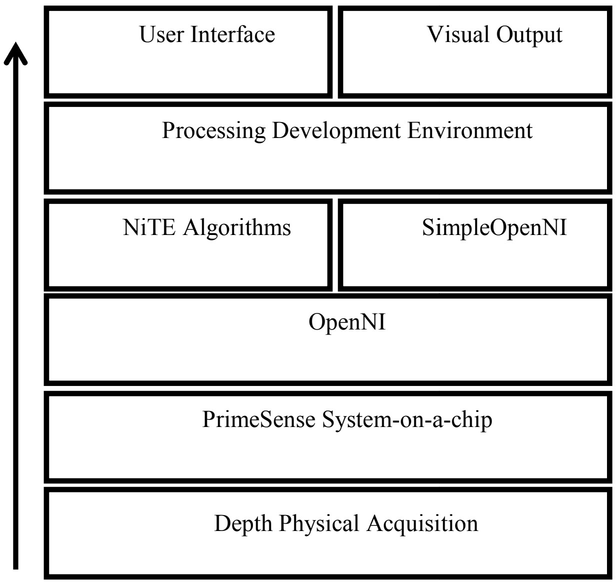

Figure 3-Software Hierarchy Overview

V. USE IN OUTREACH

Now that an understanding of the underpinnings of the Kinect hardware and software has been established, the device's application in our outreach efforts is discussed. We aim to accomplish this by providing an overview of the goals of this project, the product of our development, how it is employed in our outreach efforts, and what perceived benefits this project has yielded thus far.

In our experience, demonstrations that allow for some sort of physical interactivity serve as the best starting point for a discussion with prospective students. While demonstrations that embody this concept are abundant for many fields, embedded systems and sensing demonstrations have either been too complicated, for the length of time and level of understanding, or too simplistic to fully illustrate the importance of this field of study. With these goals in mind, we set out to develop a series of applications and demonstrations that use the Kinect to illustrate some of the fundamental concepts of ECE, and the result was a collection of engaging, interactive demonstrations that illustrate a wide range of topics.

To begin, we use a series of physics demonstrations developed by Amnon Owed [8] that involve the students being able to interact with geometric shapes that fall from the top of the screen. The Kinect is capable of detecting the user, outlining them, and then using that outline to allow them to manipulate the shapes on the screen using their movements. Using edge detection, the software is able to provide the user with the ability to hold their arms out and gather the shapes, sweep the shapes away from them, throw the shapes around, and otherwise use their physical presence to manipulate the virtual environment. Fig. 4 features a screen shot of this demonstration.

Figure 4 - Physics with the Kinect

Another powerful use of the Kinect is employing it as a controller for other software. To demonstrate this, we developed an application that allows the user to control Ableton Live, a music creation and synthesis application. Using the Kinect and the midi protocol, the "Processing" application is able to send commands to Ableton Live that allow the user to select different virtual instruments, control the volume, pitch, and various sound effects using their physical movements. This is accomplished by using skeletal detection to outline the user, and then assigning values to the relative positions of their limbs. This translates to the user being able to move their right hand towards or away from the Kinect to control the intensity of the note and up or down to control the pitch, while using their left hand to control the intensity of the reverberation or distortion present in the signal. A screen shot of the skeletal data that this application uses is shown in Fig. 5.

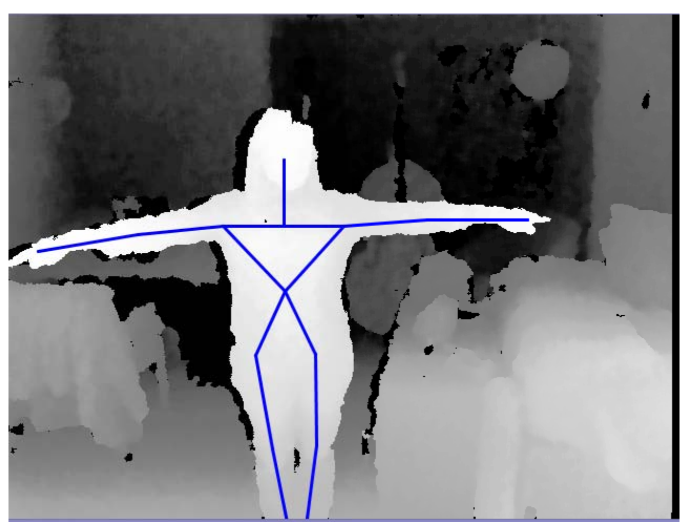

Figure 5 – Skeletal data from the Kinect

Both of these applications provide the prospective students with a novel and unique interaction, and often lead to a discussion of how these demonstrations are accomplished. Typically the student is interested predominately in either the hardware and signal chain necessary to implement the demonstration or the software employed to accomplish the interactivity, and both demonstrations lend themselves to a discussion on either topic.

When the student is predominately interested in the hardware, a quick synopsis of how the Kinect device functions is easily delivered by explaining the infrared camera as a mesh of individual data points. Using "Processing" we are able to show a view of the raw data and a simplistic rendering of a three dimensional image that allows the students to visualize the infrared mesh that the Kinect generates. This demonstration in itself is typically impressive, and often the students are surprised at the amount of information the Kinect is able to deliver. An example of the Kinects ability to render three dimensional images is shown in the screenshot in Fig. 6. The camera is sitting in front of the user, but the software is able to render the image from above.

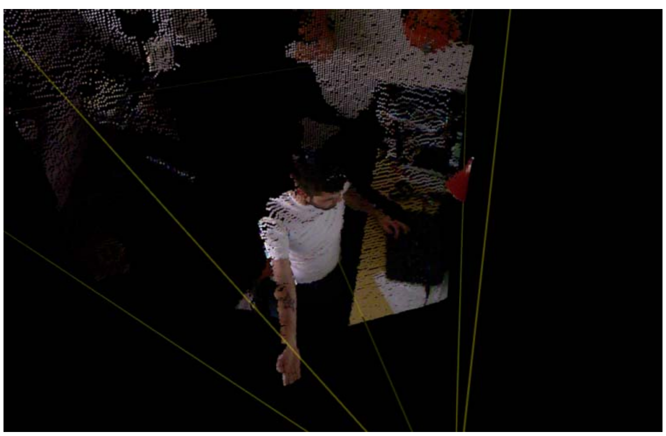

Figure 6 - Kinect data view

During the past year, we have used these demonstrations at a variety of recruiting events, both on and off of our campus and with various age levels. At a variety of traditional-format events where our recruiters are given a table and students are free to choose whom to talk to, the demonstrations were effective at catching the interest of prospective students. These demonstrations were employed at several recruiting events targeting high school students interested in attending OU, and were very well received. Through our conversations and interactions with students, we have come to believe that much of this success is owed to the familiarity of the device. As previously noted, there are over 24 million Kinect sensors in the homes of consumers. This is a device that these students associate with having fun and playing video games, and often this connection is enough to help convey the impact that electrical and computer engineers have on a wide range of activities in their daily lives.

Additionally, the Kinect demonstrations provide the opportunity to interact with students that are interested in video games that would traditionally only view Computer Science as a viable major. The associations that the Kinect brings often allow us a chance to speak with these students about the hardware and lower-level software that goes in to game development, and potentially convince them that ECE could be a better fit for them. While there are a variety of interesting demonstrations that we employ in our outreach, the Kinect creates a unique starting point for conversations with high school students about the degree and scope of ECE and helps attract students that would traditionally be interested in other areas of study.

The Kinect has proven to be an effective tool for outreach as a booth demonstration, but another important aspect of our work with the Kinect has been outreach targeted specifically to high school groups that are interested in the STEM fields. In the past year, we have used the Kinect demonstrations with various school groups, including a high school mathematics club, a high school robotics club, a high school physics club, and a pre-engineering club. When presenting to the mathematics club, we were able to relate the Kinect demonstrations to the mathematical algorithms that the Kinect uses to determine the depth of an object, the trigonometry it uses to align the color data with the point cloud, and various other applications of mathematics in technology. With the robotics club we shifted our focus towards machine vision, object detection, and the creation of responsive programming. With the physics club we focused on creating computer models and simulations, and using those simulations to predict and observe how the physical world would behave under a specific set of conditions. With each subject, the Kinect has served as a powerful tool for linking a prospective student's current interests with a related application in technology and engineering.

Using the demonstrations outlined above to broach the topic of studying ECE has proven to be effective. As we used these demonstrations over the past year, the response has been immensely positive due to the diverse applications of the Kinect, the novelty of being able to render objects in three dimensions, and the prospective student's familiarity with the device. While no specific, quantitative data has been collected for analysis at this point, our organization intends to develop the methodology measure the impact of this device and will begin collecting data in the coming months. Using the Kinect has allowed our recruiting team to reach a wider audience of students than other demonstrations and recruiting methods allowed.

VI. Future Development

Moving forward, there are several key features that we would like to implement in to our Kinect demonstrations. To heighten the effect of the demonstrations and to increase the appeal for students interested in physics, we would like to add the ability to adjust simulation settings in real time. This would give the user the ability to select the effect of various conditions such as gravity or the mass of an object. Another possible direction that we are exploring is using the LabVIEW development environment to create functional blocks that the students could use to write their own programs within a relatively short amount of time. Using this, a recruiter could allow the student to not only experience the demonstration, but actively engage in its creation. The LabVIEW development environment also lends itself to the creation of interfaces like the ones previously described that would be used to control simulation variables. Given these advantages, the possibility of simultaneous development could be beneficial.

We would also like to work on developing the Kinect in to a series of robotics demonstrations where the actions of the user would influence the behavior of a physical object. For example, the user's skeletal data could be used to determine the position of a servo motor, remote commands could be given through motion, or a robotic arm could be programmed to wave back when a user waves. The possibilities for effective, simple demonstrations are numerous, and we look forward to developing an increasing number of applications as our outreach efforts continue to grow.

VII. Conclusion

While OU-ECE's recruiting and outreach program has seen great success over the last five years, the Kinect has enabled our recruitment team to reach a greater number of students interested in a wide array of disciplines. Using a device which most students are familiar with and have had a positive association with has allowed us to introduce the fundamentals of embedded systems to a new generation of prospective students and enabled meaningful conversation pertaining to the importance of the fields of ECE. The student excitement generated by this device at recruiting events has surpassed all other demonstrations OU-ECE has deployed in the past and it has always been the most engaging demonstration of any event it has been shown. We believe others will find the Kinect an extremely useful tool for ECE outreach.

Acknowledgment

As noted, many of these demonstrations were either the direct product or derivative of other members of the open source community. To that end, we wish to thank the independent developer Amnon Owed whose work was used in our physics demonstrations, Professor Max Rheiner of the Interactive Design program at Zurich University of the Arts whom contributed countless examples that aided in our development, Professor Peter Froslie of the School of Art and Art History at the University of Oklahoma for his assistance with "Processing" and communication over the midi protocol, and independent developer Jordan Kuehn who assisted with various technical challenges as they arose. All of these people were an invaluable resource, occasionally without their knowledge or against their will.

A Novel Approach to Teaching Amplitude and Phase Distortion Concepts Using Time Domain Methods

Paul Crilly and Richard J. Hartnett
Department of Engineering, Electrical Engineering,
U.S. Coast Guard Academy, New London, CT
Paul.B.Crilly@uscga.edu

***Abstract*— We present an alternative method to teach amplitude and phase distortion concepts using time domain methods. Typically, these concepts are taught using relatively expensive network analyzers. Here we show how a transcendental waveform, generated using relatively inexpensive waveform generators, and observed using standard lab oscilloscopes, can be used to illustrate amplitude and phase distortion, enabling the student to better understand systems whose magnitude responses are not flat, or whose phase responses may not be linear. Our methods allow students the opportunity to gain more insight into the characteristics of high fidelity (audio) systems.**

***Keywords*—distortion, frequency response, fidelity**

I. Introduction

The fundamental Fourier concepts of magnitude and phase response of a linear time-invariant system are taught in varying depths in most Electrical Engineering programs. However we find that students may not fully understand the concepts of magnitude and phase *distortion*. Here we present how experimental methods of time domain analysis using transcendental waveforms can be used to illustrate amplitude and phase distortion, as well as characterize the fidelity of an amplifier. The methods presented are intuitive, and allow the quantification of amplitude and phase distortion, with or without the use of a relatively expensive network analyzer. Most importantly, the methods inherently reinforce the requirements for a distortionless system, that is flat magnitude and linear phase responses.

One conventional way to measure amplitude and phase distortion of an amplifier is to use a sweep generator, or a periodic chirp signal and a network analyzer. If one measures a flat magnitude and linear phase responses from the amplifier, one can declare the amplifier is distortionless. Unfortunately, this does require the use of a network analyzer, which may or may not be available in an undergraduate laboratory. While this method is efficient, it may actually cause students to miss out on important time-domain observations.

Most undergraduate laboratories have generators capable of generating waveforms that are rich in harmonics, as well as two channel oscilloscopes, where comparisons can be made between input and output signals. For example, if one drives an audio amplifier with a square wave and observes both the input and output signals on an oscilloscope, one can tell a lot about the amplifier.* If the output and input only differ by a gain constant and perhaps a time shift, one can say that the amplifier does not suffer from amplitude or phase distortion. Conversely, if the output appears as a single sinusoidal wave, then the amplifier exhibits a great deal of amplitude distortion since it is acting as a filter. Thus by using wide-band periodic waveforms, one can determine the bandwidth of an amplifier, and reinforce student learning of Fourier series concepts from the time domain perspective. As a final example, consider a wide-band amplifier with large dynamic range and minimal amplitude distortion, implemented using negative feedback. One might expect that when driven by a square wave, the output waveform would also be square (except for scaling and delay). Instead because of phase distortion, the oscilloscope might display something very different from a square wave. Phase distortion in an otherwise high fidelity amplifier will cause the input harmonically related components to be delayed by different amounts, so the output will not match the input.

We find that the time domain techniques presented help students better appreciate the abstract concept of magnitude and especially phase distortion, help reinforce fundamental Fourier concepts, and can be accomplished without the added expense of network analyzers.

The following is a brief survey of how systems can be characterized with respect to distortion. Most of these are from the audio engineering literature with the focus on *measuring distortion and not necessarily in explaining signal processing concepts*. Griffiths [1] and Kuhn [2] describe the widely used method of square wave testing to measure amplitude distortion. They and most others who use this method do not deal with phase distortion, probably because the human ear does not readily pick up phase distortion. However, Lipschitz et al. [3] describes experiments on how the ear can perceive the effects of phase distortion. Cabot [4], [5] presents an excellent comprehensive treatment that describes the various types of distortion, and how these can be measured using single tone inputs and Fourier analysis. Blaess [6] and French

* With many amplifiers, it is easy overdrive the amplifier and cause it to output a square wave. Therefore, it is mandatory that the amplifier is operated in its linear range.

[7] use pulses and Fourier analysis to measure system distortion.

In this paper we first will re-state the definitions associated with distortionless systems, present a brief example of phase distortion and then present some simulations to illustrate what amplitude and phase distortions look like.

II. Distortionless Systems

A distortionless system is where the output signal has the same "shape" as the input except that the output is a scaled and delayed version of the input. More precisely, a system is *distortionless* if $y(t) = Kx(t - t_d)$ with $x(t)$ and $y(t)$ the input and output, respectively, and K and t_d are constants. Thus the system function is

$$H(j\omega) = Ke^{-j\omega t_d} \quad (1)$$

where $|H(j\omega)| = K$ and $\angle H(j\omega) = -\omega t_d$

There are many types of distortion, but we will only consider amplitude and phase distortion.

Amplitude distortion is when the K term is not constant or is not "flat" over all input frequencies. One example is a low pass filter.

Phase or *delay distortion* occurs when $\angle H(j\omega)$ is nonlinear with frequency. This often occurs in feedback systems.

Unlike amplitude distortion, phase distortion is not easily observed and does not have the same degree of coverage in beginning signals and systems courses. Therefore, we present a brief example of a system with and without phase distortion.

Consider a system with flat frequency response and linear phase with an input of

$$x(t) = 10\cos\frac{\pi}{2}(t-2) + 2\cos\frac{\pi}{6}(t-2) \quad (2)$$

and $H(j\omega) = 5e^{-j3\omega}$.

It can be shown that the output response is,

$$y(t) = 50\cos\frac{\pi}{2}(t-5) + 10\cos\frac{\pi}{6}(t-5) \quad (3)$$

We observe the response meets the non-distortion criteria as defined above.

We now consider the same input to a system with constant amplitude, but nonlinear phase with

$$H(j\omega) = 5e^{-j\omega^2} \Rightarrow 5\angle -\omega^2 .$$

It can be shown that the output response is,

$$y(t) = 50\cos\frac{\pi}{2}(t-3.57) + 10\cos\frac{\pi}{6}(t-2.52) \quad (4)$$

While there is no amplitude distortion, the uneven relative time delays indicate the system has phase distortion.

Finally, in systems without phase distortion, if the input is symmetrical, then the output would also be symmetrical.

III. Simulations

To illustrate the effects of amplitude and phase distoration, we simulate systems that contain both distoration types, apply a square wave rich in harmonics and observe the responses. Figure 1 shows the output from a system that has moderate amplitude distortion and linear phase. Figure 2 is the output from a system with very little amplitude distortion and linear phase. In comparing Figures 1 and 2, we observe the effects of ampltude distortion. The output from the system with moderate ampltude distorton deviates greatly from a square wave as noted by the high degree of low frequency ripple in the output, whereas the output from the system with little amplitude distoration is a relatively close fascimile of the original square wave input. The observed ripple frequency is approximately that of the highest harmonic in the system's passband. We also observe that the time domain signal, with added ideal delay, could become an even function of time. This symmetry typically imples that the system in question has a reasonably linear phase characteristic.

Figure 3 simulates a system with the same degree of bandlimiting as the one in Figure 2, except it has moderate degree of nonlinear phase, hence phase distortion is present at the output. Note the output contains the same harmonic components as the system of Figure 2, but the phase distortion has caused the positive and negative amplitudes to develop a nonzero slope. This is due to the uneveness of the output times for each of the frequency components. This is further shown in Figure 4 which simulates a system with a much higher degree of phase nonlinearity than that of the system of Figure 3. Figure 4 shows that one of the higher order harmonics is disproportionally delayed, confirming the point made in Eq. (3). Certainly, other types of nonlinear phases can be simulated, but the main point is that systems with nonlinear phase distort the output in a different way than systems with amplitude distortion. Specifically, we note that no amount of ideal delay can produce an even function for the signals in Figures 3 and 4. Such asymmetry typically implies that the system in question has some type of nonlinear phase characteristic.

Note at first observation of Figures 3 and 4, one might draw the conclusion that the signal doesn't have nonlinear phase, but exhibits the classic "overshoot" problem. At closer examination, the spike in amplitude *occurs before the input changes* whereas overshoot occurs due to the system's response to a change in its input.

IV. Conclusions

We have developed a method to test a system for amplitude and phase distortion using a square wave input. The simulations indicate that this method is a viable alternative to the standard, but relatively expensive method of using a sweep generator with a network analyzer. Furthermore, in this technique, Fourier series concepts are reinforced.

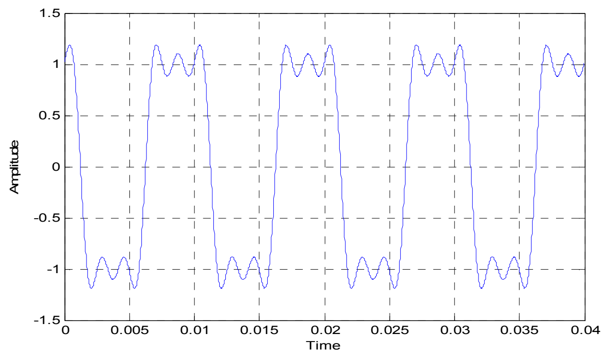

Figure 1. Waveform from system with large degree of amplitude distortion and linear phase. Ouptut only contains the the 1st, 3rd and 5th harmonics. Although there is distortion, we note that with proper delay, the output could become an even function of time. This implies no phase distortion is present.

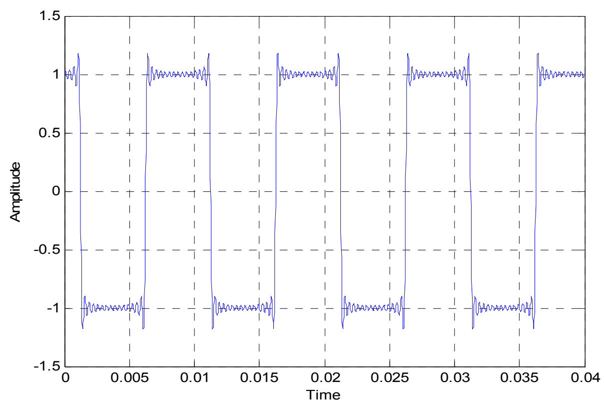

Figure 2. Waveform from system with negligible amplitude distortion and linear phase. Output contains 29 harmonics. Observe the time domain symmetry, such that an added delay could produce an even function of time. This implies the system must have exhibited linear phase.

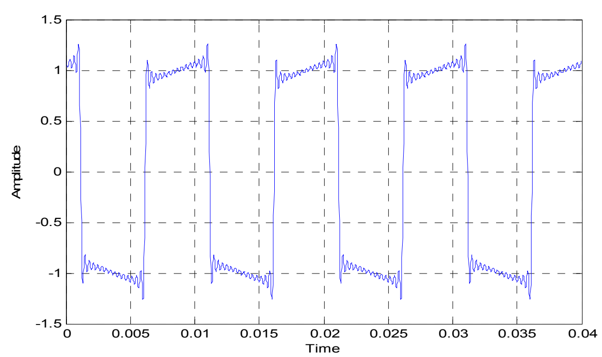

Figure 3. Waveform from system with negligible amplitude distortion and nonlinear phase. Output contains 29 harmonics. Unlike Figure 2, there is no ideal delay that could produce an even function, thus phase distortion must be present.

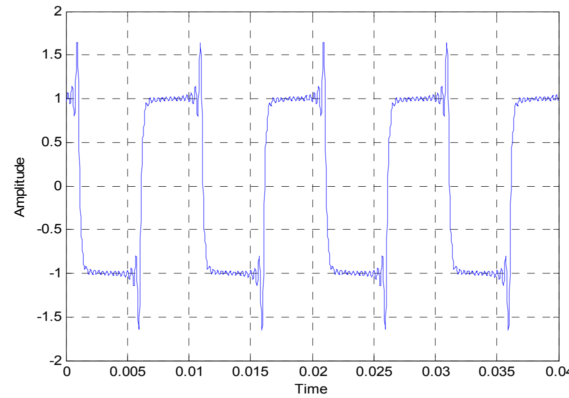

Figure 4. Waveform from system with negligible amplitude distortion and nonlinear phase. Output contains 29 harmonics. Again, there is no ideal delay that could produce an even function, so we know that phase distortion must be present.

Just Because We Teach It Does Not Mean They Use It: Case of Programming Skills

Branimir Pejcinovic, Melinda Holtzman, Malgorzata Chrzanowska-Jeske, Phillip K. Wong
ECE department, Portland State University, Portland, OR

Abstract—**We are assessing the effect of our new freshman electrical engineering course sequence on follow-on courses. One of our assessments is a survey distributed to sophomores in electrical circuits and juniors in microelectronics courses. Roughly one half of freshman year is spent on programming in MATLAB and C, and problem solving using these programming tools. Our observation is that students consider programming important and have reasonably good confidence (self-efficacy) that they can solve problems using MATLAB and C. However, when asked about frequency of use for these tools students report using them somewhere between once a week and once a month. There is a significant number of students who report almost no usage at all. Results are consistent across sophomore and junior years with a slight up-tick in frequency of use for juniors. We are hypothesizing that students do not view MATLAB and C as tools for problem solving but as yet another item to acquire in their studies. Our plan is to change instruction in sophomore courses so that more problem-solving which requires programming will be introduced. The existing survey will be used to measure future improvement.**

Keywords—assessment; freshman engineering; programming.

I. Introduction and Motivation

The student experience during the freshman year has been recognized as one of the keys to attracting more students into engineering and improving retention [1]. In the ECE department at PSU we have recently designed and implemented a set of three freshman courses that include many of the best-practices approaches [2-4]. The first freshman course (ECE 101) is meant to be more inviting and encouraging to students. Instead of trying to filter them out of the program, we present them with a spectrum of engineering challenges that are fun to work on. The following two courses (ECE 102 and 103) concentrate on problem solving primarily using MATLAB [5] and on C-language programming and were meant to improve our students' programming and problem-solving skills.

In Fall 2011 the first cohort of students following the new curriculum reached junior year. Many of our students transfer from local community colleges which do not follow the same curriculum, making analysis of effects of changes in our curriculum more challenging. Our initial goals, and our research questions, were to determine if there is any positive impact of our new freshman curriculum on a) student preparedness and b) student success in the program. For the former we developed a brief self-efficacy survey. For the latter we will be analyzing student transcripts at the point of graduation. Our first cohort will be graduating this spring. It is hoped that this will provide evidence that our changes are effective as well as point out what parts of our freshman program may need improvement.

II. Assessment

Individual courses have their own assessment of course outcomes but this does not enable a longitudinal look at what students do with the knowledge and skills they develop during the freshman year. To answer that question we developed a survey that asks students about the importance of what they learned and how confident they are in their skills. We also ask them to estimate how often they use programming tools, namely MATLAB and C. Survey details are given below.

A. Survey

The survey was administered in two courses: a) first sophomore circuits class (ECE 221), and b) first junior microelectronics class (ECE 321) as detailed in Table 1.

Table 1 Number of respondents per course and term

	Fall 2011	Fall 2012	Winter 2013
ECE 221	21	26	10
ECE 321	16	5	14

For this report the most relevant questions are:

Q4. My knowledge of MATLAB is very useful in my engineering studies
Q5. I am confident that I can use MATLAB to solve problems in ECE 221/2/3 and other courses
Q6. My knowledge of programming is very useful in my engineering studies
Q7. I am confident that I can use my programming skills to solve problems in ECE 221/2/3 and other courses
Q8. Material and techniques I learned in ECE 101+102+103 or ECE 102+103 have been useful in the follow-on courses
Q9. I use MATLAB or programming language(s)

Questions 4 to 8 use a five-point, Likert-type scale: strongly agree (1), agree (2), neutral (3), disagree (4), and strongly disagree (5). The last question is on frequency of use and has a scale: Very frequently (daily) (1), Frequently (2-3 times a week) (2), Seldom (once a week) (3), Very infrequently (once a month) (4), Almost never (5).

As a first step in our analysis we examined the data in the aggregate but separated by course. Our expectation was that we would observe some improvement in self-efficacy in the junior year. Aggregation is further justified by lack of any large differences in histograms of answers to various questions among different years. We will look at averages and histograms (distributions): averages may uncover some larger shifts or trends, while histograms give a more detailed look at individual questions. Since our data is very new we did not have time to separate out the native vs. transfer populations – this is the next step in our analysis.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

III. SURVEY RESULTS

Figure 1 presents averaged survey data for questions 4 to 9. Data is aggregated across years and standard deviation is shown. Note that lower number means higher agreement with the question. Numbers 221 and 321 indicate the sophomore and junior courses, respectively. Students' perception of importance or usefulness of MATLAB (Q4) and programming (Q6) is fairly high. However, their self efficacy, i.e. confidence in their skills in MATLAB (Q5) and programming (Q7) is somewhat lower. Remarkably, there is hardly any difference between juniors and sophomores and, if anything, juniors have somewhat lower confidence, as judged by the distribution shown in Figure 2 for Q7. This is similar to the observation reported in [6] that "data comparisons between the freshman and the sophomore courses at MSU indicate a loss of confidence in the use of some skills from the time students take the freshman course to the time they enter their sophomore year."

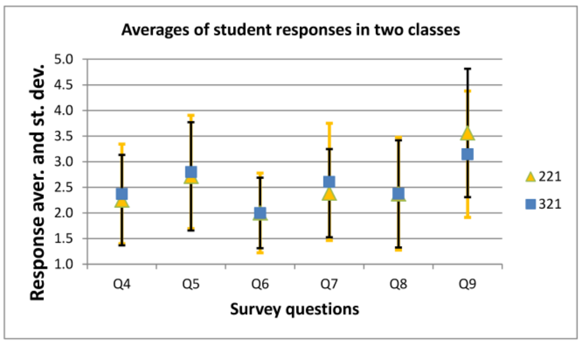

Figure 1. Average scores for questions Q4 to Q9.

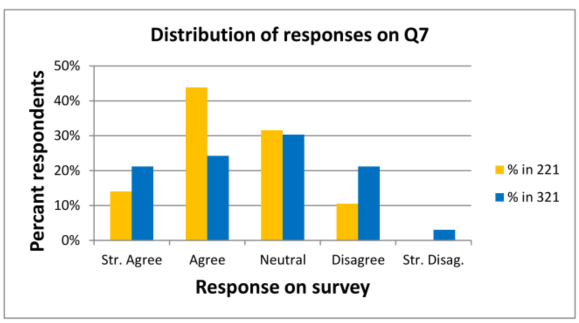

Figure 2. Self-efficacy for MATLAB skills.

Figure 3 shows the response to Q8, referring to the general preparation provided by the freshman sequence. Based on Figures 1 and 3, we observe that students find our freshman courses useful, but that there is room for improvement. Juniors also seem to be slightly more positive about their experience than sophomores. Figure 4 shows the response to Q9, referring to the frequency of use of programming tools, both MATLAB and C. Recall that "1" is the most frequent use and "5" the least. From Figure 4 we wanted to find some support for student estimate of self-efficacy, but we were not expecting to find that half of our students report using programming or computational tools once a month or almost never!

The situation improves somewhat for juniors vs. sophomores, but the frequency of use seems too low for both. Our working hypothesis is that this is due to lack of requirements in follow-on classes. Students forget the tools, or do not use them frequently enough that they become indispensable (the way, for example, a calculator is). If so, then we will have to introduce some changes in our curriculum. Our results indicate that it is not sufficient to look at self-efficacy alone, but we also need to verify that students use their skills frequently enough to maintain the initial proficiency.

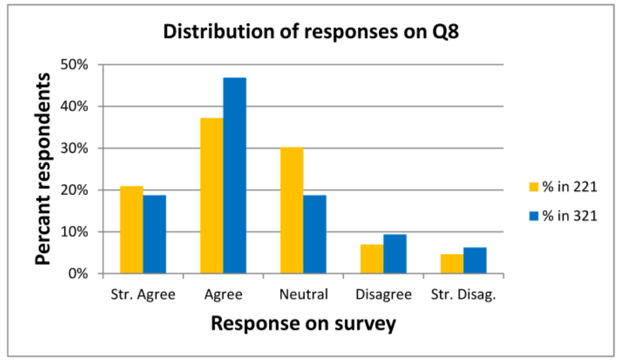

Figure 3. Students' estimate of usefulness of their freshman preparation.

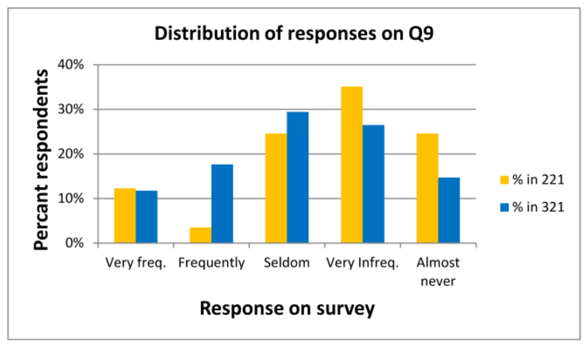

Figure 4. Frequency of use of programming tools.

In response to the first year's survey, we are including more MATLAB programming in ECE 222 and 223. In 222 a lab was introduced on symbolic MATLAB, system representations and SIMULINK. In 223, emphasis is put on using MATLAB in a filter design project. In ECE 321 we plan to use MATLAB for analyzing circuit performance under parameter variation and for projects. The survey planned for the end of the year will help us assess whether these changes improve the situation.

IV. CONCLUSIONS

Overall, our initial data and analysis show good levels of student satisfaction with their preparation in freshman year and reasonable levels of self-efficacy in the use of MATLAB and C programming. There is room for improvement, especially since self-reported frequency of use is lower than our expectations. This points to the conclusion that these tools must become an integral part of the entire curriculum if they are to become really useful to – and be used by – our students. In other words, we have to provide better scaffolding and repeated exposure to authentic computational problems across years [6,7]. These results also lead us to believe that it is critical to ask not only about student self-efficacy but also about frequency of use. Students may be confident but never use the tools, and that bodes ill for their actual proficiency.

Developing The Cellbot Learning Framework (CLF) -

An Interdisciplinary Model For Integrating Mobile Computing With Robotics To Innovate STEM Education and Outreach

Ankur Chattopadhyay, George Sellman
Computer Science Department, Adams State University (ASU), Colorado, USA

Abstract - **Mobile computing and robotics have been used as two separate approaches to engage university and pre-university students in STEM education. We are in the process of developing an innovative learning model that combines these two approaches into an integrated framework, where students would learn to make robots and control them via Android applications. By creating these cellbots, students will learn Android app programming and robot building together. Through CLF, we strive to engage both university and pre-university students in a creative environment that enables joint learning of programming logic and engineering concepts. CLF will also serve as an interdisciplinary tool to interface science with engineering. It will further pave the way for building diverse student communities by bonding different learners. The overall goal is to enhance STEM curriculum and outreach activities for recruiting more STEM majors. As part of implementing CLF, we are developing a STEM workshop for high school students, which will consist of hands-on activities on working with BERO (Be The Robot) and designing cellbots. Our future plans comprise of deploying CLF in introductory STEM courses to promote the diverse and interdisciplinary nature of STEM disciplines.**

I. INTRODUCTION AND BACKGROUND

The global technological advances of the last decade have made a major impact on STEM curricula. On one hand, new courses, based on mobile computing, have expanded STEM disciplines and on the other hand, interdisciplinary courses, based on robotics, have enhanced STEM topics.

A. *Significance of Mobile Computing*

Given the increasing demand and accessibility of Android apps, skills at developing these apps are required of present STEM majors, who need to adapt to the ever changing STEM disciplines. This has led to the advent of new STEM courses based on Android programming, an emerging topic [1]-[3].

B. *Significance of Robotics*

Robotics has been around in STEM education as a classic, multidisciplinary engineering topic [4]-[13]. Teaching programming logic and automation via robot simulators and demonstrating AI topics through robot prototypes are practices that have been successful in reinforcing STEM learning [6]-[13]. The subject of robotics has its own charm and has always drawn in students as STEM majors.

II. PURPOSE AND MOTIVATION

Even though a lot of research and innovative practice has gone into the above two STEM fields separately, not much interdisciplinary work has been done to combine the above two topics into one for the benefit of early STEM education and outreach. [14]-[15] mention the idea and purpose of combining mobile computing and robotics into one course, but the resulting learning environment is clearly intended towards upper level STEM classes, the audience being STEM juniors and seniors. What our CLF brings forth is basically a novel learner platform of mobile computing and robotics put together into an integrated model for introductory STEM education and STEM outreach. The unique purpose of CLF is innovation of STEM education and outreach for bringing together STEM students from different interest areas. CLF is a way for students to learn Android app programming while making robots. The use of Android apps to maneuver robots is intended towards stimulating the young minds and motivating them to take up STEM majors. One of the major challenges of STEM education is to teach freshmen the art of programming. CLF aims at making this job easier by demonstrating programming logic and its outcomes through robot actions via an Android app. It is meant to excite students and engage them in both Android app programming and robotics by connecting the two distinct fields meaningfully. It is also intended for attracting students to STEM majors by early hands-on introduction to advanced topics like wireless communication, HCI (human-computer interaction), AI (artificial intelligence), ML (machine learning), object detection.

III. CLF DESCRIPTION

CLF currently contains two learning components - Cellbot Building Module (CBM) and BERO Based Module (BBM). CBM involves cellbot building from scratch using robot platforms like Arduino microcontrollers [16] and pairing them with Android smartphones. BBM encourages exploring and programming BERO, which is a pre-built robot controlled wirelessly by a bluetooth-enabled Android device [17].

A. *CBM Description*

CBM comprises of building a prototype cellbot through a combination of engineering and programming techniques using hardware elements (like Arduino boards) and opensource software components [18]. The electronic Arduino board is chosen because of its ready availability, cheap price and user-friendliness. CBM is inspired by Google's cellbot project [18] with the objective of driving a robot using an Android smartphone as a remote control. The opensource cellbot app [18], as displayed in Fig. 1, is a handy Android API (application program interface) as it is compatible with several robotic platforms and operates a robot remotely from a

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

mobile device, desktop or a web browser. Once connected to a robot, this app acts as a remote control in its brain mode, rendering it easy to navigate the robot and chat with it remotely using text messages through Google Talk. Using CBM, students will get exposure to Android app programming, UI (user interfaces), robotic platforms and smartphone capabilities. The CBM hands-on activity serves as an educational tool since it teaches both programming and engineering skills over a single platform. The communication with a robot through an Android smartphone also introduces fundamental STEM technologies and HCI concepts such as voice recognition, text-to-speech conversion and basic client-server communication using chat.

B. BBM Description

BBM consists of working with the pre-engineered, affordable BERO [17], which is driven by an Android device (such as a smart phone or a tablet) via bluetooth. There are several benefits of selecting BERO for this learning module. Its major advantages lie in the following attributes:-

- Small, compact size and relatively less cost
- Opensource app and opensource code (free download)
- Full set of functionalities with advanced in-built features
- Different user modes/options (user-friendliness)
- Exhibition of simple event-driven programming logic, including events, macros, functions, data types, etc.

Fig. 1. Cellbot Android app and prototype: CBM (CLF).

IV. IMPLEMENTATION DETAILS

The CLF implementation process consists of two parts - STEM outreach and STEM education. The first part focuses on the use of CLF for reaching out to pre-university learners (prospective STEM majors), while the second part concentrates on the use of CLF for university students. We utilize BERO in its basic play mode (non-developer) for CLF STEM outreach activities, while we use BERO in its developer mode (with Android SDK and Java) for CLF STEM education sessions. By using BERO for CLF, we provide learners the advantage of early hands-on experience with many significant interdisciplinary concepts and STEM technologies, including basic programming elements, program control logic and engineering techniques.

A. STEM Outreach

As part of the CLF STEM outreach work, we will be incorporating BBM into our upcoming STEM outreach sessions. These outreach activities will be targeted towards recruiting pre-university students for STEM majors. The workshops will focus on using BERO for hands-on experience in the play mode with motion, light and sound control. The advantage of employing BERO as an outreach tool is that it is a pre-built cellbot that can be introduced as an animated, mobile, robotic toy platform for playing with. Learners do not require any prior programming background to get started in this mode. In fact, our hands-on activities for pre-university students involve only visual programming and not writing actual code. These beginner's exercises will teach them how to control BERO with its open-source Android app (as shown in Fig. 2) and how to make the robot walk, dance, play music and do other exciting stuff. The introductory BERO exercises enable easy robot manipulation through an Android device.

The hands-on topics provide many learning opportunities, as listed in Fig. 3. Witnessing the variety of different hands-on experiments with BERO leads to early understanding and appreciation of STEM subjects, thereby creating an impression and engaging young minds at a nascent stage.

Fig. 2. BERO Android app: BBM (CLF).

B. STEM Education

As part of the CLF STEM education component, we adopt both CBM and BBM. We use BERO in both of its modes - developer mode as well as play mode. Usage of both modes enhances the overall learning at the university level by revealing the full range of BERO capabilities and features. BERO programming in dual mode demonstrates more programming concepts and offers more learning opportunities. We plan to deploy CBM in the outreach activities of the ASU Robot Society [19]. We also intend to include the CLF STEM education component in our introductory CS (computer science) programming courses at the CS0 and CS1 levels. CLF STEM education for university students will include hands-on BERO programming exercises (using the developer mode) in addition to the beginner's exercises (using the play mode). BERO in its developer mode serves as a good educational tool for STEM majors as it provides a multitude of opportunities for them to study and learn different aspects of programming. The opensource BERO application code base comprises of an Android app and BERO firmware (system routines). The app communicates with the advanced BERO internal operating system via bluetooth. The bluetooth communication routines (code) are stored on the Android device. The BERO programming exercises of CLF STEM education are based on the opensource BERO app code. Some of our sample BERO developer programming exercises for CLF STEM education are cited in Fig. 4.

Topic #	*Topic Name*	*Expected Outcomes*
I	BERO Android app, GUI (graphical user interface), macro editor	See and use function control buttons, macro control buttons, BERO commands, macro data, events; learn about bluetooth (HCI, communication technology)
II	Built-in features: robot arm motion, sound playback, drive train, IR (infra-red) obstacle avoidance	Experience and learn about HCI, AI, ML, data coding/compression, object detection/tracking, IR sensor

Fig. 3. Example hands-on topics: CLF STEM outreach.

V. PROJECT STATUS AND EVALUATION PLAN

The CLF implementation process is currently in its early stages and we will be starting the pilot deployment phase in summer 2013. We have developed BBM and are in the process of developing CBM. We plan to conduct a summer STEM workshop for local high school kids and intend to deploy the CLF STEM outreach component in the workshop sessions. This workshop is through our partnership and collaboration with the local K-12 education systems (12 high schools). We also plan to incorporate BBM into one or more of our CS0 and CS1 programming classes in fall 2013. The CLF hands-on lessons of the upcoming summer workshop and the fall programming course(s) will contain programming exercises for making BERO respond and react to simple message commands/instructions through a given Android device. Additional hands-on activities will include setting up BERO's multi-motors and IR sensors to produce navigation through obstacles, dancing moves, etc. Thus, by the actual IEEE FIE 2013 conference date, we should have preliminary evaluation data for the CLF performance, including student feedbacks/survey results from the CLF STEM outreach sessions as well as the CLF STEM education activities.

VI. CONCLUSION AND FUTURE WORK

Given that Android apps and robotics are generally considered as two separate STEM areas and are treated independent of each other, CLF integrates these two different subject matters into one innovative model for enhancing STEM education and outreach. CLF looks to build a creative, fun-filled environment, which would pave the way for learning of application programming along with meaningful engineering. CLF is also meant for building diverse learner communities across STEM disciplines by bringing together students of different backgrounds and varied interests. It acts as an innovative hands-on learning tool for understanding programming strategies and STEM fundamentals while experiencing an exciting integrated application of mobile technology and robotics. Using CLF, we intend to encourage more student participation in STEM by engaging learners in creative work and making them realize the broad range and diversity of STEM applications. Possible scope of future work lies in implementing a CLF that is iOS compatible, works with iPhones and is capable of being controlled via Wi-Fi.

Exercise #	*Exercise Name*	*Expected Outcomes*
I	Change commands to BERO using control message strings	Learn about command set up using data strings, functions, parameters and parameter passing; understand string variables and learn to use them through BERO commands
II	Schedule the signal sent to BERO with a given sending rate	Learn about timing configuration; understand data types: integers, floats, assignment operators and operations; learn to use them through scheduling program
III	Decide BERO action based on obstacle detection via IR radar	Understand IF conditional statement for decision making logic and learn to use it via IR sensor input

Engineering the Human Heart in the Sixth Grade Classroom

Christina Foster, Tirupalavanam Ganesh
Arizona State University, cnhobson@asu.edu, tganesh@innovatek12.org

***Abstract*— A Framework for K-12 Science Education has been released that provides further support of K-12 engineering education by framing requirements for K-12 engineering standards for the science classroom. This study uses the engineering themes from the framework to evaluate how an engineering learning experience affects student achievement in science and engineering in the context of a science classroom. An engineering design challenge, Engineering an Artificial Heart, was developed for a pre-existing science instructional lesson, the human heart, for its use in a 6th grade science classroom with 32 students. Students' achievement of learning objectives for science and engineering concepts were measured using content assessments, student artifacts, and semi-structured interviews. Preliminary analysis shows positive learning gains for science learning objectives and evidence of performance for the engineering learning objectives.**

***Index Terms*—K-12 engineering, learning through design**

I. INTRODUCTION

The National Research Council has released the Framework for K-12 Science Education, which is serving as a guide for the Next Generation Science Standards (NGSS) and informing state-level decisions for K-12 science education [1]. Engineering has a significant role in the framework and will require the engineering education and teaching communities to develop strategies for building the upcoming engineering standards into the science classroom.

A. Engineering in K-12 Education

To date, engineering education for K-12 has been successful in building momentum. With several dozen engineering education programs and curricula in school districts around the U.S. and growing, engineering education is reaching students around the nation [2]. The implications of engineering in K-12 are being documented by several research initiatives; some of the positive outcomes include boosting learning and achievement in math and science, increasing interest in engineering as a career, and improving the technical literacy of students [2]. Despite the benefits that students have received from engineering education, these programs and curricula have come from multiple perspectives of what engineering should look like in K-12 and have varying learning objectives that are designed to meet the program's needs.

Other school subjects, on the other hand, have a long-standing history in the classroom and are supported through established learning standards. When the landmark report *Engineering in K-12 Education: Understanding the Status and Improving the Prospects* was published, engineering did not have formal learning standards and therefore engineering education did not have a consistent presence across schools and states. The NGSS offers a foundation for K-12 engineering education to build upon by providing guidelines to inform the development of engineering standards and learning progressions. This provides opportunity to address unanswered questions for K-12 engineering education that have potential to impact the pedagogy for engineering, such as how does engineering provide a context for exploring science concepts in the science classroom.

B. Engineering in NGSS

The NGSS framework is organized with three dimensions: science and engineering practices, crosscutting concepts to unify science and engineering, and disciplinary core ideas. Engineering themes are present in each of the three dimensions. Throughout the framework, engineering is represented by the systematic, iterative practice of design. Learning engineering by design is supported in the literature as useful for K-12 students and is the focus of the majority of K-12 engineering education curricula [2]. Table 1 displays the extracted engineering themes from the framework.

TABLE 1. ENGINEERING THEMES IN THE NGSS FRAMEWORK

Dimension 1: Engineering Practices	Dimension 2: Crosscutting Concepts	Dimension 3: Disciplinary Core Ideas
1. Defining problems 2. Developing and using models 3. Planning and carrying out investigations 4. Analyzing and interpreting data 5. Using mathematics and computational thinking 6. Designing solutions 7. Engaging in argument from evidence 8. Obtaining, evaluating, and communicating information	1. Patterns 2. Mechanism and prediction 3. Scale, proportion, and quantity 4. Systems and system models 5. Energy and matter 6. Structure and function 7. Stability and change	1. Engineering design 2. Links among engineering, technology, science, and society

II. IMPETUS FOR THE STUDY

The impetus of this work is to address how an engineering learning experience, built from the engineering objectives outlined in the NGSS framework, affects student achievement in science and engineering in the context of a science classroom. As a first step towards this research goal, an engineering design challenge, Engineering an Artificial Heart, was developed for a pre-existing science instructional lesson, the human heart, for its use in a 6th grade science classroom. The engineering design challenge was embedded with core features from each of the three dimensions of the framework. It is hypothesized that the engineering learning experience, using the core features of the NGSS framework, will be effective in the science classroom. Learning through engineering design provides students with opportunities to make deep connections to the material. For instance, modeling in engineering design provides an opportunity to explore the functional parts of a system, the ways in which the roles of the parts are performed, how the functions of the parts interact with each other, and what the parts of the model represent [3].

III. METHODS

For two weeks, 32 6th grade students engaged in the bioengineering design challenge, Engineering an Artificial Heart. A researcher from the university taught the learning experience alongside the 6th grade classroom teacher. Students worked in groups of four, making eight groups.

The science learning objectives were taken from the classroom teacher's pre-existing science lesson on the human heart and were:

- Students will demonstrate knowledge of the major structures of the heart and their functions. (S1)
- Students will be able to explain why the heart is a double pump. (S2)
- Students will be able to explain that blood has a direction of flow through the heart. (S3)
- Students will be able to explain that the function of heart valves is to prevent backward flow of blood. (S4)

The engineering learning objectives were developed using language from the NGSS framework. The objectives for Dimension 1 emphasized that students should be able to demonstrate their ability to engage in the engineering practices. Specifically, this included the following.

- Students will be able to define the engineering design problem that can be addressed through the development of an artificial heart model and includes multiple criteria and constraints, including scientific knowledge about the heart that may limit possible solutions. (D1-1)
- Students will be able to develop an artificial heart model to generate data to test ideas about the designed system – the artificial heart - including inputs and outputs. (D1-2)
- Students will be able to engage in argumentation from evidence to provide reasoning for the strengths and limitations of their artificial heart models. (D1-3)

For Dimension 2, crosscutting concepts, two concepts were selected for their applicability to this lesson: (1) systems and system models and (2) structure and function. The systems and system models concept required that students be able to define the system under study and its interconnecting parts (i.e. the human heart and its atria and ventricles) and make explicit a model of that system (in this case, through engineering design). The structure and function concept required that students explore the way in which an object (i.e. the human heart) is structured and determine its properties and functions. The appropriate learning progressions in the framework were used to develop the learning objectives for these concepts.

- Systems and system models: Students will be able to move beyond simple drawings of the system under study and make explicit the interactions that are invisible to the eye (e.g. movement of blood from one heart chamber to the next). Students will be able to use artificial heart models to interpret and explain a natural system, the human heart. (D2-1)
- Structure and function: Students will be able to analyze a complex structure, the human heart, and be able to communicate how shapes of the structure and substructures are related to the function. (D2-2)

For Dimension three, disciplinary knowledge, both strands were included in the learning objectives: engineering design and the link to technology and science.

- Students will be able to demonstrate their ability to engage in the process of engineering design, including problem definition, gathering information, developing possible solutions, evaluating the solutions, building, testing the solutions and identifying the characteristics of the design that performed the best, and revising the design to optimize the solution. (D3-1)
- Students will be able to gather information on artificial hearts and participate in discussions about engineering advances for artificial heart. (D3-2)

These learning objectives were then used to develop the learning activities for the engineering learning experience. These are listed in Table 2.

TABLE 2. LEARNING ACTIVITIES FOR ENGINEERING AN ARTIFICAL HEART

Day	Learning Activities
1-2	Students were introduced to the bioengineering design challenge, including criteria and constraints. Students were asked to explore what is engineering through hands-on activities. Students began to gather information on the human heart from in-class materials (e.g. models, library books, animations, etc.)
3	Students worked together to assemble their knowledge of the human heart as a system into a structure-function chart using their whiteboards and group discussions.
4-5	Students explored the double-pump action of the heart using double siphon pumps. Students explored other types of pumps and built centrifugal pumps from pens and ball bearings. Students began to develop possible solutions for their artificial heart models.
6-7	Students evaluated their solutions and built the most feasible artificial heart model from recyclable materials.
8-9	Student groups presented and compared their models. Students tested their models, collected data, and revised their models. The presentations included the strengths and limitations of the models.
10	Student groups completed the revisions of their artificial heart models and presented them to the class. Students' presentations focused on the parts (structures) of their models and the purpose of the parts (functions) and how this helps explain the human heart system.

IV. DATA COLLECTION AND PRELIMINARY ANALYSIS

Using a mixed-methods approach, qualitative and quantitative data were collected from the students. Quantitative data were collected from two science content assessments, Draw the Human Heart, an assessment that asked students to draw the structures of the human heart, label their functions, and draw arrows marking the direction of flow of blood, and The Heart as a Pump, an assessment that asked students to explain why and how the heart acts as a pump. As a preliminary analysis, these assessments were evaluated and dichotomously scored for their correct and incorrect science conceptions about the heart outlined by the science learning objectives. A paired samples t-test was performed. Table 3 presents these results. Students' performance for the science learning objectives resulted in statistically significant differences; these differences are considered meaningful due to the large effect sizes, particularly S1, S3, and S4. Figure 1 presents an example post test. A typical pre test was one where the student drew a heart shape in the middle of the body.

Qualitatively, semi-structured interviews were conducted with student groups prior to the engineering learning experience, at a mid-point, and after the conclusion of the engineering learning experience. The science and engineering learning objectives were used to probe students for their understanding of science and engineering concepts. Artifacts from the student groups were also collected, including the artificial heart model and design notebook. As a preliminary analysis, the student artifacts and interviews were examined for their satisfaction of meeting the engineering learning objectives. Table 4 is a chart of these results with the last row representing the percentage of the class meeting the particular objective. A more in-depth analysis is currently taking place.

The purpose of this work was to show how engineering design affects student achievement in science and engineering in the context of a science classroom. These results provide preliminary support that engineering design contributes to science and engineering achievement in the science classroom.

TABLE 3. STUDENTS' LEARNING GAINS FOR THE SCIENCE CONCEPTS

	Paired Samples Statistics				
	N	SD	t	p	Effect Size
Knowledge of major structures and functions of the heart (S1)	32	0.492	4.313	<0.001	0.594

V. FUTURE STEPS

Further analysis is underway, including (1) evaluating the curricula with the middle school performance standards, developed from the NGSS and released April 10, 2013, (2) comparing student science achievement to the engineering achievement across each student, and (3) coding the interviews for emergent themes. The results of this study will be used to revise and extend the learning experience for the next implementation. For the next implementation, it will be critical to collect data from a control group that does not partake in this engineering design learning experience to have a clearer picture of how engineering design affects student achievement in the science classroom. During this implementation, classroom time was a limiting factor. By including engineering design, the class time doubled. These practical issues will have to be addressed as the engineering standards are added into the classroom. The authors hypothesize that the hands-on exploration of the heart as a double pump through engineering design could aid in students' understanding of other related science content (e.g. the lungs as a pump, a typical lesson that follows the heart). It would be fruitful to measure students' understanding of the related content to evaluate the effectiveness of engineering design.

***Abstract*— This study investigates the influence of modeling instruction for a solar engineering design challenge on students' achievement goal orientations. Two classrooms received five weeks of modeling instruction using whiteboarding strategies. Students' goal orientations were measured before and after the learning experience using the goal orientation sub scale of the self-report questionnaire, *Patterns of Adaptive Learning (PALS)*. Preliminary analysis revealed that students' performance approach and avoid goals increased, but saw no improvement in the students' mastery goals. This study provided insight to the possible ways in which modeling instruction may be enhancing negative performance goals within the context of a high-stakes environment. Discussion highlights the importance of motivational supports for creating a classroom environment that supports mastery learning.**

***Index Terms*—K-12 engineering, modeling, achievement goals**

I. Introduction

The National Academy of Engineering has called for the integration of engineering into the science classrooms due to its potential to increase STEM literacy as well as increase awareness and interest in engineering careers [1]. Much of the effort has focused on the development of engineering education curricula and instructional strategies for delivering the content. Equally as important is understanding how to support student motivation in the classroom because of its key role in cognition and learning.

A. Achievement Goal Theory

Achievement goal theory is one aspect of the motivation continuum and explains how students' mastery and performance goals affect their achievement, persistence, and interest in the topic [2]. In this framework, different types of achievement goals are distinguished: performance-approach, performance-avoidance, and mastery [3]. Each of these goals represents a different relationship between an individual's valence and definition of competence [4]. With a performance-approach goal, a student focuses on demonstrating superiority and competence and attempts to outperform peers. Conversely, with a performance-avoidance goal, a student focuses on avoiding failure and appearing as incompetent. A student with a mastery goal orientation focuses on mastering tasks and learning. Each of the goal orientations has shown to have different consequences for learning, but mastery goals are considered to be the most favorable due to their ability to generate and maintain long-term interest and well being. Mastery goals also lead to improved self-regulated learning which helps students set better learning goals, monitor and assess their goal progress better, implement more effective learning strategies, seek assistance, persist better, adjust strategies better, and set more effective new goals [5].

Environments impact students' goals, and classrooms can be structured in ways that support or deter students in setting adaptive goals [6]. These support structures include providing students with opportunities to set individual goals, remain focused on the task, and de-emphasize performance based on social comparison. However, these support structures are often neglected in the classroom due to high-stakes testing, pressures for performance, and structural changes in U.S. classrooms including curriculum changes [5]. Instead, U.S. classrooms favor a more direct, authoritarian approach and are increasingly performance-oriented. The effects of this classroom climate can be damaging because it encourages performance-oriented goals. There is evidence that performance-avoid goals offer few benefits; and performance-approach goals, although may lead to improved achievement, may decrease interest [2]. To support students in developing interest in engineering, it is beneficial for the educational setting to be structured in a way that allows students to develop mastery goals. This study seeks to explore whether adaptive orientations through mastery goals can be encouraged through engineering design challenges, taught using modeling instruction.

B. Modeling Instruction

The foundation of modeling instruction is that the making of conceptual and physical models enables students to learn and do engineering [7]. Modeling is specifically useful in engineering education because it provides a method for teaching engineering design and provides opportunities for students to make connections to the scientific concepts that drive the behaviors of their models. Whiteboarding is a specific aspect of modeling instruction that supports students in reflecting upon their engineering work, developing explanations for their engineering decisions, and engaging in critique and evaluation of their own and other students' work. Because whiteboards are generally large and erasable, they allow for sharing, negotiation, and open discourse of conceptualization, modeling, and problem solving, which greatly enhances and enables modeling instruction in a classroom. Modeling instruction, and specifically whiteboarding, has many attributes that are seemingly linked to the underpinnings of mastery goals. This study explores the relations between this instructional model for engineering design challenges and students' goal orientations and interest

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

in engineering. This paper seeks to add to a larger conversation about the development of appropriate engineering education instructional strategies that will aid in a mastery emphasis within the classroom and enhance positive socio-emotional outcomes and academic achievement.

II. Research questions

(1) Do 4th grade students' achievement goals change after modeling instruction?

(2) Do 4th grade students' interest in engineering careers change after modeling instruction?

III. Methods

To determine the impact of modeling instruction on adaptive goal orientations among 4th grade students, two engineering design challenges were implemented in two 4th grade science classrooms within the same school district. The selection of classrooms stemmed from a university partnership with the school district. Instruction took place for five weeks in both classrooms with 60 minutes per class session. The first classroom had 24 students and the second classroom had 30 students. Classroom one and two are in the same school district, but serve different populations of students. Classroom one is from a Title I school with 57% students on free or reduced lunch; whereas, classroom two is an honors class and from a school that has 19% of students on free or reduced lunch. Before instruction began and after instruction concluded, students were asked to complete the goal orientation sub scale of the self-report questionnaire, *Patterns of Adaptive Learning (PALS)*. Using a five-point, Likert-style response, this scale asked students to respond to their perceptions of goal structures in the classroom and their personal achievement goal orientations. In addition, students were asked to respond to questions about their interest in engineering careers.

A researcher from Arizona State University's Quantum Energy and Sustainable Solar Technologies (QESST) - who has 13 years of science teaching experience at the school district under study and specialization in modeling instruction - worked alongside the fourth grade educator to deliver modeling instruction for two engineering design challenges on solar energy topics. The researcher and the classroom educator documented daily reflections on their perceptions of challenges with implementing modeling instruction and on the classroom climate. During the 25 class sessions, students were led through the phases of the engineering design process (identify the problem, gather information, imagine solutions, evaluate, plan, build, and revise) to design and build a solar oven and electrical circuits - series and parallel - that powered small objects (e.g. light bulb or small motor). In addition to experiencing the systematic and iterative nature of engineering design, some of the science content learning objectives included: energy can take many forms, one of which is heat and another is electrical energy; energy can be transferred between objects or systems; certain materials are better conductors of heat; electrical circuits transfer electrical energy; electricity can flow through a circuit if there is a power source and the circuit is closed; and many scientific principles of energy can be used to inform decisions about engineering design.

At the end of each class session, students were brought together in a circle with their whiteboards to discuss their daily objectives and outcomes and to engage in scientific argumentation over their thought processes. Students were asked to demonstrate their engineering and scientific understanding and were actively provided with feedback from the educator, researchers, and peers. Students were also encouraged to actively revise their engineering design ideas and were guided through revising any scientific and engineering misconceptions. The whiteboarding sessions allowed the QESST researcher and the educator to personalize learning objectives for each team and to respond to the unique design problems that each team was having.

IV. Results

This study represents a work-in-progress. The results presented here are preliminary. Despite low sample sizes, the results are being used to provide insight to the solar engineering learning experience and will inform revisions made to the experience for the upcoming school year.

A paired samples t-test was performed for classrooms one and two. The pre and post composite scores were compared for each category (e.g. type of goal orientation and interest in engineering careers) to determine the change in achievement goals and interest in engineering careers after modeling instruction had taken place. The tables below present these results. The significant findings are bolded.

TABLE 1. RESULTS FROM STUDENTS' RESPONSES IN CLASSROOM ONE

	Paired Samples Statistics			
	N	t	Std. Deviation	Sig.
Mastery Goals	18	-0.372	0.422	.357

Awareness of Engineering	14	-0.325	1.097	0.375

V. Discussion

A. Research Question 1

The 4th grade students reported that their mastery goals had little change over the five-week learning experience, but that their performance-approach and performance-avoid goals increased significantly. These results indicate an orientation towards demonstrating competence as well as avoiding failure and appearing as incompetent in front of peers. Evidence from previous studies have shown that performance-approach and avoid goals can increase when students are in a situation when social comparison is emphasized [5]. This evidence is useful in understanding how modeling instruction for this solar engineering design challenge affected students. Despite no change in mastery orientations, performance-approach goals did improve. This is important to note because performance-approach goals have been argued to contribute to adaptive outcomes (e.g. persistence and longer engagement with the materials). When combined with mastery goals, these goals have been shown to have positive effect on students' approaches to learning [8]. However, performance-avoid goals are not favorable due to their negative effects on learning. There is evidence that performance-avoid goals lead to poorer academic performance and lower levels of engagement with the material [8]. Efforts should be made to reduce these avoidance orientations by revising the structure of the classroom and delivery of instruction.

A critical analysis needs to be taken with modeling instruction to identify the aspects of instruction that are emphasizing the negative and positive aspects of performance. In addition, a comparison group is needed to further understand the effects of modeling instruction on achievement goal orientations. These changes will be made for the next implementation of modeling instruction for the solar engineering design challenge, but a preliminary discussion of modeling instruction for engineering design follows.

Modeling instruction and whiteboarding rely upon showing your work to peers, constructing explanations for your work, and receiving feedback from peers in order to inform the revision process for the engineering solution. Collaboration and communication are also a core part of the practices of engineers. However, when modeling instruction and whiteboarding are situated in a school context that emphasizes high-stakes performance and provides little time for explanation and revision due to limited science class time, then engineering design through modeling can begin to emphasize negative performance features rather than supporting mastery learning. This can be improved by identifying appropriate rewards for students, such as recognizing the students' progress and accomplishments during the public whiteboarding sessions; providing multiple opportunities for students to present and revise their understanding of engineering topics; providing students with structured autonomy (e.g. students are given some choice about how they will monitor their performance); and emphasizing that evaluation is self-referenced, meaning that it based on personal improvement and their mastery of engineering learning objectives.

B. Research Question 2

The 4th grade students in classroom two reported greater interest in engineering careers, but no change was calculated for classroom one. Classrooms one and two consist of different demographics, and the additional at-home support structures may be an influencing factor. More information is needed to explore this relation. Informing students of opportunities for engineering careers is an important aspect of engineering education because it can serve as an extrinsic motivator and increase interest in engineering. Classrooms can impact interest by creating the appropriate support structures and opportunities for learning.

VI. Future Steps

K-12 engineering education is at a critical time where K-12 engineering standards are being developed for the science classroom through the Next Generation Science Standards. As instructional strategies for engineering are determined, their impact on classroom goal structures will be of great importance due to the impact of mastery and performance goals on educational outcomes. QESST will continue its partnership with the classrooms from this study and extend the study to include additional 4th and 5th grade classrooms within the school district. The aim is to contribute evidence for best practices of modeling instruction that support achievemenet goal orientations.

Abstract— **Engineering has been shown to be an important field of study and practice for economic and technological development, as well as an opportunity for students to improve their standard of living and their communities. Engineering also has the potential to provide a powerful career path in places that suffer disproportionate economic losses from shifts in the global economy, particularly as the growth of mobile communication technologies enable virtual work and local business development in areas formerly considered "remote" or "inaccessible." Despite these opportunities, little investigative work to date has been done on recruitment of engineering students from rural cultures that are typically underrepresented in the field. To address this gap, this paper explores two such cultures: the Central Appalachians in the United States of America and the Maori in New Zealand. We present a review of the current situation in each region, along with preliminary findings from a study of Appalachian students, to identify both similarities and differences between the two peoples that can be used to enhance recruitment efforts and provide a global context for understanding the experiences of rural cultures.**

Keywords—Maori; Appalachia; Engineering; Career Choice

I. INTRODUCTION

Engineering has been shown to be an important field of study and practice for economic and technological development; pursuing engineering degrees and careers provides a potential opportunity for students from marginalized, rural and/or socio-economically disadvantaged communities to improve their standard of living and that of their community. However, geographic and cultural circumstances can limit these students' knowledge and understanding of engineering as a possible career choice. For example, previous work shows that individuals from rural cultures often lack exposure to professionals which limits their knowledge and understanding of such professional career fields [1-3]. As a result of a lack of exposure to and awareness of fields such as engineering, students may be less likely to pursue such fields.

Little research exists on the methods and impact of recruitment, specific to engineering, situated in rural geographical contexts. This work in progress explores two such cultures: the Appalachians in the United States of America and the Maori in New Zealand. We present a brief review of the current situation in each region, along with preliminary findings from a study of Central Appalachian students, to identify both similarities and differences between the two peoples that can be used to enhance recruitment efforts and provide a global context for understanding the experiences of rural cultures.

Information and data for the Central Appalachian region of the U.S. is drawn from publically accessible archives and from an NSF-funded research project aimed at identifying barriers to engineering as a career choice. Overall, the NSF funded project is a three-phase, sequential mixed method study of factors influencing engineering career choice in the Appalachian region. This paper draws on data from the first, qualitative, phase. Development of the interview protocol has been previously described [4]. Due to space limitations and our choice to highlight the research context, the data analysis is not described in detail but it followed methods prescribed by Miles and Huberman [5].

One framework being used to analyze the qualitative data is Future Possible Selves (FPS) [6]. This framework has been used to study populations of youth facing similar barriers, including barriers raised by cultural biases and socio-economic class [7-10]. FPS provides a useful lens to better understand how students view their future hoped for and feared self to allow us to see if, and where, engineering fits among the future possible selves of Appalachian high school students. Similarly, ideas from Multiple Selves theories allow us to understand how views of engineering selves might be consistent with or in conflict with other visions of the self that stem from rural marginalized identities [11].

Information about the Maori people of New Zealand is drawn from publically accessible New Zealand government archives and existing academic research to understand the culture. This information will be augmented via future field studies as the project unfolds. In this paper, we present information regarding the two cultures which can be used to 1) inform subsequent research studies regarding barriers unique to the Maori people of New Zealand and residents of Appalachia of the United States, and 2) develop interventions adaptable to rural cultures to reach potential engineering students in these underserved areas.

II. APPALACHIA AND APPALACHIAN YOUTH

Appalachia, as a region, extends from southern New York to Northern Mississippi in the United States of America. The regional definition is adopted from boundaries defined by the Appalachian Regional Commission (ARC). ARC was formed

978-1-4673-5261-1/13/$31.00 ©2013 Crown

in 1965 to address the issues of poverty found in this region of the United States [12]. At inception of the ARC, one-third of the Appalachian population lived in poverty and the per capita income was 23 percent lower than the average for the United States, and unemployment was rife [13]. Almost fifty years later, little has changed in the economic conditions and the region still contains many rural and isolated areas despite national advances in transportation and communication infrastructure [13]. Today, the Appalachian region as a whole still lags behind national averages in education and economic levels with the rural and isolated regions displaying even lower levels than more populated regions [13, 14].

Compounding the issues of lagging economic and education levels is the migration of aspirational Appalachian's for education, many of whom do not return to the area. Historically pursuing an education has caused many individuals to migrate away from the Appalachian region. This migration pattern has created the perception that education strips individuals of their roots and heritage [15]. The Appalachians who do choose to remain in the region due to the close families and communities, report high satisfaction with life [16].

Appalachia as a whole is expansive. Therefore, to narrow the scope of our study we focus on the Central Region of Appalachia. This is an appropriate choice because Central Appalachia represents the geographic and cultural conditions typically associated with the Appalachian mountains [17]. Like Appalachia as a whole, Central Appalachia has historically been heavily influenced by poverty and continues to have high numbers of rural and low income counties [17]. In addition to poverty, this region has a low college completion rate and high instances of migration out of the region [17]. These conditions support the idea that students may lack exposure to a full range of career options making this region appropriate for the study.

III. Maori and Maori Youth

Aotearoa/New Zealand is an isolated collection of islands in the South Pacific, 1,500km east of Australia. Accordingly, it was one of the last lands to be settled by humans, with Maori arriving in canoes from the mythical tropical homeland of Hawaiki around the 1300s, and British-dominated colonization occurring in the 1800s.

The urbanization of tribal Maori began with their active participation in trade with the British around settlements, and grew with the income opportunities afforded to unskilled labor in a protected economy built of supplying captive markets through the 1950s to 1970s. Many Maori advocated assimilation into British New Zealand values and norms, and Maori were alienated from their tribal people and family as they moved to the cities to work. Indeed use of Maori language by Maori students in schools was a punishable offence. This urbanization brought with it the attendant problems which reinforced the stereotype Maori as under-motivated physical beasts not too far removed from the bush, and unsuited to urban civilized life.

In 2001, Maori youth made up 17 percent of the Maori, and is projected to increase to 26 percent by 2021. In New Zealand's compulsory child education system, Maori youth are proportionally represented in primary and secondary schooling, yet only 7 percent of the total number of all students enrolled in tertiary education [18]. Forty-five percent of Maori students left school without reaching the minimum school leavers qualification, NCEA level 1, in 2006 [19], compared with 74% of New Zealanders of European background and 87% of New Zealanders of Asian background.

IV. Findings from Central Appalachia

Several similarities exist in the Appalachian and Maori people in their homelands, such as being underrepresented in higher education and wages. Further, both Appalachian and Maori peoples are founded on strong community and family values, lack of role models with exposure to post-secondary careers, and previous work suggests some are reluctant to move away to study. These similarities suggest that stakeholders interested in enhancing participation in engineering could benefit from a deeper understanding of how students in these cultures perceive engineering as a career.

Preliminary evidence in Appalachian supports the claim that exposure to careers matters to students in these rural cultures. Evidence can be seen in the data from Alyssa. She discussed how exposure to engineering changed her career path. She describes her exposure by saying:

"*I took a class senior year, called Introduction to Engineering, Principles of Engineering, we just talked about the different, various types of engineering, and like, what they're composed of and what they study and I really became interested in Chemical Engineering because I like chemistry and math, and just any kind of science. And that just really sparked my interest to engineering"*

She went on to discuss how this exposure changed her decision from becoming a pharmacist to a chemical engineer.

"Okay, well I didn't know anything about engineering until that class. I never really considered it at all. I was interested in pharmacy, which, deals with chemistry a lot. And so I went into that class, we just talked about the different types and then when I learned of chemistry having an option in engineering, I was really interested. And then the biology helped even more, and it was really cool when we did experiments and just, it really showed how cool engineering could be."

Our data also reflect a desire to remain in the area. Based on the literature, we expected this to be the case and found that it was indeed true. For example, Alyssa hopes to use her bio-molecular concentration within Chemical Engineering to contribute to cancer research in the future. One fear Alyssa has with her future career choice is relocating to a different area. When asked about this she said:

"That's one thing I'm worried about. You hear a lot of people that talk about their co-ops 'Oh, it's in Texas', 'it's in another country', it's like, oh, I don't really, I'm not prepared for that yet."

When asked why this mattered to her she replied:

"Cause I just want to, I want to be close to my family and somewhere where I'm familiar, it would just be hard to go off by yourself, somewhere, that far."

Through exposure in high school Alyssa gained an understanding of engineering as a career choice and found that it aligned well with her interests. Prior to the exposure, Alyssa describes her minimal knowledge of the engineering field. Note that few rural high schools in the region offer engineering courses similar to Alyssa's.

V. Conclusions and Future Work

The use of a framework constructed on possible selves and the inherent attention on values and socio-cultural contexts, provides a potentially useful lens to better explain the reasons Appalachian and Maori students choose engineering related subjects either while still at secondary school, or upon entry to university. The similarities and differences in Appalachian and Maori people, and the contexts they live and make choices in, suggest that a fruitful pan-cultural study be performed among the Maori of New Zealand similar to the current study in Appalachia. Such a study may reveal insights into one being ported over to the other, as well as the identification of hitherto unknown characteristics and traits of either Appalachian or Maori which may allow a tailored and unique intervention.

As the results from Central Appalachia show, barriers do exist that limit entry into the engineering field and therefore further study of similarly marginalized groups is appropriate. The results show that although exposure is important, the barriers may not be that simple. Alyssa shows us that even with exposure to engineering which resulted in plans to pursue a career in engineering, she still worries that she will not be able to find a career in her field close to family. It is therefore proposed to commence a related and interdependent study of Maori New Zealanders to build a theory that explains engineering as a career choice among these peoples. Once the barriers which limit student's decision to choose an engineering related field are understood, school systems, universities, and other stakeholders can begin to use the knowledge in the design of intervention programs. This work could go a long way in helping to economically diversify two peoples from differing parts of the world who share similar values and problems, and who are typically underrepresented within the engineering field.

Development of Interactive 3D Tangible Models as Teaching Aids to Improve Students' Spatial Ability in STEM Education

Oai Ha and Ning Fang
Department of Engineering Education
Utah State University
Logan, Utah, USA

Abstract— **Spatial abilities have been reported to be critical for success in Science, Technology, Engineering, and Mathematics (STEM) education. Research findings prove that spatial abilities can be improved significantly through training. This project develops 3D tangible models (TMs) and their corresponding computer graphics (CGs) as teaching aids to improve students' spatial abilities. The TMs and their CGs work together in a real- time, interactive manner. The TMs use a sensor board containing an attitude heading reference system to track and send their real-time 3D orientation on three axes to a computer. A program renders the 3D graphic models of these TMs on the computer screen and updates their 3D orientations. By manipulating the TMs and observing corresponding CGs on computer screens in real time, students will experience the displays of the same objects which undergo rotations in space from infinite viewing angles, resolving visual ambiguities. The system offers potential advantages over static pictures by explicitly rendering dynamic rotations of 3D figures over space, rather than requiring students to "mentally" figure out those rotations. The models in this development project will be used in an experiment to evaluate how they affect students' spatial abilities.**

Keywords — engineering education; spatial ability; STEM education; AHRS.

I. INTRODUCTION

Advances in science and engineering depend on a workforce that has solid education in Science, Technology, Engineering, and Mathematics (STEM). Research findings prove that spatial skills play a critical role in developing expertise in STEM education [1,2,3]. Spatial ability as a whole encompasses one's ability to generate, recall, and manipulate 3D objects within one's mind [3]. For engineering students, spatial ability is reported to have direct effects on academic success and retention in engineering programs [1, 2]. For high-school and pre-engineering students, spatial ability helps them understand and excel in geometry, basic chemistry, physics, and engineering graphics courses [3].

Not many people are born with high spatial ability. However, research findings prove that spatial ability can be improved significantly through training, particularly for poor spatial test performers [1,2,4]. Blasko & Holliday-Darr [2] reported longitudinal research on a spatial training program on 327 freshmen students at Penn State Erie and found that training is effective for improving spatial skills. Students who completed the training showed better spatial performance and increased grades and retention. Researchers at the University of California at Berkeley further confirmed that females improved more than males in spatial ability, and performed as well as their male peers after spatial strategy instruction [1]. Spatial abilities are not only trainable but also measurable. Spatial abilities are measured by a number of tests which include: (a) Mental rotation test (MRT) for spatial relation [4,5,6] and (b) Purdue Spatial Visualization Test - Visualization of Rotations (PSVT: R) [7].

II. THEORETICAL FRAMEWORK

Spatial abilities can be developed through a variety of activities, such as playing 3D computer games, learning geometric modeling in calculus, and sketching (by hand or computer) in engineering graphics courses [3]. For the purpose of spatial training, some studies have investigated different means of intervention to develop spatial ability within students with the aid of TMs such as construction toys, 3D blocks [8, 9], interactive computer graphics software such as augmented realities, virtual realities [10], or combination of these [11, 12].

The use of TMs in the development of spatial abilities seems to be employed by many K-12 educators. In a study investigating the effects of four types of spatial instruction on secondary students, Pillary [8] found that learning with physical models (Meccano construction sets) causes the least extraneous cognitive activities and makes available sufficient cognitive resources for learning spatial tasks. Casey et al. [9] found that the use of block-building intervention develops spatial reasoning skills in kindergartners on three measurements of spatial visualization, mental rotation, and block building. With the advances of computer technology, the approach of using interactive computer graphics software in spatial training is becoming more popular. As in [10], the interactive computer software is used along with 3D solid modeling and found to be effective in the development of spatial skills in undergraduate engineering. Sorby [11] used TMs (snap cubes) and interactive software in a study aiming to develop 3D spatial skills for K-12 students. She found that 3D shapes are highly rated as helpful training methods for modules dealing with isometric, orthographic drawings, and rotation of objects about a single axis. Reference [12] discuses the combined approach of using TMs and augmented reality (AR) models to investigate the relationship between 3D objects and their projections on engineering students in Engineering Graphics Course. This research's results indicate that the TMs and AR models significantly increased students' spatial abilities. Its finding also reveals that the use of TMs as supplementary teaching

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

materials can raise students' levels of curiosity and intention to learn and allow them to touch, and actively participate with the models.

No work has been done that combines TMs and CGs software in a real time, interactive manner in STEM education. In this development project, students can manipulate the TMs and observe their corresponding 3D CGs on a computer screen in real time. They can experience the displays of the same objects which undergo rotations in space from infinite viewing angles, resolve visual ambiguities, and explore the relationships between 3D physical objects and their 2D images. The system can offer potential advantages over traditional training with static pictures by explicitly rendering dynamic rotations of 3D figures over space, rather than requiring students to rotate mentally those figures in their minds. Students can learn with the TMs and CGs separately in manual mode or let them work concurrently in synchronous mode.

III. Methodology

This first phase of a two-phase project develops TMs and their CGs of 3D objects similar to those usually seen in Shepard & Metzler's (1971) MRT and Guay's (1977) PSVT:R tests (Fig. 1 and 2). The TM is embedded with a sensor board containing an attitude heading reference system (AHRS) and a microcontroller. AHRS is a set of sensors (gyroscopes, accelerometers, magnetometers) that measured and reported an aircraft's velocity, orientation, and altitude in space in terms of roll, pitch, and yaw information. AHRSs are designed to replace traditional mechanical gyroscopic flight instruments. With the recent advances of micro-electromechanical systems (MEMS) and sensor technology, AHRSs are very compact and cheap and have a broad range of applications in daily life, from sensors for airbags to built-in car navigation or camera's stabilization systems [13]. In this project, the AHRS tracks TM's real-time 3D orientations on three axes while the microcontroller processes orientation data from AHRS and delivers them to a computer (via wired or wireless connection). Computer program renders the 3D graphic model of that TM on the computer screen and updates its 3D orientations in real time. Fig. 3 shows a TM in a modified PSVT: R test.

On the second phase of the project, the models developed in this first phase will be used in an experiment to evaluate how the models affect students' spatial abilities.

IV. Materials

A. Tangible Models(TMs)

TMs are hollow 3D objects which are made from plastic styrene sheets and sculptural epoxy. The hollow design and plastic material are used to guarantee that the objects are light in weight so that students can hold, tilt, rotate, and observe them from infinite viewing angles (Fig. 3 and 4). The hollow space inside the TMs is also used to conceal the sensor board and batteries.

AHRS sensor boards are supplied by various providers and pre-fabricated with built-in sensors and with/without microcontroller (ATmega328) (Fig. 5). Some modifications and customized assembly are needed to suite this project application.

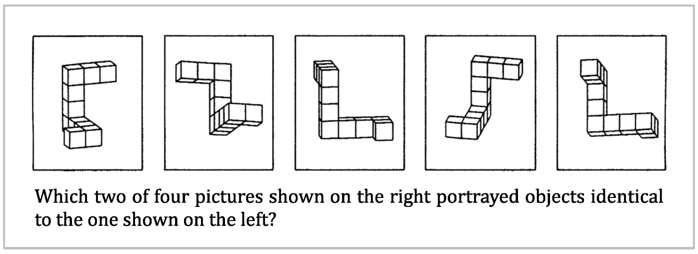

Fig.1 An item in MRT [4, 5, 6]

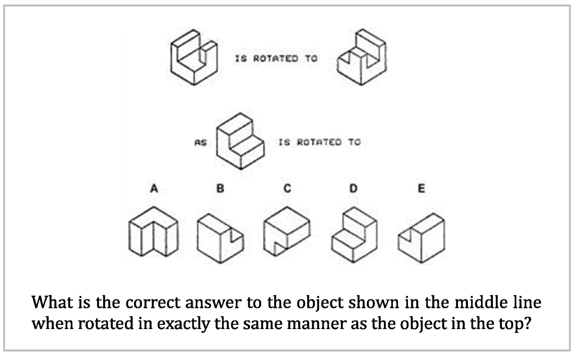

Fig. 2 - An item in Purdue Spatial Visualization – Rotation [7]

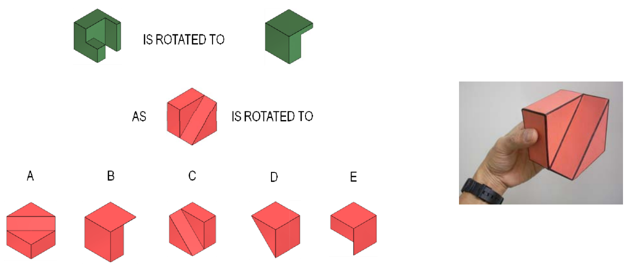

Fig. 3 - A modified Purdue Spatial Visualization – Rotation and its TM

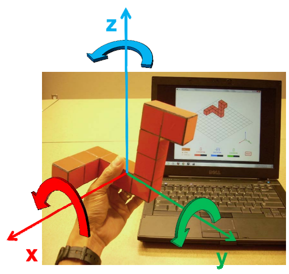

Fig. 4 - A tangible model for MRT

B. Computer Graphics(CGs)

Computer graphics models which correspond to the developed TMs are created and rendered by Processing. Processing is a open source programming language introduced by Casey Reas and Benjamin Fry from the Aesthetics and Computation Group at the MIT Media Lab in 2001 [14]. It was specifically designed to render real-time interactive 3D graphics. By making use of OpenGL, a cross-language, multi-platform application programming interface (API), Processing programs can take advantage of hardware acceleration from graphics processing units (GPUs) on graphics cards installed on most computers to render interactively 2D and 3D computer graphics. Programming codes written in the Processing language will process AHRS data generated from the sensor board inside the TMs and graphically represent rotations of CG models on a 3D plot (Fig. 6).

Fig. 5- An AHRS sensor board

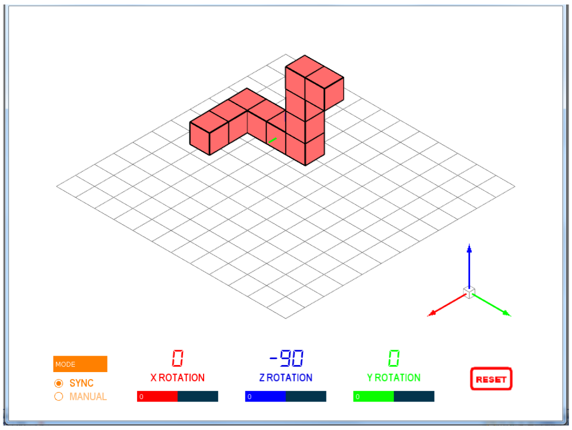

Fig. 6 - Computer graphic of a tangible model in Fig. 4

V. Preliminary Results & Future Work

A prototype of an interactive computer program in Processing, two TMs, and their 3D CGs have been created. The system works in the lab in both manual (CG rotations on three axes are controlled individually by three scrollbars) and synchronous modes (TMs and CGs rotate at the same time). TMs and CGs can be connected via wired or wireless network. More TMs and CGs that cover fundamental geometric features and engineering graphics are being added. The graphical user interface (GUI) of the interactive software is being improved to give users more control and options.

Upon completing the development phase, the system will be used in an experiment on high school and pre-engineering students in the next phase to evaluate how the models affect their spatial abilities.

Acknowledgment

This project received support in 2013 from Utah State University (USU) through a Graduate Student Senate Research and Projects Grant.

Newark, New Jersey, USA

Abstract*— The Center for Pre-College Programs at New Jersey Institute of Technology sponsors a series of summer enrichment programs designed to increase academically talented students' interest in the fields of science, technology, engineering and mathematics (STEM). Programs such as these can be instrumental in informing young students about careers in engineering and technology and helping ensure they receive the academic background required to prepare for these careers in college. One of the programs has been designed specifically for young girls in an effort to increase the number of women interested in engineering and other technological careers. Although there is much debate about the relative effectiveness of female-only programs, previous research comparing aspects of our female-only program to equivalent mixed-gender programs has shown that they can be particularly effective in reaching young girls, influencing their perceptions of engineers and attitudes toward engineering as a career. The addition of equivalent male-only programs has prompted additional research comparing changes in students' perceptions of engineers and attitudes toward engineering, as well as increases in learning and content knowledge. The three different gender grouped programs (female-only, male-only and mixed-gender) were identical in content. The single gender programs within the same grade were taught by the same teacher. Although the mixed gender programs were taught by a different teacher the curriculum was exactly the same. In addition to objective measures of effectiveness, teachers were interviewed to collect qualitative data about the climate in the classroom and students' interactions within the three different gender groupings. Results show differential effects among the programs, not only in terms of perceptions, attitudes and learning, but also in the classroom climate and students' interactions in the classroom.

Keywords*— *single gender education; engineering enrichment; female only; male only; STEM

I. INTRODUCTION

The increasing demand for more engineers in the United States workforce is expected to continue in to the next decade [1] but the number of students choosing to study engineering is not increasing at the same rate [2-3]. The chronic under representation of females in engineering is one of the major contributing factors [4-5] despite fact that gender discrimination in engineering wages has been almost eliminated, with women earning 97% of the wages earned by men [6]. To encourage more female students to pursue engineering studies, it is essential to eliminate misinformation and negative impressions about engineers and engineering [7-9]. Research on engineering recruitment indicates that many students, particularly young girls, do not know what engineering is and what engineers do, and their parents, teachers, and school counselors often do not know enough about engineering to help inform these students about careers in engineering [7,10-12]. Unlike many professions, engineers are rarely depicted in the media and outreach efforts often fail due to negative stereo-types. Therefore, not enough students explore the various fields of engineering when considering their college major and future career options and as a result do not prepare academically in middle and high school.

The Center for Pre-College Programs at New Jersey Institute of Technology sponsors a series of summer programs designed to increase academically talented students' interest in the fields of science, technology, engineering and mathematics (STEM) [12]. Programs like those offered by the Center for Pre-College Programs can be instrumental in informing young students about careers in STEM, particularly engineering, and help ensure they receive the academic preparation required to enter college programs in engineering or other highly technical fields [13-14]. One of the programs, Woman in Engineering and Technology, still called FEMME for the original name, Females in Engineering: Methods, Motivation and Encouragement, was designed specifically for young girls in an effort to increase the number of women interested in engineering and other technological careers [15-16].

The FEMME program spans grades four to eight, with each grade level focused on a different field of engineering. Middle school is not only an important time for students to begin thinking about future careers, but because boys and girls do not differ much in technical abilities until their high school years but rather in their attitudes toward technological careers like engineering [8, 17]. By the latter middle school years, girls start underestimating their own technical abilities and begin to place more importance on being popular rather than academic performance [18, 19]. During high school they enroll in fewer mathematics and science courses, and thus lack the background needed to enroll in college STEM programs [17]. Early intervention is needed to address this problem because once students, particularly females, reach college it is too late to prepare [8, 9, 20]. Although there is much debate about the effectiveness of single-gender education [21, 22], all female enrichment programs like FEMME can be particularly effective in reaching young girls, influencing their attitudes before they reach high school [23, 24].

II. Background

Initially single-gender education was for affluent students, mostly boys, but by the 1970's educators began exploring better educational options for girls in response to the emerging "Gender Gap" between the academic achievement of boys and girls [25]. Considerable research can be found describing the many benefits of single-gender education for girls, suggesting such things as girls' increased confidence, being more likely to ask questions, and maintaining behaviors that tend to disappear due to male dominance in the classroom [26]. Studies of classroom behavior in co-educational classrooms also document teachers' differential treatment of boys and girls, for example, being more tolerant of boys' disruptive behavior and encouraging boys to solve problems on their own while helping girls who experience trouble [22, 27-28], further suggesting the benefits of single gender education.

In contrast, more recent reviews of the literature summarizing the investigations of single-gender education caution that much of the research is not rigorous and scientifically based, including a focus on private and Catholic schools where subjects are basically self selected [25] and provide no strong conclusions supporting or dismissing the overall benefits [29]. Researchers have begun to recommend that there should be a clear rationale with specific goals for single-gender education [30-32]. Summer enrichment programs like FEMME, designed with the goal to increase the number of women interested in engineering and other technological careers in an atmosphere free from male dominance are consistent with this recommendation and prior evaluations of the FEMME program have been positive [16].

A. Success of the FEMME Program

Although the initial evaluations of the FEMME program were primarily formative in nature [33] results were positive. Follow-up studies of program participants who had completed high school found that almost 70% reported they were either currently enrolled in a technology based degree program or had chosen a career path in STEM [32].

More rigorous evaluations of the FEMME program [34-36] used the Middle School Attitude toward STEM survey [12]. The MASTEM has been revised to have six subscales; Interest in engineering: stereotypic aspects (Stereotypic), Interest in engineering: non-stereotypic aspects (Nonstereotypic), Negative opinions about STEM (Negative), Positive opinions about STEM (Positive), Self Efficacy for Problem Solving and Technical Skills (Self), and Gender Equity (Gender).

Girls participating in FEMME programs have been found to have significantly more positive attitudes toward STEM, particularly engineering, and significantly more knowledge of engineering careers compared to other students (both male and female) from similar backgrounds [35, 37]. Many young girls who attend a FEMME program return for multiple summers and results of pre-post attitude evaluations using the MASTEM have shown the girls' more strongly agreed with the notion that "girls are just as good as boys in the areas of mathematics and science" and disagreed more strongly that "boys are better at engineering than girls" after attending one of the FEMME programs.

B. Single Gender Programs for Boys

More recent single-gender research focused on boys suggests that the climate in all-male classrooms is much different than all-female classrooms [26, 38]; increased use of technology, more opportunities for physical activity and the presence of male role models is beneficial for the boys' learning [39-40]. But is the single-gender atmosphere or the altering of the classroom structure (e.g. using more active lessons to teach the same curriculum) responsible for the benefits?

Offering mixed gender programs and all-female programs meant that approximately 70% of the students accepted into summer enrichment programs at the Center for Pre-College Programs were female. This and a marked increase in applications from 4th and 5th grade boys prompted the addition of two all-male programs during the summer of 2012. The programs were identical to FEMME 4: Environmental Science and Engineering and FEMME5: Aeronautical Engineering and the equivalent 4th and 5th grade mixed-gender programs. Each of the programs accepted 23 to 25 students such that across all six programs there were 141 students. A semi-qualitative and objective evaluation was planned to examine differences in classroom climate, changes in students' attitudes toward STEM, increases in content knowledge and changes in students' perceptions of what engineers actually do. Students completed the MASTEM, separate grade-appropriate content knowledge tests of engineering, mathematics, computer technology and communications and the Draw an Engineer Test at the beginning and the end of the program.

C. The Draw an Engineer Test

The Draw an Engineer Test (DAET) [41], which has been adapted from the Draw a Scientist Test [42], was developed as a tool to more fully evaluate young students perceptions of who engineers are and what they actually do [43-44]. Students are asked to draw a picture of an engineer at work and provide a short sentence to describe what the engineer in the picture is doing. A checklist has been developed to quantify the appearance (gender, color, etc.) and location of the engineers in the picture, as well as to summarize other objects and/or people in the picture and inferences of action [45]. Previous research has found that purely quantitative measures derived from surveys such as the MASTEM are not always sufficient to capture cognitive changes in students' perceptions about engineers and a more qualitative measure such as the DAET can be more informative [36, 46].

The mathematics, science and engineering classes for both post 4^{th} grade single-gender programs (male and female) were taught by the same teacher as were both the post 5^{th} grade single-gender programs. Although the mixed gender programs were taught by a different teacher, the curriculum (lessons, activities, field trips, etc) was exactly the same. Field trips were attended altogether, chaperoned by all teachers. Other classes such as computer lab and communications were taught by different teachers within each subject, i.e. in computer labs all students in all programs were taught by the same teacher. No changes in teaching were made to accommodate either gender. All of the teachers had taught either the all-female or mixed gender programs previously and as such were familiar with the curriculum.

III. RESULTS

Teachers were interviewed to collect qualitative information about possible differences in classroom climate and student behavior among the three types of classes; single-gender male, single-gender female and mixed genders. The mixed-gender classes were approximately 42% female and 58% male. Although there were 141 students enrolled across the six programs (three gender groupings across two grades), only 134 completed both the pre and post measures.

Three-factor repeated measures analysis of variance techniques were used to test for changes in students attitudes toward STEM and increases in students' content knowledge as measured by the MASTEM and program specific content knowledge tests which included mathematics, engineering, computers and communication. Two between subject factors, gender and type of class (single-gender vs. mixed gender) and one within subject factor (time from beginning to the end of the program) were used to test for differential effects due to gender or type of class.

The extensive scoring protocol and analyses required for all aspects of the Draw an Engineer Test have not been completed to date and as such are not included in the current paper but, aspects related to the gender of the engineer in the picture have been completed and relevant analyses follow.

A. Classroom Climate

The teacher who taught both of the two single-gender post 4^{th} grade classes described the girls in the FEMME program as cooperative and communicative with much less physical activity than in the all-male group. The boys were much more active and less cooperative, requiring more discipline and suggestions to stay on task than the girls. This teacher had taught for the mixed gender and FEMME program during previous summers and reported the cooperation during group activities and other classroom behaviors to be very different than those experienced during mixed gender programs.

The teacher who taught both of the single-gender post 5^{th} grade classes described the girls in the FEMME program as much more task-oriented and less competitive than the boys in the all-male group. The girls' solutions to problems were not necessarily better than the boys', nor did they appear to complete tasks more quickly than the boys. The teacher just described the girls as more serious and very focused. The girls were much less competitive and more willing to share and help each other than the boys. This teacher had also taught for the mixed gender and FEMME program for several years and agreed that the classroom atmosphere in each of the single gender programs was very different than in the mixed gender groups. In the mixed-gender programs the girls tended to focus more on the task rather than interacting with the other girls and boys, where as in all-female groups, even though the girls remained focused, they interacted more with other members of the group. The girls appeared to have distanced themselves somewhat during group activities in mixed gender groups.

"Comparing notes" about identical classroom lessons or activities with the teachers who taught the mixed gender programs suggested less personal interaction during group work in mixed gender groups and a lower level of class participation from girls in the mixed-gender programs.

B. Content Knowledge

All students in each of the six programs showed significant and substantial increases in all areas of content knowledge from the beginning to the end of their respective programs. Within the single-gender and the mixed-gender programs there were no significant differences between the content knowledge scores for the males and females nor where there any differences between scores among the single-gender and mixed gender programs. All students, male and female performed equally well in all programs. See Table I for a summary of mean responses.

C. Attitudes toward STEM

In general no significant changes were found in students' attitudes toward STEM in terms of Interest in engineering: (stereotypic and nonstereotypic), Negative opinions of STEM; Positive opinions of STEM; or Gender equity. See Table 1 for a summary of mean responses. Although this might seems disappointing it is not surprising, the students' attitudes toward STEM were already very positive before beginning the programs as is typical of students who attend enrichment programs [36, 46]. But significant differences were found in Self Efficacy.

For both the male and female students in the single-gender programs the mean Self-Efficacy scores increased significantly from the beginning to the end of the program ($p<.01$, see ** in Table I). And for both males and female students in the mixed-gender programs the mean Self-Efficacy scores decreased, $p<.05$, see * in Table I).

TABLE I
MEANS AND STANDARD DEVIATIONS FOR THE ATTITUDES TOWARD STEM SCALE AND SUBSCALES AND CONTENT KNOWLEGDE TESTS

CONTENT KNOWLEDGE			Beginning Mean (SD)	End Mean (SD)
Engineering				
	Single gender:	Males	51.4 (13)	89.8 (11)
		Females	53.1 (15)	90.7 (10)
	Mixed gender:	Males	58.0 (11)	92.5 (5)
		Females	52.5 (14)	91.8 (6)
Communications				
	Single gender:	Males	65.0 (13)	78.3 (15)

	Single gender:	Males	3.7 (.9)	3.9 (.9)
		Females	3.6 (.8)	3.6 (.8)
	Mixed gender:	Males	3.3 (.7)	3.5 (.7)
		Females	3.0 (1.0)	3.2 (.9)
Gender				
	Single gender:	Males	4.1 (.9)	4.1 (.9)
		Females	4.3 (.6)	4.3 (.7)
	Mixed gender:	Males	4.0 (.8)	4.0 (.9)
		Females	4.1 (.9)	4.2 (.9)
Self Efficacy				
	Single gender:	*Males*	*3.8 (.8)*	*4.1 (.7)***
		Females	*3.7 (.7)*	*3.9 (.6)***
	Mixed gender:	*Males*	*3.7 (.7)*	*3.6 (.6)**
		Females	*3.8 (.8)*	*3.6 (.7)**

[a] Subscale items are phrased negatively, so a lower mean is desirable.

These results coupled with the differences in classroom climate and communication suggest that although single-gender programs such as these may not always significantly increase learning of content knowledge they appear to have a significant positive effect on self-efficacy, which is important.

D. *Preceptions of Engineers through Drawings*

Previous research using the Draw an Engineer Test has found the DAET to be a useful tool in more fully exploring young students' perceptions of engineers, what they believe engineers actually do, and how their perceptions may have changed as a result of attending a summer enrichment program at NJIT [36, 46].

Students' drawings of Engineers at Work are summarized using the DAET checklist [45]. The checklist begins with an examination of the engineer to check the species (i.e. Human?), actual presence, gender, skin color, and other attributes, like glasses, lab coats, crazy hair or other clothes. Then the location of the engineer (inside, outside, in space, underwater) is coded and there is a list of inferred actions that can be indicated, like fixing vs. designing, or teaching, or even NO action can be indicated. The types of other objects in the drawing are also coded, for instance, the presence of other people, animals, symbols that would indicate math or chemistry, airplanes, computers, car, trains, signs of thinking, etc. The wearing of a hat has been added to the attributes, "signs of communicating with others" has been added to the list of actions and more specific details about the species and gender of the engineer are also being explored to more fully understand students' perceptions and how they change.

For the current paper the characteristics of the engineer including gender were examined in relation to students' gender and type of program, all-male, all female, or mixed-gender. The physical characteristics of the engineer were examined for signs of gender including long hair, the wearing of a dress, facial hair, name badges, etc and verbiage in the sentence describing what the engineer is doing was checked for the use of He, She, it or "the engineer". Often the engineer students draw, particularly before attending the programs, is a stick figure with no gender or a mechanic\worker with only legs protruding out from under a rocket or car. When a stick figure, androgynous person or partly hidden person is described as "it", "my engineer" or "the engineer" in the sentence then the gender of the engineer is coded as unknown.

All students' beginning and ending drawings were examined and the engineer was coded as Male, Female or Unknown. Table II is a summary of how many engineers were coded as male, female or unknown for the single-gender male programs, the single-gender female programs and the mixed-gender programs with the responses from the male and female students in the mixed gender programs listed separately. None of the male students in either the single-gender or mixed gender programs drew female engineers at the beginning or the end of the program. Only about one third of the female students in the mixed-gender programs drew female engineers at both the beginning and the end of the program. At the beginning of the all-female program, about 25% of the girls drew a female engineer and at the end of the program over 50% of them drew a female engineer.

TABLE II
SUMMARY OF GENDER ATTRIBUTIONS FROM THE DRAW AN ENGINEER TEST

Engineer's gender is.......	Male	Female	Unknown
Single gender males			
Beginning	32	0	16
End	31	0	17
Mixed gender males			
Beginning	11	0	17
End	12	0	16
Mixed gender females			
Beginning	7	6	6
End	1	5	13
Single gender females			
Beginning	12	12	21
End	7	26	13

IV. DISSCUSSION

Overall, the results suggest that although there were no significant differences in the learning of content knowledge or changes in students' attitudes toward STEM among the single-gender and mixed gender programs, there were significant differences in self-efficacy. Both the male and female students in the single-gender programs showed significant increases in self-efficacy while students in the mixed-gender programs showed decreases in self-efficacy. Increased self-efficacy is important for continued learning and persistence when learning becomes more complex or students have difficulty.

Further, only girls in the all-female program changed their image of an engineer from a male or a person of unknown gender to a female. This seems to contradict the fact that there was no change in the girls' average response to the gender equity items on the MASTEM. And although the girls' average responses to the gender equity items were slightly higher than for the boys there were no significant differences between the boys and girls or among the different types of programs. For example, girls' did not disagree more strongly with the statement "Boys are better at being engineers than girls" at the end of the program than they did at the beginning, nor did they respond much differently than the boys overall.

Increased self-efficacy and an increase in girls' perceptions that women can be engineers suggest that there are benefits to single-gender programs for both male and female students, although boys' images of engineers should include females. Future male-only programs should address this problem.

Insignificant changes in students' attitudes toward STEM, like those found in the current study using the MASTEM have been found before with high-achieving students such as those who attend enrichment programs [35-36, 46]. Results from the current study further support the suggestion that more qualitative measures like the Draw an Engineer Test are better measures of changes in students' cognitions and\or perceptions as a result of enrichment programs than more objective types of measures like the MASTEM which are typically used to evaluate new programs or changes in curriculum.

Continued coding and analyses of the other attributes of the students' drawings of engineers will further examine students' perceptions of engineers and attempt to quantify relationships between scores from the MASTEM and summary statistics from the DAET checklist. For example, a relationship does not appear to exist between the Gender equity items on the MASTEM and the gender of the engineers in the drawings although one was expected.

Further analyses will examine correlations among other attributes of students' drawing and individual items on the MASTEM like "engineers spend lots of time working on computers," or "Engineering has nothing to do with real life."

***Abstract*—The ACM/IEEE-Computer Society CS2013 Computer Science Curricula task force is working to update the previous curricular guidelines published in 2008 and 2001. The CS2013 guidelines are scheduled to be published in the latter half of 2013. This special session is devoted to exploring the guidelines with an emphasis on migrating current curricula to curricula aligned with the new guidelines. A number of significant changes from the 2008 and 2001 guidelines have been made, including the addition of new knowledge areas (including Parallel and Distributed Computing and Security and Information Assurance) as well as the reorganization and refactoring of previous areas to create a Systems Fundamentals area and a Software Development Fundamentals area. These changes are intended to identify significant changes in the computing field over the past decade, look forward to future changes, provide greater flexibility in the design and implementation of Computer Science curricula, provide stronger guidance with respect to student outcomes, and provide diverse examples of fielded curricula.**

Keywords-computer science education, computing, curricula, CS2013.

I. INTRODUCTION

For the past 40 years, ACM/IEEE-CS Computing Curricula volumes [1][2][3] have helped to set international curricular guidelines for undergraduate programs in computing. The next complete curricular volume in the series is targeted for publication in 2013. The goal of this session is to continue the lively and engaging discussions with the computer science education community and other stakeholders about the ongoing work of the ACM/IEEE-Computer Society CS2013 Computer Science Curricula project. Since the CS2013 guidelines will be in the final stages of editing, the session will focus on the changes from previous guidelines and how programs can migrate existing curricula to curricula aligned with the CS2013 guidelines.

The development of guidelines for Computer Science is challenging due to rapid changes, expanding diversity in the computing fields, the integration of computing with other disciplines, and the need to balance the growth in possible topics and the need to keep recommendations implementable in the context of undergraduate education.

Building on the principles articulated in the CC2001 and CS2008 reports, the Steering Committee established the following principles to guide its work. A complete statement of these principles can be found on the project website at http://www.cs2013.org.

- CS2013 will identify the essential skills and knowledge that should be required of all graduates of Computer Science programs.
- CS is a rapidly changing field, drawing from and contributing to many disciplines, and requires undergraduate programs to prepare students for lifelong learning.
- CS2013 serves many constituents, including faculty, students, administrators, curricula developers, and industry.
- The curricular guidelines must be relevant to a wide variety of institution types including large and small, research and teaching, public and private, 4-year and 2-year schools. The guidelines will be used internationally as well as in the US.
- CS2013 will provide guidance regarding the level of mastery for topics and show exemplars of fielded courses covering the topics in the curricular body of knowledge.
- The curricular guidelines will provide realistic, adoptable recommendations that support novel curricular designs and attract the full range of talent to the field.
- CS2013 will include professional practice (e.g. communication skills, teamwork, ethics) as components of an undergraduate experience.

II. CS2013 BODY OF KNOWLEDGE

The Ironman draft of CS2013, available in spring of 2013, focuses primarily on updating the Body of Knowledge in computer science, organized around 18 Knowledge Areas, outlined below:

- Algorithms and Complexity (AL)
- Architecture and Organization (AR)
- Computational Science (CN)
- Discrete Structures (DS)
- Graphics and Visual Computing (GV)
- Human-Computer Interaction (HC)
- Information Assurance and Security (IAS)
- Information Management (IM)

This work has been sponsored by the IEEE Computer Society and the ACM Education Board.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

- Intelligent Systems (IS)
- Networking and Communications (NC)
- Operating Systems (OS)
- Platform-Based Development (PBD)
- Parallel and Distributed Computing (PD)
- Programming Languages (PL)
- Software Development Fundamentals (SDF)
- Software Engineering (SE)
- System Fundamentals (SF)
- Social Issues and Professional Practice (SP)

III. Summary of Changes from CC2001 to CS2013

A. *Other curricular volumes*

It was recognized during the creation of CC2001 that computing had expanded into a family of disciplines. In addition to Computer Science, the ACM and IEEE Computer Society have now published curricular guidelines for Computer Engineering in 2004 [5], Information Technology in 2008 [6], Software Engineering in 2004 [7], and Information Science in 2010 [8].

B. *Reorganization of volumes*

Two substantial reorganizations in the Body of Knowledge for Computer Science include introductory programming and systems. In the area now called Software Development Fundamentals (previously called Programming Fundamentals), we have extracted fundamental software development concepts, including topics in algorithms, design, programming, and software development processes. In systems, we have identified common themes among operating systems, networking, and computer architecture that are captured in a new area called Systems Fundamentals. Additionally, specific developments in the field in the past decade (such as the pervasiveness of parallel computing and the need for better understanding computer security) have given rise to the development of knowledge areas in Parallel and Distributed Computing, Information Assurance and Security, and Platform-Based Development.

C. *Core Tier 1, Core Tier 2, and Elective*

Earlier curricular guidelines had only "Core" and "Elective" with every core topic being required. However, many strong computer-science curricula were missing at least one hour of core material. It is misleading to suggest that such curricula are outside the definition of an undergraduate degree in computer science. Further, as the field has grown, there is ever-increasing pressure to both grow the core and to allow students to specialize in areas of interest. This is simply not possible in the context of an undergraduate degree, particularly from those programs where expanding the degree requirements is not possible.

CS2013 provides greater flexibility on coverage of core topics by identifying Core Tier 1, Core Tier 2, and Elective topics. Core Tier 1 topics are fundamental to the structure of every computer science program. A curriculum should include all of these topics and ensure that all students cover this material. A curriculum should include all or almost all topics in the Tier-2 core and ensure that all students cover the vast majority of this material. By retaining a smaller Core Tier-1 of required material, we provide additional guidance and structure for curriculum designers. In the Core Tier-1 are the topics that are fundamental to the structure of any computer-science program.

A curriculum must also include significant elective material: Covering only "Core" topics is insufficient for a complete curriculum. This enables curricula and students to specialize if they choose to do so.

D. *Levels of Mastery and Outcomes*

Previous volumes listed topics for inclusion in curricula. In CS2013, we provide additional advice on the level of mastery programs should achieve for core topics. There are three levels of mastery, defined as:

Familiarity: The student understands what a concept is or what it means. This level of mastery concerns a basic awareness of a concept as opposed to expecting real facility with its application. It provides an answer to the question "What do you know about this?"

Usage: The student is able to use a concept in a concrete way. Using a concept may include, for example, appropriately using a specific concept in a program, use of a particular proof technique, or performing a particular analysis. It provides an answer to the question "What do you know how to do?"

Assessment: The student is able to consider a concept from multiple viewpoints and/or justify the selection of a particular approach to solve a problem. This level of mastery implies more than using a concept; it involves the ability to select an appropriate approach from understood alternatives. It provides an answer to the question "Why would you do that?"

E. *Exemplars instead of stylized courses*

CS2001 took on the significant challenge of providing descriptions of stylized courses incorporating the knowledge units defined in that report. While this was a valiant effort, it was felt in retrospect that such course guidance did not have much impact on actual course design. As a result, CS2013 takes a different approach: identifying existing successful courses and curricula as fielded exemplars of how relevant knowledge units can be addressed in actual programs. This bears similarity to the report by CRA-E [4], although that report focused on preparing students for research careers. CS2013 includes examples of actual fielded courses—from a variety of universities and colleges—to illustrate how topics in the Knowledge Areas may be covered and combined in diverse ways. Importantly, we believe that the collection of such exemplar courses and curricula provides a tremendous opportunity for further community involvement in the development of the CS2013 volume.

F. *Changes in the Body of Knowledge*

As should be expected for a maturing field, the body of knowledge for CS2013 has a great deal of overlap with previous volumes; but it also has significant changes, as should be expected for a vibrant and dynamic field. These changes include:

- The topics related to systems and networking have been substantially reorganized to recognize the fundamental principles common among operating systems, networking, and distributed systems.
- Similarly, foundational topics related to software development have been reorganized to produce a more coherent grouping and encourage curricular flexibility.
- Digital logic and numerical methods are not emphasized. A fundamental coverage of digital logic can be found in Systems Fundamentals, but more advanced coverage is considered to be the domain of computer engineering and electrical engineering.
- Numerical methods are elective material in the CN knowledge area and are treated as a topic geared towards a more selected group of students entering into computational sciences.
- There is expanded emphasis on Parallel and Distributed Computing.
- There is a significant new emphasis on Security, Privacy, and Reliability.
- There is no distinguished emphasis on building web pages or search engine use. We assume that students entering undergraduate study in this decade are familiar with internet search, email, and social networking, an assumption that was not universally true in 2001.
- The Programming Languages core in CC2001 had a significant emphasis on language translation. The CS2013 core material in PL is more focused on language paradigms and tradeoffs, rather than implementation. The implementation content is elective.
- The Social Issues and Professional Practice (SP) knowledge area has changed to great degree, particularly with respect to modern issues.

IV. Description of the Special Session

The goal of this panel is not simply to provide an update on the state of CS 2013, but to actively engage the community in work that will eventually manifest in the migration of computer science curricula to meeting the expectations described in the Guidelines. Holding this panel at FIE is an important step in further engendering that engagement in a broad forum.

The desired outcomes of the session include

- Increased awareness of the CS 2013 curricular guidelines among the computer science community;
- Increased understanding of the changes between CS2013 and previous versions of the guidelines;
- Action plans for the revision of curricula at participant institutions.
- Understanding of mapping individual course syllabi to CS2013 knowledge areas

The session will start with a brief overview of CS2013 and model curricula and exemplars. Participants will then break out into small groups based on their areas of interest to review sections of the Guidelines with an emphasis on migrating curricula to meet the CS2013 recommendations. Members of the Steering Committee will facilitate these discussions.

***Abstract* — *The Portuguese-speaking countries are home to more than 240 million people located across the globe but having cultural similarities and a shared history. The CPLP (Community of Portuguese Language Countries) nations have a combined area of about 10,742,000 square kilometers (4,148,000 sq. mi), which is larger than Canada. The proposal of this paper is to show and discuss with some details how engineering education is developed in countries of Portuguese languages due to the peculiarities in the historic development of the countries.*

***Keywords* — *Bologna process; policy makers; public school; polytechnic schools; university schools.*

I. Introduction

The discussions about engineering education in different geographical parts of the world are of great importance. This is a way to promote and increase awareness of contemporary engineering education efforts and, simultaneously, to explore the views of young people, teachers, engineering lecturers and policy makers from other parts of the world. The organization of such panel Engineering Education in Countries of Portuguese Languages is important to bring teachers, researchers and engineering lecturers together to discuss and think over the different ways engineers are formed. It will contribute for the development of innovative engineering curriculum in order to increase the numbers of young people entering engineering courses.

Hereafter we present texts about education in the countries with the objective of briefly informing about how education has developed in countries separated by the sea but sharing common cultural roots, the issues faced by countries and the perspectives for the future.

The real discussions will be developed during the panel session that counts with high level lecturers, very well informed and involved with engineering education in their respective countries. They will bring updated information and the framework adopted to defeat the present obstacles and demands in order to face the 21st century's educational crisis. A number of questions about the systems of present are expected to be raised, mainly the ones related to the Bologna Process in Europe, as it is reshaping higher education in the member countries. Regarding the Portuguese ex-colonies countries, the education has still without any doubt a lot of Portuguese education style mixed with new world people and natives.

II. Portugal: History and Nation

Portugal is one of the oldest nation states in Europe: its foundation in 1139 predates that of its neighbor, Spain, by nearly 350 years. The Romans who arrived in 216 BC called the whole Peninsula Hispania, but the region between the Douro and Tagus rivers was called Lusitania after the Celt Iberian tribe who lived there. When the Roman Empire collapsed in the 5th century, Hispania was overrun first by Germanic tribes, then by Moors from North Africa in 711. Military reconquest by the Christian kingdoms of the north began in earnest in the 11th century and it was during this long process that Portucale, a small country of the kingdom of León and Castille, was declared independent by its first king, Afonso Henriques. It is a sophisticated society present in many parts of the globe, helping to shape the world's civilization. Let us point out some facts brought by Martin Page in his book:

Portuguese Jesuits lived in Japan for generations before our ancestors were aware of the introduction of words in the Japanese language, e.g. "irrigate" which means "thank you." They brought the recipe for tempura. They introduced the technique for manufacturing weapons. The Portuguese also taught the Japanese how to construct buildings to withstand earthquakes and artillery attacks. The pepper plant was brought to India allowing "curry" to be invented.

Portuguese is the third most spoken language in Europe (English, Spanish and Portuguese) even before French and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

German. It is the language of cattle ranchers in Northern California and fishing communities along the coast of New England. With over 210 million native speakers, Portuguese is the fifth most spoken language in the world..

III. Antecedents of Engineering Education in Portugal

Until the nineteen seventies, the following aspects characterized technical teaching in Portugal:

- Exclusive State responsibility, that centralized, funded and defined course programs;
- Weak specialization in technical university courses, with a strong common training component verified in all courses;
- Reduced dimension and concentration of Engineering Schools, which only existed in Lisbon and Porto;
- Dichotomy teaching, based on a hierarchical and exclusive model (since it defined who could be and who could not be an engineer) and by the fact that its output resulted in an inverted labor force pyramid.

New engineering university courses were established in Coimbra, Braga, Aveiro, Lisbon and a few other places from 1972 onwards.

In 1986, a binary separation of the higher educational system was established in Portugal, through the Education's System Basic Law, which integrated higher education engineering institutes into polytechnic teaching in 1988.

In 1988, the Law concerning University Autonomy was also approved. Through this Law, universities were defined as centers for the creation of culture, science and technology transmission and diffusion, which, through their expression of study, teaching and research, enabled them to perform their role in society.

The evaluation of the science and technology system, carried out in 1996 and 1999, confirmed the need to promote connections between research centers, civil society and companies, as well as the need to promote scientific cooperation at the level of national and international mobility [1].

IV. Some Remarks about the Bologna Process

When analyzing engineering education today in Portugal, (and in Europe) the Bologna process must be mentioned. It is likely to be a unique chance for Europe to modernize its higher education, according to the same principles, with a perspective of reaching a new level of understanding and readability. It has touched off an impressive set of reforms. Nevertheless it must be admitted that the Bologna process may give rise to various criticisms:

- It implicitly links itself to a singular model of higher education (following the same rationale and being directed by the same values);
- It has been designed without considering the reality of the job market (top-down policy);
- It seems to have taken its inspiration from the North American model, which could provide a certain guarantee, but appears indeed to be following a very different path.

For these reasons, which should inform an open and critical debate, the application of the Bologna principle should remain very pragmatic and open to other dimensions, such as:

- The importance of having a limited number of universities in a position to be competitive at the world level;
- The importance of placing some universities, with credible expertise and know-how, in some fields – the so-called technological clusters;
- The importance of keeping a high level of flexibility and response, to launch new types of programs [2].

V. Higher Education in East Timor

As a new nation, East Timor is working to develop in several sectors and the education sector has been identified as a top priority by the government of the Democratic Republic of East Timor.

Of the 14 institutes listed, only Universitas Nasional Timor Lorosa'e (UNATIL) is a government university. UNATIL has been receiving 70% of its funding from the government; professors are paid by the government as civil servants. The institution has also received educational infrastructure and other material support to rehabilitate the campus, and for chairs, desks and library facilities from East Timor's government, as well as from other countries including Portugal (Agriculture and Teacher Training), Australia (Economics and Social Sciences), the United States (building reconstruction) and Japan (Technology).

Many private higher education institutions have been opened, in general with the same goals of enabling high school graduates to continue their education and developing East Timor's human resources. The first goal is probably already met. During the UNTAET transitional period, East Timor already had two universities, UNATIL and UNDIL, but they did not have space for all the high school graduates seeking higher education and the students who had their studies interrupted in 1999. UNATIL evolved from Universitas Timor Timur (UNTIM), the public university under the Indonesian occupation. That university was destroyed in 1999 by the Indonesian military and militia violence, and most of the professors, who were Indonesian, left East Timor. Under UNTAET, it was rebuilt and renamed UNATIL, which has become a public university under the now-independent government.

The Higher Institute of Economics and Management (Instituto Superior de Economia e Gestão, ISEG), a private higher education institution focusing on economics, was formed in 1998. Under UNTAET this institute used existing facilities in Balide, Dili. After independence, ISEG evolved into a full university and became UNDIL [3].

VI. About Education in Brazil

Brazil's Higher Education has a history of success that has been facing some problems of both social and financial order. It starts with the creation of Public Universities in the many states of the country, which have worked very well for many years; the Country has achieved and has built a solid reputation even abroad also creating generations of Brazilian scientists and educators. In that aspect, there is still a long road to travel, involving three agents: the State, that has to generate and to apply public politics of science and technology, besides funding them; the University, which responsibility is to form qualified personnel and to create basic science; and the Industry, that should invest in technology creation, besides accomplishing applied research, to incorporate qualified personnel and, therefore, to win competitiveness.

With the creation of Public Universities in many states of the country, which have worked very well for many years, the country has achieved and has built a solid reputation even abroad also creating generations of Brazilian scientists and educators [4]. Despite all problems, professionals and educators of every field of science and technology have been discussing the destiny of education in the country, taking into account the historical moment of the world. Certainly some of these discussions have generated some practical actions at governmental level as a response to the society that considers itself as the most interested party in the issue. In Brazil, the situation is very delicate for engineering and technological fields. Although the proliferation of private universities all over the country expanded the number of 3rd grade students, it does not assure the increase of students in engineering and technology areas.

VII. The Role of Engineering in Science and Technology in Brazil

Brazil is five hundred years old with a history of races meeting towards the construction of a peoples' identity marked by diversity and cultural richness. Five hundred years which bring the challenge of starting this new millennium building up a new Brazil, a Country where quality of life in daily basis is a concept of its 166.113.000 inhabitants and not only of a minority. Considering the present history of humanity, the importance of engineering and engineers in the development of science and technology is noticeable, they have shaped a new social world order having as a straight consequence the new life style and therefore a new way of thinking.

Recognizing the importance of engineering in the world scenery, Brazil has been working to get the competitiveness of national goods and services by means of incentive to create projects of qualification of professionals through continuing education, for example, and others. Many representative groups, leaderships and agencies have been implementing programs to prepare engineers to increase the efficiency of research system, experimental development, engineering, producing system and market [5].

All these efforts have been having a kind of smooth effect once it is one of the most difficult and also expensive programs of College level, which does not help considerably the inclusion policy. However some Colleges have opted for a softer engineering program offering them in the evening. These programs are lighter and more focused in technical knowledge and less focused in basic sciences. The students in general work all day and choose engineering programs because it is a way to be promoted at work. A third degree diploma opens some doors, it means not only the possibility of earning more money but also of reaching an upper status, socially speaking. It is a fact that, even being a lighter program for the students, it is very hard and in general it takes them more than five years to finish it. The diploma has the same value of a program that prepares engineers of conception. In a certain way, it helps the inclusion policy of education although the number of engineers has been decreasing considerably in the last 10 years [6].

VIII. Final Remarks

It is important to point out the fact that engineering is now of the interest of countries and governments, so engineering education is also of great interest. It is important to know more about the development of policies and actions in different countries, in order to understand the global educational demands. The search for changing to train the professional engineer for the present labor markets as well as the search for the best system in all the countries is clear now.

It is possible to notice that even with the colonization process in Portuguese speaking countries, due to the several other sources of influence because of the immigration waves, the fight for excellence is an ongoing process with peculiar aspects. It is clear that even nowadays, the importance of a language as identity is very high and so is the way it reflects on education.

The knowledge about these countries' engineering education systems will contribute for the reflection about engineering education in a larger spectrum not only centered in west north hemisphere regions of the world. Moreover this overview is a glimpse of education in some corners of the world that can contribute for the global perspective of higher education that is, now more than ever, important for the development of programs such as Engineering Programs.

STEM Literacy and Textbook Biases in K-12

Gisele Ragusa, Ph.D.
Division of Engineering Education
University of Southern California
Viterbi School of Engineering
Los Angeles, CA.
ragusa@usc.edu

Abstract— **Textbooks are a common source of science information in K-12 science education. Science literacy is a major challenge of students in K-12 and this dramatically affects students' achievement. Biases in textbooks negatively influence students' interest and achievement in science and engineering.**

This study explores types of biases in K-12 science texts. These biases primarily relate to gender, race and ethnicity. Textbook biases negatively affect students' views of science as a field, as a career and as a college major. Achievement may also be affected by such biases. Accordingly, this research study explores the biases in K-12 science textbooks. The textbooks were analyzed using a multidimensional rubric and accompanying scoring checklist. Results of these analyses revealed dramatic biases in textbooks particularly for early elementary and high school texts. Both print and photographic biases were noted in the textbooks. In particular, the books that focused on biological sciences were found to contain significant biases especially related to gender. These biases may influence how students feel about careers in science, technology, engineering and mathematics (STEM) areas and therefore may impact future workforces in STEM fields.

Keywords—science literacy; achievement in K-12; science textbooks.

I. INTRODUCTION

Engineers and scientist utilize the principles and theories of science and mathematics to design, test, and manufacture products that are important to the future of our nation and the world.[1] The percentage of college students seeking degrees in math, science and engineering disciplines has been declining for the past two decades. This is in part because fewer potential science, technology, engineering, and mathematics (STEM) majors are completing rigorous college preparatory programs that would enable them to be accepted in undergraduate engineering programs after high school.[2] The number of people from racial and ethnic minority groups and women are especially sparsely represented in science and engineering fields. This shortfall has raised concerns among leaders in STEM fields regarding future STEM workforces.[3]

To meet the changing demands of the nation's science and engineering labor force, recognition of the importance of pre-college education and implementation of challenging curricula that captures and sustains students' interest and addresses their academic achievement in science and engineering is critical. Textbooks are a primary source of scientific information in K-12 science education. Science literacy is a major challenge of students in K-12 and this profoundly impacts students' achievement. Biases in textbooks negatively influence students' interest and achievement in science. This is of particular concern for women and underrepresented minority groups. When students are not represented positively and equitably in books, they are less interest in engaging with them and this limited engagement in turn leads to poor reading achievement.[5] This is of particular concern in subject areas where content is challenging because difficult subjects require deep engagement with vocabulary and comprehension to fully understand the content. Essentially, if students are "turned off" by texts, they will disengage and learning will be compromised. This could be devastating for K-12 learners.

Content area literacy is particularly difficult for learners whose primary language is not English. The United States has the greatest number of minority students in the country whose primary language is not English (over 1.5 million, 25% of total school population). Ironically, these students are often most underrepresented in photos and graphics in K-12 science textbooks. Under No Child Left Behind[6] schools must ensure that English learners (ELs) show significant yearly progress in developing English skills as well as meeting grade level standards in all academic content areas. According to the latest report card on the implementation of NCLB, schools are falling far short of meeting the academic needs of their English Learners.[7] These students struggle to develop the cognitive academic language proficiency (CALP) necessary to comprehend content-area textbooks particularly in science. Chall, Jacobs, and Baldwin[8] note that the breakdown in academic achievement in STEM content areas as particularly significant. Content-area texts contain a large number of content-specific vocabulary words and concepts that are beyond the students' English language abilities. Students need to be taught how to read content-area texts as well as to develop the academic language and discourse associated with each content area, particularly as they proceed through cognitively demanding curricula such as science. As such, if students are disengaged because they see that texts do not represent them equitably, their engagement and most importantly their achievement may suffer.[5] In other words, textbook biases effect both engagement and achievement as it relates to literacy.

II. Review of current research

A. Textbook Bias in General

Importantly, textbook bias is not a new area of research persay, as it has been studied for the past two decades. Unfortunately, much of this research has been conducted in early childhood education and has not addressed the scientific disciplines.[9,10] Within studies of bias, research that investigates the presence of bias in textbooks focuses primarily on gender bias. Several scholars have undertaken a quantitative approach of analyzing the content of textbooks. Such studies provide a foundation for similar research, yet they are different from the present study, which has as its purpose to specifically identify the biases in science textbooks that may interfere with students' science interest and ultimately, their achievement in STEM disciplines.

B. Textbook Biases in Various Disciplines

Various researchers have studied textbook biases disciplinarily. Peterson and Kroner[11] investigated the presence of gender bias in psychology and human development in university textbooks. These researchers developed two coding schemas to categorize the types of biases that they observed in the texts in their study; one that was used to analyze introductory psychology texts and the other that was used to analyze human development texts. The authors' research goals were to (a) develop a measurement tool for evaluating gender bias in textbooks, (b) to determine how much change had occurred since the American Psychological Association's guidelines for non-bias text had been issued, and (c) to evaluate the current level of equity of gender representation in texts. The researchers found gross inequity in gender representation in the textbooks that they analyzed. Women were often portrayed as "passive participants" rather than "active agents" in the texts. Peterson and Kroner also suggest several useful guidelines for creating more inclusive texts derived from a careful review of photos and character description in the texts. Similarly, Campbell and Schram[12] reviewed psychology and social science texts for gender bias. They searched for examples of "nonsexist" language and "profeminist" language. Using both qualitative and quantitative analyses, Campbell and Schram[12] found results similar to Peterson and Kroner[11] illustrating that the reviewed texts included sexist language.

C. Textbook Biases in Science Texts

Garcia[13] undertook one of only a handful studies that focused on racial bias in texts. He analyzed high school science texts for the presence of a "Hispanic perspective." While the research is useful as it is one of the first studies to focus on Latina/o representation in science textbooks, the study is quite dated.

In a more recent and somewhat related study, Ndura[14] investigated cultural bias in high school textbooks for the potential impact on English learners. Ndura analyzed texts by focusing on three important themes: (1) stereotyping, (2) invisibility, and (3) non-reality. Ndura argued that both teachers and students needed to be trained to analyze textbooks utilizing a critical lens as a means for addressing bias in classroom.[14] As such, with this recommendation, even when stereotyping or invisibility occurs, students are able to dialogue about the problems in texts that they are reading, thus addressing biases head on, while making connections to larger social issues of biases. This study prescribed an intervention associated with confronting biases in texts in addition to an analysis of texts that may be applied in diverse K-12 settings.

Wilkinson[15] undertook a quantitative analysis of physics textbooks for the emphasis on specific components of science literacy. The textbooks he analyzed were chosen from a twenty-year publication timeframe. Wilkinson wished to understand what particular content was emphasized in physics texts within four themes that had been previously used in other science text analyses: (a) knowledge of science, (b) the investigative nature of science, (c) science as a way of thinking, and (d) the interaction between science, technology, and society. Wilkinson adapted an instrument for his analyses that was previously designed to uncover text biases in other areas. The instrument utilized a checklist, which described the four themes. He found that all four thematic areas within the physics textbooks contained biases.

Eide and Heikkinen[16] investigated the inclusion of multicultural material in middle school science teachers' resource texts. Noting that teacher resource texts (often referred to as teachers' editions) are highly used instructional resources, the authors analyzed the extent of multicultural content in twenty-one teachers' editions of middle school science texts. The authors did not focus on illustrations and images in their analyses. Rather, they designed a systematic arrangement for classifying units of communication from the printed material in the texts and transformed the print quantitatively by assigning numeric codes to categories of content within text. They found that multicultural content was present in only small amounts in middle school teachers' editions. This finding led Eide and Heikkinen[16] to recommend additional inclusion of this important material in the science resource texts. They posited that it would be very difficult for teachers to teach multiculturally using their resource books given the sparse representation of this content.

Similarly, Delgato[17] reviewed biology textbooks for the presence of multicultural science educational material. Delgato[17] assessed the portrayal of minority groups, in both image and text, with an emphasis on "indigenous people" and "indigenous knowledge." The results of this study indicate that

This research is supported by the National Science Foundation and CA. Department of Education

minority groups were often portrayed as undereducated. Delgato[17] recognized a stark need for text rewrite in his study as the vocabulary presented in the texts that was examined were from dominant groups and not often representing the perspectives of indigenous groups.

As described in the review of the research above, significant gaps in the literature on textbook biases have been identified. The bulk of research on textbook bias utilized content analysis to uncover and empirically categorize instances of bias. Checklists and unsystematic analyses dominate this literature. Few studies have explored texts across broad grade levels with the intention of recognizing trends in textbook biases. Additionally, multidimensional rubrics have not been used to systematically and empirically analyze features of bias in texts. Such instruments are useful because they have potential to make results of bias analyses accessible for teachers, students, and parents who are interested in recognizing and addressing biases similarly as was described as an intervention by Ndura.[14] Additionally, biases discussed in contemporary research most commonly identified gender at the exclusion of other types of biases including race, class, and sexual orientation. Accordingly, further analyses of textbooks must include attention to other groups that have been traditionally affected by bias in society and in education.

III. Research design and approach

The present study attempts to address some of the gaps in the research described above with particular attention to multiple types of biases in K-12 science textbooks across grade levels. Potential biases of focus in this study include gender, race and ethnicity in science texts in addition to socio-political biases. Each of these biases can negatively impact students' views of science as a field, as a career and as a college major. Accordingly, these biases have potential to limit options for future scientists and engineers. Additionally, as previously described, K-12 students' achievement may be impacted by such biases, so the need for their identification and alleviation is rather urgent. As such, the purpose of the present study is to identify the types and to determine the prevalence of biases in science textbooks across K-12 grade levels. Therefore, this study answers two important research questions:

- What are the nature and prevalence of biases in science textbooks in K-12 education?
- What types of text biases are present in the science disciplines and at what grade levels are they most prevalent?

The study employs anti-bias theory as a framework for the text analysis. Anti-bias theory builds upon the work of Ndura,[14] Derman-Sparks and Hohensee,[10] (described above) utilizing an activist approach in which one challenges prejudice or biases, links these biases to societal challenges, and proposes change for societal improvement. In this paper, an attempt is first made to identify the type and prevalence of textbook bias and then to propose recommendations for changes in practice to address the biases utilizing an anti-bias approach similar to that which is described in Ndura's research.

A. Instrumentation

This study employed a multidimensional scoring rubric with a checklist addressing each rubric dimension (listed below). The rubric facilitates both a granular and holistic investigation of science textbook bias. The rubric includes four important dimensions that are aligned with anti-bias theory:

- Visual content bias: Visual content is important as science texts contain many visual images that are either photographic or graphic. These images can be analyzed for how underrepresented groups are presented or misrepresented.
- Written content bias: Written content bias refers to the way underrepresented groups are described or depicted in writing. Word choice and written language use is a necessary part of this bias dimension.
- Author's perspective bias: This bias dimension refers the author's hidden message he/she is sending via the text.
- Omission as bias: The omission as bias dimension refers to when particular groups are omitted from texts as an means of exclusion of representation.

The multi-dimensional rubric is structured such that on one half of the rubric there is an element checklist aligned with the four dimensions of bias (described above) and on the second half there is a holistic scoring schema (using a 4-point scale). The four-point scoring schema utilizes a continuum to determine the "level" or prevalence of bias in each of the four analytical dimensions. Inclusion criteria with examples for each of the four points on the continuum are included in the textbook scoring rubric as a guide for determining where the particular element of bias is best represented in terms of "level."

B. Instrument Validation

Group calibration techniques were used to determine the rubric's construct and content validity in addition to its internal consistence.[18] As an initial rubric calibration procedure (recommended by Mark Wilson[18] for sound measurement and in particular item response theory; IRT) , raters were provided with examples of textbook bias that fit into the different dimensions and bias levels (1-4) and were asked to rate each example using the rubric independently. They were then asked to share their ratings and build consensus in their results as a means of calibrating the rubric. Examples were then rescored after discussion of the initial individual example ratings, and once an accurate and acceptable calibration (~ .5 standard deviations from the mean) with the example biases was reached, the criteria on each dimension and level of the rubric was adjusted in accordance with the raters' calibration.

C. Data analyses

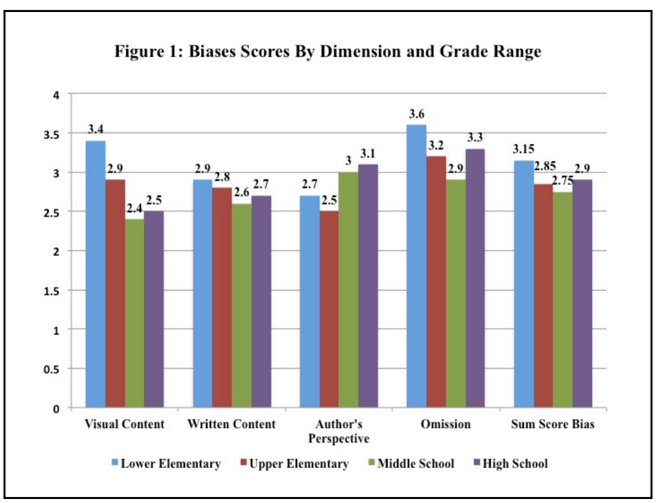
All textbook data (print, visual elements, etc.) was analyzed according to the four dimensions of the multi-dimensional scoring rubric (described above). Notes were taken on each on the rubric related to the dimensions for each analyzed text and these notes were categorized in accordance with the four dimensions to provide rationale for scoring on the rubric. In turn, the checklist portion of the rubric was used only to determine the existence of a particular type of bias within the four dimensions for which notes could be taken and categorized, thus forming evidence for scoring the text on each bias element in accordance with the rubric criteria.

D. Textbook Selection

A total of forty-three science textbooks were analyzed for this study. Approximately 20% of the texts were used in elementary school (grades K-5) , 20% were used in middle school (grades 6-8) and the remaining 60% of the texts were high school texts. The textbooks were chosen from a broad selection of science textbooks commonly used in three of the largest school districts in the western United States. Importantly, the greatest number of the analyzed books were high school texts because of the diverse subject areas within high school science. These included various advanced placement (AP) and honors science course textbooks.

IV. Study Results

Each of the forty-three analyzed texts were found to have biases in each of the four dimensions of the multi-dimensional scoring rubric to a lesser or greater degree. Figure 1 illustrates the distribution scores of the texts by rubric dimension and categorized by grade range. The ranges are divided as lower elementary (grades K-3), upper elementary (grades 4-5), middle school (grades 6-8) and high school (grades 9-12) to illustrate the range and prevalence of text biases.



The results of these analyses are interesting and diverse. The lower elementary texts had the greatest bias noted overall (M=3.15, SD=.79) followed by the high school texts (M=2.9, SD=1.01). In terms of the greatest bias prevalence, the dimension with greatest noted bias was that of omission of a traditionally underrepresented group, (M=3.25, SD=.91), although there was definitely a broad distribution across the four dimension of the rubric. These descriptive findings indicate that much work needs to be done to equitably and accurately represent historically underrepresented students in science majors and careers in K-12 textbooks.

That which is not fully represented in the numeric values in the bias scores is the hidden messages behind the bias dimensions in the analyzed texts. Accordingly, examples of these biases are provided herein. The omission dimension is not possible to fully depict in this paper because omission, by definition refers to a group "not present" in the analyzed text. Omission typically was represented by underrepresentation of people of color and or women as scientists or engineers in the textbooks that were analyzed. Additionally, when inventors were discussed in the texts, historically underrepresented groups were omitted. To determine authors' perspective in K-12 informational texts, it was important to review the backgrounds (educational and otherwise) of each of the contributing authors and editors and then to determine where and in what ways in the text that these backgrounds influenced the textbook message choices. This was somewhat different than that which is often found in a fictional text where authors' voice is often overt.

Photos and illustrations (the visual dimension) were quite marked with biases in the science texts across grade ranges and science subject areas. These were especially prevalent in the life science, biology and physiology texts that were part of the study, where the study of human life and organisms were presented. However, even in non-life science type texts, bias was present in visual images within the textbook. Figure 2 (below) illustrates such bias.

In this photo, (Figure 2), one would note that only males were featured in this photo of a scientific experiment in progress. Not only are only men depicted in the photo (above), the photo does not represent any ethnic diversity. While at first glance one might think that this visual depiction the norm in the scientific world, if the desire is to "change the face" of science nationally and world-wide, one must not only be to sensitive to the hidden messages sent by textbook photos, one must also make deliberate efforts to diversify scientific images in texts in order to positively influence diversity in future science workforces.

Words in science textbooks often have as many hidden messages and meanings as visual images. They can present scientific history in a highly biased manner. This has most recently been portrayed in the following ways. A science textbook may feature a glossy pullout of female scientist, however include precious little text-based narrative of the scientific contributions of women. As an example of this, the following quote was uncovered during analysis of a middle school science text in the study: "Businessmen are now looking for entrepreneurial thinkers that can take the place of the traditions of the American scientist." The word "men" in the first phrase of the sentence sets the stage for a gender-biased text excerpt. Indeed not all business people are males. Secondarily, the statement is American-centric, as it refers to the traditions of American scientists, thus potentially setting up omission of contributions of non-American scientists.

While some may view these two examples as singular, these types of biases have been found via the present study to dominate K-12 science textbooks. Putting an end to such biases may contribute to building an anti-bias framework in K-12 STEM, thereby increasing equity is science fields long term.

IV: Discussion and Future Directions

This research represents a starting point for exploring and ultimately ending both the negative influence of science text bias on academic achievement and decreased interest in science for girls and other underrepresented minority groups. The textbook biases present across the K-12 lifespan are quite alarming. This is especially evident in visual images and in the life science related subject areas. The finding that the greatest amount of bias was found in early elementary level textbooks is quite alarming because the message sent by informational texts to young children could have lasting adverse effects on the choices that they make career-wise. Additionally, this could affect our world's most vulnerable children's interest and motivation to read science texts, which could ultimately negatively impact their science literacy and achievement. This can inform the future of science and engineering fields.

To carry this research forward, future research should be conducted in which K-12 learners are interviewed as to their thoughts about representation and biases in science texts. Teachers should also become a part of such research to determine the impact that these texts have on teacher instruction and associated biases. Once these interviews are conducted, students and teachers from diverse groups should engage in exercises that explore the relationship of such biases to societal issues in broad scientific and engineering contexts. Solutions for ending such biases could be posed by K-12 learners, thereby providing content and context for anti-bias curricular reform in K-12 STEM education.

Additionally, research should be conducted that explores the relationship between textbook biases and science achievement longitudinally in students who have been historically underrepresented in the science fields. Finally, interventions should be developed in K-12 science classrooms in which students themselves analyze their texts for biases and use these identified biases as a means for activist projects that focus on confronting and changing biases in STEM fields. In that way these biases can be called out, discussed, and processed by those who may be most affect by them. Change can start on the grassroots level with the future of STEM workforces at the helm of curricular change.

Acknowledgments

The author wishes to thank the National Science Foundation and the California Department of Education for funding to support this study and the classroom teachers who provided their current textbook titles for my acquisition of texts to analyze ffor this research.

jskardon@csumb.edu

***Abstract*—United States renewable energy businesses require well trained high school and college students to fill key positions as technicians, engineers, and other high paying jobs. Project based learning programs offer a way to train students in these emerging fields with realistic, intensive student-designed and built projects. This paper reviews the challenges and some of the lessons learned in developing a four year high school curriculum in renewable energy and clean technology. A primary challenge in developing this kind of program is the time and complexity of gathering relevant technical material in this field and adapting it for high school students. Related to this challenge is the selection of projects that the students pursue. We've learned that these two challenges require a content area expert and substantial technical support to insure that student design projects are age and skill appropriate, safe for the class, but also keep students engaged. One key learning from this program has been the successful introduction of novel, table-top scale "minisystems" that emulate full scale projects such as electric vehicles. These minisystems are also low-cost enough so that a typical class can to assign one minisystem to a two person team. The renewable energy focus also enables the discussion of key environmental and economic challenges. Student designed and built thermal storage units mimic residential-scale systems. Energy arbitrage, the differential in peak and low demand prices for electricity, helps the students understand why and when these systems can be economical to operate. Other projects in biofuels also facilitate discussion about the sustainability of using food or other renewable natural resources for energy. Each course contains six to eight projects. Projects topics are developed through an interactive brainstorming session including leading teachers in the State and representatives from prominent local industry. The project topics are further refined to focus on a key problem area. This curriculum is currently in the pilot phase at numerous high schools in the Southeast.**

Keywords: renewable energy, energy efficiency, clean technology, fuel cells, thermal storage, biogas, biomass, water efficiency

I. INTRODUCTION

Advanced Careers™ is a multi-state initiative created by the Southern Regional Education Board (SREB) to create a new high school curriculum that prepares students for entry into the workplace and into science, technology, and mathematics intensive college programs. This program is a direct descendent of Project Lead the Way (PLTW) but deviates from PLTW in several important ways. This paper reports from a curriculum development and deployment perspective how science, mathematics, and literacy are embedded in a project and problem based curricula that is focused on a specific application area- clean energy. Examples of projects are used to illustrate challenges and opportunities in curriculum development, teaching, and standards implementation. While AC is a new program, its predecessor is studied for clues about how AC might succeed in the education marketplace. Suggestions and next steps for improving project based learning are included.

Advanced Careers™ is targeted at the unique skill requirements of specific states . Currently more than ten states are actively developing AC curricula- each targeting the needs of a specific industry or application area. This chapter focuses on the development of one of those states: a four year curriculum targeting clean energy technology (CET), a key area of investment and job growth in the state of South Carolina. As the lead curriculum writer for this program in South Carolina since its inception in 2010, I bring a perspective on STEM curriculum development that is both current and still evolving, but narrowly based on a single field of application.

For readers not familiar with PLTW or project based learning, SREB's Advanced Careers program is attempting to do for career/technical training what Advanced Placement courses have done for academics. The AC program focuses heavily on creating intellectually demanding, industry relevant coursework coupled with extensive hands-on application of the technical skills taught in each AC course of study.

II. OVERVIEW OF THE PROGRAM

The AC curricula for Clean Energy Technology is a four year program of study. The first year of CET focuses primarily on introducing students to fundamental science, physics, and engineering concepts within the context of existing clean energy challenges. The second year program applies these concepts to more challenging projects. Each of the projects introduces students to one element of renewable energy, fuels, or energy storage. A brief introduction to nuclear energy and physics is discussed, but within the context of nuclear batteries, the primary power source for satellites. The third year program advances the education bar a bit further by adding more complex math, software programming, and science content. The fourth and final year is focused on original student research, a problem-based learning paradigm, in one of several pre-selected categories under the general aegis of CET. While

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

local industry and government participation is used in the first two years, the final two years rely heavily on the direct involvement of local industry, government, and nonprofits as direct advisors and consultants to the student project teams.

Embedded within the project format are State Common Core standards for math, literacy, and science. Curriculum and content development for each project is subjected to intensive review in the three core standard areas and also subject to overall "go/no go" approval. Common core, twenty-first century, and state level standards taught in the projects are documented at the beginning of each project. The exact frameworks employed, internal methodologies, and method of implementation is outside the scope of this writing.

Within each year long course, the unit of study is a single, hands-on project. A typical course may have 6-8 projects, with each project consuming 20-30 educational periods. Most of the work in each project is team-based while a smaller portion of class time is spent in individual learning. The scenarios that initiate each project describe the problem or challenge Students must will then follow either a "Science as Inquiry" or "Science as Technological Design" process- the two key process oriented components of the current national science standards. In general, inquiry-based science projects are introduced "gently" in the first two years and become more challenging in the latter two years of study to align with the student's expected progress in the math courses offered by the school.

Ensuring the authenticity of projects developed by States and their curriculum writers is an area of concern in the AC program. SREB uses research from the work of Newman and Secada at the University of Wisconsin to critique the individual projects [1]. The SREB multi-disciplinary project editing team provides detailed feedback to curriculum developers on each project prior. Projects must pass an SREB review prior to being taught at the high school.

The AC program departs sharply from previous programs such as PLTW in several areas. While hands-on projects are a requirement, the socio-environmental impacts of science and engineering are integrated into the projects. For example, a project on bio-diesel also incorporates several known economic externalities associated with converting food crops into motor fuel. Students explore the conflicting claims in the ongoing "food vs. fuel" debate. This kind of student engagement also helps develop critical thinking and writing skills.

Secondly, the projects are open-ended. This allows the student teams to investigate different methods and materials of assembly. No two classes studying Course 1 for example will produce exactly the same final product. A typical first year project requires the student teams to build a 10 to 40 watt solar panel from polysilicon solar cells and basic construction materials. Solar panel assembly is rife with potential problems, driven heavily by the need to physically mount and electrically interconnect the brittle silicon solar cells. Circuit design basics like Kirchoff's laws are taught in a just-in-time (JIT) method to teach students how to interconnect the solar cells to achieve a desired voltage or current output. Students may produce very different sized solar panels in each class and employ a wide variety of mounting and assembly materials.

Finally, the projects are evolving over time as students and teachers gain more familiarity with the diverse materials, sensors, electronics, and science concepts used in the projects. Students found in the previous solar panel project through trial and error how to use non-conducting conformal coatings to protect the backside of the solar cells and to make the solar panels more light-weight and lower cost. This has lowered the cost of the projects, and lead instructors to incorporate other ideas and other directions. In another project, an air-to-air geothermal heating and cooling system using a low cost Styrofoam cooler was initially developed by one of our teachers. The project has since evolved to a liquid-air system by using low-cost personal computer cooling pumps and heat exchangers.

The role of economics in driving technology choices is taught throughout the program. Technology choice such as fuel cells versus biomass as an alternative energy source is driven by more considerations than simple comparisons of overnight costs or operating costs. Throughout the projects, opportunity costs are integrated into the projects.

One second year project begins with the students studying a combined solar pump/storage drip irrigation system developed in equatorial Africa for small land-holders [2]. Student teams are challenged to identify ways to improve this system. The teams use commercially available energy modeling software called HOMER™ to model the system's performance. HOMER allows students to configure and compare many different implementations. One of the first questions students face is: why not use a diesel powered generator, rather than solar to power the pump? Through investigation and research, students learn that diesel supply in the more rural parts of equatorial Africa is spotty at best, and fuel prices are often inflated by middle-men to a level that small farmers simply cannot afford. HOMER allows the students to iterate on the cost of fuel so that the levelized cost of electricity (LCOE) between a diesel-fueled system and solar system is at breakeven. This breakeven price of diesel is the point of departure for adding the cost and complexity of energy storage systems and other technologies needed to assure availability of electrical power in a remote off-grid setting.

One of the most radical departures from existing science education is the project and problem based methodology. AC uses much of the pedagogy from the Buck Institute's research and practice on project and problem based learning[1]. Teachers become facilitators rather than instructors, aided by external experts from industry and government that volunteer their time to assist in the projects. Students are the "doers", performing the vast majority of the work, while teachers advise and monitor the student team's progress. The absence of "row-seat" instruction and well-developed texts suitable for high school students presents some major challenges for content developers and conceptual challenges for teachers. Just-in-time instruction that is context specific, such as the by-products and economics of bio-diesel production, must be developed and presented in a way that enable teachers to quickly grasp the essential elements but also transfer much of the learning onto the students. This requires content specialists or experts to

[1] The Buck Institute for Education

train a cadre of teachers in advance and to insure the content is both industry relevant but also contains enough science and math content to warrant inclusion into the project.

Overall, the AC program attempts to integrate multiple standards into a multi-year curriculum that is framed by the key job skills that industry expects from state high school and college graduates. The focus is project and problem based- putting the student in a role of directly of much of the learning. The program is pedagogically rigorous, with State Common Core math, literacy, and science standards embedded throughout each project. Cross-cutting concepts such as creative thinking and entrepreneurship are used to help students develop more depth in their understanding of the industry challenges. By allowing states to develop their own area of focus, clean energy technology in the case of South Carolina, SREB is essentially creating a large catalog of contemporary industry-relevant curricula.

III. History and Lineage of The advanced Careers program

Advanced Careers draws upon many excellent and well managed programs for its inspiration. As an example, AC includes Project Lead the Way (PLTW) as one of it's predecessors. PLTW was developed in the New York State school system. The initial goal of the PLTW program was to increase enrollment in STEM college programs in New York [3]. PLTW is currently the premier pre-college engineering program in the United States with more 400,000 students [4]. The widespread adoption (all 50 states have some PLTW adoption) suggests that the program fits well within the existing public education system in the United States.

IV. Key Facets of Project Based Clean Technology Curriculum

One of the most radical departures from existing science education is the project and problem based methodology [5]. Teachers become facilitators rather than instructors, aided by external experts from industry and government that volunteer their time to assist in the projects. Students are the "doers", performing the vast majority of the work, while teachers advise and monitor the student team's progress. The absence of "row-seat" instruction and well-developed texts suitable for high school students presents some major challenges for content developers and conceptual challenges for teachers.

Technical, safety, scale, and cost challenges abound with this strategy. Creative solutions are needed to keep the cost of the projects within reach of a majority of high schools while not sacrificing realism and relevance. Building and erecting a functional wind turbine with a six foot rotor might be realistic but presents many challenges . An alternative to this approach developed in this program was to focus on table top system from KidWind as the learning platform. The bulk of the project has the students focusing on optimizing turbine blade design while learning the science and engineering principles that derive from the blade design

The wind energy project (blade design) project is much more than simply cutting wood or plastic and mounting to a table top wind turbine assembly. The competitive nature of the project, where 2 person teams attempt to design the most efficient blade, requires a metric and also creates a measurement problem. Tip speed ratio (TSR), a key figure of merit for blade designs, requires calculation of angular velocity of the tip of the rotor.

Calculation of the angular velocity requires knowledge of the rotational speed of the shaft. At this point, we ask the student's to recall earlier training in motors and generators to determine how to measure the shaft speed by examining the voltage output of the turbine. A three pole generator will produce 3 voltage peaks per revolution. Students employ National Instruments LabVIEW™- an industry standard data acquisition hardware and software system, to measure the motor's output and calculate the frequency. From the frequency, students can then complete the task of calculating the angular velocity and TSR.

In a simple task like blade design, a project-based learning exercise can employ all three dimensions of the next generation science standards: science and engineering practices, cross-cutting concepts, and disciplinary core ideas. Within science practices, students collect and analyze the data in the frequency domain and use this data and their knowledge of trigonometry and geometry to calculate a key figure of merit for turbine blade. Cross cutting concepts include the use of energy flows to explain why there is a limit to the amount of energy that a turbine blade may extract from a moving air mass, formally known as the Betz limit. Finally, the core disciplinary ideas include elements from physical sciences (why moving air causes the turbine to spin), earth and space sciences (what causes the wind), engineering/technology and application of science.

Some of the simplest sounding projects can enable teaching of a wide variety of science topics. An essential concept within career and technical training is heat transfer: conduction, radiation, and convection. We found that the design and testing of a passive solar collector is a great way to teach all three components in a single project. The context of the project is a challenge to develop a low-cost, passive solar hot water heater for the developing and underdeveloped world. By shrinking the size of the student built collectors to approximately one foot square, we could use a low-cost thousand watt halogen lamp to simulate the sun. Halogen lamps have a different frequency distribution than solar energy but it is close enough for most basic laboratory work. Students experiment with coatings and materials optimize heat gain in passive collector.

Utility grade renewable energy projects that students often hear about in the news require careful analysis and site planning to optimize energy production and to maximize return on investment. Extensive simulation and modeling is performed before these projects ever break ground. The projects in the CET curriculum leverage many of the same commercial-grade simulation, analytical and web-based data collection software used by utilities, consultants, and contractors. The software and web-based applications dramatically extend the reach of teachers and hide much of the underlying complexity.

Students might be asked to determine whether solar or wind is a good solution to drive an energy storage requirement. A JIT-based module on wind introduces the students to the underlying factors that create the diurnal variation in wind speed. Students are directed to, or must find on their own, one of many websites that allows access to hourly wind speed data. To apply the theory, students can download the wind speed hourly data and then create a simple plot of wind speed by hour. Geography lessons abound, as a comparison of different sites can illustrate why wind driven energy storage might be better suited one location rather than another, or might have a strong seasonal component. Rather than lecture students about why wind energy cannot be used everywhere, students can employ critical thinking skills to answer open-ended questions. Through dialog, peer-review and feedback, students can deduce pretty quickly why some locations are better suited for wind.

A software program mentioned earlier, HOMER™, can be used in a similar way. HOMER can import detailed climate data for many areas of the world. Internally, the program will calculate solar insolation and average wind speeds by hour and month. Students can then use the program's simulation features to develop their load profile and specify the configuration of the renewable energy equipment used. HOMER will then simulate operation of the student-designed system to calculate the levelized cost of electricity. By closely examining the graphs created by HOMER, students can tailor energy storage and load profiles minimize the cost of electricity produced.

Opportunities for cross-cutting learning exist in this project also. Developing a solar irrigation system near the equator can create many challenges. Students may start their investigation with a standard load profile- electricity is needed from 9AM to 4pm to power irrigation pumps. It's a pretty a simple task to then configure a pump and solar panel to provide this electricity. However, simulations will show errors; that not enough electricity is available. Students can dig into the monthly insolation graphs but will find that twice a year, the solar insolation is only at 10% of the level needed to power the pump. As students investigate this more deeply, they learn that this part of the world experiences two monsoon seasons per year. Obviously during the monsoon, there is no need to irrigate. But more importantly, this kind of exercise shows that simplistic assumption such as a standard daily load profile, leads to over-design and inefficient solutions.

One challenge faced in this type of project-based curriculum development is what I call the "mini-macro" problem. Clean energy projects rely on scale, among other things, to achieve financial support. Electric vehicles (EV) are an example of this problem. EVs are a key embodiment of clean technology with a simple electric motor drivetrain and battery energy source. Depending on the application of the EV, a fuel cell may be more appropriate than batteries as an energy source. Batteries have an advantage of maintaining their output voltage over much of the discharge cycle while fuel cell output can very dramatically with load. Most simulation and analytical software available for students in this area is targeted at undergraduate and mostly graduate level automotive engineering programs. How then, can we introduce electric vehicles, drive trains, and fuel cells to 9th and 10th graders in meaningful way so that twelve two-person teams in a typical class can each have their own EV and vehicle test bed?

SREB along with its industrial partner National Instruments created and implemented a concept called the "mini-system" to address this type of challenge (cite SREB website). The mini-system is a low-cost engineered electro-mechanical system that enables student exploration of a specific topic. In this EV project, the industrial partner (National Instruments) developed a dynamometer on a printed circuit board approximately six by ten inches. Mounted on top of the dynamometer, is a remote controlled hobby car. Via the software user interface customized for this mini-system, students can adjust the load on the car and throttle position to simulate driving conditions. Measurement points on the PCB enable students to monitor the input voltage and current to the RC car. The car is powered by 4.5volt battery pack or a commercial miniature PEM fuel cell. The PEM fuel cell is powered through an electrolysis unit.

At first glance, this system is very under-whelming and appears to be more of a toy than an engineering system for exploring electric vehicles. Over several months we developed a project that leverages the mini-system's features to provide the students with a unique challenge. The clean energy project requires students to "drive the car", by adjusting the load and throttle, over a specific route. The goal is to reach the final destination without running out of battery charge or overloading the fuel cells. Since fuel cells can be refueled in minutes with the addition of hydrogen, the time penalty is very short. Battery recharging, though, can take hours. Students are given different routes and distances to allow them conceptual room to explore a longer, flatter route in lieu of a shorter, hillier route. Students calculate distance travelled by measuring the dynamometer rotational speed at each throttle setting. Then, a single measurement of the diameter of the dynamometer roller and the R/C car wheel diameter enables the students to calculate virtual distance travelled at any throttle and load setting.

But this project goes much further. The fuel cell manufacturer provided us with hydrogen consumption data for the fuel cells and also information about the electrolysis unit. With this knowledge, we can lead the students through a discussion and calculation of the efficiency of the hydrogen powered car concept. This leads into more complex discussion and exploration of the so-called "well to wheels" or life-cycle assessment of the transport system. By extension, one can easily lead this discussion to a key limitation of current proton exchange membrane fuel cells- the cost of generating hydrogen and storage of the hydrogen.

Within a single mini-system, we can develop projects with a wide range technical and conceptual difficulty. If these units are purchased for course 2 initially, they can be reused for courses 3 and 4. Because the mini-systems have the vast majority of their features implemented in software, this enables a software developer to make many refinements and improvements to the student and instructor user interface. But the capabilities of leveraging LabVIEW for this application extend much further.

LabVIEW, for the uninitiated, has what can only be inadequately described as a comprehensive and extensive set of built-in measurement, communications, analysis, graphical, computational, and system features. Building a software application on a LabVIEW platform allows developers to use more college/professional level techniques such as fast Fourier transforms (FFTs) implemented in software to calculate the rotational speed of the previously mentioned dynamometer by simply measuring the generator's voltage output. The built-in functions within the software provide the conversion of time based voltage data to the frequency domain. Thus, the user interface (UI) hides this calculation from the student, allowing the instructor to focus on the science and math dimensions of the project.

Limitations of this approach for academia are similar to those found in industry. LabVIEW requires training and practice for proficiency. Data acquisition boards and modules have finite limits on current, voltage, and the number of channels. Distributed measurement systems using wireless technology, which would be a huge benefit for high school programs, is still quite expensive per measurement point. All of these challenges will be overcome at some point in the near future.

While min-systems are suitable for several projects, implementation for others proves problematic at this stage in the program's development. Previously, I mentioned a project involving solar drip irrigation in Africa. There were numerous ideas and a few attempts to develop a mini-system for a growing environment: complete with sun, computer controlled irrigation, and integral soil moisture sensing. Conceptually this approach was quite attractive as the small volume of soil used, about one cup, would enable rapid wetting and drying. This "fast cycle time" would allow the students to accelerate the time base of the projects- not currently feasible with conventional agriculture. However, this approach created a large set of additional problems. Abandoning this approach, we next explored using small integrated indoor greenhouses, about the size of a small bookshelf, so that students could grow real plants. The time requirement for the students to generate meaningful data was beyond the time allowed for the projects.

The current solution to the challenge of simulating a real growing environment in a rapidly compressed time frame was a hybrid solution. Rather than using plant growth as the primary measurement, we focused in on the widespread problem of soil moisture variation. Many farms around the world plan their irrigation needs based on evapo-transpiration (ETo) models. Formally, if one knows the sunlight, the type of soil, the crop, and temperature, the amount of irrigation needed to wet the soil to the specific root zone depth can be calculated. However, ETo models may lead to major swings in soil moisture both above and below what is needed. Soil moisture sensors can be used to augment ETo calculations. Since pumps are used to provide irrigation water, over irrigation leads to higher power consumption and costs. But more broadly, ground water fed irrigation systems that employ ETo can also cause over draughts of the underlying aquifers. This problem, originally centered in Africa to start the project, then takes on a more regional and global importance.

To implement this irrigation project within a narrow time frame, we made several changes. First, we used a simple five gallon bucket filled with commercial topsoil (depth is important) as our field. Next we used our halogen lamp under computer control to simulate sunlight. We purchased a state of the art, blade-type capacitive soil moisture sensor to monitor water in the soil in real time. To simulate the pumping/storage of water, we used a five gallon bucket suspended about 2-3 feet above our "field". The bucket was mounted with a spigot and computer controlled valve. From the valve, quarter inch commercial drip irrigation tubing conveyed water to the soil. A conventional adjustable dripper was used to release water into the soil. Students monitor the volume of water released into the "the field" by measuring the change in the volume of water in the bucket.

We then structured a competition among the student teams to develop a software algorithm to maintain the soil moisture within a close tolerance. Points are awarded to teams based on the least amount of water used and lowest variation in soil moisture at a specific depth. The challenge for the students in this project is managing the interaction between the type of soil, the rate at which water is applied, and the response time of the sensor. Instructors can add stochastic variation to the project by altering the timing and amount of sunlight, adding or modifying the soil depth, or even allowing the students to explore concepts such as no-till planting.

A key component of renewable energy and fuels is the role of biology and more specifically molecular biology and genomics. Integration of engineering concepts with biology is probably a challenge for most teachers, as well as curriculum developers. One bio-project that has gained favor with instructors and students uses a so-called "dirt battery" to generate a small amount of electricity. Like the earlier project that began with drip irrigation in Africa, this project begins with the need to develop the simplest possible form of electricity to power an LED lamp in a rural, underdeveloped country.

We purchased a commercially "dirt battery" and had the students collect "muck" from around the various streams and rivers near a school. The students then add the mud to the device, insert the electrodes and wait. Within 5-7 days, the LED mounted in the top of dirt battery began blinking – an indication that a small electric current was charging a capacitor. During the wait time, students spend several class periods learning about microbial fuel cells.

One clever instructor extended this concept in a different direction. He and his students had several of the dirt batteries operational. He then posed to the students the question of fuel: what do the bacteria consume? Students figured out that sugar might be a good thing to add to the mud. After adding sugar to one of the dirt batteries, the LED indicator began blinking much faster than the rest.

This prior observation about the blinking LED leads inductively to the question: where does the electricity originate? The answer for AP biology students would be obvious- the cell's electron transport system. But this concept is well beyond existing 9th and 10th graders. However, we don't stop the learning because the material is not grade-appropriate. The key concept in biological systems of this sort is the effect of temperature on reaction rate. Analysis of the Arrhenius equation can provide the classic treatment but is taught in upper division classes. For course 1 and 2 students, this relationship can be shown graphically or using a JIT lecture. Observationally, the students can deduce that an increase in the temperature should result in a faster reaction rate.

In the dirt battery example, students learned that rate of electron transport can be visualized with the blinking LED. The faster the LED switches on and off, the faster the rate of electron flow in the biological system. In one high school, first year students put the dirt battery in a student-built temperature controlled water bath (crock pot plus low cost computer controlled power switch) and then began to log the number of "blinks" at a steadily increasing temperature. Sure enough, a graphical relationship between temperature and reaction rate emerged that supported the prediction from the Arrhenius equation.

Finally, a key facet in the design of a project is the use of student engagement scenario at the beginning of the project. To get the students to engage quickly, we've used a combination of real job and environmental problems. In some projects, we introduce the students to startup companies as examples of what can be done in this field. Entrepreneurship coupled with science-based project learning is proving to be an effective way to gain student interest. In other projects, we may put the student in the role of a technician that has been asked to solve an ongoing business or technical problem. In others, students are entering a regional or national entrepreneurship competition such as the Department of Energy's Solar Decathalon.

V. SUMMARY

Overall, the AC program is employing many cutting edge concepts to drive science literacy and attract more students into STEM disciplines. The program does leverage many of the competencies and infrastructure developed for PLTW but takes a very different approach toward learning. The support of industry partners, local business, content experts, and compelling projects enable the teachers to take the role guide and advisor and allow more student-driven learning.

As of this writing (June, 2013), the Advanced Careers program is in the roll-out stage. A number of states have begun fielding their curriculum at select schools. Data collection and detailed observations about the program are currently limited to feedback from teachers and a small cohort of students. However, both AC and PLTW share a common pedagogy- project and problem based learning. Much of the PLTW infrastructure is being leveraged to launch the AC program. The implementations between the two programs within the projects are very different but the previous experiences of PLTW may hint at the challenges ahead for AC.

VI. ACKNOWLEDGEMENTS

I would like to acknowledge the generous support from the State of South Carolina that funded the work discussed in this paper and especially the management and leadership team at SREB for their guidance and on-going training. I would also like to specifically thank Dr. B.T. Martin and Ms. Joan Anderson from the South Carolina Department of Education and Dr. Gene Bottoms of the Southern Region Education Board for his valuable comments and encouragement. Many thanks to the pilot teachers in South Carolina, Mr. Tom White, Mr. Richard Blais, and the staff at National Instruments for their collaboration and assistance. Any opinions, mistakes or errors in this work are mine alone.

Abstract— **Science, Technology, Engineering and Mathematics (STEM) education is slowly becoming an important part of American culture. STEM educators try to promote 'hands on' science, where students can actually interact with and see the results of their work. Unfortunately, not all paths of education for STEM related fields can have exciting, interactive teaching methods. At the Millard Oakley STEM Center, we have taken advantage of the interactive experience in our planetarium show. In this paper, we take an in-depth look at the Definiti Theater System and the software that runs it, Digital Sky 2. This software package is created by Sky-Skan and is considered to be the standard for many new planetariums across the country and beyond. We take the software in new directions by building new elements through the Sky-Skan scripting engine and by also exploring its 3D engine for creating a novel experience. The primary purpose of this paper is to provide a roadmap of observations and enhancements for other educators that wish to improve the learning experience of students and visitors to their planetarium.**

Keywords—STEM, education, planetarium, Digital Sky 2, 3D

I. INTRODUCTION

The goal of STEM education centers is to engage students of all ages enough so that they will find an interest in a STEM career path. The scientists, engineers, and mathematicians of tomorrow are hidden among the children of today. Any moment of a child's life could be that special moment that shapes who they will become. To try to capture the minds and interests of students, STEM programs employ a hands-on technique to their offered programs [1]. This approach sets a STEM program apart from other programs. Instead of students simply learning about the laws of physics, they will learn about them as well as build a rocket with which they experience physics in action. They can then compare and talk about their results, and what they observed and experienced.

It is in this area where programs like astronomy shows tend to fail. As the very name implies, it is a "show". Regardless of how knowledgeable or enthusiastic the program host may deliver the show, it is still the same material. When a student experiences the show, they know their peers will see the exact same thing, outside of the differing questions other students may pose. Few students will talk about their experiences in an astronomy theater with their peers because they all have the exact same experience.

In our previous shows, we used minimal 3D assets and relied heavily upon the speaker to convey what various dots and circles and lines on the screen meant. In shows that did feature 3D models, none of the models were original or custom built to showcase that particular show. The shows were built only around what was pre-existing within the system, and limited the creativity of the developers. Also because a show was 'a show', the thought never occurred to the developers to allow the on-screen action to be directed by the students.

To better achieve the expected STEM experience from our existing astronomy program, a redesign of the previous creation methods was necessary. What we desired was a new program that could support the hands-on approach to learning through a virtual experience. Ideally, the program could involve numerous choices, each with different events and moments. In order to harness their interest and spark conversation outside of the show between students, events needed to be different and interesting – or at least different enough that each student could have his or her own story. Key events would tie back together, so the goal of the educational material would still be achieved, but additional material would be different from student to student.

This paper will discuss the topics associated with not only the discovery process and the angling of the concepts of a new interactive astronomy program, but also delve into the details of the program itself. The topics will include methods of setting up interactive features using Sky-Skan's Definiti planetarium software, Digital Sky 2, to achieve a fully interactive environment [2]. Pitfalls, workarounds, and tips encountered by our team will be discussed at each step. While much of the paper will be covering the Digital Sky 2 software, the basic concepts used can cover a wide variety of software where an educator may be having a difficult time building interactive features for their students. The goal of this paper is to provide a roadmap for transforming a non-interactive presentation into something that will not only further STEM objectives, but also will capture the attention of students.

II. RELATED WORK

For our approach to be useful to others, we researched a myriad of ways to implement the necessary interactive features. However, up until now, little work has been done in this area. We were able to discover some of the simpler features through work by others by reading the private forums associated with Digital Sky 2 purchasers. To the best of our

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

knowledge, more complex functionality such as asset creation and implementation has never been fully explained or well documented.

Planetarium web pages across the United States prove they follow a standard approach to their astronomy centers. They tend to feature a scripted planetarium segment and a non-interactive, pre-recorded movie. Generally the show's commentary is prerecorded, occasionally by a person of note within the science community or an author. Any interactive features available by the system are either unused, or used in such a way that there is no dedicated show built specifically around those capabilities.

One such example of this is The Morehead Planetarium and Science Center at the University of North Carolina at Chapel Hill [3]. The shows look spectacular, but the experience is the same for everybody. Since there is limited or no interaction with the audience, the experience is an educational movie.

While most planetariums follow the route of the non-interactive feature, the Lawrence Hall of Science's planetarium at the University of California, Berkeley does provide an interactive experience [4]. They also use the Digital Sky 2 software – the same software that we use at the Millard Oakley STEM Center. In this case, the show is hosted by a real person and the host can answer questions posed to them and direct the screen to whatever object a person may want to see. This type of feature is fully within the operational boundaries of the Digital Sky 2 software, but it still does not fully realize the goals presented in this paper.

In short, to the best of our knowledge, what we are presenting in this paper is novel. For most planetariums the word interactive describes a show run by a live commentator. The commentator controls the system in a pre-existing way, such as to view a certain object. The commentator has control of the *navigation mode* already built into their software. This method is useful, but it will not grab the imagination of an audience and pull them into a different world where they are in the driver's seat. In fact, this interactive method is traditionally how we have used the software in the past. This level of interaction lacks the excitement of what we are aiming to do with our interactive story approach to education. We believe that the Digital Sky 2 software has a great deal of 'interactive potential'. So, our goal is to capture the essence of what 'interaction' means in an educational setting, and refocus it into something that will grab students' attention by literally pulling them into the story.

Through a system such as Digital Sky 2, we have the capability to create a lasting, educational experience. However, the capability to do that is not simply inherent within the software in and of itself. There are certain techniques, which when applied, have helped to move our presentations to another level of excitement, where the student can literally take part in an adventure driven by education.

In other words, our goal is to not just show a movie. We want to surprise the audience with a story where *they* are the author of something exciting. The following is our proposed approach to implementing a truly interactive planetarium show, with detailed steps and examples that will allow other practitioners to do the same.

III. Proposed Solution

A. Storyboard / Event Flowchart

Before beginning to build a show, it is important to answer the following questions: What do you plan to teach? What do you plan to talk about? What do you want to start with and what do you want to end with? Even for practitioners who are not using the Digital Sky 2 software package, this step is critical to any feature event, whether it is interactive or non-interactive. It is easy to skip this step and dive directly into building a vision, but this haphazard approach will often result in a confused, incoherent project. To get around future difficulties, it is good practice to create a *storyboard* at the beginning of development. A storyboard is not a new concept, and is something many people familiar with the entertainment industry will recognize [5].

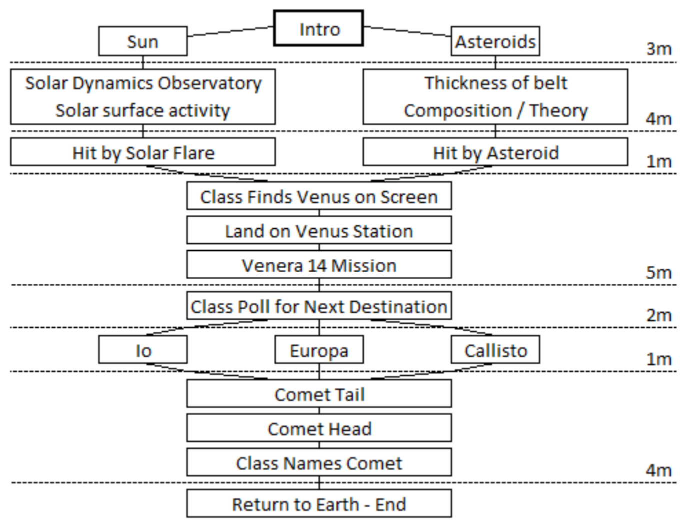

Figure 1: Example Storyboard Flowchart

To implement one's strategy, one must storyboard ideas using a medium that is easy for all to view and edit freely. For our purposes, we storyboard our ideas on large white boards. Ideas undergo numerous changes until brain storming is finished. Our initial storyboard consists of a flowchart of topics we want to cover, and the amount of time we want to take talking about each topic. Lines connect the different branches the feature will take (Figure 1).

Since our feature will have key topics we want to cover, we use a 'diverge and converge' system. Each major topic will be talked about, followed by an ancillary topic the students would choose as a next destination. Those destinations would ultimately return to our main topic again. This initial flowchart storyboard not only gives us a way to 'see' how the show will play out, but it also gives us rough estimates for timing. These estimates can be taken into action for writing the speaking portions of the show.

Additional work with a storyboard may be necessary to achieve the desired look and feel. It may be necessary to draw out individual scenes, complete with timing for smaller events, including the timing for audience participation. For each individual event in the flowchart, we follow the standard method of storyboarding. We draw comic book-like panels of pictures describing what occurs. This helps us further recognize assets we need to create, as well as what we would say and when.

With the storyboard visible to the development team, all creative thoughts and ideas are never lost. Since a 20-minute show may take a year to develop, preserving ideas for later implementation is a critical key to success. The storyboard also provides a convenient metric to measure the completion percentage of the overall presentation.

B. Understanding the Model & Brief History

Creating models is necessary for custom content, and understanding the format of the model file is necessary to create professional looking models. Digital Sky 2 uses DirectX models in the .x format [6]. This is an older and depreciated format, and to the best of our knowledge no fully compatible Digital Sky 2 model exporter exists. For certain features, such as applying *shaders*, additional model editing must be done.

We initially used Blender to export our models to the DirectX format [7]. In our version of Blender, we enabled the ability to export to the DirectX format through the *Add-ons* menu. However, we discovered some issues exporting certain materials, and creating animations was difficult as well. This led us to look for alternatives.

What we use now is Autodesk 3D Studio Max 2012 [8]. Autodesk 3D Studio Max is very expensive to buy, but for students it is free to use. Although we are not able to build DirectX *shaders* compatible with the Digital Sky 2 software using the *shader* creation tools within 3D Studio Max, we are able to resolve animation issues and ease of exportation. Sky Skan also uses 3D Studio Max to create their content, which further justifies our selection of this software. However, between the version Sky Skan uses and the current version of 3D Studio Max, the ability to natively export to DirectX models has been removed.

Therefore, since we did not want to lose the great modeling and animation features present in the newer versions of 3D Studio Max, we had to locate a third party exporter. After a lot of failed attempts, we found Pandasoft's DirectX Exporter [9]. This exporter covers all of the bases, including animation, and even allows for direct export of models with a basic texture map material without the need to edit the .x file.

Digital Sky 2 can be very picky if certain modeling actions are taken. If an object is not modified at the *sub-object level*, it may be deformed in the Digital Sky 2 environment. Translating, scaling, and rotations of objects performed outside of a *sub-level* of editing can all lead to these deformation issues, even if the model looks normal inside the modeling program.

The Digital Sky 2 environment can also support models with a very large file size. The International Space Station model which comes with Digital Sky 2 is a very detailed, large model. The model can be displayed on the screen with no performance loss.

However, it is also important to know that when working with large file sizes, the development team will need to plan ahead on how to load these assets, since it will take time for a larger model to load than a conservatively smaller sized model. If there are also large textures associated with the model, this will also have an impact on file loading times.

C. Landscapes, Flat Surfaces, & Billboards

One of our major goals with the project was to create land-based scenery and events. This was a challenge due to the high field of view of our system. Flat objects were distorted to look curved. This resulted in a fisheye appearance to all of our content, and while it was acceptable for space scenes, it ruined landscapes and anything else we wanted to look 'flat'. Digital Sky 2 is set with a *field of view* associated with the connected display, and for us this editable value is set at around 170 degrees. However, it is a system-wide setting, and cannot be set on a per-scene basis. This led us to the conclusion that adjusting this setting will harm all our previously created shows, and was not an option.

Our billboard graphics, which are .JPG or .GIF images put directly onto the screen, also suffered from the fisheye problem. The further towards the top of the screen we put an image, the more distorted it was. We noted, that if we set a billboard low at the horizon, which was the bottom of the screen, it was flat, albeit cut off by the screen itself.

We discovered ideal ways to combat this distortion. The ideal display to use for billboards is *panoramic*. To shift a billboard upwards on the screen without distortion requires two values on two different lines to be changed. On the billboard setup line, the *Y-Offset* has to be an increasing positive value, and the display line has to keep the *elevation/declination* setting to a value close to zero (Figure 2).

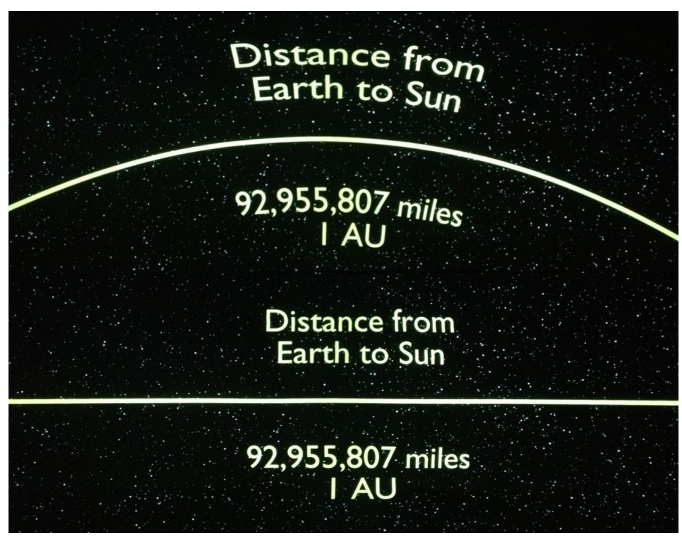

Figure 2: Top – No Y-Offset; Bottom – Y-Offset Used

Each billboard has different settings, since the size of the associated image is different. The *Y-Offset* has a maximum value it works at, so juggling between it and the *elevation/declination* value is required for an optimum image. Discovering that images placed along the horizon have very little bending to them helps to pave the way for landscape creation. If one creates a landscape by placing it at the base of the screen and pointing the camera 'skywards', the landscape will remain flat along the bottom of the screen.

Unfortunately this technique does not meet expectations when we want the camera to look at the landscape itself. When rotating the camera 'side to side', the fisheye effect is not very obvious. However, when rotating the camera 'up and down' the effect is dizzyingly prevalent. Due to the *field of view* setting, the screen is viewing an entire hemisphere.

Once one fully understands how the camera acts because of the field of view, one can come up with strategies to get around it in their models. What we discovered to work best was to create the scene we wanted, and then bend and distort it afterwards. By bending and extending the edges of the model to curve inwards, the camera will not be able to see the end of the landscape. It is also important to bend the model around where camera is to be located.

To build a good centerpiece terrain, it should be modeled from 'strips' of terrain, then overlapped them from the camera's point of view. This gives a good effect for distance. These strips should taper larger towards the edges to prevent them from appearing to shrink as they near the edges of the fisheye camera (Figure 3). This technique provides for excellent panoramic scenes.

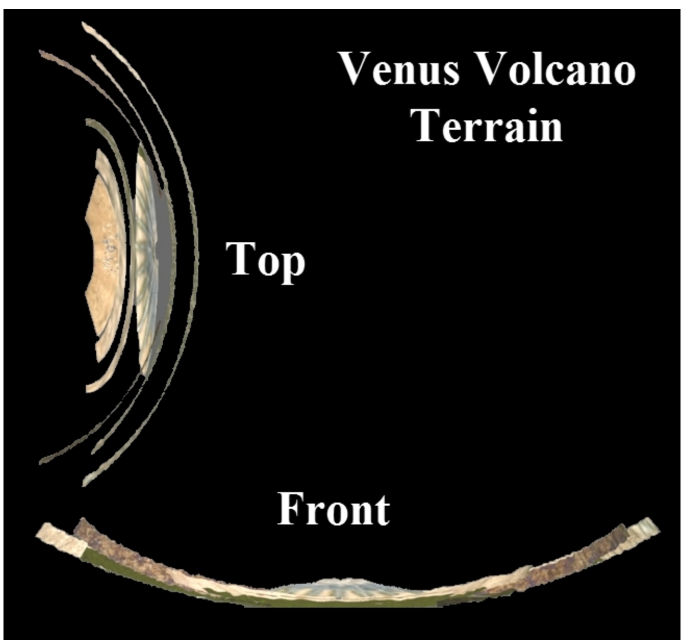

Figure 3: Terrain Bending for Camera Compensation

When building a scene it is important to know how the camera will act and what it will show to the audience. The design of the model will need to be based entirely how it is seen by the camera. Once a scene has camera compensation bending applied to it, going back and making changes can be difficult, and even impossible for complex scenes.

D. Scene Animation

Digital Sky 2 allows for at least two types of animations: *bone-based* animations and the more standard *rotation and translation* animations. Bones animation involves the object being rigged with bones to animate it, and allows for more realistic animation [10]. The rotation and translation type animation allows for full objects to be rotated and translated, and may be useful for solid objects moving from one location to another location. Animations are built by setting *keyframes* for actions, which are fully implemented by Digital Sky 2.

For most complex animations, separating a static background model from an animated model is very challenging using Digital Sky 2 due to its own system complications. The primary reason to have two or more separate models in an animation is due to how the *shader* system works in Digital Sky 2. If a model is animated using bones with a basic bitmap applied to it, the bones will animate as expected. If that same model has a *shader* applied to it, the model will 'break apart' at the polygon level as the bones animate. This means that instead of having the polygons bend and shift to accommodate the movement of the bones, they are instead static and unable to shift, causing the model to literally rip apart at the seams as it animates. What this results in is static models that can have nice looking *shaders*, but any animated model must use only standard bitmaps. Being able to mix an animated, bitmap-only model over a nicely *shader*-enabled static model would be useful, however, actually getting this to work proved to be more of a challenge than we could afford given our time limit for the project. Mixing static and animated models together is possible, but it takes a considerable amount of work, and any changes to the animation or static scene has adverse effects on the Digital Sky 2 settings and positions of the models.

For optimum control over a fully animated scene, it is best to keep the animating objects in the same model as their background. All of the scene objects must also be connected together as a single object, or there may be unexpected results. With a single large object, the only way to animate it is by using the bones system. Surmounting object interaction and positioning is difficult, and using this technique for precision will save countless hours for different animations.

It is important to keep in mind that Digital Sky 2 mirrors everything when it loads it into its environment - just like models. So an animation of something going left will go right inside the Digital Sky 2 environment. This can be circumvented by mirroring the scene prior to exporting.

E. Applying Bitmaps and Shaders

Creating a quality model is a two-part event. First, a detailed model must be developed, and second, good bitmaps and shaders must be applied to it. Digital Sky 2 allows these features with shader support available for non-bones animated objects. Getting a basic bitmap on an object requires nothing more than exporting the bitmapped model with the Pandasoft exporter. Applying a shader to the model requires significantly more work.

To apply a shader to a model, first one must export the model as normal using the exporter software, like Pandasoft. The shader file itself will need to be created separately. Shader files have a .fx extension, and pre-existing .fx files can be found within Digital Sky 2 to use as a starting point [11]. Digital Sky 2 supports many types of *shaders* that are not normally available within the default .fx files, such as self-illumination. These shader additions can be built into custom .fx files if necessary for a particular model.

With either a custom shader or a pre-built shader from another Digital Sky 2 file, one must then connect the shader with the model. This requires editing the .x model file. To best understand how this works, one can investigate the *Shuttle.x* and *StandardFX_ds2.fx* files which come with Digital Sky 2. *StandardFX_ds2.fx* by itself can handle *normal* mapping, *specular* mapping, and *diffuse* mapping techniques.

To apply the .fx file to the model, open the .x file in an editor and search for *MeshTextureCoords*, locate the texture method above that block. If this is a fresh export using the Pandasoft exporter, there will only be the bitmap pointing to an image file. In order to get the *StandardFX_ds2.fx* shader applied within model, replace the entire bitmap block with the contents of the block in the same location as shown in the *Shuttle.x* file. To use custom bitmaps, change the file names pointed to in the *Shuttle.x* block.

If the model is using multiple objects inside of a single file, each object will need to have the bitmap block replaced with the associated shader block. This can become time consuming, but it is possible and it will allow for different objects within a scene to use different shaders. Good usages for multiple objects in a single file would be for such things as a space station and a space ship docked together. Instead of trying to wrestle with the Digital Sky 2 environment for precision, simply merge the two objects into a single file and position them as a single model.

Another important note concerning mapping and Digital Sky 2 is that any model will be mirrored once it is inside the environment. This means that readable text inside the modeling program will be backwards inside of the Digital Sky 2 environment. This issue can be circumvented by mirroring the model prior to exporting.

Figure 3: Self-Illumination Shader Bitmap

We discovered that many 3D-engine specific shader functions work with the Digital Sky 2 engine, such as self-illumination. Self-illumination bitmaps need to have the diffuse bitmap edited to where the light is shining and black where there is no light (Figure 3).

The shader system used by Digital Sky 2 does not provide any documentation. However, we have observed that shader equipped models can be built to the level of current generation graphical expectations. Many of the same concepts used by high profile video game models can be employed within the Digital Sky 2 environment as well [12].

F. Large Project Development

Larger projects have their own development dynamics. Since Digital Sky 2 does not feature any way to speed up or slow down the speed of a show, a developer must sit through the entire segment before they can see the effect of their changes. This issue takes center stage as sound components are added to a presentation.

One way to combat this issue involves creating event-specific buttons on the control program. If a single button controls an exceptionally long segment, one can break that segment up into two or more buttons. Good split locations are most often camera change events. If one copies the last camera change made into the top of the new event button with a time value of zero, the camera will start at the end of the previous segment.

By using this technique, it has cut our own development time considerably. When we add sounds or make small changes to the movement of the camera or an object, we no longer need to wait for 20 minutes before we see the impact of that change. In other words, once editing is complete, one can cut and paste the fragment back into the original button event, and remove the camera position line.

When we develop large segments, we develop them as small partitions from the outset. Once all of the partitions are complete without error, we transfer them to a final button as a single event.

An important element to keep in mind when using this design method is locality. For example if segment 12 is being edited and requires elements from segment 2 to exist, there may be complications due to these missing elements. Ensure that all of the resources a segment requires have been loaded and are in their proper positions for that segment's time frame.

G. *Loading Time and Memory Management*

As a show is running, one hopes that the audience will become immersed in the newly created world. Suddenly, the picture stutters, and the audience is jolted back into reality. Or even worse, one of the computers crashes, and suddenly the audience is watching a Windows desktop. These issues arise from asset loading and poor memory management. For large, ambitious projects featuring considerable custom content, loading times and memory management become a problematic hurdle to overcome.

Currently in Digital Sky 2, when an asset loads, it is loaded in the background. This loading can be almost seamless for small billboard images or sound bites. However, when the system needs to prepare for a scene shift, and a large number of assets are loading, this a noticeable on-screen hiccup. This problem can also occur for a small model if it happens to use *shader*s, since it may have four or more large bitmaps to load before it can be displayed. Hiccups can also occur when loading a large video file for playback. In fact, any large file has the potential to impact the quality of the on-screen frame rate.

One of the best techniques to combat this behavior is to load assets when the camera is stationary. The frame rate will still be impacted, but because the camera is not actually moving the loss of frames will not be noticed. Using a fade to black type transition also makes use of this technique. A fade to black also looks more professional than simply switching from one scene to another instantly.

The least effective method to utilize is to gradually load assets. For instance, in the feature's code, one can add *keyframes* between camera positions which do nothing but load assets. In this case, loading assets one at a time over a period of time may not result in a noticeable frame rate impact. For example, if a camera moves over a 20-second period, adding additional *keyframes* at 3 second intervals will not affect the movement of the camera or how long it takes to move. However, one should also make sure that the final load takes place before the initial 20 second camera movement has completed.

Digital Sky 2 has no automatic memory management features. This means that for every asset loaded, it must be unloaded or it will continue to take up memory until the system is reset or crashes. When a crash takes place, one of the computers usually will shut down Digital Sky 2 and return to the desktop. This problem may arise when playing many concurrent shows, since one of those shows may have a memory leak. A general good rule of thumb is to hit the reset button between shows to prevent any unexpected behavior.

To combat this problem and keep a show running smoothly, assets should be unloaded when they are no longer used. If an asset is used more than once for different scenes, hiding it may be more useful than unloading and reloading it.

At the completion of a show make sure all assets are completely unloaded. Breaking a large feature into segments will make memory management easier to handle, since loading and unloading can take place on a segment-by-segment basis.

H. *Building an Interactive Presentation*

The interactive feature is the reason why we began working on this project. Surprisingly, it is simple to accomplish with Digital Sky 2. Not only are the event buttons useful for creating a single large feature, but they can also be used to control an interactive show.

The buttons can mirror what the storyboard overview depicts. Each button can control that particular segment from the storyboard. The show's presenter will then be able to easily follow the flow of the show from one button to the next.

Helper buttons may also be implemented. We use helper buttons for naming the spacecraft of our show to what the students chose. This involves us needing to edit that button during the show, which contains the code to give a name to an object already loaded on the screen, and then activate that button. The students enjoy seeing that they could really interact with and change what was visually on screen. Being able to give key objects custom names helps to keep the show personal and individualized.

IV. Conclusions

The ending product for our project was very close to our vision for graphical fidelity. Using the techniques we learned, we were able to use Digital Sky 2 to seemingly bring people not only to the far reaches of space, but also to the surface of Venus and Callisto. We were able to create branching events and tie it all together to create a new kind planetarium presentation. Our success was the approval of teachers as well as the interest of the students. Our premier show aired all day long to nearly 300 people, and the show has been added to the regular schedule for schools visits. Using the tools and techniques described in this paper, we have successfully brought student interest into an area that previously had very little interaction.

Measuring the success of a public show, where no grades or surveys are involved, can be a difficult task. However, most educators can recognize the difference between students that are truly interested versus those that are "just attending". Following the premier and consequent presentations of our pilot interactive feature, we observed more inquisitive students than we had previously. There was also more of a buzz about their experiences during lunches, and more activity between "project zones". When the general target audience is middle school children, data gathering can be anything but simple and often inconclusive. We are therefore left to our own observations of the students' reactions, such as smiles and eagerness.

If nothing else, we hope that our own success and direction provided in this paper will help other educators create an exciting educational environment. Even if one is using something other than Digital Sky 2, this paper still holds valuable resources for an educator to outline and create a larger production. It is not easy, but capturing the minds and sparking the curiosity of students and adults alike is a reward only measurable by our future society.

V. FUTURE WORK

With the success of our project, the Millard Oakley STEM Center on the Tennessee Tech University campus is actively looking to continue to create new interactive content. We know there is more tweaking and tricks that can be utilized by the Digital Sky 2 system. For instance, one of the tricks we have been thinking about has been a way to employ a Java program to cause 'on the fly' edits to a script in the Digital Sky 2 system. This can allow for students to interact with the system via a computer set up in the room for them, and it would remove the necessity for an operator to script in whatever custom event a student would build. One of the tweaking techniques we are currently looking into is the reason behind a model breaking during bones-based animation if it has a shader applied to it as opposed to a regular bitmap. We are investigating the impact that other files within the system may be having on this issue. We are also still investigating the unknown object physics that can cause two models to 'collide' with each other and move each other out of position. This appears to happen at random, and as of the writing of this paper, we have been unable to determine how to compensate for this behavior by the system. We are hoping to investigate this problem further and discover a workable solution.

VI. ACKNOWLEDGEMENTS

This project could also have not been possible without Marc Robinson, who was the co-creator of the presentation from conception to giving the show to students. This project would also not have been possible without Dr. Sally Pardue, who has incredible dedication to STEM activities and is always looking for ways to improve student learning and experiences.

***Abstract*— Vertical garden and green wall structures have been introduced to the K-12 environment as vehicles for learning as part of a larger green construction trend. This paper considers the design and construction of a biowall as a case study for green engineering design projects in the K-12 setting. The research, conducted in participation with 123 10th-grade public school students, investigates further learning opportunities posed by a biowall design-build project. We claim that the highly visible plant component of the wall makes the project more accessible to students that would have been immediately averse to a "rigid" engineering project, allowing for increased perceptions of competency in engineering through willing practice. Further, we claim that the large-group organizational structure of the project, with students working in multiple specialist sub-groups to complete a larger project, increases students' perceptions that good communication skills are required in engineering. This article provides methods employed and qualitative and quantitative results.**

Keywords— problem-based learning; active learning; K-12 education; engineering design; green case study; green construction; biowall; vertical garden; green wall; living wall;

I. Introduction

In recent years, the US has seen an increasing number of sustainable, or "green," construction projects [1]. A recurring feature in such projects is the "green wall," "vertical garden," or "biowall," a vertical structure supporting plants for aesthetic value, small-scale food production, or indoor air quality improvement, respectively [2][3][4]. This trend has made its way into the K-12 environment in the form of green walls constructed by independent contractors (Sanchez Middle School, San Fransicso, CA and Drew School, San Fransisco, CA) and kits for students to create vertical gardens (Wooly Pocket Wooly School Garden initiative and Green Bronx Machine edible walls) [5][6][7][8]. Such projects are meant to supplement student learning in biology, chemistry, and environmental science but lack the student-driven design component that could, simultaneously, cultivate an understanding of engineering practice.

The green engineering design case study discussed in this paper was conducted with 10th grade biology/chemistry classes at Science Leadership Academy (SLA), Philadelphia, PA. The school, a partnership between the School District of Philadelphia and the Franklin Institute, is described as an "inquiry-driven, project-based school" where "core values of inquiry, research, collaboration, presentation, and reflection are emphasized in all classes" [9]. The project was developed, collaboratively, by two Graduate Fellows from the Drexel University NSF STEM Fellows in K-12 Education Program ("GK12 Fellows") and SLA's two 10th grade teachers ("Teachers") as a culmination of earlier engineering design projects meant to supplement the course goals and increase students' understanding of engineering. The general engineering education goals that were used to inform the choice of the project content were:

(a) increase students' perceptions of their competency in engineering through practice,
(b) emphasize the importance of communication skills in engineering, and
(c) illustrate the interdisciplinary and collaborative nature of large engineering projects.

We hypothesized that the biowall design-build project would help further these goals through (1) its specific content and (2) the organizational framework required to complete it.

Existing work shows general support for cooperative, problem-based learning as an effective method for achieving positive increases in student perceptions and attitudes [10] [11]. Green engineering has been acknowledged as a highly interdisciplinary practice, though disciplinary egocentrism has been observed as a barrier to understanding the complex contributions to interdisciplinary problems at the undergraduate level [12][13]. We choose to proceed with this in mind, leaving an open question as to whether early high school students would exhibit the same discipline-specific mindset as university students.

Biowall design was chosen as the content for the project over other greening topics, such as energy or resource use, because the most visible features of a biowall are the growth, maintenance, and display of plants, tasks not generally associated with engineering [14]. We believed that this overt biology-based subject matter would support the curriculum and encourage the participation of students that may not be as interested in engineering. For example − and without attempting to explain any cause here − women and underrepresented minorities' participation in biosciences and biomedical engineering is greater, in the US, than their

participation in engineering-at-large [15]. More practical reasons for the choice, over a project such as green roofing, include the ease of execution in the classroom and the structural design element. Additionally, the proximity of Drexel University's biowall at the Papadakis Integrated Science Building and other local projects provide good motivating examples [16].

It is commonly accepted that engineers are viewed as lacking in interpersonal skills, though communication and collaboration are integral to the discipline [17]. The organizational structure of the project was designed to address these stereotypes, as well as demonstrate that engineering may be interdisciplinary. Students were organized into large groups, of approximately 16 students, to design and construct a single biowall panel. Each large group is separated into specialist sub-groups focusing on watering systems; lighting systems; supporting structure; and plant selection, growth, and maintenance. The GK12 Fellows and one classroom Teacher, per class, provided only loose guidance for the project, leaving many decisions to the project groups and forced them to create networks for coordination among the large number of students and specialist groups.

In this paper we describe the implementation of the project over a three-month period, providing the loose project structure and the general practice employed by the GK12 Fellows and Teachers in the day-to-day administration of the project. We provide representative data from student surveys administered before and after the project and discuss the results as they relate to the three goals given above. We found that, over the course of the project, students' perceptions of their potential to become engineers increased at a statistically significant level. Students' perceptions that engineering requires good communication skills also increased. No significant increase was observed in perceptions of engineering as an interdisciplinary practice, though initial responses tended to be in high agreement with such statements. Roughly four of the eight walls were seen to completion, integrating most-to-all required systems.

II. Background

The biowall engineering design-build project ("biowall project") was run with all of the SLA's 10^{th} grade joint biology/chemistry courses. This consisted of 123 students across four separate classes. A single SLA Teacher taught two of the four courses each, for a total of two SLA Teachers. As a public magnet school, the demographic breakdown tends to reflect that of the city of Philadelphia. The project class's self-reported demographic breakdown can be seen in Table 1.

Two Drexel University PhD candidates in engineering worked with all project classes over the 2011-2012 school year as part of the Drexel University STEM GK-12 Program: "Catalyzing STEM Education via the NAE Engineering Grand Challenges" [18]. As part of this program, the GK12 Fellows collaborated with the two classroom Teachers to develop lessons, activities, and projects centered around the NAE Engineering Grand Challenges in order to supplement course curriculum and increase students' understanding of the engineering discipline. The biowall project began in late-January, so the students were familiar with the GK12 Fellows from previous projects meant to incrementally introduce them to the engineering design process.

TABLE I. SELF-REPORTED DEMOGRAPHICS OF STUDENT PARTICIPANTS

Race	Percent[a]	Gender	Percent
Black	37.1	Male	50.8
White	30.8	Female	49.2
Asian	7.5		
Other	24.5		
Hispanic or Latino[b]	14.3		

a. Percentages may not sum to 100 because students may have identified with multiple groups.

b. "Do you consider yourself to be Hispanic/Latino?" was a separate question from race.

The biowall was intended to be a culmination of the classes' study of engineering practice. The GK12 Fellows and SLA Teachers collaboratively generated the general structure, goals, and assessment surveys for the biowall project in the weeks before intoducing the project. A form completed durring the planning process to explain curricular goals, in Understanding by Design format [19], can be found at [20]. Later corrections or deviations from the original structure were made during weekly planning meetings to address problems, teaching opportunities, and time constraints. The project structure presented in this paper reflects these changes.

III. Implementation

The biowall project took place over 14-week period, beginning late January 2012. Each of the four classes spent one one-hour class period per week on the project, though they were occasionally given an additional class period to work when nearing deadlines. The project consisted of a background research and design phase (four weeks); a construction phase (five weeks); and a documentation and reflection phase (two weeks), with field trips and visits by specialists taking place intermittently.

As motivation, the students were taken on a short field trip to see the biowall at Drexel University Papadakis Integrated Sciences Building before beginning the project. This 22-foot by 80-foot biowall is a research platform created to study the effects of root-based microbial communities on indoor air quality, specifically the removal of volatile organic compounds [21]. The students heard from and asked questions of a faculty member from Drexel Civil, Architectural, and Environmental Engineering involved with research on the biowall. The students were given some time to examine the biowall from several floors and were, by all appearances, excited about the trip and the upcoming project.

To begin the project, each class was split into two "project groups" of approximately 16 students that would be responsible for designing and constructing their own biowall panel, for a total of eight project groups across the four classes. Within each project group were four "specialist groups" that would work together on a specific aspect of the biowall: the structural system ("structure group"); watering and nutrition system ("water group"); lighting system ("lighting group"); or plant selection, growth, and maintenance ("plant group"). Classes were originally divided into specialist groups through a "Four Corners"-style game, where students indicated what subject matter they were most interested in by going to a corner of the room, following other questions about their life and interests. This provided a method for the students to, somewhat unknowingly, chose what specialty they were going to work on. After one period of researching the considerations for their specialist tasks, each class-wide specialist group was halved and grouped with others to create the project groups.

The general problem posed to the project groups was to create a self-sustaining biowall panel that serves some function beyond its aesthetic value. Further, it was stated that the panels should be suitable for public display in a to-be-determined location and have dimensions of approximately 4' x 6' in the vertical plane. The specialist group responsibilities follow, with sample considerations that were posed to the groups, either formally or through discussion with the Teachers/Fellows:

Structure group: Design and build a free-standing or wall-mounted structure that can support living plants and the required watering and lighting systems for those plants.

Sample considerations: *What are the benefits and drawbacks of various materials? Are there any options that would be low-cost or recycled? How much weight should the wall be able to support? What can we learn from existing biowall or vertical garden structures?*

Water group: Design and incorporate a watering system into the biowall structure that can provide the appropriate amount of water and nutrition to the wall's plants. This system should require little human maintenance beyond infrequent refilling.

Sample considerations: *Will you circulate water or will the system only be driven by gravity? What nutrients will your plants require, and how will these be supplied? How will you manage water flow rates to supply the appropriate amount of water to the plants?*

Lighting group: Design and incorporate a lighting system that will provide the appropriate amount of light for plant growth.

Sample considerations: *How does photosynthesis work? What wavelengths of light are most useful to plants, and will specialty lighting be required to provide this most effectively? Is it important to turn the lights off for some amount of time? If so, how will this be controlled?*

Plant group: Chose plants, appropriate for indoor conditions, to incorporate into the biowall that will perform some task beyond providing aesthetic value. Care for the plants before including them on the wall, and monitor their condition after they have been incorporated.

Sample considerations: *What are the relevant biological mechanisms that will allow your plants to perform the chosen task? What are the lighting and nutrition requirements for the chosen plants, and what do other specialist groups need to know so that the completed wall can sustain the plants?*

General classroom practice for the Teachers and GK12 Fellows was typical of a problem-based learning environment [22]. The SLA Teachers are well versed in the pedagogy, and the fellows attempted to follow and learn from the teachers' leads over the course of this and previous projects. During these classes, students were given freedom to use the time as they thought appropriate, and teachers and fellows would move through the classroom to assist students and keep them on task. We attempted to guide students towards appropriate solutions by asking questions, rather than make explicit suggestions.

Students worked on the biowall project for one hour each week, and this was commonly called "engineering day." The GK12 fellows were commonly referred to as "the engineers." Where, other days of the week, the teacher referred to the students as "scientists," a point was made to call the students "engineers" on the days in which they worked on the project. This was an attempt to have the students identify as engineers and, possibly, increase their perception that they had the potential to become an engineer.

In the design phase, students were asked to research information relevant to their specialist topic in order to inform their design decisions, with Teachers and Fellows providing prompts similar to those above given. The majority of research was performed using the Internet. Project groups were given three weeks, from the start of the in-class portion, to document an overall design, through descriptive diagrams, and provide requested material lists, including estimated costs. They were given a $100 budget and were encouraged to use found or recycled materials in order to afford costly, but essential, items. It was suggested that, rather than working as a 16-person committee, specialist groups nominate a representative to confer with those from other specialist groups in order to make large-scale decisions.

As a deadline to complete designs and opportunity provide feedback to the students, we arranged for an expert from the Pennsylvania Horticulture Society (PHS) to visit during class time. Each project group was given half of the class to explain their biowall design, receive and discuss feedback, and ask questions. These discussions centered on the choice of plants for the given biowall function and what the groups might not have thought about, in terms of supporting the plants.

Over the two-week period of expert visits, the students were also taken on a walking field trip to the Grumman Greenhouse. This sculptural greenhouse, on the campus of the Pennsylvania Academy of the Fine Arts, is in the shape of a crashed Grumman Tracker II Naval airplane and houses nutritive and medicinal plants within the cockpit area [23]. After viewing the greenhouse, the students were asked to discuss considerations important to displaying a piece of work in public and question why certain elements had been included: for plant care or artistic intent?

Project groups moved on to the construction phase after making refinements to their proposed design, having it approved by the Teacher and GK12 fellows, and submitting a list of requested materials. The fellows acquired requested items to the best of their abilities, using some discretion. The Teachers, Fellows, or colleagues brought in tools that were needed. The fellows advised students on specific tool use and safety, often demonstrating use. Over the course of several weeks, the students attempted to assemble biowall systems. Common construction efforts included:

- *building a wood frame with shelves by fastening with screws;*

- *building a frame of PVC piping, fastening with glued joints and screws;*
- *planting plants in plastic bottles or pots to be mounted on a frame;*
- *drilling holes in a plastic basin to stick tubing or allow water to drip through;*
- *assembling tubing and fasteners with an electric pump to pump water to a desired height;*
- *experimenting with different clip lights and bulbs on a test frame.*

Some specific completion requests were made, such as having the wall in a state that plants could be mounted and sustained over spring break, following the third week of construction. The project groups were encouraged to have their walls complete by Week 12, the fifth week of construction, so that some could be displayed as part of the Philadelphia Science Festival. The Teachers and Fellows chose two biowalls to be displayed as part of the festival's Science Carnival on the Benjamin Franklin Parkway.

The project was concluded with a two-week documentation and reflection phase. Most work ceased on the walls and the students were asked to reorganize their project groups into four new sub-groups, each consisting of a student from each specialist group. These "recap groups" were each asked to produce a different product to either explain their project or reflect on challenges, failures, and lessons learned. Ideally, all of these products would exist together on a web page about the project group's biowall. The groups' tasks were as follows:

- **Video presentation**: A short video overview of the features of project group's biowall, addressing why specific design decisions were made.
- **Assembly diagrams**: Step-by-step diagrams that would explain how to reproduce the wall that the group created. It was strongly suggested that these be in a wordless format such as IKEA, Lego, or K'nex instructions.
- **"Fail blog"**: Similar to the namesake's style of photographic documentation, this would be a weblog that shows humorous photos of mistakes that the group made along the way, with short descriptions of what was learned from these mistakes as well.
- **Informational poster**: This poster would act as an explanation to the public of what the biowall was, including some science and explanation of the biowall's function, and refer viewers to the other web content.

The project groups presented this content to their classmates, Teacher, and the GK12 Fellows in the final week of the project. Through the documentation/reflection phase and the few weeks following, several small groups of students continued to work on the biowalls during extra class time or after school. Though attempts to have the biowalls displayed in other, more-public locations fell through, three wall panels were displayed outside the main office of SLA.

Fig. 1. Student with example biowall project. This biowall held soil and plants in individual pockets. Water was pumped, from the basin at the bottom, into drip tubes that ran through each pocket.

IV. Results

A. Quantitative Results

Quantitative results were attained from survey responses collected before and after the biowall project. The questions were self-created by the Teacher/Fellow team in an attempt to evaluate the project's effectiveness in changing students' perceptions of engineering and gauge their opinions about the project. Additional questions were included, out of interest, in attempt to find out how much students believe they had contact with or consciously observed plants in their environment.

Surveys were issued through an online form during the class period, and anonymous tracking numbers were used to pair a single student's end survey with their initial survey. The initial survey included 36 questions, and the end survey included 51 questions. Of the total 123 unique respondents, only the 98 that responded to both surveys are included in the analysis, except in the case of student opinion and open-ended questions only available in the end survey. All prompts where students were asked to indicate their agreement with a statement were given as a 5-point Likert scale, with options: "Strongly Disagree" (1), "Disagree" (2), "Neither Agree nor Disagree" (3), "Agree" (4), and "Strongy Agree" (5). All p-values given here are the result of a paired, two-sided Student's t-Test. For the sake of brevity, we only provide analysis of questions relevant to the research goals here. The full list of survey questions, with statistics, can be found at [24].

Based on survey responses, the project appears to have been successful in increasing students' perceptions of their competency in engineering (Table 1). This is evidenced by students' increased agreement with the statement "I have the potential to become a scientist or engineer." (p = 0.024) and increased disagreement with the statement "Other factors, besides my abilities and/or determination make it difficult for me to become a scientist of engineer." (p = 0.010). The latter question was intended to be very open to the student's personal interpretation concerning their barriers to becomming a scientist or engineer, and we will leave the interpretation of the result open to the reader as well. We believe that the highly visible, biology-based subject matter of the project kept students that may have been averse to engineering in general from rejecting it quickly. Further, we believe that systematic attempts towards inclusion, such as encouraging all students to try "heavier" assembly tasks with power tools and calling all students "engineers," helped students to realize potential that they might not have had the opportunity to otherwise.

We acknowledge the inclusion of the optional "scientist" term in both statements as a reason to doubt the effectiveness of the project in increasing perceptions of competency in engineering explicitly. Notice that this occurs, with the exception of Prompt 3d, only in questions related to competency/future in engineering. This was an attempt to gauge success of the GK-12 program's broader goal of increasing participation in STEM fields, rather than just engineering. All questions related to the project-specific goals listed above are engineering specific. It is unlikely that removing respondents only identifying with the "scientist" portion of the prompt would bring the results above 5% significance, as the change occurred over the course of a project for which all effort was made to identify as engineering. Some doubt could be cast from no significant change in the response to "I am interested in science or engineering as a career," but no explicit point was made to encourage students towards the discipline over the course of the project, only increase their understanding of the practice.

The project also appears to have been successful in its goal of emphasizing the importance of communication skills in engineering. This is gathered from increased agreement with the statement "Engineers must be good at communicating with others to successfully complete engineering task" (p = 0.016). While there was also an increase in agreement with the statement "Most engineers are good communicators," the result lacks statistical significance at any reasonable level. Though we have not indicated correlation between responses to these prompts, it seems that students differentiated between the need for communication skills and engineers having those skills, at least in stereotype. This distinction strengthens the result because it shows that students appear to understand the fundamental practice and are able to separate it from the practitioner. We believe that the large group organizational structure of the project and the documentation/reflection phase centered around relaying the design and construction process to a wider audience contributed to this result, though it is difficult to isolate either of these factors as playing a dominant role.

The results concerning the project's success in demonstrating large engineering projects as interdisciplinary and collaborative are mixed. Students overwhelmingly increased in disagreement with the statement "Engineers usually work alone" (p = 0.011) and started with high agreement with the statement "Engineers need to know things from many different subjects to successfully complete engineering tasks." (3.93 pre, 4.02 post). This somewhat favorable result shows that the necessity to communicate over the large-group structure of the project was recognized and extrapolated to general engineering practice. However, there were mild decreases in agreement to statements such as, "Engineers often work with doctors, biologists, and other people who work with plants." or "Studying engineering will allow you to become a doctor or biologist," which more explicitly address engineers communicating with people outside their field, rather than possibly only each other.

TABLE II. SURVEY RESULTS WITH STUDENT'S T-TEST VALUES.

Prompt	Pre	Post	Dif.	p-value
1a. I am good at science and/or engineering.	3.77	3.90	0.13	0.118
1b. I have the potential to become a scientist or engineer.	3.71	3.94	0.23	0.024
1c. I would be able to become a scientist or engineer if I work hard.	4.08	4.13	0.05	0.525
1d. Other factors, besides my abilities and/or determination, make it difficult for me to become a scientist or engineer.	2.94	2.68	-0.26	0.010
1e. I am interested in science or engineering as a career.	3.35	3.38	0.03	0.765
2a. Engineers must be good at communicating with others to successfully complete engineering tasks.	3.87	4.09	0.22	0.016
2b. Most engineers are good communicators.	3.44	3.58	0.14	0.127
3a. Engineers usually work alone.	2.57	2.31	-0.27	0.011
3b Engineers often work with doctors, biologists, and other people who work with plants.	3.71	3.58	-0.13	0.107
3c. Engineers need to know things from many different subjects to successfully complete engineering tasks.	3.93	4.02	0.09	0.266
3d. It is important for me to understand science and engineering, even if I do not plan on having a career in those fields.	3.82	3.89	0.07	0.461
3e. Studying engineering will allow you to become a doctor or biologist.	3.20	3.10	-0.10	0.213

Statements intended to gauge student feelings of success and interest in the project show that students were largely dissatisfied or disappointed with the project or the biowalls produced. We see significant decreases in agreement with statements such as, "We will be successful in creating a biowall or vertical garden." when compared to the past tense version of the same statement given in the end survey ("We were successful…" at p = 0.02). Of the 10 related prompts, five showed significantly decreased agreement at, at least, a 97% confidence interval, though we acknowledge that a paired t-test may not be appropriate for comparing different statements. We believe that this general disappointment could have occurred due to the high expectations set for the project. Several of the biowalls were largely incomplete at the close of the project,

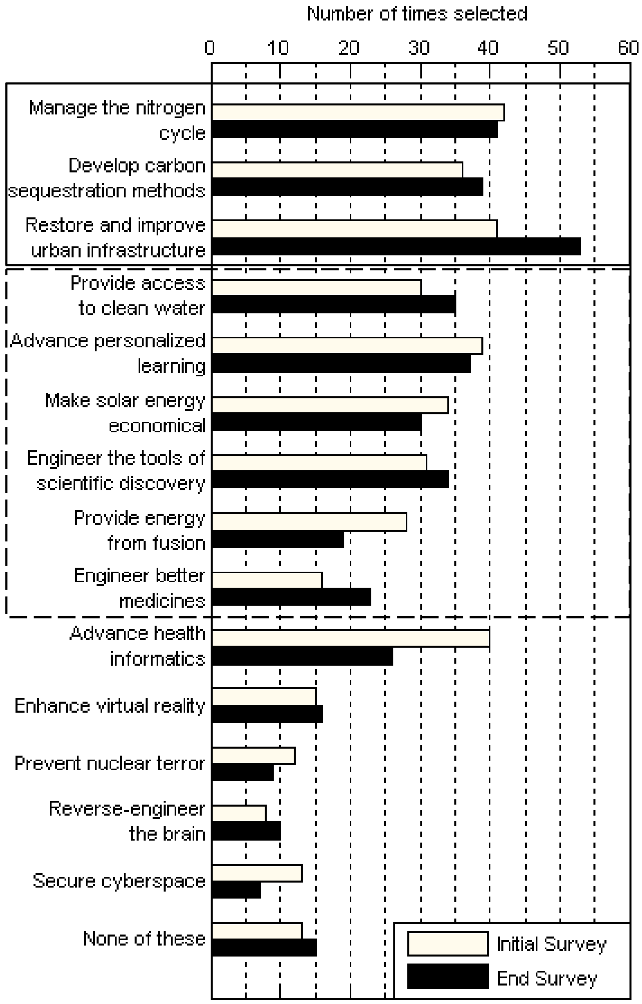

Fig. 2. Number, out of 98, of student respondents that selected each NAE Engineering Grand Challenge, believing it was related to the biowall project, before (white) and after (black) the project. The Grand Challenges within the solid box were indicated as "mostly related" and the Grand Challenges within the dashed box were indicated as "somewhat related" by four GK12 Fellows.

and, where the students were originally led to believe their projects might be publicly displayed outside of SLA, only a few were actually displayed outside the main office for a short time at the end of the year because no formal agreements could be made with other institutions. Other shortcomings could have been due the fact that this was the first time the Teachers and GK12 Fellows implemented the project. Regardless, we are optimistic to see positive results towards the given goals even though the students were not altogether pleased with the physical output, as this shows much of the structure and practice of the project was likely sound.

To assess the effectiveness of the biowall, as it relates to the overall Drexel GK-12 Program objectives, a multiple-selection question on the survey was preceded by the prompt: "The biowall/vertical garden project is related to some of the NAE Grand Challenges of Engineering. Please check any that you think apply." The results are visualized in Figure 2. Four GK12 Fellows, familiar with the project and NAE Grand Challenges, judged the "correctness" of responses. We see a general trend, both before and after, of students accurately identifying more relevant challenges, which indicates that the students had a fair understanding of the project content, likely from the Drexel biowall visit, and Grand Challenges before participating on the biowall project. No clear trend can be observed in increased selection of accepted Challenges or decreased selection of non-related Challenges from the end survey. There are as many increases as decreases in all levels of relation to the project. However, most notable is the increase in correct selection of "restore and improve urban infrastructure." This increase is most likely due to the Teachers' and Fellows' discussion of biowall and vertical gardens' relevance in urban environments. Students also increased their choice of "engineer better medicines" most likely because a small number of project groups attempted to theme their biowalls around medicinal plants.

B. *Observational Data*

We observed that, when students selected specialist groups based on their interests, the structure groups for all classes tended to be heavily male. The imbalance in the structure groups was generally compensated for by more female students in plant and water groups, with one class having two plant groups that were entirely female. Upon observing this trend, we attempted to encourage some remixing, with only mild success due to students' complaints. Throughout the project we attempted to compensate for these imbalances by finding opportunities for female students to get involved in structure assembly. We believe these conscious efforts contributed to some of the quantitative results observed, in terms of perceived competency.

Roughly 50% (four out of eight) project groups produced a biowall for which all requested systems were integrated into the structure. As stated previously, this is most likely due to high expectations and the fact that this was the first time running the project, with little precedent. During the construction phase, most project groups did not appear to have specific design points to follow, so the students tended to design all minor points on-the-fly and were forced to learn from doing. This, of course, caused the construction phase to take a considerable amount of time and require extra materials, which were previously unforeseen by the students. Teachers and Fellows could have prevented groups from moving to the construction phase with incomplete designs, but we felt it would be appropriate, for the sake of time and momentum, for them to continue as long as they had an overall vision for their wall.

V. Discussion

Though not all groups successfully completed the project, we view the project as a success, particularly in light of the quantitative data. The data suggested that the project was effective in achieving the goals of increased student perception of their competency in engineering and their understanding that engineering requires good communication skills. Considering that this was the first iteration of the project, we would hope that the lessons learned would improve the products created in future iterations, while maintaining the same increases in student perceptions of engineering.

Communication about the biowall project with other Teachers and Fellows within the Drexel GK-12 program has spurred interest in similar projects. Another new Teacher-Fellow pair has also implemented their own biowall design project, with an emphasis on urban gardening and maximizing useful area. A third Teacher with the program is attempting to have their school build a green wall within a stairwell, having biology classes select appropriate plants.

The self-created survey used in this research was meant to search broadly for interesting outcomes from this project. Future research should be concerned with selection/design and implementation of instruments that could more rigorously assess constructs of interest, for example: student perceptions of their competency in engineering or, not studied here, student perceptions of barriers to studying engineering.

Returning to the point raised in the introduction, there is some question as to whether forcing students into specialist groups caused students to exhibit specialty egocentrism similar to the disciplinary egocentrism observed in [12]. There is some evidence this occurred. Specialty groups were consistently observed blaming other specialty groups when project group goals were not met. Survey results also show the least support for success of goals related to understanding the interdisciplinary aspects of engineering, though it is difficult to attribute it to this. It would be valuable to repeat this project with smaller project groups (about four students) and do away with specialist groups in order to remove this confounding issue.

This research shows the potential of green engineering design projects to help students improve their perceptions of engineering and themselves as engineers. We believe that the less traditional engineering content provides the opportunity to subvert student expectations and appear more inclusive. When followed with continual insistence that the students are practicing engineering, students may be surprised to realize potential that may have been missed by reluctantly participating. However, it would be valuable to separate the subversive content (in this case, the biowall) from the continual insistence that the students are practicing engineering in order to determine the effects of either alone, i.e., conduct the biowall, or similar, project while rarely stating that it is an engineering project and conduct a stereotypical engineering project while continually referring to all students, even those that are reluctant, as "engineers."

ACKNOWLEDGMENT:

We would like to thank Dr. Michael Waring, Drexel CAE, and Sally McCabe, PHS, for volunteering time to speak to the students. We would like to thank the Drexel GK12 Program, the Pennsylvania Horticulture Society, and Lowe's Home Improvement for providing funding for building materials. W.A. thanks Stephanie Dunda, Tim Best, and SLA for their openness to trying new things in the classroom and Dr. Timothy Kurzweg for mentorship over the whole process.

Abstract—**This paper describes a STEM outreach program for 9-12 grade physics courses. The goal of the program is to provide students with hands-on technologically relevant learning activities for concepts in electricity and magnetism. The three parts of this program include providing schools with the appropriate technology, training the teachers, and developing relevant and sufficiently detailed lesson plans. This program began in the summer of 2011. Being at the beginning of a work in progress, very few results are available so this paper describes the program itself and some of the lesson plans.**

Keywords—STEM; K-12 outreach; physics education; electronic instrumentation; active learning;

INTRODUCTION

Modern technology is starting to bring into common language concepts such as LED lighting, low power electronics for longer battery life, and electric vehicles. To interact effectively with this modern world and solve future problems, students need to know at least some minimal level about this technology. Introduction to the necessary concepts in electricity and magnetism can come in the physical science curriculum in high school. Unfortunately, even for those students that do choose to take physics, exposure has traditionally been very limited due to lack of resources and expertise.

The United States is currently facing a crisis with regard to high-school physics education and in particular with concepts in electricity and magnetism. According to a 2010 report, approximately 400 high-school physics teachers are hired each year, but there is a need for over 1200[1]. As a result of this need, only a third of the high-school physics teachers have a major in physics or physics education, while two-thirds have other science related backgrounds such as biology and chemistry. Another national survey showed that, while physics teachers felt comfortable with Forces and Motion, they felt much less qualified to teach concepts in electricity and modern physics[2]. Due to lack of teacher training, most students have very little, if any, hands-on experience with modern concepts in electricity. Given the state at which modern technology is advancing, students are very naïve about the field, meaning that fewer people will enter the industry or related fields in higher education. Data from the National Science Foundation through 2008 indicates that while enrollment in other engineering disciplines is increasing, enrollment in electrical and computer engineering is falling[3].

The work presented in this paper is an attempt to provide high-school physics teachers with necessary resources and training and the students with motivation and experience. This outreach activity was inspired in part by the NASA Threads program, which provides an entire year's curriculum that is based on the Boe-Bot platform[4]. In contrast, the program described in this paper is more flexible in that the activities can be integrated into any curriculum at any level and at the appropriate time.

In August of 2013, the program will be entering its third year. It has supplied 9 Indiana high-schools with equipment for performing technologically relevant hands-on activities related to electricity and magnetism. More importantly, the program is providing continual teacher training and refining lesson plans, which are both essential in order for the equipment to be used most effectively. This paper focuses on the program's development and current state. Examples of lesson plans are provided. Some student outcomes and teacher responses are included to provide a very preliminary sense of value and impact.

THE ENABLING TECHNOLOGY

Exposing students to more modern technology has traditionally required complex equipment. In order to see time-varying voltages it is necessary to have a function generator to create and an oscilloscope to measure voltages. A variable power supply provides control over DC voltages while supplying larger currents. One set of this equipment could cost approximately $10,000-$20,000, which is well out of reach of most public school systems. Fortunately, cost-effective portable electronic instrumentation solutions exist such as the Digilent Analog Explorer system and the Analog Discovery System. While these devices are not as accurate or powerful as the more expensive equipment, they are more than sufficient for simple experiments. In fact, many of these devices are being used in undergraduate engineering courses.

These instrumentation systems provide varying levels and numbers of power supplies, oscilloscope channels, and function-generator outputs and are controlled by software that runs on a PC. The Digilent Analog Explorer device was chosen for this STEM program because it has a built in prototyping board, user friendly software, sufficient resources for complex

This work was supported by a grant from the Tellabs Foundation.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

experiments, and the highest wattage power supply available that could drive small motors and incandescent lamps. A separate PC is required to control the instrumentation, but the cost of a sufficient PC laptop is approximately $300. A single complete instrumentation station that was used in this program cost approximately $600 and consisted of 1 laptop, 1 Digilent Electronics Explorer system, 1 DMM, and a parts kit. For approximately $6000, a classroom for 20-30 students can be supplied with 10 stations.

Development of the Current program

During the development of this program some important issues arose that morphed the original idea into the final program. Through an odd turn of events, this program began with funding that had no plan or proposal. The original plan was developed between Mario Simoni and Glenn Cook to work with teachers on an individual basis. This original plan focused on the Vigo County School Corporation because of its vicinity to Rose-Hulman. As such, regular face-to-face meetings between the engineering faculty and 6-12 grade teachers were possible. The goal was to involve as many middle- and high-school math and science teachers as were interested in a week-long workshop that would demonstrate how the technology could illustrate concepts from the state curriculum map. Because the equipment is so portable, this plan called for mobile sets of equipment that could be moved between classrooms and schools for whichever teachers wanted to use it. A proposal was written and submitted to the Tellabs Foundation in order to keep the funding.

The proposal was accepted by the Tellabs Foundation, and, eventually, the Vigo County school board was involved because of the need for corporate wide participation of teachers and resources. The board saw several problems with this original proposal. First, there were limited resources to move equipment between schools, and it was feared that equipment would be lost or broken in the process. With a lack of clear ownership they feared that the equipment would not be properly cared for. The equipment then had to be permanently located at specific schools. Second, the 6 middle schools and 3 high-schools had to be treated equally, meaning that all 9 schools had to receive the same amount of equipment. The grant was insufficient to do that for 9 schools. It was decided then to focus on just the 3 high-schools. Third, it was stated that there was no room in the math curriculum for teachers to supplement with other activities. The math teachers had been told on a daily basis what had to be covered in class and how to cover it. It was decided then to focus on physical science classes, for which there was only one teacher per high-school. Fourth, because of the teacher union, it was required that we pay the teachers at the standard rate for all meetings attended.

During the first year of the grant, the 2 large high schools (> 2000 students), North and South, were supplied with 10 experimental stations each and the smaller higher school, West, (approximately 600 students) with 6 stations. Initial meetings with the three teachers revealed a diverse set of backgrounds. Two teachers had Physics Education degrees, but the third received a physics teaching certificate from a summer course. One teacher had previous experience with amateur radio and building circuits, another was familiar with basic concepts in electricity and magnetism from college courses but did not feel comfortable enough to go into detail in the classroom, and the third had very limited experience with any technology. The three teachers were very willing to participate in the program, but requested as much training as possible in order to feel comfortable teaching the concepts and using the equipment.

The teachers wanted to be able to understand and perform much more complex experiments than what the students would do. Monthly meetings between the three teachers and engineering faculty began in August before classes began and continued throughout the year. The Physics and AP Physics courses did not begin electricity and magnetism until the spring, so there was time to develop confidence. Each of these monthly meetings lasted approximately 1 to 1.5 hours. They typically began with a discussion of a concept and the physics behind it, which then led to the construction and testing of a circuit on the instrumentation system. The teachers were able to verify their understanding of the concepts and learn how to use the instrumentation under supervision. The discussion then led into how these activities could be adapted for use in the high-school courses. Topics that were covered during these meetings included voltage, current, Kirchoff's laws, time constants, different types of capacitors, inductors and transformers, diodes and LEDs, transistors, operational amplifiers, frequency and waves, and oscillators

The second year's goal was to involve other schools in order to test the program with more varied conditions and begin developing a community of experienced teachers. In the summer of 2012, six additional high-school physics teachers from across the state of Indiana were invited to become part of the program. Of the six teachers, two were chosen from large high-schools, two from medium-sized schools, and two from smaller more rural schools. Each school was given a number of stations according to the size of the school. The teachers participated in a 2 day workshop that was held at Rose-Hulman Institute of Technology. During the workshop, the new teachers were introduced to the equipment and electronic components; exposed to concepts in electricity and magnetism; instructed on practical matters such as how to wind inductors and soldering; and how to use operational amplifiers. During the evening, the teachers were given the opportunity to design their own experiments using the equipment, and were able to generate 4 new experiments that had potential for lesson plans. The workshop ended with a discussion about assessment, but nothing tangible came of the discussion.

After the summer workshop, approximately monthly online meetings were made available to all 9 teachers. These meetings were met with varying levels of success and participation. One challenge was that the software being used, Microsoft Lync, had bugs and many teachers had firewall problems at their school. Despite the difficulties, we still met 6 times during the academic year. Prior to each meeting the teachers were given a circuit to build and test and during the meeting, the circuit and concepts were discussed and any problems or questions that were encountered were addressed. The Lync software permitted sharing of video feeds and computer screens among all participants, which greatly aided in debugging circuit problems or answering questions about the equipment.

THE LESSON PLANS

There are several levels of physical science education in the Indiana Public School system. At the most basic level is the Integrated Chemistry and Physics (ICP) courses for students who have little to no interest in entering science fields. The next level up is the Physics course and then at the highest level are the AP Physics courses. For the ICP and Physics courses the required daily curriculum is provided by the state, but there is a little more flexibility for the AP Physics courses to augment the curriculum. The rigidity of this schedule means that, especially for the lower level courses, any developed lesson plans must apply directly to the state curriculum and not cause the teachers to fall behind the lecture schedule.

There are already many online training materials and lesson plans available for the Digilent systems. However, most of these materials were designed with the undergraduate engineering student and faculty member in mind and assume a certain level of proficiency with the concepts and technology. As such, while the actual lesson plans that were developed for this program may be similar to the ones currently available, the presentation must be altered significantly to account for the audience. In order to prepare the students for the experiments, it was found very helpful to provide them with a photocopy of the breadboard so that they could draw the components on the paper with the proper wiring. This paper could be collected and graded prior to performing the experiment.

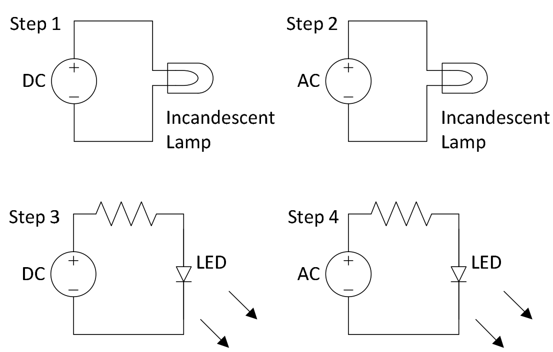

Fig. 1: Schematics associated with a lesson plan.

One of the first experiments that was created consists of a lamp, an LED, and a resistor as shown in Figure 1. In the first part of the experiment, the students connect a single Christmas-tree light bulb between the power supply and ground. The advantage of this equipment, is that students now have control over more variables. The students can vary the voltage while measuring the current and see the results in real time. Then they can record the data and plot the results, tasks which are crucial to high-school curriculum. In the second step, an AC voltage can be connected to the function generator and a low-frequency sinusoidal voltage is applied so that the light is seen to repeatedly turn on and off. Students can gain much intuition by changing the amplitude and frequency of the voltage. For more advanced classes, the lamp can be switched to an LED and resistor. When the same voltages are applied, the students will measure a much lower current, showing that much less energy is required to generate the same amount of light. When an AC source is used to drive the LED, the directionality of diodes can be discussed.

RESULTS AND IMPROVEMENTS

The equipment provided to the schools has been used in all levels of the physical science courses. The simple light-bulb experiment was done in an ICP course. The teacher reported that many students became excited about the technology and wanted to learn more. At the Physics and AP Physics level students performed experiments with time constants and LEDs in series and parallel. Other groups were able to measure Plank's constant by looking at different colored LEDs.

Two key events stand out as somewhat measurable results. At Terre Haute South High School, the average score on the electricity and magnetism portion of the AP Physics test from 2007-2011 was 55%. In 2012, the first year of this program, the average score was 72%. This is a single point of data and there are many variables involved, but the verbal feedback from the teachers indicated that this program did have some impact. From Terre Haute North a student was able to use the instrumentation for his science fair project to construct a pill dispensing system. The following year this student enrolled at Rose-Hulman as a mechanical engineer, but expressed a new-found interest in a double major with electrical engineering.

Before the program can be expanded further, some important improvements need to be made. First, the two day workshop needs to be expanded to a weeklong workshop. While the online meetings help, many of the teachers still feel insecure about using and experimenting with the technology. The workshop should also occur closer to the start of the school year, so that there isn't so much time to forget everything that is presented. Second, each lesson plan needs to have much more detail including the underlying physics. Separate lesson plans with additional content need to be provided for the teachers.

Ideas for assessment tools have been expressed, but still need to be developed. Scores from the AP Physics test can provide historical data and a measure of change. Quizzes and surveys to be done prior to and after doing an experiment can provide a better evaluation of individual lessons. Care must be taken to not overload the students. Enrollment statistics from the involved high schools could provide some measure of how many students are entering undergraduate electrical engineering programs.

Using LEGO Mindstorms to Engage Students on Algorithm Design

Ainhoa Álvarez, Mikel Larrañaga
Department of Languages and Computer Systems
University of the Basque Country, UPV/EHU
Vitoria-Gasteiz, Basque Country
{ainhoa.alvarez, mikel.larranaga}@ehu.es

Students on *Basic Programming* courses often have difficulties with program design tasks. This problem mainly arises from their lack of program solving skills. To overcome this lack, students' need to practice. Manipulating real entities can be a useful and motivating strategy to engage students in such endeavor. In this context, several authors have used *LEGO Mindstorms* robots to help students on basic programming courses. In this paper, we present the results obtained from an experience conducted on a *Basic Programming* course using those robots to motivate students and to involve them in algorithm design.

Basic Programming; increase student motivation; LEGO Mindstorm

I. Introduction

Basic Programming is a first year mandatory course for the *Computer Engineering* degree at the University of the Basque Country (UPV/EHU). This course is the first contact many students have with programming, which is an essential and core topic of the degree. This course primarily centers on providing the students with the essential programming skills, giving a great importance to the analysis and algorithm construction phases using both pseudo-code and flow charts.

Despite being aware of how the *Basic Programming* course relates to *Computer Engineering*, students may feel disappointed as algorithm construction, and especially some of the proposed exercises, are far from what they expected from the course. Therefore, engaging students on algorithm design is a hard task as most first year students are not aware of its relevance, and are expecting to start coding as soon as possible. Moreover, some students already have some programming experience and it is still even more difficult to motivate them on design tasks. These facts might be some of the main reasons for first year students to drop out of the course.

LEGO Mindstorms are programmable robots aimed at fomenting reflection, analytical thinking and problem-solving skills in children. They are provided with a graphic environment that allows programming the robots to perform simple tasks by means of graphical elements similar to those of flow charts.

Our working hypothesis is that using this kind of robots in *Basic Programming* can lighten the learning curve for newcomers on programming and might also increase the motivation of the students. To evaluate this hypothesis, the authors have been using *LEGO Mindstorms* robots for two academic years in the *Basic Programming* course. After the positive comments received from students and the perception of the teachers the first year, a more detailed experiment has been developed on the second year. The results of that experience are presented throughout this paper.

The paper is organized as follows: first, some preliminary experiments on using *LEGO Mindstorms* for programming courses and how they might improve learning are described. More details of the *LEGO Mindstorms* are procured in Section III. The conducted experiment is depicted in Section IV. The results and discussion of this experiment are presented in Section V. Finally, the conclusions and future work are portrayed.

II. LEGO Mindstorms for Programming Courses

To master *Basic Programming*, students need both declarative and procedural knowledge. The first one is related to the syntax and semantics of programming languages and the second is related to problem solving and program design skills [1]. The main problem students have is related to the second kind of required knowledge; their problem begins at the first phase, when "*Students have to understand and apply abstract programming concepts to create algorithms to solve concrete problems*" [2].

A main solution for this learning/teaching process is to help students to obtain a good problem solving basis [2] to which end practicing is essential [3].

Considering these statements, several efforts have been carried out using *LEGO Mindstorms* robots as a means to increase students' motivation, interaction and retention [4], [5]. These experiences indicate that students acquire basic concepts in an easier way using robots [6].

It is worth mentioning that some authors have done studies in which the robots were used for all the practical sessions of the course and the obtained result was that students' using the robots had even worse results than those obtained by the

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

control group [7]. However, the authors consider that this was mainly because the students on the experimental group could not bring the material home; therefore, they could not think over and reflect that much on the exercises. According to [5], iconic environments appear to be better for the initial learning stage but later that advantage is lost. Therefore, we have not introduced the robots for all the course practical sessions but for the first two, which were especially devoted to algorithm design.

III. LEGO MINDSTORMS ROBOTS

LEGO Mindstorms are programmable robots aimed at developing analytical thinking and problem solving skills through gamification, i.e., the use of games in non-game context to engage students in learning.

LEGO Mindstorms kits contain both the hardware and the software that can be used to create and program robots. The main element is the NXT brick, which allows controlling the set of modular sensors and motors installed.

Fig. 1 shows one of the robots used for the experiment. It was constructed using three servo motors and three sensors: ultrasonic, color, and touch sensors. It also shows some elements that were used on the exercises of the experiment. In particular, in the illustrated exercise the robot had to move towards the barrier and hit the blue ball.

Students used the NXT-G graphical environment, provided with the *LEGO Mindstorms* kit, aimed at programming the robots to perform simple tasks by means of graphical blocks (see Fig. 2). The graphical blocks can be attached together to construct programs. The NXT-G environment includes support, among others, for control statements, simple procedures and variables. Fig. 2a shows the representation of a conditional block, whereas Fig. 2b presents an iterative one. Parameters for each structure can also be defined. For example, we can state that a certain action is carried out when a certain time has elapsed (Fig. 2c) or when a sensor detects certain situation, e.g., a distance to an object is smaller than a particular value or certain sound is detected (see Fig. 2c).

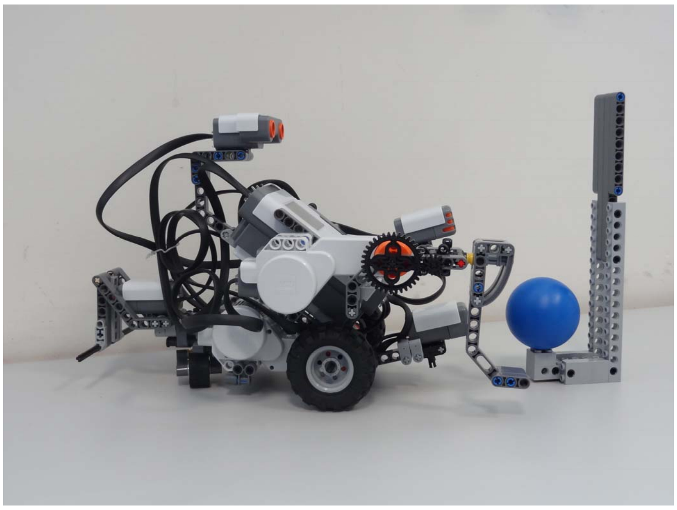

Fig. 1. LEGO robot used for the experience

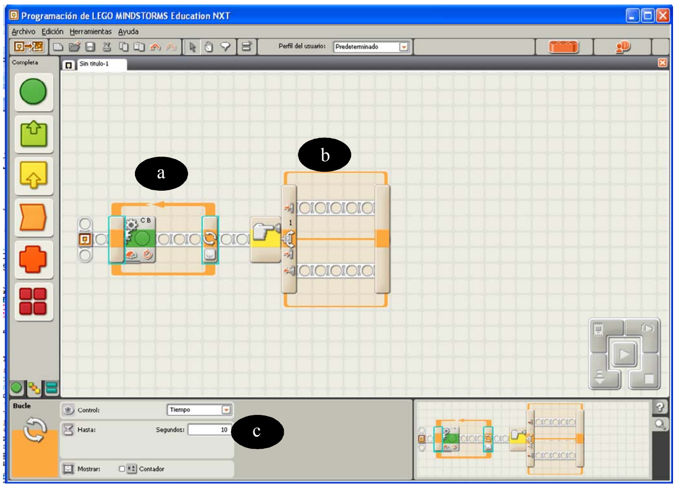

Fig. 2. LEGO robots graphical environment

IV. EVALUATION EXPERIMENT

As mentioned above, this work relies on the hypothesis that the use of the LEGO robots may lighten the learning curve for newcomers in programming and may also increase the motivation of the students. The experiment here described has been conducted to prove the working hypothesis. Following deeper details on the experiment are provided.

A. Objectives

The general aim of this work is to improve the teaching of *Basic Programming*. In this experiment, we have focused in the use of robots in the first phase of the course to engage students by increasing their motivation and to improve their skills in algorithm design construction. Therefore, the four specific objectives of the experience have been:

- **O-Motivation**: Study how the experience affects students' motivation.
- **O-Perception-S**: Study students' perception of the learning process using robots
- **O-Improvement**: Identify improvements derived from the use of the robots in students' algorithm design construction.
- **O-Perception-T**: Analyze the teachers' perception about how the use of the robots influence the students' learning process.

B. Used Tools/Techniques

The experience presented throughout this paper has been evaluated using both qualitative and quantitative methods. Quantitative methods allow statistical analysis to be applied to data results by limiting the set of answer categories for each question. On the other hand, qualitative methods give more freedom to users by using inquiry techniques, e.g., open questions, interviews, surveys, observation or logbooks. These techniques allow participants to give their personal opinions. Although qualitative results are more difficult to analyze, they are able to capture users' subjective perspectives. Therefore, a combination of qualitative and quantitative evaluation methods [8] has been used.

To evaluate the motivation, both surveys and interviews have been conducted. Knowledge improvement has been measured by two classic means: pre and post-tests, and experimental and control groups. The first involves the same subjects in pre- and post- tests, which are developed before and after the use of the tool; the second splits up the subject set into two groups, those who used the robots (*experimental group, G_Experimental*) and those who did not use it (*control group, G_Control*).

C. Procedure

The experiment followed the sequence of six steps illustrated in Fig. 3.

Step 1: To test students' prior knowledge, they were requested to answer a short questionnaire about their background on programming. Next, students were provided with the problem shown in Fig. 1 and requested to indicate how they would solve it. After that, answers of the exercise were analyzed to evaluate whether they were capable of identifying the correct step sequence, and had properly used the conditional and repetitive structures. This step was carried out the first day of the course with students on G_Control and G_Experimental groups.

TABLE I. PRETEST EXERCISE

You want to paint all the rooms of your flat. Take into account that you may need several coverings of paint to vanish all the spots. The paint has to dry before the next covering and the employed tools must be properly cleaned. Specify the steps needed to carry out the described task.

Step 2: Being the experiment oriented towards improving algorithm design skills, no emphasis was given to the robot construction. Therefore, students were provided with already constructed robots (such as that shown in Fig. 1). In this step, these robots and the software to be used were presented to the students.

Step 3: During two 90-minute laboratory sessions, the students were provided with the robots and the set of problems to be solved (see example in TABLE II.). They had to design the programs using the provided software and then load the program in the robot and execute it to test the program performance.

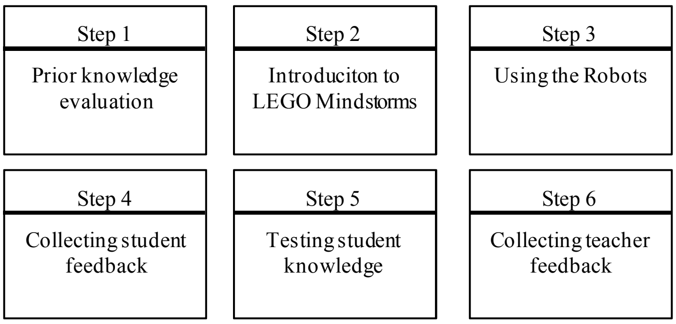

Fig. 3. Step sequence for the evaluation

TABLE II. PROBLEM EXAMPLE

Given the robot and the objects shown in Fig. 1, design the program that enables the robot to perform the following task: it must move forward until it is close enough to hit the ball. Then, the robot must check whether or not the ball is red. If the ball is red, the robot will raise the hand and hit the ball. Otherwise, it will move backwards and play a sound.

Step 4: Two instruments were used to collect the students' feedback: logbooks and surveys. Students were encouraged to fill in a logbook (Fig. 4) to describe both the problems they had and every impression or perception about the experience.

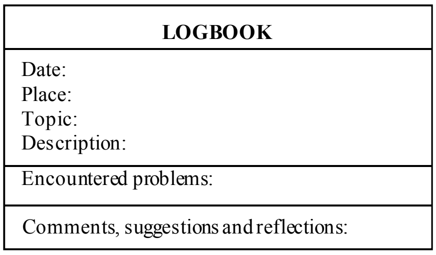

Fig. 4. User logbooks for recording comments, suggestions and reflections

In addition, a survey was used to evaluate the achievement degree of the objectives of this work, in particular the O-Motivation goal. TABLE III. shows an excerpt of the survey used for this work. The survey entailed 13 five-level format Likert items [9], two yes/no questions and an open-ended question. The yes/no questions were aimed at identifying if the students felt disappointed with the use of the robots whereas the open-ended question allowed us to gather more detailed information of their opinions [10].

TABLE III. EXCERPT OF THE SURVEY USED TO COLLECT FEEDBACK FROM G_EXPERIMENTAL STUDENTS

		1	2	3	4	5
1	Did you find it easy to use the software?					
	O-Motivation					
2	Using the robots has increased my motivation					
3	Using the robots has made the course more interesting					
4	Using the robots has helped me identifying the course usefulness					
5	Would you have preferred not to use LEGO robots?	**YES/NO**				
	O-perception					
6	Using the robots has helped me understanding conditional statements					
7	Using the robots has helped me understanding iterative statements					
8	Using the robots has helped me learning design concepts					
9	Additional comments or suggestions regarding the experience					

The Likert items were oriented to measure the motivation of the students (O-Motivation), along with their perception of how the use of the robots might have influenced the learning of basic programming concepts such as variables, conditional, or iterative statements (O-Perception-S). Considering that the usability and difficulty of the employed software might influence the students' motivation and perception, question 1 was included to measure this issue.

Information from the students on the control group (G_Control) regarding the feelings transmitted by the students on the Experimental group (G_Experimental) in relation with the experience was also collected. To this end we used a survey with two questions (see TABLE IV.).

TABLE IV. EXCERPT OF THE SURVEY USED TO COLLECT FEEDBACK FROM G_CONTROL STUDENTS

		Yes	No
1	Would you have preferred to used the robots?		
2	Have any comments from your classmates on G_Experimental motivate your answer to question 1? Which ones?		

Step 5: The course evaluation follows a continuous process where the students have to sit for three exams. The first one is composed of a set of questions that ask students to develop the program design for a certain number of problems. The results of this first exam have been used to evaluate the knowledge improvement of students.

Step 6: Teachers lecturing practical sessions fulfilled a logbook (see Fig. 4) to describe the discovered problems and their impressions and perception about the whole experiment

D. Participants

Students enrolled in the Basic Programming course are usually very heterogeneous; ranging from students with no prior knowledge on programming to those repeating the course. Besides, some students have attended programming courses outside the university, which mainly focus on syntax learning and give no emphasis to problem solving. Therefore, those students are highly confident in their programming knowledge, but lack algorithm design skills.

Students were randomly divided into two groups: the experimental group, which used the Robots (G_Experimental), and the control group (G_Control), those who did not used them. Therefore, using the robots was not elective for students.

G_Experimental had 14 students taking the course for the first time and 8 were retaking the course. On G_Control 9 were taking the course for the first time and 13 were repeating. This shows the heterogeneity of the groups, which has also been confirmed with the analysis of the pretest exercise.

V. RESULTS AND DISCUSSION

The results obtained in the experiment are presented throughout this section.

As mentioned above, the usability of the employed software can influence the students' performance and perception. To this end, question 1 (*"Did you find it easy to use the software?"*) was included. In general, students' found the provided software easy to use; only 22.7% of students indicated that had some problems with it (see Fig. 5).

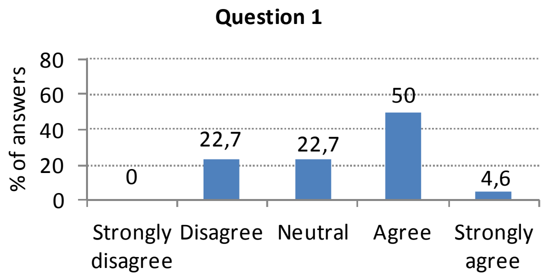

Fig. 5. Answers to survey question 1 –"Did you find it easy to use the software?"

Next, the results for each defined evaluation objective, i.e. O-Motivation, O-Perception-S, O-Improvement, and O-Perception-T, are described

A. Results regarding how the experience has influenced students motivation

From answers to question 2 *("Using the robots has increased my motivation")* and 3 (*"Using the robots has made the course more interesting"*) related to motivation and interest of students, we can derive that students were motivated and interested because of the use of the robots (see Fig. 6). 59.1% of students indicated that their motivation had highly increased due to the use of the robots; moreover none of the students answered that using them had not increased their motivation (Fig. 6 a). Similarly using the robots greatly increased 68.2% of students' interest in the course (Fig. 6 b).

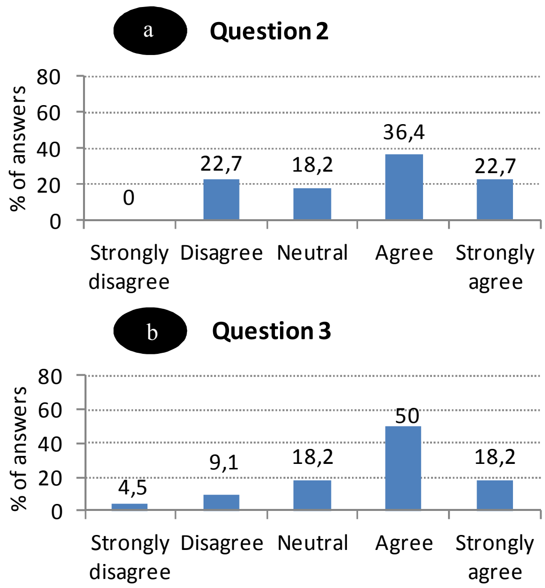

Fig. 6. Answers to survey question 2 "Using the robots has increased my motivation" and 3 "Using the robots has made the course more interesting"

Furthermore, students were asked if the robots had contributed to better identify the usefulness of the course in question 4. Regarding this question 91% of students agreed with this assertion (see Fig. 7 a)

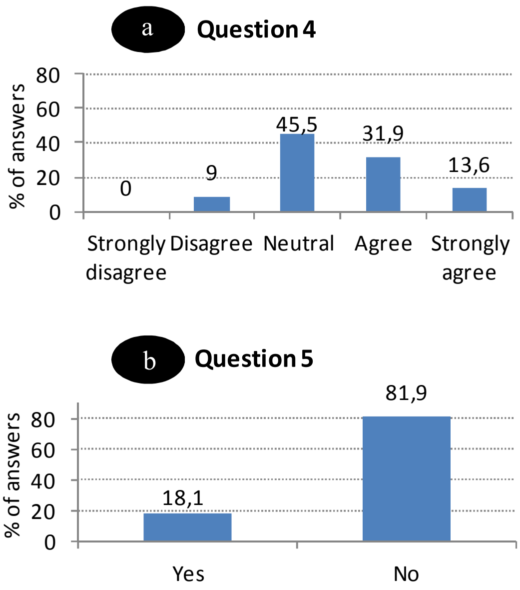

Fig. 7. Answers to survey question 4 "Using the robots has helped me identifying the course usefulness" and 5 "Would you have preferred not to use LEGO robots?"

For evaluating the O-Motivation objective we also took into account the answer to the survey of students on G-Control. 68% of students on this group would have liked to use robots. This value increases up to 100% for newcomers. The main motivation for these answers were the comments heard from students on G_Experimental indicating, for instance, that using the robots *"was entertaining, pleasant and had increased their interest in the course "*.

In accordance with this, only 18.1% of students (see Fig. 7 b) indicated that they would prefer not to use the robots (Question 5 on the survey, *"Would you have preferred not to use LEGO robots?"*). However it is worth noting that the students preferring not to use them were the ones retaking the course.

B. Students perceptions

Students' knowledge awareness is essential for the learning process. Therefore the survey included some questions for analyzing the students' perception of their learning process using robots.

Only 18% of the G_Experimental students stated that using the robots had not helped them much in learning design concepts (Question 8). None of them considered that the robots were useless (see Fig. 8).

More specifically, students' were asked whether they felt using the robots had helped them in understanding the concepts of conditional (question 6) and iterative (question 7) statements. Regarding conditional statements, 50.1% of the students thought that it had helped them, 22.7% did not have it very clear (Fig. 9 a) and 27.2% indicated that it did not help them. For iterative statements, 45.5% indicated it had helped them, 22.7% did not have it very clear and it did not help 31.8% of students (Fig. 9 b).

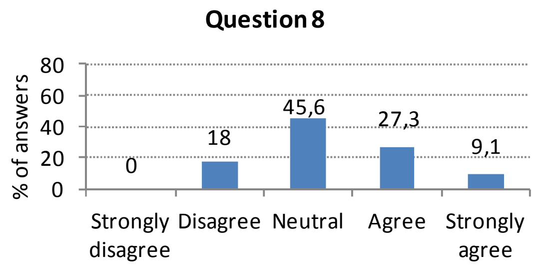

Fig. 8. Answer to survey question 8 "Using the robots has helped me learning design concepts"

In the open-ended question (Question 9, *"Additional comments or suggestions regarding the experience"*), students provided positive feedback associated to their perception. They pointed out that *"my classmates not using robots, progress more slowly than those using them"* and *"is a useful means to introduce newcomers programming concepts"*.

C. Learning improvements

A statistical analysis has been conducted to determine the impact of the use of robots in the students' learning process.

A between-subjects study [11] has been carried out, comparing the marks obtained by students using robots (G_Experimental) with the marks of those not using them (G_Control). For this analysis both posttest and final marks have been considered.

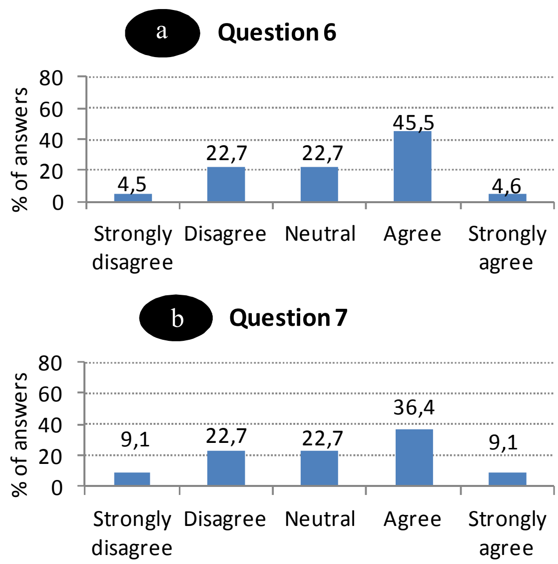

Fig. 9. Answers to survey question 6 "*Using the robots has helped me understanding conditional staments*" and 7"*Using the robots has helped me understanding iterative statements*"

The average marks have been compared and the Wilcoxon test has been applied to check the significance of the average differences.

The obtained results have not shown any statistical significance between the groups; although teachers expected that the robots would improve the students' marks.

D. Teachers' perceptions

Teachers participating in the experiment have detected an increase on students' motivation and improvement of classroom atmosphere. G_Experimental students were more active and participative in the practical sessions with the robots; this continued for the rest of the term.

Teachers observed that G_Experimental students were able to properly use conditional and iterative statements much earlier and easily than G_Control group students. Therefore they expected more positive answers to questions related to objective O-Perception-S and better exam marks on G_Experimental.

VI. CONCLUSIONS

This paper has described the experiments carried out with LEGO Mindstorms robots on the 2012-2013 academic year on the *Basic Programming* course at the UPV/EHU. 44 students and 2 teachers have participated on this experience that has been focused on four objectives: O-Improvement, O-Motivation, O-Perception-S and O-Perception-T.

Concerning O-improvement, the results show that there have not been significant differences between the groups. The use of robots has not improved students' mark but has neither decreased them as in the experiment presented in [7].

Analyzing the survey results, G_Experimental students were highly motivated and interested using robots. G_Control students express that they also would have preferred to use the robots.

G_Experimental students perceived that using the robots helped them to learn programming design concepts. Similarly teachers also observed that G_Experimental students were more engaged with the design aspects. All this improved the classroom atmosphere.

The obtained results encourage us to continue the experience for the following academic years. However some difficulties inherent to the use of physical devices have been detected: factors related to the movement of the robots and rooms' light conditions. Aspects such as the different surface frictions (for example on the table or on the floor) or the battery load affected the movement of robots. In addition, the lightening of the room was not homogeneous so the parameters for discovering whether a ball was blue or red varied from one place to another in the room. Therefore, exercises must be designed considering these factors.

Due to the motivation increase produced by LEGO robots, our objective for the next academic year is to continue using them in the *Basic Programming* course. However, the approach must be enhanced to appropriately tackle the O-Improvement objective. Therefore, a deeper analysis of the number of laboratory sessions to use robots in must be conducted. Also, given that the students of the course are very heterogeneous (e.g. newcomers or repeating students), they should be classified using a more exhaustive pretest in order to adapt the proposed exercises to specific student characteristics to improve their performance.

Acknowledgments

This work is supported by the Basque Government (GIC12/79) and the University of Basque Country (UFI11/45). We thank the students of the Computer Engineering degree at the UPV/EHU in Vitoria-Gasteiz that participated in the experience.

***Abstract*—The concept of "Internet-of-Things" will undoubtedly emerge as the technology of the future. Educating specialists ready to bring the concept to the reality remains challenging in the scope of traditional university courses. The main challenge is how to enable students to think outside the boundaries of the particular discipline and therefore to enable the innovative thinking. This article describes an experiment with teaching Internet-of-Things as a common red thread across three courses which ran in parallel during fall semester 2012 at Luleå University of Technology in Sweden. We discuss the teaching methodology, the technology blocks which laid the ground for our teaching philosophy as well as the experiences and lessons learned.**

I. INTRODUCTION

While the term "Internet of things" (IoT) was coined for quite a while now, a systematic education of specialists in this area has not yet taken off. Traditionally, courses in Computer Science programs at universities offer a standard set of disciplines focusing on specific aspects of the IoT technology. The courses vary from different flavors of hardware-near "Wireless Sensor Networks" classes to higher-level "Web-Design and Service Oriented Architectures" and similar. The demonstration of a place of the particular discipline in the holistic view of the IoT universe is often rather vague and in many cases is limited to one or two theoretical classes discussing problematics of adjacent subjects. This is in no way a surprising situation. Prior to all, the IoT concept only now starts to grow out of its embryonic, academic research phase. It is today it begins to be filled in with specific implementations.

One message is important to convey to students already now - the future of IoT technologies is about: a.) Innovations; b.) Cross-disciplinary knowledge; and c.) Multi-face programming. These principles formed the ground for an educational experiment conducted at Luleå University of Technology in the fall semester of 2012. During the experiment, further in the text referred to as *triple-run*, three courses of the Computer Science program were aligned in their theoretical and practical parts to convey a holistic view of an IoT ecosystem. The classes were taught in parallel.

The theoretical content of the three courses allowed creating a scenario covering the entire technology chain of the Internet of Things: gathering and communicating sensory data; scalable and distributed processing of big data; value-added, human relevant network services. In the practical part students in the three classes (60 in total) acted as startup companies in the respective technology domain. These startups were assigned a task to deliver a common holistic system given time, performance and budget constrains. This task required students in a particular course to constantly communicate to other students outside the courses boundaries. In particular, through these activities students were trained on skills for industrial level development and integration of complex IT systems and innovative thinking by exploring problems, methods and solution spaces of each other.

On the technical side the triple-run experiment was conducted using Amazon Web Services [1] as a common computing platform. This choice allowed us to draw interesting conclusions about students work load, the degree of their actual involvement in the learning process as well as the cost of the triple-run. A pedagogy-oriented and close-to-reality real-time simulation environment was used in Wireless sensor networks course included in the triple-run experiment to substantially facilitate experimentation with large quantities of communicating sensors. This simulation environment is our main technical contribution supporting teaching of principles and advances of "communicating things".

The article is organised as follows. Section II elaborates the theoretical background and the related work. The syllabi of the courses under the experiment are summarised in Section III. The scenario behind the triple-run trial is described in Section IV. Section V presents the technology blocks used in the experiment. We present our reflections and outline future developments in Section VI before concluding the article in Section VII.

II. THEORETICAL FOUNDATION OF THE TRIPLE-RUN EXPERIMENT AND RELATED WORK

It would not be a big discovery to make that one of the largest motivating factors for today's Computer Science students is their excitement about the success of young innovators behind such IT giants as Facebook, Google, Skype and similar. The key to success is on the one hand evident: It is the innovative thinking, entrepreneurship and team-work. On the other hand, it is less evident how to foster such skills in the framework of the traditional education system.

The importance of empowering students with tools and opportunities to exploit the knowledge and to stimulate self-learning is reflected in many sources on modern methodologies in higher education. For example, [1], [2] asserts that by giving students tools, guidance and freedom as part of contextual understanding the educators encourage both innovation and the spirit of entrepreneurship. Commonly a range of student-centered education methods where learning is supported by projects, problems of discovery nature and just in-time teaching is referred to as *inductive education* [3]. The goal of

TABLE I. SUMMARY OF COURSES' SYLLABI *before* THE TRIPLE-RUN EXPERIMENT

	Courses		
	D7015E	D7001D	D0036D
Credits	7.5 ECTS		
Level	Graduate. First year of MSc.		Undergraduate. Second year.
Goal	The student should know fundamentals of modern short range radio transmission technologies on all layers of the communication stack and the specifics of WSN network architecture like data-centric communications, in-network processing, etc. The student should be able to understand research articles in selected areas of the course and be able to present their analysis for a wider audience. The student should develop skills of modeling an advanced networking functionality as well as developing it in one of the main-stream operating systems for WSN.	The student should understand the fundamentals distributed networked applications, e.g. in-depth understanding of threads and associated performance problems, fundamentals of fault detection in distributed application, etc. The student should be able to understand research articles in selected areas of the course and be able to present their analysis for a wider audience. The student should master the skills of programming of parallel events with threads, timers, counters and communication security in Java programming language.	The student should understand fundamentals of network programming including relevant aspects of TCP/IP stack, main communication paradigms, basics of threads, sockets and remote method invocation. The students should develop skills of programming a simple to medium complex network functionality, e.g. a threaded TCP server and a simple networking computer game with in-advance prepared skeleton of the functionality.
Structure	In-class lectures, student seminars and practical work.		Lectures and practical work.
Examination	Continuous examination. Final score is computed as a weighted average of the score in three examination moments: Labs, Seminar and Mini-project.	Traditional closed book final written exam.	

inductive education is to develop essential social and teamwork skills [4] by tackling real-world and open-end problems [5] which is is highly appreciated by students [6].

In our triple-run experiment we combined the inductive collaborative learning approach with the product-based learning. One of the important goals set to students were understanding project management and production processes. This approach applied previously in computer science education [7] showed positive results and is highly valued by industry.

Finally, we followed concepts of *adaptive expertise* or *deep learning* [8], [9] enabling students to motivate their solutions both from the technology and economical perspectives.

A. *Related work*

Clearly, we are not alone looking at the problematic of educating innovators of the future Internet of Things. A very recent work (as of February 2013) from the Open University in the UK [10] build their education approach using similar motivation. The work also includes the references to other world-leading schools in the US and Europe being active in the development of the IoT directed education lines. While sharing common objectives and parts of the methodologies our experiment described in this article is, however, different in several important ways:

1) We are not developing a single overview course, instead we make students from three focused courses to interact and collaborate with each other in the scope of a common IoT vision.
2) We target students with diverse backgrounds aligning the courses on the second year bachelor and the last year master levels. This step allows students on lower education stages to get insight to the diversity of problems considered at higher stages.
3) We do not use play environments, our students work with real software and hardware platforms which they later on meet on the job market.

The key points listed above make our experiment a unique contribution to the methodology of education in the area of the Internet of Things.

III. COURSES UNDER EXPERIMENT

The courses selected for the triple-run experiment were: Wireless sensor networks, further referred to by its catalogue code D7015E for brevity reasons; Network programming and distributed applications, further referred to as D7001D; and Network programming, further referred as D0036D. In the Swedish education system an academic year is divided in quarters (teaching periods). The duration of each quarter is 2 months. A regular course span over one quarter. The triple-run experiment was conducted in the first quarter of 2012 starting from the last week of August and ending with the exam week on the last week of October. Table I summarises relevant aspects of the courses' syllabi as of before the experiment. While the theoretical part and the goals of the syllabi remained unchanged, the practical part and the emphasis of the courses was shifted to IoT enabling technologies.

By the time of the experiment the D7015E course was given at two occasions in 2008 and 2010. The previous results of the course evaluation for both occasions were positive. On a methodology side the students highly evaluated the continuous form of examination, highlighting that this examination form assisted them in pacing their learning process properly and overly contributed to better learning. On a criticism side the students continuously highlighted difficulties with time-consuming programming and debugging of the code on real wireless sensor devices in foreign for them development environment. During the triple-run experiment we decided to adopt the continuous examination form in all three courses.

The common to both D7001D and D0036D courses problems were shortcomings associated with lab infrastructures required to perform the practical parts. Although both courses are based on Java programming language, proper access rights to low-layers network configuration facilities were needed. In many cases students resorted to experimenting with very

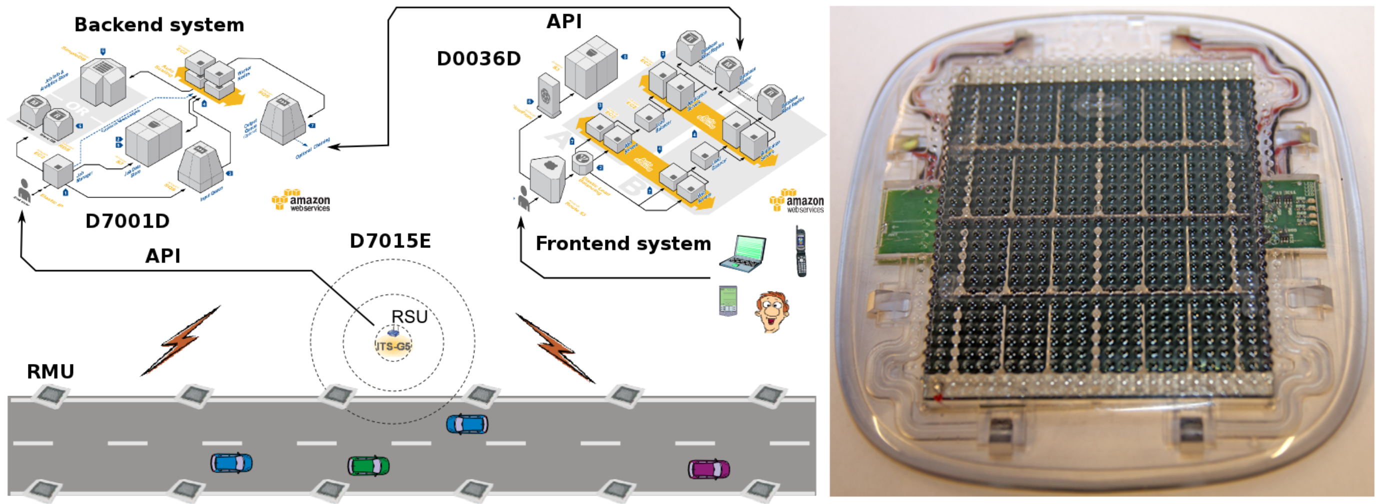

Fig. 1. A graphical representation of the scenario for the triple-run experiment.

simple network topologies basically consistent of their own computers (where they had the appropriate rights) and few hosts in the university network. In general, we the course instructors experienced major differences in developing non-trivial practical scenarios linking to the theoretical content of the course. The typical course-book-like code examples constantly raised students' critique as missing sufficient connection to real-life applications. The major change in the syllabi of the D0036D and D7001D courses was introducing the "Cloud" and the "Internet of Things" topics as the main themes both into their theoretical and practical parts. Looking ahead, by performing the practical part of the courses in the Amazon Web Services environment lifted up students' satisfaction and their experience of programming networking functionality dramatically.

IV. The *triple-run* structure

The theoretical content of three courses described above allowed creating a scenario covering the whole technology chain of the Internet of Things: gathering and communicating sensory data; scalable and distributed processing of Big Data; value-added, human relevant network services.

A. Common IoT scenario script

The offered to the students common IoT scenario is rooted in the ongoing at LTU research project iRoad[2]. In short the project aims at enabling a non-intrusive and anonymous detection of vehicles using on road sensor networks [11]. The core of the iRoad technology is a specially designed *Road Marking Unit*, which is shown in the right part of Figure 1. It consists of a wireless sensor unit built on 16-bits Renessas microcontroller and put in a specially designed robust polymer casing resistant to overriding by heavy vehicles. The RMU is equipped with a magnetometer sensor and a ZigBee-compatible low power radio transceiver. Technologically, the RMUs are thermally glued onto the road surface. After that they detect vehicles by sampling the readings of the magnetometer. The samples are then transmitted via a gateway serving several such RMUs to a powerful computing backend system for advanced signal processing and execution of application-specific functions. While in the scope of the project we performed installations with several tens nodes[3], within the triple-run experiments we let students to work with virtually unlimited number of such sensors generating realistic traffic.

The overall concept behind the triple-run application scenario is shown in Figure 1. The students in the three courses were treated as start-up companies getting a contract to develop a part of the global IoT system. In particular, the start-up of the D7015E course was responsible for organisation of communications from RMUs to the gateway and from the gateway to the back-end system. The D7001D start-up was responsible for the design and development of a scalable cloud-based architecture for real-time processing and storage of the incoming data as well for serving the requests coming from a front-end system. Finally, the D0036D start-up was responsible for the implementation of a scalable web-based front-end system visualising the results of the computations. It is essential to note that on all stages of the project the students were faced with the real data traffic as it would come from real physical devices, see Section V for more information.

B. Implementation

The work flow of the triple-run experiment is illustrated in Figure 2. The classical style lectures gave students the theoretical skeleton of the courses' content. The first three introductory lectures were common to all three courses. Besides the introduction of the triple-run concept the common lectures gave a crash course on machine-to-machine communications, the Internet-of-Things ecosystem and the basics of the cloud computing using Amazon Web Services. After the introductory lectures all three courses followed their own lanes in the lecture part. All lectures in the three courses, however, were

[2]iRoad project. [Online] Available: http://www.iroad.se

[3]iRoad project's demonstrator [Online] Available: http://www.youtube.com/watch?v=GYyWkYfsJhk

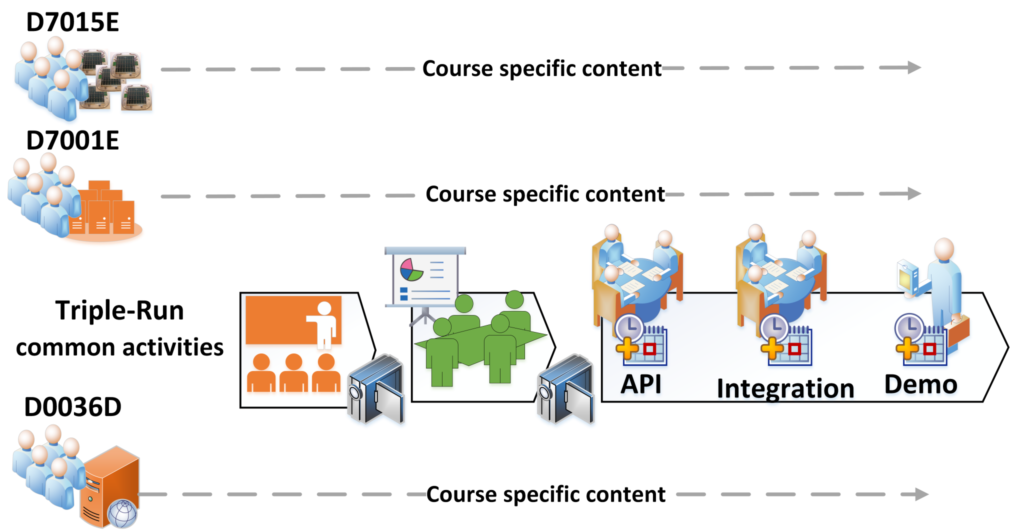

Fig. 2. Workflow of the triple-run experiment. At the course start two common lectures were given to all three courses. The lectures included course structure and introduction, presentation of the common scenario, general overview of IoT and involved technologies as well as hands-on tutorials for AWS programming. Further, common seminar presentations and concertation meeting, and demonstration of final solution were carried out commonly.

recorded using the Adobe Connect[4] facility and the recordings were available in a common to all three courses space of e-learning system Fronter[5]. This step allowed interested students of the particular course an option of following selected parts of another course.

The seminar series of the MSc-level courses D7001D and D7015E were made open to students of all three classes. The students could either attend the events physically as an optional course moment or watch the recorded presentations off-line. The themes offered for student seminars in the particular course aimed at presenting different design choices on selected functionalities, which later on should be developed by students in the practical part. For students from other courses attending the seminars, the aim was to introduce them to the world of the adjacent course. Not completely unexpected we were happy to observe that 20 to 30% of students from the adjacent courses attended the seminar series of each another motivating it by pure curiosity.

The practical part was structured similarly in all three courses and consists of three stages. At the first stage a hands-on exercises with Amazon AWS environment were intended to familiarise students key aspects of practical cloud computing. At the second stage a set of course-specific lab assignments emphasised the core practical issues of the particular subject. Finally, at the third stage the knowledge and skills from the previous two phases were applied to execute a corresponding part of the common to the three courses project. All practical stages were carefully synchronised across the three courses so that student groups would avoid unnecessary delays due to dependencies on the results from other student groups.

In order to orchestrate and pace collaboration and the joint progress two concertation meetings for students from all three courses were planed: a.) For agreeing on the common API between the subsystems and b.) For integrating the developed parts into a holistic IoT system. In practice students from different courses clustered in groups, which met together outside the scheduled meeting hours in order to synchronously develop the final demonstrator.

Finally, the culmination of the triple-run experiment was a *general assembly* where all students were gathered in a large auditorium for demonstration and presentation their solutions. We organized this gathering as poster-session where student pitched they solutions to other participants. This event was made open to a wider public both for publicity reasons as well as to give students a feeling of a technology fair.

V. Technology used in triple-run courses

In this section two technology blocks laying the ground for the triple-run experiment are described. In the sensor network course a pedagogy-oriented simulation environment named Symphony [12] was used to give students skills of developing a real sensor network software while reducing the frustration of debugging the code on real hardware.

The practical tasks in all three courses were conducted inside the Amazon Web Services IaaS environment. While students in the D7015E course used Amazon AWS only as a virtual computer to run the Symphony simulator, the students of other two courses experimented with more or less the entire spectrum of the AWS functionality. For the triple-run experiment we received an educational grant from Amazon covering all needs in computing infrastructure for all students in the three courses. In the next section we report the cost details of our approach.

A. Symphony - a Pedagogy Oriented WSN Simulation Framework

Simulation framework Symphony [12] is rooted in the authors' own experience while teaching the D7015E course

[4]Adobe Conect. [Online] Available: http://www.adobe.com/products/adobeconnect.html

[5]Fronter LMS. [Online] Available: http://com.fronter.info/

as well as when developing and testing a real-life medium-scale distributed WSN application in the domain of intelligent transportation systems. On the teaching front we were confronted with a dual challenge. On the one hand students really appreciated to work with real WSN software and hardware. On the other hand, however, we observed that students were literally suffering from painful debugging of their (rather simple) distributed network functionality and got frustrated from time consuming reprogramming of devices. Even though at the end most of the students get used to the development environment, we the course instructors understood that this in many cases is done by the cost of devoting less time to conceptual understanding of the problems related to the design, analysis and deployment of resource constrained wireless sensor networks.

An architecture of Symphony is illustrated in Figure 3. It consists of three operating and programming scopes: an operating system (OS) scope, a hardware (HW) scope, and an orchestration and communication scope. The OS scope provides necessary tools and a set of rules for building existing operating systems for sensor devices (e.g. Contiki, TinyOS, FreeRTOS) to a virtual image. To the best of our knowledge Symphony is the only environment where students may seamlessly work with different operating systems in a single experiment avoiding a hustle of installing them on the devices. The HW scope of Symphony contains a set of models accurately emulating time behaviour of hardware components. From the teaching perspective this scope gives a possibility to demonstrate the effect of resource constraint hardware elements on the performance of higher layers' communication protocols, which otherwise is at least challenging if not impossible to demonstrate on real devices. Network simulator *ns-3*[6] offers the orchestration and communication scope of Symphony. The choice of a popular network simulator as a provider of communication models allows considering non-trivial network topologies and communication scenarios. Moreover *ns-3* provides a possibility to run simulations in real-time and establish network connection with any computer connected to the Internet. We utilised this capability of Symphony extensively by letting the students to direct the simulated sensory traffic to the back-end system developed by students from the D7001D class.

Finally, since the framework is executed on a PC a favourite integrated development environment supporting main stream programming languages could be used. This makes experimenting with WSN functionality in Symphony more methodological and less time consuming. Although Symphony could be installed on any physical computer, during the course of the triple-run experiment we ran Symphony in the cloud. The rationale behind executing the simulator in the Amazon AWS is twofold. Firstly, we gave students from the D7015E course a taste of working in the IaaS cloud environment, which was appreciated. Secondly, this choice simplified our assistance to possible technical problems since we as the instructors had full access to the virtual machines of the students. In order to shorten the starting up time we prepared a Virtual Machine Image with all necessary software and development environment pre-installed.

[6]Ns-3 simulator, [Online] Available: http://www.nsnam.org/.

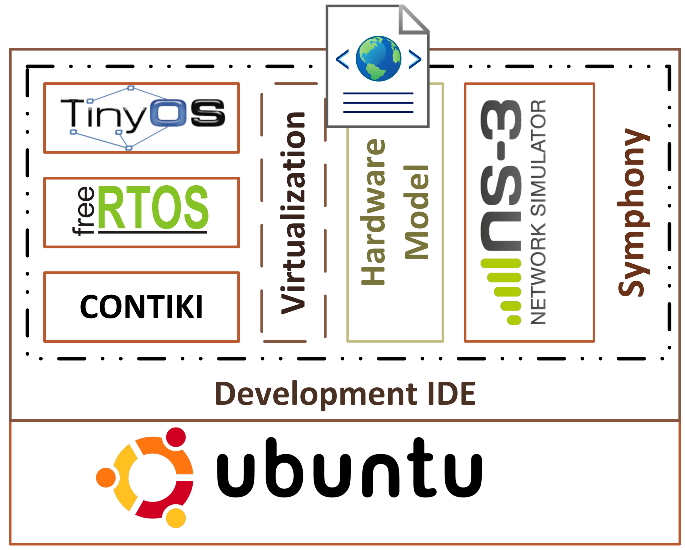

Fig. 3. Symphony framework set up.

B. Amazon AWS as the base computing infrastructure in the triple-run experiment

The choice of the cloud infrastructure in general and Amazon AWS in particular is rather straightforward. Prior to all we intended to give students skills of working with the cutting-edge platform for production of commercial ICT solutions. Secondly, the flexibility, the diversity and the availability of the Amazon AWS infrastructure go far beyond similar parameters of the university's own. Thirdly, as the courses in question assume programming of rather low level network functionality an IaaS cloud modality, where one gets an access to raw computing resources is virtually the only choice.

While teaching network programming related courses using an IaaS cloud infrastructure infrastructure provides many methodological benefits a substantial amount of time were spent on making the cloud environment ready for education purposes. Amazon AWS being a tool for professional developers needed to be adapted for the triple-run experiments in the following ways. Firstly, we introduced naming conventions for tagging different functional elements, such as authorisation keys, EC2 instances and others. In order to keep the resource usage under control we developed a "cloud-crawler" script, which cleaned up the unused and orphaned resources at scheduled time periods. Although we did not place any restrictions on the usage of a specific operating system we prepared an Ubuntu-based Virtual Machine Image with all necessary network configurations and pre-configured an integrated development environment. The image was available to students before the course began.

VI. Reflections, Lessons Learned and Future Developments

"The concept with combining three courses is a great one!", "I loved an idea of working on the same project between three course", "To work with real tools and systems, which are currently used in the industry was great!". "It was the first time I've got an impression of working in a company with real project, interesting topics, and nice atmosphere in the class[7].". These are examples of the overall impression about the triple-run courses, which we got as the result of courses' evaluations by students. Our general impression from the triple-run experiment is overly positive and we definitely will work further towards improving and polishing the concept. In this section we present selected observations we made during the course of the experiment.

The main critique from many students was about *their feeling* of the work load being un-proportional to the course credits[8]. We analyzed the usage pattern of virtual machines (EC2 instances) available from the Amazon management console as a reference of the actual time an average student spent on programming. The de-facto maximum load in the practical part is approximately 100 hours per student. This number also met our expectations before the course start. We advocate that this *feeling* comes mainly because of the diversity of techniques the students were *offered* to use and the nature of *open end problems* in the practical part. This observation, however, does not increase the student satisfaction index by itself. Our on-going work on the next edition of the *triple-run* is directed towards improving this situation.

A. *Enabling innovative thinking in CS students*

Innovation, as the catalyst to economical growth, is enabled through combining existing products, processes, services and technologies into a unique (novel) constellation, which is more effective for solving a particular problem. Our credo for enabling the innovative thinking in students includes exposing them to technologies outside the boundaries of the particular subject and giving them free hands to solve open end problems.

In particular, for the D7015E sensor networks course we built a line of reasoning for counter-weighing the processing of real data in resource constraint sensor devices (in-network processing) to processing of real-time data in the high-end back-end systems.

The implementation of our "free-hands-on-open-end-problem" concept is best visible in Figure 4 showing the usage pattern of virtual machine resources (EC-2 instances) of different types. At the course start the main concepts were explained using the least powerful *Micro* instance shown by the green solid line in the chart. Closer to the courses' midterm the students could try the entire palette of cloud functional elements (the dotted red line). Naturally, closer to the end of the course the students converged to an optimal configuration (the dashed blue line), which suits just their needs for implementing their particular design.

B. *Issues connected to using Amazon AWS in programming courses*

Although cloud computing is a mature technology, using it for education purposes in programming-related courses is not trivial. The biggest challenge we encountered is unavailability of an easy to use student and resource management facility.

[7] An interview with one of the triple-run student, [Online]. Available: http://www.ltu.se/ltu/media/news/Utbildningsnyheter/Unikt-projekt-lar-studenter-jobba-i-molnet-1.99264?l=en

[8] According to regulations of Swedish Ministry of Higher Education a course worth 7.5 ECTS credits should generate work load amounting to 200 hours.

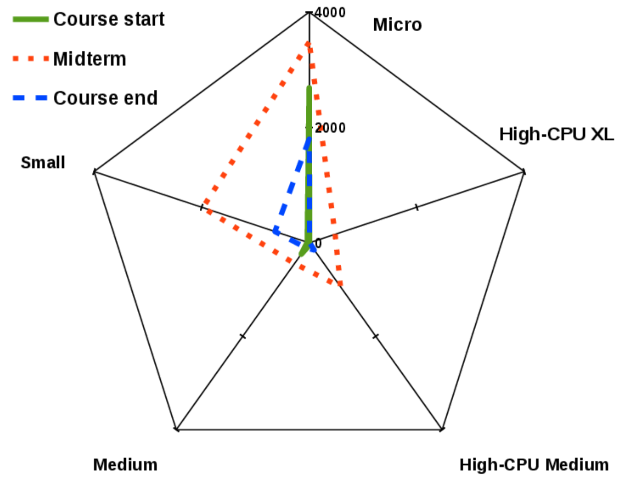

Fig. 4. The de facto work load distribution in terms of hours of usage and types of used EC2 instances.

As a matter of fact the web-based management console of Amazon AWS does not meet the demands of a large group of students with diverse programming skills. For example, when starting an instance of a virtual machine manually, one needs to select an machine image, a security group, and a key pair used for login. With more than 60 students creating own instances under the same AWS account the size of drop-down menus offering functional element quickly became too large making even simple manipulations with the environment long and sometimes frustrating. Although as the course progressed the students started using scripts to manage their resources and the above mentioned issue became less critical, we conjecture that education oriented management tools are a desirable feature in cloud infrastructures.

C. *Economy of the triple-run experiment*

The resulting accounting showed a cost of $200 per student for the duration of the trial. In fact this is a first occasion when we can see the real cost of giving a computer science course per student. This information is normally hidden when using University infrastructure. The question whether this cost is appropriate should be considered while weighting the flexibility and possibilities, which the cloud-based infrastructure provides. Figure 5 shows a distribution of costs per different functional elements of Amazon AWS. The resource allocation amongst different Amazon AWS elements was unequally distributed as depicted in the figure. Most monetary resources were consumed by students using the DynoDB data storage component. In fact this element was not critical for the triple-run practical part and was optional to use. It, however, contributed to almost 70 % of all costs. This is due to a very unclear charging model making it difficult to calculate in-front costs when using this resource. Without this component the cost per student would reduce to a much more reasonable $60.

VII. Conclusions

We presented a teaching experiment named "triple-run". The content and the time line of three courses covering the

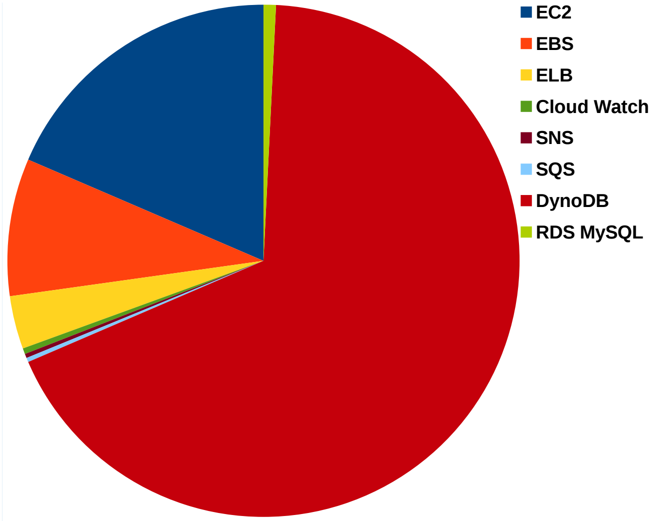

Fig. 5. Distribution of consumed resources per different functional elements in terms of cost.

entire technology chain of Internet of Things were aligned to present a holistic picture to students and enable innovative thinking. The first experiences are definitely positive and we intend to develop and improve the triple-run philosophy further. Main challenges, which remain to address are connected to the logistics of using cloud infrastructure for education purposes.

ACKNOWLEDGEMENT

We would like to thank all students participating in our experimental courses for their patience, understanding and valuable feedback. Also Amazon AWS for providing educational grant used for these courses.

Writing Groups in Computer Science Research Labs

Adam Doupé and Janet L. Kayfetz
University of California, Santa Barbara
{adoupe, kayfetz}@cs.ucsb.edu

***Abstract*—Researchers must excel at writing to effectively engage the scientific community. Clear and engaging writing advances new knowledge and increases the impact of a researcher's work.**

As developing researchers, it is essential that graduate students learn to write clearly and effectively so that their work is accessible to their peers and colleagues. An essential part of graduate school education should include the teaching of formal writing skills. In most graduate programs, students learn formal writing skills from two sources, their advisors or a writing class. We identify a third source: the graduate student peer group. In this paper, we describe how we leveraged the existing collaborative research dynamic among students in a graduate research lab and created a writing group, similar in spirit to the concept of a reading group.

We describe the inspiration, implementation, and impact of a writing group in a real-world research lab. We show how the writing group started organically after a PhD student took a graduate writing class in the Computer Science Department and thereafter initiated the writing group in his research lab. We also describe how a writing group can be implemented in other research labs to improve the writing of graduate students worldwide.

I. Introduction

Ask any established researcher and she will tell you just how important writing skills are for being a successful researcher and scientist. It is through our writing that we achieve one of our main goals: To spread our ideas to our colleagues and to the general public. Some of the main vectors for the spread of ideas are through written research papers, journal articles, book chapters, email communications, posters, and magazine and newspaper articles, all of which, we hope, are read by our peers.

Graduate students are the next wave of researchers and scientists, and it is our job as educators and advisors to instruct graduate students on all aspects of the research endeavor. We do an excellent job of teaching our students to carry out scientifically sound research, but are we doing an equally excellent job in the related areas of graduate study? In particular, are we teaching our graduate students how to write and communicate their ideas effectively? Do we illuminate all of the components of the writing process and give students the tools for excellent writing?

Excellent writing skills are vital for graduate student success. Great writing can increase the chances that a student's paper is accepted for publication, increase the impact of the student's work, and hopefully increase the number of citations of the student's work. However, more importantly, writing skills provide students with a base of knowledge that will benefit them regardless of their career trajectory—writing skills are equally valued in academia, in industry, in government, and in entrepreneurial ventures.

Traditionally, graduate students learn formal writing skills from interactions with their advisors, either in the form of red-ink editing corrections on a student's manuscript or one-on-one mentoring. A second way that graduate students learn formal writing skills is by participating in an academic writing class focused on the rhetorical demands of science writing [1].

But there is a third source where graduate students can learn formal writing skills—their peer group. In addition to developing the skills of research design and data interpretation, the graduate student peer group provides the ideal social dynamic for the discussion of writing. Building on the culture of group analysis and discussion that already exists in the graduate student research lab, we created and introduce here the concept of a *research lab writing group,* inspired by the idea of the reading group, a common activity in many science research labs.

In the research lab writing group, graduate students not only learn the techniques of formal writing from their peers, they also learn the writing and research norms of their specific research field. Students also gain insights into how other students in their lab approach the writing process.

In this paper, we present the concept of a research lab writing group and describe the high-level goals that such a group should achieve. We also describe the structure of the writing group and the roles and behaviors of the group leader, the authors, and the audience. Our discussion is meant to inspire other graduate students and their advisors to start their own writing groups, thus improving graduate student writing skills in graduate research labs all around the world.

II. Idea Germination

The writing group concept came about after a PhD student completed a graduate-level academic writing course for scientists offered by the Computer Science Department at the University of California, Santa Barbara [1]. After attending the class and soaking up all the writing skills that were offered [2], the student wished to share this knowledge with his fellow graduate students in his research lab.

The student modeled the writing group concept after a common practice in his lab: the reading group. For those who are not familiar, a reading group is a common activity among research labs. The purpose of a reading group is to stay on top of newly published research in a specific field. In most formats, one student is selected to present a research paper to the rest of the group. Most reading group formats meet weekly from 30 minutes to an hour. The student presenting the paper begins by leading the group through an overview of the paper. The

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

presenter then moderates a discussion of various aspects of the paper, including the positive contributions of the research, the appropriateness of the topic for the venue, experimental design, weaknesses in any aspect of the work, and future research work related to the paper.

The aspects of a *reading group* that we wish to capture in the *writing group* are the weekly meeting format, the group discussion, and the rotation of student presenters.

We have been running our writing group for 20 weeks in a real-world computer security research lab with 14 PhD students and five interns. Participation is completely voluntary and peer-motivated. Importantly, while the faculty advisors of the research lab encourage the idea, they do not attend the writing group—the creation of the group, the attendance, and the interactive discourse are 100% student driven.

The writing group initially lasted for nine weeks, one week short of the standard 10-week quarterly course. The group went on hiatus after the first 9 weeks, not because of a lack of interest from the students, but because the leader left for a summer internship. Interestingly, as a direct result of writing this paper, the students in the research lab were motived to reestablish the writing group. The second phase of the writing group has been continuing successfully for 11 weeks and is still going strong.

III. Goals

When developing the design of the writing group, we had multiple goals in mind.

To improve the writing of the research lab. It may seem obvious, but our goal, first and foremost, is to enhance the writing of the graduate students in the research lab. We want to foster a culture of writing excellence and support each other through the difficulties of the writing process. We also want to build the confidence of the students and help nonnative English speakers develop advanced English writing skills.

To maximize participation. We want to maximize the number of graduate students who attend the writing group. This increased participation is important for two reasons. First, the more people who attend the meetings, the more impact we can have on their writing. Second, because the writing group is a collaborative meeting, the group as a whole benefits from having the perspective from the most number of students.

To maximize interaction among the participants. We see interaction during the meeting as being different from simply showing up. It is one of our explicit objectives to encourage each lab member to share her ideas and opinions. In addition to looking at writing, we also hope that participants feel increased confidence in their ability to analyze and discuss a research text.

To develop core writing skills as well as a successful and useful approach to the analysis and discussion of texts. Our purpose is to impart the concepts and vocabulary taught in a formal academic writing class, including rhetorical positioning, audience, purpose, development of the problem space, data commentary, clarity, tone, register, coherence, transitions, readability, and so on [3], [4]. We also want to focus on the important sub-genres of a science text like abstracts, introductions, data commentaries and results, literature review, and conclusions.

To be focused on current writing tasks. We want our writing group to focus on current writing tasks so that we can have a direct impact on the quality of the texts produced by lab members. This focus increases the relevance for group members because we look at real texts instead of contrived writing samples. By doing real work, we see increased attendance in the writing group as students are offered the opportunity to read and review current work by their peers.

To spread knowledge among the group about the ways to structure and write about research issues that are idiosyncratic to our area of Computer Science research. We want to make sure that all lab members are aware of the norms and subtleties of science discourse in our specific subfield. These subtleties apply not only to issues such as paper structure, but also to research design and research focus.

IV. Group Structure

We now turn our attention to a description of the specific mechanics of our writing group sessions. We describe the roles involved along with the format of the writing group.

A. Roles

For a writing group to operate successfully and achieve all of the goals we set out in Section III, the roles of each of the participants in the writing group should be well defined. Here, we define the roles in the writing group as we have experienced them, and in Section V we describe the suggested actions and behaviors of each of the roles.

1) Leader: The leader of the writing group is ideally a student who cares deeply about both the writing process and improving the writing of her peers. The leader should have a solid grounding in formal writing skills because it is the leader's job to teach scientific writing concepts. In our writing group, the leader had completed a class in academic writing in our Computer Science Department taught by a linguist on the Computer Science faculty. The leader is in charge of founding and starting the writing group, and preparing the lesson for each meeting.

2) Author: The author is a member of the writing group who is either selected or who volunteers to share her writing with the rest of the group. This role rotates for each meeting. Each author must get ready for the writing group beforehand by preparing her writing sample to share with the group.

3) Audience: The audience is anyone who attends the writing group meeting, excluding that session's author. Nothing is required of these students before the meeting except for an open mind, a passion to improve their writing skills, and the willingness to offer helpful feedback to peer authors. If a faculty member chooses to attend a meeting, she assumes the role of an audience member.

B. Format

We ran our writing group meetings weekly for a total of 20 weeks. To increase attendance, we made the time requirement manageable for the students—30 minutes. And we kept to this time limit strictly, respecting students' busy schedules.

We worked hard to find a time that was convenient for everyone and that did not conflict with regularly-scheduled recurring meetings. Because most graduate students do not have consistent working schedules—some come in to the lab early while others come in much later—we chose a meeting time of 5 PM, as this did not conflict with any other meetings, and the time was late enough in the day that all students in the lab who wanted to attend could be present.

The 30 minutes of the writing group are broken down into two different sections. The first section, lasting ten minutes, is dedicated to teaching and discussing a specific writing concept selected by the leader, such as tone, audience, abstracts, and so on. The leader—the student who had taken the writing class—introduces the writing concept for the first few minutes, and then leads a group discussion about the specific concept.

The second phase of the writing group, lasting 20 minutes, is a group editing session of the author's writing. The author projects her writing onto a screen so that the entire audience can read the text. An important point here is that the author must prepare the text in a format that is easy to edit and change. Specifically, this means either OpenOffice or Google Docs, rather than a LaTeX file that needs to be compiled. The ability of the author to edit text quickly during the group editing session is critical so that all group members can see and evaluate in real-time the changes the author is making to the piece of writing.

Figure 1 shows a real-world group editing session. The author, situated in the upper left, is facing the audience and is ready to make changes to his text. The author's text is projected onto a screen so that the author and the audience can easily read the text at the same time.

Finally, at the end of a writing group session, the leader announces next week's topic, and the group chooses the author for the next week's session.

V. Behavior

Now that we have discussed the roles in the writing group and the format of the writing group, we turn our attention to the behaviors and actions necessary for the writing group to achieve its goals. These observations come from our hands-on experiences with our writing group and clarify the responsibilities of the leader, the author, and the audience.

A. Assembling the Writing Group

Before considering any other part of the writing group, the leader must first get the writing group started. To start the writing group and get maximal attendance from the leader's research peers, it is important for the leader to get buy-in about the writing group idea from some of the students before proposing the creation of a writing group to the entire research lab.

In our case, the leader used a persuasion technique that originated in the business community called pre-wiring [5]. Before announcing the idea for the writing group to the entire lab, the leader personally met with the four students who had been with the research lab the longest to explain the concept and the specifics of the writing group. The goal here was to address any concerns from these students about the writing group and to get them excited about the idea. Then, when the idea was proposed to the entire lab, these four students chimed in that they thought the writing group was a great idea. We believe that using pre-wiring increased attendance and buy-in from the entire group.

B. Ten-minute Teaching Session

The leader begins the writing group by leading a ten minute lecture and discussion about a writing concept announced at the previous meeting.

After the leader lectures and explains the concept, there is an open discussion among the audience facilitated by the leader, focused on the concept. The conversation is meant to address any questions about the concept, to get each member of the audience thinking about how to apply the concept in their own writing, and also to identify areas where the lab's sub-field may apply the concept differently from the general scientific community.

C. Twenty-minute Group Editing Session

The group editing is supervised by the leader. The leader guides the group editing session to focus on the specific topic of the week. For instance, when the leader introduces the concept of the Introduction and how to structure an Introduction in a research paper, the author should be willing to share and discuss the Introduction of her research paper, and the audience should limit its analysis and feedback to the Introduction as well. While it is very useful to focus on the particular "concept of the week," it is equally important that the leader also allow other topics to bubble up organically from the audience.

The leader follows a format for the group editing session. First, the leader asks the author to read her text aloud to the audience. Having authors read their own work out loud is important. First, it is vital, especially for nonnative English speakers, for authors to get a feel for how the writing sounds [6]. The group picks up on sentences and phrasings that do not sound right. Also, places where the author stumbles while reading are possible red flags for revisions and improvements.

After the author reads the text out loud to the group, the leader asks the group for comments and suggestions about how to improve the writing. However, before asking for comments, the leader must make several things clear. First, the author is in complete control of the text and any changes suggested by an audience member are ultimately up to the author's discretion. At the same time, the leader should encourage the author to experiment with changes.

Another important thing that the leader should mention to the group is how nervous an author can feel when their writing is criticized. Therefore, the leader should ask that the group be respectful of the author's feelings when critiquing the text. At the same time, the leader should remind the author that the group is there to help, and that the author should not take comments about the writing personally.

Fig. 1. Group editing session. Note how the author is situated in front of the group and that the author's text is presented on a screen for the entire group to easily read.

The group discussion is so valuable because it offers the writer the unique chance to receive insightful feedback from real readers. The responsibility of the audience, then, is to give helpful suggestions that advance the writer's story, the clarity, the organization, and the readability of the text. We are particularly fond of using Weissberg's approach to keeping audience comments "as specific as possible" [7].

Ideally, the leader lets the group and nature of the discussion develop in a natural manner. Of course, the leader should not hesitate to give her own opinion about the writing and what should be done. The leader must be aware, however, that because of her leadership role, others in the group may perceive the leader's opinion as carrying more weight. It is a subtle but very important aspect of the group dynamic that the leader should tread lightly with her own comments and feedback, and instead engage the group to focus on a specific area by asking leading questions about specific aspects of the text.

During the discussion, the leader should ensure that no one is dominating the conversation (including herself) and that everyone is participating. This can mean directly asking quiet members their opinions about the current topic or directing frequent contributors to let other students have a chance to speak.

We advocate a thorough and detailed approach to group editing. We talk about word choice, idioms, sentence restructuring, sentence combination, adding sentences, deleting sentences, adding connections, reducing repetition, and many other topics. We also play around with different variations and keep working at finding the right phrasing and sentence structure until the author and group are happy. We should also note that the author is not a passive participant in this process. It is the responsibility of the author to take an active role in reworking the text by interacting with each group member who offers feedback.

D. Choosing the Next Author

An important component for the continuing success of the writing group is to have a different author present her work for the group editing session every meeting. The leader should ask, at the end of the current meeting, for volunteer authors for the next week. Some coercion may be necessary to identify a volunteer. It is vital that the leader get a student to verbally commit in front of all her peers to be the author for the next week [8]. This verbal commitment creates a social contract between the author and her peer group, increasing the likelihood that the student will take the responsibility seriously and be prepared to discuss her writing at the next meeting.

VI. Leader Feedback

In this section, we discuss the leader's perspective on what can be improved with the writing group and what is going well.

A. Cons

The biggest drawback of the writing group approach as we implemented it was reliance on a single leader. Once the student had left the lab, no other student stepped up to take over the leadership role. We believe that in the future, reliance on a single leader can be mitigated by the leader actively recruiting assistant leaders to take over when necessary. The leader can ask the assistants to lead a writing group every few weeks, thus cultivating a group of students who feel confident and capable of leading the writing group in the original leader's absence. The reliance on one leader was probably the biggest drawback of the current approach, and when we started up the writing group again the leader made a conscious effort to build a group of capable leaders. Because of these capable leaders, this latest incarnation of the writing group has survived the absence of the original leader.

Everyone is busy (yes, even graduate students), so it is difficult to convince students to attend the writing group. Attendance would frequently dip close to a conference submission deadline, because the students are busy writing papers to meet the deadline. This problem is further compounded because all the students in the lab share the same deadlines. Hence, these deadlines can drop the attendance of the writing group significantly.

Unfortunately, as the leader is a peer of the students, she cannot force them to attend if they are busy. The best way to mitigate the effects of deadlines on the students' attendance is to demonstrate to them, before the deadline, that they will benefit greatly through a group editing of their work. The leader should choose authors to present their work for group edit even when they have a deadline. The rationale here, which must be explained to the authors, is that the authors will get the most out of a group editing session when their text is relevant and about to be submitted. Unfortunately, this approach is not fool-proof, as often before a deadline students are still running experiments rather than writing. Thus, they do not see the benefit of "wasting" a half hour to polish their writing when they still have experiments to run to complete the paper.

Another problem of the writing group is that the learning of the concepts and vocabulary necessary to be able to talk about student texts develops slowly. A shared vocabulary allows students to use statements like "I think that the tone of that paragraph is not appropriate for the given venue," rather than saying "That sentence sounds wrong." A better idea might be to spend more time, perhaps even the entire first meeting, going over the most fundamental writing terms and concepts. The risk here is that the students may lose interest in the writing group because they do not get to participate immediately in the interactive group editing session.

Finally, the role of leader is a huge responsibility. It requires out-of-group time to get things organized, and it asks for focused concentration and real-time teaching and leadership. These responsibilities of the leader are critical for the success of a writing group. At the same time, we want to point out that because the leader is teaching and guiding the group dynamics, she actually receives less benefit from the sessions that the rest of the group members.

B. Pros

Once everyone was on the same level of understanding concerning basic academic writing principles, the group editing sessions increased in efficiency, and we were able to cover more text. This shared level of writing vocabulary had ancillary benefits as well. We observed that the students who participated in the writing group used these concepts when working with each other on other papers. The benefit came not just from students collaborating on the same paper, but also when one student asked another to review or edit her individual paper.

While it is difficult for an author to bare her unfinished work to the world and subject it to the critique of other students, getting the students used to this kind of criticism and feedback was immensely beneficial. Once the students understood not to take the feedback personally, this tolerance and open-mindedness carried over to receiving feedback from others outside the group, including advisors and anonymous reviewers. Developing an open mind and a willingness to listen to feedback without becoming defensive, is an important skill not just in writing but in many other aspects of the career of a scientist.

A benefit for the authors when participating in the writing group editing session is that they learn to think through and justify their writing choices. Often, this process happens before the actual writing group takes place, as the author scrutinizes her work more carefully when she knows that it will be reviewed in the writing group.

During the group editing exercise, the group proposes changes to the author and the author decides to implement the changes or not. The author is encouraged to discuss with the group why she is making the change or why she is not making the change. Teaching authors to look at their own writing and justify the choices they make is an important writing skill, because good writing is all about choices, and a writer who is able to defend those choices, or has at least thought about the choices, will be more deliberate and clear with her writing.

Another huge benefit of the writing group is the transfer of knowledge from the "older" students to the "younger" students. Here, we are not referring to the age of the students, but rather to the length of time they have been in their graduate program. Older students have, on average, read more papers, written more papers, and have an understanding of how their specific field works. This means that the older students have a lot to teach the younger students.

Note that this transfer of knowledge is not limited to writing. Often, we see a lot of benefit from the writing group when older students explain to younger students the idioms and particulars of our field. There are also explanations and discussions about the different writing styles of our advisors. One specific example is our discussion about how one professor prefers to put the Related Work section at the end of a paper, rather than after the Introduction, which is more typical. We feel that this transfer of knowledge among students is critical to the development of the younger graduate students. It helps prevent them from making the same mistakes that the older students made in the early stages of their writing development. Another benefit is that the younger students pay attention to the points the older students make when they read new papers.

While our specific writing group meetings involve only the peers in our lab, a benefit of the writing group is the possibility to have an advisor or even a writing professor attend the meetings and participate in the writing group. The format of the writing group does not need to change to accommodate the newcomer. The beginning ten minute session might be replaced with a lecture from the experienced advisor about any topic related to writing. One caveat to address is that the leader should remind the new attendee, before the meeting and in private, to please consider their words carefully when critiquing the students' work, especially when the new attendee has role power over the student. It is essential for the openness and frank discussion that no student feel ashamed to make a comment because their boss or teacher is in attendance.

Finally, a writing group has a lot of benefit for students who are nonnative speakers of English. As long as there are a few native English speakers in the audience who have an ear for appropriate English usage and idioms, the nonnative speakers can benefit greatly. This transfer of knowledge is similar to the transfer of knowledge from older students to younger students. The native speakers can help the nonnative speakers with the subtleties of English. Specific areas of attention are word choice and phrases or sentences that, while grammatically correct, are not the common or correct way to express a thought.

VII. Student Feedback—In Their Own Words

We asked the students who have participated in the writing group the following three questions: (1) What specifically about the writing group did you find valuable? (2) What would you change about the writing group? (3) Are there any other information or inspiring quotes you'd like to share about writing or the writing group? We selected some of the student comments to share here to provide insight into their experiences with the writing group.

One first-year PhD student wrote that the most valuable part of the writing group was gaining insight into the writing process:

> You see how everybody (even the good writers) are struggling to write even a single paragraph: If you are a bad writer and your writing skills-related self-confidence is near zero (i.e., me), it's a *huge* help to boost your confidence! Writing is hard. Period. It's good to know.
>
> I believe everybody should develop his own writing process: When you don't have one, it's really useful to see how the good writers are actually producing a good paragraph of text! In fact, you are usually able to just "read" a good paragraph, but you don't know what the process is behind it (the really important part).

A third-year PhD student appreciated seeing other students' viewpoints and how they criticized a text:

> I liked to see how others criticize a piece of writing. It certainly widened my view. Particularly, knowing why someone prefers a piece of text to be written in a certain way helps considerably.
>
> I like to hear the unedited version of why others like a style of writing. I prefer their comments to be more about why they personally like it, and not the cliché formatting bugs. This way I can recognize what most people like and why they like it, and not only a standard way of writing (which, by definition, is one of many ways you can write a good text). The personal feedback enables me to change my style more freely, without religiously sticking to unbendable formats.

Another first-year PhD student commented on specific topics that we covered, particularly about the organization of a paper:

> The discussion we had about the paper's organization was really valuable as well. For example, understanding that there is no fixed-rule about where to put the Related Work section is a good thing to know. More in general: Bad writers (me) need to understand which rules are "fixed" and, more importantly, which are *not*!

For improvements to the writing group, one second-year student wanted more focused meetings:

> [An improvement could be] small themed meetings. Like we pick a specific topic (how to connect paragraphs for example) and we speak about it and work on some sample texts. Specifically if we do it on our own papers it will help a lot and improve our writing.

VIII. Concluding Remarks

The goal of the scientist is to share and spread her ideas. An exceptional scientist will write her thoughts clearly and express her ideas elegantly, creating a persuasive story that is readable and interesting to her audience. We believe that developing a culture of excellence in writing should be a fundamental aspect of graduate school education. To achieve this lofty goal, we require new ways of teaching writing skills to train the next generation of scientists who will make breakthroughs we can only dream of.

A research lab writing group, as discussed in this paper, is a novel approach to helping graduate students develop the tools necessary to refine their formal writing skills. In fact, if you have a single student who has completed an advanced writing course who is motivated to form a writing group, an entire research lab can participate in what realistically amounts to a mini-writing class.

We hope you steal our ideas and adapt them to your own research lab. Together we can improve the writing of graduate school scientists in labs all over the world.

Teaching Web Engineering using a Project Component

Daniel E. Krutz and Andrew Meneely
Rochester Institute of Technology
{dxkvse, axmvse}@rit.edu

***Abstract*—Web applications are an intricate part of the world today. Everything from banking to checking our Facebook status may now be done through the use of web applications. Todays students need to balance numerous concerns in order to create a web application that is robust, on time and on budget.**

At the Department of Software Engineering at the Rochester Institute of Technology, we created a course called *Web Engineering*. As part of this course, we developed an innovative project component which focused on students following software engineering principles such as elicitation, requirements generation, testing and deployment.

I. Introduction

Web applications represent a confluence of diverse technologies and numerous challenges. Some of which include networked environments, persistent storage, concurrency and usability. Web engineering is defined as the systematic, disciplined and quantifiable approach to development, operation and maintenance of web-based systems and applications [11] [7] [9]. While similar to software engineering, the concept of web engineering differs in several key areas [3]. The planning of continual growth and change has a higher significance in web applications [2].

Last year, the Software Engineering Department at the Rochester Institute of Technology (RIT) added a course entitled Web Engineering to their curriculum which is typically comprised of upper level 3rd through 5th year students. A signficant component to this course was a cross course collaborative effort with a focus on security. The cooperation is beneficial because it allows students to gain experience working with a an adjacent software team. Students will often collaborate in teams in industry, but are often unprepared to do so [6]. Additionally, focusing on security is valuable as web applications expose powerful technologies and assets to the Internet. Application security is an area which students and even workers in industry are typically deficient in [12] [4].

This project component is also distinct in the way it mimics a real world project as closely as possible. Students are not handed a firm list of requirements. They are expected to elicit, negotiate and comprehend changing requirements. This is an area that is extremely important for students have proficiency, but far too often lack [1] [10]. The project also utilized contemporary web technologies that allowed students to create a final product which they were actually interested in using and sharing with friends. This helped to foster student enthusiasm in the project.

In the following experience report, we describe the project as well as future improvements to be implemented in subsequent course offerings. Our goal is to allow other instructors to learn from our experiences and to be able to enact a similar project in their own web engineering courses at their own institutions.

II. Method

A significant aspect of our Web Engineering course was a project component. The main premise of the project was for each group to create a web application using both custom built and already existing components through web service and Application Programming Interface (API) calls while adhering to proper security standards for several vulnerability categories. Some of which included authentication, message encryption, authorization and session management.

The instructor took on two distinct roles for the project: teacher and customer. The way the customer reacts to student questions significantly differs depending on what role the instructor is currently playing. While representing the role of teacher, the instructor may give project advice and answer technical questions wherever possible. As the customer, they attempted to mimic a client in the real world and students were encouraged to clarify requirements with them. So students may understand which role the instructor is playing, students are encouraged to ask whenever they are unsure and begin their inquisitions with As the customer or As the teacher.

The goal of the project is to create a personalized web portal that would be customized for each user. The user initially logs in with their Facebook account. Once the user logged into the application, they are exposed to several pieces of personal, customizable information. One of the most significant is a section on the main page which is very similar to the wall in the traditional Facebook application. For this section, students were asked to again tie into the Facebook API to retrieve the necessary data. They were required to modify the appearance of these items and utilize aspects of usability covered in the course. Various other Facebook APIs such as photo albums, chatting with friends and status updates were used in similar ways. We selected these requirements not only because the Facebook API was readily available, but because we felt that incorporating Facebook here would help to encourage student interest in the project.

Several other aspects of the project required the students to write custom software to interact with extra data services or feeds. Students were asked to incorporate a stock viewing web page into their project. The user would initially enter in a stock that they mythically purchased along with the purchase price and number of shares. This information would

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

be stored in a student created relational database. For all of these simulated purchased stocks, information would be retrieved from a third party web service and the page would be expected to display the current stock price, the day's high and low price, along with the amount of money the investment has thus far made or lost for the buyer. A chart is also displayed for the stock which is retrieved using an external feed of the groups choice. Other aspects of the application include a weather based component and a chat feature based upon HTML5. The reason for this chat component is to both familiarize the students with HTML5 and to acquaint them with how to properly place and utilize such an interactive element. In order to acclimate students to development environments like they would encounter in industry, several virtual machines were provided to each team. These were intended to act as development, staging and production environments.

During the ten week quarter, each team was expected to produce several deliverables. The first few weeks of the project aspect of the course focused on building up a base for understanding web engineering along with team formation. Teams of 4-6 students were created since this is often the size of groups in industry and has been found to be conducive to student learning in previous projects [5] [8]. Several roles exist on each team. These included team, development and testing coordinator. Since the course was comprised of upper level students, they were given the opportunity to self-appoint these roles. Students have indicated their satisfaction with this freedom. However, if the class was primarily made up of more novice students, the instructor may want to appoint team roles.

In the third week of the quarter, the students were asked to complete a requirements document and in the subsequent week, a design document. The expectation was laid out to each team that these were to be constantly evolving documents. The grading on these initial deliverables was not aimed at ensuring that the students had a completely accurate document on their first attempt. The main goal was for the students to have followed the proper guidelines for producing these deliverables and that an adequate effort was at least given to create them as accurately as possible. During the second half of each class session, teams were given the opportunity to meet with the instructor to ask requirement and general project questions. In these interactions, the students were also able to negotiate expectations with the customer. They were encouraged to show prototypes, screenshots and anything else they desired to the customer. The goal was not to limit customer interaction, or punish inquisitions as long as they were reasonable. The aim was to encourage customer interaction and elicitation.

The first software release was due in the sixth week of the quarter. Teams were asked to deliver a fully functional version of their application, but with only the functionality agreed upon with the customer for the first release. Less emphasis was placed upon appearance than functionality. Aspects such as mobile compatibility and cross browser support were not evaluated. Teams are also asked to provide updated requirements and design documentation, along with thorough test plans with the implemented tests. Some of which include unit and acceptance tests.

The Software Engineering Department at RIT places a large emphasis on public speaking, presentation and overall communication skills for their students. For the first release, each group was asked to give a 20 minute presentation about some of the major aspects and technologies used in their project. Other areas discussed were team roles and dynamics, a short demonstration of their application and their plan for the second release.

Immediately after the initial release, each group is asked to work on a team self-reflection document. Components of this paper include identifying areas of the project that went well, along with portions of the project which can be improved and how. Students are encouraged to deeply think and elaborate on these areas of went well and what can be improved.

Ensuring an adequate level of security is an important aspect of web based applications [4]. A week after the first release, each group is asked to release their application to a group in a concurrent software security course. The security course, entitled Engineering Secure Software, is a class designed to train students on the principles and practices incorporating security into the entire software development lifecycle. One of the class projects was the development of a web application fuzz testing tool (fuzzer), that automates the discovery of inputs and potential vulnerabilities in websites. Students would develop a set of scripts that would crawl a local website, discover the inputs, and then attempt to exploit those inputs using commonly-used attacks. Each fuzzer team was given a different web engineering product to fuzz, and was asked to report their fuzzing results to the web engineering team.

The second and final release occurs during the last week of the term and is conducted in a very similar fashion to the first release. The major difference is that the appearance and functionality are now both thoroughly evaluated. Additionally, applications are expected to be mobile device friendly. On the final day of class, each group again conducts a post mortem and investigates what went well and why along with what may be improved upon.

A goal of the project is to supply the groups with enough guidelines to provide them a solid direction, but allow them enough freedom in order to be creative. Additionally, the teams were encouraged to work with the customer to formulate extra features for the project which would be beneficial for the customer. This aspect was helpful in stimulating the students ingenuity for the project, working on their elicitation skills and in helping to add variability to each team's final product.

Future instructors are encouraged to deviate at moderate levels as they desire with the requirements for this project. These aberrations will not only keep the projects fresh and allow for freedom from both the instructor and the students, but will allow the instructor to explore and evaluate possible alternative paths for the project so it may be enhanced in future iterations.

III. Outcome

Before the beginning of the term, students expressed their excitement over the course and specifically for the project. They were interested in the real-world aspect of the project and how it interacted with contemporary technologies, tools and practices. Additionally, they were attracted to the freedom that the project structure would afford their teams.

At the conclusion of the course, an anonymous process was used to gather student feedback and was only made visible to the instructor after final grades had been submitted. Generally, the student feedback regarding both the course and project was positive. We feel that some of the reasons for dislike need to be addressed in upcoming course iterations. Other issues are ones which the students may not necessarily enjoy, but are essential for a proper student learning.

The students indicated that they felt the most beneficial learning aspect of the course was the project. Based upon this feedback, we believe that we are on the correct path with the project and feel it only needs tweaking in several areas. Student feedback also indicated several areas which they felt were beneficial. One of the most prevalent was the use of APIs and web services from groups such as Facebook and Google. They enjoyed using current and well known technologies for both their allure and practicality. Students also appreciated beginning the project with a reasonable list of requirements and not having to begin the elicitation phase from scratch. Other areas of positive feedback included the availability of the customer and the ability to self-appoint teams. The following are representative samples of written feedback we have received:

> I really like this project because it is giving us [software engineering students] experience with technologies that companies are truly looking for that without this class there was no formal way to learn. It was really interesting because it covered multiple aspects of web development from using certain frameworks, dealing with social aggregation, hosting our own chat service, and also learning about API's etc. Also it allowed us to see how rapid web development can be and how fast paced the field is

> After taking Web Engineering, I can confidently say: Why isn't there more of this class in our curriculum? As students living a web world, fast requirement shifts and one-click deployment are the norms for modern software vendors. Companies are now, more than ever before, looking for students with skills like JavaScript, Web Application Frameworks, and third party web API's. So far, this is the only class that has managed to capture the buzz that's ultimately here to stay.

IV. Conclusion

This paper presents some early findings regarding a project based component in a web engineering course. The primary areas of the project were discussed. These included the technical details, major deliverables and how the team was expected to interact with the customer. A main goal of this activity is to emulate a real world project situation as closely as possible. The role of the instructor acting as the customer was also conveyed. An interesting aspect of this project was the cross course collaboration which occurred with an adjacent security course. We will evolve and improve this collaboration in future course offerings.

While the course and project component generally went well, several areas can be improved upon. These include altering project requirements to aid in security testing and spending more time acclimating students with various technical concepts of web engineering. Future research will be done to discover how different technologies can be incorporated into the project in order make it both more appealing to the students, but more educational as well. This information will be gathered from instructor observations, official student feedback forms, and informal conversations with the students. We hope that our work in creating and refining a project based component can help others build a more educational and enjoyable web engineering Course for their students.

***Abstract*—Service-Oriented Programming (SOP) has emerged as a new programming paradigm that allows the wrapping of existing software as web services, thus permitting the development of new software applications by using existing web services as building blocks. SOP has attracted great attention from industry as it dramatically increases software reuse. Despite the growing demand for an SOP-trained workforce, SOP has not been adequately covered in coursework for undergraduate students in Computer Science (CS) and Software Engineering (SE). This project addresses this curricular shortcoming via the design and creation of SOP materials for undergraduate CS and SE. The concept of *course modules*—self-contained units of instruction that can be incorporated into several existing courses—is used to make these materials accessible at multiple educational institutions. This paper describes an exemplification and visualization framework that supports the teaching of SOP, along with three course modules that can be folded into typical courses currently offered to CS or SE undergraduates.**

Keywords—service-oriented programming; service-oriented architecture; web services; computer science; software engineering

I. Introduction

With the increasing popularity of Service-Oriented Computing (SOC) and Cloud Computing, more and more businesses have started offering various services on the Web [1], [2], [3], [4]. Of the three major types of services, i.e., Infrastructure as a Service (IaaS), Platform as a Service (PaaS), and Software as a Service (SaaS), SaaS has attracted a fairly large and rapidly increasing number of service providers. With SaaS, the Web is transformed into a programming platform with a large number of software services, which in turn serve as building blocks for constructing new software applications. This dramatic change has thus enabled a new programming paradigm, Service-Oriented Programming (SOP) [5], [6], which is centered on software reuse. SOP's importance is illustrated by a WinterGreen Report [7] that concludes that the global service-oriented middleware market will grow to at least $8.2 billion by 2016.

Unfortunately, these developments in web services, service-oriented computing, cloud computing cloud computing and SOP have not been properly incorporated into undergraduate Computer Science (CS) and Software Engineering (SE) curricula. Courses currently offered are typically aimed at graduate or senior undergraduate students, and focus on research thrusts and open issues in these areas. Few attempts have been made to teach SOP holistically at the undergraduate level, i.e., to teach students how to program using the large number of software services on the Web using SOP. Lim, Hosack and Vogt [8] is the one major exception: they use a web service-oriented approach for teaching SOP as part of freshman computing. Our project draws upon their experiences but makes significant extensions, for example, we provide a more comprehensive coverage of key SOP concepts and technologies; a structured, vertical incorporation of SOP across the undergraduate curriculum; and identification and usage of effective pedagogical methodologies to deliver SOP knowledge to undergraduate students.

Our approach employs two pedagogical methods for effective and timely incorporation of SOP into CS/SE undergraduate curricula. First, an SOP platform is being developed to exemplify and visualize SOP concepts and technologies. Our approach is motivated by *teaching by example*, an effective pedagogy, especially when introducing new technologies to students. Students will learn SOP via the proposed platform that showcases techniques for developing, outsourcing, and composing web services. Second, the curricular materials are being developed in the form of *course modules*, which are well-defined, self-contained units of instruction that can be incorporated into one specific course, either as-is or with minor modification, within several courses currently offered in diverse computing disciplines such as CS or SE. Course modules are becoming common in computing pedagogy, and have been used in introductory programming, computer graphics and security. This modular approach also allows for vertical integration of SOP into the undergraduate curriculum.

The reminder of this paper is organized as follows. Section II presents an example where SOP is used to develop a complex application, and Section III describes our SOP framework that supports the development of SOP applications. In Section IV, we present an overview of three course modules that can be used for teaching SOP and how these modules can be incorporated into existing CS/SE courses. Section V

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

summarizes the current status of our project.

II. An Example SOP Application

Suppose we want to develop a web-based hotel query application that allows users to view information about hotels, given a specific location. This is a fairly common web scenario that most people are accustomed to. More specifically, the application may take an address as input from users and then return a list of hotels nearby, perhaps with other related information such as local weather, and driving directions to each selected hotel from another specified address

Obviously, to build such an application from scratch, i.e., without outsourcing any functionality to existing service providers, would take considerable effort and would also require direct access to resources such as database content (hotel, weather and routing information) and efficient query mechanisms for processing and presenting the needed information. However, under the SOP paradigm, we first decompose this application into three components: (1) a *hotel query* component that takes an address as input and returns a list of hotels nearby and related information such as names, addresses, contact phones; (2) a *weather query* component that takes an address as input and returns the local weather information such as temperature and wind; (3) a *route query* component that takes two addresses as input and returns the driving directions between them. To build this application, we then investigate existing web services that can be used to create each of these required components; examples of such web services include the Expedia APIs, the Weather Underground API, and Google Directions APIs. We can finally develop the application using these APIs and connecting them together appropriately.

III. The SOP Framework

The backend of our SOP framework contains a *web service pool* and an *SOP application pool*. The services and the applications are registered in the *registry* that will handle the service queries from students. Students may specify and submit their queries via the *query interface*. They can also publish their own developed services in the registry via the subscription interface, and log the development steps using the logging manager. The *visualization interface* provides a mechanism to visualize the process of SOP application development.

The service pool contains web services that can be outsourced for constructing new applications. For the purpose of exemplification, the services vary in their types, e.g., the two typical interfacing approaches, SOAP (Simple Object Access Protocol) and REST (Representational State Transfer); functionality, e.g., movie service or weather service; and domain, e.g., travel or medical. From these sample services, students can explore the external features such as Web Service Definition Language (WSDL) and Universal Description Discovery and Integration (UDDI) descriptions, and internal features such as implementation code and configuration files, of these services. Beside these "in-house" services, the service pool includes services from third-party providers, e.g., Facebook APIs and Twitter APIs, to enhance service diversity that improves overall learning. The application pool contains those applications built from the services in the service pool.

Our framework uses the two major development platforms for developing web services and SOP applications: J2EE and .NET. In J2EE, web services and applications are implemented using Java on a widely used Integrated Development Environments (IDEs) such as Eclipse and NetBean. In .NET, web services and applications are developed using C# on a current version of Microsoft's Visual Studio.

The framework provides a convenient and flexible interface that can be used by students to search for their desired services and applications. The search criteria can include the service types, development platforms, functionality, and domains. Students can get access to the implementation codes and configuration files of all of the in-house services and applications, as well as WSDL descriptions or documentation of all services in the service pool.

The visualization interface helps to demonstrate how applications may be created by putting together existing services. The interface also shows students how different component services collaborate with one another. In this regard, the visualization interface provides a holistic view that helps students gain a deeper understanding of SOP development, including the generation of message exchanges and invocation orders.

The subscription interface allows students to register their own services and applications to the registry for future use. This helps students enhance their understanding of the fundamental SOP architecture consisting of service providers, service consumer, and service registry. Meanwhile, by allowing them to query and reuse their own services/applications to develop new applications, the subscription interface further strengthens student understanding of software reuse.

IV. SOP Course Modules

A course module is a collection of curricular materials that typically addresses one specific course learning outcome. It removes barriers by providing adoptable materials, summarizes required background expertise, and makes it easier to gain institutional acceptance [9]. Each course module is independent and a faculty member can individually select a course module to experiment with and adopt it to his or her own courses. Table I shows the components of our course modules.

To teach SOP and incorporate the developed course modules into CS/SE curricula, we designed three course modules to be offered at three levels–introductory, mid-level and senior–in both CS and SE. These course modules are discussed next.

A. Course Module 1—Introductory Level

This module targets CS2, the second course in the problem solving sequence typically required for first year students in several computing majors such as Computer Science, Software Engineering, Computer Engineering, and Computational Math. The major components of this course module include lecture slides, sample questions, demos, and labs. The lecture slides provide a brief overview of service-oriented architecture, key Web service standards, including WSDL and UDDI, and the fundamental principles of SOP. Topics span the motivation and historical overview of SOP, typical SOP applications, a comparison of SOP with other problem solving methodologies, and an introduction to the state-of-the-art SOP technologies.

TABLE I. COMPONENTS OF A COURSE MODULE

Component	Brief Description
Overview	Description of module, prerequisite knowledge, and module learning outcomes
Rationale	Motivation for the module
Recommended use	Recommendations for typical usage
Slides	Module content for lectures or independent learning activities
Sample questions	For use in low-stake quizzes
Labs/assignments	For hands-on experiences in solution design, implementation, and verification
FAQ	Answers to students frequently asked questions
Readings	Introductory or supplementary materials referenced in the module
Links	Pointers to online and other materials used in the module
Module evaluation	Assessment tools to measure learning and module effectiveness

In our first offering of this module, we covered these slides between one and two weeks. The sample questions focus on basic SOP concepts and technologies, for example, *"Describe the three roles in a service oriented architecture," "Explain the difference between SOAP and REST,"* and *"Explain the structure of a WSDL document."* The demo showcases the development of a Web service using NetBeans, and of an application that uses several services from the platform's service pool. The labs provide step-by-step instructions for developing web services and SOP applications.

B. Course Module 2—Mid-level

This module targets a mid-level course such as a Programming Language Concepts course, which typically examines various high-level programming languages and different programming paradigms such as imperative, functional, and logic. This module presents SOP as a programming paradigm for reuse, with the lecture slides covering topics including service-oriented architecture, service discovery, service description, service invocation, and service composition. In the first offering of this module, we spent around two weeks on the lectures. Students develop a program library for reuse and clearly identify the contract between the library and its clients; wrap the library as a Web service using that contract; register the service to the platform's poo; perform a UDDI query to the service pool to select the desired services; and use the selected services to construct a client application using Business Process Execution Language (BPEL) or XML Process Definition Language (XPDL).

C. Course Module 3—Senior Level

This module targets a senior level SE course, e.g., Software Engineering of Enterprise Systems, which focuses on the architecture, design, and implementation of enterprise-critical software systems. Topics include service-oriented architecture, cloud infrastructure, service-based workflow systems, adaptive service composition, and Web service security. The course module also includes several elective topics such as efficient service discovery, change management, privacy protection, and Web service transaction management. Two to three weeks of the course schedule is allocated to this module. A team-based, term project provides students with the opportunity to develop an application reflecting a real-world scenario. Students investigate cutting-edge research efforts on the topics covered during lecture, choose appropriate approaches, and integrate them into their projects.

V. CURRENT STATUS

We have developed several sample web services in various domains, including travel, entertainment, and finance, and SOP applications using both Java and C#; we have implemented an initial version of the query, subscription, and visualization interfaces. We have also developed the first versions of the three course modules and have offered two of these modules in spring term in 2013: course module 1, both at Howard University, and SUNY at Oswego, and course module 2 at Rochester Institute of Technology (RIT). We have scheduled workshops on SOP at RIT and at FIE 2013. Once the developed curricular materials and the SOP framework are ready, we plan to post them on our project website.

***Abstract*—Educational remote laboratories are a software and hardware tool that allows students to remotely access real equipment located in universities as if they were in a hands-on-lab session. Their integration in Content and Learning Management Systems (CMSs or LMSs) has been an active research topic for years, supporting mainly ad hoc solutions. A notable exception has been the use of federation protocols –commonly used for sharing laboratories from one university to other–, for actually sharing laboratories from a remote laboratory system to a C/LMS. This approach opened new doors in the simplification of the process, since it did not require the remote laboratories to make any type of change. The focus of this contribution is to provide a solution to decrease the number of functionalities required for creating an integration by providing a software component that reuses them. As shown in the contribution, this component has been implemented and two remote laboratory management systems (which provide access to multiple remote laboratories) are already supported, and a third one is under development. In the C/LMS side, all the LMSs supporting IMS LTI are supported, and HTTP APIs are provided for being supported by other systems. Indeed, the contribution describes its support in the Joomla CMS and in the Moodle 1.9 and dotLRN LMSs which do not support IMS LTI. The solution, called gateway4labs, is an open source initiative which targets to be used in production.**

I. INTRODUCTION

An Educational Remote Laboratory is a software and hardware solution that enables students to access real equipment located in their institution, as if they were in a hands-on-lab session. There are many kinds of remote laboratories, including fields such as Physics, Electronics, Robotics or Chemistry. Once these laboratories are available through the Internet, it becomes possible to share them with other universities. Given that both traditional and remote laboratories pass long time unused (nights, weekends, weeks which no practical lessons…), if *University A* shares two laboratories with *University B* and vice versa, then both have 4 labs with similar maintenance costs. For this reason, remote laboratories federations have been explored and been used in production for years.

Integrations of remote laboratories on Content Management Systems (CMSs) or Learning Management Systems (LMSs) –in the rest of the document, C/LMS– have been addressed in the literature. The focus is to integrate remote laboratories (which are educational resources after all) into LMSs (which is where the students and teachers meet and where students find other educational resources). While this integration has always been a relevant topic in the area of remote laboratories, most solutions in the literature have been ad-hoc: this remote laboratory developed in *University A* is integrated in the LMS used in University A and will not work with other C/LMSs. Not supporting this integration forces remote laboratory systems to duplicate certain structures (e.g., authorization) commonly already available in the C/LMS. Additionally, the user experience would be improved if the remote laboratories were treated as yet another educational resource in the LMS.

Last year, the usage of remote laboratories federations for the integration of remote laboratories in C/LMSs was proposed and evaluated [1]. In that contribution, a particular remote laboratory management system (WebLab-Deusto) was integrated in one LMS (Moodle) and one CMS (Joomla) to validate that federation protocols enable this integration in a simple approach. While the approach of using federation for this integration was novel, and it was noticeable that it did not require changes on the remote laboratory management system, it still required much of the logic to be implemented as plugins in the different C/LMSs.

The focus of this contribution is to present a novel and open

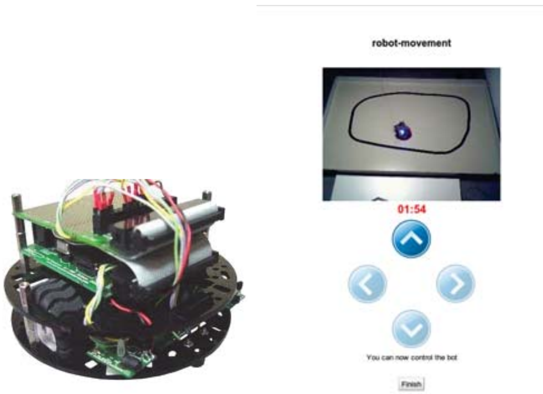

Fig. 1. Robot laboratory [2]. At the left, the mobile robot itself. At the right, the user interface once the program has been submitted.

source software component, called gateway4labs, that makes it possible to support different LMSs through the use of IMS LTI, as well as other systems (such as LMSs not supporting LTI, or CMSs) with lighter plug-ins than it was in that contribution. This component also supports a set of plug-ins for integrating new remote laboratory management systems, so it is extensible in both sides. It has been evaluated testing it in Moodle LMS (through IMS LTI), the .LRN LMS (without IMS LTI) and the Joomla CMS.

The paper is structured as follows: Section II introduces the concepts of remote laboratory, remote laboratory management system and remote laboratory federation. Then, Section III shows what integrations of remote laboratories in C/LMSs are available in the literature. Section IV explains the proposed solution and the analyzed use cases. Finally, Section VI describes the conclusions and the future work.

II. Remote Laboratories Federations

This section introduces the concepts of Remote laboratories, Remote Laboratory Management Systems and remote laboratory federations.

A. Remote Laboratories

A remote laboratory is a software and hardware tool that allows students to remotely access real equipment located in the university. Users access this equipment as if they were in a traditional hands-on-lab session, but through the Internet. To show a clear example, Figure 1 shows a mobile low cost robot laboratory described in [2]. Students learn to program a Microchip PIC microcontroller, and they write the code at home, compile it with the proper tools, and then submit the binary file to a real robot through the Internet. Then, students can see how the robot performs with their program through the Internet (e.g., if it follows the black line according to the submitted program, etc.) in a real environment.

In this line, there are many examples and classifications in the literature [3], [4]. Indeed, remote laboratories were born nearly two decades ago [5], [6], [7], and since then they have been adopted in multiple fields: chemistry [8], [9], physics [10], [11], electronics [12], [13], robotics [14], [15] and even nuclear reactor [16].

B. Remote Laboratory Management Systems

Every remote laboratory manages at least a subset of the following features: authentication, authorization, scheduling users to ensure exclusive accesses -typically through a queue or calendar-based booking-, user tracking and administration tools. These features are common to most remote laboratories, and are actually independent of the particular remote laboratory settings. For example, an authentication and queuing system is valid both for an electronics laboratory and for a chemistry laboratory.

For this reason, Remote Laboratory Management Systems (RLMSs) arose. These systems (e.g., MIT iLabs[1], WebLab-Deusto[2] or Labshare Sahara[3]) provide development toolkits for developing new remote laboratories, as well as management tools and common services (authentication, authorization, scheduling mechanisms). The main idea is that by adding a new feature to one of them (e.g., supporting LDAP, or LMSs), all the laboratories which are developed on top of them will support this feature automatically.

C. Federating Remote Laboratories

One of the features that RLMSs started supporting was federating their remote laboratories. For example, if two universities (*University A* and *University B*) install a particular RLMS, they support federation protocols so *University A* shares a laboratory with students of *University B* without knowing these students. The key here is that the provider university does not need to register particular students, but rather groups or simply universities. It is the consumer system who defines that a set of local users can access a particular laboratory of the provider system.

Therefore, the relationship between two federated entities is the following:

- The consumer system manages the authentication and authorization of its students.
- The provider system manages the scheduling and the access to the laboratories, storing what the users did.
- The consumer system will later ask for results to the provider system.
- In every moment, the provider system does not need to know anything related to the particular students.

D. Relevance

Remote Laboratories have been considered as part of the *Five Major Shifts in 100 years of Engineering Education* in the Special Centennial Issue of the Proceedings of the IEEE [17], in respect to the influence of Information Communications and Computational Technologies.

In particular, the interest on federation of remote laboratories is growing. The Labshare project survey [18], made on all 34 Australian universities offering undergraduate engineering programs, reflects that the interviewed executives were more

[1] http://ilab.mit.edu/
[2] http://www.weblab.deusto.es
[3] http://labshare-sahara.sf.net

interested in getting involved for the pedagogic merits of the remote laboratories, and were more inclined on initially being laboratory consumers than providers. Indeed, the European Union Commission is investing 60 million euros in research actions, projects and network of excellences in Technology-Enhanced Learning (TEL), under the objective ICT-2011.8.1 of the call FP7-ICT-2011-8. One of the target outcomes is precisely *"Supporting European wide federation and use of remote laboratories and virtual experimentations for learning and teaching purposes"*[4]. Indeed, the IP project Go-Lab[5], funded by this call with 10 million euros, aims to support a wide federation of remote and virtual laboratories. Parallel and related efforts have been placed on systems that index remote laboratories located at different institutions such as lab2go [19] or even grant access to laboratories as LiLa [20], [21], [22].

III. Existing Integration of Remote Laboratories in Learning / Content Management Systems

The relevance of this field is that, as detailed in [23], there are several services duplicated between remote laboratories and learning management systems. The administration and user experience would increase if they were merged. Both systems usually support user authentication, authorization, group management, administrative tools, user tracking, and even scheduling. Some integration approaches suggest to delegate all these services to the LMS, but some of these services will still be at least shared, such as scheduling (especially when federation systems arise) or user tracking (since some interactions with the remote laboratory might occur outside the scope of the web browser).

There are two types of solutions in the literature for using Remote laboratories in C/LMSs: ad-hoc solutions or based on federation protocols.

A. Ad-hoc Solutions

In order to integrate remote laboratories and LMSs, [3] discusses the usage of SCORM and [21] implements an architecture around it. This technology is designed to be supported by different LMSs and indeed multiple LMSs have implemented different versions. However, since it is a client-side technology and therefore it cannot contain any server code, it does not support a secure way to exchange credentials, ensure reservations or return results to the LMS.

Other approach is to develop an ad-hoc plug-in to include a particular remote laboratory on a LMS, applying the required changes in the remote laboratory [24]. This approach is common in the literature, and sometimes it is implemented by just copying or exchanging the users among both systems. Within the field of integrating remote laboratories on electronic tools appears the integration of remote laboratories on CMSs. In [25], the remote laboratory relies on Joomla to perform all the administrative tasks. This approach is interesting since it does not duplicates all the tasks refered in [23]. However, it is an example of an ad-hoc integration which does not support the integration of other remote laboratories neither the integration on other CMSs.

[4]http://cordis.europa.eu/fp7/ict/telearn-digicult/telearn-objectives_en.html
[5]http://www.go-lab-project.eu/

B. Federated Solutions

In [1], it was proposed other approach to integrate remote laboratories in C/LMSs, relying on the existing federation protocols already existing in certain RLMSs. The advantage of this approach is that indeed, federation protocols have the same targets as the integration protocols of remote laboratories in C/LMSs, where the consumer system is the C/LMS. Indeed, if in the description of federations presented in Section II-C, the term *consumer system* was replaced by *C/LMS*, the following description would be presented, which applies very well to the definition of integration of remote laboratories in C/LMSs:

- The C/LMS manages the authentication and authorization of its students.
- The provider system manages the scheduling and the access to the laboratories, storing what the users did.
- The C/LMS will later ask for results to the provider system.
- In every moment, the provider system does not need to know anything related to the particular students.

So as to demonstrate this, [1] presented two use cases, both using the WebLab-Deusto RLMS and using plug-ins which consumed the federation protocol for two C/LMSs: Joomla and Moodle. In both cases, the development was dependent on the federation protocol of WebLab-Deusto, and two C/LMS plug-ins which required some administration tasks (for managing the authentication and authorization) were required. The use of federation for integrating different tools has also been addressed in the literature [26].

IV. Discussion

As it was already presented in [1], it is possible to use federation protocols to integrate remote laboratories in C/LMSs. However, the solution presented in that contribution was only suitable for those particular systems (WebLab-Deusto, Joomla, Moodle). However, RLMSs need to support multiple C/LMSs, since they are installed in multiple universities which may use different C/LMSs.

If 3 C/LMSs were aimed, and 2 RLMSs were attempted to be supported, then 6 integrations (and testing) would be required. This does not only increases the time required to support other systems, but also decreases the chances of doing such implementations until it is well known that somebody is going to require them.

Another problem is that these C/LMSs plug-ins shared certain logic. Concepts such as *course A and course B have permission on laboratory L* needed to be implemented in all of them. The implementation and maintenance of the federation protocols of the RLMSs was also required, and it is not a trivial task.

However, let us assume that there was a new component in the middle, between RLMSs and C/LMSs. C/LMSs would build plug-ins aiming this middle component, instead of focusing on a particular RLMS. This component might have a plug-in system, and RLMSs would do the work of developing plug-ins for it, instead of focusing on particular C/LMSs.

The result would be that only 3 C/LMS plug-ins would be required for supporting all the RLMSs that had developed plug-ins. In the same way, 2 RLMS plug-ins would be required for supporting all the C/LMSs. Using this approach, if a RLMS is deployed in a location where a fourth C/LMS was used, it would be easy that they developed the support for that C/LMS. The interesting point is that once they do it, all the supported RLMS (present and future) benefit from this. In the same way, if a RLMS aimed to be supported using this system, it would suddenly be available for all the C/LMSs supported by this component.

Furthermore, once the component supports other existing protocols, RLMSs can be used by them automatically. For example, several LMSs support IMS Basic LTI, which is a standard for interoperability among Learning Tools. Once the component supported Basic LTI, RLMSs could be used by those LMSs supporting Basic LTI without any plug-in or change in the LMS, as it is evaluated in the next section. This approach also opens new opportunities. The GLUE! architecture [27] supports that certail tools (where gateway4labs could be a tool) are consumed by other systems, such as Mediawiki or LAMS. While not tested, it is theorically possible to connect both architectures in a seamless way to benefit each other and extend their tools to be connected.

The target of this contribution is precisely to propose and demonstrate that it is possible to develop such a canonical component, and this improves the current state of integrations of remote laboratories in C/LMSs.

V. Evaluation

So as to evaluate, such component has been implemented and released under an Open Source license, and it has been called gateway4labs[6]. A number of plug-ins to support C/LMSs and RLMSs have been implemented. This section describes this component and how this addresses the contribution of this statement and analyzes it.

A. Overall design

The architecture of gateway4labsis described in Figure 2. In the middle, there is a component called *LabManager*. Then, there are two parts:

- The C/LMS side or *consumer side*, where the different C/LMSs implement one of the supported protocols. The LabManager is not aware of the particular type of C/LMS which consumes it.
- The RLMS side, or *provider side*, where the different RLMSs are managed. The LabManager has a single plug-in for each RLMS, and the RLMSs remain unchanged, since their federation protocols are used.

The LabManager has a registry per each C/LMS, and it is aware of what courses are in each of them. The LabManager administrator configures what laboratories are available in each RLMS, and what C/LMSs have permissions on which laboratories. Then, when an administrator of the C/LMS system enters in the LabManager, he can select which courses will get permissions to each laboratory available for that C/LMS.

[6] http://github.com/gateway4labs

Finally, students enrolled in those courses are automatically enabled to use those laboratories.

The LabManager is Open Source so it can be deployed in each institution, but also the RLMS side can install it to enable access to those universities interested in consuming their laboratories.

B. Consumer side

In the C/LMS side there are two supported approaches: IMS LTI or plug-ins in the C/LMSs by using a RESTful HTTP interface.

The *LabManager* implements IMS LTI (Learning Tools Interoperability, a standard developed by IMS), so any C/LMS implementing it can consume the *LabManager* and therefore, all the laboratories supported by those supported RLMSs. At the time of this writing, this includes Moodle since its 2.2 release, as well as Blackboard, Sakai, WebCT among others. This way, all these LMSs will automatically support all the supported RLMSs directly, without implementing any type of plug-in.

However, not all the C/LMSs support IMS LTI. Ilias, dotLRN, older versions of Moodle still used in production, and most CMSs do not support it. For this reason, gateway4labsalso provides a simple bidirectional HTTP interface that can be consumed by other systems.

The following is a sample request which the C/LMS must perform to the *LabManager*, stating that there is a valid user called “john” (which neither the *LabManager* or the RLMS know), authenticated in the C/LMS, who is requesting the laboratory identified as “robot” for that particular C/LMS. This student is enrolled in a set of courses as student.

```
POST /gateway4labs/labmanager/requests/ HTTP/1.0
Authorization: Basic dW5lZDpwYXNzd29yZA==

{
   "user-id"    : "john",
   "full-name"  : "John Doe",
   "is-admin"   : true,
   "user-agent" : "Mozilla/5.0 (X11; Ubuntu; ...",
   "origin-ip"  : "192.168.1.1",
   "referer"    : "http://.../",
   "courses"    : {
        "01"    : "s",
        "02"    : "s",
        "03"    : "t", // "t" = teacher, "s" = student
        "04"    : "s",
   },
   "request-payload" : "{
        'action'     : 'reserve',
        'laboratory' : 'robot',
   }"
}
```

The *LabManager* relies on the C/LMS for guaranteeing this information. With it, it can check the permissions of those courses to see whether the user can use the “robot” laboratory or not, and this laboratory has previously been mapped by the *LabManager* administrator to a particular RLMS. These courses have previously been added by the C/LMS administrator in the LabManager, using other HTTP interface, but this time provided by the C/LMS through a plug-in.

It is important to remark that this protocol is between the C/LMS server and the *LabManager*. This way, the information

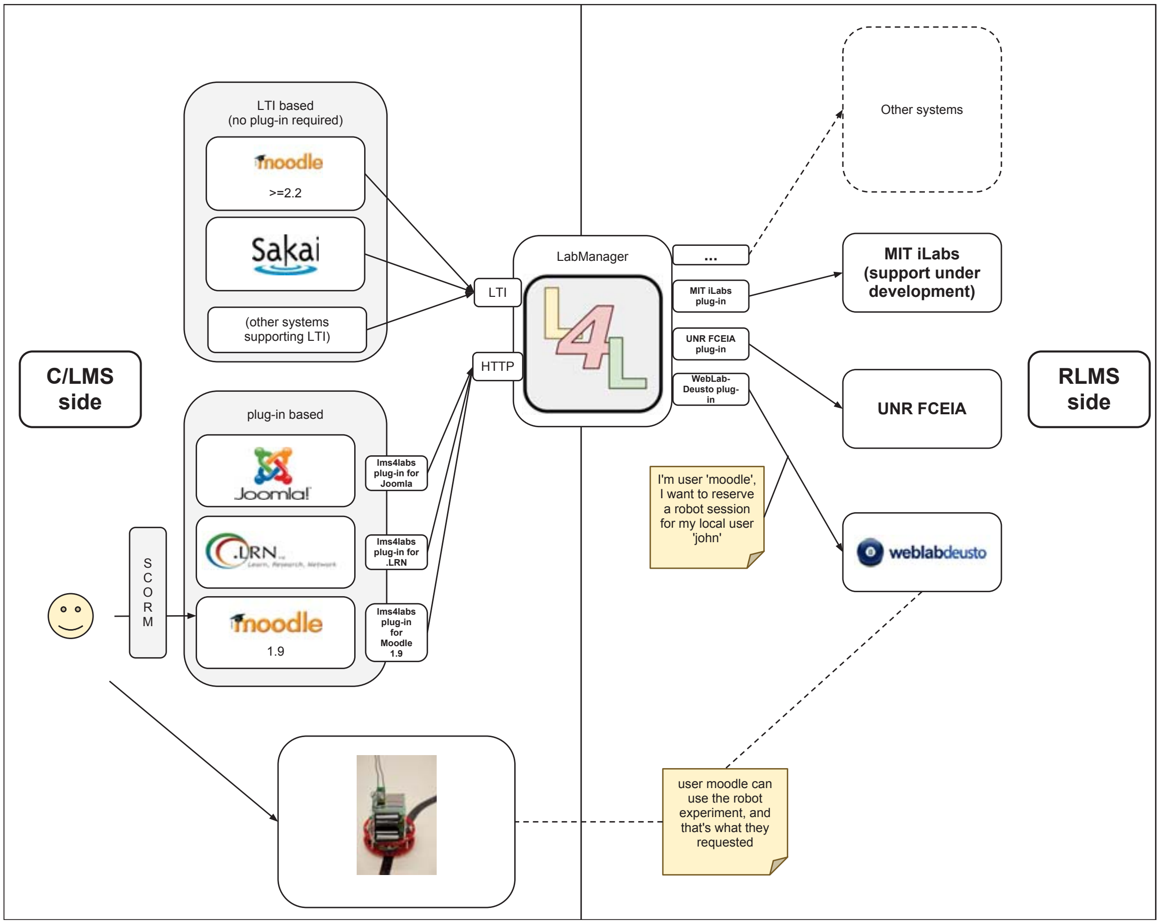

Fig. 2. Architecture of gateway4labs

is securely submitted, but it is required to modify the C/LMS (usually through a plug-in) to do this.

To make the development of this task easier in the case of LMSs, it is optionally possible to rely on SCORM. SCORM is a standard well supported in LMSs which enables instructors to upload contents in a generic format. This format does not support server side code and therefore any solution only relying on it will be insecure. However, the LMS plug-in could implement a simple HTTP API defined by gateway4labs, which enables SCORM objects to be shared among different LMSs supporting gateway4labs. This way, the SCORM objects call this HTTP API, which is implemented by the particular LMS plug-in and calls the HTTP interface explained above at the *LabManager*. This way, the LMS plug-in remains small, since even the contents are developed by the instructors. Unfortunately, for CMSs or systems not supporting SCORM, the user interface must be implemented from scratch.

The IMS LTI approach has been tested with Moodle 2.3, without requiring any development at LMS level (no plug-in was required). The HTTP interface approach has been tested with two LMSs (Moodle 1.9 and dotLRN, both using the SCORM approach mentioned above), and with one CMS (Joomla, without using SCORM).

C. Provider side

The provider side refers to the part of the *LabManager* which supports the different RLMSs. At the time of this writing, a simple interface has been defined, and two implementations have been developed on top of it. The interface basically defines operations such as: *what laboratories do you provide?* and *perform a reservation to a user called "John" to the "Robot laboratory"*, relying on the RLMS federation protocol. The RLMS trusts the *LabManager* and does not need to know "John". The RLMS generates a URL which is passed to the user through the *LabManager*, and therefore the user will finally go to the RLMS with the scheduled session.

At the time of this writing, this interface is always requesting an access *now*, so it fits very well with queueing systems, where students are granted URLs which make students wait in the queue until they use it. However, it has not yet been defined its counterpart for calendar-based booking.

The two plug-ins developed for supporting RLMSs are WebLab-Deusto and FCEIA-UNR. WebLab-Deusto [28] is a pure RLMS on top of which multiple remote laboratories have been developed, mainly in the University of Deusto (Spain) but also in other universities. FCEIA-UNR [29] is a remote laboratory developed in the Universidad Nacional de Rosario (UNR, Argentine).

Support for MIT iLabs is still under development at the

TABLE I. SUPPORTED C/LMSS AND LINES OF CODE. ADMINISTRATION PAGES LINES OF CODE INCLUDED.

C/LMS	Type	Approach	Lines of code

dotLRN	LMS	HTTP + SCORM	708
Joomla	CMS	HTTP	676

TABLE II. SUPPORTED RLMSS AND LINES OF CODE.

RLMS	Lines of code
WebLab-Deusto	890
FCEIA-UNR	141

time of this writing.

D. Results analysis

This subsection analyzes the approach presented, mainly from the point of view of the complexity and flexibility of the system.

First, let us analyze what is required to support a new C/LMS. In the case of those supporting IMS LTI, nothing is required. As seen on Table I, supporting Moodle 2.3 costs zero lines of code, since no plug-in is required. In the case of those systems where a plug-in is required, the system does not need to deal with authorization (which courses can access which laboratories is implemented in the *LabManager*), neither with the particular laboratories (the plug-ins for the RLMSs are implemented in the *LabManager*), but only implementing the HTTP interface. Additionally, it is possible to support the HTTP interface for supporting SCORM objects and therefore the same SCORM objects can be shared among different LMSs. As seen on Table I, implementing this requires really few lines of code (and take into account that code for administration pages is included).

Second, let us analyze what is required to support a new RLMS. A plug-in must be developed in Python in the *LabManager*, and it will be automatically used by all the C/LMSs. This plug-in depends on the complexity of the RLMS interface. Table II shows that it still requires few lines of code in the case of WebLab-Deusto and FCEIA-UNR.

These results show that a small amount of code is actually required for both C/LMS and RLMS support. This is so since the *LabManager* already implements some of the key shared features, such as user interfaces and selecting which RLMSs are available for each particular course (see Figure 3).

Third, it is remarkable that using this design, every component is implemented only once. The FCEIA-UNR plug-in is developed using Python in the *LabManager* and it is automatically available for all the C/LMS, present and future, regardless they are implemented on PHP (Joomla, Moodle), TCL (dotLRN), Java (Sakai, which supports IMS LTI) or any other technology. No re-implementation is required. This should encourage RLMS developers to develop and provide their own plug-ins to support a wide range of C/LMS systems.

Fourth, as explained in [30], in the RLMS side, depending on its complexity, it is possible to achieve more complex chains. For example, WebLab-Deusto supports transitive federation (University A sharing a laboratory to University B automatically enables University B to re-share it with University C). Applied to this case, this means that being the *LabManager* in University C still enables students to access laboratories of University A.

Finally, from the point of view of efficiency, it might seem that so many layers add an notable latency. However, while the reservation process might add this latency due to the different networks that could be involved (user $\rightarrow$ C/LMS $\rightarrow$ *LabManager* $\rightarrow$ RLMS), the interaction with the final RLMS is direct, so the added latency once using the laboratory is zero.

VI. CONCLUSIONS AND FUTURE WORK

This contribution is based on the assumption that it is possible to integrate remote laboratories in C/LMSs using federation protocols [1]. On top of this assumption, it shows how it is possible to use this approach collecting several common features (e.g., authorization or federation protocols clients) into a single software component. This way, instead of multiplying the supported C/LMSs by the RLMSs for calculating the number of integrations (e.g., supporting 4 C/LMSs in 3 RLMSs would require 12 ad hoc integrations), the number of integrations are notably decreased (e.g., supporting 4 C/LMSs in 3 RLMS would only require 4 integrations with the middle component plus 3 RLMS plug-ins, which not only sums only 7, but each integration is much smaller). Additionally, this encourages different RLMS developers to work together in the support of C/LMSs that will be automatically supported for them.

So as to demonstrate it, this middle component has been implemented, as well as support for certain RLMSs (WebLab-Deusto, FCEIA-UNR) and C/LMSs (using both IMS LTI –which includes Moodle since 2.2 and Sakai among others–; as well as through plug-ins in Joomla, Moodle 1.9 and dotLRN). The number of lines of code have been presented to verify that once the middle component (called *LabManager*) is implemented, all these integrations become small, therefore reusing a lot of code (the whole *LabManager*). This implementation is open source and available for being tested[7].

Regarding future work, ongoing efforts on polishing the system target to use it in production in different universities with students. There are other efforts to support other approaches in the consumer side, to not only support C/LMSs but also Personal Learning Environments (PLEs) such as Graasp[31], as well as other architectures that connect different tools, such as GLUE! [27]. Additionally, one of the drawbacks of the current provider API is that it only supports requests for accessing the remote laboratory at the time of the request, instead of also supporting a calendar-based booking scheme. With its support, more RLMSs will be supported. Finally, the system does not support usage retrieval at this stage.

***Abstract*—Embedded Systems design courses are important components in software, computer, and electrical engineering programs and curricula. We describe topics for inclusion in these courses and associated hands-on experiences as required portions of the courses including example development systems based upon two popular microcontrollers. We also describe the challenges of offering these courses in distance format and provide examples of how the hands-on component may be included for distance students.**

Keywords—embedded systems; distance education

I. Introduction

A significant number of computer and software engineers practice in the area of embedded and real-time systems design. Embedded Systems (ES) are found in virtually every application domain such as transportation, defense, communications and industrial control and are also ubiquitous in consumer products such as appliances and televisions. The application settings usually require that the embedded system must adhere to real-time constraints. Therefore, a mainstream topic within modern computer and software engineering curricula is embedded systems design and implementation. Such courses can be very effective when combined with practical laboratory exercises that involve hardware interfacing and the development of systems-on-chip comprised of a processor core, memory, peripherals, and real-time firmware. Using this approach, the student learns the necessary skills of software and hardware design that will provide the foundation for future embedded system design.

Many educators agree that an effective means for administering classes in these areas is to combine a lecture portion with hands-on projects [7][8][9][10]. Consistent with this viewpoint, traditional embedded system courses have separate lecture and laboratory sessions. Students learn embedded system theory and concepts in the lecture session, and then apply this knowledge to practical applications in the laboratory session.

However, there is an increasing number of distance education students who need to participate remotely through various forms of synchronous and asynchronous distance learning. Coupled with the desired content of an embedded systems class is the need for supporting distance education students. The number of students requiring distance education formatted courses continues to increase as more and more students are moving from traditional on-campus class attendance to remotely administered courses [11]. While many methods exist for delivering the lecture session to distance education students, a significant challenge is the delivery of the laboratory sections remotely.

This paper addresses the challenge of offering an embedded systems class containing content consistent with modern processors and design methods in both a traditional and distance education format. Distance education classes that are comprised of laboratory content require carefully crafted experiments and hands-on experiences in order to be successfully administered to distance students. However, there are significant challenges to providing a meaningful laboratory experience to students at a distance. In this paper we describe these challenges and propose some approaches to delivering such a course.

In particular, we describe embedded and real-time systems classes that are based upon the ARM® and Arduino® processor architectures with associated laboratory/project sections that are designed to be accessible by both traditional and distance students. We address the challenge of offering the class in a distance format while also incorporating a required laboratory. A description of experiments and projects is included and is accompanied by an evaluation of different types of equipment, software, and simulators available to support the laboratory section. One of the discussed approaches utilizes a HDL (Hardware Description Language) softcore version of an ARM® processor and HDL descriptions for the interfacing portions of the project. Using these resources, laboratory experiments and course projects can be conducted remotely by distance students.

II. Embedded Systems Background

Embedded systems are generally defined to be any system composed of input/output devices, at least one processor, and dedicated memory that are integrated subsystems within a larger overall system. These systems often have real-time or near real-time constraints in that the production of an output response must occur within some specified time frame after the occurrence of a corresponding input event. For this reason, most embedded systems contain dedicated timers or other means for meeting application-specific deadlines. Other commonly included support circuitry includes data converters for transformation of analog to digital signals and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

vice versa. Many embedded systems involve significant amounts of signal processing capability and the designer must determine which portions of the signal conditioning and processing should be ported into dedicated hardware or implemented in software. The microcontroller unit contains the CPU and is responsible for running the application-specific software as well as providing internal embedded system control.

In modern embedded systems, the CPU is present in the form of a single integrated chip (IC) that is typically comprised of other cores such as timers, on-chip memory, data converters, and hardware accelerators. Many products that have anticipated large volume sales in the marketplace contain custom microcontroller chips that are designed for the specific application and are referred to as a 'System on Chip' (SoC). The design flow for a SoC generally involves the selection of a set of third party vendor cores such as a CPU, memory, I/O interfaces, and hardware accelerators with little custom circuitry. These cores are interconnected within the custom microcontroller through the use of custom or industry standard busses. The use of standardized busses is more common and includes busses such as AMBA, I2C, and others. Bus controller and interface cores are available from third party vendors for inclusion in custom SoC microcontroller designs.

In terms of supporting software, the microcontroller within an ES is most usually intended for a specific function and it is thus uncommon to find commonly known general-purpose operating systems (OS) such as Microsoft Windows in use. Some ES do utilize an OS specifically designed for the ES design space such as open source software variants of Linux or commercial real-time operating system, while other more simple ES rely on simple monitors or even a main controlling program that contains system housekeeping within the dedicated application [5]. Because a typical ES must have the capability to reboot at the time of power-up, the controlling software is typically present in on-board non-volatile memory such as Flash and is referred to as 'firmware'. Those ES that utilize an OS have different requirements as compared to an OS for a general purpose computing system such as a laptop and generally do not need the capability to support a large variety of I/O devices and virtual memory support. Furthermore, most ES utilizing an OS do require a real-time component, thus such OS often support timing relating features.

Many ES are implemented as portable devices such as a cell phone or hearing aids and thus require careful consideration of power usage. Additionally, performance is an important consideration due to processing time constraints. These two design constraints present a tradeoff since power savings is generally inversely proportional to performance. In order to meet ES requirements, the systems level design process involves the determination of a hardware/software co-design partitioning followed by determining how the individual hardware and software components will be implemented. Hardware implementation is accomplished through a selection of third party hard- or soft-cores and the choice of technologies for any custom hardware devices. If it is determined that some hardware components will be directly designed, a further choice is made regarding the use of commercial off-the-shelf (COTS) programmable logic devices versus a standard cell or custom implementation. Similar tradeoffs are made with regard to software implementation with those most crucial portions of the software implemented in low-level assembler language and those less crucial portions implemented in higher-level languages such as *C*. It is often the case that high-level language paradigms such as object-oriented programming are avoided due to the overhead required by the compiler to support features such as operator overloading being to costly in terms of performance.

III. ES Course Core Topics

Embedded system classes are taught at both the undergraduate and graduate levels. Given the description of an ES architecture as provided in the previous section, it is clear that several core academic topics may be present in a typical ES design class. Particular program curricula at a given institution often include some of these topics in prerequisite courses. In this case, the corresponding topic may not be present in the actual ES course syllabus.

1) Digital Logic Design and Implementation
2) Computer Architecture
3) Operating Systems
4) Software Design and Implementation
5) Systems Design and Implementation

Each of the core topics comprises an extensive amount of material and they are typically present in most curricula as one or more stand-alone courses. The IEEE and ACM jointly developed a model undergraduate curriculum for the embedded systems component of a model curriculum as shown in Table I.

TABLE I. ES Class Knowledge Units from 2004 IEEE/ACM Model Curriculum [9]

Topics/Knowledge Units	Importance	Time Allocated
History and Overview	CORE	1
Embedded Microcontrollers	CORE	6
Embedded Programs	CORE	3
Real-Time Operating Systems	CORE	3
Low-Power Computing	CORE	2
Reliable System Design	CORE	2
Design Methodologies	CORE	3
Tool Support	ELECTIVE	variable
Embedded Multiprocessors	ELECTIVE	variable
Networked Embedded Systems	ELECTIVE	variable
Interfacing and Mixed-Signal Systems	ELECTIVE	variable

Uthariaraj and Babu suggested that (a graduate course) in ES should have the following components in [12]:

*"**Introduction**: Embedded computing, characteristics of embedded computing applications, embedded-system design challenges, constraint-driven design, IP-based design, hardware, software codesign*
***Development environment**: Execution environment, memory organization, system space, code space, data space, unpopulated memory space, I/O space, system start-up,*

interrupt response cycle, function calls and stack frames, runtime environment, object placement
Embedded computing platform: *CPU bus, memory devices, I/O devices, component interfacing, designing with microprocessors, development and debugging, design examples, design patterns, data-flow graphs, assembly and linking, basic compilation techniques, analysis and optimization*
Distributed embedded-system design: *Interprocess communication, signals, signals in UML, shared-memory communication, accelerated design, design for video accelerators, networks for embedded systems, network-based design, Internet-enabled systems*
Design techniques: *Design methodologies and tools, design flows, designing hardware and software components, requirement analysis and specification, system analysis and architecture design, system integration, structural and behavioral description, case studies"*

An ES course when offered at the upper-level of an undergraduate curriculum will likely need to include a survey of the most important subtopics within the listed core topics as it is unlikely that a typical undergraduate student will have completed standalone courses for each. The core topic 'Systems Design and Implementation' is likely to be the one where students have the least amount of prerequisite knowledge and will likely represent the area comprising the majority of the ES course content. From this point of view, we describe those subtopics that are most important within each category.

A. Digital Logic Design and Implementation

To support the design of the one or more SoC present in an ES, an intermediate understanding of digital logic design and implementation is needed. Most digital systems designed with FPGA or standard cell technology targets are based upon specification of the desired functionality in the form of a hardware description language (HDL) such as VHDL or Verilog. This HDL description is then used as input to automated logic synthesis tools that result in configuration bitstreams for FPGAs or a 'tape-out' file used by standard cell ASIC manufacturers. Other uses of the HDL specification are to perform pre- and post-synthesis timing analyses and for verification of correct functionality. To perform these tasks, students need familiarity with the use of HDLs and the accompanying electronic design automation (EDA) software tools such as logic synthesis, timing analyzers, simulators, and verification. Additionally, due to the large variety of FPGA architectures, students need some familiarity with the different types of available FPGAs and their strengths and weaknesses.

Another important aspect of this subset of knowledge areas is familiarity with commonly used standards and protocols for digital systems such as the I/O and internal bus standards to be used. It may be the case that familiarity with these standards is not included in a prerequisite digital design course, thus this subject matter is included in the ES course. Another topic that may not be covered to a sufficient degree in a prerequisite digital design course is the interfacing of the ICs that comprise the ES. Knowledge of digital circuit I/O signaling standards and how to select the most appropriate I/O standard is needed.

When ES classes are implemented with an FPGA development board as the principle equipment for the hands-on component, it is important to include a processor core in the system. Some FPGA development boards have dedicated processor chips as on-board assets, but these can be prohibitively expensive. Another alternative is to use a synthesizable processor core such as the NIOS II processor available from the Altera Corporation. This processor is available in softcore format and can be used as an ES microcontroller. The advantage of this approach is that manual wiring and circuit construction skills are not required by students.

B. Computer Architecture

Because the ES contains one or more dedicated CPUs, students must have sufficient knowledge of architectural varieties so that appropriate CPUs can be selected. Furthermore, since it is common that the ES firmware will be implemented at a low-level to exploit performance, knowledge of internal CPU architecture is required to effectively generate the software. Students may have been exposed to CPU architecture in previous courses; however, it is likely that they need more emphasis on how to exploit a particular architecture to achieve gains in performance or to minimize power dissipation.

C. Operating Systems

Because many ES are designed with multiple concurrent tasks and must adhere to real-time deadlines, the inclusion of pertinent OS topics is an important component of an ES class. If an OS class is not a prerequisite course, selected topics must be included in the lecture portion of the course to enable students to utilize an RTOS properly. Such topics include memory protection, critical sections, and RTOS mechanisms for their enforcement such as mutual exclusion and semaphores.

D. Software Design and Implementation

Depending on ES course prerequisites students often have varying degrees of software development experience. The approach taken by some of the authors includes a review of assembler programming concurrently with a study of microcontroller architecture concepts. This provides context for assembler language programming as hands-on experiments involving arithmetic and logic instructions can be included while studying concepts such as fixed-point usage and ALU structure. During the study of memory system architecture and I/O device interfacing, hands-on exercises can also include material that enables students to gain familiarity with various addressing modes in the assembler instruction set and provides a convenient place in the curriculum to review the concepts of pointers in *C*.

Most students are familiar with application development and are accustomed to generating software with a distinct halting state. They are also aware of deterministic finite automata as state machines or counters encountered in a basic digital logic course. Because many ES controller programs have no halting state, the structure of the controlling program as a non-halting state machine is included in the course curriculum. This provides a review of basic *C* control structures and is a good way to begin introduction of Operating System (OS) services. Initially I/O interaction can be implemented in software through the use of polling and delay loops and then follow-on projects can replace delay loops with use of on-board HW programmable timers and polling loops can be replaced with interrupt-driven input.

E. Systems Design Concepts

Concepts from companion courses such as signals and systems, mixed-signal design, and computer arithmetic are important foundations for the ES course. These concepts are briefly reviewed in the ES course as reminder to students who have taken these courses and to provide necessary background for those who have not. Because many ES do not support floating-point HW units, a review of Q notation for fixed-point representations and fixed-point algorithms are included in the ES course. System level concepts include the choice of fixed-point word size and tradeoffs in using fixed- versus floating point.

Many ES contain sensors and output devices that are analog in nature and thus contain data converters for both A/D and D/A conversions. Detailed design of data converters is beyond the scope of a typical ES course; however, system-level concepts regarding data conversion is an important component. The specification of converter resolution and dynamic range are included using logarithmic units (dB) and the resulting effect on system performance are included. This knowledge enables the ES designer to specify and select appropriate data converters for a specific application.

While many students have taken courses in circuit-level design, they are often not aware of various IC signaling standards for IC I/O pins and may not have experience in IC interfacing. Topics that include calculation of pull-up and pull-down resistance values and source and sinking current calculations are provided.

IV. PREVIOUS AND RELATED WORK

Because ES design is a creative activity where multiple unique solutions are possible, we recommend that ES courses contain requisite laboratory sections. A good overview of typical embedded systems laboratory projects is described by and summarized in Figs. 1 and 2.

The laboratory exercises may be implemented as a series of independent experiences that provide experience within each identified topic, or as a cumulative set of exercises culminating in a course design project for an example ES. Regardless of the approach taken, the inclusion of the laboratory portion of the course can present a challenge for distance students. We survey several of these laboratory sections including those used by the authors.

There have been previous attempts to develop laboratory assignments for distance education students. Distance laboratories can be classified as the following two types [4]: (1) Virtual, which use GUI's to simulate physical systems, and (2) Remote, which allow control of real physical systems in a remote location. Examples of virtual laboratories include using simulators for computer architecture and organization courses [3] [13] [18], while examples of remote laboratories include real-time embedded systems for remote controlled robots [2] [14] [15].

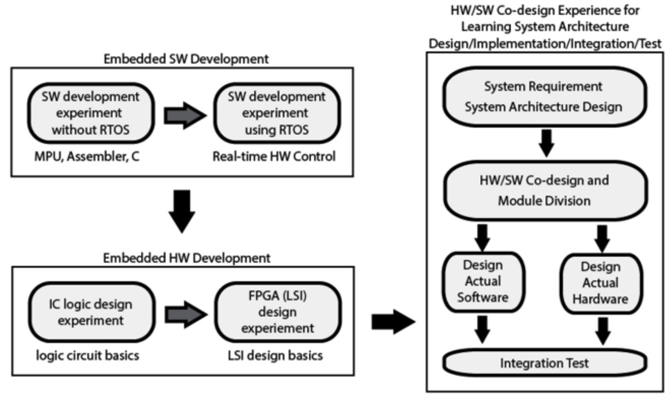

Fig. 1. Embedded System SW and HW Exercise Relationships

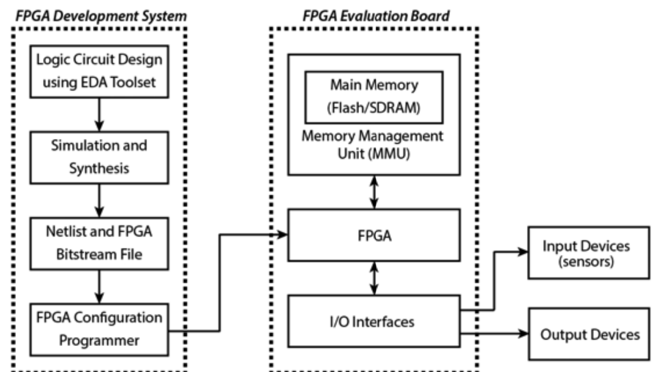

Fig. 2. FPGA-based ES Development System

Some researchers have experimented with virtual laboratories for embedded systems teaching purposes [17] [19] [20] [21]. Virtual laboratories are relatively easy to establish at low cost, but can only model a limited degree of realism [14]. Remote laboratories offer a more realistic laboratory experience; however, this approach often requires expensive equipment and networking resources [6]. Therefore, a common way to address this issue has been to have distance education students combine simulations with using a low-cost, stand-along kit to construct and test their design at their home site [4] [16]. Brejcha et al also developed an online undergraduate embedded systems laboratory course using a remote, virtual laboratory but their results have yet to be reported [1].

The authors' institutions deliver distance courses via the Internet in a number of ways including providing streaming video recordings of course lectures. Distance students can communicate with course instructors through a variety of means including email, phone calls, and web-hosted conferencing services. Examinations are provided to pre-designated proctors for each distance student, or are provided as web-based forms with authentication. This model of course delivery is very similar to that used in some of the recently instituted 'massively open online courses' (MOOCs) offerings.

A. Laboratory Requirements

The at-a-distance laboratory needs for an embedded systems course depend on the concepts to be taught. One model for such a laboratory at different levels is shown in Table II for non-electrical engineers. In this course, the projects and experiments were developed using the Arduino® microcontroller.

TABLE II. ARDUINO®-BASED LAB CONCEPTS AND EQUIPMENT

Level	Concepts	Equipment	Cost
1	• Basic Embedded Systems • Real-time Control • Device Interfacing • High-level Language Programming	• Arduino® board, Sensors, Actuators, wire • Arduino® SW (open src)	• $95 • Free
2	• Adv. Dev. Interfacing • Sampling Theory • Signal Processing	• A/D, D/A, OpAmp • O-scope on chip • Multimeter • Soldering equip.	• $25 • $50 • $40 • $40
3	• ASIC/VLSI • HDL (Verilog)	• EDA Design Tools	• Free
4	• FPGA • SoC	• EDA Design Tools • FPGA board	• Free • $200

- **Level 1**: Arduino® uses a modified *C* language subset with additional language constructs useful for constructing embedded systems such as interrupt control functionality.
- **Level 2**: A/D and D/A converters , op-amps and timers. amd more sophisticated device inputs and control. We assume students own some basic tools such as pliers, screwdrivers, magnifying glass, etc. otherwise these will need to be purchased. $40 for good multimeter and $50 for an oscilloscope on a chip.
- **Level 3**: HDL based design for standards-based peripherals. Utilize an open source simulator or EDA tools on university servers.
- **Level 4**: HDL based design for custom peripherals with implementation on an FPGA evaluation board. Utilize the EDA tools on the FPGA board.

Another ES course that we have offered to 4th-year and new graduate electrical and computer engineering students is shown in Table III. This course is based upon the ARM® processor core and uses the Keil MDK software development system. In contrast to the Arduino® course, the students are assumed to have prerequisite experience in basic digital logic and undergraduate signals and systems. However, the level of programming experience by students in this course is less and many students are unfamiliar with the theory of operating systems and software engineering methodology. For this reason, more emphasis is placed upon low-level programming concepts and less upon digital design.

- **Level 1**: The STM32C board contains memory, I/O interfaces, and external I/O device ports. Additionally it contains user switches, a joystick, and a small graphics output display. Because this class contains students with previous experience in digital circuit design, all ES peripherals are modeled using the buttons/joystick as input sensors and the graphical display as an output. This alleviates distance students from obtaining basic hardware components and performing construction activities remotely. The companion Keil MDK-ARM® software provides support for direct generation of assembler, *C*, or mixed C/assembler programming.

TABLE III. ARM®-BASED LAB CONCEPTS AND EQUIPMENT

Level	Concepts	Equipment	Cost
1	• Computer architecture • ES architecture • CPU architecture • Assembler programming • *C* language programming	• Keil STM32C board • MDK-ARM Lite SW	• $350 • Free
2	• Polling vs. interrupts • Device drivers • Basic OS concepts • Timing and RTOS • Multi-tasking	• MDK-ARM® (RTL)	• $200
3	• Memory interfaces • Parallel bus standard • Serial bus standard	• Standards documents	• Free
4	• A/D and D/A • Memory technology • IC interfacing/signalling	• none	• Free

- **Level 2**: Supported through laboratory exercises that utilize polling and software timing loops, followed by replacing these constructs with interrupt driven input events and the use of on-board programmable timers. OS systems concepts are described in class with emphasis on multi-tasking, deadlock avoidance and prevention through MUTEX blocks and semaphores, and the enforcement of timing deadlines for multiple tasks. Experiments using the Keil RTL RTOS Kernal functions are accomplished in the hands-on portion of the class.
- **Level 3**: This portion of the course begins with memory interfaces and memory decoding design and is followed by extending these concepts to memory mapped I/O interface circuitry. Because the students in this class have previous digital design and Verilog HDL experience, the laboratory portion of the course is implemented by requiring students to implement interface logic in Verilog and to simulate their designs using on-campus tools. It is also possible for students to utilize open source or evaluation versions of HDL simulators on their personal computing devices. HDL testbenches are provided as well as modules that simulate the processor and peripherals and students must design the interfaces. This portion of the course also focuses upon various bus standards and similar approaches to laboratory experiments can be accomplished.
- **Level 4**: This portion of the course consists of a collection of topics that are comprised of a survey of data converter architectures, converter requirements/specifications, internal memory

architecture, and IC interfacing topics. Students are not expected to design data converters but they do gain experience in selection of appropriate converters with respect to performance, dynamic range, resolution, and distortion. A survey of both volatile and non-volatile memory cells at the transistor level is presented so that students may choose the most appropriate types of memory devices to use in ES designs. Finally, students are exposed to concepts involving the calculation of source and sink currents and I/O signaling standards for chip set ICs including how to calculate pull-up and pull-down resistor values and basic topics involving slew rate calculations.

V. Project Examples

In the Arduino® course, students design, build and test a real-time system. Projects that have been completed in the blended graduate course using a "Level 1" laboratory include:

- Traffic light control system
- Anti-lock braking system
- Elevator control system
- Train control system (using model train parts)

Students have written their own operating system (e.g. for one of the embedded platforms), used an open source real-time solution, or simply used non-interrupt driven approaches to achieve simultaneity (e.g. a simple cyclic executive).

Student pilot study involved level-2 laboratory equipment and built a USB interface for Guitar Hero drum-sets that allowed users to play the drums through a Personal Computer or Laptop. The project included the development of the hardware interface design prototype then fabrication on printed circuit board via third party service (cost was less than $20 for fabrication). Software programming included the *C#*, Python, and Arduino® *C* languages.

In the ARM® version of the ES course, the hands-on experiences are provided as a series of experiments or mini-projects. Table IV summarizes one set of experiments for the ARM® version of the course.

VI. Assessment

Multiple choice, fill-in-the-blank, matching and related exams are a widely accepted mechanism to assess learning along the Bloom's knowledge (recall), comprehension (understanding of meaning), application and analysis levels of learning. For example, the professional licensure exam for electrical, computer, and software engineers in the United States uses multiple-choice exams to assess minimal competence and we can model course assessment exams after these instruments. Massively open online courses (MOOCs) also use online assessment to assess student learning. Therefore, we intend to use frequent multiple choice, fill-in the blank, matching, and short answer exams for learning assessment. Where applicable, students will also be required to submit project artifacts such as circuit diagrams, FPGA netlists, Verilog or VHDL files, and *C* and assembler language program source code and block diagrams for manual grading by instructors or instructional assistants.

The hands-on aspect of electronics courses presents certain challenges in assessment of learning from a distance, particularly in demonstration of some level of competence in the construction of demonstration circuits and systems. While for many of the student produced designs hardware description languages can satisfy proof of concept, it may be desirable for students to deliver as-built projects via post or parcel services to the instructor for assessment. As a minimum, distance students are required to email their design files (both HDL and software language) to course instructors who then synthesize, recompile, and implement the distance projects for evaluation.

Shortly after the midterm examinations, students prepare proposals outlining the course project in the form of a brief written document and a presentation slide deck. On-campus students deliver brief presentations of their proposals in class and distance students email their presentations and narrative notes to the distance instructor. In the future, we intend to experiment with remote delivery of project proposals using inexpensive web-cams and Internet communications software such as Skype. This portion of the course provides for assessment of educational objectives involving communication and presentation skills. While the majority of students choose the suggested course project, the proposal activity allows for the possibility for students to propose custom embedded systems projects that are better-suited for their particular interests and provides a mechanism for approval of such projects by the course instructor.

Finally, course evaluation surveys will be administered at the end of the course and these will include questions for students to self-assess learning.

VII. Conclusion

It is possible to build effective laboratories at a distance for embedded systems courses – the blended graduate course and pilot undergrad course as well as the successes of other researchers demonstrate this potential. Distance students face challenges in that live instructor help with respect to circuit debugging is lacking and some degree of maturity in trouble-shooting is required. The availability of low-cost evaluation boards and evaluation versions of software development systems enable students to create their own personal laboratory and project environments. If on-campus licensed software is used, students must have the capability to use their personal computing devices as remote terminals and must login remotely through ssh services or through the establishment of a VPN connection. An alternative to actual circuit construction is the use of HDL simulators; however, students need prerequisite experience in digital logic design based upon RTL HDL descriptions and familiarity with EDA tools and methods is desirable.

It is anticipated that more synthesizable processor cores will become available for student use in the future. One such core that is currently available is the NIOS II core from the Altera corporation. Discussions with personnel at ARM® indicate that a version of the ARM® Cortex-M0 processor core will soon be available for educational use. As these cores become available, ES courses will have more flexibility in choice of equipment for the hands-on portion of the course. To support distance education, it will become more important for students to have familiarity with the use of HDLs for digital design so that softcore processors and FPGAs can be used to support interfacing experiments remotely.

TABLE IV. ARM®-BASED COURSE EXPERIMENTS/MINI-PROJECTS

***Abstract*—Engaging students across geographically distributed teaching and learning activities can be a challenge in contemporary higher institutions. Often, technical constraints, e.g., hardware and software availability, network connectivity and support availability, affect the quality of teaching and learning activities in remote sites. Student participation in the remote sites decreases if the quality of activities is appalling. This paper reports the approaches taken by the faculty and support staff to overcome the challenges in student engagement in a joint graduate research level course on Information Systems geographically distributed in multiple sites in Hong Kong and China. A combination of Web LiveCast and local Voice over IP (VoIP) messaging tools have been deployed on existing thin client hardware to deliver the "quick and dirty" solution. The solution was proved to be effective in improving student engagement, in terms of improved quality in teaching and learning activities, minimal interruption to the students and teachers by preserving the "natural" way of conducting teaching and learning activities, in the remote site without additional resources input on existing solutions.**

Keywords— geographically distributed course, disruptive innovation, localized solution, student engagement, resource utilization.

I. INTRODUCTION

Technical and pedagogical issues on distance learning have been widely discussed in early e-learning literature [1]. During the time when collaborative learning technologies, e.g., Learning Management Systems (LMS) incorporating communication and social media functions, were not widely available to the general users, learners' participation in the distance learning courses were primarily individual and asynchronous in nature. This is exemplified in the evaluation of distance learning models in the past century. Passer and Granger [2] summarize the trend of distance learning models by media and communication. In the matter of the delivery media, the trend of content delivery has been switched from paper content (or physical materials) towards electronic media (e.g., radio broadcast, television broadcast and Internet delivery). In respect of communication mode, the trend tends to shift from asynchronous (e.g., pre-recorded content) to synchronous (e.g., live broadcast from the instructor) and from unilateral delivery (e.g., viewing instructor's teaching) to bilateral interaction (e.g., discussion through text and video conferencing).

The teaching and learning process always involve transferring ambiguous and complex information in a high-speed manner in which quick feedback is desired. Face to face (F2F) settings are always considered to be ideal in education but are always limited in the process of distance learning. "Rich" media, defined as the media that can (1) handle multiple information simultaneously; (2) facilitate rapid feedback; (3) establish a personal focus and (4) utilize natural language, are always the best option to facilitate distance learning [3].According to these criteria, it seems that live broadcasting instructors' teaching with real-time interaction among students would be an ideal option for conducting distance learning. Resources and technical constraints, however, often hinder the implementation of this ideal solution.

One direction to explore the solutions that overcome the constraints is to look at contemporary disruptive innovations [4] that are low cost and low resources demanding, which are potentially useful in distance learning. Building a localized solution with low cost disruptive technologies would be more effective, efficient and, most importantly, practical than introducing a "good quality" solution. One key area of promising disruptive innovation is Peer to Peer (P2P) technology as it eliminates the high cost in conducting traditional interactive sessions through video conferencing with relatively acceptable performance. In developing countries, alternatives to the "good quality" solutions are more realistic to educational institutions because of heavy resources and technology constraints.

The purpose of this paper is to discuss how low cost disruptive technologies can be used to facilitate student learning across geographically distributed campuses of a joint research programme. Resources in these campuses vary significantly in which the "good quality" solution cannot be replicated in other campuses. We chronicle our efforts in designing and implementing a locally built low-cost solution utilizing disruptive technologies to bring real-time engaging student experiences across different campuses in a synchronized manner. Lessons learnt are presented.

II. LITERATURE REVIEW

This section presents two theoretical frameworks on media richness and disruptive innovations respectively. Research on computer-supported distance learning always assert that rich media, e.g., synchronous F2F learning, yield the highest level

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

of participation and result in the lowest level of conflicts and misunderstandings among learners and instructors [5]. Richness of media, however, is a subjective perception which is heavily influenced by users' perception on usefulness, ease of use as well as prior usage experience [6]. This implies that IT solutions commonly used in the daily life of learners can positively lead to better learning experience as they are considered as relatively "richer" media than a completely new solution. Notably, integrating disruptive innovations [4, 7] with learning technologies provides a completely user-friendly model on distance learning consuming little resources with acceptable quality.

A. Media Richness and Learning Experience

Media Richness Theory [3, 8] explains the relationship between communication media and the effectiveness of communication. While the purpose of communication is to reduce uncertainty and equivocality, the choice of communication media (electronic or non-electronic) should always achieve this purpose in an effective manner. Although the definition of "rich" media is subjective with respect to different individuals, generally a "rich" medium should possess the following four characteristics: (1) support the provision of fast feedback (e.g., synchronous/ concurrent or asynchronous/ sequential); (2) transmission of multiple non-verbal cues (e.g., emotional tone, attitude or formality); (3) delivery of multiple communication languages (e.g., graphics, tables and text); and (4) provision of personalized messages based on the receiver and the context in which the communication takes place [9].

Concepts of media richness have been integrated into e-learning systems and have positively influenced learners' experience. Rich media has already been included in the design of early desktop videoconferencing system for cooperative tele-learning almost two decades ago [10]. Longitudinal studies show that students at the remote side having access to the rich media for collaborative activities (i.e., cooperative conversation, debate, analysis, interpretation, and information sharing) tend to outperform in the higher level thinking activities than the control groups [10]. Feasibility of wide adoption of this distance collaborative tele-learning model, however, was limited at that time because the network resources (i.e., dedicated ISDN line) and hardware were extremely expensive.

Later research on media richness further confirms that individual and social behavioral factors play an important role in influencing individual's perception on the richness of media. Contemporary work on behavior analysis in electronic collaborative environment shows that users' prior experience with a new collaborative medium and peer effect with communication partners affect individual's perception on media's richness [9]. The effect of good rich media (e.g., virtual world) in knowledge exchange can be comparable to F2F meeting [11].

Even the benefits brought by rich media in delivering more engaging and effective learning to students in geographically distributed learning environments are acknowledged, attempts to implement technical solutions for delivery have been challenging due to technical and financial constraints. Next section presents the framework on disruptive innovations in which practical solutions would be built upon low cost and local resources.

B. Disruptive Innovation in Education

The key concept of disruptive innovation is the displacement of established products (services) by initially basic (simple) products (services) that are rapidly improving to meet general users' needs [7]. From a general users' viewpoint, functionalities that once considered expensive or resource demanding, in terms of financial cost or skilled manpower, will gradually be available in an affordable manner. Classic examples of disruptive innovations in IT include: digital camera (vs. film camera); personal computers (vs. mini computers); cloud computing (vs. mass storage media) and email (vs. fax).

While providing rich media in distance education through traditional educational technologies (e.g., video conferencing with ISDN line [10]) is not always possible, disruptive technology shows a promising direction to support distance learners with engaging and personalized learning environment that seamlessly bridge the local and remote sites in an affordable manner [4]. Personalized applications were once difficult to implement but are critical in e-learning systems as they build up users' habitual and long-term usage [12]. With mobile devices and a variety of disruptive applications, e.g., instant messaging, providing personalized rich media to learner is now possible in a low-cost and user-friendly manner.

User's satisfaction towards the distance learning solution by disruptive technologies, however, should be managed carefully. User's confirmation (i.e., whether the expectations on the solution are met) and satisfaction towards a new IT solution are critical in determining user's future use, and often influential to peers' willingness to use the solution [13, 14]. Once learners encounter disengaging experience when using the new solutions (e.g., unreliable connection or poor multimedia quality), it is likely that they will resist and discontinue in the future.

Next section presents some example of learning technologies used in geographically distributed courses incorporating rich media in different eras.

III. RELATED WORKS

E-Learning solutions for distance learning have been developed progressively with extensive support of rich media and disruptive technologies. This enables the learners to have better learning experience through engagement via active participation. This section examines two selected e-learning solutions that include rich media and social elements for distance learning.

The first case, known as Classroom 2000, was reported in 1999 [15]. Classroom 2000 was an innovative prototype aiming to bring a "living educational environment" to distance students through courseware production. The whole system attempted to make the production of lecture capture easy by simplifying the stages in production, and to provide a sustained way of rich media educational content production. Real-time student-teacher interaction was enabled through a specially developed tool simulating the whiteboard in a physical classroom. The author acknowledged that cost (financial and skilled manpower) and equipment were the major constraints at that moment, but asserted that it was the promising direction for future development.

Until mid-2000's, cost and equipment still remain bottlenecks for synchronous learning [16]. In late 2000's there was a bloom in synchronous learning. Shanghai Jiaotong University in China reported a self-developed integrated mobile learning solution for distance learning in rural branch campuses [17]. The purpose of the development is to provide distance students with live learning experience, i.e., real time interacting with the instructor and students in the main campus hosting the course. The solution includes an in-house developed live web broadcast system specially designed for mobile devices. A localized solution was designed to utilize CDMA network, which was popular among the learners at the time, to deliver rich media lecture. Interaction from students to teacher, however, could only rely on simple text messages.

General trends concluding from the above cases showing the development of distance learning technologies shows that the focus switches from the system development to solution delivery through existing software packages, and from a fixed computing device to mobility at the remote sides. Llamas-Nistal et al. also share similar views, asserting that the solutions have already been integrated in learning management systems [18]. We, therefore, attempt to follow these trends to deliver our solutions with rich media synchronous support by integrating existing low cost solutions. Next section presents the case background, followed by the directions on solution development.

IV. CASE BACKGROUND

At City University of Hong Kong (CityU HK), the history of live education conducted in geographically distributed classrooms can be traced back to the late 1990s. This section presents two cases at CityU that adopts different solutions to facilitate synchronous teaching and learning in geographically distributed classrooms.

A. Remote Classroom: Specialized Venue and Equipment for Overseas Lectures

Early attempts were made to broadcast live lectures hosted from a United States institution to Hong Kong in synchronous mode. As a pilot scheme, this project involved significant resources input, from sophisticated hardware and venue to a team of specialized technical support personnel. A dedicated control room in the university computing services center was set up to facilitate the events with special video-conferencing hardware, e.g., PictureTel video-conferencing products, ceiling microphones, video cameras, CRT projectors, switch signals and a delicate line linking Hong Kong to US classrooms. Apart from the expensive fixed assets, operational cost was high as a team of support staff would be necessary to hold an event. As specialized training was needed to operate the hardware equipment, the whole process could not be carried out smoothly without extensive technical support. The pilot scheme was eventually discontinued due to finance and manpower constraints. High financial cost hindered the institutionalization of the pilot project. Apart from the need for intensive technical support, transparency to the instructors and students, therefore, became an equally important issue negatively affecting user experience as the "natural" way of teaching and learning could not be preserved.

B. Host: Broadcast and Capture for Weekly Research Seminars

The Department of Information Systems (IS) has been hosting weekly research seminars for many years. The research seminars are formally included as a university course for the research postgraduate students in IS. Using video-conferencing tools, the research seminar was broadcast to Suzhou campus (near Shanghai, China) with a dedicated ISDN line. Similar to the previous case, video-conferencing tools have been installed in Hong Kong and Suzhou. Advancement in technology makes it less resources consuming to conduct the seminars but a staff is still needed to operate the video-conferencing system at both sites. Until January 2013, this approach has been implemented in association with the BlackBoard Learning Management System with the following workflow:

- A teaching assistant in Hong Kong collected the presentation materials from the speaker before the seminar and uploaded the materials (e.g., PowerPoint files) to BlackBoard.
- Students from the Suzhou campus downloaded the presentation materials from BlackBoard.
- The technical staff in Hong Kong would establish a dedicated ISDN connection with Suzhou. Often, long distance call was needed to communicate with the teaching assistant in Suzhou.
- The seminar began. Live broadcast was made to Suzhou. Recording would be provided after the seminar on BlackBoard for review.
- Interaction between speaker in Hong Kong and students at Suzhou was facilitated by video-conferencing.

With the expansion of new remote campuses in the mainland China, scalability becomes an issue because of the installation of the designated video-conferencing hardware with a support staff at individual site. This involves extra financial and human resources costs as the existing solution is replicated across multiple sites. The problem intensifies as these remote sites are under tight resources constraints. Often, there is no designated staff member to manage the computing resources at the remote classrooms.

To cope with the resources constraints, especially the constraints on hardware and manpower at the remote campuses, we attempt to design solutions that utilize existing resources available at CityU HK, and at the same time requiring minimal extra input at the remote sites. Localized applications are always the first priority to reduce the technical barriers for users, mainly students at the remote sites, to operate the systems smoothly without needing routine technical support.

The next section discusses the design of our solutions with existing CityU HK resources and promising Voice over IP (VoIP) application.

V. DESIGNING A LIVECAST SOLUTION

Although engagement of remote students are generally higher with extensive use of educational technologies [19], we witness that remote students are dissatisfied and eventually discontinue joining the research seminar course if the technology is unstable (e.g., poor video or audio quality, frequent network breakdown) or difficult to use. The e-learning team of CityU HK, therefore, aims to design a solution that is more reliable and scalable, with low-cost existing applications (e.g., disruptive technology) that are user-friendly at the remote sites, with rich media (e.g., real time audio, video and presentation video) support.

CityU HK has been adopting Echo360 Active Learning Platform institutionally throughout its campus in Hong Kong since 2008. Recent advancement in Echo360 extends its capability from a mere lecture-capture application for review to a platform supporting live broadcast which captures the audio and video of the speakers and materials synchronously, in a fully centralized and automated way. Different stakeholders are involved in the operation of Echo360 LiveCast event held across different campuses:

- CityU HK e-learning team: management and operation of Echo360 infrastructure institutionally
- CityU HK IS technical support team and teaching assistant: on-site technical support for IS research seminar
- Teaching assistants at remote sites: connection to IS seminar LiveCast with a computer and video projector

As the e-learning team in Hong Kong will handle all support centrally, there is no extra financial and manpower cost incurred to remote sites. Echo360 is included in the LiveCast solution in addition to the disruptive technologies. Table 1 shows the design with respect to the IS research seminar.

TABLE I. DESIGN OF SOLUTION USING DISRUPTIVE TECHNOLOGY AND ECHO360

Hardware/ Service	**"Old" solution**	**Proposed solution with disruptive technology**
Networking	Dedicated ISDN lines connecting different sites	The Internet, i.e., using WebCast
Video-conferencing service	PictureTel / PolyCom systems Switch Signal and Control room	Echo360 Lecture Capturing with LiveCast feature (licensed at CityU HK) VoIP applicaion, e.g., Skype/ QQ
Projectors	Two CRT projectors at each site	One video projector at each site
Video/ Audio input	Ceiling microphone and video camera	Web cam or a fixed camera with a wireless microphone
Post-event feedback	Text-only BBS	Discussion Board in BlackBoard

Workflow of our LiveCast solution is summarized below:

- The teaching assistant in Hong Kong informs the e-learning team at CityU HK to schedule the IS Seminar broadcast at the beginning of every semester. The broadcast will be launched automatically every time by the central Echo360 server.
- Before the start of each seminar, the teaching assistant in Hong Kong posts the hyperlink of the LiveCast on BlackBoard.
- Teaching assistants at the remote campuses connect to the LiveCast with a web browser and a standard notebook computer connected with a projector and the Internet.
- Teaching assistants connect to each site with VoIP tools (e.g., Skype or QQ) for questions and answers among speakers and all students at various campuses.

Next section presents the actual implementation of the solution at CityU HK and two remote sites.

VI. IMPLEMENTATION OF SOLUTION: LOCALIZATION WITH DYNAMICITY

To cope with IS Department's extension to two more remote sites (Shenzhen, approximately 40km from Hong Kong and Hefei, approximately 1100km from Hong Kong, see Fig. 1), the e-learning team at CityU HK conducted a series of testing with Echo360 LiveCast inside and outside the Hong Kong campus with the workflow described in the previous section from December 2012 to January 2013. The e-learning team could only use the existing technical and manpower resources to implement the solutions to a more diversified population of new users. The new solution, therefore, should address all technical and resources constraints. At the same time, the solution should provide a user-friendly environment and good user experience to the remote users, especially those users who had negative experience in the "old" sophisticated system with occasional breakdowns. Local testing and remote site testing sessions in Shenzhen have been conducted to optimize the performance of the solution before the first LiveCast event took place in late January 2013.

Fig. 1. *Distibution of CityU HK remote campuses*

A. Local Testing

The workflow of LiveCast establishment described in the previous section was tested in Hong Kong internally at CityU HK and externally with fixed and wireless network connection by a few local telecommunication operators. Results of the testing within the territory of Hong Kong were proved to be satisfactory in terms of synchronous learning experience provision, i.e., coherent audio and video without any interruption or significant delay. Minor technical issues, e.g., screen resolution and network latency, were addressed. Adjustments were made to optimize the system performance during the local testing process, e.g., adjusting the resolution of live seminar capture.

B. Remote Testing in Shenzhen

A visit to Shenzhen site by CityU HK e-learning team was conducted to: (1) identify the inadequacies of the existing video-conferencing solution; (2) figure out the technical limitations, especially on hardware and network connectivity, that restrict the adoption of LiveCast solution; and (3) stakeholders' needs and expectations of the new LiveCast solution. Figure 2 shows the existing ISDN solution for research seminars in Shenzhen.

Fig. 2. *Existing ISDN solution implemented at Shenzhen Campus. The right screen shows the live capture of the seminar in CityU HK using ISDN.*

Hardware in Shenzhen campus were comparable to Hong Kong's venue settings. On the other hand, software installed at the venue becomes a challenge to the e-learning team as local security software would occasionally prohibit the most updated contents (specifically, the most updated hyperlink to the LiveCast event) in Echo360 to be displayed in the browser.

With respect to video and audio quality, new Echo360 solution outperformed the existing solution. However, the interaction from Shenzhen to Hong Kong (e.g., letting participants in Shenzhen to ask questions to the speaker in Hong Kong) became a more complex issue. VoIP solutions (e.g., Skype) was not very stable and did not seem to be very comfortable to the participants.

Addressing the Shenzhen side's concerns, provisional amendments were made to the protocols. First, the e-learning team sets the starting time of the LiveCast 15 minutes earlier to allow sufficient time for the Shenzhen side to connect to the service. Second, a hyperlink directly links to the LiveCast event will be sent separately through BlackBoard to Shenzhen participants. This ensures that the remote side will always receive the most updated contents in case the contents are not displayed in the browser due to the local security software's effects.

The Shenzhen experience is extremely valuable to all stakeholders for the setup of the first IS research seminar using LiveCast event. As Suzhou campus will eventually be relocated to Hefei in the coming year, the e-learning team decided to focus on Hefei site on the first LiveCast.

C. The First LiveCast Event with new Solution: Hong Kong, Hefei and Shenzhen

With the experience in Shenzhen, one staff member from CityU HK e-learning team travelled to Hefei in late January 2013 to replicate the Shenzhen protocol in Hefei for preparation of the first LiveCast event, and to act as the on-site support during the first IS seminar LiveCast on 24 January. Resources are more constrained in Hefei. Table 2 shows the comparison of resources available in different campuses:

TABLE II. COMPARISON OF RESOURCES AVAILBLE IN DIFFERENT CAMPUSES

Hardware/ Service	**Hong Kong**	**Shenzhen**	**Hefei**
Fixed computer	1	1	No
Video projector	2	2	1
Wifi coverage	Yes	Yes	No
LAN coverage	Yes	Yes	Yes

Figure 3 shows the venue settings in Hefei, with only fixed network ports and one video projector available in the venue. As no fixed computer is available in the Hefei classroom, the teaching assistant generously brought her private notebook computer to connect and project the broadcast from Hong Kong on the screen to the whole class.

Fig. 3. *Conference room in Hefei where IS Seminar takes place*

User experience was reported to be unsatisfactory by the Hefei students in the previous IS seminars. Students expressed their dissatisfaction over the quality of broadcast, i.e., frequent breakdown and instable audio and video quality due to the adoption of phased out software, Macromedia Breeze, for IS Seminar in Hefei site. The poor quality was very disengaging to participants and some students eventually did not attend the Live Broadcast of IS Seminars. Quality of LiveCast, therefore, remains the key to engage the students in Hefei.

The Shenzhen protocol was replicated in Hefei for the first IS Seminar event with LiveCast. While the teaching assistant had no difficulties in connecting the personal notebook computer to the Echo360 LiveCast server and Skype connection across sites between Hong Kong, Hefei and Shenzhen's broadcast were not as coherent as expected. On-site support by local technicians was not readily available. Therefore, the on-site e-learning team staff from CityU HK took an active role to co-ordinate the parties at three different sites to work out the adjustment to the broadcast audio and video settings. Figure 4 shows the first LiveCast event took place in Hefei campus.

Fig. 4. *The first IS seminar LiveCast at Hefei. The presentation materials and the speaker from Hong Kong were synchronously available at the remote site.*

VII. User Feedback and Lessons Learnt

Users' immediate comments after the first LiveCast event were positive and encouraging in terms of significantly improved quality of contents and sense of real time engagement, i.e., the sense of being together as a group. The teaching assistant from Hefei emphasized that the audio and video quality of our LiveCast solution was "*far beyond the expectations*" and users at Hefei "*were totally satisfied with the quality*".

Issues arising from the VoIP application were mainly on the audio quality during interaction sessions between various campuses, and the operational issues with respect to its application. First, by nature of the LiveCast solution, a 5-second delay was observed between Hong Kong and other remote campuses. When communicating with VoIP applications across the campuses, echoing effect cannot be avoided especially when the same personal computer is used for both LiveCast and VoIP application. This seriously degrades the audio quality and is can be disturbing to the audience at all campuses. Second, Skype performance is not always reliable in China and is less favorable to the users than the domestic VoIP application.

These problems have been eventually addressed by adding existing hardware and adopting a localized VoIP application. A Hefei student offered to use his private notebook computer solely for VoIP application purpose minimizes the echoing effects. Instead of Skype, a local VoIP application known as QQ is adopted. This gives the local users a more familiar environment.

Resources constraint on hardware and support personnel at Hefei had previously led to the dissatisfied user experience, which in turn demotivated students from attending the seminar broadcast. They felt that downloading and watching the IS seminar archives after the seminar would be more comfortable. Faculty, however, are concerned that real-time group collaboration would be more engaging for active learning. Our solution would solve the previous technical problems by providing more engaging environments for research students to interact together as a group with diverse student populations geographically apart.

We, however, acknowledge that it is only at the preliminary stage of trial run and it is still a long way to institutionalize the whole model. The system log provides some preliminary evidence on the high utilization of our implementation. During this semester, average hit count of seminar archive is reported to be 27 per video archive. In the previous semester when the LiveCast technology was not available, the average hit count is only 2.5 per video archive. This figure confirms the new LiveCast technology is becoming popular among the users.

VIII. Discussion

With all these experiences in facilitating remote classroom, promoting the application in other courses will be the next step. As long as meeting physically is a challenge, the descripted tools and workflow may fine-tune to address the need. Nevertheless, such ad hoc solution needs to be carefully implemented as it lacks enterprise structure for institutionalization. After all, the current solution is adequate for course level applications instead of a completely online programme. The distinctions between such quick and dirty approach and an established protocol for university wide support must be emphasized. A system failure in one of the IS seminar Livecast sessions exposed the reliability issue in the absence of a contingency plan. This leads to the necessity of adjusting users' expectation when alternative solution does not exist.

Analysis on the exponential rise in the hit rate provides us with additional insights on developing technical and non-technical best practices for providing more engaging learning experience to learners in geographically distributed courses. In the technical domain, new solution adopting the "thin" client approach with emerging disruptive technologies is more preferred. Generally, this strategy requires less hardware and human resources. In our IS seminar case, all hardware at the remote sides are "standard" or "common" devices coming from the existing sources (e.g., devices readily available from and commonly used by the students or departments) without additional resources input. This is extremely important if there is a tight resources constraint at any of the remote sites beyond control of the host. "Standard" devices e.g., PC with Internet connection require minimal technical support as users (including students) are familiar with the operations. After the launch of our LiveCast solution, Teaching assistants at the remote campuses have successfully managed the subsequent IS seminar LiveCast events after the short briefing by CityU HK e-learning team staff. The technical support staff who managed IS Seminar at Hong Kong main campus no longer needs to take up an active role in the IS Seminar as the process is now automated. Technical support staff now only handles unexpected events instead of taking up the routine job in operating the ISDN video-conferencing system.

In the non-technical domain, providing good user experience is the key to sustain students' participation in geographically distributed classrooms. Synchronous rich media provide the ideal environment for knowledge exchange but system instability would negatively impact user experience. Hence, intention to continue participating in future event is decreased. Apart from choosing the right hardware and the right applications with carefully designed workflow under the local constraints, users' prior experience with the new solution (particularly on the disruptive technologies) and support availability (logistics and technical) can influence users' level of engagement. Adopting a popular disruptive technology among the user community is more preferred as it reduces the level of fear to technology. Likewise, ease to get support from related parties, although not always available at remote campuses with tight resources constraints, can further facilitate the formation of good user experience.

The new solution also attracts a number of new participants locally in Hong Kong. Further analysis on the hit rate gives us encouraging results on widening the participant population. A number of hit counts have been found from Hong Kong users outside CityU HK campus. While most of the students and faculty in IS Department at CityU HK attend the IS Seminar at the venue (face to face), some students and staff located at offices further away from the Department opt to view the LiveCast. We also discover that graduates from the IS Department continue to participate in the seminars through LiveCast. Before that, they could only have access to the post-seminar video archives.

IX. CONCLUSIONS

While higher institutions are expanding through satellite campuses in different territories, engaging students across different geographically distributed campuses with technology becomes a challenge. Ideally, all students at geographically distributed classrooms should feel being connected together. Synchronous rich media e.g., video-conferencing solutions provide solution but often cannot achieve the outcomes due to financial, hardware and human resources constraints. We aim to solve this problem by designing solutions that (1) utilize existing resources with minimal extra input; (2) integrate promising disruptive technologies to provide useful functionalities in an affordable way; (3) adopt locally popular applications to minimize the support needs. These principles have been applied in a Hong Kong – mainland China joint research level course with dynamic input from the Chinese users at the remote campuses. Results show that the remote students are now more engaged through improved satisfaction on content quality and ease for operation. Surprisingly, our solution brings in more local participants in the local Hong Kong campus.

Enhanced Recommendations for e-Learning Authoring Tools based on a Proactive Context-aware Recommender

***Abstract*—Authoring tools are powerful systems in the area of e-Learning that make easier for teachers to create new learning objects by reusing or editing existing educational resources coming from learning repositories or content providers. However, due to the overwhelming number of resources these tools can access, sometimes it is difficult for teachers to find the most suitable resources taking into account their needs in terms of content (e.g. topic) or pedagogical aspects (e.g. target level associated to their students). Recommender systems can take an important role trying to mitigate this problem. In this paper we propose a new model to generate proactive context-aware recommendations on resources during the creation process of a new learning object that a teacher carries out by using an authoring tool. The common use cases covered by the model for having recommendations in online authoring tools and details about the recommender model itself are presented.**

***Index Terms*—Authoring tools; Recommender systems; Learning objects; Proactivity; Context-awareness**

I. Introduction

In the area of e-Learning, authoring tools can help educators to repurpose digitized resources or create complex Learning Objects (LOs) using existing contents from third-party learning repositories. These tools usually present an overwhelming variety of resources, causing a problem related to identifying what are the best ones considering the personal needs of the teacher.

This issue is mitigated in other areas of Technology Enhanced Learning (TEL) by using recommender systems [1]. But in the authoring tool field the use of such kind of systems has not been exploited yet. Authoring tools usually do not take into account the teacher's background and current context while the LO creation process is carried out. The recommender should take into account the history of the user in the current process so as to recommend similar resources. For these reasons, the application of a context-aware recommender system [2] could improve the teacher experience because sometimes simple suggestions following a user-request pattern are not enough when teachers do not know exactly what type of resources are available or when it is possible to request them in the creation process.

In this scenario, a proactive recommender system can play an important role in the decision of which educational contents are more appropriate for a given situation. By analyzing context-awareness information related to the user's needs, like the topic of the LO (i.e. physics) or the target audience (i.e. students level for a school teacher), the system could suggest suitable resources without explicit user request being needed. Therefore, the user would discover the resources at the same time as the requirements appear during the creation process.

Bearing in mind the previous scenario, in this paper we present a new general model to improve previous work on proactive context-aware recommendations in e-Learning systems [3] to be applied in online e-Learning authoring tools. It covers several use cases related to common situations involved in the use of authoring tools to create new LOs based on existing educational resources.

II. Related Work

E-Learning authoring tools are computer based tools that allow a general group (habitually teachers) to create (or author) educational content and LOs that can be usually integrated in a Learning Management System [4].

In TEL a great variety of research and practical applications exist in the area of recommender systems [1]. They are not used only in LO repositories but also in other TEL environments like learning networks and teaching communities [5] or personal learning environments [6]. In addition, they are not exclusively used to recommend interesting LOs but other users and activities [7].

Finally, as Verbet et al. show in their recent survey [2], the use of context-aware recommender systems is becoming relevant in the area of e-Learning. These systems take advantage of contextual information [8] about the user and his/her circumstances so as to increase the level of personalization in the suggestions provided. One specific research line that is getting very popular associated to utilize context is the introduction of *proactivity*, giving rise to proactive context-aware recommender systems [9]. These systems push recommendations to the user when the current situation seems appropriate, without explicit user request, going beyond traditional recommender systems. [10] propose a proactive recommender system in computer-supported learning that works on LO repositories and adapts to a student's profile. Whereas in [3] we propose a proactive context-aware recommender system capable of recommending both, LOs and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

similar peers in an e-Learning social network based on social, location and user context-awareness information.

III. A Model for Proactive Context-Aware Recommendations in Authoring Tools

Fig. 1 presents the general model to incorporate proactive recommendations into e-Learning authoring tools. It covers the following use cases that appears attending to its temporary nature from the point of view of a user utilizing the authoring tool in a general scenario: 1) *Recommending when the user is starting the creation process*, 2) *Recommending while the user is creating the learning object* and 3) *Recommending novel resources when reviewing or editing learning objects*.

A. Context

Using context-awareness information is now a common feature to improve recommender systems in e-Learning on the basis that the more information you have from a user, the more personalized and accurate the results provided will be [2].

We understand context as any information that can be used to characterize the situation of an entity [8]. Therefore, our system is based on two context categories to provide proactive recommendations on relevant educational content related to the LO creation process the teacher carries out: *User context*, i.e. the current activity of the user during the creation process in the authoring tool (e.g. idle or checking educational content like a video); and *Educational context*, i.e. the information related to the educational resources the teacher is using for creating a new LO (e.g. topic, language or target age).

B. Initial Input

The model begins with an optional step consisting of providing initial input about the main educational context values related to the LO the teacher wants to create, like the general topic (e.g. biology), the target level of his/her students (e.g. 14-15 years old), the language (e.g. English) or the target device where the LO will be consumed (e.g. mobile device or desktop computer). Having such kind of data since the beginning would help the system to focus the recommendations sooner, achieving this way the use case 1.

This initial input also covers the use case 3 presented above. When a teacher reviews a LO previously created or edits a LO in a draft state, all the resources used on it are considered to generate an initial educational context input. This allows the recommender to look for novel resources in the same area that did not exist or maybe were not considered relevant in the past.

C. Phase I: Resource Profiling

This is the first step of the 3-phase loop illustrated in Fig. 1. It is in charge of gathering all the metadata related to the resources used during the creation process in order to answer the question *What kind of content have been used?*. This set of metadata conforms the educational context of the LO the teacher is creating. Therefore, the more information the system knows about the resources the teacher is using, the more accurate would be the recommendations provided in the third phase. As a result, the educational context is generated and sent to the next phases.

D. Phase II: Situation Assessment

The second phase tries to answer the question *When to make a recommendation?*. To do it the system calculates a score S1 which is a number between 0 and 1. If S1 exceeds a threshold T1, the third phase will be initiated. If S1 = 1, the highest possible value, then a recommendation would be triggered in any case. If the current situation does not warrant a recommendation, no matter how high a particular resource score, S1 is set to 0 and the recommendation process is aborted without considering resources to recommend. Note that this phase does not take properties of resources into account (i.e. the educational context previously generated). However it considers the current user context represented by the teacher's activity in the authoring tool. For instance, a situation would be more appropriate for a proactive recommendation if the user is idle or browsing resources in the system, compared to a situation in which the teacher is viewing a resource (e.g. a video) to decide if it is suitable or not. This appropriateness factor can be derived by the level of interruptibility allowed by the users in every situation involved in proactive systems. As Gallego et al. [9] shown, the system should avoid disturbing the user if he/she is focused on other important task.

That contextual information related to the user is needed as a prerequisite to calculate S1. In our model, the user context is provided by the platform through the connections between the authoring tool and the recommender system. The parameters related to this user context are domain dependent, and have to be studied for each specific scenario.

Furthermore, the score S1 has an impact on the threshold T2 of the third phase, i.e. the higher S1 is, the lower T2 is set. Therefore, the threshold T2 is a function of S1 in the form: $T2 = |1 - S1|$.

E. Phase III: Resource Assessment

The third phase evaluates the suitability of particular resources trying to answer the question *Which resources to recommend?*. Any recommender algorithm that considers the educational context information provided is valid. A content-based [11] would be a good option as it recommends items that are similar to those that a user has utilized or liked in the past, or as in our case, has selected in the current LO creation process. Hence, various candidate resources would be compared with other previously used by the user and the best-matching resources are recommended. This can be improved by adding the information store in the recommender data base that allows the system to increase the weight of those resources that have been used intensively by other teachers, meaning their relevancy in that area of knowledge.

The result must be a score S2 normalized to [0, 1] (with S2 = 1 being the best possible score) for each resource in the candidate set. S2 corresponds to the predicted rating of the recommendation algorithm selected. The candidate resources

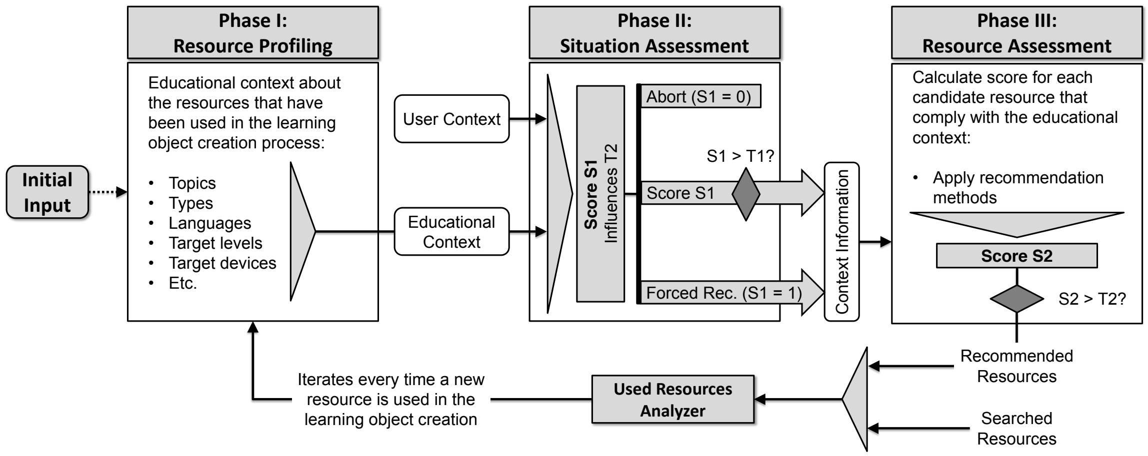

Fig. 1. Model for generating proactive context-aware recommendations in e-Learning authoring tools.

would be ranked according to S2 and tested against the threshold T2. If S2 $>$ T2 for a resource, then it is finally considered for recommendation and the user is notified. If no resource score S2 exceeds the threshold T2, then no one is recommended, the process is aborted and restarted when the condition to loop again is met.

After the recommended items are communicated to the teacher, he/she might select one of them or might not (i.e. by accepting or rejecting the recommendation). This occurs also with the resources the teacher looks for in the authoring tool (as they can be suitable or not for his/her interests). In Fig. 1 this is represented by the loop linking the last phase with the first one. It takes into account all the resources (i.e. recommended or searched) to be evaluated by the *used resources analyzer*. Each time a new resource is added to the LO the teacher is creating, the analyzer fires a new loop that initiates the model again (as new resources information is available for the first phase). As a result, the use case 2 is achieved because the loop is continually repeated while the previous condition is reached.

IV. Conclusion and Future Work

In this paper we have presented a novel model for generating proactive context-aware recommendations in e-Learning authoring tools. It is based on analyzing the current user activity as well as the educational context related to the resources the teacher selects during the learning object creation process to recommend similar resources. This is done in several temporal instants: at the beginning of the creation process, during the process itself and when the learning object is reviewed or edited to be improved with novel material after it has been created. The recommendations are provided in a proactive way when the situation seems appropriate without explicit user request.

The model has been designed to support a general scenario in which no previous information about the user is needed, being the only requirement the necessity of having connection to online general content providers and educational learning repositories.

Open challenges consists of implementing the model in a real scenario related to an existing online e-Learning authoring tool in order to validate it. In relation with this, studying the impact in the user experience of teachers having such kind of proactive recommendation in an authoring tool would be an interesting research line to investigate.

***Abstract*— Participation in online courses has significantly increased in recent times. Student performance in online mathematics classes lag behind their counterparts in other subject areas. We hypothesize that one of the main reasons for this is the lack of technological tools for effective communication of mathematics via the Internet. We propose to test our hypothesis by implementing new technologies and evaluate the difference in course performance and attrition rates between the students who use these technologies and a control group.**

Keywords—distance education; mathematics education; developmental algebra; learning technology

I. Introduction

In the past decade, demand for distance learning courses has soared due to the entrance of many nontraditional students into the realm of higher education [1]. For courses that require only reading and discussion, online environments provide the medium for students to share their ideas and communicate. Where mathematics is concerned, however, the situation changes. Mathematics students are expected to learn specific objective skills which often have a prescribed set of concepts that must be successfully mastered. Because of the notation and computations required, students often have difficulty communicating ideas in a distance learning mathematics course [2].

Since online courses rely heavily on written communication, one can see how problematic this situation may be. While online course management systems do have the technology to incorporate mathematical equations and formulas into discussion boards, they are usually only rudimentary in nature [3]. That is, the students are able to insert equations and mathematical notation into documents and discussion boards, and not much else. The technologies that do exist may be insufficient and/or cumbersome to implement. Although typesetting of mathematics is typically done with LaTeX in an offline environment, a universal standard for displaying equations on the web does not exist, although there are several tools that can be used to publish LaTeX on web pages.

Research shows not only that the attrition rates in distance learning humanities courses is significantly lower than in mathematics courses but also that there is not a significant difference in attrition rates of humanities and mathematics courses in the traditional classroom [4]. Not only that, but additional research exists that indicates course management systems need to be diversified across disciplines to meet the very different course objectives that each discipline requires [5]. Many of the existing course management systems seem to be created with generalization in mind. In fact, some research indicates that students in different disciplines use course management systems very differently, accessing different types of available course resources [5]. Clearly, one size does not fit all, and we see from prior research that the online courses in the discipline of mathematics need additional specialized tools to help students overcome the challenges they present.

With this information in mind, we can infer that there is something amiss in the delivery of mathematical content via distance learning. We conjecture that the difficulty in online communication of mathematics is a significant portion of the reason that students do not succeed in distance learning mathematics courses, and that many existing course management software packages do not include sufficient support for mathematics content, even if some support is already included.

II. Discussion

Besides a coherent and thorough curriculum, the most obvious need that must be met for students taking distance learning mathematics courses is an effective medium of communication. Many of the discussion board functions of popular course management systems do not offer anything beyond rudimentary means of displaying mathematial equations, and even so, users did not feel they were effective tools [6]. This, however, is not entirely the fault of the software developers. Given that there is no defined standard for displaying mathematical equations online in addition to the limited research on distance learning in mathematics, software developers may be unaware that a need exists or are waiting for a broad standard to be defined before spending a significant amount of time and funds on these functions.

The lack of software solutions provided by the developers of popular learning management systems has not impacted third-party software creation, however. An example of software developed for use in online mathematics courses is Wiris Editor [7]. Wiris Editor is a cross-platform solution used to include simple and complex mathematical formulas and graphs within discussion forum posts and other areas in an online classroom. This enables both instructors and students to include a variety of mathematical content in an online course

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

without cumbersome technological workarounds and difficulties. Due to the cross-platform nature of Wiris Editor, it can be utilized with many different course management systems seamlessly.

Additionally, there is an expanded version of Wiris Editor called Wiris CAS [8], which is a full computer algebra system that also has graphing capabilities. This further expands the students' ability to communicate using multiple representations of mathematical concepts and techniques as well as providing them with just in time computational and graphing abilities to verify answers. By using these tools, students will be able to explore a variety of topics that are taught in both developmental and credit college mathematics courses.

Finally, a third technology, which uses Wiris CAS as an engine for its computations is called Wiris Quizzes [9]. This application is a flexible addition to an online mathematics course, allowing an instructor to assess students, or even by providing a way for students to obtain additional experience with the types of problems taught in the course. Wiris Quizzes allows for parameterization of questions, so each student receives a unique problem to work. While this is useful for assessment, it is also an excellent method to provide students with a virtually limitless set of practice problems to master the objectives of the course.

By providing students with enhanced means to to display complex equations and provide explicit examples online for both their instructor and their peers, we believe that they will gain facility in communicating mathematically. Not only this, if students have questions, they will be able to ask the community within the class for assistance, or even test hypotheses and conjectures themselves by using the computational components of these tools to assist them. Tools like the Wiris suite allow a student to be more eloquent and precise in their explanations, thus making it easier for the online community to pinpoint and remedy the confusion they are experiencing. We believe that the more support students have, the more likely they are to succeed in the course. Mathematical learning can be frustrating and slow when working in isolation, especially for those who struggle with mathematics in a traditional classroom.

III. Research Plan

We are at the beginning stages of this endeavor. Our plan is to study several developmental distance learning mathematics classes at a large community college in the southern United States starting in Fall 2013. Our primary goal is to determine if providing additional technological tools within a distance learning mathematics course will have an effect on the attrition as well as the passing rate of the students in the given courses. Since there are many possible reasons for attrition and/or failure in an online mathematics class, our study will be a multidimensional quantitative study with use of blocking to reduce confounding variables. Our pilot will include at least four classes with approximately 50 students in each of them. The classes studied will be randomly assigned to either receive the treatment (consisting of the Wiris Editor, Wiris Quizzes, and Wiris CAS software used within the course) or the control group, which will receive no treatment and only use the basic online course system with no modifications. Since we must also control for outside factors, we will also block by type of problem, such as computation, graphing/visual, and word problems to see if the type of problem has an effect between groups.

Additionally, to control for unexplained variation in the results, the courses will use the same assessments and be graded with the same rubric by the grader. In an ideal situation, we would like the courses to have the same instructor, but for practical purposes, we will attempt to study classes where the instructors have similar levels of experience teaching the course. At the end of the courses, we will examine the data to see if there is a significant difference between assessment results (summative unit assessments and final examinations) from the experimental group versus the control group. We will also see if the attrition rate is different between the two groups.

As a basis for comparison, we will request attrition and grade distribution data for the same course taught within the community college in a traditional classroom environment. We will then compare the three groups (modified distance learning, unmodified distance learning, and traditional classroom) to see what differences may exist between all the methods of delivery. Finally, we will collect demographic and other academic information (such as overall GPA and SAT/ACT score) to determine if there are overarching external factors that may attribute to students' likelihood for success in distance learning mathematics courses. We may also investigate any other anomalies or unexpected results discovered during the course of data analysis since we are collecting a large amount of data on the participants in the study.

If our pilot study shows significant gains in the treatment versus the control group, we will expand the study for at least one further semester to increase our sample size and see if the pilot study's results can be replicated.

Closing Remarks

By investigating the use of technology to provide students with better opportunities to read and communicate mathematics in an online environment, we hope to take the first steps in improving the success rate of those in distance learning mathematics courses. With the rapid expansion in numbers of students taking courses in this fashion, it is imperative that we address these issues and work toward successful outcomes for these students.

INFLUENCE OF ENTREPRENEURIAL APTITUDE ON TECHNOLOGY ENTREPRENEURSHIP COURSE PERFORMANCE

Anthony Joseph
Department of Computer Science
Pace University
New York, New York, USA

Abstract -- In a computing technology entrepreneurship course offered in fall 2011, students were separated into teams of three and four students and taught the concepts and skills of teamwork, innovation, and entrepreneurship. They applied these concepts and skills to an open-ended project for a niche market financial or healthcare information technology product. Each team produced a product supported by a business plan and PowerPoint presentation as the project deliverable. The course was supported by mentors for the teams and guest lecturers. In spring 2011, a Data Mining course was offered where no direct instruction in teamwork, innovation, and entrepreneurship was provided, but the student teams were assigned a similar open-ended project. The objective of this exploratory study is to evaluate students and teams' relative increase in entrepreneurial aptitude. The two courses' performances were determined by the project quality and course grades (average in-class and final examinations) supplemented by a post survey of student perceptions of course related gains and changes in attitudes. As expected, the quality of the team projects produced and the correlation analysis of the examination grades in the Technology Entrepreneurship course showed relative improvement over those produced in the Data Mining course.

Keywords— Technology Entrepreneurship; Data Mining; Entrepreneurial Aptitude; Teamwork; Innovative Intelligence; Financial Projects; Healthcare Projects

I. INTRODUCTION

In order for engineering and computing professionals to become effective leaders in industry and government, they need to acquire the skills of well-rounded individuals who are not only versed in disciplinary knowledge, but who are also proficient in such professional skills as communication, teamwork, interpersonal, problem solving, critical thinking, and entrepreneurial skills [1, 2, 3, 4, 5]. To ensure that engineers and computing professionals acquire both technical and professional skills, these skills must be given emphasis during their education and training. For example, engineering and computing students should be taught and trained in teamwork and innovative thinking skills as well as business skills through technology entrepreneurship experiences. Moreover, there are sufficient explicit and implicit ABET engineering and computing criteria supporting the need to also train today's graduating students in these professional competencies [3, 4, 5]. During teamwork experiences, students should utilize the complementary skills of technical and functional expertise, problem solving and decision making, and interpersonal skills as well as exercise good working relationships among team members in order to get challenging task successfully completed [6, 7]. Entrepreneurial companies are the current backbone of the American economy. They tend to create more jobs than other companies. In addition, they are the engine of innovation; they produce more technological innovations per research and development dollar and more innovation per employee than large companies [8]. Within large corporations, entrepreneurial individuals tend to be relatively more productive than other employees, thereby providing added and critical values to their organizations [9, 10, 11].

Over the past 40 years, entrepreneurship has become a rapidly growing discipline within the United States of America and across the globe being promoted by industry, governments, and academia [9, 11, 12, 13, 14, 15]. Its presence is felt from K-12 through college and in industry. Entrepreneurship education at all levels is a global phenomenon [11].

In a 1999 survey of business school graduates, Charney and Libecap [9] found that the entrepreneurship program graduates were typically more highly paid and wealthier. Reynolds et al [16] reported that Americans of all ages over 18 years old engage in entrepreneurial endeavors with many started by teams of individuals and that ethnicity/race, gender, education, household income, and demography affect entrepreneurial propensity. Entrepreneurs who are highly skilled and more experienced tend to be more successful over time [8]. Moreover, it was reported in Wadhwa, et al [13] that most founders of technology companies held bachelor's and master's degrees – 44% and 30% respectively -- with nearly 50% of the degrees being STEM related disciplines and 33% being business related. The report also revealed these technology company founders graduating from computing disciplines entered their first business venture sooner after

This material is based upon work supported by the National Science Foundation under Grant Number 0942732.

graduation than those graduating from engineering disciplines; but that engineers started business ventures at about three times the rate of computing professionals. The higher incidence of entrepreneurial ventures among engineers might be caused by the higher prevalence of engineering entrepreneurship education compared to computing related entrepreneurship education at the baccalaureate level [12].

Integral to entrepreneurship is creativity, innovation, and teamwork. Innovation is applied creativity in a business context [8, 11, 17, 18, 19]. “Since World War II, entrepreneurial firms have been responsible for half of all innovation and 95 percent of all radical innovation in the United States!” [11]. Similar findings are reported in Zimmerer and Scarborough [8] as stated earlier. As reported in Weiss [19], innovative intelligence is as critical to an entrepreneur as analytical and emotional intelligence. It endows the entrepreneur and his/her team with the ability to understand and solve seemingly complex problems. Altshuller [17] subdivided innovative problems into five levels of complexity with each level consisting of six stages that can be systematically solved once the appropriate heuristics for the problem solution is found, but that heuristics for problems at levels four and five may have to be developed.

Since many new ventures are started by teams of individuals as previously stated, it is imperative that aspiring entrepreneurs know and practice the value of completing a task on schedule while maintaining working relationships and keeping the mechanisms for team cohesion intact [6, 7]. Teaching students about teamwork and training them in its practices can help students develop greater awareness and appreciation for its inherent professional skills such as communication, decision making, conflict management, social, leadership while acquiring them [1, 20]. Moreover, Passow [21] found that undergraduate engineering alumni consistently rated teamwork, communication, data analysis, and problem solving more highly than any other ABET related competencies.

The pervasiveness of entrepreneurship today has direct implications not only in industry, but also in academia. Although the research and adoption of entrepreneurship activities are still ongoing, entrepreneurship currently is emerging as an independent discipline. Entrepreneurship education and training can be experienced in life sciences, architecture, liberal arts, engineering, music, medicine, and pre-college [11]. There is an increasing body of research in recent years that supports the theory of entrepreneurship as a discipline [10, 14, 15]. Nonetheless, there is still an apparent general lack of an agreed upon body of educational content and appropriate assessment instruments for evaluating student experiences in entrepreneurship courses [22, 23]. At the core of this theory is the entrepreneurial process [10]. Other related concepts include the entrepreneur, organizational context, resources, business concept, performance, impact, and the environment [10, 15]. To create a new business, the entrepreneur needs a compelling story about the venture and a business plan [8, 11, 18]. The survival and growth of the new venture will directly or indirectly depend on the “entrepreneur’s traits, skill, and motivation” [14, 15, 24].

It is becoming imperative, that all institutions of higher learning prepare their graduates for the uncertain workplace that most of them are likely to face upon graduation. The world of work is changing to one of mainly contingent workers regardless of where you are on the globe [12, 23]. According to an Intuit 2010 report [25], over 80% of big corporations expect to significantly increase the percentage of contingent workers in the future. By 2020, the number of contingent workers in the United Stated is projected to approach 50%. This suggests that few graduating students can expect a traditional career with full benefits. Most graduates can expect to become contingent workers who are responsible for their own career as well as medical and pension benefits. As contingent workers, they will become more dependent on their co-workers for referrals, collaborative endeavors, and an awareness of the intricacies of conducting a business. Being trained in entrepreneurship, innovation, and teamwork will help students to better cope with the “rapidly changing” workplace they are increasingly more likely to experience. Today, an increasing number of engineering schools [3, 12, 26, 27, 28] and to a much lesser extent computing schools [29] are implementing programs to educate and train future engineering and computing graduates in entrepreneurship and innovation to make them more career ready.

This is a comparative case study of two courses with different entrepreneurship instructional methods. In fall 2011, a Technology Entrepreneurship course was offered to computing and business students at a private university in the New York City metropolitan area. The students were primarily undergraduates, but two of them were graduate computing students. The students were educated in the principles of teamwork, innovation, and entrepreneurship and were trained in applying these principles to either financial or healthcare practical problems. The principles of the course were supplemented by case studies as well as guest lecturers from academia and industry. To complement the principles taught, student teams were created and trained in teamwork. In addition, each student team was assigned a project to identify and solve a financial or healthcare problem for a niche market. They were required to develop a business plan to support the problem solution. The training of each team in entrepreneurship and innovation was aided by an assigned mentor who was an industry professional at the managerial level or an independent practicing entrepreneur. Each team was required to meet with its mentor regularly for advisement on its project idea, feasibility and scope, design and development, and supporting business plan as well as to provide progress reports and obtain feedback and guidance. The students and teams were assessed on the project and exams. Two external evaluators helped with the in-class project evaluation process. In addition, an independent educational project evaluator reviewed the Technology Entrepreneurship products (business plans and PowerPoint presentations) and Data Mining products (project reports and PowerPoint Presentations) to determine their relative intellectual merits and potential societal impacts, and concluded that the Technology Entrepreneurship products were better.

This material is based upon work supported by the National Science Foundation under Grant Number 0942732.

II. COURSE DESIGNS

The Technology Entrepreneurship course covered three major topics inclusive of teamwork (two lessons), innovation (two lessons), and entrepreneurship (four lessons). While most lessons were given in one weekly session, two lessons were given in two weekly sessions, and one was given in three weekly sessions. One class session was devoted to the submission and presentation of the assigned team project and one class session was devoted to the final examination. The lessons covered such topics as teams and teamwork; team development, and teamwork skills; innovation, innovative intelligence, and innovative thinking; applied creativity; economic growth, opportunity, and technology entrepreneur; vision, competitive strategy, business model, innovation strategies, and risk and return; business and marketing plans; and ventures, knowledge, learning, design, and contemporary issues in technology entrepreneurship. The two textbooks used to produce the lessons were [17, 18] in the reference list. These textbooks were supplemented by six reference books: *Innovative Intelligence* (Weiss and Legrand) [19], *How to Think about Algorithms* (Edmonds), *Information Technology Entrepreneurship and Innovation* (Zhao), *Entrepreneurship for Scientists and Engineer*s (Allen), *The Wisdom of Teams: Creating the High-Performance Organization* (Katzenbach and Smith) [6], *Teamwork and Project Management* (Smith and Imbrie) [7], and two entrepreneurship related magazines -- Entrepreneur and INC. The lessons were complemented with case studies of successful and unsuccessful entrepreneurial ventures and supplemented by guest lecturers who presented on such topics as innovation and technology entrepreneurship, business plan development, and marketing and selling as well as mentors who coached and advised the student teams on their project idea, feasibility and scope, product design and development, and business plan development. The project description required each student team to identify a potential product, service, or process in finance or healthcare that satisfied the need of a niche market of consumers in New York City and beyond, and is supported by a business plan for a real or fictitious financial or healthcare information technology company. No team had to implement its developed product design beyond the algorithmic level because of the time limitation of one semester. Forty percent of the course grade was assigned to the project and 20% to team and class participation inclusive of interactions with mentors. The final examination accounted for 24% of the course grade while the remaining 16% was divided equally among five in-class quizzes. The project deliverable included a business plan and a PowerPoint presentation.

Of the 12 students enrolled in the Technology Entrepreneurship course, 10 were undergraduate and two were graduate students. Two of the undergraduates were business students who were grouped into separate teams with computing students. One business student majored in business management and the other double majored in entrepreneurship and finance. The two graduate students were computing majors – one majored in computer science and the other in software development and engineering; they were grouped together to form a team. There were three undergraduate teams: two with three students and one with four students. The teams were purposefully designed by the professor using demographic and learning style type information respectively obtained from the students through a questionnaire and an adopted multiple intelligence test used a proxy for learning style. Undergraduate students with similar learning style type were grouped together in teams. It was assumed that students with similar learning styles would function better in a team with less interpersonal conflict, retention of team members, and smoothly transition from forming to performing [1]. Moreover, 50% of the undergraduate and graduate students worked at least part-time; 80% of the undergraduate students and 100% of the graduate students had self-reported grade point averages above 3.0; and except for one of the business undergraduate students being a sophomore, the other undergraduate students were either juniors or seniors. Furthermore, the teams were monitored and supported through regular interviews, surveys, and feedback on in class performance, interactions with their mentors, and project development issues.

The Data Mining course enrolled 19 graduate students and five undergraduate students. As in the Technology Entrepreneurship course, the teams in the Data Mining course were designed and maintained in the same ways with undergraduate and graduate students grouped separately. The project was a similar type open-ended assignment with a project report and PowerPoint presentation of a financial or healthcare problem solution for a niche market as the project deliverables. The Data Mining course covered a single topic: *data mining*. There were other differences with the Technology Entrepreneurship course: the graduate students were not assigned mentors; the project accounted for only 15% of the course grade while the final and in-class examinations were 35% and 30% respectively; no lessons were given on teamwork, innovation, or entrepreneurship, but students were expected to function well in their teams as well as be innovative in their problem solution, and entrepreneurial in their product design and development. Two external evaluators assisted in scoring the student teams in-class PowerPoint presentations.

The external evaluators used in the in class project evaluation process in both courses assisted in judging the student teams' project deliverable through the team's PowerPoint presentation based on five criteria: creative ability, computational thinking, thoroughness, technology entrepreneurial skills, and presentation skills with creative ability having the highest allowable score of any category: 24 points. This adopted team project scoresheet was originally developed for the evaluation of student computing products in the annual New York City Science and Engineering Fair. The evaluators were trained in the use of the project scoresheet by the professor who has several years of experience in using this instrument as a project evaluator for the New York City Science and Engineering Fair. Based on this experience with the evaluation instrument, the professor determined that ±10 percent would be an acceptable margin of error for all evaluators' total scores. Moreover, the evaluators were familiarized with the course objectives beforehand as well as they shared their prior experience in the evaluation of other related student projects at local competitions at the project

This material is based upon work supported by the National Science Foundation under Grant Number 0942732.

evaluation training sessions. The professor participated in judging the presentation, and graded the business plans/reports.

After both courses were offered, the independent educational project evaluator reviewed and evaluated the business plans and PowerPoint presentations for the Technology Entrepreneurship products as well as the project reports and PowerPoint presentations for the Data Mining products to determine their relative intellectual merits and potential societal impacts. This person is an experienced program evaluator and assessment developer with background that includes review and revision of performance based instruments to determine their validity and reliability and evaluation of projects to determine their intellectual merit and broader impacts. In the capacity of independent reviewer for both courses, this person assessed the relative merits and potential impacts of the student projects with respect to each other to determine if they were consistent with the general rubric for team products as specified by the professor. The independent evaluator's product/service ratings were not factored into the teams' project grade.

III. ENTREPRENEUR TEST

The entrepreneur test used was adopted from previously used entrepreneur propensity self-administered tests obtained from online sources. These sources include the U.S. Small Business Administration, Entrepreneur magazine, and the Center for Rural Entrepreneurship. The adopted questions relate to creativity, risk taking, self-motivation, work ethic, and teamwork. Since all of the questions on the test were adopted from previously validated entrepreneur tests, the test offered to the students was assumed to be valid and a reliable predictor of entrepreneurial propensity. This test was given to students twice during the semester: on the first day of class and on the last day of class.

IV. DATA

For Technology Entrepreneurship course the data used to determine the relative changes in student entrepreneurial aptitude were obtained from the individual pre- and post-entrepreneur test as well as the overall post-course survey, Students Assessment of their Learning Gains (SALG), but for the Data Mining course only SALG was used. There were 25 items in the entrepreneur test, with each item having a yes or no response. The course survey had one multiple choice item that dealt with student interest in taking another course in the subject area as well as several open-ended items where students could indicate the impact of the course on their entrepreneurship understanding and attitudes. The students' responses provided information on learning gains and changes in attitudes and knowledge resulting from taking the course. Additional data from both courses were related to students' performance: team project quality, project grades, and the average in-class and final examinations. These data provide a holistic view of student performance; those produced in the technology entrepreneurship course were compared to similar ones in the data mining course.

V. RESULTS

In the Technology Entrepreneurship course, the pre-test mean percentage of correct responses on the entrepreneur test was 77% for undergraduate students as compared to 78% for the two graduate students. The mean percentage of correct responses on the post-test entrepreneur test was 82% for the undergraduates compared to a mean percentage of 80% for the graduates indicating that the percentage of correct responses increased for both groups of students. The average percentage change in test scores was 8% for the undergraduate students and 5% for graduate students. These positive findings were corroborated through correlation analysis of the undergraduate students' entrepreneur test and course grade. There was statistically significant moderately high correlation between the pre- and post- entrepreneur test scores of 0.586 with significance level within 10% (0.08) as well as statistically significant moderately high correlation between the post entrepreneur test and the course grade of 0.637 with significance level of 5% (0.05). Moreover, 60% of the undergraduate students indicated that they had at least a "good gain" in interest in taking another course in the subject area and 100% of the graduate students stated that they had a "great gain" of interest in taking another course. These data illustrate that most of the students were very much interested in pursuing technology entrepreneurship study.

With regard to the relative course performance of the Technology Entrepreneurship students in comparison to the Data Mining students, their performance was generally better than the Data Mining students. Specifically, the Technology Entrepreneurship student teams' project grades were generally higher by about 10% while the graduate team's project grade was higher by 7%. In addition, the scores that were given by the two external evaluators and the professor to each Technology Entrepreneurship team for the business plan PowerPoint presentations were within ±10% of each other. For the Data Mining teams' project report PowerPoint presentation, the three evaluators' scores were generally within the 10% margin of error. Moreover, the independent evaluator's comparative review and assessment of the project deliverables (business plans/reports and PowerPoint presentations) of the Technology Entrepreneurship and the Data Mining courses found that the business plans of the four Technology Entrepreneurship teams indicated that the teams each had innovative projects that covered all aspects of the project assignment including discussion of the strengths of their product in contrast to alternative solutions as well as the product's ability to meet an identified need. This evaluator also found that the project presentations and reports of the Data Mining student teams generally did not contain a discussion of the strengths of their product in comparison to alternative solutions, thereby providing relatively less intellectual merit information; there was also limited discussion regarding the potential broader societal impact of the proposed product/service. Moreover, the Technology Entrepreneurship student teams' average of the in-class and the final exams also indicated better course performance than the Data Mining student teams. The undergraduate Technology Entrepreneurship teams' had an overall average score increase of about 15% over the undergraduate Data

This material is based upon work supported by the National Science Foundation under Grant Number 0942732.

Mining teams. This relative performance relationship was maintained by the graduate teams from each course with the Technology Entrepreneurship graduate students achieving an overall 20% increase over the Data Mining graduate student teams. These findings were further substantiated through correlation analyses. For the Technology Entrepreneurship course, the correlation between the in-class and final examinations was weak to moderate and statistically not significant (0.15) for undergraduate students with a value of 0.491 and moderate and statistically significant (0.06) for the entire class with a value of 0.552. For the Data Mining course these correlation values were weak and statistically not significant being 0.139 for both the undergraduates and the entire class with significance values of 0.861 and 0.528 respectively. As to the review of student statements on the post-course SALG survey of changes in course related knowledge, skills, attitudes, and aspects that will be carried over into the students future life, most students in both courses made positive statements; although the percentage of positive statements were greater in the Technology Entrepreneurship course.

VI. DISCUSSION

The entrepreneurship pre- post-test data as well as the other the aspects of course performance indicate that the students in the Technology Entrepreneurship course out-performed those in the Data Mining course. These results might imply that direct instruction in teamwork, innovation, and entrepreneurship contributed to the positive impact on course performance. For example, statistically significant moderately high correlation was found between undergraduate student post entrepreneur test and the course grade. Nonetheless, other factors might have also contributed to the relatively better results: some students may have had family histories of entrepreneurship, some might have simply liked the course because they saw the potential value to themselves, and the inclusion of business students in two of the undergraduate teams might have also helped to improve the course outcomes. Yet, the students in the Technology Entrepreneurship course seemed to have scored higher than those in the Data Mining course on all the metrics used including exams. In fact, there was greater consistency between the in-class and final examinations in the Technology Entrepreneurship course as revealed in correlation analysis. Moreover, it is interesting to note that the student products in the Technology Entrepreneurship course were more innovative and students were better able to address a particular market niche problem in finance or healthcare than the students in the Data Mining course. This too might have been partially influenced by the direct instruction in teamwork, innovation, and entrepreneurship. Souitaris, et al [30] found that the teaching of entrepreneurship is very beneficial to some students in that it increases their "attitudes and the overall entrepreneurial intention." In fact, some of the products produced by the Technology Entrepreneurship teams showed market potential. For example, an undergraduate Technology Entrepreneurship team's business plan for a prescription transaction machine that would eliminate customer waiting time for pharmacy's to fill a prescription was judged by one of the external project evaluators to be worthy of further product development and implementation; this evaluator is a senior manager in the healthcare industry. This type of endorsement corroborates the growth in students' understanding of course content and objectives in innovation and entrepreneurship.

Students' perceptions of both the Technology Entrepreneurship and Data Mining courses were generally positive, but were more positive in the Technology Entrepreneurship course. Some examples of the responses from undergraduate students in the Technology Entrepreneurship course are the following as reported on the Students Assessment of their Learning Gains (SALG) post course survey:

One student commenting *on how his understanding of technology entrepreneurship changed* as a result of taking the Technology Entrepreneurship course stated the following: *I did not really know what to expect but after the class started everything changed. Being an entrepreneur is the way to go right now.*

Another student commenting on the *skills* gained from taking the technology entrepreneurship course reporting the following: *Teambuilding, motivating others, identifying opportunity and innovating*.

A third student commenting on how the technology entrepreneurship course *changed his attitudes* towards the subject reported the following: *I am no longer intimidated by entrepreneurship as I once was.*

A fourth student commenting on what will be carried *with him* into other classes or other aspects of …his life reported that *I will carry just about everything I've learned in this course into my life because every aspect holds value to me*.

A fifth student commented on how the technology entrepreneurship class activities helped his learning stated that there could have been more activities: *I wish there had been more*.

The students in the Data Mining course also had mainly positive comments on the SALG post course survey as the following examples shows:

One student commenting on how his *understanding* of data mining *changed* as a result of taking the course said that *the course has taught me to be more disciplined and organized when dealing with complex issues*.

Another student commenting on the *skills* gained as a result of taking the data mining course said that the skills were *teamwork, taking initiative, delegation of tasks, cooperation/collaboration*.

A third student commenting on how his/her *attitudes* changed towards the data mining course said: *Entrepreneurship in data mining*.

A fourth student in commenting on how the class activities helped his/her learning said the following: *There weren't any class activities*.

This material is based upon work supported by the National Science Foundation under Grant Number 0942732.

The comments from the Data Mining course students seemed to suggest that these students generally were less engaged in the teamwork and entrepreneurship aspects.

Despite students' generally positive comments, they could have gained more from the Technology Entrepreneurship course had they more fully utilized the services of the mentors. One of the four mentors commented that the team he mentored did not sufficiently take advantage of his entrepreneurial skills, knowledge, and time in practice after their first valuable meeting, and felt the team members missed out on preparing communications in a way to attract an investor eye as well as perhaps the use of invaluable contacts.

VII. CONCLUSION

As anticipated the Technology Entrepreneurship students' team projects produced relatively better products than the Data Mining students. This might have been influenced, in part, by direct instruction on teamwork and innovation along with entrepreneurship. Nevertheless, the Technology Entrepreneurship teams could have yielded even better outcomes had they more fully utilized the services of the mentors while gaining their friendship, an important contact for workplace references and potential employment. Another mentor commented that the students in his team tended to view the project more as a regular class assignment rather than an actual workplace assignment. This seemed to have been truer in Data Mining than in Technology Entrepreneurship as evidenced by the students' post SALG survey comments and the correlation analyses that may be partially because there was no teamwork and entrepreneurship direct instruction. In future offerings, the Technology Entrepreneurship course will be made project based inclusive of time-tables for deliverables, with deliverables and their presentations replacing standard in-class exams. This will be done to address some of the concerns of the mentors as well as to make the project aspect of the course emulate an industry perspective as much as possible. With regard to the Data Mining course, direct instruction in teamwork and entrepreneurship will be provided.

Three implications that can be derived from these exploratory case studies relates to the direct instruction of teamwork, innovation, and entrepreneurship; apparent link between entrepreneurial propensity and course grade, and the positive impact of the mentors on the student teams. Direct instruction on teamwork, innovation, and entrepreneurship seemed to have positively influenced students' attitudes towards these professional skills as evidenced by the relatively greater number of students in Technology Entrepreneurship commenting on the gains made in these skills. The statistically significant positive relationship between the post entrepreneur test and the course grade seemed to suggest that entrepreneurial propensity may link to work ethic. The consistent use of mentors with the undergraduate students of both courses seemed to have positively impacted student attitudes to the open-ended project. A student from Technology Entrepreneurship reported the following in the SALG survey: *The mentor was informative; she aided us with our understanding of business in general*. A similar statement was reported by a student of the Data Mining course.

This study is exploratory in nature with regard to the evaluation of two case studies – a Technology Entrepreneurship course relative to a Data Mining course with emphasis on changes in entrepreneurial aptitude as evidenced through the products student teams produced, course examinations, and the SALG post course survey. There are some inherent limitations. They include small sample size, uneven mixed populations, and dissimilar courses and course design. Therefore, the results produced are only suggestive, and should not be generalized without confirmation from a more comprehensive follow-up study.

***Abstract*—An analysis of hiring patterns showed emerging trends: the complexity of information technology (IT) is shifting from development to post-deployment and integration needed for services. Given the complexity of deployed service systems, generated big data, and the national dialogue on educating engineers, we asked ourselves related questions. Do our graduate students have evaluation skills needed to work at the most advanced level of Bloom's taxonomy? Can they learn to frame and solve the problems within complex industry environments while applying the current research? How do we structure a graduate curriculum and an environment that provides experiences in innovation within the constraints of the academic calendar? Here we present an interdisciplinary curriculum comprised of three components: a service interaction blueprint for framing the industry problem, agile principles focusing on aspects of the solution, and Christensen's theory-building to frame the next iteration of research. The environment for industry problems was created through an National Science Funded Industry & University Cooperative Research Center. The feedback from a pilot graduate-level class is positive and provides insights for further research. We show through feedback discussions that it is possible to have translational activity at the industry-university enterprise boundary resourced in by advanced experiential learning.**

Keywords—complex systems, design, innovation, performance metrics, services science, technology management

I. Innovations for Complex Enterprise Systems

As early as 2004, an analysis of graduate student hiring patterns within industry showed several emerging trends: the complexity of information technology (IT) was shifting from the development phase to post-deployment. Enterprise IT departments were becoming brokers of cloud, social, mobile and information services [3]. And there is significant interest in converting data pumped out by these service complexes into actionable intelligence within enterprise workflows. This is now popularly known as the *big data problem* [4]. At the same time, we found little within the academic programs that teach the skills to frame problems related to the use of complex systems, learn from solutions and failures, and extract research that can provide real, perceptible value to their sponsors.

Computer science graduate students enter their second year with little insight into what it means to deliver services in the context of a complex enterprise system. They are mostly familiar with development methods and typically take the viewpoint of a programmer when approaching projects. . We use the term *complex enterprise system* here to mean both intra-enterprise and inter-enterprise services that collectively enable a business goal. As in [1, 2], we view these as networks (e.g. a value chain, supply chain, or service value network) with nodes as agents (i.e. humans, organizations, software and hardware) that are all creating, communicating, or consuming information.

The environment of the case study reported here is the specific National Science Foundation Industry & University Cooperative Research Center (I/UCRC) for Experimental Research in Computer Systems (CERCS). This is a multi-university center with CERCS at Georgia Tech researching complex enterprise systems, including their hardware, communications and system-level software, and applications. Complementary to this, the CERCS research site at The Ohio State University, the Center for Enterprise Transformation and Innovation (CETI), studies the applications of technology to achieve innovation. Thus by emphasizing the experimental method, CERCS promotes the creation of knowledge through the design, implementation, and measurement of large-scale systems. The goal is to conduct research that involves graduate students in industry research projects, yet is of interest to both the industry and the university [5].

Bridging the gap between technology consumers and technology providers is a key goal of CETI and the curriculum design discussed here. To accomplish this, graduate students need to think of how their services, when implemented, will benefit their sponsors and consumers, rather than focus on providing a technology implementation alone. However, we found that dealing with continually increasing dynamic complexity within the enterprise and its accompanying *wicked problems* [6] is rarely addressed in the typical graduate computer science curriculum. Often, even when an idea is adequately developed, the solution may not yield perceptible value to the enterprise, in that it fails to deal with the reality of delivering services with product and process innovations. Nevertheless, this is still good feedback for researchers and technology developers.

In order to address these gaps, we developed a graduate-level computer science course in applied information technology. We selected a set of interdisciplinary methods that focus on innovation-directed experiential learning and teach problem framing and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

research skills. Keeping in mind the time constraints present in the academic curriculum, we used a set of simple yet effective frameworks comprised of:

- *service blueprints* [7] for problem framing;
- *agile development practices* [8] as the process for delivering value to sponsor; and
- Christensen's *theory building process* [9] to extract the research statement from the project.

We assume here that by 1) framing problems to derive an innovation and development plan that applies within their sponsor companies, and 2) identifying research towards improving existing theories, the students will demonstrate evaluation skills to deliver improvements to complex systems. Thus they will function at the highest level of Bloom's taxonomy [10].

In this paper we begin with how we used the service blueprint to bridge from the *technology providers* (e.g. industry research labs, engineers in academia) to *technology consumers* within complex enterprise systems. Using this framework, we show how students use agile practices in their projects and extracted research statements from their project, all within one semester. We present feedback from students and offer insights toward improvements. We conclude with discussions of how graduate students can benefit project stakeholders (including themselves) through innovation-directed experiential learning.

II. Design of Curriculum Bridging Technology Consumers and Providers

We begin with issues in experiential learning and then introduce and justify the methods for use in the curriculum.

A. Importance of Context for Design

It is now well established that engineering design requires 1) an understanding of the context or environment for the correct framing of the problem, and 2) interdisciplinary approaches to solution development. For example, architectural design is viewed as its own integrated field of study, and is compared to other engineering disciplines; it is multi-disciplined, since the field seeks integration of electrical, plumbing, lighting, and other systems within its overall building design. Capture of contextual knowledge as *design patterns* was also first introduced by the architect Christopher Alexander [11, 12]. These design patterns are a way of making tacit knowledge explicit. Design patterns have been enthusiastically endorsed by software engineers leading to many framework technologies that improved the development of software. However, far less has been done in integrating interdisciplinary frameworks[1] related to complex enterprise services within the graduate software and systems engineering curricula.

Recent NSF workshops have looked at the process of introducing design thinking into the engineering curriculum [18, 19]. In addition, *grounded theory* provides a systematic methodology in the social sciences involving the discovery of theory through the analysis of data captured in the field [20]. It is mainly used in qualitative research, but is also applicable to quantitative data. All these ideas and methods bridge the gap between technology development and technology consumption in industry.

Finally, related to technology, engineering research continues to focus primarily on normative theories related to technology while business, such as management information systems, and healthcare focus more on descriptive or operational aspects, leaving a gap to be bridged. To address this *design science* [21] emphasizes the need for the information systems researcher to bridge the gap between existing knowledge and its context of use.

B. Experiential Curriculum Needs

In experiential learning, students learn to solve an industry-sponsored problem and the solution and outcomes are not predetermined. Many have identified the need to develop an advanced engineering "workforce of the future" capable of working more effectively with complex systems [22], the related need for advanced education that creates "T-shaped" individuals in technology areas [23], and new IT roles, such as a data architect or data scientist, with the appropriate complex skills [24].

While there is considerable focus on undergraduate education and accreditation, less national dialogue exists at the master's level. Related to software engineering master's requirements, the Integrated Software and Systems Engineering Curriculum has identified experiential capstone skills that "[can] reconcile conflicting project objectives, finding acceptable compromises within limitations of cost, time, knowledge, existing systems, and organizations. [25]" This type of work is at the highest levels of Bloom's taxonomy.

To address this curriculum need, we return to the technology consumer-provider gap and note that traditional engineering curricula have focused primarily on the creational (technology provider) aspects of software and hardware. To some extent, courses in management information systems cover operational (technology consumer) aspects. With the exception of industry best practices - TOGAF and ITIL – Enterprise Architecture curriculum assets that cover complex technology infrastructures and their related continuous improvement are limited. The challenges of enhancing the overall functionality and performance of a deployed complex system are left unaddressed within the curricula, with negative consequences illustrated below.

Problem-driven experiential learning is often interdisciplinary and questions that arise require faculty and

[1] Examples used by CETI include basic frameworks include: lean software development [13], TOGAF [14], ITIL [15], the balanced scorecard [16], and Porter's Five Forces model [17]. These frameworks are covered within different disciplinary silos.

practitioners from different disciplines to at least start with a shared understanding to develop solutions in a timely manner. To use a simple example, for a typical software engineer the word "activity" refers to a node in a finite state machine; for an industrial engineer this refers to a workflow task; and for a typical business graduate this term refers to an entire organization. While these terms are related in the field, they are rarely related in the disciplinary curricula.

Similar points are made in the emerging interdisciplinary field of Services Science, Management, Engineering and Design. Educators and researchers have pointed out that despite the increasing contributions of services to economic growth, there is no common understanding of what phenomena underlying services and the dynamics of services ecosystems create and drive value [26]. It has been argued [27] that existing models, traditionally used for describing the exchange of physical products, will not apply in the services context, in which close interactions between suppliers, service providers, and customers exist, where knowledge is created and exchanged, and experiences, capabilities, and relationships are an integral part of the transaction. In summary, an advanced experiential curriculum is important, difficult to resource, and demanding in terms of knowledge and needed skills.

Finally, students have limited available credit hours in their programs for the experience needed to correctly frame problems and solve them. Thus the methods selected for the course had to be simple to introduce, but effective in providing a structure for future growth as innovators. These methods are presented below.

C. Service Blueprint

In an effort to capture the needs of the service consumers of a complex enterprise, we selected a tool that is used in consumer sciences known as the service blueprint [7]. This framework identifies the core, peripheral, and enabling services within the enterprise. In the service blueprint, the core requires the student to identify the customer experience, from a tangible and emotional perspective. The blueprint is augmented with other services (organizational and technology) that have to be in place, thus requiring the student to elaborate on how a customer interaction moves through the organization. The service blueprint builds on methods of both computer and consumer sciences.

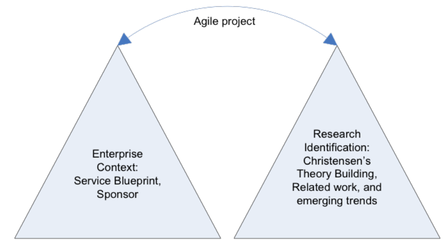

Fig. 2: The course frameworks and relationships: Service Blueprint for discovery, Agile for development; and Christensen for research identification.

D. Translational Process

Translation usually uses research to improve the methods of working to producing goods and services. The result is an innovation. The term *complex innovation* is innovation related to complex enterprise services. Complex innovation requires students to fully understand the underlying translational process cycles that are needed. These cycles often start from *in situ* observations and

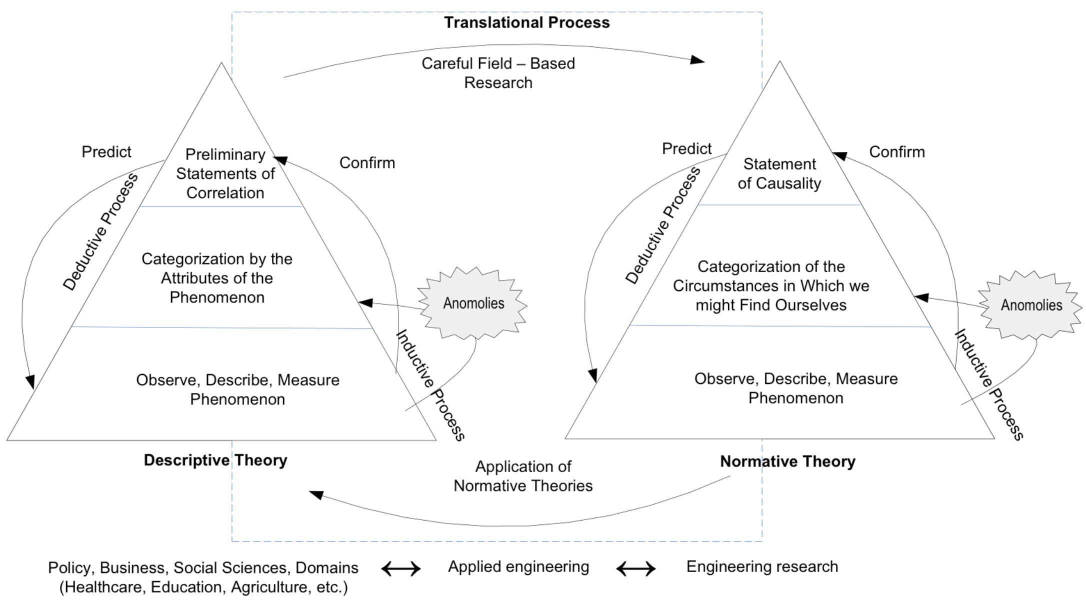

Fig. 1: The Engineering Translational Process bridging from descriptive to normative theories, based on [9].

understandings, i.e. development of descriptive theories (Fig. 1, left). Next, these lead to subsequent cycles of theory building that are well explained in [9]. In particular we next wish to build on key points about theory building that Christensen makes and relate them to the translational process involving, in particular, engineering innovation research.

First, the descriptive stage of theory building (Fig. 1, left) is viewed as a preliminary stage because translational engineers must understand the context and causalities that occur in the real world, e.g. the complex healthcare system. They then pass this understanding on to the development of a normative theory (Fig. 1, right). The right side is the typical realm of more academic engineering researchers. Normative theories have the ability to predict outcomes of interest, not just what is correlated in the field. Anomalies are treated with great interest as they often refine theories. We use the term *translation* here for the process bridging between descriptive and normative theories in order to cycle between understandings to causalities.

Second, the translational process (as in Fig. 1) is not simply a one-way process of taking ideas from university labs out to be applied in industry. Careful field-based research, anomalies and correlations must also move back to inform technology and engineering research in the university.

This deeper, normative understanding of predictability and repeatability is exactly what is needed as the basis for service automation and the development of enabling technology. For example, the design of telemedicine solutions must be based only on theories of automation because they are also repeated in human interactions. Care must be taken not to over-automate at the expense of usability. This type of nuanced understanding begins with observations and the development of a descriptive theory regarding the context of use.

The typical innovation goal is often initially stated in broad terms (e.g. social media can be used to improve the health care enterprise). Such a claim may never be warranted by existing underlying research, yet the innovation might be successful. In contrast, each academic research hypothesis and its accompanying goals are typically narrow and rigorous (e.g. text analytics tools can be used to extract the positive sentiment of entities in micro-blogs). In other words, within complex systems we may never complete all the research (e.g. due to wicked problems [6]) and we may have to acknowledge that a single good research result might not have a perceptible impact on the economic performance of the whole system.

There also is no guarantee that research investment will be successful in practice. Innovation may be the result of research and development, but also more rarely, it could be due to a "Eureka" moment. Thus, many wicked problems and different disciplinary perspectives need to be addressed for a typical complex system innovation. And, to achieve results, many translational cycles will typically be involved. Ways to enable translational activity within the university are discussed in [28].

E. Agile Translation

Last but not least we introduced agile development practices, which form the process used to conduct the projects. It consists of the following principles, based on [8]. Since the industry sponsor approves all work products based on achieving a translational goal state that is also funded, we point out that the work products are of value to an industry process or product. Thus, each work product contributes incrementally to a final innovation.

III. Implementing Innovation – Directed Experiential Learning

The students taking the course in Advanced Enterprise Architectures in Services were first- and second-year master's and doctoral students seeking real-world experience. Most were new to research and most had a year of previous work or project experience. The steps in the course (see Fig. 2) and curriculum is as follows:

1) Project triage: At the start of class the students were assigned projects and industry sponsors to work with. These projects are typically in the domains of healthcare, education, insurance and finance, and government services. The industry projects serve as a living laboratory or sandbox, meaning the projects represent the full messiness and complexity of real-world enterprises. In this early phase, the students were mainly introduced to the problem.

We assigned team members as follows: the team leader was a doctoral or second year master's student. The remaining team members were first year students with an interest in the project topic. Thus there was a mentoring relationship.

2) Develop service blueprint: In this phase, the students had to distill the messiness of the problem into an abstraction that identified, from the consumer's perspective, the true value of the final project. They were given a lecture on Service Blueprint.

3) Follow agile practices: On an on-going fashion, the students interacted with their sponsors and created project implementations. Concurrently, they did background and secondary research on related emerging trends.

4) Identify research: Using Christensen's theory building framework, the students began to understand and document where the unique contributions of their work might lie and developed a future project plan. They were introduced to Christensen's theory in two lectures.

5) Wrap-up: The groups present to their sponsors the project plan and the value of the project. And, they produce a research report describing their publishable work.

The course format was a hybrid online-offline classroom. Required reading materials were posted to the course website prior to class and five classes (of a total twenty-four) were spent on lectures. Thus more time was spent on in-class project discussions applying theory building and service blueprint methods.

The project environments included weekly activity tracking of students, kept private between the student and faculty advisor, and a project environment with blogging for team collaboration. Google sites were used for access to the work products by sponsors.

IV. Results

Twenty students took the pilot course in Spring 2013: six doctoral students, five second-year master's students, eight first year master's students, and one non-traditional undergraduate. The course was being offered for the first time so we had little understanding on what to expect. Thus we viewed the course as a way to discover and frame hypotheses for future research.

To assess the effectiveness of this course and the instruction method, we therefore prepared a survey for a longitudinal study to capture improvement in students' evaluation skills consequent to their instruction with the service blueprint. Christensen's framework was presented at the end of the class (they had previous knowledge of Agile).

We asked the same questions week three and week ten:

How do you define computer science research? How well do you feel you are equipped with methodological knowledge for research? How do you define computer science innovation? How well do you feel you are equipped with methodological knowledge for coming up with innovations? Do you consider innovation skills to be essential for employment? Do you consider research skills to be essential for employment?

The three groups are – *group 1:* nine first year masters students including one senior, *group 2:* nine second year masters, and *group 3:* three doctoral (playing mentor roles).

We administered these questions at the start and towards the end of the semester. Given small numbers and absences, we found no statistically significant change between the pre-instruction and post-instruction surveys. But taken the responses taken along with additional feedback solicited at the end of the class from each group was insightful and useful for developing hypotheses for further research. We have thus organized our results from the perspective of hypotheses forming evidence below.

Hypothesis: Graduate students understand the need for evaluation skills at the highest level of Bloom's taxonomy. They can define terms like service, innovation, and research and state the importance.

Group 1: Several saw the need for project skills but did not see the value of research and innovation skills for their future job search. They saw that the structure of the course as "different", "more autonomous", "bigger picture', and "not just "start coding". They could see that they have to gather requirements and understand what they are doing. Relationship with companies leading to internships is a plus; multidisciplinary perspective is a plus (much higher-level class, more than coding, gives aspects of industry that s/he's never seen). Suggestions for the course: "precisely define the terms", "give examples of hypothesis – unsure what it looks like", "good on-boarding", "started off seeming like an implementation course, and not a research course".

Our observations: We did not structure the relationships between project and research adequately enough to ask more precise questions. In retrospect, we think this was because the class was a combination of project and lecture based, with project discussion dominating. Thus the students focused on the Agile project aspects, but did not focus on the vocabulary even though that was presented and tested.

Hypothesis: Technology Graduate students can be taught to focus on technology consumers and innovation with Service Interaction modeling.

We noted by examining the project work products, that with the introduction of the service blueprint each team shifted its thinking process from implementation (technology provider mentality) to the consumer value. Most teams modified their blueprints several times as they thought more globally. In addition three Group 2 masters students developed satisfaction questionnaires for the technology consumers of their own innovations based on this. This was an important behavioral shift we were attempting to achieve. Consequently in the next iteration of the class, we plan to have work product related questions.

Hypothesis: Mentoring is helpful.

Group 1: "discussions with the team were helpful", "enjoyed working with partner (mentor), who is helpful", "class lectures were unclear; I now understand enterprise projects, so the class was helpful".

Group II: Several group II students mentioned "benefitted a lot from working with a Ph.D. student". Suggestions for the course: "start earlier with Christensen's Theory Building", "too long of a warm-up period, not enough time to do the research", "no direct tie between the EA (enterprise architecture) foundation and the class work, improve teaching of EA".

Hypothesis: Graduate students need to be taught all three frameworks and the relationships between them.

Group III: "Was previously unsure of how to write an academic paper", "the time wasn't too short, as s/he came in with more preparation"; "got good insights for own personal research"; "didn't know previously how to proceed with research, now has some sense on how to do research", "difficult to extract research from projects". Out observations, Group II and Group III were more able to see the benefits of the service interaction model and the relationships to the Christensen's model.

These responses provide some overall guidance on how to improve the experiential learning:

1) Include more explicit in-class discussions on the terminology.

For instance, include an explicit discussion about both Christensen's theory building model and innovation versus research. One way to proceed, given limited time, is to introduce a class simulation that illustrates the differences between research and innovation and the different types of reasoning processes.

2) Make the doctoral student experience more explicit.

Doctoral students gain because they get several teams working on exploring different ideas related to their research. This needs to be made more explicit.

3) Poor access to relevant knowledge.

We also make other, broader observations related to the environment. The conduct of an experiential curriculum and its accompanying translational activities is knowledge intensive and the resourcing has related challenges, as the faculty member has to have both explicit research background and deep industry experience. Confronted with typical sponsor needs in industry, we have also found that the typical academic research paper is often too narrow to solve the whole problem and show benefits to the end consumer. This, we believe, makes it increasingly difficult to derive innovations in short academic timeframes.

For example, during the problem framing stage it is typical to find thousands of academic publications that match keywords of interest. A simple search in Google Scholar for "adaptive complex enterprise" yields over six million results. Even so, most academic research papers do not address the whole problem and are too discipline-specific. Practice papers are too generic or vendor-specific. More integrative approaches to presenting research and practice must be explored to further the translational process. In particular, new approaches to the publication of translational work products and data sets related to the paper should be considered.

V. Conclusions

There is a growing gap between technology consumers and technology providers. This is also mirrored as the related gap between academic research rigor and effectiveness in practice. Thus, from an I/UCRC perspective, we are interested in asking: can advanced graduate students within experiential courses become the engine for translational activities and innovation related to complex systems?

The challenges to be addressed include lack of understanding of the 1) enterprise context, and 2) research and innovation processes. To address this we have proposed an advanced interdisciplinary curriculum framework integrating service blueprints from consumer science, Christensen's theory building from business, and agile practices from software engineering. We provide specifics of implementation and observations based on a pilot implementation.

Our preliminary results show that, while the application of technology increasingly depends on consumer context, this context can be quickly abstracted using available tools like service blueprints. Subsequent agile management of projects and extraction of research abstractions using Christensen's theory building is feasible within the constraints of one semester.

This approach has the potential of a sustaining industry-university structure that can benefit graduate student learning experiences and translational researchers. We have shown that students can acquire all the needed knowledge and deliver value within a limited time.

Acknowledgment

This work was done under the aegis of the Center for Experimental Research in Computer Science at Georgia Tech and The Ohio State University, funded by the National Science Foundation's I/UCRC program (NSF IIP 0753710). Funding was also provided by The Ohio Board of Regents Computer Science Graduate Education program and by the National Science Foundation Course, Curriculum, and Laboratory Improvement program (NSF CCLI Phase 0837555). We wish to acknowledge the helpful ideas by our colleagues, especially Dr. Jay Kandampully for his presentations and insights into the service blueprint, CETI members, and sponsors.

***Abstract*— Studies have identified institutional or programmatic interventions that can be implemented to address lack of fit and related individual variables that may impact success and retention in engineering programs, especially among underrepresented groups in science, technology, engineering, and math (STEM) fields. One such intervention is a living-learning community (LLC). Informed by best practices in the literature, inVenTs is a new interdisciplinary residential community offered at a Research I university that is designed to encourage the development of innovative and entrepreneurial thinking skills while at the same time offering programming that is linked to retention and success. Linked to the activities being offered in this residential community, our research is examining what curricular and co-curricular initiatives have been shown to retain undergraduates and at the same time develop students' ability to be innovative. This paper discusses initial findings from assessment efforts and future assessment plans as findings are being used to inform future programmatic initiatives.**

Keywords—innovative thinking skills; living learning communities, retention

I. INTRODUCTION

InVenTs is a new interdisciplinary residential community offered to engineering, science, and business undergraduates that is designed to encourage the development of innovative and entrepreneurial thinking skills while at the same time offering programming that is linked to retention and success, especially among students from under-represented groups. Providing this opportunity to students targets two areas of international importance by offering targeted programming that can improve retention and to what extent that programming can improve innovative thinking skills among STEM majors. Several recent reports have highlighted the need for innovative thinking skills as the U.S. looks to maintain a viable national economy[1, 2]. These skills include the ability to exercise innovative and entrepreneurial thinking skills[3, 4]. As calls for retention and graduation rates for engineering graduates that can provide innovative solutions mount, there are clearly great gains to be made in the numbers of under-represented minority (URM) students earning engineering degrees.

African Americans, Latinos, and females of all racial and ethnic groups are woefully under-represented within the engineering profession in comparison to their representation in the general population[5]. We would anticipate that students that participate in the inVenTs community would be better prepared to enter into the workforce as well as be retained at a higher rate than non-participants given the support and engagement that is part of the LLC.

II. CONCEPTUAL FRAMEWORK

Research provides two separate bodies of knowledge that are providing the foundation for the inVenTs initiative and related research study. First, several studies document the important role that support and engineering self-efficacy play in the retention and success of under-represented groups in engineering [6,7]. Increasing student confidence and providing them with mentoring, role models that they can readily identify with, and opportunities to practice and apply content knowledge among a supportive peer group has been shown to have a positive relationship to increased self-identification with engineering as a major and career choice, or increased sense of "fit"[6,8]. Studies have identified institutional or programmatic interventions that can be implemented to address lack of fit and related individual variables that may impact success and retention in engineering programs. One such intervention is a living-learning community (LLCs)[9]. LLCs can create a critical mass that increases the supportive peer interactions taking place among women and other underrepresented groups[10] and can also alleviate negative stereotypes[11]. Other interventions

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

such as mentoring and placement with role models have also been identified as important ways to mitigate isolation and improve retention, especially among underrepresented groups [9,12].

Part of the programming associated with inVenTs is designed to provide opportunities that can counteract negative influences; thereby, facilitating support, increasing fit and retention to degree. For instance peer mentoring, weekly seminars that bring in role models, and block scheduling residents in first year courses so they have ready-made study partners are part of the programming offered to participants. The new inVenTs program, instituted in Fall 2012, is sponsored by the Center for the Enhancement of Engineering Diversity (CEED) within the College of Engineering at Virginia Tech and builds off of four existing programs, Hypatia and Galileo for engineering undergraduates, and Cajal and Curie for science undergraduates. The inVenTs community in its first year of implementation has pulled together these four communities into one community that also includes business majors. Approximately 500 students are participating this fall in the interdisciplinary inVenTs community that is designed to build innovative thinking among undergraduates.

When considering the body of literature that surrounds the development of innovative thinking skills among engineering undergraduates several studies provide a framework that creates the inVenTs living-learning experience. Literature has attempted to highlight skills that innovative engineering undergraduates would demonstrate[3,4,13]. Using problem-solving methodologies, and a variety of corporate based literature as references, engineering educators suggest that students would be able to set goals for their own learning and identify when they need to seek new knowledge to solve problems. Innovative thinkers should be able to give and receive feedback on new ideas as well as possess the ability to represent those ideas visually and contextually. Students should also be able to think critically so that they can assess the value of their prior knowledge and elaborate, translate, and summarize known and new information[14,15,16]. Activities that have students use concepts in new and different contexts such as those provided by open-ended problems that need to be solved and then sharing that information with others for critical feedback can help develop innovative thinking [17,18,19]. Based then on what is known about the development of innovative thinking, in addition to what is currently offered in the way of academic and social support, inVenTs residents have the chance to engage in hands-on activities that are designed to encourage and develop innovative thinking. Residents are involved in activities that allow for direct involvement in the full chain of innovation from research and transition to translation and commercialization.

Linked to the activities being offered in this residential community, our research is examining what curricular and co-curricular initiatives have been shown to retain underrepresented minorities and at the same time develop students' ability to be innovative. Quantitative and qualitative methods being employed to study what factors impact retention and development include student surveys, focus groups, and direct methods of observation of skills demonstrated during design competition. A control group of STEM students that have not participated in a LLC is being used for comparison of findings. Results related to this research will share the best practices identified and resources that can help educators in teaching innovation, while at the same time encouraging retention and success among engineering undergraduates.

This paper reports on the assessment efforts linked to three weekend design competitions that were offered to the inVenTs students. Using different topics the competitions have provided students with problem-based learning opportunities and the chance to design solutions through hands-on applications and resources provided to students. Similar assessment tools have been used across the competitions. Student activities and interactions in their teams are observed and their behaviors are recorded using a rubric. In addition, after the event students are given a follow-up survey online that they complete individually that asks them whether participating in these activities have enhanced key innovative skills as proposed by Zheng[19]. In addition, students are asked to report on what they enjoyed about the activity and what they found frustrating through open-ended comments.

III. FINDINGS

A total of 46 students participated in the design competitions and responded to the survey. Students reported their perceptions of the impact they felt the design competition had on their innovative thinking skills. As shown in Table 1 students reported a positive impact in several areas.

TABLE I. STUDENT SELF-PERCEPTIONS OF INNOVATIVE THINKING SKILL DEVELOPMENT AFTER PARTICIPATING IN DESIGN COMPETITION (N=46)

Question	**Student Self-Perceptions**	
	Survey Question	***M***
1	Participating in this activity helped me think about things I already knew in new and different ways.	4.12
2	Participating in this activity allowed me to test out different ideas to see if they would work.	3.96
3	Participating in this activity allowed me to generate new solutions, processes, and ideas.	4.14
4	Participating in this activity helped me make connections between solutions and ideas being generated and how they could be applied to solve other problems.	4.19
5	Participating in this activity allowed me to think about how to commercialize the ideas, processes, or solutions generated.	4.10

In terms of the external observations of the stages of innovation among competition participants, in the first competition two reviewers used a rubric to observe and then score teams on innovative thinking skills demonstrated during the competition. Criteria that captured the different stages of innovation were listed in the rubric and a scoring key was used to rate the level of innovative skill development (Not Observed = 0; Below Average = 1; Average = 2; Above Average=3; Not Applicable = NA). The reviewers met prior to the competition to establish common expectations for what might be observed among students and how they would score the range of different skills they might observe. After rating the students the reviewers again met and discussed how they rated participants and provided justification based on field notes as to why those teams were scored accordingly. Any discrepancies in scoring were resolved through this discussion. This process was used to establish inter-rater reliability. Following is the list of the stages of innovation demonstrated during the competition that participants were assessed on: a) Demonstrates critical thinking and effective generation of new ideas; b) Demonstrates application and integration of science/engineering content knowledge; c) Demonstrates ability to organize new information/ideas/products in an understandable way; d) Demonstrates ability to communicate ideas to peers, faculty, and potential industry representatives in presentation; e) Demonstrates effective use of technology/tool selection in design process; f) Demonstrates complex thinking process that transforms creative ideas into useful services/products; g) Demonstrates potential for prototyping/commercialization

IV. Discussion and Conclusion

In terms of the stages of innovation demonstrated in the first competition among teams, participants demonstrated below average to average innovative thinking. The level of innovative thinking demonstrated would be expected given the participants were made up primarily of first-year engineering students. The related survey responses indicate that students are benefitting developmentally from participating in the design competition activities. The open ended comments collected among students indicated that the competition gave them an opportunity to think about concepts they are learning in their classes in new and different ways.

In order to build off what was learned during the first competition the following activities are being undertaken. Doing so might benefit all of the participants as well as future participants in the design competitions. A seminar will be offered where the more highly ranked teams discuss the approach they used for each stage of innovation (e.g., criteria in the rubric). This could allow participants to learn from one another and gain skills they are lacking. We will conduct interviews with students in order to have them provide more detail about why they responded in certain ways to the items in the self-assessment. Results could be further analyzed to determine what training or activities could precede the design competitions in order to enhance the innovative thinking skill development of students. Our next steps will be to correlate participation in these activities with the retention and continued enrollment of participants and examine whether there is a different between students that participate in these activities and those that do not in their reported innovative thinking skills and progress towards degree attainment.

***Abstract*—"BitLab" is an innovative classroom that integrates scientific history, sensor technology with quick prototyping and public speaking in a team-based interactive learning environment. In order to inspire the students' spirit of innovation, everything in this classroom is built by small "Bit". Electronic sensor-based "BitLab Bricks" enable the students to conceive their own innovative design, which covers daily life applications. A prototype is then built using geometric shapes. In the end, each team writes up a description of their "product" and gives a presentation on its features and functionalities. The interactive learning platform is delivered through team-based "BitLab Curriculum". The status and impact of BitLab in Chinese schools are presented.**

Keywords*—*Classroom teaching; Engineering Education; STEM; Public Speaking; Innovation.

I. INTRODUCTION

In an increasingly globalized and technology-driven world of 21st century [1], students need multi-dimensional abilities in order to solve complex problems, such as the so-called "7Cs" [2], which consists of critical thinking and problem solving; creativity and innovation, collaboration and teamwork; cross-culture understanding; communications and information literacy; computing and ICT (Information & Communication Technology); career and self-learning. To address this challenge, innovative methods of teaching, learning and new-type classrooms are required to make the connection between theories and practical applications.

The traditional examination-based teaching method based on well-defined problems and formal definitions is still widely used at schools in China [3]. In general, such teacher-led approach consists of lecturing, doing exercises, and testing. This approach engages a low level of learning as students gather information from lectures and memorize facts and procedures in order to pass exams. These students often possess ineffective habits and skills, which hinder their future learning and working abilities in real life.

In this paper, we present a new type of classroom, called "BitLab", designed to foster effective problem solving skills under traditional learning environment. This innovative classroom integrates scientific history, sensor technology with quick prototyping and public speaking in a team-based interactive learning environment. In order to inspire the students' spirit of innovation, everything in this classroom is built by small "Bit". Electronic sensor-based "BitLab Bricks" enable the students to conceive their own innovative design, which covers daily life applications. Then, the students conceive a conceptual design to house the electronic components using transparent geometric shapes of different colors. In the end, each team writes up a description of their "product" and gives a presentation on its features and functionalities. The interactive learning platform is delivered through the team-based "BitLab Curriculum".

We will first describe the hardware, sensor bricks and geometric bricks. Then, we'll describe the curriculum. In the end, we see that the curriculum is well-received by the students. More than 100 patents have been filed from ideas created by the students.

II. THE HARDWARE

The materials used in BitLab consist of three parts: (1) Self-assembled sensor-equipped chairs and desks with transparent desk surface for tablet computer use; (2) Sensor-based electronic bricks with real-life applications; (3) Eight transparent geometric shapes of different colors, used to build 3-D prototype of student inventions.

Fig. 1. The BitLab classroom with chairs and desks

A. Self-assembled sensor-equipped chairs and desks with transparent desk surface for tablet computer usage

The desks and chairs in Chinese classrooms are individual-based units. It is not suitable for team-work activities. It is difficult to repair as the entire desk or chair is one piece and cannot be dissembled. We design desks and chairs in BitLab so that they are built using same-sized building blocks. The frames of desks and chairs are made of iron or wood, as shown in Fig. 1. The desk top is made of transparent acrylic material. Students can put textbooks and tablet computers under the transparent surface while doing the experiment on the table. Students can assemble their own tables and chairs for different team-work configurations.

B. Sensor-based electronic bricks with real-life applications

The electronic bricks contain different sensors, such as light sensor, sound sensor, ultrasonic sensor, motion detector, temperature sensor and so on. Some sensor-based electronic modules are shown in Fig. 2.

These electronic bricks can be connected together, using a common interface connection, to build real-life applications, such as a sound-activated light or a smoke detector. In BitLab, just by connecting electronic bricks together with standard wires and connectors, one can easily build a home safety monitoring system controlled by mobile phones. Students are much more motivated since school work is closely coupled with real life.

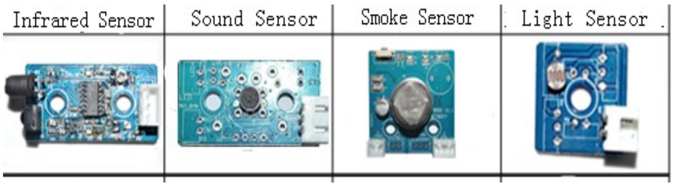

Fig. 2. The sensor-based electronic brick

The real-life applications built in BitLab can be categorized into four areas: energy saving and environmental protection (motion-activated light to save electricity), home security with smart control (smoke alarm and home monitoring system) game and entertainment (iPad or cell phone controlled car), sports and health (pedometer to measure the number of steps taken).

By using BitLab's electronic bricks, the time and effort one needs to build these real-life applications is greatly reduced. With different combinations of these electronic modules, it enables students to quickly build an electronic prototype for various applications. It also enhances the students' interest in the design of electronic systems, and stimulates students' creative thinking and hands-on abilities.

C. Eight transparent geometric shapes of different colors, used to build 3-D models.

In order to allow quick prototype of students' creative design, eight basic geometric shapes are used. The electronic bricks are affixed onto the geometric shapes, which resemble a house, a helicopter or any form from the students' imagination. These eight basic geometric shapes consist of square, triangle, quarter circle, rectangle, circle, small rectangle, small square and angle, as shown in Fig. 3. These bricks are made from colorful acrylic material. Specially designed push-pull rivets and plastic screws and nuts are used to connect acrylic plates into 3-D models.

The 3D body design provides an innovative hands-on design platform that enable students to transform their abstract ideas into a physical prototype without much effort.

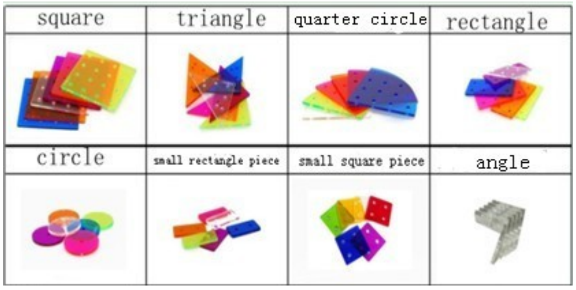

Fig. 3. 3D building blocks of BitLab

III. CURRICULUM

The interactive learning platform is delivered through team-based "BitLab Curriculum", which consists of four components: inventor's story, technology introduction, design and prototype, and product presentation. Each team consists of 3 to 4 students of various abilities and both genders.

A. Learning inventors' story

The purpose of this part is to stimulate students' desire for knowledge and curiosity and to inspire students' spirit to explore and innovate. There are some great inspiring stories such as: How did Edison invent the electric lamp? Who discovered the infrared light? What is the history of the invention of the thermometer?

B. Building electronic sensor-based systems

Students assemble the electronic bricks into a real life application, such as a door bell with a voice recorder or an infrared activated radio receiver or a light-sensor activated LED (Light Emitting Diode) lamp.

C. Building 3-D body

It gives students a good exercise to conceive and implement their design for real-life applications. The students build different kinds of prototype with electronic systems, such as "Penguins radio", "World Expo China Pavilion", "Intelligent Home", "Environmental Protection Car", "Animal House" and even "Space Shuttle". Some creations made by students are shown in Fig.4.

D. Presentation and public speaking

Each team writes up a description of their "product" and gives a presentation on its features and functionalities.

It encourages the students to give a speech to talk about his own design in front of other people, including the naming and creative process, comment on other people's ideas. As the students have made their own product in a team, they feel proud of themselves and speak out more naturally. This greatly increases student's speech confidence and leadership ability.

A student once said: "I'll never forget the first time speaking: shyness, the second time : improving, and the third time : excellent."

Fig. 4. Student's creationresult

In China, there are 30 BitLabs built since 2009, including 13 primary schools, 12 secondary schools, 3 tech museums and 2 public youth centers. A survey is conducted at Nanhu Primary School, where a total of 228 students, including 116 boys and 112 girls, attended fifteen BitLab lessons over one semester. Each lesson is 45 minutes; which sums up to 11.25 hours in one semester.

At the start of the course, each student filled out a self-evaluation score chart for ten abilities. After a semester study each student filled out the score chart again. Each ability is measured on a scale of 1 (poor) to 10 (excellent).

Fig. 5 shows the percentage of improvement of ten abilities. For example, a student has a score "2" of creativity at the beginning, and a score "6" at the end. The percentage of the improvement of creativity can be calculated as (6-2)/10 x 100% = 40%.

Analysis: As seen from the bar graph, for boys, the hands-on ability and creative ability are generally improved; for girls, the innovation ability, leadership ability and hands-on practice ability are generally improved.

We have collected hundreds of creative ideas from the students who had BitLab lessons. The students are encouraged to first find problems in daily life and then try to solve these problems with his/her inventions. Among them, more than one hundred patents have been filed.

IV. CONCLUSION

BitLab is an innovative classroom that integrates scientific history, sensor technology with quick prototyping and public speaking in a team-based interactive learning environment. The interactive learning platform is delivered through the team-based "BitLab Curriculum", which consists of four components: inventor story, technology introduction, design and prototype, and product presentation.

BitLab has made a great impact on education in China, but it still faces the barrier of the traditional examination-based education. Most Chinese parents think that college entrance examination is the only way to success. So it is necessary to set up a new evaluation standard for Chinese students in order to find talented students.

ACKNOWLEDGMENT

We would like to thank Yan Huang, Liang-Fang Chao, Jinping Lu and Scott Carpenter for their valuable support in preparation of this manuscript.

***Abstract*— Design-by-analogy is considered to be a powerful tool for engineering design. The difficulty of finding suitable analogies for solving a given design problem gives rise to the current efforts on computational tools for analogy-based design. In searching for analogies, the critical functions in a design problem are potential search criteria. The study described in this paper investigates whether novice designers identify an expert-derived critical function in a design problem under three scenarios: when they are asked to report the important functions in the problem, when they are directly asked to report the critical function and when they are asked to use design-by-analogy. It is observed that student designers do not identify the expert-derived critical functions when directly asked or when asked to list important functions. However, they inherently use the expert-derived critical functions in their analogical mapping process. This suggests that, during analogical reasoning, designers tend to identify and use the same critical functions regardless of experience, and also that critical functions are valid search criteria for deriving analogies from a computational database. This insight is highly valuable for current efforts to develop computational tools for analogical reasoning.**

Keywords—Analogy; Critical functions; Design by Analogy; Graduate Design Projects

I. INTRODUCTION

Innovation and creativity are highly sought after skills in engineering design. Generating novel design ideas is a very challenging task. Design-by-analogy is an effective tool that can help designers in this process [1-5]. In design-by-analogy, designers derive their inspiration from an analog system that they have or gain familiarity with. These systems may be derived from nature, engineering products, or their own day-to-day experiences. However, finding an analog suitable for a particular design problem is not an easy task, especially when the analog is from a field that the designer is not familiar with [6]. The ongoing efforts to develop computational tools to aid analogical reasoning supplement this process.

In order to develop an efficient computational tool, it is important to understand how designers naturally search for analogs during design. Anecdotal observations suggest that highly innovative products often add or improve the performance of one or more functions in an existing product [7]. Such functions are called "critical functions" further in this paper. The open question asks whether student designers effectively identify these critical functions on their own or whether they need help with that process. If they can identify the critical functions, those functions can lead them to effective analogies and subsequently to innovative design concepts. The study presented here aims to answer this question.

This study aims to investigate the use of critical functions by student designers as compared with an expert designer. Two different hypotheses are investigated here: (1) when instructed to identify critical functions, students will list the same critical functions as an expert designer and (2) during design-by-analogy, students will identify and use the same critical functions as an expert designer. The students in a graduate design class are given specially designed homework assignments to investigate these hypotheses. The details of the homework assignments along with a detailed discussion of the results are available in the further sections of this paper.

II. BACKGROUND

Design-by-analogy is an effective technique for design innovation. Naturalistic studies of design-by-analogy along with anecdotal evidence demonstrate that analogy is a common and effective strategy for design innovation [1-5]. Controlled experiments further demonstrate the power of analogy as a design tool [8, 9]. Designers often borrow ideas from the systems they are familiar with, without realizing that they are using analogical reasoning. Further, studies show that both expert and novice designers use analogies frequently in their designs [1, 10-12].

Analogies do have an undesirable potential to cause "design fixation" [13-17]. When designers fixate on an initial idea or an example, they think of similar ideas and most of the ideas generated are the variations of their initial ideas or the analogy. However, distant domain analogies carry little risk of design fixation and have shown potential to overcome fixation [15, 18]. Retrieving distant domain analogies is a challenging task and most of the existing efforts to develop computational tools for analogical design aim to supplement this task [19-23].

Most of the computational tools for analogy retrieval rely upon databases of analog systems [19, 24-26]. The analogs relevant to a given design problem are retrieved from such databases using various search criteria including functions, behaviors, and other keywords. However, it can be suspected

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

that when designers naturally derive analogies in their design process, they use a few functions that are critical to the design problem. Hence it can be argued that these critical functions can be particularly effective search criteria for analogy retrieval from computational databases. For the purpose of this study, a critical function is defined as follows:

"A critical function represents significant design decisions within a functional model that significantly influence the performance of a design".

The purpose of the study presented in this paper is to understand if student designers use critical functions in their idea generation process, specifically in design-by analogy. It also investigates if novice designers can identify the critical functions of a design problem when they are instructed to do so. The following hypotheses are investigated further in this paper:

Identification Hypothesis: When instructed to identify critical functions in a design problem, novice designers will list the same critical functions as an expert designer.

Mapping Hypothesis: When searching for analogies, novice designers will identify and use the same critical functions as an expert designer.

III. Method

A classroom study was conducted to investigate the similarity between the search criteria followed by novice designers and an expert in analogy mapping. Three different scenarios were investigated in this study: identification of the most important functions, identification of critical functions, and analogy mapping. According to the hypothesis presented above, the students were expected to identify critical functions in these scenarios. In the first scenario, the students were asked to list the most important functions in the design problem to obtain the unbiased opinions of students about the functions they perceive to be important. In the second scenario, a definition of critical functions is included to see if that affects their opinions. The third scenario investigated how students identified and used critical functions for an analogy search.

A. Data Collection

The data for this study were collected from a graduate design course offered in the Mechanical Engineering Department at Texas A&M University. In this one semester course, graduate design teams were trained in the engineering design process outlined by Otto and Wood [27]. Throughout the course, the students were guided through community service-based and industry-sponsored projects. The teams were expected to cover all the stages of the engineering design process beginning with the customer needs identification and ending with the testing of proof-of-concept models. Teams consisted of three or four students, and project topics ranged from industry-sponsored issues to challenges related to developing countries. As the students were involved in realistic design situations, this course presented an ideal opportunity to collect data related to real-life designs by novice designers.

In order to collect data relevant to the current study, specially-designed assignments were employed. A set of three homework assignments were developed and assigned to the class by the instructor. The students were given one week to complete them. Figure 1 shows the timeline of data collection. The students were informed that their assignments would be used for research purposes, but the actual research aim was not mentioned to them. A total of 21 students volunteered to participate in this study and their assignments and team reports were analyzed for the purpose of this study. The participants received extra credit in their class for their participation. Some additional data were collected from the final reports submitted by the design teams.

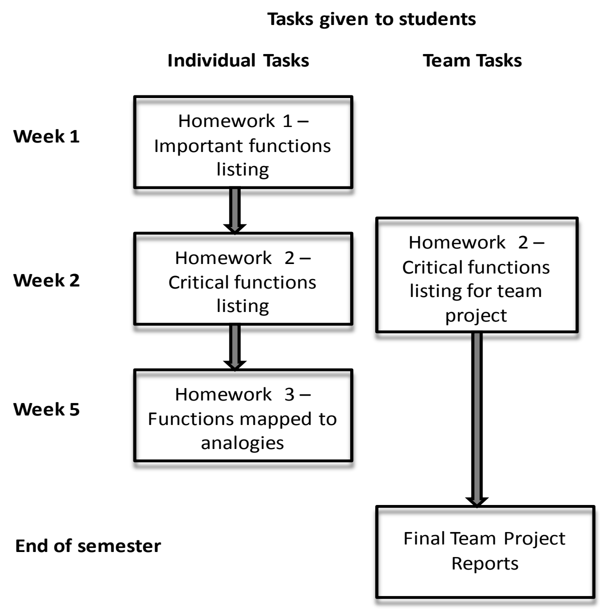

FIGURE 1. TIMELINE OF DATA COLLECTION

B. Design Problem

For this study, a specifically developed "can opener" design problem was used. The problem instructed students to design a simple and portable device to open cans for the aging population. The customer requirements given to the students included quickness in opening cans, use of minimum human force, non-electric operation and avoidance of any sharp edges after removing the lid. The problem of opening a can was familiar to most of the students; hence this design problem was appropriate for the study presented here. The functional model for this problem was neither too simple nor too complicated (Figure 2), again making it ideal for the study.

C. Details of Homework Assignments

The first assignment instructed the students to develop a function structure for the can opener design problem and list the most important functions in their function structure. This assignment was assigned a week after teaching them about the functional modeling. The students were expected to use the functional basis [28], so that their functional models were standardized. They were given a template that required them to list the important functions they perceive and the rationale for their choices. The template had five rows, so that they could list up to five important functions, but were not expected to fill all the rows. However, on the first trial of this assignment, it was observed that students tended to fill all the rows. This could lead to the listing of the functions that the students did not perceive as important. In order to avoid this problem, this homework was reassigned (homework 1-redo) to the class a week later, with specific instructions clarifying that they were not expected to fill all the available rows. This was also explained to them by the instructor while reassigning the homework. The students were also told that there was no single "correct" answer to this assignment and they were instructed to use their own judgment to fill in the table.

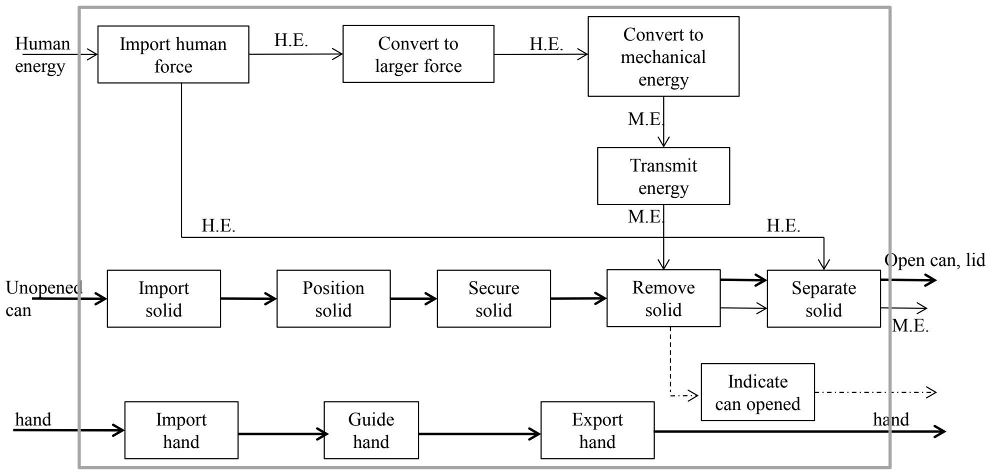

FIGURE 2. FUNCTIONAL MODEL DEVELOPED BY THE EXPERT FOR THE CAN OPENER DESIGN PROBLEM

The second assignment instructed the students to identify the critical functions from the function structure and list them. It defined a critical function as follows: "A critical function is one that represents critical design decisions within a functional model that significantly influences the performance of a design". A functional model developed by the authors for the can opener problem was provided to the students in this assignment. The students were given a template to record the critical functions they identified and the rationale for their choices. As with homework 1, they were told that it was not necessary to fill all the rows in the table. Again, they were told that there was no single "correct" answer and to use their own judgment. In addition to identifying the critical functions in the can opener design problem, the students were instructed to identify the critical functions in their team design project too. Each design team was expected to submit one assignment for their team project.

The third assignment instructed the students to identify analogies that could help to solve the can opener problem. It was given to them after they were taught design-by-analogy and the word tree method for analogy mapping. In this assignment, they were instructed to report the analogies they identified along with the functions they mapped between the analog and the design problem (TABLE I.). The template shown in table was provided to them for reporting these. The research aim of this assignment was to understand whether they identified the same critical functions during analogical reasoning as an expert would for the same design problem.

In all the assignments, the students were given specific instructions to list functions based on the functional basis [28] in order to get a standardized set of functions for analysis. However, a few students listed customer needs instead of functions in their first assignment. The instructor clarified the differences between a function and a customer need to them and instructed them to resubmit the assignment. Even in the re-submissions, two students listed customer needs. They repeated the same mistake for their remaining two assignments as well. Hence their data were removed from the analysis, bringing the sample size to 19 students.

TABLE I. TEMPLATE GIVEN TO STUDENTS IN HOMEWORK-3 TO REPORT THE ANALOGIES IDENTIFIED AND THE FUNCTIONS MAPPED

Analogy identified	Function(s) mapped to the can opener

Additionally, we sought to observe how students identified and used critical functions for analogy search in their team project. These data were collected from their final reports. In the reports, the teams were expected to describe identified analogies and concepts generated from analogies. These data were collected from the reports by one of the authors. However, some of the final reports were missing data, as the teams failed to follow reporting instructions. The available data were collected and analyzed for this study.

D. Data Analysis

All the homework data were analyzed to find the occurrences of critical functions in the can opener design problem. Prior to the study, one author developed a function structure for the can opener and identified the critical functions. The author denoted "Separate solid" as the critical function in this design problem. This function was designated as the "expert-derived" critical function, and all students' responses were compared against this function in our analysis.

The functions listed by students in each assignment were tabulated and the frequency of occurrence of each function from the functional basis [28, 29] was studied. If most students identified a particular function as critical in each assignment, the frequency of the function should be significantly greater than the other functions.

In order to study the identification of critical functions by teams in their design projects, the team assignments listing the critical functions in their design problems were also analyzed. Additionally, we also analyzed the data from team final reports on the functions they mapped to analogies. Since each team worked on a different design problem, these data were directly tabulated and appear in the next section.

IV. Results & Discussion

To understand students' use of critical functions and evaluate our hypotheses, the frequency of identified critical functions in the can opener problem was studied for each scenario. The following subsections outline the results obtained.

A. Homework 1 – Listing Most Important Functions

We observe that students list a variety of functions as important functions in their functional model for homework 1. Figure 3 shows frequencies of students' listed functions. As evident from the figure, students list "Convert energy" most often as an important function in the design problem. "Separate solid/material" only appears 6 times among 19 students, showing that most novice designers do not identify the expert-derived critical function when reporting the most important functions.

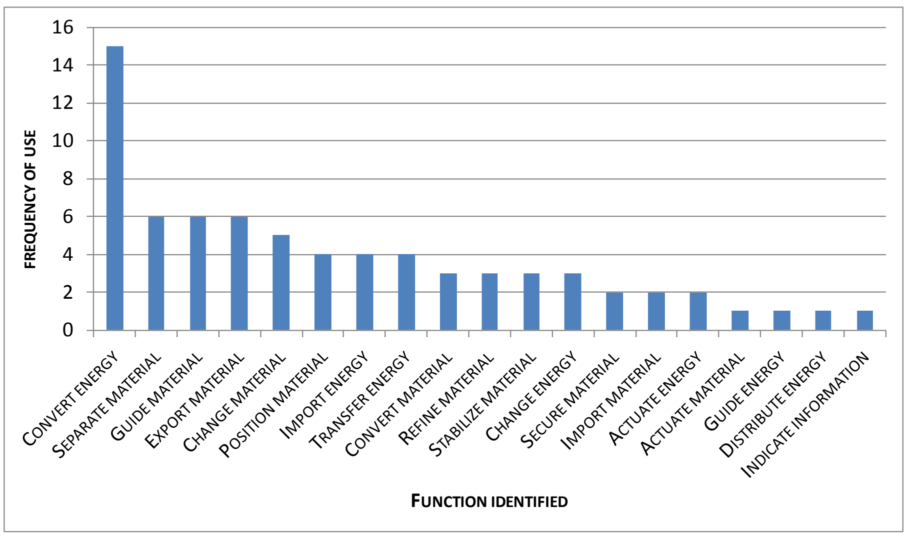

Figure 3. Frequencies of functions in homework-1 (listing of most important functions)

B. Homework 2 – Listing Critical Functions

According to the Identification Hypothesis, after students are instructed to identify critical functions, they will identify the same critical functions as an expert would. In homework 2, the students are given the definition of a critical function and instructed to list critical functions from the provided functional model of the can opener. However, despite receiving instruction on critical functions, most students again do not identify the expert-derived critical function. Figure 4 shows the frequency of functions that the students listed as critical functions. As with homework 1, most students considered "Convert energy" as a critical function. 8 of 19 students identified "Separate material" as a critical function, but 11 did not do so. Students do not identify the expert-derived critical function when specifically instructed to do so, which contradicts the Identification Hypothesis.

C. Homework 3 – Analogy Mapping

The functions mapped by the students during analogical reasoning in homework 3 reveals a very interesting trend. Figure 5 shows the frequency of various functions used in analogy mapping. As evident from the figure, in most of the cases, students list "Separate material" as a primary search criterion in analogical reasoning. They also use other functions for analogical reasoning, but the expert-derived critical function of the design problem appears most frequently in this scenario. This is consistent with the Mapping Hypothesis.

TABLE II shows the number of students that identified each function as critical in each scenario (assignments 2 and 3). It appears that more students identify the expert-derived critical function of the design problem when doing analogy mapping than when directly identifying critical functions. A Chi-square test of independence [30] is used to confirm this difference statistically. The results indicate a significant difference ($\chi^2 = 8.88$, $p < 0.01$). In other words, even though the students do not list the expert-derived critical function when asked to list critical functions, they do identify critical functions during analogy mapping.

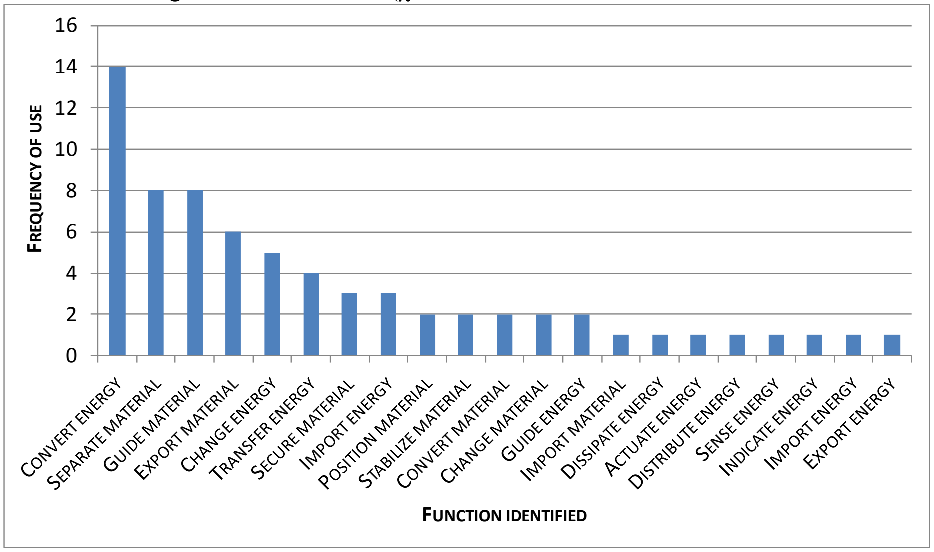

FIGURE 4. FREQUENCIES OF FUNCTIONS IN HOMEWORK-2 (LISTING OF CRITICAL FUNCTIONS)

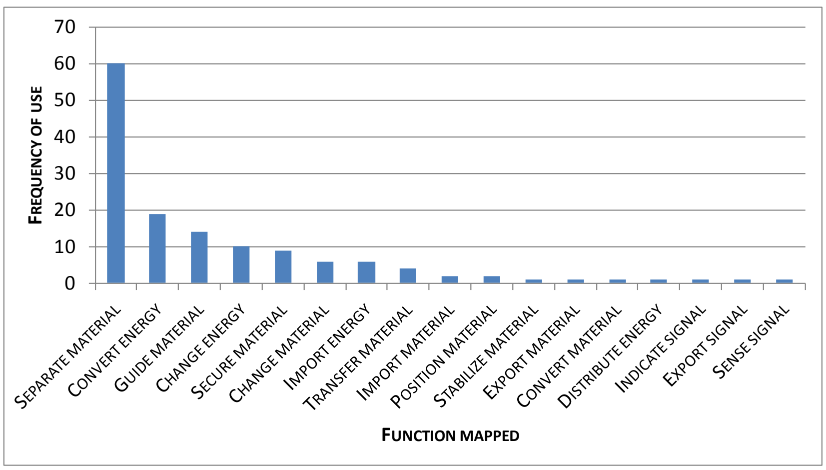

FIGURE 5. FREQUENCIES OF FUNCTIONS IN HOMEWORK-3 (ANALOGY MAPPING)

D. Identification of Critical Functions in Team Projects

The ability of student teams to identify critical functions in their design problems is studied using data from team assignments and final reports. These appear in TABLE III. Though some data are missing, the table shows that in most cases, the teams identify the expert-derived critical function during analogy mapping but do not do so in their critical function listings. These results are similar to those from the can opener problem.

The low occurrence of students identifying the expert-derived critical function of the design problem may stem partially from the instructions they received. The definition of critical functions given to the students is very simple; however, it may not have conveyed the correct idea to the students. Due to the time constraints of the course, re-running the assignment with a different definition of critical functions was impossible and will be completed in future work.

In addition, there may be alternative explanations for why novices do not identify the expert-derived critical function. For example, perhaps "Separate solid" is more amenable to the analogy mapping exercise, or perhaps students took a differing perspective that led most them to believe "Convert energy" was more critical toward performance, in contrast with the expert opinion, even when looking at the same functional model.

TABLE II. NUMBER OF STUDENTS WHO IDENTIFIED THE EXPERT-DERIVED CRITICAL FUNCTION IN EACH SCENARIO

Scenario	Identified Expert-Derived Critical Function?	
	Yes	No
Asked to list critical functions	8	11
Asked to use analogy mapping*	16	2

* One student did not submit the analogy mapping homework

TABLE III. IDENTIFICATION OF CRITICAL FUNCTIONS BY THE DESIGN TEAMS FOR THEIR DESIGN PROJECTS

Team	Did the team identify/use expert-derived critical function?[1]		
	Listing critical functions	Searching analogies	Idea generation with analogies
1	No	Yes	Yes
2	No	Yes	Yes
3		Yes	
4	Yes[2]	Yes	
5			
6	No	Yes	Yes
7	No	Yes	Yes

1. Empty cells show that the corresponding data are missing
2. Identified one out of two critical functions

The most interesting result from this study is the identification of critical functions by novice designers during analogical reasoning. In most cases, experienced designers use critical functions in analogy mapping, which often leads them to innovative designs [7]. One of the open questions is whether novice designers need help in identifying the same critical functions for analogical reasoning, so that they can identify the most effective analogies for improving design performance. The results from this study show that they identify the same critical functions as an experienced designer without much trouble during their analogy mapping process. This is a very valuable insight for ongoing efforts to develop automated tools for analogical reasoning too. Currently, the authors are developing a tool for analogy retrieval based on critical functions in design problems [31]. This tool assumes that designers can agree on what functions are critical in a design problem, regardless of their experience. This study validates this assumption and suggests that the use of critical functions may be a very effective approach for the analogy retrieval tool.

According to the observations made on the data collected from the design teams' final reports, student teams often face problems with analogy searching. They try to map surface features in many occasions or search for functions that are not critical to the given design problem. Still, most teams use analogies mapped by critical functions for their further idea generation. Since analogies identified using critical functions are more potentially useful, we need to devise more methods or techniques that can help students identify critical functions and map them to find effective analogies. This will be done in our future work.

V. CONCLUSIONS

Anecdotal observations suggest that highly innovative products often add or improve the performance of one or more functions present in an existing product [7]. We refer to these as "critical functions". Prior data indicate that the potential for product innovation is likely to be improved by focusing on critical functions. The purpose of the study is to investigate the identification and use of critical functions by graduate students while solving a realistic design problem. This study uses the problem of creating a can opener for the elderly. Prior to the study, one function of the can opener is determined to be critical by an author and denoted as the expert-derived critical function. In the study, students are first asked to create a functional model of the can opener and then to identify the most important functions. Later, they receive a definition of a critical function along with a functional model of the can opener and asked to identify the critical functions. Lastly, they are asked to identify analogies that are useful toward solving the can opener problem, along with the functions that they use for analogy mapping. Additionally, they are instructed to list the critical functions in their team projects, and these are also studied through their reports. The results show that while graduate student designers are very effective at finding innovative solutions, they do not identify the expert-derived critical function early in the design process. However, at a later stage, most of them use the expert-derived critical functions during analogical mapping, leading them to useful analogies and highly innovative solutions. These results support efforts to develop computational analogy retrieval tools that use critical functions as primary search criteria.

ACKNOWLEDGMENTS

Partial support for this work was provided by the National Science Foundation Award No. CMMI-1234859 and CMMI-1304383. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation. Partial data used for this study was analyzed independently and differently for another study [31]. In [31], the functional models developed by the participants are analyzed to understand the frequency of various functions.

***Abstract*—Promoting computational thinking is one of the top priorities in CS education as well as in other STEM and non-STEM disciplines. Our innovative NSF-funded IC2Think project blends computational thinking with creative thinking so that students leverage their creative thinking skills to "unlock" their understanding of computational thinking. In Fall 2012, we deployed creative exercises designed to engage Epstein's creative competencies (Surrounding, Capturing, Challenging and Broadening) in introductory level CS courses targeting four different groups (CS, engineering, combined CS/physical sciences, and humanities majors). Students combined hands-on problem solving with guided analysis and reflection to connect their creative activities to CS topics such as conditionals and arrays and to real-world CS applications. Evaluation results (approximately 150 students) found that creative thinking exercise completion had a linear "dosage" effect. As students completed more exercises [0/1 - 4], they increased their long-term retention [a computational thinking test], $F(3, 98) = 4.76$, $p = .004$, partial $Eta^2 = .127$ and course grades, $F(3, 109) = 4.32$, $p = .006$, partial $Eta^2 = .106$. These findings support our belief that the addition of creative thinking exercises to CSCE courses improves the learning of computational knowledge and skills.**

Keywords—CS1, Creative Thinking, Computational Thinking, College, Computer Science

I. Introduction

Computational thinking is an approach to solving problems, building systems, and understanding human behavior that draws on the power and limits of computing [1]. Computational thinking includes skills such as conceptualizing at multiple levels of abstraction, defining and clarifying a problem by breaking it down into relational components, and testing and retesting plausible solutions. Already considered to be one of the top priorities in computer science (CS) education, computational thinking is becoming more important in both STEM and non-STEM disciplines given the reliance of these disciplines on computational techniques for data collection, archiving, processing, and analysis. In this way, computational thinking has become an *enabler* that promotes problem solving in a wide range of disciplines and a *bridge* that allows for interdisciplinary innovation and discovery. It has even been argued that computational thinking is as fundamental as skills such as reading, writing and arithmetic [2].

The increased demand for computational thinking has led to numerous articles in educational research venues such as the proceedings of FIE and the communications of the ACM. These articles demonstrate the increasing momentum of research addressing the need for effective education in computational thinking, both for CS and across the broader spectrum of STEM and non-STEM disciplines. This research is diverse, ranging from course specifications to course development, from community building to setting policies, and from teaching and learning to assessment [2][3][4][5][6][7].

However, there is a potentially serious problem for expanding computational thinking from CS into STEM and non-STEM disciplines. The students in non-CS disciplines come from diverse backgrounds and many are likely to ***have limited understanding of computing concepts*** that are used as the basis for computational thinking. Without a basic level of understanding, these students will have a very difficult time developing computational thinking fluency. As noted by Epstein et al. [8] and Shell et al. [9], one cannot think beyond the boundaries of one's cognitive tools or knowledge. Students who are forced to use computational thinking based on concepts that they do not understand may become frustrated, potentially lowering both their motivation and their self-efficacy. As both student motivation and self-efficacy are strongly connected to student learning [10][11], if learning computational thinking leads to lowered student motivation and self-efficacy, then ***it could actually be detrimental—reducing learning for students in STEM and non-STEM disciplines alike—instead of being beneficial***.

Our innovative solution is to improve the learning of computational thinking by blending it with creative thinking. Creative thinking is thinking patterned in a way that tends to lead to creative results [12]. Creative thinking is not limited to the arts but is an integral component of human intelligence that can be practiced, encouraged and developed within any context [13][14][15]. Epstein's Generativity Theory breaks creative thinking down to four core competencies: *capturing* novelty, *challenging* established thinking and behavior patterns, *broadening* one's knowledge beyond one's discipline, and *surrounding* oneself with new social and environmental stimuli [8]. By blending computational and creative thinking students can leverage their creative thinking skills to "unlock" their understanding of computational thinking [9]. As an example, rather than trying to directly explain multiple levels of abstraction in computer programming, we ask students to think about why a corporation is organized using layers. Students are likely to reach the conclusion that having executives who are experts on a single layer is the most efficient and effective way to identify and solve problems. Thus, by using creative thinking skills students have unlocked why programs use multiple layers of abstraction. In this way, we make computational thinking more generally applicable to STEM and non-STEM disciplines where students may have creative thinking skills but lack understanding of computing concepts. The reverse is also true: students who understand computational thinking could leverage it to improve their creative thinking skills.

We have designed four creative thinking exercises that blend computational and creative thinking. These exercises are designed to provide instruction on CS concepts such as conditionals, arrays, modular programming, and debugging. However, these exercises completely lack any programming code. Instead, these exercises involve tasks seemingly unrelated to CS such as individually writing the chapters for a story based on separate plot points and then working in a group to revise the story to make the content more cohesive. These exercises are designed to foster development of Epstein's creative competencies by engaging multiple senses, requiring imaginative thought, presenting challenging problems and combining both individual and group efforts. During these exercises, students are given explanations, which we call CS Light Bulbs, which relate the tasks directly to the CS topics. Finally, the students answer analysis and reflection questions designed to further promote both computational thinking and creative application of computational skills.

We deployed these creative thinking exercises during the Fall 2012 semester at the University of Nebraska, Lincoln. Over 200 students in four different introductory CS courses took the exercises and the exercises counted as part of their final course grades. Each course was tailored to a different target group (CS majors, engineering majors, combined CS/physical sciences majors, and humanities majors) and so these courses contained a mix of students with both computational and creative thinking skills. Our evaluation results found that after completing the exercises creative competency was significantly correlated with computational thinking as measured by a computational thinking test. Further, completion of the exercises improved both long-term retention of course content and course grades—even when student motivation was factored in. Overall, these results support the effectiveness of blending computational and creative thinking.

II. Creative Thinking Exercise Design

All our exercises combine hands-on problem solving with written analysis and reflection and are designed to be completed by a group of students working collaboratively in order to facilitate creative thinking from students with multiple backgrounds. Each exercise requires approximately 1-2 hours per student but students are given two weeks to work on the exercises because of the collaboration required. The exercises have four common components (Objectives, Tasks, CS Light Bulbs, and Questions) described in more detail below. Exercises are designed so that the students have hands-on and group tasks first, in Week 1, and then reflect on their Week 1 activities in Week 2 by answering questions. Both Week 1 and Week 2 are graded.

Objectives. The Objectives component, at the beginning of the exercise handout, lists the computational and creative thinking objectives for the exercise. These objectives help the student understand why they are doing these exercises by showing how an exercise lacking any programming code is related to CS concepts and how students can use relevant creative thinking skills (described in terms of Epstein's core competencies of Surrounding, Capturing, Challenging and Broadening) to solve the exercises.

Tasks. The majority of the content of an exercise handout is the Tasks component which lists all the tasks the group of students must complete during the two weeks of the exercise. These tasks require students to work collaboratively (and may require individual contributions as well). Tasks are designed to engage group members with different backgrounds, to encourage creative approaches and to promote open-ended discussions as the group produces concrete, specific artifacts.

CS Light Bulbs. The CS Light Bulbs are self-contained explanations which make explicit the connections between the exercise tasks and a set of CS topics. By being embedded in the exercise handout within the Tasks, the Light Bulbs help students stay aware of the underlying computational thinking skills while they are performing the creative thinking tasks.

Questions. The Questions component, at the end of the exercise handout, uses open-ended questions that require collaboration among students as they engage in both analysis and reflection. To answer these questions, students must apply *creative thinking* to CS problems and revise the results of their original tasks using *computational thinking*. Questions thus build upon the CS Light Bulbs and reinforce the connections between the creative thinking fostered by the tasks and the computational thinking in the CS topics.

III. Individual Exercises

Here we describe each of the creative thinking exercises in more detail. We developed four different exercises for the Fall 2012 deployment: (1) Everyday Object, (2) Storytelling, (3) Cipher, and (4) Exploring. These exercises, each of which has the set of components described above, are summarized below, but due to space considerations we provide just one example for each exercise of the multiple CS Light Bulbs. Furthermore, we highlight Everyday Object and Storytelling exercises and only summarize the other two.

A. Everyday Object Exercise

Objectives. ***Computational***: (1) Learning about the description and design process for modular programming by describing an everyday object in detail including why the object is needed and how the object functions; (2) Learning about abstraction and function characterization by identifying properties of an everyday object

Creative: (1) Surrounding: looking at an everyday object in new ways, using all of your senses to understand how it's made and how it functions; (2) Capturing: using written language to describe all the different details and characteristics of this everyday object so you can work with it in new ways; (3) Challenging: describing the operations of an everyday object with words and also as a computer program; (4) Broadening: imagining that this everyday object doesn't exist and acting like its inventor who is trying to fulfill a need by creating something new and useful

Tasks. For the next two weeks, you will be using language to try to clearly and thoroughly describe the functions of an ordinary object that you might use every day. You will be acting like the inventor of that object, imagining that it does not yet exist and trying to describe what need would be fulfilled by your (new) object and how (specifically) it will function.

Your group will choose a common, everyday object from the list. Your challenge is to imagine that this object does not exist and to describe in written language (1) the mechanical function of your object, (2) what need is fulfilled by this object, and (3) the physical attributes and characteristics of your object.

You must describe the object's function, the need it will fulfill and its attributes in clear, non-technical language which any user could understand. Your description must be specific enough so that someone who had never seen the object could recognize it and understand how it works and understand what benefits it provides.

Note: Students were given a list of objects (zipper, mechanical pencil, binder clip, Ziploc bag, scissors, tape measure, stapler, nail clippers, umbrella, flashlight, can opener, clothespin, sticky notes, toilet paper holder, revolving door) from which to choose.

CS Light Bulbs. This description process is very important for developing algorithms in computer science. An algorithm consists of the series of steps necessary to solve a given problem. By using algorithms, we can solve problems without having to constantly "reinvent the wheel" and spend the time, money, etc. to figure out each step ourselves. However, if one or more of these steps are unclear, we can have difficulty following the algorithm which can lead to serious repercussions as described in the following two examples. First, if the formulation algorithm used to mix the concrete for a road or bridge is unclear, workers may make a mistake during pouring leading to reduced service life. Second, if the business plan algorithm for a new company is confusing, venture capitalists may be reluctant to invest leading to failure of the business. To avoid these repercussions, the developer should make every effort to make the algorithm's description as clear as possible for all steps. In other words, characterization of processes is key; it allows us to abstract a process and then convert it into a formal problem or solution. *Note: The handout also includes three other Light Bulbs on writing functions in CS, the diagramming process, and abstraction in programming languages.*

Questions. ***Analysis***: (1) Consider your object as a computer program. Draw a diagram that shows all its functions as boxes (name them), and for each function, its inputs and outputs. Are there shared inputs and outputs among the functions? (2) Consider the list of physical attributes and characteristics. Organize these such that each is declared as a variable with its proper type. Can some of these attributes/characteristics be arranged into a hierarchy of related attributes/characteristics?

Reflection: (1) Consider your response to Analysis 1, are there functions that can be combined so that the object can be represented with a more concise program? Are there new functions that should be introduced to better describe your object such that the functions are more modular? (2) Have you heard of abstraction? How does abstraction in computer science relate to the process of identifying the functions and characteristics as you have done in this exercise?

B. Storytelling Exercise

Objectives. ***Computational***: (1) Learning about how large programs are developed using modular programming by separately writing chapters for a story which are connected with fixed story points at the beginning and end of each chapter; (2) Learning about the need for the debugging and testing process by revising the chapters to make the flow of the story more logical and cohesive; (3) Learning about the need for a methodical and logical debugging process to make sure that a program's observed output matches the expected output; (4) Learning about identifying logical inconsistencies in a product or solution and using methodical approaches to resolve them

Creative: (1) Surrounding: using your senses of sight, sound, smell, touch and your imagination to connect two seemingly unrelated things (two story points) in a logical and coherent way; (2) Capturing: learning to take novel and spontaneous outputs (your two story points) and use language to fill in the blanks by writing your way from one point to another; (3) Challenging: applying computational debugging to a story by taking independently generated chapters and editing them so they form a consistent narrative; (4) Broadening: increasing your ability to problem-solve and to collaborate by taking the inputs of others (your group's individual chapters) and making them into an effective and functional whole—a logical and cohesive story.

Note: The following is an example of the story points to be developed as chapters: (1) "OPEN UP! THIS IS THE POLICE!", (2) Panting, Kevin ran down the unfamiliar alley, hoping there would be an exit ahead, (3) The pendant wasn't particularly remarkable, but something drew his eye to it…something he couldn't quite put into words, and (4) "It doesn't respond like that for everybody," the green-eyed girl said. "You're the first person it has activated for in over 25 years."

Tasks. For the next two weeks, your group will be telling a story with several short chapters. However, you won't write the story as a linear line from A to B. Rather, you will be given a series of story points. These story points will be the pivotal moments in the story. They will act as inputs and outputs to your individual chapters. Each person in your group will write a chapter of the story that falls between two story points. You will all write your chapters independently of each other. All you know is how the story (and each chapter) starts and how it ends up; the input and the output.

During Week 1, group members will separately write the chapters. You will not consult with your group members and you are not allowed to share your chapter with your group members. You will shape your chapter solely on the story points.

During Week 2, review the chapters which have been written by your group members. Most likely not all of your chapters will make sense in the context of each other (this is normal and expected). After you review all of your group's chapters, you need to reconcile the differences. Pick one chapter as the anchor and make minimal changes to it. Then revise the other chapters so that they logically fit with this anchor chapter.

CS Light Bulbs. Writing a chapter based on story points is similar to how we write functions in computer science. To make the design of large programs feasible, the inputs and outputs for a function are generally known before that function is written. In a sense, the way the code for the function is written is less important than whether it produces the correct output value for a given input value. Of course, the function must mesh seamlessly with all the other functions in the program. Additionally, the function must work for all possible input values not just one or two. For example, a function which controls airbag deployment must work for all manner of collisions not just one at 30 mph. Meanwhile, a program solution is often made up of a sequence of functions, where the output of the first function is fed into the second function as input, and the second function's output is fed into the third function, and so forth.

Note: The handout also includes two other Light Bulbs on the debugging and testing process and finding logical errors in programs.

Questions. ***Analysis***: (1) What was the most difficult part of "debugging" your story? Did entire chapters need to be rewritten? Or could you manage to reconcile between each chapter with each other by making only minor changes? (2) What would you have changed about your initial story telling process to make the debugging process easier? Would you have made your story more straight forward and logical, or more ridiculous and expansive? Essentially, how would you go about writing the story so that it includes the fewest number of "bugs"?

Reflection: (1) Compare this process to working in a large team on a software project. In what ways are the two processes similar? In what ways are they different? (2) How would you change the rules of the assignment to guarantee that a minimal number of "bugs" are created? Assume that all chapters must still be written simultaneously.

C. Cipher Exercise

For the Cipher exercise, student teams are required to come up with three ciphering rules to "code" several questions during Week 1. In Week 2, all teams will try to decipher these coded questions by answering the questions in the same code. Computational objectives include (1) Learning about the code generation process for ciphers and encryption programs by creating rules and a one-to-one mapping to encode messages and (2) Learning about the trial-and-error code breaking process by trying to guess the mapping to read coded messages; while creative objectives include (1) Capturing: creating new outputs and using new ways to represent and save data by inventing, testing and documenting a simple system of rules to transform English sentences into a cipher so that their meaning is obscured; and (2) Broadening: acquiring new information and skills by understanding how just three simple rules can generate complex products (ciphers) and how your everyday experience with the English language or with the world can inform your code-generating and code-cracking efforts

In the Questions component, the analysis questions include: (1) Analyze the questions asked by other teams. Were they too easy to answer? Were the questions faulty? (2) How easy would it be to implement your cipher in a computer program? What would your concerns be with implementing your cipher? Reflection questions include: (1) How strong are your rules? Are they clear, or is there some level of ambiguity? Could anybody follow them and understand them? How could you improve your rules? (2) Reflect on your "code cracking" approach. What kind of weaknesses and strengths did it have? Imagine you had to decode over 9000 characters rather than just the 26 in the English alphabet. Could you scale your approach? Would brute force work (i.e. simply try to determine a mapping of characters to their cipher)?

D. Exploring

In this exercise, each group is required to pick a location on campus from one of ten locations on a campus map. Each member of the group must make several observations at the group's location, as well as taking a photo of him- or herself making observations at this location. They are also required to use a data collection form to record their results and to verify that they have gathered sufficient data.

Computational Objectives include: (1) Learning about the data collection process used in many fields by making observations about a specific location on campus; (2) Learning why the ability to brainstorm and visualize the "big picture" is important for writing programs; (3) Learning why the data collection process is important for evaluating existing products and programs; and (4) Learning about capturing and representing different aspects and patterns of an environment for solving a problem

Creative Objectives include: (1) Surrounding: looking at a familiar location on campus in a new way and using all of your senses (sight, sound, smell, touch and thought) to become more aware of what is around you; (2) Capturing: Making a written inventory of everything you observe at a site—plants, animals, people, sounds, and smells—and also documenting your observing by taking a photo of yourself at the site; (3) Broadening: Increasing your ability to solve problems by looking at tables of data in new ways. What did you expect to observe at the site? What did you actually observe? What does the data document about the site and your experience at the site? What does it leave out?

In the Questions component, the analysis questions include: (1) What would be the benefits and drawbacks of using arrays, cell arrays, or structures to store the data you have collected? (2) After completing the previous analysis, you must now analyze the applications of the data you collected. To do this, each team member must brainstorm at least three different real world applications of the data—"Be bold, think big, do not constrain yourself to feasibility or practicality!" Reflection questions include: (1) What other data (that you might ordinarily ignore) could be collected that could be manipulated programmatically and exposed to solve some problem? (Think along the lines of Google scanning and analyzing millions of books to observe long term cultural and language changes.); (2) Speculate on how you might broaden the classes of data, and on how you might capture overlooked data.

IV. Exercise Deployment

The exercises were deployed using the Written Agora system [16]. This is a wiki system designed to facilitate online collaboration between groups of students. The wiki system includes a content page where students can work together on completing the tasks and an online forum where students can discuss, with group members, the responses to the analysis and reflection questions. As the wiki was always online, students could log in and work on the exercises whenever it was convenient. The wiki also kept track of all the revisions so that we could determine which students were contributing to the group.

The exercises represented 3-5% of the final grades depending on the course. After completing the tasks and answering the questions, students in each group were assigned individual grades based on their contributions to the group's wiki page.

V. Evaluation Methods

Students voluntarily participated in evaluation data collection which was approved by the UNL Institutional Review Board. The courses had 241 students initially enrolled and 196 students who completed the courses. Of those who completed the courses, 150 students (133 male; 17 female) consented to participation in the evaluation and 129 students (114 male; 15 female) consented to the use of their course grades and university grade point average. Not all students completed all measures. Sample for specific analyses are shown in Table 1.

Course grades were used to determine impact on student achievement in the course. Retention of core computational thinking knowledge and skills was assessed by a test developed by CSCE faculty [17]. The computational thinking knowledge test contained 13 conceptual and problem-solving questions for the core computational thinking content common to all CS-1 classes. The coefficient alpha reliability estimate was .76. The computational thinking test was administered on a Web platform (Survey Monkey) during the last week of classes as part of evaluation data collection. Students reactions to the exercises were obtained in two ways: (1) after each exercise, 3-6 volunteer students participated in a focus group; (2) using instruments adapted from Shell, Snow, and Claes [18] students were asked to rate exercises and provide open-ended comments in surveys done as part of evaluation data collection. Students' overall GPAs were obtained from university records and were used as a covariate for analysis.

VI. Results

A. Impacts on Student Learning

We used Analysis of Covariance (ANCOVA) to test whether the number of exercises completed (0-1, 2, 3, 4) was associated with higher course grades and computational thinking test scores. We included students' cumulative Grade Point Average (GPA) adjusted to remove the grade for the course as a covariate to control for differences that might be attributable to students' general level of academic ability.

Cumulative GPA was a significant covariate with course grades ($F(1, 109) = 56.26$, $p <.0001$, partial $\text{Eta}^2 = .340$) confirming that students' achievement in the class generally reflected their overall achievement record. With GPA controlled, the number of exercises completed was significantly associated with course grade (Table I: $F(3, 109) = 4.32$, $p =.006$, partial $\text{Eta}^2 = .106$). There was a significant linear trend (p=.0001) from 2 to 4 exercises completed.

TABLE I. Mean Scores By Exercise Completion

	Computational Thinking Test			***Course Grade***[a]		
Exercises Completed	***M***	***SD***	***N***	***M***	***SD***	***N***
0-1	4.31	3.09	13	2.48	1.38	14
2	6.91	3.20	23	2.33	1.16	26
3	7.41	3.22	29	3.24	1.17	33
4	8.21	2.26	38	3.53	0.59	42

[a]Grade=12-point scale from 0=F to 4.0=A.

For the computational thinking test, cumulative GPA was not a significant covariate ($F(1, 98) = .296$, $p = .588$). This suggests that long-term retention of course content is not necessarily the same as course achievement reflected in grades. This distinction was also confirmed by the relatively moderate correlation of $r = .35$ between course grade and the computational thinking test. The number of exercises completed was significantly associated with computational thinking test score (Table I: $F(3, 98) = 4.76$, $p =.004$, partial $\text{Eta}^2 = .127$). There was a significant linear trend ($p < .0001$) from 0-1 to 4 exercises completed.

These findings indicate an apparent "dosage" effect, i.e., learning and course achievement increase with each additional creative thinking exercise completed. The increases are not trivial. Students completing 2 or fewer exercises averaged approximately a C to C+; whereas, students completing 3 exercises averaged a B and those completing 4 averaged a B+. Similarly, students improved on the knowledge test by about 2 1/2 points from 0-1 to 2 exercises completed, another 1/2 points from 2 to 3, and over 3/4 points from 3 to 4. Results for the knowledge test did not differ for CS majors and non-CS majors. Non-CS majors; however, appeared to benefit more in relation to grades with an increase from 1.67 for 0-1 exercises, to 2.33 for 2 exercises, to approximately 3.5 for 3 and 4 exercises. CS majors did not exhibit as sharp of increase but those completing all 4 exercises achieved a 1/2 grade point higher score than any other group. In relation to traditional findings for classroom educational interventions, these are strong effects. They also demonstrate meaningful "real world" impact. Of course, we cannot conclusively determine that the results are solely due to the exercises; however, by controlling for students' cumulative GPA, we can say that the results are not due to students who are better students in general completing more exercises than poor students.

B. Student Reactions to the Creative Thinking Exercises

One focus group was conducted for each of the four exercises with each done in one of the four participating classes. A majority of students reported that they did not enjoy completing the exercises and found it difficult to understand how they related to course objectives. These comments were mirrored in open-ended survey responses. When asked general questions in focus groups and in the survey about impacts on computational thinking and computing, most students indicated little impact expressing that exercises were unrelated to the concepts covered in the class. Most reported that the exercises did not have enough payoff in terms of grades or learning to justify the amount of time they took. Students expressed difficulty communicating with classmates outside of class which impacted their willingness and ability to complete assignments. Students felt that instructor facilitation of the exercises was too limited and they found it problematic that little class time was devoted to discussion of the exercises.

When asked to rate exercise effectiveness, about 75% of students indicated that they thought the exercises were either not effective or *neither* effective *nor* not effective in preparing them to use computational and CS tools in their field, helping them problem solve more creatively, and helping them creatively apply computational thinking in their field. These ratings of effectiveness were not significantly correlated with the number of exercises completed suggesting that perception of effectiveness was not a motivating factor for doing the exercises. The usefulness and interestingness of the story telling and cipher exercise were rated somewhat higher and received more positive responses in focus groups.

This dissatisfaction and self-assessment of impact is in stark contrast to the significant 'dosage' effect identified for exercise completion on grades and computational knowledge. However, when probed in focus groups for exercise impacts on specific computational thinking and computing skills, many students indicated that these were improved by completing the exercises. Furthermore, students stated that the exercises were successful in helping them understand how programming relates to the world around them and how they might apply concepts in a practical setting. These findings suggest that students are not necessarily able to recognize the value of educational activities for enhancing their learning, especially in their first or general impressions of an activity. But, if prompted to reflect further, they may begin to recognize the value.

VII. LESSONS LEARNED AND NEXT STEPS

Completing the exercises appears to have benefited student achievement and learning. Both their long-term retention (as measured by a computational thinking test) and their course grades improved the more exercises they completed. It appears that the use of creative thinking skills does help students "unlock" their understanding of computational thinking as we proposed. Students did not always recognize these benefits, however. They generally expressed dissatisfaction with the exercises and thought they were unrelated to the course and did not help their learning of course content. Only when pushed for specific impacts did students begin to recognize positive impacts of the exercises on their understanding and problem solving. To explain, the creative thinking exercises involve a level of abstraction that may mask the connections between the exercise activities and the underlying computational thinking principles. As a result, students may not be able to see these connections, leading them to question the relevance and benefits of doing the exercises.

This student feedback demonstrated the need for us to better and more specifically explain how creative thinking helps CS students and how the creative exercises relate to specific CS topics. This feedback also made clear the need to improve the logistics of exercise deployment. To address these student concerns and to make the benefits of the exercises more visible to students, we have taken the following steps for future deployment: (1) continually revised the objectives in all the exercises to make their connections to CS topics more explicit, (2) designed an "Exercise 0" so students can practice using the system before the graded exercises are assigned, (3) bundled the exercises together with learning objects on those same topics [19] to provide more detail on CS topics, and (4) assigned students to groups so that there were fewer delays in forming groups and so that students were on an equal footing in groups.

We discovered that the logistics of exercise deployment—how large the class was, how often it met, whether students took other courses together, whether they interacted outside of class—had a greater impact than we anticipated on how smoothly the exercises ran and how satisfied the students were with their experience. Students were especially sensitive to difficulties working with other students in their groups. Accordingly, we are in the process of identifying how to combine real-time experience (such as in-class explanations of the exercises) with these improvements to the exercises and with improvements to the online wiki in order to minimize student frustration with the logistics of the exercises. Given the evidence of real benefits to the students from our blending of computational and creative thinking, it is now our creative challenge to improve our exercise design and delivery so that students are eager to complete the exercises and recognize their value in enhancing their learning of computational thinking.

An Analysis of a Pre-Engineering Program Model Used to Predict a Student's Persistence to Graduation

Reginald J. Perry
FAMU-FSU College of Engineering
Florida A&M University
Tallahassee, Florida USA

Abstract— **This paper presents the evolution and implementation of the pre-engineering program at the joint Florida A&M University-Florida State University College of Engineering. The program was initiated in 2004. It was revised several times between 2004 and 2009. These revisions were made to accommodate unexpected or unattended consequences in the program's implementation. The current program consists of five courses taken by engineering students including First-Year Engineering Laboratory, Calculus I, Calculus II, General Chemistry I, and General Physics I. Chemical engineering students replace General Physics I with General Chemistry II Between 2004 and 2008, almost 2000 first-time in college (FTIC) engineering students participated in the program. The analysis suggests that students who successfully complete the pre-engineering program graduate from the college with a degree in engineering at a very high rate. Additionally, it appears there are no statistically significant differences in graduation rates among pre-engineering program completers with respect to home institution, gender, and race/ethnicity.**

Keywords—Pre-engineering program; First-Year Engineering, Freshman Engineering

I. INTRODUCTION

The Florida Agricultural and Mechanical University – Florida State University (FAMU-FSU) College of Engineering is a unique joint college between Florida Agricultural and Mechanical University (Florida A&M University, or FAMU) and The Florida State University[1]. Florida A&M University is the largest single campus historically black university in the United States. It had a Fall 2012 enrollment of over 11,000 students. Florida State University had a Fall 2012 enrollment of over 40,000 students. In the early 20th century, it was known as the Florida State College for Women. In 1982, the Florida Legislature authorized the two universities to offer engineering degrees with a mission to "attract and graduate a greater number of minorities and women in professional engineering."

As of Fall 2012, the total college enrollment was over 2500 students with 2200 undergraduate students and 300 graduate students. Undergraduate students complete all of their general education course work (e.g., English, mathematics, science, humanities, and social sciences) on their home campus. However, all of their engineering coursework is taken on a separate engineering campus. After completion of their curriculum requirements, students are awarded a degree by their home institution. The engineering campus is a shared facility of the two institutions. The faculty, staff, and facilities virtually belong to both institutions. In this way, resources are leveraged for engineering students.

The college currently offers six undergraduate engineering degrees: chemical, civil, computer, electrical, industrial, and mechanical. It also offers M.S. and Ph.D. degrees in biomedical, chemical, civil, electrical, industrial, and mechanical engineering. All undergraduate degree programs are accredited by the Engineering Accreditation Commission of ABET, Inc., http://www.abet.org.

In the fall of 2004, the college implemented a major reorganization of its undergraduate programs. Instead of enrolling students directly into one of its degree-granting majors, first-time-in-college (FTIC) students and transfer students matriculated into a new pre-engineering program major. This change was primarily made to provide some uniformity in the experience of new students. But, more importantly, it introduced an academic milestone new students would need to meet in order to progress towards earning an engineering degree.

Models for pre-engineering (also known as first-year engineering or freshman engineering) programs have been reported for other institutions [2]-[4]. Underlying factors for persistence in engineering also have been examined[5],[6]. This paper presents a quantitative study of the pre-engineering program at FAMU-FSU to predict a student's persistence to graduation based on academic performance in specific courses designed to be completed during a student's first year.

II. PRE-ENGINEERING PROGRAM HISTORY

Although a pre-engineering program did exist at the college prior to the fall of 2004, it was informal, voluntary, and primary involved undecided engineering majors. The formal program began with the entering FTIC class of 2004. Any student already coded as "pre-engineering" was included in the new program. Returning students who were already classified in a degree granting major were "grandfathered" and not required to satisfy the new requirements.

The program has had four major revisions since its initial inception in 2004. It has maintained (with one exception) the following three features: (1) an unconditional transfer component, (2) a conditional transfer component, and (3) a "not permitted to transfer" component. Under an unconditional transfer, a student has met all pre-engineering program requirements, and he or she is permitted to transfer

This material is based upon work supported by the National Science Foundation under Grant Number: HRD 05-06110

from pre-engineering to the engineering degree program of his or her choice.

A conditional transfer permits a student who partially meets the pre-engineering program requirements the ability to complete additional coursework to transfer into an engineering degree program. These courses are specified by the academic program and generally consist of the entry-level course for the degree. A student who does not meet the full or conditional requirements is not permitted to transfer from pre-engineering. These students are assisted in transferring to a non-engineering degree program.

Another common feature of all revisions is the list of courses which constitute the pre-engineering program curriculum. They include: First Year Engineering Laboratory (FYEL) (1 semester hour), Calculus I (4 semester hours), Calculus II (4 semester hours), General Chemistry I (3 semester hours), and General Physics I (4 semester hours). In the summer of 2006, General Physics I was replaced with General Chemistry II for chemical engineering majors. This is described in detail below.

Revisions to the program were made to account for unexpected or unintended consequences or to streamline its implementation. These changes were designed not to adversely penalize students who matriculated in previous years.

A. Pre-Engineering Program Requirements – Summer 2004 to Summer 2005

The initial program requirements were implemented in the Summer 2004 semester. For an unconditional transfer, a student needed: (1) a grade of "C" or better in the First-Year Engineering Laboratory course (one repeated attempt was permitted), and (2) a cumulative grade point average (GPA) of 2.5 or better in Calculus I, Calculus II, General Physics I, and General Chemistry I. One course repeat could be excluded from the GPA calculation. Students who had a cumulative GPA between 2.3 and 2.5 were considered conditionally. Student who had a cumulative GPA below 2.3 were not permitted to continue. Laboratory courses were not included in the calculation unless a single grade (i.e., laboratory and lecture) was given for the course.

B. Pre-Engineering Program Requirements – Summer 2005 to Summer 2006

The first program change occurred during the next academic year. Florida State University uses a plus ("+") and minus ("-") grading scheme and a grade of "C-" is considered passing. Additionally, FSU does not permit a student with a passing grade to repeat the same course again. Because the program requirements excluded one repeated attempt, it was theoretically possible for a student to get a "D" in a course, repeat it with an "A" and be permitted to continue. Conversely, another student could receive a "C-" in the same course, not be allowed to repeat, and not satisfy the GPA requirement. This could lead the "C-" student to consider purposely receiving a grade of "D" or "F" in order to repeat the course again.

To prevent this possibility, the requirements were change to allow a student to "substitute" a higher level course for a lower level one. For example, a student could substitute his or her grade in Calculus III for a "C-" grade in Calculus I or Calculus II. However, a student could not use both substitution and exclusion in his or her GPA calculation.

C. Pre-Engineering Program Requirements – Summer 2006 to Summer 2007

As the program entered its third year of implementation, the college was informed that the program might not be in compliance with a state-level education regulation. Specifically, permission must be granted by a state board to use cumulative GPA requirements for degree progression above university minimums. However, there is a provision in the rule which granted programs the authority to use individual course grade requirements in place of a cumulative GPA. Additionally, the State of Florida has very strong regulations regarding the transfer of students from its community college system into one of its state universities. In short, programs could not add additional first- or second-year requirements that could not be obtained at a community college.

Based on the new information, the program was revised by replacing the cumulative GPA with specific course grade requirements. A student now needed a grade of "C" or better, from any institution attended, in Calculus I, Calculus II, General Chemistry I and General Physics I. Also, a change was made to accommodate chemical engineering majors by replacing General Physics I with General Chemistry II.

Students were permitted a single repeated course attempt and a course substitution if a student earned a grade of "C-" in the first attempt. Additionally, transfer students were given an exemption for the First-Year Engineering Laboratory course, if the student satisfied all of the other course requirements. That is, a transfer student who had completed the four other courses prior to transferring to the college would be placed directly into an engineering degree program after completion of an orientation session. Otherwise, the student would be required to complete the FYEL course along with the student's remaining pre-engineering course requirements. The conditional transfer category was removed. And, the "Not permitted to continue" category was redefined as a student who needed two or more repeated attempts or had more than two grades of "C-."

D. Pre-Engineering Program Requirements – Summer 2007 to Summer 2009

The conditional transfer was re-introduced during the Summer 2007 semester. Students with two repeated attempts or two or more grades of "C-" were now considered conditional. The "Not permitted to continue" category was redefined to include students with more than two repeated attempts. This modification was made to account for the student who failed to obtain a grade of "C" or better in two courses during his or her first semester at the university. The re-introduction of the conditional category gave this student another opportunity to succeed. Also, this revision permitted the “C-” grade to be considered “partially” passing instead of failing.

E. Pre-engineering Program Requirements –Summer 2009 to Current

The present pre-engineering program requirements have remained stable since 2009. The last change was the inclusion of the First-Year Engineering Laboratory (FYEL) course in the main list of pre-engineering courses. Previously, for an unconditional transfer, a student could have a separate repeated attempt in FYEL in addition to the single repeated attempts in one of the other four courses. Now, the five courses are considered as a single group and a student may only have one repeated attempt in the five. For a conditional transfer, a student may have two repeated attempts in the five. This change simplified the program requirements making it easier to verify and explain to incoming students. The current pre-engineering program requirements are as follows:

“All first-year engineering students (first-year in college or first-year transfer students) are initially coded as pre-engineering students until they satisfy the following pre-engineering requirements: Students must have an overall GPA of 2.0 or better and achieve a grade of ‘C’ or better, from any institution attended, in First Year Engineering Laboratory, Calculus I, Calculus II, General Chemistry I and General Physics I to be admitted to an engineering major. Intended chemical engineering students shall replace General Physics I with General Chemistry II. A single repeated attempt in only one of the five (5) courses listed above with no more than one grade of “C-” is allowed.

Students completing a second bachelor’s degree, or who have completed a similar course at another institution, or who transfer into the College already with credit for all of the other pre-engineering courses listed above may be eligible to receive an exemption from having to complete the First-Year Engineering Laboratory course. Any student who needs two repeated attempts to complete the five courses or has two or more grades of ‘C-” may be considered for continuation in engineering if additional grade and coursework requirements are satisfied. Any student who needs more than two repeated attempts to complete the five courses listed above does not satisfy these requirements and will not be allowed to continue in the engineering program. There are NO exceptions to these requirements. Grades of “W” are not considered as a repeated attempt.”

Although the program does not consider a “W” or course withdrawal as an attempt, students are limited in the their total number of course withdrawals between the seventh and tenth week of each semester.

III. Implementation Details

The pre-engineering program is managed by the Office of the Associate Dean for Student Affairs and Curriculum. Each university has assigned to the college dedicated full-time academic advisors to advise their pre-engineering program students. These individuals have offices on their respective main campus as well as at the College of Engineering. Although these advisors are under the direct supervision of their home university, they work very closely with the college staff to ensure clear communication of degree requirements to students. Pre-engineering majors must see their academic advisor at least once a semester. In addition, the college provides advising and academic support to all pre-engineering students.

Prospective students are informed of pre-engineering program requirements during each university’s Spring Preview session. This is an event which allows these students to visit the campus. Admitted students are further informed during their summer orientation session when they are registering for their fall semester classes. After students arrive on campus, enrolled students are given an in-depth instruction and examination of pre-engineering program requirements in the First-Year Engineering Laboratory course.

After a student has completed pre-engineering program requirements, the student makes an appointment to see his or her academic advisor. The advisor checks the student’s transcript against the current requirements. If the student does not satisfy current requirements, the advisor checks the student’s transcript against all requirements in place since the student’s initial matriculation to the college. In general, the later requirements are more relaxed than the former ones. If the student does not satisfy any of the requirements, the student is assisted in transferring to a non-engineering major.

IV. Findings

A quantitative study of the academic performance of first-time-in-college (FTIC) students who matriculated to the College of Engineering from the Summer/Fall 2004 semester through the Summer/Fall 2008 semester is presented below. Although, as described above, specific aspects of the pre-engineering program naturally evolved over this period, the core principles of the program remained the same. Incoming FTIC students are informed they are expected to achieve a specific level of academic performance in order to continue in the engineering program. Students are told that satisfying pre-engineering program requirements should be considered the “first graduation requirement” toward earning an engineering degree. Beginning with the Fall 2011 semester, the college presented students who completed the program with a “College of Engineering Pre-Engineering Program Completion” lapel pin as a small token of recognition of their achievement in reaching this important milestone.

A total of 1997 FTIC students matriculated into the pre-engineering program between 2004 and 2008. Their distribution by university and cohort is given in Fig 1. The difference in enrollment between the two universities is approximately the same as their overall undergraduate student population ratio. Table I provides the gender and

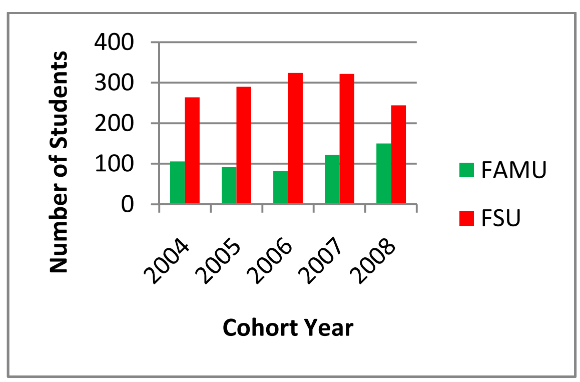

Fig. 1. College of Engineering Student Distribution by univerity and cohort.

race/ethnicity distribution of engineering students from both universities. Fig 2 shows the percentage of the population by university and demographic group. While white males are the largest single demographic population at the college; almost half of the college's overall undergraduate student population is composed of groups historically underrepresented in engineering including African-Americans, Hispanics, and women.

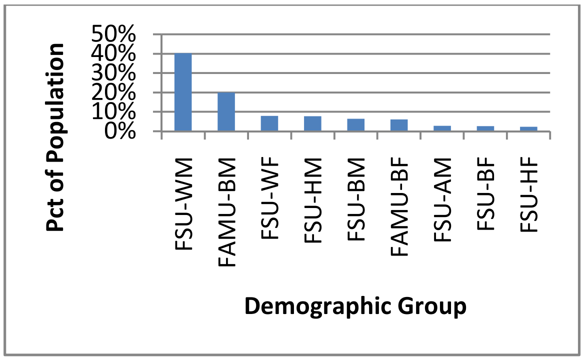

Fig 2. College of Engineering Demographics Distribution . W=White, B=Black, A=Asian, H=Hispanic, M=Male, and F=Female

The degree progression model used to analyze the performance of these groups is given in Fig 3. All students are initially classified as pre-engineering majors. At the first transition point, students are either: (A1) are still enrolled in pre-engineering, (A2) have completed the pre-engineering program, or (A3) did not complete the pre-engineering program. For students in the A2 or A3 categories, they are either (1) still enrolled, (2) have graduated, or (3) are not enrolled. For students who completed the pre-engineering program and have graduated, they either (A) graduated with a degree in engineering or (B) graduated with a non-engineering degree.

Student data are given for the overall population and by gender, race/ethnicity, and race/ethnicity/gender in Table III below. For example, of the 1997 total students in the 2004 to 2008 cohorts, 14 are still in enrolled in pre-engineering, 799 (or 40%) satisfied pre-engineering program requirements, and 1184 (or 60%) did not complete the program. Of the 799 completing pre-engineering, 149 are still enrolled in engineering, 5 are still enrolled in a non-engineering major, 579 have graduated, and 66 are not enrolled. On the other hand, of the 1184 not completing pre-engineering program requirements, 152 are still enrolled, 380 have graduated, and 652 are no longer enrolled.

V. Analysis of Findings

Since the pre-engineering program is designed to provide entering engineering students an early milestone towards attainment of an engineering degree, it is instructive to analyze the data comparing non-completers and completers of the program. Table II shows retention rates and graduation rates between the two groups for the population categories given in Table III. The overall retention rate for pre-engineering program completers (92%) is more than double that of the non-program completers (45%). The same results are also seen for graduation rates with 72% of the pre-engineering program completers graduated by the end of the Spring 2012 semester compared to only 32% of the non-completers. The last two columns in the table examine the engineering graduation rate. The overall rate is 68% for all pre-engineering program completers. If currently enrolled engineering students are excluded from the total, this rate increases to 83%. In other words, more than four out of five students who have completed the pre-engineering program and are no longer enrolled have graduated with a degree in engineering.

A statistical analysis using SPSS version 21 shows that there is no statistically significant differences in the engineering graduation rates (excluding currently enrolled engineering students) based on home university ($\chi^2 = 1.16$, $n = 645$, $p = 0.31$), gender ($\chi^2 = 0.443$, $n = 645$, $p = 0.61$), and race/ethnicity ($\chi^2 = 9.39$, $n = 645$, $p = 0.153$). Therefore, any student who satisfies pre-engineering program requirements has approximately the same chance of graduating from the College of Engineering with a degree in engineering.

VI. Pre-Engineering Program Conversion Rates

However, when the pre-engineering conversion rate is examined, which is defined as the percentage of pre-engineering program completers to the total number of pre-engineering students, we do find statistically significant differences between some population groups. The largest difference occurs between students at the two universities. At Florida State University, the overall conversion rate is 46%. While at Florida A&M University, it is approximately half the rate at 25%.

It was assumed that students were not completing the pre-engineering program because they were "failing" more than the allotted amount of course attempts forcing them to change majors from engineering. However, for students enrolled through Florida State University, less than 10% of the non-completers actually had three or more failing attempts in one

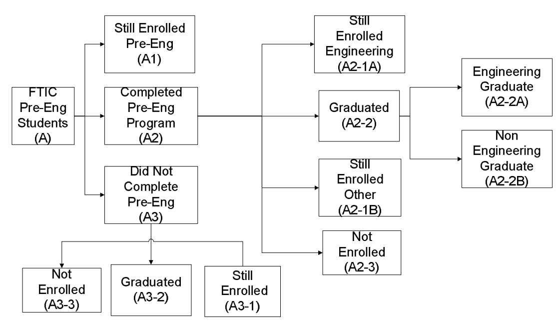

Fig 3. College of Engineering Degree Progression Model

or more pre-engineering courses. In fact, almost 60% of the Florida State University non-completers had zero (0) "failing" attempts in any of the pre-engineering courses. When examined more closely, it was discovered that including course withdrawals 17% of the non-completers did not complete a single pre-engineering program course.

To gauge the motivation of students to pursue an engineering degree, we examined the performance of students in First-Year Engineering Laboratory (FYEL). Again, to our surprise, 44% of Florida State non-completers never completed FYEL. Less than 10% of the non-completers received a grade below “C” in the course. Apparently, failure to satisfy the academic requirements for the pre-engineering program was not a significant factor in explaining why Florida State students did not complete the pre-engineering program.

At Florida A&M University, the results were almost completely opposite. For Florida A&M University students only 11% of the non-completers had zero attempts in any of the pre-engineering courses. On the other hand, over 32% of non-completers had three or more “failing” attempts in one or more of the pre-engineering courses. Additionally, about 28% of Florida A&M University non-completers never took the First-Year Engineering Laboratory course.

For this group of students, academic performance appeared to have an effect on degree progression. The course which seemed to give students the most difficulty was General Chemistry I, which accounted for almost 30% of the total “failing” attempts. The Department of Chemistry at Florida A&M University has since instituted a new placement protocol for all students registering for this course.

VII. Summary

The history of pre-engineering program at the joint Florida A&M University-Florida State University College of Engineering has been presented. After its initial implementation in 2004, the program has remained stable since 2009. The retention and graduation rates obtained from the first five classes suggest that the completion of the pre-engineering program requirements is a strong indicator of successfully obtaining an engineering degree from the college. The data also suggest that the graduation rates for pre-engineering program completers are statistically equivalent regardless of the student’s race, ethnicity, gender, or home university.

The analysis of the pre-engineering conversion rates shows that there is a difference between the two institutions. Additionally, the behavior of non-completers in their motivation to obtain an engineering degree also appears to be substantially different between the two universities.

Integrating Cohorts to Improve Student Career Self-Efficacy

Lesley Strawderman, Ph.D., Katherine King
Department of Industrial and Systems Engineering
Mississippi State University
Mississippi State, MS, USA

***Abstract*— Past research on student efficacy shows that students felt more confident in their selection of career field when they were able to "try it on for size." Students have a desire to get their hands dirty and try using engineering tools early in the curriculum. Additionally, students often report a great deal of uncertainty about the curriculum and their ability to be successful in their academic and future careers. In this paper, we describe the integration of a discipline's introductory course within the rest of the discipline's curriculum. Student reported self-efficacy in the introductory engineering course was measured before and after the course activity was completed. Four questions were used to assess efficacy on a 5-point Likert scale. The largest increase in score was seen on the final efficacy question (M_{pre4}=3.59, M_{post4}=3.87). The average efficacy for all students and all questions was 4.04 (*sd*=1.01). Inferential results based on student classification, gender, prior work experience, and perceptions of the mentoring activity are discussed. Finally, implications and suggestions for the use of cohort integration in engineering programs are discussed.**

Keywords—self-efficacy; introductory course

I. INTRODUCTION

Student self-efficacy is often the focus on engineering education studies, as it has been shown to accurately predict student success in engineering (Figure 1). Efficacy has been shown to influence student behavior [1], persistence [2], and success [2]. The use of efficacy is critical in large introductory classes, where retention and attrition tend to be magnified, and where students tend to leave an engineering major before they may have a firm understanding of the career field in front of them [3-4].

A number of past studies have examined how introductory courses can serve to improve self-efficacy [5-8]. Introductory course design, including the specificity related to the chosen major, including projects or lab activities, and assigning team tasks are all capable of improving self-efficacy [9-11]. Past studies have shown a positive influence on introductory students when including upperclassmen on projects, in courses, and through mentoring [12-13].

The objective of this study is to investigate the impact of integrating cohorts on students' self-efficacy. A class module was developed to expose students to a hands-on industrial engineering project early in the curriculum. The project involved applying industrial engineering principles from the field of human factors to the redesign of a device. Learning objectives of the class module project include:

- Increase students' awareness of tasks and jobs performed by industrial engineers
- Expose them to the industrial engineering field of human factors and ergonomics
- Increase their skills, abilities, and confidence in industrial engineering

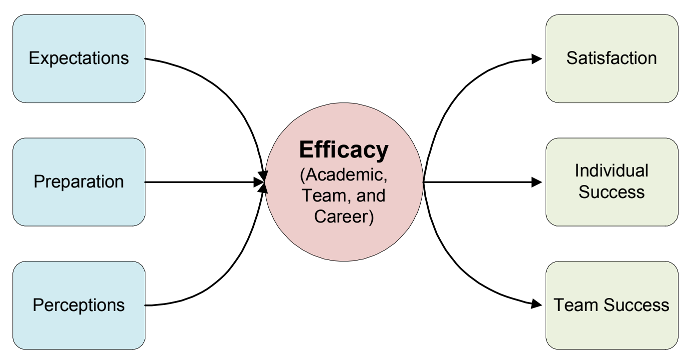

Fig. 1. Overview of student self-efficacy

II. METHODOLOGY

A. Participants

The participants of this study consisted of 54 students (38 females, 16 males). The average age was 19.679 with a standard deviation of 1.851.

This study was conducted primarily in a required introductory course, Introduction to Industrial Engineering, a required undergraduate course in the Department of Industrial and Systems Engineering at Mississippi State University. An advanced level course, Industrial Ergonomics, also participated in this study, acting as the consultants for further design evaluation.

B. *Class Material*

The module is designed to supplement the other topics presented in the introductory level course. It includes lecture material, quiz and homework material, activity guidelines, and pre and post-activity survey questions. This material is intended to expand the students' knowledge and awareness of the field of human factors and to expose them to real world tasks industrial engineers might perform on the job.

Lecture. In class the students received a lecture summarizing some of the core principles of Human Factors and Ergonomics and how to apply them to the design of processes and products. The topics covered in the lecture include:

- Scope and terminology definitions within Human Factors and Ergonomics
- Importance of research in this area in the design of many systems
- Techniques used to quantify aspects of human capabilities

Activity. For the activity the students are split up into easier, working groups. The activity is intended to have the introductory students put the information and knowledge collected in the lecture into practice. They were given a device, a single-hole puncher, and were asked to evaluate its performance and suggest a redesign to improve its capability. The students were also required to set up a consultation appointment with "experts", the advanced level students in the Industrial Ergonomics course, to further enhance their knowledge of ergonomic principles and collect suggestions for improved redesigns. The Industrial Ergonomics class consisted of 36 advanced students who were trained as part of their course lab assignment. For consulting, the advanced class was split into groups of four to five people and each group served one or two of the introductory design groups. The advanced groups provided the same information, but the feedback and advice varied based on the introductory student groups' designs.

C. *Procedure*

Pre- and post-activity surveys were used to assess the effectiveness of the class module, as well as assess student perceptions of industrial engineering. These surveys consisted of both structured and open-ended questions. The structured questions aimed at determining the students' confidence in their choice of and ability to succeed in industrial engineering (Table 1). The level of confidence was measured on a 5-point Likert scale. The open-ended questions were used to gain a sense of the students' general feelings toward industrial engineering. These questions can be found in Table 1. Furthermore students also completed a quiz and homework assignment to assess their retention of the information presented in the assignments.

III. RESULTS

A. *Student Efficacy*

The descriptive statistics for the efficacy questions are shown in Table 2. Paired t-tests were conducted to examine significant differences between pre- and post-activity responses. The first three questions inquire about the students' confidence to gain the skills needed in industrial engineering and given the challenges within this field, their confidence to overcome these to be successful. These questions, at their base, asked students' to assess their work ethic in accomplishing tasks and goals presented.

The fourth question inquired about the students' confidence in choosing industrial engineering as a long term career. Therefore, this question specifically inquires about their attitudes toward industrial engineering as a whole, versus simply the ability to gain the skills within this field.

TABLE I. SURVEY QUESTIONS

Efficacy Questions	
E1	I am certain that I can be successful in my industrial engineering program.
E2	I am confident that I can master the skills needed for the field of industrial engineering.
E3	I am confident that I can overcome challenges in my industrial engineering career.
E4	I am certain that industrial engineering is the right career choice for me.
Open-Ended Questions	
Q1	The most appealing thing about industrial engineering is___.
Q2	The most intimidating thing about industrial engineering is __.
Q3	When I think about a career in industrial engineering, I am most confident in my ability to __.
Q4	When I think about a career in industrial engineering, I am least confident in my ability to __.
Q5	I feel __ about a career in industrial engineering.
Q6	Why did you choose to major in industrial engineering?

TABLE II. EFFICACY QUESTION RESULTS (MEAN (SD))

	Question			
	1	*2*	*3*	*4*
Pre-activity	3.98 (1.11)	3.98 (1.09)	4.00 (1.10)	3.59 (1.16)
Post-activity	4.07 (1.01)	4.07 (0.99)	4.13 (0.93)	3.87 (1.10)
Change	0.09 (1.14)	0.09 (1.07)	0.13 (1.15)	0.28 (1.07)

Although none of the questions showed significant differences (α=0.05), responses to question 4 were broken down to examine the impact of demographics on students' confidence in choosing industrial engineering as a career. With regards to gender, males had higher increases in question 4 scores (M=0.3947, sd=1.128) than females (M=0.000, sd=0.8944) upon completing the class module, though the difference was not significant ($t(35)$= 1.37, p=0.181). When assessing the differences in class, upperclassmen reported the highest increase on efficacy question four (M=0.55, sd=1.30), compared to underclassmen (M=0.094, sd=0.856), though the difference was not significant ($t(33)$= -1.43, p=0.162). Furthermore, those with prior work experience had higher increases on question 4 (M=0.4103, sd=1.1173) than those without (M= -0.0667, sd=0.8837), although this difference was not significant ($t(32)$= 1.64, p=0.110). Finally, question 4 was evaluated assessing students' whose parents attended college or not. Those whose parents did not attend college reported a higher change in efficacy score (M=0.6667, sd=1.6330) versus those whose parents did attend college (M=0.2292, sd=0.9944), though the difference was not significant ($t(5)$= -0.64, p=0.549).

B. Open Ended Responses

The students in the Introduction to Industrial Engineering class were also asked a series of pre- and post-activity questions, listed in Table 1. Both pre- and post-responses were divided into categories unique to each question. Student responses were categorized by student research assistants in order to evaluate patterns in the data. Categories with less than five responses were not included in the analysis. Only categorized responses are shown below.

Student perceptions regarding the appealing and intimidating characteristics of industrial engineering are shown in Figures 2 and 3. Before the class activity, the most appealing factor for students was job availability. After the activity, the appeal of jobs was still high, but more students were interested by the task variety and human aspects of the major. Students reported being intimidated by the coursework required in the major.

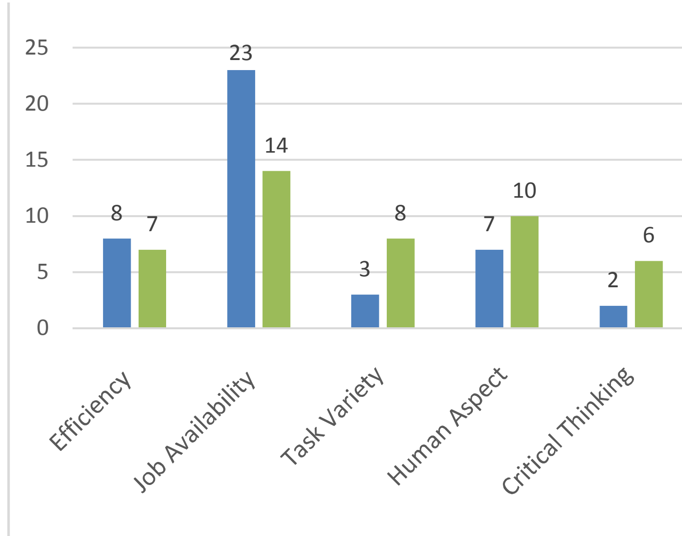

Fig 2. The most appealing thing about industrial engineering (Q1), pre- and post-activity

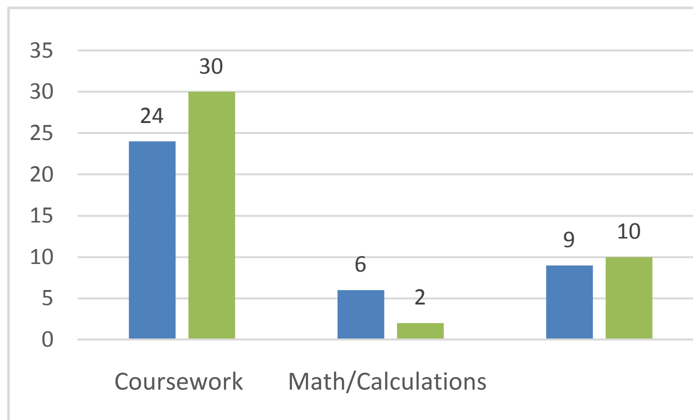

Fig 3. The most intimidating thing about industrial engineering (Q2), pre- and post-activity

When asked to consider their own sets of abilities, students were most confident in their abilities to solve problems and work with others (Figure 4). Student responses regarding what they were least confident in were varied, including responses such as recalling information and managing others (Figure 5). There were not many changes in these responses based on the activity.

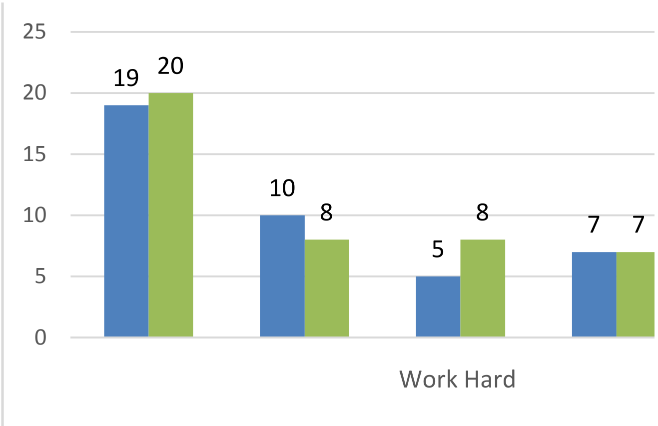

Fig 4. Industrial engineering students were most confidence in these abilities (Q3), pre- and post-activity

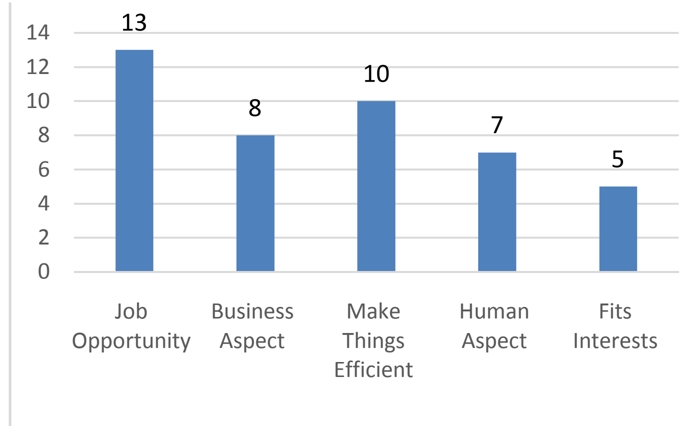

Fig 6. Reasons for choosing industrial engineering (Q6)

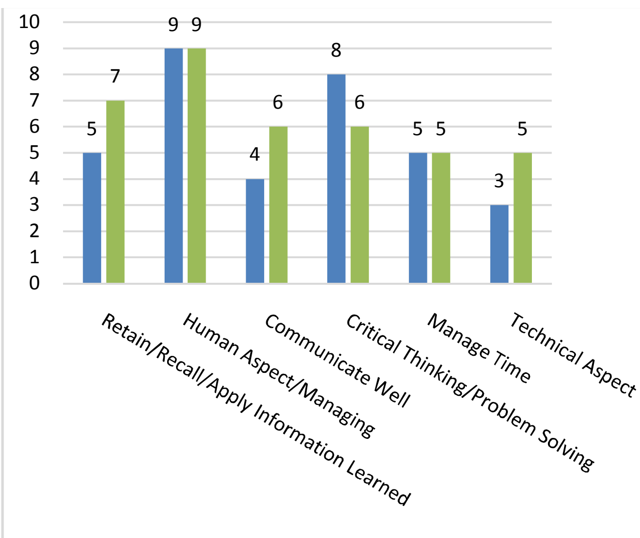

Fig 5. Industrial engineering students were least confident in these abilities (Q4), pre- and post-activity

Students reported a number of reasons for choosing industrial engineering (Figure 6), including job opportunities, the desire to make things efficient, and the ability to incorporate business aspects into an engineering discipline.

IV. DISCUSSION

Although none of the structured efficacy survey questions provided significant data, question 4 did reveal some change in the students' general feelings and attitudes toward industrial engineering as a whole. When further evaluated, this question revealed that student responses were affected by some demographic factors such as their gender, class, prior work experience, and whether or not their parents attended college. It is expected that the efficacy results will show significance in future work with an increased sample size.

We can conclude from the open-ended response data that the module as a whole had an impact on students' feelings and awareness of industrial engineering. Specifically, the students' gained more awareness and interest in a unique field of industrial engineering, human factors engineering. Question 1, which asks about the most appealing aspect of industrial engineering, saw an increase in the categories of "task variety" and "human aspects", and "critical thinking" (Figure 2).

The hands-on aspect of the activity aided the students' confidence in their critical thinking and problem solving. This change is seen in question 4 which asked the students' what ability needed in industrial engineering they were least confident in. Furthermore upon completing the activity students' reported more confidence in their ability to work hard and solve problems.

Although the survey questions provided a surplus amount of data on the introductory students' attitudes toward industrial engineering, there were some limitations. For example, the efficacy data collected via structured questions did not show any significant change in perception post-activity ($\alpha = 0.05$). This could be due to the types or phrasing of the questions used. Furthermore, the consulting phase of this assignment could be improved. For example, the introductory student teams could meet more than once with the advanced level student consultants. Also, it might be useful to consider other sources of consultation other than an advanced level class. For example, one possible alternative could be to involve a few experts from industry to assist in the consultation.

Another limitation of this study is the sample size. Although all students in the introductory class were new to the department, not all were freshmen classification. In future work, the introductory class will be composed entirely of freshmen. This change could provide stronger perception and efficacy results.

To further investigate the influence of integrating cohorts, additional studies are needed. In future semesters, additional combinations of courses will be assessed. Interviews with students will also be conducted to allow for a deeper exploration of the perceptions and efficacy of students, particularly freshmen. Finally, additional engineering disciplines and additional universities will be included to provide a more robust set of participants.

Abstract—**Engineering students need research skills to effectively complete research and design projects; information literacy education during the first year of college positions future engineers to complete projects both during their college years and when they move into their careers. This study provides evidence that faculty-librarian collaboration is an effective method to train students in these critical skills, and proposes an efficient model that can be adapted to other courses. This work-in-progress, in the third year of a four year analysis, assesses and develops a method of sustainable faculty-librarian collaboration that improves information literacy outcomes in a first-year, project-based engineering design course at Worcester Polytechnic Institute (WPI). To assess the effectiveness of information literacy instruction methods, citation analysis of group project bibliographies, faculty feedback, and student opinion survey data will be used. Preliminary citation data and faculty feedback suggest that increased librarian contact with students, development of resource guides, and design of grading rubrics to incorporate reference list requirements improve student projects and information literacy outcomes. The end result of this four year study will be a recommendation of a sustainable and effective faculty-librarian collaboration that improves information literacy outcomes among students and can be easily adapted to other courses.**

Keywords— Engineering Design, First Year Students, Citation Analysis, Information Literacy

I. Introduction

This paper presents the first three years of a four year faculty-librarian partnership aimed at improving information literacy outcomes in a first-year engineering design course. Information literacy skills are critical during the college years and set the stage for effective information seeking at the professional level. The outcomes assessed in this project are based on standards developed by the Association of College and Research Libraries and include the students' ability to effectively find and use relevant and varied information sources for the completion of a project [1]. Total citations of final group reports for each class are analyzed for diversity of sources, increased use of in-text citations, increased use of scholarship and decreased reliance upon web sources. The total number of citations reviewed over the first three years is 205 across 36 engineering design project reports. The first year of analysis reviews citations and reports from prior to the faculty-librarian collaboration; years two and three review citation data after the librarian and faculty member began to partner. The final year will include review of both citation data and student opinion survey data in order to get a fuller picture of the impact of the faculty-librarian collaboration.

II. Background

The citations analyzed are from ES1020: *Introduction to Engineering Design*, a first-year, project-based design course at Worcester Polytechnic Institute (WPI). Students work together in groups of 4-5 with a total of 12 groups per class. This course has been the subject of innovative teaching for over a decade. For example, in 2003 it was one of the earliest reported first-year engineering design courses built around project-based learning [2]. A 2005 paper describes the use of case studies and reverse engineering activities in the course [3].

One objective of ES 1020 is for students, within seven weeks, to complete an engineering design and prototype, often in the area of rehabilitation engineering. Literature on information seeking in the engineering disciplines makes it clear that to effectively complete such a project, students need a variety of information ranging from scholarly articles and books, to trade publications and patents [4,5]. The instructor had attempted to introduce this concept into the course without much success. In 2011 the faculty instructor and librarian initiated a partnership after the instructor realized that the first-year students enrolled in the course lacked skills to conduct a proper literature search related to their design project and locate appropriate references for constructing prototype devices. Prior to 2011 group project reference lists reflected that student groups lacked the ability to judge the quality of the references cited and were relying almost solely on web based searches. The instructor and librarian had collaborated previously, in an upper level mechanical engineering design course, so adding information literacy instruction to this first-year course was a natural extension of their prior work.

III. Methods of Instruction

Yearly increases in faculty-librarian collaboration over the first three years of the project have included longer librarian face-to-face instruction with students, development of source analysis rubrics to provide formative assessment to students early in the term, and development and promotion of a

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

customized online information portal. In the final year the grading rubric will incorporate more clearly defined information literacy requirements for final project reports. Details of each year's evolving collaboration are described in the following paragraphs.

In 2010 all research instruction was facilitated by the faculty instructor. Library inclusion was informal and limited to the faculty instructor encouraging students to visit the library and consult with a librarian as needed. In 2011 instruction was collaborative, with the librarian visiting class for ten minutes of contact time with students. For final grades on project reports, references were mentioned within one portion of the grading rubric as a part of the final project report grade. This section of the rubric, worth 20 points out of a maximum of 85, incorporated other project requirements in addition to references.

In 2012 there was a major shift in instruction methods since the instructor saw beneficial results from the previous year's collaboration. First, librarian contact time with students was increased from 10 minutes early in the term to 45 minutes over two class periods. Second, the librarian created an online resource portal (http://libguides.wpi.edu/es1020) and provided a low-risk source analysis rubric to help students determine whether they were successful in finding and citing sources effectively on an early homework assignment designed by the faculty instructor. Through the rubric students were made aware of the need to 1) collect a minimum number of sources, 2) find diverse sources (scholarly research, news, trade publications, patents, and websites), and 3) cite sources both in text and in a reference list following a specified citation style. After reviewing a sample of the first sets of papers using the rubric, the librarian made specific recommendations to students for ways to improve on final project reports. The comments reinforced the importance of the information seeking concepts taught at the librarian's first visit and included reminding student to avoid heavy reliance on commercial websites, use library resources, and cite sources using a standard citation format. Students were also reminded that if they were unsure of who published or created a source of information that they should avoid citing it in their project report.

In 2013 information literacy instruction will increase in several ways. First, the librarian's in-class instruction will extend from 45 to 75 minutes over two class periods. Second, students will be introduced to a citation management tool. Third, they will be given an opportunity to provide opinions on the librarian-led instruction through a required end of term survey. Finally, the summative assessment rubric for the final project will be more descriptive, and include specific grading criteria for references. These additions are anticipated to yield further improvements in student performance and increased assessment data.

IV. Methodology

Citation analysis has been the primary method used to assess the effectiveness of the faculty-librarian collaboration over the first three years of the project. A total of 205 citations from 36 project reports (12 per year) were analyzed from the 2010-2012 student reports. Information types were simplified or updated based on the methods used in prior research [5,6,7]. The citation analysis consisted of reviewing each group report for number of in-text citations and reference list entries, and types of sources in the reference list. The types of sources fell into the following categories: books, standards, government regulations, reports, scholarly articles, patents, trade news, general news, websites (.com, .org, .edu, etc.), government websites, or indiscernible. Secondary methods of assessment are faculty feedback gathered over the first three years, and a student opinion survey to be administered in the final year.

V. Preliminary Results

Results from the first three years of analysis suggest that librarian-led instruction and faculty collaboration in the development of grading rubrics is effective in improving information literacy outcomes. An increase in librarian contact time with students appears to have a direct relationship with the quality and diversity of sources students use in their papers and the quantity of sources included in reference lists. In each year of the study 12 group project reports were completed and reviewed. Between the first and third years of the study, there was a significant increase in the number of sources cited by teams, both in text and in reference lists (Table 1). Class-wide reliance on web sources decreased from 34 cited in 2010 to 21 in 2012. The number of scholarly sources increased from 0 to 18 over the same period. Another significant finding is that students in year one (2010) cited only four types of sources. By 2012, the diversity of source types increased by over 100% to 9 types of sources, and included books, scholarly articles, government regulations and standards. The increase in book citations was modest over the first three years growing from 0 used in 2010 to 3 in 2012.

TABLE I.

Year	**Total Citation Counts for Team Projects by Year**	
	Total In-text Citations	***Total Sources in Reference Lists***
2010	43	52
2011	37	72
2012	72	81

VI. Discussion and Future Work

The faculty-librarian collaboration has improved student outcomes regarding the use of information sources throughout the design project. During the fourth year of the project, data from student surveys will be analyzed to learn about what portions of the faculty librarian collaboration were perceived as most helpful for students to successfully complete projects. There is little research that provides this type of citation analysis as a tool to assess a long-term and evolving method of information literacy instruction in a first year engineering design course. At the completion of the four year examination the authors will provide a detailed assessment of citations used, and student and faculty opinion, and will contribute an example of a sustainable, effective model of librarian-faculty collaboration in teaching information literacy outcomes that may be generalized to other engineering design courses.

Teaching with Unfamiliar Pedagogy for Engineering Design Instructors

Omowunmi Isaacs-Sodeye and Micah Lande
Arizona State University, omowunmi.isaacs-sodeye@asu.edu, micah.lande@asu.edu

Abstract - **In recent years, increasing amount of attention has been paid to the teaching of engineering design. This increase stems from response to calls for reform in the way engineering graduates are trained and many engineering programs reacted by adding more practical courses such as engineering design to their curriculum. Unlike traditional engineering courses, teaching engineering design requires adopting a type of pedagogy that many engineering educators are not familiar with and are often resistant to implement. Thus, it is the need to understand resistance that makes the study of concerns that faculty members may have implementing active teaching strategies relevant. Teachers' concerns have been examined extensively at K-12 level, but few studies have examined the same issue in undergraduate engineering education. The purpose of this study is to investigate the concerns of faculty members teaching a freshman engineering design course using an unfamiliar pedagogy, and map these concerns to a model developed for understanding concerns related to adoption of innovation. Themes that do not map unto this model would be deemed specific to the teaching engineering design.**

Index Terms – engineering design, design thinking; teaching engineering; active learning

INTRODUCTION

Current popularity of engineering design as an undergraduate engineering course is the result of engineering institutions' responding to calls from employers, the industry, Accreditation Board for Engineering and Technology (ABET), and the National Research Council (NRC) for reform in the way engineering graduates are trained [1,2,3]. Initially, engineering schools addressed this call by introducing senior capstone projects where students apply knowledge of the engineering design process to create discipline related artifacts [1]. Consequently, some institutions began to teach freshman design courses with the additional hope that such courses will help promote students' interest and retention in engineering; motivate learning of upper division courses; and promote students performance in senior capstone projects [4, 5].

SENIOR CAPSTONE AND FRESHMEN DESIGN PROJECTS

Engineering design has been defined as "a systematic, intelligent generation and evaluation of specifications for artifacts whose form and function achieve stated objectives and satisfy specified constraints" [6]. This statement alludes to the purpose of engineering design: the development of products that meet pre-defined objectives and criterion. The goal of design education extends to include helping students focus on, understand, and experience the engineering design process [4, 5]. Senior capstone projects allow students to experience the integration of knowledge from various contents areas with the practice of engineering design in a final hands-on project [1]. While senior design courses have been used as a tool for enlightening students about the profession, freshmen design on the other hand, is taught mostly to gives new admits into engineering colleges the opportunity to experience what engineers really do [5].

TEACHING ENGINEERING DESIGN

The predominant pedagogy in engineering is lecturing with the instructor seen as the ultimate authority and dispenser of factual truth [8]. However research has shown that engineering educators are beginning to realize that in order to meet the demands of the new mandates and help students develop the non-technical communications and socials skills required in the workplace, they would have to learn and adopt new teaching strategies [3, 2].

Teaching in engineering has always being a private affair, whereby faculty members adopt the approach that is most convenient [10]. This approach to teaching has been claimed to have originated from the fact that only a small percent of engineering faculty receive training regarding their teaching practices during their graduate education or at the onset of an academic appointment [11]. Thus, it is expected that having to change from lecturing to pedagogy of engagement will not be an easy transition for many engineering educators. Research already shows that when asked to use other teaching strategies, engineering educators tend to be reluctant [12].

The types of strategies that are better suited for teaching design are those associated with active learning. Brawner, et al [13] and Felder et al [14] defined active learning as "getting students to do anything course related other than watching, listening to instruction and taking notes". Design courses are fashioned to allow students work in teams while solving ill-structured problems that may have multiple "correct" solutions and undefined constraints that influence the choice of solution. Such learning environments are ripped with ambiguity, lack of procedural and declarative rules than the type of learning environments normally encountered in traditional engineering classrooms [8, 15, 16]. Yet, research tells us that such teaching pedagogies are beginning to gain attention within the engineering community [3, 17].

TEACHING CONCERNS

Teaching design education requires implementing strategies that are unfamiliar to many engineering educators. Therefore, it is expected that faculty members asked to teach design courses would exhibit some concerns about their assignment. Bright et al [18] in their article about the inception of Harvey Mudd College's engineering clinic stated that faculty members received the idea with mixed feelings. They noted that some faculty members expressed preference for teaching what they believe students need to know as opposed to skills that would be learned within the first few months on the job. In their review of how engineering design is taught via capstone projects, Duston et al. [1] reported that engineering faculty members were concerned about teaching design because (1) they believed it will take more time and man power than a traditional course, (2) many of them do not know how design is done in practice, and (3) they perceived that they may not be supported in their endeavor to teach the course. In addition, Turns et al [10] added that engineering educators are also concerned that the time spent teaching design may hinder their chances for tenure and promotion.

Extensive studies have been done to examine educators concerns regarding their teaching at the K-12 levels, but teaching concerns of engineering educators have not been widely studied [10]. Teachers' concerns have been studied using Frances Fullers model for understanding the stages of skills development of teachers and Hall's Concerns-Based Adoption Model (CBAM) for studying teachers concerns during the process of adopting innovative teaching strategies [19& 20]. Fuller's model consists of three stages namely: Self, Impact, and Task, while Hall's model consists of six stages namely: Informational, Personal, Management, Consequences, Collaboration and Refocusing. It is important to note that Hall's model was developed from Fuller model as an instrument for understanding how concerns evolve during the process of adoption of new teaching strategy. These two models have been used to study concerns of engineering educator about their teaching in general. However, no data was found that showed that teaching concerns with regards to a particular course in engineering has been studied.

PURPOSE

The purpose of this work is to investigate the concerns of engineering faculty members selected to teach a first-year engineering design course using a pedagogy with which many of them may not be familiar. These faculty members were pre-selected by the administrative team based on the perception that they were best suited to teach a project-based course. By studying instructors' concerns, this study aims to answer the questions:

- What concerns do educators have teaching design using an unfamiliar pedagogy?
- How do these concerns align with CBAM adoption-based model?
- What concerns are emergent to the context of the study?

CONTEXT

The design course understudy was taught in five separate sessions, with a different instructor assigned to each session, to all incoming engineering students in their first semester. The goal of the course was to introduce the students to the engineering design process in a context free, project-based learning environment. The course was designed such that students of all abilities can be successful, and enrollees were assigned to teams to work on given projects. The course instructors and member(s) of the administration jointly designed the course contents and assessments. The five projects used in the course were designed by each instructor and made available for others to teach. Most of the instructors made slight changes to the materials, especially the presentation slides, before using them. Students were evaluated based on ability to demonstrate the competencies listed in the course objectives.

METHOD

The concern theory framework was used for this study because it offers a lens for understanding the growth and developmental process teachers [21] go through as they develop their teaching expertise overtime. The concern-based model that was considered most suitable for the study was Hall's Concern based adoption model specifically developed for evaluating instructors concerns when adopting new teaching practice. This model was deemed appropriate because the researchers believed that the instructors may not be familiar with students' engagement strategies and implementing such strategies in a design class could be considered adoption of innovative teaching strategy.

Faculty members selected to teach sessions of this course were interviewed about their concerns when they were first assigned to teach the course as well as those that emerged during the course of teaching. The semi-structured interview sessions allowed the instructors to express the issues that were most important to them. Interview transcripts were "searched" for issues that represent concerns, and identical 'concerns" were categorized into themes. Observed themes were mapped unto stages in the Hall's CBAM Model for adoption of innovation.

INITIAL FINDINGS

Our initial analysis showed that the instructors had the following concerns:

- *Engagement*: ensuring that all students are actively participating in team as well as individual assignments.
- *Ambiguity*: dealing with, and managing the ambiguous nature engineering design and students' behaviors in a student-centered learning environment.
- *Class management:* managing students' behavior while still allowing for flexibility required in engineering design and a project-base course.
- *Confidence:* being confidence of one's effectiveness at implementing active teaching strategies.
- *Others Project*: Implementing and managing issues that arise from facilitation projects developed by others.
- *Attitude*: Managing students' attitude while allowing for freedom of expression in demonstrating competency.
- *Assessment*: managing competency based assessment process and ensuring that assignments accurately measure the learning objectives.

Observed concerns were found to map unto most of Hall's CBAM theory with the exception of information and refocusing. The researchers believed that the results mapped as such because of the closed nature of the pilot. It was also observed that all the instructors have had prior experience teaching project-based course and thus are familiar with students' engagement teaching strategies.

Future plans include extending participation to teachers of other project based courses, k- 12 teachers learning to teach design, and further interview of the initial cohort of instructors to examine how their concerns may have evolved over time.

CONCLUSIONS

Studying engineering educators concerns with regards to teaching design mapped well unto Hall's CBA Model for adoption of innovation. Results showed that all the instructors have had some experience with using students' engagement strategies in their classroom. However, despite their experience, the instructors still have concerns about teaching design, especially regarding their ability to interpret the effectiveness of the active teaching strategies adopted.

***Abstract*—An innovative laboratory methodology for simulation of microcontroller based virtual kits is presented. Microcontrollers are widely applied in the field of industry to solve engineering control problems. Today's embedded world uses variety of microcontrollers as heart of processing. These simulation softwares are used to study the functionality of circuit. Students have blindness when they first contact the experiments because of the complexity of the circuit, so this usually leads to the damage to the experiment device. Therefore, it is necessary to make the students to know the theory, models and adjustable parameters of the experiments before the practical experiments. The mixed software stimulation platform based on Proteus, LabVIEW, MATLAB and Arduino was designed for this purpose.**

I. INTRODUCTION

Experiment teaching is an important link in teaching activity[1]. It is playing an important role in the ability and the quality of training student's scientific ideological mode, solid professional knowledge and experimental techniques. Laboratory at colleges and universities is bearing the weight as an important link to foster students to get to work carrying out. With the fast development of electronic technology, circuits, components and equipments have been updated. The existing laboratories are unable to meet the conditions of the various circuit designs and debug requests which affect the results of the circuit experiment teaching to a certain extent.

Specialized basic courses are very important during the electron information specialty teaching, they play the role connecting link of the specialized courses teaching in the whole course system. Simulation tools are used to assist teaching, utilizing intuitionist graph, picture, animation to help students understand abstract theory. Microcontrollers are widely applied in the field of industrial control such as process control, intelligent instruments, electromechanical integration and intelligent interface for features of small size, low power consumption, control functions, expansion flexibility[3].

II. MIXED SIMULATION PLATFORM BASED ON PROTEUS, LABVIEW, MATLAB AND ARDUINO

Students design the corresponding theoretical models based on the learned content. These models were allowed to be designed in corresponding simulation environment. Students also can understand each part in the models by changing the parameters and observe the waveform of the various nodes to see the change in the result. The simulation model is obtained untill the satisfactory response and its corresponding parameters are found in the MATLAB or LabVIEW. Then the students devise the proper circuits according to the optimized model in the Proteus. They are able to observe the response by setting the appropriate parameters of the circuit in the simulation environment. Comparing the results between the theoretical simulation model in MATLAB or LabVIEW and the circuit-level simulation model in Proteus, they identify differences and find a solution by analysis. Finally the practical circuit system which could meet requirements is finished. Then the students realize this system in the actual experiment platform and observe whether the actual response can achieve the requirements or not. These platforms can help students understand not only the basic theory but also the differences between the theoretical model and the actual system. The students are trained to acquire the basic skills and posses quality as engineer. In addition, the damage caused by the wrong operation to the experiment equipments is avoided. This is applied to Analog signal processing and digital signal processing.

III. OVERVIEW OF SIMULATION PLATFORM

The platform is mainly used in courses teaching and experiments, the courses include circuit analysis, analog circuit, digital circuit, high - frequency circuit, automatic control theory, embedded system and so on. Proteus is mainly used to make circuit-level simulation. LabVIEW and MATLAB are to complete the algorithm-level and modeling simulation. Arduino software is mainly used to make programs.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Microcontroller is a technical course with very strong practicality, undoubtedly the experiment is one of most important practice links of teaching. Due to limited fund and hardware experiment resource, the students can not have enough chances to exercise. If we full use the simulation emulation of the software as the auxiliary experiment means, it will greatly promote the teaching of the microcontroller.

Proteus VSM can facilitate co-simulation of complete microcontroller-based designs. VSM is uniquely suited to buliding virtual lab for microcontroller for its full virtual debugging interface. With the aid of Proteus VSM, teachers and students can develop and test application systems before physical prototyping. The virtual lab obviates the need for expensive hardware and allows the students the freedom and flexibility to design and develop microcontroller solutions without the need for a physical prototype.

V. EXPERIMENT

For experiments, we have selected Arduino hardware platform which is simulated in Proteus.

A. Project 1: Temperature sensor Interfacing of Proteus with LabVIEW

Virtual interfacing of Proteus(Arduino) with LabVIEW. This module comprises of temperature sensing implemented using Arduino simulated in Proteus. The changes in the temperature are communicated to LabVIEW through virtual serial port. The results are displayed in LabVIEW.

VI. CONCLUSION

From the above examples, the conclusions could be drawn that establishing a mixed simulation platform by Proteus, LabVIEW, MATLAB and Arduino on a computer can easily build all kinds of experiment models, in addition to carry the simulation and the test to the system. The mode of virtual experiment combined with practical experiment may not only enable students to master basic theory and skills of electronic technology curriculum, but also give full play to the initiative, and ultimately enhance the students' practical ability and scientific innovation consciousness. It plays a very important role in updating experiment teaching method, improving teaching quality of circuit courses, and optimizing the effect of teaching.

A Full-Featured Remote Laboratory For Hands-On Engineering Education

Timothy R. Pearson
Raptor Engineering
Belvidere, United States
tpearson@raptorengineeringinc.com

Abstract—***This work-in-progress paper briefly describes the uLab, a new method and framework for remote hardware design laboratories, which uses Linux and FOSS to provide real-time design and debug services to students over standard RDP channels. A secure, encrypted, plugin-based remote laboratory framework allows customization of programming and debug/test services to match physical laboratory resources. Industry standard technologies such as LDAP and Kerberos are utilized to ensure scalability, security, and ease of management. Emphasis is placed on direct access to real hardware, with the normal array of simulation tools and design software also being provided. In contrast with many of the remote laboratories currently in existence, this system places strong emphasis on direct, long-duration access to real, physical hardware for non-trivial design and evaluation tasks. In order to achieve this goal, secure, network-enabled hardware "pods" were created from inexpensive COTS components, and a blend of new and existing open-source software was used to connect with the overall laboratory framework. Hardware-design software and tools, including the software for physical hardware access, are preloaded and made available within the desktop session, allowing students to log in and start working almost immediately.***

Index Terms—**Client-server system, cost effective, engineering education, hardware-access pods, hardware design, Internet access, Kerberos realm, remote laboratory access, TDE, uLab, Universal Laboratory**

I. Introduction

A typical hardware design laboratory consists of several workstations and associated hardware in an access-controlled room with rigidly scheduled laboratory dates and times. This laboratory model inherently presents several drawbacks. One of the largest issues with this type of laboratory is the low average utilization ratio; there normally are large portions of each day when the laboratory is nearly or completely idle with no student access permitted. Another drawback is a relatively short window for laboratory sessions, during which the students are more focused on completing particular assignments within the allotted time frame than they are on learning vital concepts via semi-structured, hands-on interaction with design tools and hardware. Additionally, in many institutions, there are insufficient resources available to handle simultaneous usage by all students within a particular laboratory period; this forces multiple students to be assigned to a given workstation and further removes each student from hands-on interaction with the design software and physical hardware. Remote laboratories, such as the uLab system described in this paper, not only alleviate many of the drawbacks listed above, but also provide exciting new opportunities for students to interact with the laboratory hardware in a non-traditional manner.

In contrast to many of the remote laboratories currently in existence, the uLab places strong emphasis on direct, long-duration access to real, physical hardware for non-trivial design and evaluation tasks. In addition, most of the existing laboratories offering access to real, physical hardware, such as MIT's iLab[1], [2] or the VISIR system[3], require expensive, proprietary software packages, such as LabView, in order to function. By contrast, the new uLab laboratory system, which derives its name from the goal of providing a "Universal Laboratory," is not only open-source itself, but also is built entirely upon open-source software and, where possible, open hardware. This frees institutions from the requirement of purchasing expensive software licenses for each new hardware workspace, and allows them to, instead, focus on providing the best possible experience for their students. This characteristic also enables institutions to modify the uLab system to meet their particular needs rather than adjusting their curriculum to work around any limitations present in existing, closed-source software. A comparison of features between the new uLab system and selected existing laboratories is given in Table 1.

II. Design

The uLab system is comprised of three main components: infrastructure, terminal services, and hardware-access workspaces. The infrastructure component provides relatively mundane but essential services, such as Kerberos authentication, to the other two main components; the infrastructure component, therefore, plays a critical role in the provision of a unified laboratory experience. The terminal services component provides a full-featured remote desktop environment, complete with hardware design and simulation tools, to the end user over a standard Remote Desktop Protocol

(RDP) link. These terminal services leverage the provided Kerberos infrastructure to enable single sign-on functionality across all uLab components, presenting a more unified environment to the end user. Finally, the hardware-access workspaces component provides the end user with access to real, physical hardware. This component also leverages the Kerberos infrastructure for authentication and encryption of both client-server and server-server connections, thereby

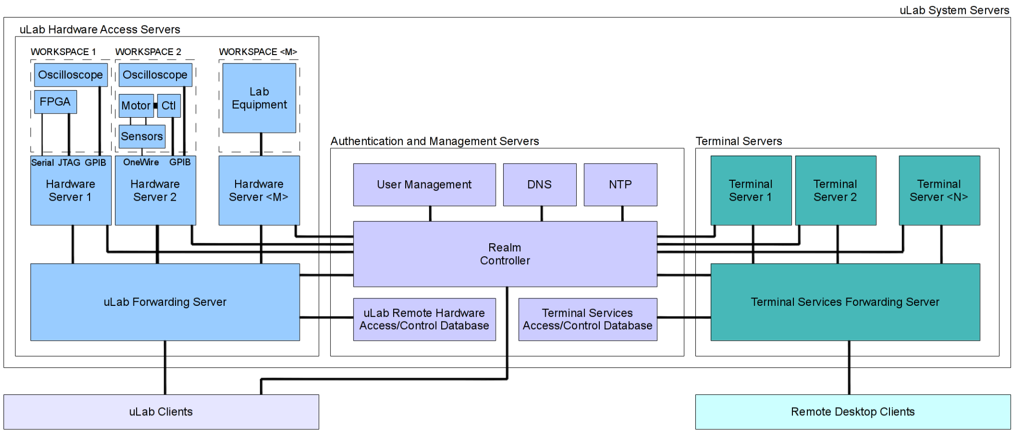

Fig. 1. Major components of a generic uLab system

maintaining the security of all hardware-access components. A diagram illustrating the relationships between major components in a typical uLab system is shown in Fig. 1.

A significant innovation within the uLab system is the use of self-contained hardware-access "pods." In the current uLab implementation, each pod consists of a Raspberry Pi ARM Single Board Computer (SBC) to which various hardware devices are connected. The Raspberry Pi runs one or more hardware-access daemons which interface with the attached hardware devices. These daemons make the attached hardware devices available to the main uLab system, and thus available to remote users via the uLab client software. Each hardware-access pod needs only 5V power and an Ethernet connection with access to the uLab arbiter in order to function, simplifying installation in most laboratory environments.

III. Future Work

Although the uLab system is currently installed and verified as fully operational, it has yet to be used by students within the framework of a standard academic course. This usage is expected by the fall semester of 2013, when the uLab at Northern Illinois University will be used in an undergraduate FPGA-based hardware design course. Because the laboratory does not currently provide signal generation or waveform capture equipment, future work may also include the addition of fully open-source and open-hardware waveform capture and signal generation equipment. This equipment is not essential for the original intended use of the uLab, but its addition would allow additional courses to take advantage of the uLab for distance education. This new hardware would become part of the existing FPGA-design hardware-access pods, maintaining the ease of pod installation described above.

IV. Conclusion

In this paper, a new method and framework for remote laboratory access has been introduced. Several current remote access laboratories were identified, along with their major features and limitations. The three main components of the new uLab system were discussed, and the concept of self-contained, network-attached hardware-access "pods" was introduced. Future work was discussed, along with intended usage of the new uLab system at Northern Illinois University.

Because a major goal of this research not only was to prove that a fully open-source remote laboratory can be built, but also to ensure the sustainability of such an environment for multiple institutions to use, all source code written for the uLab system has been released in a set of Git trees. As of this writing, project code repositories and detailed design documentation are available at http://ulab.trinitydesktop.org. In addition, a highly condensed set of installation instructions for a lab using the design detailed herein is available at the same location.

***Abstract*—In this study, we perform a device evaluation from trial device production (a computer simulation) using technology CAD (TCAD) in an integrated circuit consistent education system, which consists of a series of processes: system design, semiconductor process, trial device production, and device evaluation. By changing the device parameters (kinds of material, film thickness, impurities density) of the semiconductor process, the simulation can more closely approximate the electrical property of the desired target performance. By integrating the simulation technology using TCAD with each piece of knowledge mastered by the integrated circuit consistent education system, which is currently under development, we are able to construct an education system that can be mastered not only for an integrated circuit for information processing but also for the semiconductor process and the global perspective of the device structure in a power device. Furthermore, the possibility of applicability to a new device structure and process development is shown by means of a simulation using TCAD in virtual processing conditions.**

Keywords—education system; integrated circuit (IC); technology CAD (TCAD); power electronics; power device; SiC;

I. Introduction

As a result of the remarkable progress made in integrated circuit technology in recent years, integrated circuits have improved in terms of high speed, high performance and high integration. As a result of these advances, the importance of integrated circuit education is seen as an issue in electronic technical education. It is necessary to implement education through which one can learn about the technologies involved in the field, such as the circuit design of electronic devices, the semiconductor process, device structure, and the evaluations of electrical properties in the integrated circuits. It takes a lot of time and a great deal of money to learn the above, and the engineers and students studying integrated circuits face many difficulties. Furthermore, because the application domains of electronic devices are increased, it is becoming ever more difficult to respond to the research and technological development solely by possessing knowledge of individual electronic devices. In light of this, we are developing a consistent integrated circuit education system to solve the above difficulties, and to support the understanding of a global perspective on electronic devices. We believe this system will prove useful in raising the abilities of technical developers by providing an overview of integrated circuits as a whole, because this education system can be implemented as part of consistent education in the design, creation, and evaluation of an electronic device using a basic circuit.

Power electronic systems such as the smart city and the smart grid are being introduced into society, and an environment-friendly society is being constructed. In such a system, power devices play an important role, thus research on power devices and the education relevant to power devices are vital. However, because detailed information of the process, device structure, and circuits in general power devices is not disclosed, this presents a problem in education on how we deal with these matters.

II. Integrated Circuit Consistent Education System

A. *System Structure*

The overall design flow of our trial IC fabrication is illustrated in Fig. 1. On the first occasion, the training is exploratory in nature, but starting with the second session, training operations are documented. As a result, a manual is compiled and updated on every subsequent occasion. The trainees do not merely record their operations, but analyze them so as to improve the manual, which has a great educational effect.

In this study, AND circuits are considered, and a CMOS layout is designed aiming at a basic familiarization with practical modern information and technologies related to system LSI. Examples of layout design and fabricated MOSFET are given in Figs. 2 and3.

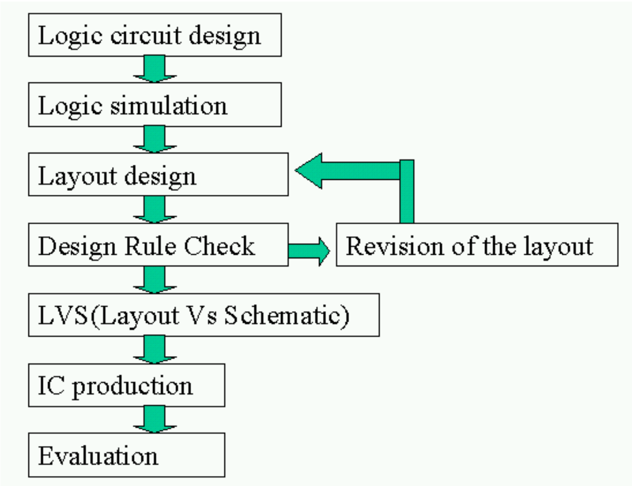

Figure 1. Design flow of integrated circuit production.

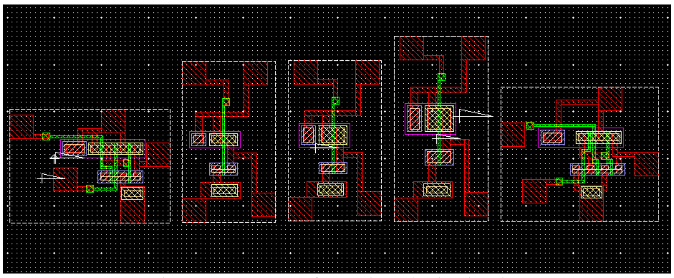

Figure 2. Layouts for various logic circuits.

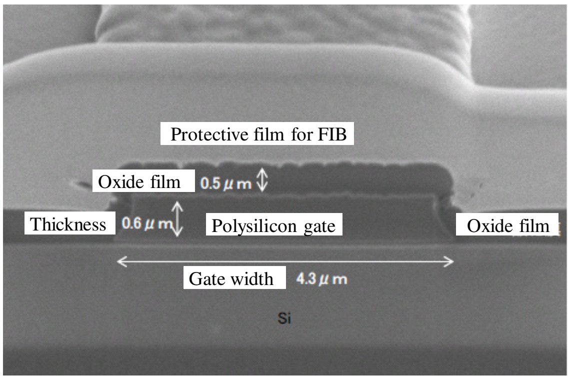

Figure 3. SEM photograph of cross-sectional view of the gate in a MOSFET.

III. Power device

The key device in power electronics technology is the power device. In power devices, the function (switching) that turns on and turns off the electric power, and the function (rectification) to cause current to flow in one direction are important. Therefore, power devices need a low-loss conduction capability, a low-loss switching capability, and good current interruption capability [1]. The electrical connection resistance leading to a power loss is proportional to the square of blocking voltage, and in inverse proportion to the third power of the dielectric breakdown strength. Therefore, materials with a high breakdown strength are required for power devices.

A. PowerMOSFET

A power MOSFET is MOSFET that can handle the comparatively high electric power used for a power converter. Because fast switching is possible, MOSFETs are used as the main parts, such as a DC-DC converter.

A power MOSFET has the source electrode on the substrate face side, and the drain electrode on the substrate back side, and the electrons serve as a carrier from the source and the drain, that is the electrons flow through the back surface from the substrate surface, therefore a current flow through the substrate surface from the substrate back surface (Fig. 4).

B. Necessity of Compound Semiconductors

There is demand for Si semiconductor devices with a higher performance. However, the current technology is beginning to approach the limit of the physical properties of Si, which is the material from Si semiconductor devices are made, and it is difficult to further increase performance. In order to overcome this limit, the development of semiconductor devices using SiC (silicon carbide) and GaN (gallium nitride) with physical property values that are different from Si is expected.

With wide-band-gap semiconductors such as SiC and GaN, low loss, high-speed switching, and high-temperature operation exceeding the limit of the physical property values of Si is expected. SiC is excellent with respect to the stability of the material at high temperature compared with GaN. Because their ability to be miniaturized, their low loss, their high efficiency, and because their nature allows for a simplification of cooling design, much is expected of SiC devices. If SiC devices are used in power devices, a more effective use of electrical energy can be expected.

C. Compound Semiconductor Properties

Table 1 shows the physical properties for 4H-SiC, GaN, and Si. 4H-SiC has a large band gap compared with other crystal structures (such as 6H and 3C) especially among SiC, and has a high heat resistance and high electron mobility (index of the electronic ease of moving), so its use reduces the resistance of devices, and is expected due to its physical, mechanical, and electrical properties to be used for semiconductors for next-generation electronic devices. Research and development are is being conducted from substrate growth through to device application by many research institutions and companies [1].

Because SiC has a high breakdown strength—about ten times than Si—it can lead to a reduction in the electrical connection resistance at the time of ON operation, and can lead to a reduction in power loss from devices. For this reason, the thickness of the drift layer holding the blocking voltage can be made thin—about one-tenth that of with Si power devices of the same element blocking voltage, and the impurity density can be designed to be high, as in unipolar devices, so ON resistance can be reduced by more than a one three-hundredth in theory (Fig. 4). Furthermore, when the thickness of the drift layer is the same in SiC and Si power device, this can realize a blocking voltage more than ten times that of Si devices.

Table 1 List of physical properties.

	4H-SiC	GaN	Si
Band Gap	3.26	3.39	1.12
Electron Mobility	1020	900	1400
Hole Mobility	115	150	600
Breakdown Strength	2.2×10^6	5.0×10^6	3.0×10^5
Thermal Conductivity	4.9	1.3	1.5
Dielectric Constant	9.7	9	11.8

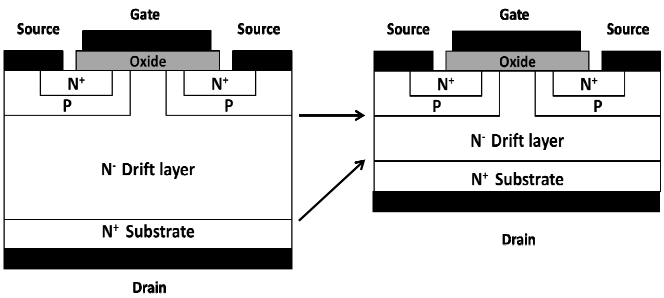

Figure 4. Comparison of structure of a power MOSFET in Si and SiC.

IV. Simulations of power device using TCAD

TCAD is a framework that integrates tools for the semiconductor process, device structures and the circuit simulators. It also can save time and costs because it can optimize a device design and a semiconductor process without actually producing a trial device. Moreover, by using TCAD, we can solve the partial differential equation of fundamental physics such as diffusion and transport equation, and can simulate the structural characteristic and electric operation of a device. Therefore, the semiconductor process and device simulation tools of TCAD can be applied to broad applications such as CMOS integrated circuits, memories, and power devices. In order to perform a simulation, it is necessary to consider the resistivity and the breakdown voltage that are related to the impurity concentration and the band gap.

Thus, we performed a device simulation of an SiC-MOSFET (power MOSFET), which a power device that uses TCAD. We verified that an SiC-MOSFET can handle a large current at high voltage from the simulation results of electrical characteristics results in Fig. 5. Furthermore, by optimizing device parameters with simulations, we were able to deepen the understanding of power devices.

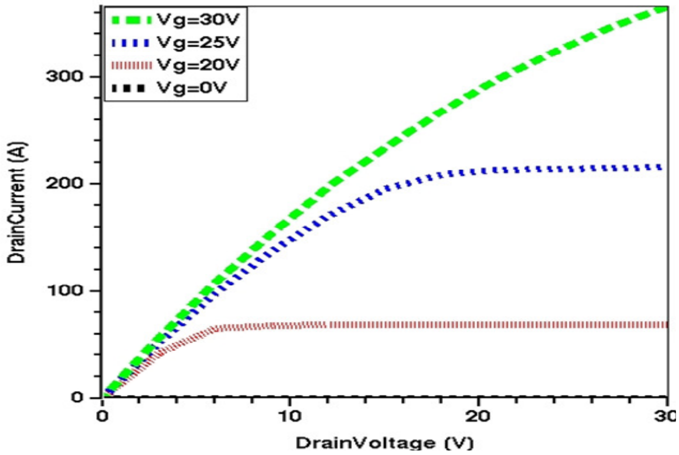

Figure 5. I-V characteristics of SiC-MOSFET (simulation).

After designing a device structure for power electronics, we verified it by using basic knowledge such as that on solid state electronics and the properties of materials. We then described the parameters of the device structure and performed a TCAD simulation, which enabled us to obtain basic data such as the electrical properties of the device. We were able to construct these consistent systems as an education system aimed at elementary engineering education.

This educational system makes it possible to provide education on making a comparison of the width of the depletion layer, resistivity and breakdown voltage that simulated a rudimentary device structure. We consider that the developed system will prove to be useful in the general education of students and engineers in the future.

V. Conclusion

In this research, we performed a device evaluation from trial device production using TCAD in an integrated circuit consistent education system. By integrating the simulation technologies using TCAD, we were able to construct an educational system to learn the whole picture of the structure and the semiconductor processes of power devices as well as integrated circuit devices for information processing. Furthermore, the possibility of applicability to a new device structure and process development was shown by conducting a simulation using TCAD in non-actual process conditions.

Java Tools for Teaching OFDM Principles in Undergraduate Courses

Sai Zhang, Mahesh K. Banavar, Andreas Spanias, Cihan Tepedelenlioglu, Xue Zhang
SenSIP Center, School of ECEE, Arizona State University, Tempe, AZ
szhang98@asu.edu, maheshkb@asu.edu, spanias@asu.edu, cihan@asu.edu, xzhan154@asu.edu

***Abstract*—In this paper, we describe a new set of software functions and associated exercises that can be used for teaching orthogonal frequency division multiplexing (OFDM) concepts in undergraduate DSP and communications courses. These tools can be used to simulate, visualize, and analyze the performance and behavior of OFDM systems by considering different input signals and communication channels. OFDM is a compelling paradigm because of its utility in WiFi and LTE. It is also a good demonstration of the use of the FFT in a communication system. We have developed the proposed set of functions as a part of the Java-DSP (J-DSP) visual programming environment. The functions can be used in undergraduate DSP and communications courses, in order to demonstrate to students, the application of DSP concepts in a communication system, as well as concepts such as FIR filter design, properties of the DFT matrix, random signals, and circular effects.**

Keywords—orthogonal frequency division multiplexing (OFDM); modulation; FFT; channel; noise

I. Introduction

There is a need to present real-life scenarios and applications for several physical and mathematical principles taught in STEM courses. In particular, the undergraduate courses on signal processing and communications are mathematically rigorous, and students are often unable to relate those concepts to practical engineering systems. Teaching the design of an OFDM system for communications can be an ideal methodology to bridge this gap. In addition to being an interesting paradigm for teaching DSP concepts, OFDM systems find widespread use in several standards for technologies such as 4G communications, digital audio/video broadcasting, ADSL, WLAN, and WiFi.

In order to teach principles of DSP and communications in undergraduate courses, the freely accessible online simulation software Java-DSP (J-DSP) (Fig. 1) was selected as the host environment. J-DSP is being used for education and research in different areas of signal processing and communications [1-4]. Simulations in J-DSP can be performed by simply placing and connecting blocks that correspond to different signal processing functions. As a result, using J-DSP requires little programming or coding experience. The intuitive interface allows for visualization of DSP concepts and students can focus more on understanding the system.

In this paper, we describe the orthogonal frequency division multiplexing (OFDM) system [5], and related function modules.

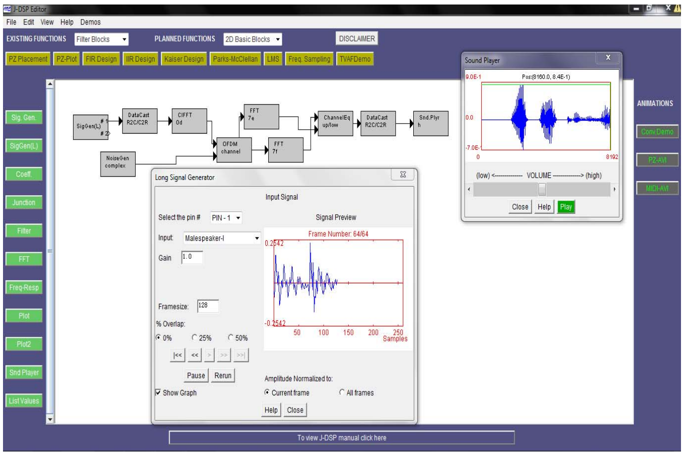

Fig. 1. Example of an OFDM simulation in J-DSP.

We will describe laboratory exercises, which are comprised of basic simulations for understanding frequency domain processing. By simulating an OFDM system using the proposed functions, students will have a better understanding of basic DSP concepts such as FIR filter design, FFT/IFFT, properties of the DFT matrix, convolution, circular effects, and random signals.

The rest of this paper is organized as follows. First, a brief description of the OFDM system is given in Section II. In Section III, we present the modules designed for the OFDM system in J-DSP. In Section IV, an exercise of the OFDM system and the analysis of the system with different parameters are shown. Assessment results are summarized in Section V, and concluding remarks are presented in Section VI.

II. OFDM Principles

We choose OFDM because of its utility as a modulation/multiplexing system in modern communication systems, including compelling LTE and WiFi applications. OFDM shows students how the IFFT is used as a modulator. It also exposes students to channel modeling, fast deconvolution, DFT matrix properties, channel noise and circular effects.

Mobile radio communications are generally subject to multipath propagation [5, 6]. The received signal will therefore be a combination of several distinguishable signals and the channel can be modeled as a finite-length impulse response (FIR) filter, and the process of data transmission over the channel can be represented as a convolution sum of the

Fig. 2. Signal flow diagram for the OFDM system.

transmitted signal and the filter coefficients. OFDM is one method that can be used to mitigate the effect of such multipath channels. In an OFDM system, an IFFT of the input frequency domain signal is first performed as subcarrier modulation. Then, the process of adding the cyclic prefix, filtering by the channel (linear convolution) and finally removing the cyclic prefix simulates circular convolution. By taking the FFT of the received signal, the data is transformed into frequency domain. The basic model of the OFDM system is shown in Fig. 2, and basic principles of the corresponding process can be found in [6-8].

III. OFDM Modules In J-DSP

As shown in Fig. 3, we have developed several functions that are designed for the simulation for OFDM systems. By using this Java tool, we will be able to introduce students to the basics of OFDM and enhance their understanding of the basic principles of signal processing and communications [9].

In Fig. 3(a), the process of OFDM is captured in the OFDM simulation shown in J-DSP. Using the *SigGen(L)* block, an audio signal is generated and segmented into frames for further processing. The signal is first passed though the *IFFT* block. The *OFDM* block (Fig. 3(f)), which is next, adds a cyclic prefix, simulates the channel, and then removes the cyclic prefix. The length of the cyclic prefix, as well as the length of the channel can be provided by the users. Additionally, the users can also select between randomly generated channel coefficients (Fig. 3(f)), or set their own values for the filter coefficients. The users also have the option of adding noise to the system using the *Complex Noise Generator* block (Fig. 3(e)).The *OFDM* block is followed by the *FFT* block to transform the signal back into the frequency domain. Finally channel equalization or channel deconvolution is achieved by dividing the FFT output by the frequency response of the channel. The *Channel Equalization* block is shown in (Fig. 3(c)).

In the following subsections, we will present an overview of the modules and functions developed for simulating OFDM in J-DSP.

A. The OFDM Module

The *OFDM* block (Fig. 3(f)) performs the processes of adding the cyclic prefix, filtering using a FIR filter, adding the transmission noise, and removing the cyclic prefix.

The channels are modeled as FIR filters of a given length. The filter coefficients can be Gaussian distributed or user defined. The block also has a second input pin for the channel noise that users can feed into the system.

In this block, users can define parameters for the FIR filter, the length of the cyclic prefix, frame size, and channel filter coefficients.

B. Complex Noise Module

Using the *Complex Noise* block (Fig. 3(e)), complex-valued random signals (Gaussian, Uniform or Rayleigh) can be generated, and added to the signal as noise, as an input to the *OFDM* block.

In the *Complex Noise* block, users need to set the noise type, signal length, and the mean and variance of the noise.

C. Channel Equalizer

In the *Channel Equalizer* block (Fig. 3(c)), the output of the FFT is fed into the upper pin and the FFT of the FIR filter coefficients (frequency response) is fed into the lower pin of the block. The block performs element-by-element division of the FFT of the signal by the channel frequency response to achieve deconvolution in time.

D. Other Modules

Other modules that are used in the simulation of the OFDM system include the *FFT* block and the *IFFT* block, which have been previously developed in JDSP [4].

IV. Sample Exercises

In this section, some parts of an exercise developed for the OFDM system using the modules described in the previous section are described. The exercise can be used to introduce the OFDM system to the undergraduate students in signal processing and communication courses. In the exercise, by building an OFDM system, students will be able to relate the concepts learned in undergraduate courses to the real applications. The exercise helps students relate the concepts learned in STEM courses including the FFT/IFFT operations, properties of the DFT matrix, random signals, FIR filters, circular effects, convolution, and random processes. In what follows, a brief description of the exercise will be given.

In the first part of the exercise, a simulation model for the OFDM system is introduced to the students. System parameters including cyclic prefix length, channel coefficients, input signal, and noise type can be modified in the simulation. By comparing the output signal with the input signal, the OFDM system is analyzed. The simulation introduces the concept of cyclic prefix and transmissions over a wireless multipath channel to the students. In the second part of the exercise, students modify the cyclic prefix length and the order of the FIR filter to study the effects of the cyclic prefix on the performance of the system. In this way, students can learn that in OFDM, the cyclic prefix should be at least as long as the order of the filter. In the third part of the exercise, students build an audio processing model using the OFDM system. In the simulation, an 8192-sample speech signal is generated in the *SigGen(L)* block. The signal is processed frame-by-frame with 128 samples in each frame and a total of 64 frames, with no overlap between frames. Noise is introduced into the system to simulate a noisy channel. The *Sound Player* block provides students with a graphical view of the audio signal and students can also listen to the output audio signal and draw conclusions about the performance of the system.

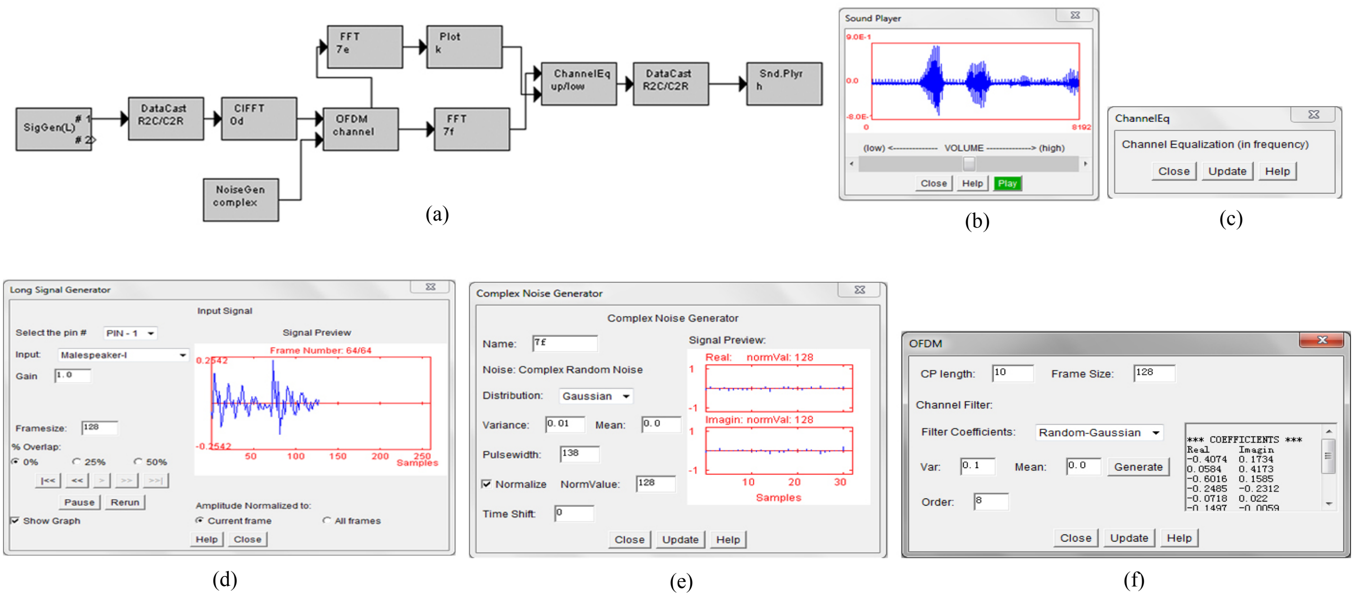

Fig. 3. OFDM simulation in J-DSP, and related blocks.

V. ASSESSMENT RESULTS

Preliminary assessments for the effectiveness of JDSP in DSP and communications education have been conducted [4, 9]. The results show the effectiveness of using JDSP in the classroom environment and the benefits of using JDSP in undergraduate DSP and communications classes. A workshop for signal processing and communications graduate and undergraduate students will be conducted for testing the OFDM system simulation in J-DSP and assessment results will be collected. The assessment questions are based on the OFDM exercise described in Section IV. Questions that are related to the performance of the system due to different noise parameters, channel coefficients, and effects of the cyclic prefix are asked. Some questions about the general design of the modules and suggestions for improvement of the software will also be solicited. Detailed assessment results will be presented at the conference.

VI. CONCLUSIONS

In this paper, we described the OFDM system simulation using the free web-based online Java tool J-DSP. The blocks developed can be combined to create a complete OFDM system. The system will perform the functions of IFFT, addition of a cyclic prefix, channel filtering, removal of the cyclic prefix, and an FFT, all components of an OFDM system. The simulation can also include features for adding channel noise, and for channel deconvolution. Using these blocks, students can learn the concepts of IFFT-based modulation, properties of the DFT matrix, convolution and circular effects, and noise processes and statistics.

Education for STEM courses can greatly benefit from the J-DSP OFDM modules. Students can relate the basic concepts with real applications, using the JDSP-based simulations. Since using J-DSP requires no coding background, students with limited programming ability or students from areas outside engineering can also perform the OFDM simulations.

ACKNOWLEDGMENTS

The Java-DSP project was funded in part by NSF TUES program grant DUE 0089075. The authors were also supported in part by the SenSIP Center, School of ECEE, Arizona State University.

Developing a New Advanced Microcontrollers Course as a part of Embedded Systems Curriculum

Vignesh Subbian, Fred. R. Beyette Jr.
Department of Electrical Engineering and Computing Systems
University of Cincinnati
Cincinnati, OH.

***Abstract*— This paper presents our experiences in developing a new advanced microcontrollers course within the Department of Electrical Engineering and Computing Systems at the University of Cincinnati (UC). This course was developed and offered for the first time in Spring 2013 to undergraduate seniors and first-year graduate students in electrical and computer engineering. It is also open to interested students in other relevant science and engineering programs. The course aims at providing advanced skills in designing and developing microcontroller-based embedded systems. It adopts an instruction model that integrates active learning techniques with in-class lectures and laboratory projects. The paper elaborates on the course structure and schedule, pedagogical techniques used in the course, and student feedback results. It also explains how this course fits in to the existing embedded systems curriculum at UC.**

Keywords— course development; embedded systems; interdisciplinary education; microcontrollers

I. INTRODUCTION

Instruction in embedded systems is multifaceted and multidisciplinary. First, embedded computing systems are designed and built through different levels of abstraction (hardware, system software and application). Second, it involves concepts from multiple disciplines that include, but not limited to electronics, computer science, software engineering, and control theory [1]. Most importantly, the field has pervaded into a myriad of application domains, and the design approaches are different in each domain. Hence, from a pedagogical point of view, there are a number of considerations that influence instructional design in advanced embedded systems namely, abstraction layers, application domains, and breadth of concepts.

The objective of this paper is to present experiences from developing and teaching a new advanced microcontrollers course, *EECE 6038C – Advanced Microsystem Design*, that primarily focuses on hardware peripherals and interfacing, and developing microcontroller-based solutions to application-specific requirements. This class is intended to supplement introductory embedded system design courses and provide specific expertise in high-level programming (rather than assembly language programming) to integrate standard input/output hardware using low-cost and high performance microcontrollers.

II. ADVANCED EMBEDDED SYSTEMS CURRICULUM

In addition to an introductory microcontrollers course, there are three courses that form an integral part of the advanced embedded systems curriculum at UC. Table I shows an overview of those core courses.

- *EECE 6017C - Embedded Systems* is a comprehensive embedded/real-time system design and development course that is open to seniors and graduate students in applied sciences and engineering programs. This course was recently redesigned and expanded to facilitate interdisciplinary instruction in advanced embedded and real-time systems [2]. This course introduces several hardware/software concepts with major emphasis to software modeling for embedded systems, prototyping using FPGAs, and real-time operating systems.
- *EECE 6015C – Instrumentation and Industrial Control* focuses specifically on designing systems for industrial automation and control. It covers topics related to selection and utilization of analog, digital and piezoelectric sensors in electric energy, power system, manufacturing and other industrial plants. Students learn how to connect these sensors to digital controllers and program the controllers for electrometrical device monitoring and protection.
- *EECE 6038C – Advanced Microsystem Design* (See Section III).

TABLE I. CORE COURSES IN EMBEDDED SYSTEMS CURRICULUM

III. EECE 6038C Course Design

This section explains the course design and structure of *EECE 6038C – Advanced Microsystem Design*, in detail. This course was offered for the first time in Spring 2013 at UC.

A. Learning Objectives

The ABET learning outcomes for this course are as follows:

- Identify major architectural components of a PIC® microcontroller and understand their purpose (a, k).
- Construct and demonstrate microcontroller-based systems that integrate standard input/output hardware and custom software to address common embedded systems tasks (a, b, c, e, g, k).
- Demonstrate using a commonly available CAD environment the ability to write, debug, simulate, and test programs for the PIC® microprocessor family (a, c, e, g, k)
- Design, verify and document a microcontroller-based solution to a general problem statement that utilizes common architectural features of the PIC microcontroller that may include digital/analog inputs, digital outputs, counter/timers, and interrupt driven program flow (a, b, c, e, g, k).

B. Hardware and Development Tools

The course is based on low-cost16-bit PIC microcontrollers (PIC24F family of microcontrollers or dsPIC33 family of digital signal controllers) available from Microchip Inc. Students may use a development or demonstration board such as the Explorer 16 development board but are not required. Some laboratory assignments use a PICtail™ Plus daughter boards for audio/video interfacing and I/O. MPLAB® X Integrated Development Environment (IDE) and MPLAB-XC C compiler are used to develop and debug applications. Both the IDE and the compiler are freely available for all commonly available operating systems.

C. Topics

The course starts with a review of basic microcontroller concepts, programming with embedded C, overview of microcontroller architecture (16-bit PIC® microcontroller family), interrupts and memory model. Next, we explore concepts related to interacting with external devices including synchronous and asynchronous serial interface, LCD displays, and devices that produce analog signals. Finally, from these basic interfacing concepts, we then explore concepts related to connecting with standard interfaces such as PS/2 and USB, producing composite video, and managing larger storage devices such as SD and MMC storage cards [3].

D. Laboratory Projects

Eight laboratory projects were assigned to provide hands-on experience in microcontroller-based development, peripheral interfacing, and embedded-C programming. Table II gives a summary of laboratory assignments and their objectives. It also lists the cognitive level of learning based on Bloom's Taxonomy.

TABLE II. Summary of Laboratory Assignments and Objectives

Lab #	Lab Objective	*BT Level
1	a) To get the development environment set-up and then, use it to acclimatize to the PIC24F microcontroller and relevant CAD tools. b) To review interrupt mechanism and memory allocation techniques.	K
2	- To demonstrate knowledge of using the Serial Peripheral Interface (SPI) that enables synchronous serial communication with an EEPROM device.	A
3	- To understand the UART interface that enables asynchronous communication with a serial port.	A
4	- To use the Parallel Master Port (PMP) to communicate with an LCD display module.	A
5	a) To learn how to use a 10-bit ADC module to read and process analog signals. b) To combine techniques from lab #1 and lab #4 to create a temperature sensing system.	S
6	a) To implement interfacing methods that can support connection of a PS/2 keyboard to the microcontroller. b) To test the PS/2 connection by allowing UART communication to a terminal emulator.	L
7	- To understand how a video card works and implement a simplified version of a video card that produces a standard composite video signal for a monochrome video display	L
8	a) To develop an understanding of i) how to interface the PIC demonstration board to an SD card, ii) how to interact with a FAT16 file structure, and iii) how to use the PWM functionality of PIC24 to create analog waveforms. b) To create and test a simple music player by integrating the concepts and techniques in 8a.	S
9	Final Project (See Section III E)	A, S, E

* *Bloom's Taxonomy of Cognitive Domain:* K-Knowledge, C-Comprehension, A-Application, L-Analysis, S-Synthesis, E-Evaluation.

E. Final Projects

The goal of the final project is two-fold. First, the project gives an opportunity to demonstrate the ability of students to utilize the skills and concepts learned in this course. Second, it also gives an opportunity to explore technologies related to the core content of advanced microcontrollers. Students define their own design project that must use a 16-bit microcontroller from the PIC24F family of microcontrollers or the dsPIC33 family of digital signal controllers. Students may use custom design printed circuit boards for either daughter boards or full implementation.

F. Instructional Methods

The course is designed to include several methods of instruction: 1) Traditional lectures, 2) Collaborative learning through in-class discussions, and 3) Participatory learning. The class meets thrice every week. The majority of learning in this course is through weekly laboratory assignments. Hence, at least one lecture is presented at the beginning of every week to cover concepts related to that week's laboratory assignment. The remaining class sessions in the week are used to facilitate discussions on concepts and problems related to the lab assignment.

A participatory session called *Unlecture* was held towards to end of the term. This is an informal discussion session that is primarily driven by participants (students). The goals of this session are: 1) To enable an open-ended discussion on the discipline of embedded systems, and gain insights on gaps between education and industry trends in the field of embedded/real-time systems, 2) To examine the potential of such participatory sessions as a pedagogical technique for future offerings of this course. The theme of the session was "Current Trends in Embedded Systems Design". A wide-ranging theme was chosen on purpose to encourage participation among students.

IV. Course Assessment

The first offering of the course received an enrollment of thirty five students from three majors – electrical engineering (24), computer engineering (10) and applied physics (1). Of the 35 students, 24 were undergraduate students and 11 were graduate students. Data and feedback presented in this section were collected through three surveys at periodic intervals during the semester (pre-class, mid-term, and final).

A. Project Proposals

A wide range of projects were proposed by students as a part of the course requirement. Fig.1. shows a categorical chart of various projects. Uncategorized projects include network-based designs, research projects, and custom circuit designs.

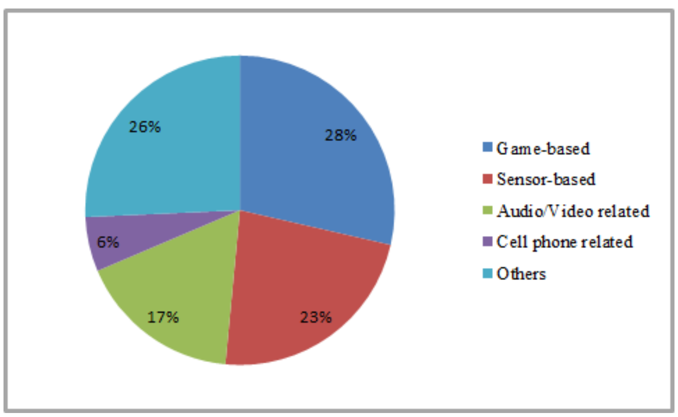

Fig. 1. Categorical chart of project proposals

B. Student Assessment

Students are assessed based on the following grade distribution: Weekly laboratory assignments (40%), Laboratory demonstrations (30%), Final project (25%), and In-class activities and participation (5%).

C. Student Feedback

Responses to course-specific questions are shown in Table III. The majority of students thought that the course was well-structured and informative. Most students found the laboratory assignments to be involved and challenging. However, there were some comments about lab assignments being less rigorous at the beginning of the term. The course was intentionally organized to be less intense at the beginning to allow students from different backgrounds familiarize with the design tools and course content.

The collaborative sessions received mostly positive reviews. Students felt that in-class discussions were a great way to collaborate on common problems related to the design environment. Also, there were specific comments about teaching methods being unique and different.

TABLE III. Responses to Course-Specific Questions

Course-specific question	Strongly disagree	Disagree	Neutral	Agree	Strongly agree
Increased my interest in microcontrollers	3%	7%	3%	56%	31%
Developed skills that will help in seeking employment	3%	3%	14%	60%	20%
Final project increased my understanding of several concepts that were covered in the class	0%	0%	3%	50%	47%
Rate your expertise in microcontroller-based design and programming*	5.93 (Pre-class) →7.07(Mid-term) →7.83 (Final)				

* Rating Scale: 1 to 10 (1 being least, 10 being highest); Values are average of rating responses.

V. Discussion and Ongoing Work

It can be seen from Table III that the average expertise level in microcontroller-based design and programming has significantly increased during the course. It can also be observed that the course project has improved students' confidence levels in their ability to demonstrate such skills after the completion of the final project and the course itself.

The first trial run of the *Unlecture* session gave a better understanding of how this technique can actually be used to deliver technical content. Based on the session outcomes, the technique was formally modeled, and is currently being deployed in an upper-level computer engineering course. Overall, the advanced microcontrollers course (*EECE-6038C*) was successful in integrating and formulating active learning techniques with traditional lectures and laboratory projects. Also, the first offering has helped in streamlining and creating a feasible set of laboratory assignments and other course content. As a part of next steps, the following topics are being expanded or added to the course catalog: PCB design, digital signal processing using dsPIC, bluetooth and ethernet interfacing, and advanced file management.

Engaging Students for Success in Calculus with Online Learning Forums

Angela Minichiello

chris.hailey@usu.edu

***Abstract*— It is said that we face an engineering "talent crisis" [1]; the United States is failing to keep pace in educating a highly skilled and diverse engineering workforce. Emphasis is currently placed on recruitment and retention of underrepresented minorities. Newer distance-delivered programs seek participation of non-traditional and geographically underrepresented students.**

With expansion of educational offerings in engineering, one issue that emerges is student attrition during the first two years. It is suggested [2-4] that success in first year calculus reliably predicts persistence in engineering. To increase retention, new strategies are needed. Effective interventions may have the most impact if employed within the first year calculus sequence. Pedagogies that support traditional classroom learning as well as hybrid instruction and distance education offer the greatest transformative potential.

This work-in-progress paper describes research underway to evaluate the use of online learning forums during first year calculus. A freely available, wiki-based online learning forum is employed during a mixed-methods study. The study is conducted within sequential calculus courses distance-delivered across two academic years. Qualitative and quantitative data are used to evaluate the effect of forum use on student achievement, engagement and attitudes. A usage model is developed to disseminate within the STEM education community.

Keywords—distance education, engineering retention, social learning theory, mixed methods research

I. INTRODUCTION

A heightened focus on retention in engineering is evidenced in a number of research studies conducted to evaluate innovations in engineering mathematics instruction. These studies investigated the use of structured experiences [5], new curricula [6] and targeted interventions [7, 8] to improve retention. Other studies [2-4] have reported strong correlations between academic performance in first year calculus and attainment of an undergraduate engineering degree. A recent longitudinal study [2] indicated that success, measured solely by the grade achieved in *first semester* college mathematics and independent of secondary mathematics preparation or achievement, is itself a reliable predictor of retention among engineering undergraduates.

Recent data for the 2009-2011 academic years, gathered locally in conjunction with the Utah State University (USU) Advising Center, show that an average of 28% of USU engineering students enrolled in traditional (face-to-face) sections of Calculus I either withdrew from or failed the course (final course grade of W, D or F). This rate was nearly double - *an attrition rate of 52%* - during the same time frame for the engineering students enrolled in distance delivered (synchronous broadcast) sections of Calculus I.

Additional data, gathered in conjunction with the USU Office of Analysis, Assessment, and Accreditation from the same time period, indicate student satisfaction in the calculus sequence is lower for distance delivered than for traditional sections. During the 2009-2011 academic years, data from end of course student evaluations show that distance sections scored almost one full point lower (on a scale of 1-poor to 6-excellent) than traditional sections of Calculus I in ratings of instructor effectiveness (4.10 distance | 4.91 traditional) and overall quality of the course (3.96 distance | 4.90 traditional).

These data suggest that intervention strategies that target retention in calculus should not only focus on improving student academic achievement (knowledge and skills), but should also address affective outcomes such as student engagement and attitudes towards learning, the learning environment, available support, and the overall sense of learning community within the course. Researchers [9] have discussed that these are typical areas where students experience isolation, disconnectedness and dissatisfaction with the distance instruction. Thus, these are important areas to consider in designing interventions with a goal of improving retention.

II. ONLINE LEARNING FORUMS AS INTERVENTION

A. What are Online Learning Forums?

Online learning forums are discussion sites accessed via the internet by participants in a course. Online discussion sites allow individual learners to hold conversations with other individual learners, groups of learners, teaching assistants and instructors by posting text-based messages to the forum. Student access to a forum occurs asynchronously and apart from other synchronous learning sessions, meetings, or activities. Thus, despite their online nature, online learning forums are useful across the spectrum of educational delivery platforms (e.g. traditional, web-enhanced, online, etc.).

Support for this work is provided by the National Science Foundation under Award DUE 1245194. Any opinions, findings, conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

B. Theoretical Framework: Social Learning Theory

Social learning theory, as pioneered by Vygotsky, claims that learning is not simply "...an unfolding or maturation of pre-existing 'ideas'; on the contrary, it is the formation of such ideas-out of what originally was not an idea- in the course of socially meaningful activity" [10]. Online forums support important social influences on learning namely "competence" and "social" motivation to learn, "learner-friendly" formative assessment, and a community approach to learning [11].

1) Motivation: Student motivation is linked to learning achievement because the amount of time a student is willing to put into a subject is directly related to their motivation for learning the subject material. Competence motivation to learn decreases when learning "challenges" are either too easy or too difficult [11]. The goal of a learning forum is to provide enough timely feedback, whether from instructors, teaching assistants, or fellow students, so that students do not become frustrated and lose motivation for learning calculus and/or for pursuing engineering altogether.

Social motivation to learn increases when students perceive themselves to be helping others [11]. The online learning forum creates a virtual meeting place where students can meet online to share ideas and offer solutions that directly lead to learning. Thus, the benefits of the student as teacher paradigm can be realized even as students are geographically dispersed, studying alone during late night hours, or otherwise participating in distance education out of convenience. Moreover, use of the online forum can not only be adapted to differences in time and place between students and instructor, but also to differences in student learning styles and pace that are particularly prevalent among adult learners [12].

2) Formative Assessment: A system for continuous formative assessment is vital to promoting student learning and informing day-to-day instruction [11]. For pre-calculus high school seniors, researchers [13] found that frequent instructor interaction helped students to express and refine their level of mathematical understanding. The optimal occasion for formative assessment is during time of deep student engagement, usually during problem solving and homework preparation. Traditionally, instructor office hours have provided opportunity for this critical discourse to develop. With increasing numbers of non-traditional and working students and rising enrollment in distance education classes, physical attendance at instructor office hours is no longer feasible for many students. Thus, the availability of a 24/7 online forum that allows for more flexible instructor-student or student-student interaction could be transformative.

3) Community Approach to Learning: Learning is most effective *and* lasting when the environment is communal rather than punitive. In a true learning community, students are encouraged to attempt understanding, make mistakes, seek feedback, and revise their knowledge [11]. Creating a sociable learning community, however, can be difficult in classrooms when the subject matter is quantitative and presents "right" and "wrong" answers. Creating a true community for open discussion and problem solving may be easier to accomplish virtually, as students may sense some degree of anonymity and be more willing to ask questions or offer solutions online.

The growing popularity and common use of online social networking tools imply that students today may be more apt to converse in an online environments than in traditional classrooms. As evidence, researchers [14] have documented the growing use of "free, open, online, internet help forums" to learn mathematics. In these online mathematics forums, students voluntarily access help and communicate online anonymously with volunteers located throughout the world to get help on their homework and assignments.

III. Research Project

A. Description of the Research Project

1) Pilot Study: The researchers piloted Piazza in seven sophomore level engineering courses between Fall 2011 and Spring 2013. Six courses were small (5-14 students) and taught via synchronous video broadcast and one was large (>150 students) and taught traditionally (face-to-face). Students were surveyed to judge their use of and satisfaction with the forum. The results were overwhelmingly positive. Student responses in Fall 2011 and Spring 2012, 19/20 students reported that Piazza was at least somewhat effective in improving their learning and attitudes towards the course. Therefore, we hypothesize that use of the forum will improve both cogntive and affective student outcomes in calculus.

2) Quasi-experimental Study: In Fall 2013, we will implement the online learning forum as the treatment condition of a quasi experimental study conducted in distance delivered (via synchronous broadcast) sections of first year calculus across two academic years. Because random assignment of students is not feasible, a quasi-experimental nonequivalent control group design will be employed [15]. Assessment will measure the extent to which the online learning forum improves engineering student cognitive (academic achievement) outcomes as measured by quantitative data (student exam scores, post test results).

3) Student Surveys, Observation and Interviews: Student affective (engagement, attitudes, motivation) outcomes will be assessed and compared across both treatment and control groups of the quasi-experimental study using quantitative (end of course surveys) and qualitative (classroom observation, forum posts, artifact analysis, and targeted student interviews) data. Interviews will focus on students that fail or withdraw from the course. Quantitative and qualitative data will be used to develop a usage model to aid implementation of online learning forums througout the STEM education community.

4) Research Questions: Our research questions and associated assessment measures are:

1. How does student academic achievement vary with respect to participation in the forum?
(exam scores, artifact analysis)
2. How does student interest in and attitudes toward learning calculus vary with respect to participation in the forum?
(survey, observation, interviews)
3. How do students involve themselves in social interaction within the online forum?
(survey, observation, interviews)
4. What motivations increase participation by high achieving vs. low achieving students?
(survey, observation, interviews)
5. How can on-demand support be sustained over time?
(survey, observation, interviews)

B. Contribution of the Research Project

Researchers report a gap in the literature, particularly within undergraduate engineering education and the sciences, concerning “networked learning” [16], and the implementation of online forums [14]. The term “networked learning” is defined by the authors [16] as the use of information computer technology (e.g. asynchronous email and text messaging) to promote learning connections and directly fits the purpose and function of online learning forums described in this study. Therefore, there is potential for this project to break new ground in assessing the effects of online learning forums and in developing usage guidelines for dissemination throughout the STEM education community.

C. Choice of Online Learning Forum

We choose to implement Piazza [17], a freely available, wiki-based online learning forum. Wikis are collaborative “groupware” that enable geographically dispersed, “virtual” teams to write “peer-produced” documents using a only text editor and a web browser [18]. The wiki nature of Piazza is one of its most unique and compelling educational features. Wiki based forums stand in contrast to traditional online forums using threaded discussions because wikis allow participants to edit for both organization and content [18]. It has been suggested [19] that threaded discussions are problematic for education because they exhibit incoherence and a lack of convergence that prevents learners from seeing the main ideas of the discussion or interchange. Since topics in threaded discussions are organized historically rather than conceptually, threaded discussions make it difficult for learners to place information into the correct context or conceptual framework, a skill that is needed for deep understanding. Additionally, Piazza’s built-in equation editor and symbolic editing features make it an advantageous choice for STEM applications.

IV. SUMMARY

Results of this mixed-methods study will be useful in formally assessing the effects of online learning forums on student cognitive and affective outcomes in STEM education settings. Quantitative and qualitative data will guide the development of a usage model to facilitate the use of online forums throughout the STEM community. Data gathered will provide deep insights into the role(s) that virtual learning communities and the social aspects of learning play in STEM education, pointing toward new avenues for investigation.

***Abstract*—Along with the rapid development of computer and Internet technologies, efforts have been conducted to include design, development, and evaluation of computer applications for learning activities. Although extensive research has defined the use of computer applications in various disciplines, few studies have systematically investigated students' self-regulated learning skills while learning with an interactive learning module specifically in computer science education. The purposes of this study are to investigate high school students' computer self-efficacy, cognitive, and metacognitive strategies while students learn with the interactive learning modules and performing a mixed-methods study. Data collection included students' self-reports and traces of student activity. The quantitative analyses applicable to this study included descriptive and non-parametric statistics. Qualitative data were gathered from interactive learning module screen-captured videos and interview transcripts to support findings from quantitative data. The outcome of this study will inform policy makers, educators, researchers, developers, and others of the importance of a self-regulated learning perspective when designing instruction using an interactive learning module.**

Keywords—computer self-efficacy; interactive learning module; mixed-methods study; metacognitive strategies

I. Introduction

A common goal has been made between educators and policy makers to improve teaching of science, technology, engineering, and mathematics (STEM) subjects in the U.S. The calling for the improvement comes from the Committee on Highly Successful Schools or Programs in K-12 STEM Education, Board on Science Education, Board on Testing and Assessment, Division of Behavioral and Social Sciences and Education, National Research Council, and many others [e.g., 1, 2]. The concerns on STEM education are related to the U.S. competitiveness in the global economy. The National Academy of Sciences, National Academy of Engineering, and Institute of Medicine published *Rising above the Gathering Storm: Energizing and Employing America for a Brighter Economic Future* [3]. One of key recommendations suggested in this report is improving mathematics and science education in K-12 level in order to maintain the U.S. competitiveness.

Along with the rapid development of computer and Internet technologies, many studies have been conducted which include computer applications for learning activities. Tremendous effort has been made to design, develop, and evaluate computer-based learning environments for different purposes and areas, for example in chemistry, mathematics, and reading achievement [4-6]. Thus, there are many available definitions related to computer-based learning environment. Previous research suggests that an interactive learning module as part of computer-based learning environment can be used as a tool to provide responsive feedback and flexibility in accessing materials [7].

This study will focus on computer self-efficacy, cognitive, and metacognitive strategies while students learn with the Interactive Learning Modules (ILMs). The researchers use computer self-efficacy to understand students' background knowledge and perception of computer usage. Computer self-efficacy can be defined as personal judgment of capabilities to use computers in different situations [8, 9]. While cognitive strategies represent actions on a specific context (e.g., reading, working with computer, etc), metacognitive strategies are

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

represented by planning, monitoring, and regulating strategies related to the actions.

Previous research has suggested that college students' self-efficacy beliefs are strongly related to the use of cognitive and metacognitive strategies [10, 11]. In addition, at the junior high school level, the use of cognitive and metacognitive strategies was positively correlated with self-efficacy judgment [12]. Also, Compeau, Higgins, and Huff [8] found that computer self-efficacy increased computer usage in general. However, it is not yet clear how students' beliefs about their performance capabilities when using computers (i.e., computer self-efficacy) is related to cognitive and metacognitive strategies while learning with ILMs specifically at the high school level.

II. Purposes and Objectives

The purposes of this study are to investigate high school students' computer self-efficacy, cognitive, and metacognitive strategies in a self-regulated learning (SRL) framework while utilizing ILMs and performing a mixed-methods study. The researcher hypothesizes that computer self-efficacy is positively correlated with cognitive and metacognitive strategies while the students are engaged with ILMs. The metacognitive strategies in this study include planning, monitoring, and regulating strategies. Butler and Cartier's SRL model [13, 14] will be used as the framework for this study. The following objectives will frame and guide the research: (1) to investigate the relationship between students' computer self-efficacy and cognitive and metacognitive strategies while using ILMs; and (2) to investigate the relationship between students' cognitive and metacognitive strategies while using ILMs.

III. Research Method

A. Participant of the Study

A high school student classroom is ideal for evaluation of the ILMs. In a college classroom, the modules tend to be used differently. Because time is more closely monitored and because most college classrooms do not have individual computers, on a college campus, ILMs are primarily used as teacher demonstration or as part of homework exercises. Students at School X who take the Career and Technical Educational course (i.e., Programming 1A and Math 1) and students at School Y who enrolled in a physics class in spring 2013 were invited in this study. One hundred and thirteen students participated in this study. Student participants were informed of the purpose and methods of the project in which they participated.

B. Instrumentation

1) Demographic questionnaire: The questionnaire includes: gender, age, ethnicity, class, GPA, the highest math class already taken, and whether they are considering majoring in a field of engineering, technology, or computer science in college.

2) CSE questionnaire: The researcher assessed students' computer self-efficacy (CSE) by modifying the work of Durndell, Haag, and Laithwaite [15]; the work was based on Torkzadeh and Koufteros [16] and Murphy, Coover, and Owen [17]. The CSE questionnaire has very high internal reliability scores. The Cronbach's Alpha coefficients of Beginning Skills, Advanced Skills, File and Software Skills, and Mainframe Computer Skills are .93, 88, .90, and 95, respectively. The questionnaire responses range from 1 to 5 (i.e., 1 = *not at all true of me*, and 5 = *very true of me*).

3) SRCBL questionnaire: The development of a SRCBL questionnaire contextualized to the interactive learning module is required. Schunk [18] argued that SRL skills and strategies appear to be "highly context dependent." The researcher modified an instrument developed by Lawanto [19] using Butler and Cartier's SRL framework and focusing on cognitive and metacognitive dimensions of the framework. The 21-item SRCBL questionnaire consists of four components: Planning, Cognitive, Monitoring, and Regulating Strategies. Measurement scales of the SRCBL Questionnaire responses will range from 1 to 4 (i.e., 1 = *almost never*, 2 = *sometimes*, 3 = *often*, and 4 = *almost always*).

C. Material: Interactive Learning Modules

Interactive Learning Module (ILM) is a type of computer-based instruction developed at Department of Computer Science, Utah State University which reinforces computing ideas by utilizing immediate feedback and user manipulation of computer science models [20]. This study focuses on three modules called the Boolean Logic, Minimum Spanning Tree, and Modeling Using Graphs. These ILMs were chosen for this study because of their correlation to the high school curriculum. For example, in the Boolean logic ILM, students perform a variety of activities which include predicting the result of Boolean operations and experimenting with simplifications of expressions.

D. Data Collection and Analysis Procedures

In this paper, the researcher only reported the data collection and analysis procedures without any finding because the analysis could not be completed by the time this paper was submitted. Data collection was conducted in a classroom or lab equipped with Internet ready computers. Students filled in the surveys online and learned with the interactive learning modules that were also available online. The students were not required to use username and password to access the online survey and the modules. Instead, they were given an ID code to protect their privacy. The students were also given an orientation to the research protocol.

As explained earlier, data collection included quantitative and qualitative data. The researcher gathered quantitative data from CSE and SRCBL questionnaires and qualitative data from screen-captured videos and interviews. Participants were expected to complete an online CSE questionnaire preceded by a short demographic survey on the first day of the data collection. After completing the questionnaires on the first day, participants were asked to use the learning modules and then complete the SRCBL on the last day.

Purposive sampling was used to investigate students' cognitive and metacognitive strategies with high and low CSE. The sampling process was conducted by categorizing the participants based on the CSE level. Students' CSE levels among the participants were identified by applying cluster analysis. The results were used in the selection for screen-captured videos and interviews. In this study, the screen-capture tool captured all students' activities while using the ILM. Data regarding ILM navigation were gathered in selected class sessions in which the learning modules were investigated. In addition, the recorded interview sessions assessed students' perception about their learning strategies. The questions asked the students on how they used features of the modules, arrived at solutions in a learning exercise and problem-solve, and what strategies they used. Different questions were asked to selected participants, depending on how the researcher interpreted the findings from questionnaires and ILM screen-captured videos related to specific students.

Descriptive statistics will be applied to analyze quantitative data from the demographic, CSE, and SRCBL questionnaires. Given the likelihood of a relatively small number of students, the researcher will also apply nonparametric statistics in order to conduct correlation and significance tests (i.e., Spearman and Wilcoxon tests). Target students for ILM screen-capture analysis and audio-taped interview sessions were chosen based on the results of the cluster analysis. Two graduate students, who have already taken the cognition class, will code the sequence of events, and categorize the sequence of events into relevant cognitive and metacognitive strategies. Interview transcripts will be segmented, coded, and analyzed.

IV. Expected Outcomes

The outcome of this study will inform policy makers, educators, researchers, developers, and others of the importance of a self-regulated learning perspective when designing instruction using an interactive learning module. The results will also identify the relationships between (1) CSE and cognitive strategies, and (2) CSE and metacognitive strategies while using the ILMs, and benefit researchers who are interested in developing methodologically suite of tools for an interactive learning module specifically in computer science context. The results of this study will be presented at the 2013 FIE conference.

***Abstract*—Online courses have the promise of extending the horizons of today's academic landscape with their cost-effective and convenient model compared to traditional learning environments. Despite the promising nature of the learning model, there continue to be several challenges that hinder learning, one of which is lack of instructor presence. This study aims at understanding the effect of instructor presence on student satisfaction in an online setting of a course in engineering.**

We conducted a student-centered pilot experiment to assess engineering students' perceptions of two modes of online mini-lectures: the first, a presentation with the instructor appearing in window, created using an off-the-shelf screen-capture software; the second, a presentation with the instructor overlaid in the slides created using recent visual communication technology that overlays the video of the instructor without any background images or outline boxes. The instructor was the same in both the presentations. Our focus here is on the following factors: 1. Comparing overall student satisfaction after watching the two modes; 2. Comparing the perceived non-verbal immediacy factors of the instructor; and, 3. Comparing the preference of video mode for future online courses.

Preliminary results suggest a preference of the video mode with the instructor overlaid over that with the instructor in a box. The effect sizes of the differences in overall satisfaction between the experimental groups and their perceived levels of non-verbal immediacy factors when viewing the online lecture in the two modes are encouraging enough to pursue more longitudinal studies with the set-up.

I. Introduction

The advent of online learning has extended the horizons of today's academic landscape. The new model is being promoted as being more cost-effective and convenient than traditional learning environments while providing educational opportunities for larger communities of learners regardless of geographic location and independent of time. Despite the promising nature of the learning model, there continue to be several challenges that hinder learning in such environments.

One of the oft-cited disadvantages of the new learning model is its being not as effective as traditional classroom learning owing to the lack of face to face interactions. Several case studies [1], [2] have cited instances where students felt disconnected from others in this type of learning environment, citing lack of facial expressions and other features common to a traditional classroom environment. Unfortunately, until recently there have been very few ways for an instructor to create this sense of instructor presence in the online learning environment aside from a handful of interactions in online discussion environments and in the pre-recorded video lectures. In this study, we explore how different visual modes that incorporate instructor presence in an online lecture are perceived differently by students.

II. Background

Research in psychology, communication and online learning reveal that learners need to have a sense of relatedness to their instructors and that this sense of relatedness is often communicated through information that is superfluous to the learning objectives [3]. A recurring finding of empirical studies on motivational agents in the context of embodied interfaces is that these agents make the user experience more engaging (a phenomenon termed persona effect) - users find that the visual and auditory presence of a virtual person renders these interactions more human-like and more social (e.g. [4], [5]). Moreover, research suggests that pedagogical agents have a supportive role when learners are working with complex tasks [6] and that in multimedia learning environments they increased both learners' retention and transfer scores [7].

Research in nonverbal communication has identified a number of nonverbal cues (nonverbal immediacy), that include bodily behaviors such as proximity, gaze, gestures, posture, facial expressions, and touching as well as vocal behaviors such as vocal tone and expressions, as critical components of human to human communication [8], [9]. That nonverbal immediacy behaviors positively affect student motivation, participation and attendance, affective and cognitive learning in classroom scenarios has been well studied [10], [11]. It has also been found that these positive effects prevail in large classes [12], and under high workload demands [13]. However, only recently is the use of non-verbal modalities being harnessed in virtual communication scenarios (e.g, access to the course instructor teaching in a window at the corner of the presentation screen in a video lecture). It is likely, though, that increased amounts of non-verbal communication in a video lecture can improve an instructor's sense of presence in an *online-only* learning environment and thus improve students' learning and

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

their desire to stay engaged in their learning. Unfortunately, research is still inconclusive regarding which elements of a pedagogical agent's non-verbal communication is critical to learning. Moreover, studies on the effects of instructor non-verbal behavior on student satisfaction and performance in online learning scenarios are only in their incipient stages creating an immediate need to address this heretofore unexplored aspect of online learning.

III. Objectives of the Study

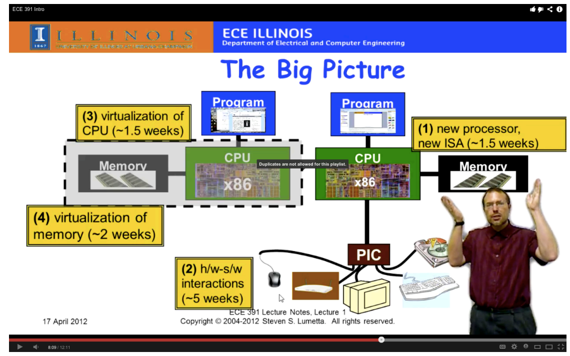
This study aims at understanding the effects of instructor presence on student satisfaction and choice of preferred visual mode in an online course setting. A fundamental question that arises towards this end is - how can we make the essential modalities of human communication accessible to students in an online setting?

A number of previous research studies suggested that an interactive teaching style and high levels of learner-to-instructor interaction are strongly associated with high levels of user satisfaction and learning outcomes [14], [15]. Until very recently, most instructor to student communication in online courses was textual. However, with the recent use of streaming media, online course materials now make instructor voice and video accessible to students, making instructor non-verbal immediacy behaviors more accessible to learners.

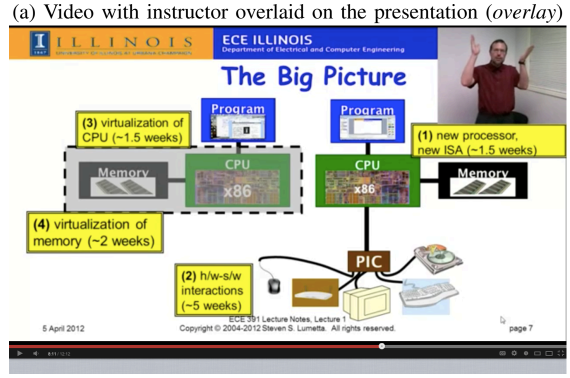
Recent advances in video capture technology allow the creation of video lectures that increase instructor's presence in the online classroom. While previous technologies such as Camtasia can embed a video of an instructor inside a recording of a video lecture, the instructor appears inside a small window that includes extraneous background information from the room that the instructor was in. New screen capture tools from Personify[1], are able to capture only the instructor sans background and overlay video of the instructor into a presentation such as PowerPoint Slides. Thus, a human avatar can be overlaid into any video lecture with a minimal level of effort and without adding the extraneous information present in older technologies such as Camtasia. We thus have two modes of visual communication that make instructor non-verbal behaviors available to the students and the question then, is whether one mode is better than the other for online learning.

As a first step towards answering the research question, we conducted a student-centered pilot study to assess engineering students' perceptions of an online mini-lecture created in the two modes (mentioned above) with increased presence of the instructor. The two modes differ fundamentally in how they make instructor non-verbal immediacy factors accessible to the students 1. One mode (termed henceforth *window*) is a presentation with the instructor appearing in a window of the screen, created using an off-the-shelf screen-capture software Camtasia; the second, a presentation with the instructor overlaid in the slides created using Microsoft's Kinect camera and Personify Live technology that overlays the video of the instructor without any background images or outline boxes (henceforth termed *overlay*). The same instructor appeared in

[1]Personify Inc., a start-up spun off from the University of Illinois is the maker of Personify Live, a tool that uses state-of-the-art machine vision techniques to include an embedded video of the presenter alongside the central material being presented



(a) Video with instructor overlaid on the presentation (*overlay*)



(b) Video with instructor appearing as picture in picture (*window*)

Fig. 1: Screenshots of the two video modes, *overlay* and *window*. The instructor without any distracting background is embedded in the *overlay* mode and dynamically points to material on the slides; the *window* mode has the instructor relegated to a corner in the screen.

both the modes and the recording was done simultaneously. In particular, our focus in this study is to answer the following questions: a) How do the two video modes affect overall student satisfaction? b) Is a video mode better at making non-verbal immediacy factors, such as that of instructor's gestures and eye gaze, available to the student? c) Among the two video modes, do students have a preference for future online courses?

IV. Methods and Data Source

Our experiment involves 60 students from the department of electrical and computer engineering at the University of Illinois, Urbana-Champaign. In the study, the students watched an introductory online lecture summarizing the course objectives and tasks of an optional course (Computer Systems Engineering). The course would be offered by an instructor who was rated high for teaching quality and had not taught the students before. Students were randomly assigned to two groups (A and B) to watch a video mode online and then asked to answer a questionnaire. The questionnaire solicited participants' demographic information and asked them to rate their level of satisfaction and perceptions of non-verbal immediacy behaviors of the instructor. Overall satisfaction was sought on a scale of 1-5 (1=Poor, 5=Excellent). The ratings of the non-verbal immediacy behavior of the instructor were obtained via questions based on the non-verbal immediacy behavior (NIB) scale originally constructed in [16] adapted to an online learning scenario. In the end, the subjects were asked to watch the video in the other mode and indicate their preferred mode for an online course upon having watched the two visual modes. The variables obtained from this section of the survey are students' overall satisfaction score and students' perceived level of non-verbal immediacy behaviors of the instructor (derived from students' response to the NIB scale).

There were 28 students in Group A (that watched *window* followed by *overlay*) and 32 in Group B that watched the videos in reverse order from that of Group A. The majority of participants in both the groups were sophomores (A: 36%, B: 53%) but there were freshmen, juniors and seniors as well. 82% of Group A and 91% of Group B were male. A majority of the participants (A: 61%, B: 56%) reported that they had no prior online course experience.

V. RESULTS

	Group A ($n = 28$)		Group B ($n = 32$)		
Factor	Mean	SD	Mean	SD	Cohen's d
Satisfaction	3.67	0.98	4.03	0.74	0.40
NIB	19.46	3.45	21.34	4.30	0.49

TABLE I: Descriptive statistics of the two groups with Cohen's effect sizes for mean ratings of satisfaction and perceived non-verbal immediacy.

Our analysis seeks whether overall student satisfaction, perceived level of instructor non-verbal immediacy, and preferred mode for an online course differed between the two groups. The results are summarized in Table I. Two-sample t-tests for difference between mean satisfaction scores, ratings of the instructor's nonverbal immediacy between the two groups, suggest that based on this sample of subjects there is no difference between the means between of the two groups at the 0.05 level (p-values 0.13 and 0.06 respectively). However, given that measures of statistical significance are critically dependent of sample sizes, we consider Cohen's effect sizes of the mean scores to see whether the differences are meaningful. We find medium effect sizes in the differences in mean scores between the two groups (0.40 and 0.49 respectively), suggesting that the means of Group B are bigger than that of Group A. Further, in choosing their preferred video mode for future online courses, 82% of subjects in Group A and 88% of subjects in Group B preferred the overlay mode to the window mode. This indicates that the overlay mode was preferred by a majority of the subjects in both the groups.

VI. SIGNIFICANCE OF RESULTS

Results suggest a student preference of the overlay video mode over the window mode. The medium effects in differences in overall satisfaction between the experimental groups and their perceived levels of non-verbal immediacy factors when viewing the online lecture in the two modes are encouraging enough to pursue more longitudinal studies with a larger set of subjects and in other online learning scenarios. Assuming that the overlay mode permits better access to gestures and eye-gaze of the presenter, the preliminary results obtained are in-line with the background literature on the positive effects of access to instructor non-verbal immediacy.

Our planned extensions to the study include conducting experiments over the duration of an entire course (including a massively open online course) and augmenting the factors studied to include aspects of performance by including pre- and post-tests to assess the influence of the visual mode on learning and transfer.

The emerging virtual environment for engineering education presents a great opportunity for learners and educators. New research in pedagogy informed by psychology and cognitive science combined with the technological enhancements in the area of visual communication can make online classes more engaging and an active learning environment.

ACKNOWLEDGMENT

We would like to thank Steven Lumetta from the University of Illinois, Minh Do, Sumant Kowshik and Sanjay Patel from Personify Inc. for their support during the data collection phase of the experiment.

Assessment of Online Participation through Social Network Measures: A HLM Approach

Abstract— **In this research, we bring attention to one of the largest electrical and computer engineering (ECE) online discussion forums AllAboutCircuits.com. There are close to two hundred thousand learners contributing more than a million messages to this forum for over more than a decade. The massive archives of educational data raise an important question for engineering educators: How do we assess online participation? In this work-in-progress, we propose a multilevel approach to assess online participation based on social network measures and Hierarchical Linear Modeling (HLM) techniques. Specifically, we consider the employment of HLM to model the association between online participation and measures of social capital. Predictors of social capital are established, at both the individual and group levels, to examine the association between these predictors and learners' participation frequencies. We discuss our choice of HLM as a modeling approach over ordinary least squares (OLS) regression methods. We then describe how data is collected from the site of study, AllAboutCircuits.com, and how the modeling approach is conceptualized and used for assessment purposes. The importance of this work lies not only on sheer participation figures – it derives from the argument that online discussion fosters productive collaborative learning and individual reflection.**

Keywords—assessment; online discussion forums; hierarchical linear modeling; electrical and computer engineering

I. Introduction

Since the advent of the Internet, online discussion forums have emerged as effective educational tools capable of supporting teaching and learning in a variety of educational settings [1]. The use of online discussion forums in college curricula can enhance student learning, including facilitation of individual reflection [2] and social interaction [3]. Online discussion forums feature heavily in learning management systems (i.e. Blackboard) and online courses as a web application to facilitate computer-mediated communication between students and instructors. However, more recently, there is growing evidence that online discussion forums are also used to build and support online communities in many areas of interest and practice [4]. In the Electrical and Computer Engineering (ECE) domain, online communities have flourished in membership and some of the most popular online communities associated with the ECE domain feature thousands of learners and millions of learning contributions. They include Arduino.cc (>120,000 members), AllAboutCircuits.com (>190,000 members) and Electro-tech-Online.com (>180,000 members). The large numbers of learning activities that take place in these forums indicate that online communities are learning spaces with significant reach and alert us to the growing importance of assessing online educational data. These numbers also suggest that ECE online communities have flourished in membership and have become a powerful complement to informal learning opportunities available to engineering learners. As such, it has never been more important to understand technologies that assist engineering students with their learning beyond the classroom.

II. Assessment Challenges

There are two major challenges in the assessment of learning and participation on of online discussion forums, and they are posed by the inherent structure of online forums and the nature of online educational data. The first challenge is concerned with the hierarchical structure of online discussion forums. Discussion threads (which consist of messages arranged by order of posting) are contained in distinct sub-forums and result in the formation of a hierarchical structure [5]. Assessment approaches have to account for contextual differences between distinct sub-forums. Secondly, there are methodological challenges in assessing massive archives of educational data originating from learners' participation in online activities and interactions with each other. Participation and interaction data are not explicitly represented on discussion threads, and will require further data processing before educational measurement and analysis can be performed. With these challenges in mind, our research goal is to propose an assessment approach that takes into account: 1) the hierarchical structure of discussion forums in which discussion are carried out in distinct sub-forums each catered for a specific ECE area or purpose; and 2) the interactions among participating learners which are indicative of collaboration and social interaction.

III. Theoretical Framework

Within the broader context of education, there is growing realization that the situativity (contextual and social aspects) of learning are as important as cognitive considerations [6]. For instance, situated cognition theories suggest that learning is conceived as a social process of enculturation and participation in a community of practice [7]. In addition, social constructivist views of learning suggest that knowledge is socially constructed rather than transmitted from one to another. With this heightened emphasis on the social aspects of learning, social capital has emerged as a concept that relates to the assessment of learning and participation [8]. According to this view, the accumulation of social capital can be viewed as the outcome of the process of learning interactions between members of a community and exist as knowledge or identity resources [8].

The concept of social capital affords insights into the strength of ties between individuals in a social network and the extent of individual access to the social connections that give access to information or resources [9]. Particularly, social capital can be understood through Burt's theory of structural holes [10]. According to this theoretical perspective, social capital is defined as the ability to broker information and resources over structural holes. In particular, an individual develops social capital when positioned in a gap within a social network (called a structural hole) to broker the flow of information or resources between unconnected parts of the network. Researchers studying online communities have suggested that internet use supplement an individual's social capital and that the amount of social capital available to an individual directly influences the quality of information received [8, 11]. These notions suggest that social capital is an appropriate construct for examining the quality of participation in online discussion forums.

In order to derive quantitative measures of learners' social capital, we first construction the social network of the online discussion community using parsed data of web pages (see section VI) before applying network measures across the individual and group levels. At the individual level, we turn to three measures that are indicative of an individual's social capital: betweenness, closeness and degree centrality. Betweenness and closeness allows us to measure the extent to which individuals occupy advantageous positions within the social network [12]. On the other hand, degree centrality refers to the measure of the number of direct ties an individual has with others [12]. At the group level, social capital can be characterized by 1) network density which reflects the overall intensity of connected units in the social network; and 2) group size which refers to the number of learners who have contributed to the discussion group [13].

IV. Research Site

The education setting for this research is an informal online discussion forum for electrical engineering titled "All About Circuits". Asides from being a prominent online community with close to 200,000 members, its explicit emphasis on electronics and electrical circuits makes it an appropriate site to assess engineering learning and participation. The forums comprise of numerous discussion sub-forums which serve as open spaces for discussion on a variety of topics associated with electrical and electronics engineering. The discussion forums are hierarchically structured. Take, for instance, the site of study for this research AllAboutCircuits.com. There are five main discussion sections comprising of 1-4 sub-forums: "Electronics", "Software, Microcomputing, and Communications", "Circuits and Projects", "Abstract" and "Community" (see Table 1). As shown, the hierarchical structure of the forums requires an assessment approach that is capable of analyzing nested data – and we highlight why and how HLM is used in this proposed study.

TABLE 1 Hierachical Structure of AllAboutCircuits Forums

Discussion Section	# of Sub-Forums	Titles of Sub-Forums
Electronics	4	General Electronics Chat, The Project Forums, Homework Help, Electronics Resources
Software, Micro-computing, and Communications	4	Programmer's Corner, Embedded Systems and Microcontrollers, Computing and Networks, Radio and Communications
Circuits and Projects	1	The Completed Projects Collection
Abstract	3	Maths, Physics, General Science
Community	3	Off-Topic, The Flea Market, Feedback and Suggestions

V. Proposed Methodology

HLM is a regression approach that readily accounts for the nested nature of data and the estimation of the impacts of factors at different levels of analysis [14]. HLM offers advantages over OLS as it allows for the estimation of a separate set of regression coefficients for each organizational unit and does not assume independence between cases, which can result in more accurate calculations of Type I error rates [14]. These considerations are of importance as online discussion forums are often hierarchically structured into smaller sections and learner collaboration violates the assumption that observations are independent of each other. Furthermore, HLM also allows the researcher to better address the issue of aggregation biases and the heterogeneity of regression [15].

In this research, we propose to use HLM, a multilevel modeling approach, to assess the quality of online participation through examining the association between learners' participation frequencies and social capital measures at both individual (Level 1) and group (Level 2) levels. Individual level measures include betweenness centrality (X_{1j}), closeness centrality (X_{2j}) and degree centrality (X_{3j}). Group level measures include network density (W_{1j}) and group size (W_{2j}). Our proposed models are as follows (the variables can be consulted in Tables II and III):

Level 1 Model: $$Y_{ij} = \beta_{0j} + \beta_{1j}X_{1j} + \beta_{2j}X_{2j} + \beta_{3j}X_{3j} + r_{ij}$$

Level 2 Model:
$$\begin{aligned} \beta_{0j} &= \gamma_{00} + \gamma_{01}W_{1j} + \gamma_{02}W_{2j} + u_{0j} \\ \beta_{1j} &= \gamma_{10} + \gamma_{11}W_{1j} + \gamma_{12}W_{2j} + u_{1j} \\ \beta_{2j} &= \gamma_{20} + \gamma_{21}W_{1j} + \gamma_{22}W_{2j} + u_{2j} \\ \beta_{3j} &= \gamma_{30} + \gamma_{31}W_{1j} + \gamma_{32}W_{2j} + u_{3j} \end{aligned}$$

TABLE II. Level 1 Variables

Variable	Description
Y_{ij}	Participation frequency of learner *i* in discussion section *j*
β_{qj}	Level 1 coefficient associated with discussion section *j* where q = (0, 1, 2, 3)
X_{qij}	Level 1 predictor for learner i in discussion section *j*
r_{ij}	Level 1 random error

TABLE III. LEVEL 2 VARIABLES

Variable	Description
β_{qj}	Level 1 coefficient associated with j where q = (0, 1, 2, 3)
γ_{qs}	Level 2 coefficient associated with predictor s where s = (0, 1, 2)
W_{sj}	Level 2 predictor for discussion section j
u_{qj}	Level 2 random error

VI. DATA COLLECTION

The data was collected from the online discussion forum "All about Circuits" using an automated web crawler. In total, a total of 87,264 HTML web page files spanning eight years across 16 discussion sections were collected. A Python scraping program was written to extract participant information and textual contribution from the web pages into a MySQL database (See Table IV). Then, learners' longitudinal contribution data was compiled from extracted information through a MySQL script and includes several variables such as post count, thread count and learners' tenure in the forums. The social network was then developed from this database.

TABLE IV. PARTICIPATION DATA SUMMARY

Variables	Total Count
Membership	192,643
Discussion Topics	87,592
Messages	504,040
Word Count	4,313,551

VII. SUMMARY

In this paper, we propose an HLM approach towards the assessment of participation in online discussion forums which can be further extended to engineering coursework or Massive Open Online Courses (MOOCs). This is especially so considering that many engineering classes use learning management systems such as Blackboard and Moodle where online discussion forums are widely used. Similarly, MOOCs instructors rely heavily on discussion forums to interact with students and to foster collaboration between learners [16]. The immediate next step is to evaluate our statistical model with the collected dataset.

Instructional Strategies for Teaching Science Online

Dazhi Yang
Department of Educational Technology
Boise State University
Boise, United States

***Abstract*—This work in progress reports the design and initial implementation of a complete online statistics course. It focuses on applications and adaptations of effective instructional strategies based on current research and best practice of teaching quantitative oriented courses (math, statistics, and engineering) online. The online statistics course was an introductory course and covered common statistical concepts and their applications in educational research for graduate students in educational technology. The course was equivalent to an undergraduate level statistics class for students majoring in science, technology, math, and engineering (STEM). Thus the implications of this project in terms of effective instructional strategies and online course design are relevant to a board audience including course designers, instructors, and students in science and engineering.**

Keywords--teaching online; statistics; instructional strategies

I. INTRODUCTION

Online courses continue to grow unprecedentedly in higher education. According to the tenth annual survey released by the Sloan Consortium, more than 6.7 million students took at least one online course during the fall of 2011 [1]. In addition, thirty-two percent of postsecondary students took at least one course online in 2011. In practice, more instructors are teaching or will teach online courses. However, teaching online is fundamentally different from teaching in a face-to-face setting [2], [3]. Instructors teaching online find it more difficult and time-consuming to teach. It is even more difficult to teach science and other quantitative orientated courses completely online because these courses usually require more hands-on activities and live demonstrations [4]. Meanwhile more educators agree that quantitative orientated courses such as math and statistics can be effectively taught online despite of their application-based nature [4], [5]. However, little has been done in developing effective instructional strategies for teaching such courses online [4]. The research aspect of this project in addition to the design and implementation of an online course was to investigate student's feedback and perspectives on the effectiveness of the instructional strategies and activities adopted in a complete online statistics course.

This work in progress reports the design and initial implementation of a full online statistics course, focusing on applications and adaptations of effective instructional strategies based on current research and best practice of teaching quantitative oriented courses online. The statistics course was intended for graduate students who were pursuing their masters' degrees in the field of educational technology. The course covered common statistical concepts and their applications in educational research. It was equivalent to an undergraduate level statistics course for students majoring in STEM fields.

II. INSTRUCTIONAL STRATEGIES ADOPTED

There were not many studies on effective instructional strategies for teaching science online. Thus the author extended the literature review on effective instructional strategies and best practice for teaching science online to quantitative oriented courses which include math, statistics and engineering. Four main strategies are most frequently adopted and implemented: (1) promoting interactivity through asynchronous and synchronous communications or delivery [7] - [8], [2], (2) facilitating the applications of concepts using strategies such as problem-based learning [10], [12] ; (3) using video demonstrations (such as screencasts for demonstrating tools and programs) [13], [14], and (4) conveying a strong social presence or a sense of belonging to a learning community [17] - [18].

Main instructional strategies adopted in this online statistics course included: online discussion forum, video demonstrations of statistical tests and procedures in SPSS, case studies of published research articles, mini projects, learning module reflections. The course used Moodle (a learning management system) to host all the course content. Table 1 briefly summarizes the literature review and instructional strategies adopted in the course

Interaction can be promoted through either synchronous or asynchronous communication modes. Synchronous communication involves real-time interaction such as instant messaging, chat rooms, and online office hours. They address concerns immediately [8] and are believed to be more effective than asynchronous delivery mode [9]. However, they are often not practical for students that have difficulty meeting at fixed times. Asynchronous communication allows students to have more flexibility and work at their own pace [8], [11]. A drawback to this approach is a delayed time response and difficulty in collaboration. Regardless of delivery modes, conveying a strong social presence is essential to connecting with students in online

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

courses [17], [18]. This improves perceived instructor support [17] and promotes students' participation. Effective teaching strategies also include the use of problem-based learning [11], case studies [3], and video demonstrations [13], [14]. Although time consuming and challenging to implement online, these methods promote engagement, help students construct their own knowledge [5], [3], and enhance teaching statistical software packages [15].

III. PRELIMINARY RESULTS

The preliminary analysis of all students' reflections submitted for six modules of the course indicated that all instructional strategies adopted were effective. Due to the page limit, we will not discuss details of the results. This online course will be redesigned based on the student's feedback (reflections) on the initial implementation and will also be incorporated with some mobile learning components during the summer of 2013. The mobile learning components include but are not limited to the following: allowing course website accessible via smart phones and iPads; incorporating some components for motivating and alleviating students' fear and anxiety toward learning statistics; incorporating some content-based Apps. for students to manipulate some difficult concepts, such as types of errors. The redesigned course will be offered again in Fall 2013.

TABLE 1. EFFECTIVE INSTRUCTIONAL STRATEGIES REVIEWED AND ADOPTED

Strategies/ activities	How to achieve?	Pros & Cons
Interactivity, [6], [7], [2]	Synchronous communication/delivery mode [8], [9] •*Instant message through course website* •*Chat rooms* •*Office hours provided*	• Pros: More effective than text-based asynchronous delivery mode [9]; Enables students to be active & collaborative learners [7]; Promote higher level cognitive skills [7], [2]; Address concerns immediately, and immerse in problem-solving and decision-making processes [8]; • Cons: Cost more for equipment; Not practical –meet in fixed time/travel [11]
	Asynchronous communication/delivery mode [8], [12] •*Online discussion forum* •*emails*	• Pros: Enables students to be active & collaborative learners [6] -[7], [2]; Work at their own pace, offers greater flexibility and have more time to reflect on their learning [8], [11]; • Cons: Unsatisfied with instructors' responses at a delayed time [5]; Unease of collaborating [5]
Applications of concepts [10], [12]	•Problem-based learning (PBL) [11] •Case studies [3] •*Case studies* •*Mini projects*	• Pros: Increase engagement [5], [3]; Help students construct their own statistical knowledge [5], [3]; Allows students to play a more proactive role in their learning [3]; • Cons: Time consuming to prepare; Not easily implemented in online
Video demonstrations [13], [14]	•Different tools/programs •Existing videos from Internet •*Screencasts* •*Introduction videos*	• Pros: Enhance teaching statistical software packages online [15]; Cons: Length limit and should only contain the right amount of information [11], [16]
Social presence [17], [18]	•Video introduction & instructor profile [16], [19] •Discussion forum •Different communication channels [20] •*Video introduction & instructor profile* •*Discussion forum* •*Different communication channels*	Pros: Improve perceived instructor support [17]; Promote students' participation in learning activities;

***Abstract*—Allegories have been used to represent ideas, concepts, and processes, primarily in classical literature. In engineering education, allegories have been used to describe the different roles within academia [1]. Here, we focus specifically on the path of a doctoral student in engineering working towards earning their degree and completing a dissertation. The path will be discussed as an allegory to "The Lord of the Rings" by J.R.R. Tolkien [2]. This allegory explores the milestones, characters, barriers, and support doctoral students will meet along their journey. The session will utilize identity-trajectory to guide discussion and encourage attendees to explore and share their experiences. The session is aimed at providing guidelines to students progressing through a doctoral degree and to assist graduate advisors in supporting their students on this journey.**

Keywords—Graduate Education, Identity-Trajectory

I. Goals of the Session

The goal of this session is to help graduate students reflect on the journey toward graduation as they begin to navigate their way through a doctoral degree; highlighting the different people and events they will meet along the way. The broader purpose of the session is to inform graduate students of the challenges and difficulties that will arise on the journey and the friendship, guidance, courage, and risk and that will be required to succeed.

II. Description of Session Content

When pursuing a PhD, many students struggle with the process and expectations of the degree. This can discourage degree completion and cause frustration for students, advisors, and all involved. This special session aims to describe the PhD process in a way that many students and faculty may be able to relate to.

This session will use an allegorical approach to highlight the similarities between obtaining a PhD and the fantasy series "The Lord of the Rings" by J.R.R. Tolkien [2]. Frodo (the graduate student) is given the one ring (dissertation funding) by Gandalf (his PhD advisor) and asked to shepherd the ring to its end (a PhD dissertation). Throughout the story, Frodo encounters a variety of individuals and faces a number of challenges that can be compared to the process that a graduate student follows in order to achieve their degree.

The use of identity-trajectory will guide the discussion and the key points that are discussed throughout the special session. Identity-trajectory has been used to theorize the development of graduate students and early career academics through three primary strands: *intellectual*, *institutional*, and *network*. These strands will be tied into the allegory as it is discussed. The *intellectual* strand deals with the contributions a person makes to their field through coursework, research, and publications. This will be discussed through the lens of the outcomes of various events within the story. The *institutional* strand deals with the resources, department structure, rules, and organization that contribute to the identity of a professional. This will be discussed in the context of the path taken and the various tools and resources utilized in shepherding the ring. Finally, *network* addresses the professional relationships, relationships, collaborations, and affiliations that contribute to the professional identity of an individual [3]. The different relationships between the characters in the story will be compared to the relationships a PhD student establishes during their graduate career.

III. Session Agenda

The session is planned to run on the following timeline:

(00 - 05 min) Introduce the beginning of the story to the Lord of the Rings

(05 - 15 min) Have participants in groups explore who each character is within the story, and what aspects of a PhD the story represents following the key components of identity-trajectory. Each group reports their perspective

(15 - 20 min) Have participants identify who they are in the story, where they are in the process, and who are the people they have met along their journey

(20 - 80 min: in 15 minute increments) Dividing the story into four arcs, facilitators will present a summary of the key story elements and characters. Participants will then work in their small groups to discuss and identify who/what those key elements are within the context of the discussion and

how they fit within the story of obtaining a PhD. After each small group discussion, facilitators will present their interpretation of the work and who/what each of the characters/events represents.

- Arc 1 (Access to intellectual development experiences, institution)
  - Hobbiton - BS, MS work
  - The Prancing Pony - Graduate course work
  - Weathertop – Qualifier

- Arc 2 (Institution, Network)
  - Rivendell - Committee Formation

- Arc 3 (Institution)
  - Moria - Advisor leaving/a change in advisor/advisee relationship
  - Orc battle at the end of Fellowship – Prelim
  - Meeting Gollum - Proposal (setting a path to the end)

- Arc 4 (Intellectual/ Network)
  - Shelob - Unexpected challenge collecting data
  - Climbing Mount Doom - When you need Sam to carry you to the end
  - Inside Mount Doom - Defense

(80-90 min) Wrap up

IV. Description of Anticipated Audience

The anticipated audience for this special session primarily includes students interested or currently pursuing a PhD and those involved in guiding graduate students through the PhD process (graduate advisors & committee members). Graduate coordinators and heads of graduate committees may also benefit from the content and discussion being raised. While the presenters are all current or former PhD students from engineering education programs, the ideas and issues presented should apply to all PhD programs and the discussion will not be engineering education-centric beyond recognizing engineering education as the lens through which the presenters have the greatest experience.

V. Outcomes and Future Work

Participants will reflect on their experiences, share their perceptions of the path to a dissertation, thus providing participants working towards a PhD with the knowledge of what to expect on their journey beyond the logistical milestones. The workshop also intends to provide faculty and academic administrators a constructive avenue to "re"-understand the graduate education experience to ensure success of their graduate students.

The research team will continue to investigate the barriers and constructive experiences of life in academia in order to highlight resources and tools that help participants with their career routes in engineering education.

VI. Author Information

James Pembridge graduated from Virginia Tech with a PhD in Engineering Education. His recent work has explored the formation of doctoral committees within the field of Engineering Education. The work specifically identifies the technical, professional, and personal characteristics of both the committee chair and the committee members [4].

Stephanie Cutler is a PhD candidate in Engineering Education at Virginia Tech. She was an NSF IGERT Fellow and assisted with the assessment of the VT IGERT program focusing on the impact of an interdisciplinary curriculum the on graduate student experience [5, 6]. She also assisted with the development and implementation of an orientation program for the VT Engineering Education PhD program [7].

Matthew Verleger graduated from Purdue University with a PhD in Engineering Education. As a graduate student, he helped launch the ASEE Student Division [8] in an effort to help provide a voice to student members within the larger national organization. He was also extensively involved with university-level training of graduate teaching assistants [9].

Lauren D. Thomas is a PhD candidate in Engineering Education at Virginia Tech. Her dissertation explored the identity-trajectory of graduate students in optics and photonics doctoral programs. She has chaired the Graduate Engineering Education Consortium for Students, GEECS, an organization focused on the development graduate students invested in engineering education research [10].

Integration by Design: Bringing Science, Math, and Technology Together Through the Engineering Design Process

Susan K. Donohue and Larry G. Richards
University of Virginia, susand, lgr@virginia.edu

Abstract – **The primary goal of this mini-workshop is to assist participants in developing engineering- and art-based design projects that reinforce concepts in mathematics and science, thus providing an integrative environment for learning. The emerging STEAM (STEM + art, which is also a design discipline) approach emphasizes a hands-on, project-based, interdisciplinary approach to the study of science, technology, engineering, and math (STEM). To emphasize the importance of using engineering design principles to integrate learning in science and math and gain technological literacy, we refer to this approach as STEAMd. This mini-workshop will be of interest to those involved in P-16 engineering education and in developing a philosophy of engineering education that stresses an integrative approach to instruction and practice grounded in design, the fundamental process of engineering.**

Index Terms – Engineering design process, Engineering Teaching Kits, integrative STEAMd, P-16 engineering education.

INTRODUCTION

Engineering is a design-based profession. We develop artifacts, be they objects or processes, as solutions to an identified and investigated problem. The artifacts are referred to as "technology," and their design is grounded in principles of the natural world as expressed by mathematics and science even though the principles may not be well-understood or even articulated. As pointed out by Henry Petroski [1], engineering can occur and has occurred ahead of scientific knowledge. The act of engineering may also further our knowledge of mathematics and science, providing a synergistic, integrative environment for learning.

The primary goal of this mini-workshop is to assist participants in developing engineering- and art-based design projects that reinforce concepts in mathematics and science. Art joins its fellow design profession, engineering, in developing artifacts that are both aesthetically appealing as well as functional. The emerging STEAM (STEM + art) approach emphasizes a hands-on, project-based, interdisciplinary approach to the study of science, technology, engineering, and math (STEM). To emphasize the importance of using engineering design principles to integrate learning in science and math and gain technological literacy, we refer to this approach as STEAMd.

Engineering Teaching Kits (ETKs) serve as guides for developing the design projects. ETKs are self-contained STEAMd education standards-based units grounded in the constructivist philosophy of education [2], [3] and the principles of guided inquiry and active learning [4] which engage students in a series of age-appropriate engineering design challenges to reinforce selected concepts in math, science, and technological literacy. They were initially developed in conjunction with the Virginia Middle School Engineering Education Initiative (VMSEEI) for students in grades 6 – 8 [e.g., 5 and 6], but have been proven scalable for use by students throughout P – 16.

By the end of the workshop, participants will be introduced to key concepts in the engineering design process and to the STEAMd movement, and be able to identify methods for using engineering design to integrate STEAM studies seamlessly and transparently as well as strategies for strengthening students' key "21st century skills" such as systems thinking, critical thinking, and problem-solving.

STEM TO STEAMD

While the intersection of engineering and humanities has long enhanced and reinforced learning in the disciplines, the active integration of art, music, and composition activities in STEM studies has been gaining prominence during the past few years; see, for example, [7] and [8]. The Claremont Graduate College has started publishing *The STEAM Journal* [9], and papers on STEAM initiatives are increasingly being presented at conferences [e.g., 10 and 11]. The addition of "d"esign to the STEAM acronym recognizes that art and engineering are design-based disciplines, design is an integrative process, and that creativity is a necessary skill for engineers to master [12].

ENGINEERING DESIGN PROCESS

The engineering design process is at the heart of the discipline. ABET Student Outcome 3(c) directly addresses the need to know and apply the process. The cornerstone and capstone model, providing design education at the beginning and completion of the undergraduate engineering program, is widely used.

There are many process models in use, but for the most part they have several features in common: engineering

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

design is problem-based and starts with the identification of a problem and research on an issue; a design space is defined; solutions are developed and evaluated; the best solution is selected for prototyping; an internally iterative cycle of build-test-evaluate occurs; and, when a stopping rule is encountered, the artifact is reviewed to determine if it meets expectations (within tolerances) or whether the design team needs to re-enter the process at a phase appropriate to the amount of redesign needed. Throughout, there is communication among team members and with client(s).

ETK BACKGROUND

Since 2002, teams of students and faculty at the University of Virginia (UVa) have developed, tested, and distributed ETKs for use in middle school science and math classes [5], [6]. An ETK is a set of five 50 minute standards-based lesson plans designed to teach targeted math and science concepts in the context of the engineering design process. Lessons are structured to develop understanding of key concepts at both abstract and concrete levels.

The primary goal of ETKs is to promote awareness of and excitement about the nature of engineering. Each ETK emphasizes the engineering design approach to problem solving through a series of design challenges, and includes real-world constraints such as budget, cost, time, risk, reliability, safety, and customer needs and demands. Students develop an appreciation for the tradeoffs involved in the practice of engineering, and how engineering decisions have an impact on society and the environment.

ETKs are also designed to integrate other subjects in the curriculum with the exploration of math, science, and engineering concepts. For example, an interdisciplinary team of eighth-grade teachers at a Central Virginia middle school uses the *Catapults in Action* ETK as the basis for a week-long series of integrated classes on medieval history, folding history, art, and language arts activities into the study of catapults and projectile motion. The potential for similar multidisciplinary activities can be found in all ETKs and thus make them appropriate for use in STEAM activities.

A recent addition to our ETKs is a set of activities and instruments to assess and remediate misconceptions in mathematics and science. A concept is a mental construct or model that helps a person organize knowledge. It is inductively built from interactions and experiences. [3] Misconceptions, also known as an alternative framework or theory develop from an incomplete or flawed development process and can be resistant to change [3, 13, 14]. We are using adapted/authored concept inventories to assess misconceptions, and discrepant events to provide an opportunity for reformulating misconceptions; see, for example, [15]. Another addition is a detailed guide for parents and teachers, in part to promote the family engineering movement [16] and in part to provide additional support to activity leaders.

Over 50 ETKs are in various stages of development; a dozen are in frequent use in schools in the United States and several other countries in both classroom and professional development workshop settings. The most popular ETKs are *RaPower* (solar cars), *Save the Penguins* (heat transfer), *HoverHoos* (hovercrafts), *Under Pressure* (submersible vehicles), *Brainiacs* (brain surgery/biomedical engineering), *Catapults in Action* (projectile motion), *Bridges to Engineering* (bridge design and construction), *Electricity Rocks* (electromagnetism and sound), *Filtering Ideas* (water filtration), and *Aerospace Vehicles* (planes and rockets).

WORKSHOP AGENDA

The workshop is structured as follows:

- **Welcome and Introductions** (10 minutes)
- **Initial Exercises** (20 minutes)
  Participants will work through a set of multimedia STEAMd activities designed to pique interest in the practice of the engineering design process. ETKs used include *Art in Motion* (robotics). See Figures 1 (a) and (b).
- **Overview of Important Concepts** (15 minutes)
  We will review research on the STEAMd movement and its demonstrated abilities to engage students in integrated learning, on best STEAMd practices, and on the engineering design process. A group discussion of experiences and concerns will follow.
- **Follow-on Activities** (30 minutes)
  Participants will work in groups with the facilitators to continue working through the design activities. We will also discuss scaling the activities to various grade levels. This discussion will include a review of expectations as to cognitive development and skill levels for students in those grades.
- **Concluding Activities and Discussions** (15 minutes)

ACKNOWLEDGMENT

We are grateful to the Payne Family Foundation and the National Science Foundation for their prior financial support of the development and implementation of ETKs; to current and former ETK development teams for their contributions to the ETK library; and to the reviewers for their feedback and recommendations.

***Abstract*— Collaborative learning is an effective educational method that plays an essential role in theories such as Constructivism and Knowledge Building. Studies have shown that collaborative work in small groups significantly improves learning when supported by concept maps. Although useful in collaborative environments, most applications available for the development of concept maps are designed for personal or small tablet computers, which can limit student communication in a team. In addition, the use of these applications usually requires learning or training periods, which can also interfere with the learning process. In this paper, we present a software tool for generating concept maps and constructing learning spaces under both local and distributed collaboration scenarios. Our system uses a natural interface with multi-touch and multi-user capabilities. It was specifically designed for tabletop systems, which provide a large horizontal interactive surface suitable for collaboration and face-to-face communication. The tool is also available in other platforms, which makes it useful in a variety of classroom orchestration settings. Finally we present the results of a preliminary usability study of our tool in a real educational environment.**

Keywords— collaborative learning; natural interfaces; tabletops; concept maps

I. Introduction

Several educational theories, such as constructivism and knowledge building, support teaching techniques based on collaborative learning. According to these approaches, learning is a gradual process where each member of the group feels committed to the learning of the others, generating positive interdependence. This is a type of active learning that happens in a non-competitive community, in which all group members, the students, play an active role in the process, collaborating in the construction of knowledge, and contributing to the learning of their teammates. In a collaborative environment, knowledge resides in the group instead of the individual, and it is the student himself who draws his own knowledge.

Different tools can be used to support collaborative learning. Concept maps, for example, are one of the most popular. Concept maps are tools for organizing and representing knowledge in a graphical form. Several studies have shown that when collaborative work is supported by the use of concept maps, the overall learning experience improves significantly.

In general, technology can be a valuable tool in the development of new techniques for collaborative learning, particularly in the construction of concept maps. There exists a vast collection of software available that facilitates the creation of concept maps. Most applications, however, are designed for personal or small tablet computers, which can limit face-to-face communication in a team. Additionally, the learning curve for many of these tools is steep, which can interfere with the teaching/learning process, especially with young students.

Collaborative learning experiences can be greatly enriched when teams from different schools, or even different nationalities, are included in the learning group. This feature, however, is not fully covered by existing tools, at least in a simple and non-invasive way.

In this paper, we present and evaluate our own computer system (hardware and software), designed to create concept maps using graphical information and combining real and virtual elements. Our system provides a natural interface, with multi-touch and multi-user capabilities, that is intuitive (so no training is required) and intended for devices with large interactive surfaces, like tabletops, where communication between students in a team can still be face-to-face.

Our system promotes collaborative work in an intuitive way and is suitable for different classroom orchestration scenarios. In the most general case, users can define a collaborative group comprised of multiple teams, which may be geographically dispersed, and create a common virtual workspace where students can interact with their teams or with remote teams, sharing experiences and information in real time.

II. Related Work

Many studies have demonstrated that teamwork is beneficial for learning. When working in small groups, communication between students promotes positive cognitive and affective outcomes [1, 2, 3, 4, 5].

Concept maps are graphical tools for organizing and representing knowledge that can enhance the learning experience when used in collaborative learning scenarios. In a study by [6], the authors reported that when students work cooperatively and construct concept maps to guide their learning, significantly greater learning outcomes occur.

In general, technology is useful in a team environment because it facilitates the exchange, retrieval, organization and presentation of information and results. On the other hand, technology can become a barrier in the learning process if it interferes with student communication within a group. When students work in teams, but in front of a computer, their focus is on the screen space [7], which significantly reduces communication between team members. A solution to this problem was suggested by [8]. In this work, the authors concluded that the use of interactive tabletop systems as teaching tools can favor a true collaborative environment and face-to-face communication between students. Tabletop systems provide a large multi-touch surface suitable for gathering around, so multiple users can interact with the information collaboratively. Recent work in collaborative development of concept maps using tabletop interfaces is described by [9].

In terms of classroom orchestration in collaborative learning scenarios with tabletops, students are placed in small groups working as teams in "local mode". In these cases, instructors must remain attentive to the evolution of each group. A classroom orchestration of similar kind was analyzed by [10]. In this case, the authors proposed the automatic generation of team participation indicators, which may be useful to the instructor in terms of evaluating the students.

III. Description of the System

In this paper, we present a tool to manage and organize graphical information in a structured way using diagrams with hierarchical relationships, and suitable for the creation of concept maps. Our tool was designed as a multiplatform application and compatible with the TUIO protocol [11], which guarantees compatibility with the majority of the Human Centered Interface (HCI) devices based on large tangible multi-touch and multi-user surfaces, like Tabletops. In a classroom environment, the tool offers the best functionality when used with devices with large horizontal interaction surfaces, which facilitates face-to-face communication between students. Additionally, tabletops provide natural interfaces, so users can use their hands and fingers to interact with the system and break the barrier that may be present with other type of technology.

A. *Interface*

As one of the goals of this work, we decided to simplify the interface of the tool as much as possible to guarantee minimum interference with the teaching/learning process.

Initially, an empty board is presented to the users. Concept maps can be defined by adding available information items to the board. Information items are simple images in JPG or PNG format located in a specific folder. Our software continuously checks the contents of this folder and automatically updates the information on the board when changes are detected. When a new image is added to the folder, it automatically appears on the board. To protect the internal integrity of the application, the folder with the content files must only have permissions to add files. The delete operation can only be performed from the tool itself.

The content folder can also be synchronized with a file hosting service that offers cloud storage (like Dropbox). This way, the information items can be shared by multiple computers on the Internet and new items can be added to the board remotely.

Every image available on the board behaves like a real card or "token" which can be moved by dragging it with one finger. Tokens can be rotated and scaled by using two fingers (via gestures on a multi-touch interface). Additionally, since it is a multi-user system, many students can interact with the tokens simultaneously. We can also zoom and pan the board using gestures by tapping on any available space on the board.

To establish a hierarchical relationship between two tokens, the child token should be moved until it interferes with the parent token, resulting in a hierarchical tree. A tree can be linked to another tree in a similar manner, by simply dragging their root node until it interferes with the token to which it must be linked. When a tree is moved by dragging its root node, all its children move with it.

To break a hierarchical relationship between two tokens, users can drag the tokens apart (with one finger on each token). If the application is used on a computer without tactile capabilities, the right mouse button can be used to click on the link between the two nodes.

When tapping and holding the finger on an item, a contextual menu appears beside it, offering the following options: copy item, copy sub-tree, delete item and delete sub-tree. To paste an object, we must tap and hold on an available area of the board, and the object will appear on it. If all instances of an object on the board are deleted, the information file associated with it inside the folder will also be deleted. Again, the right mouse button can be used to simulate this behavior if using a computer with no tactile capabilities.

Creating a Concept Map with our tool required adding "concepts" in the form of images (as described previously) and establishing relationships between them using connections to create propositions (see Fig. 1).

In order to make the digital information items as natural as possible, we propose the use of handwritten text. Since the tool uses only graphical information, text is also represented as images. To add concepts or transitions in textual form, users can write the text on a piece of paper and a take a picture with a digital camera or smart phone. Software tools for digital image processing or any other system which allows representing text graphically may also be used.

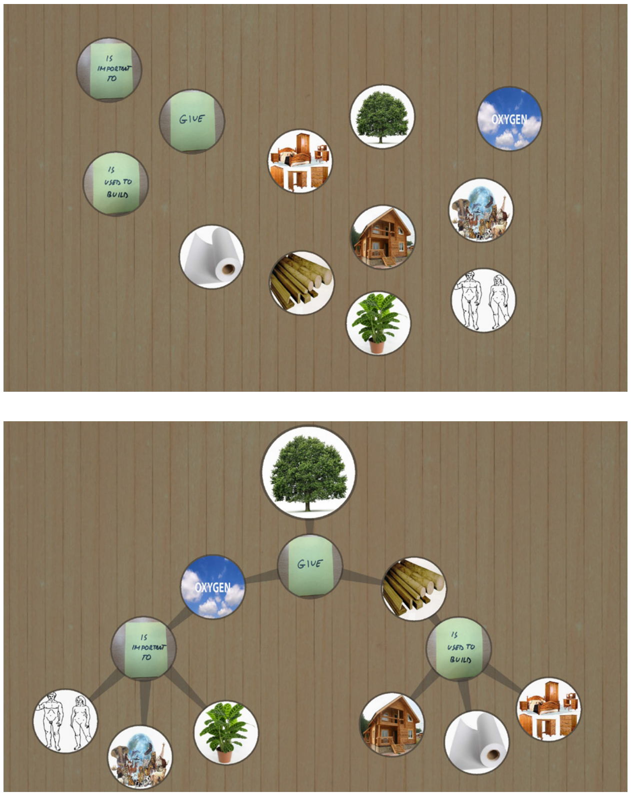

Fig. 1. Concepts and labels added to the work space of the system (top) and with relations (bottom).

B. *Tabletop System*

We developed our own tabletop system (see Fig. 2), which turns any physical flat surface into an interactive surface with multi-user and multi-touch capabilities. The system is comprised of a stereo video projector and two cameras that provide a stereoscopic view of the interaction surface. The cameras take images (stereo-pairs) of the user's hands and the objects placed on the surface and the software recognizes the position of each finger, including the distance to the table.

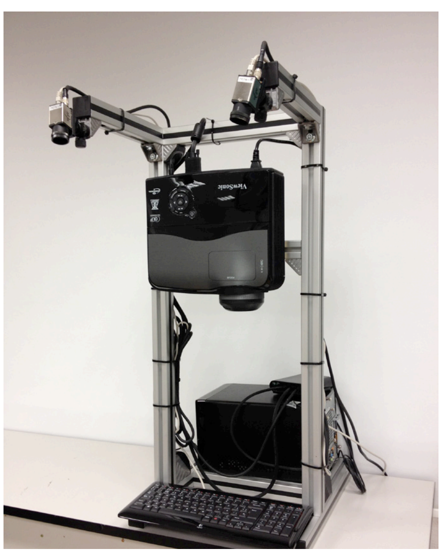

Fig. 2. Tabletop system designed by our research group.

Using our tabletop system, students can convert their own workspace into an interactive surface, i.e. the same surface can be used as a traditional workspace or as a digital space, combining the advantages of both scenarios (see Fig. 3 and Fig. 4).

When used in "digital mode", the software interface integrates virtual content with the real world according to the principles of ubiquitous computing and natural interfaces. An interesting aspect that we observed when our system was tested in an educational environment is that in "digital mode" students maintained the same levels of communication that they did when working in "traditional mode."

Fig. 3. Students working in "traditional mode" before turning the tabletop system on.

Fig. 4. Students working in "digital mode" with the tabletop system.

Our software can also be used in conjunction with Augmented Reality (AR) technology. When an AR marker is detected, its position and orientation in space is calculated and the 3D content is rendered in real time.

C. *Other platforms*

Although tabletop technology is ideal for collaborative learning environments, the use of other devices, such as desktop computers, tablets, and interactive whiteboards (see Fig. 5), offers interesting possibilities for classroom orchestration, particularly in distributed collaborative scenarios.

Fig. 5. Students using our system with a digital whiteboard.

IV. SYSTEM ARCHITECTURE

The two major pieces of our software system include the use of Unity as the 3D engine and the TUIO protocol to ensure compatibility with most multi-touch and multi-user interface devices.

The system architecture is based on classic client-server model, where a server supports the entire application, and multiple clients (different teams) connect to it via TCP/IP, as shown in Fig. 6. The entire workspace is created on the server and each client has a view of it. All clients' interactions are transmitted to the server, which updates the scene and transmits the changes back to the clients.

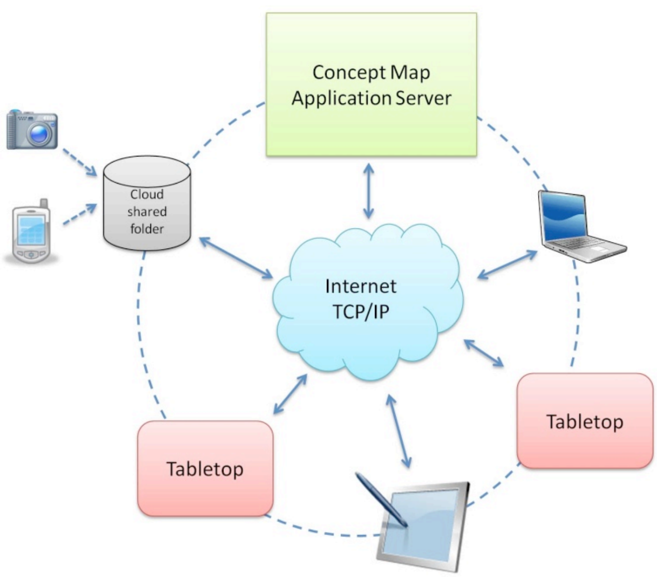

Fig. 6. Representation of the system architecture.

The exchange and sharing of information between teams takes place according to the concept of cloud computing. Basically, the exchange of information is carried out through a folder that is shared by all computers in the workgroup, including the application server, in a file server located in the cloud. The application server continually checks the contents of this folder. When changes are detected, the scene is updated for all clients. For instance, if the server detects the addition of a new image, it will automatically build the object and place it on the board.

Most file servers in the cloud provide applications for smart phones to automatically synchronize the images captured by the device camera with a shared folder on the file server. We take advantage of this feature as a simple alternative to add new information to the concept map. Therefore, users can add information to the board just by taking pictures of images on a book, handwritten notes, etc. Our system automatically synchronizes new images with the shared folder on the server. Few seconds later, captured images will appear on the interactive surface.

V. COLLABORATIVE LEARNING SCENARIOS

We propose three collaborative scenarios for our system: local collaboration, extended local collaboration and distributed collaboration.

A. *Local collaboration*

In this scenario, students gather around a common workspace generated by the tabletop system developed by our research team (any interactive surface that is TUIO compatible can be used). This common workspace is created by converting a traditional working environment (e.g. a table) into an interactive surface with multi-touch and multi-user capabilities. In this setting, students can interact simultaneously with the surface and still maintain face-to-face communication.

B. *Extended local collaboration*

With our system, students can collaborate remotely with team members who may be in different locations. For instance, two geographically dispersed teams can establish a connection to the application server, which will create a common workspace that simulates the same physical space for all users. In this type of collaboration, not all members of the team have a physical face-to-face communication, but this gap can be filled by a video conferencing system running in parallel.

C. *Distributed collaboration*

In a true collaborative learning environment, students' interactions are not limited to the domain of one team. There are also interactions between teams. Students typically walk around the room talking to other teams and looking at the work done by other students.

Our system can simulate this form of collaboration by presenting a large common space around which the respective boards of each team are arranged, as shown in Fig. 7. The common area reinforces the idea of collaborative learning and represents a common working space independent from team locations.

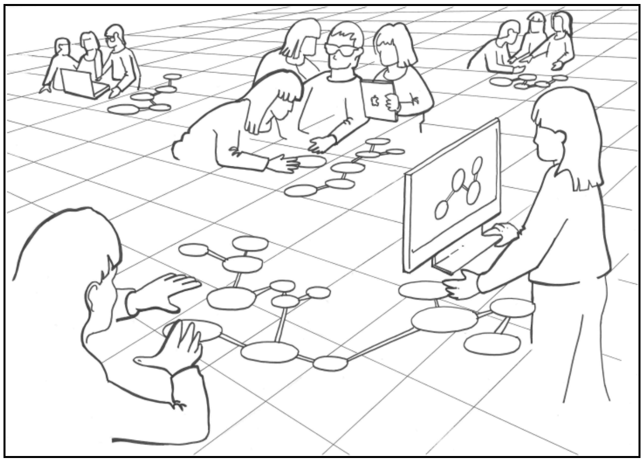

Fig. 7. Representation of the virtual workspace in a distributed collaborative scenario.

To establish a minimum organization, colored zones are used to identify each team, as shown in Fig. 8. With pan and zoom operations, teams can move to the work areas of other teams and look at their work, or collaborate with them. By zooming out far enough, it is possible to see the common area and all team workspaces at the same time. As mentioned above, zoom and pan operations are performed by gestures on the board.

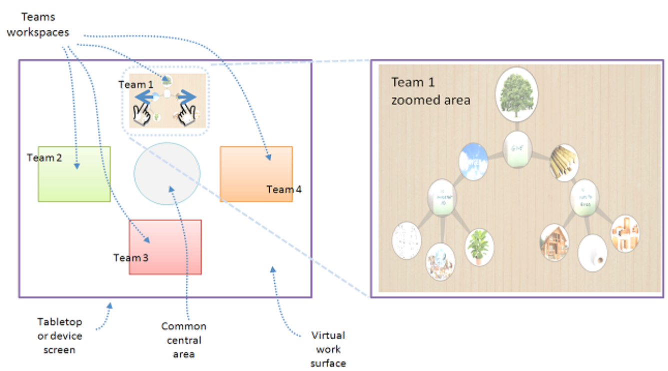

Fig. 8. Schematic representation of the work surface with the areas reserved for teams and common central space (left). Representation of a zoom operation to visualize a team area over tabletop or device screen (right).

If a team needs to use information from other teams, copy and paste tools can bring that information to the team workspace. The common area of the board is used as a shared repository of information, where teams can go and get information items. In a distributed collaborative scenario, when a new image is added to the shared folder of the system, its associated virtual token will appear on the board in this common area.

VI. Pilot Experience and Usability Study

A usability study of our system was conducted with twenty high school students. Participants were divided into four groups of five. The experience was conducted in two rounds, with two teams at a time. No students had prior experience with the system. Basic operating instructions were given by the teacher at the beginning of the session.

For our test, we asked participants to create a concept map about the historical evolution of computing, from its beginnings to present. Both groups of students were equipped with our tabletop system. Initially, participants were asked to collect relevant information from textbooks, the internet, papers, etc, and place the materials on the workspace to start building the concept map. Students worked in a distributed collaborative scenario, sharing group information using copy and paste operations.

To add textual information to the concept map, participants used paper labels, which were then photographed with a smart phone and introduced into the system via the synchronized shared folder on the server in the cloud (see Fig. 9).

Fig. 9. Student using a smart phone to capture a handwritten text note.

Collaboration and teamwork using our tabletop system was successful both at the local level (members of the same team) and between the two teams that participated in the distributed collaborative scenario. In addition, teachers were pleased with the quality of the concept maps submitted by the teams.

Finally, a five-point Likert scale was used to evaluate the usability of the system and the participants' opinions. The questionnaire and the results are summarized Table I.

TABLE I. Usability Questionnaire and Results

Question		Mean	Std. deviation
1	The tool is easy to use	4.60	0.50
2	The tool is easy to understand	4.20	0.70
3	Learning how to operate is easy	4.70	0.47
4	Learning how to operate is fast	4.90	0.31
5	Remembering how to operate is easy	4.65	0.49
6	Teamwork is easy	3.90	0.64
7	Overall, I found the system easy to use	4.60	0.50
8	Overall, I found the system useful	4.35	0.49

Although this is a simple evaluation with a small sample of twenty students, the results obtained provide a positive first impression.

VII. CONCLUSIONS AND FUTURE WORK

Collaborative learning is a teaching methodology well recognized by the educational community. Concept maps are tools that can effectively support this paradigm.

In this paper we have presented a system that facilitates the creation of concept maps based on collaborative learning workspaces. Our tool was specifically designed for tabletop systems, which offer a large multi-user and multi-touch interactive surface and facilitate face-to-face communication between students. These devices can transform traditional workspaces into digital ones, blurring the lines between the two.

Because of its distributed architecture, our system can accommodate multiple student groups in a variety of learning and collaborative work configurations, including teams located in different geographical locations. The flexibility of the system opens many possibilities for classroom orchestration.

A preliminary study was conducted to evaluate our tool. Although a relatively small sample of students was used, positive results in terms of usability and user satisfaction were obtained, confirming the effectiveness of the system as a collaborative learning tool.

Further evaluation with larger samples of students is still pending. A more comprehensive analysis will provide more reliable and statistically significant results. We are also interested in comparing student performance and communication levels in environments where only tabletop systems are used as opposed to more traditional settings.

Experiencing Disruptive Behavior in a Team Using "Moles"

Daniel E. Krutz, James R. Vallino
Department of Software Engineering
Rochester Institute of Technology
Rochester, NY, USA

***Abstract*— The ability to work on a team is a paramount skill for every engineer. The capability to understand, identify and work through team problems will significantly enhance the engineer's ability to deliver a high quality product on time and within budget. Far too often, however, the experience of working as a team, with its challenges, is overlooked in the student's education. The Department of Software Engineering at Rochester Institute of Technology introduced an activity in their Freshman Seminar course to help students work in a team-based environment. The specific focus was interacting with problematic team members. This team activity involved student "moles" covertly being inserted to act in a disruptive fashion. At the end of the activity, the teams reassembled to discuss the task the team had been assigned to do. The instructor revealed the role of the "moles" at this point, and the teams discussed the effect their behaviors had on team effectiveness and the strategies used to deal with the disruptive behaviors. The students have praised the activity, finding it to be different, exciting and educational. This paper describes the "mole" activity, our observations of the results, and provides suggestions for future use in coursework.**

Keywords—Teamwork, software engineering, group activity, group project, team dynamics

I. INTRODUCTION

Rochester Institute of Technology has offered an undergraduate degree in software engineering for over 15 years. All first year Software Engineering students are required to take a Software Engineering freshman seminar course [1] during their first term. The learning outcomes for the course are to instill in our first year students a sense of engineering practice and professionalism, along with the distinctive perspective of software engineering.

During each session of the course, students are exposed to different software engineering principles. Some of which include requirements gathering, software testing, general problem solving, software development processes and working as a team. The "mole" activity is conducted during this team activity. To achieve its learning outcomes, our course couches all the activities in the context of software engineering, but many of the exercises, and particularly this "moles" activity, have broad applicability for other disciplines.

Today's software applications are often very large and complex, and must be created by teams of software developers [2]. Proper and meaningful collaboration among the team members is of paramount importance for ensuring the success of the project. Even though working as a team is an important skill to have, many engineering students graduate without sufficient preparation to function as part of a team and are unable to cope with many of the inherent challenges of teamwork [3-5].

In order to address these issues, we created the "mole" activity as part of our freshman seminar course. The goal of this exercise is to have students experience many of the challenges of working on a team, and specifically in this case, dealing with problematic team members.

II. ACTIVITY OVERVIEW

The "mole" activity was first introduced in the Fall of 2011 and has seen very positive results and outstanding student feedback. There are exercises in the course where the students experience aspects of teamwork, including team-based coding and presentation activities. The "moles" activity was created to broaden the exposure to team activity, and to have the students directly deal with problems a team may face, such as troublesome team members. These are issues which were reported by many students in subsequent courses and in the workplace during their co-ops.

The purpose of this exercise is to allow students to gain experience identifying several positive and negative team dynamics and to understand how to remain the most productive when encountering these situations. An additional goal is to help students identify when they themselves are unknowingly falling into one of the described detrimental roles.

III. ROLES

There are identified roles each mole may play. These may change over time and instructors are encouraged to modify these roles or add others as they see fit. Many of these roles closely align with problematic areas that have been identified in previous research [6].

The Absentee: The goal of this role is to mimic a team member who is missing or otherwise not in contact with the team for large periods of time. The student is instructed to excuse themselves without providing any reason for leaving, and stay away for a significant portion of the activity. When physically present, the students are asked to contribute to the team and act like they normally would. Students have carried out this role by simply walking out of the meeting location for a few minutes randomly during the activity. In subsequent school related work, students have expressed problems with team members showing up late for team meetings, having to leave early, or just missing a significant number of meetings. This is a common occurrence in a university setting where students have a wide variety of other activities and classes that also demand their attention [7]. Similarly, in the workplace team members may be unwilling or unable to attend many team meetings because they are overcommitted to several projects.

The Disagreer: The purpose of this individual is to actively impede the progress of their team by arbitrarily disagreeing with decisions that their group makes. One option is for this team member to disagree with every third decision that their team makes, no matter what it is. This may be something as minor as the type of font selected for a presentation or disagreeing on a key decision for the assignment. This is a role which students will often encounter, for both productive and detrimental reasons. Many times, teammates will disagree regarding a topic, which may lead to constructive outcomes. The ensuing conversation and subsequent possible evolution is something which is a key advantage to the team environment. However, sometimes these disagreements can sidetrack a team and lead to unnecessary problems [8-10]. A key lesson for students is how to react to these individuals in the future. Will they react to them in a constructive manner or will they respond destructively? Will the team try to work through the disagreements to form a consensus, or merely try to ignore the person?

The Disruptor: The mission of this role is to disrupt or sidetrack their team in any way necessary. This may be done by showing irrelevant YouTube videos to their team, creating side conversations wherever possible, or frankly doing whatever they can in order to get their team off topic. This role mimics a situation that students will inevitably encounter in both the classroom and the workplace [6, 8, 9]. Based on conversations with students, one of the biggest pitfalls that is detrimental to their productivity is being side tracked during team meetings.

The Know-It-All: This role is slightly related to The Disagreer role discussed earlier. The student in this role will purport to being an expert in every aspect of the team's work. The know-it-all's ideas are always better than all the other team members' ideas and should be adopted by the team. This team member often will speak the loudest and shout down others. It is common for the other team members to disconnect from the team work and let the know-it-all do everything, especially if work already completed by others is redone the way that the know-it-all thinks is best. To have productive meetings where each team member has an equal voice, a team needs to find ways to not let the know-it-all dominate all team decisions, such as, voting on a choice when a consensus it not reached, and having all team members agree to abide by the results of the vote.

The Non-Contributor: This role is instructed to not play any part in their team’s activity. This person's main focus is to not directly affect their team’s progress in any way. They should neither assist nor impede their team. If they are explicitly asked by their teammates to contribute in some way, they should shrug off this request. The purpose of this role is to mimic a team member who contributes nothing to their project. Unfortunately, the reality, in both academia and industry, is that some team members do not contribute to projects. This is for a variety of reasons, including “senioritis” or simply a lack of overall motivation to work on the project [11]. In this activity, students have performed this role by merely putting their heads down and sitting quietly for the duration of the team meeting, or to work on homework for another course. Students will often complain about being penalized if there is a non-contributor on the team. On the one hand, it is the instructor's task to identify when this has happened, and make appropriate adjustments to the grading using peer evaluations [12] or another mechanism. This is also an opportunity for students to learn to deal with a non-performing team member, who despite what students believe, are not immediately fired, and often live long lives in the industrial setting being a challenge for each team on which they work.

IV. ACTIVITY DESCRIPTION

The first step in the activity is to break the class into groups of roughly 5 students. This will create teams that are large enough to only be partially affected by the “moles”, but small enough so that they will be adequately felt. Additionally, this is often close to the size of the team that most students will subsequently work on in their future careers in both industry and academia [13, 14]. Once the teams are formed, students are told they will be given approximately 40 minutes to work on a small presentation. The exact activity does not matter, and instructors can select an exercise that links to the goals of the class. The activity should be relatively easy and allow for a high level of interactions amongst the team members. In our case, the stated goal of the exercise was to prepare a presentation on the challenges of communicating with a customer during requirements gathering.

Immediately before the teams are released, one person from each group is asked to speak privately with the instructor for a few moments under the guise that there was some minor problem with a homework submission or another trivial issue. These individuals are to become the “moles”. In the private conversation with the instructor, the true roles for the selected students are revealed to them. Each of these "mole" students is assigned a different role and may even assist in the assignment process. For example, a student with a fancy new smartphone would be a good candidate to be a disruptor because they could lead their team off topic by showing them the features of this new and interesting device. It is important that the students have a reasonable level of input in the assignment of their roles because each student will be more likely to do a good job acting out the role if he or she is more confident and comfortable with the one assigned.

After the roles have been assigned, the students join their teams for the activity in the most discreet way possible. It is important that each team have their own, relatively secluded area to work on the faux activity. This is so they will not be disturbed by any other groups. In the past, teams have been alerted that something was awry when they not only witnessed their own teammates acting abnormally, but when other groups had team members also acting in an atypical fashion. For the purposes of the post-activity discussion, the instructor needs to observe each team and how they react to the moles. The instructor should do this in a discrete fashion so as not to tip off the team to the true motives for the activity. In our course, this is not much of a problem because the students are accustomed to the instructor and student course assistants observing team activities which occur in every class session.

Once the allotted activity time has concluded, all the teams come back to the classroom and the moles are revealed along with the roles they were playing. It is important to not force the students to guess the "moles" as they will likely be far too shy to make public accusations. Additionally, this could lead to some awkward situations if any students incorrectly state that a teammate was a mole, when in fact they were not.

V. GOALS OF POST-ACTIVITY DISCUSSION

Students derive a large part of this activity's benefits during the post-activity discussion. This is an exercise which the instructor is expected to moderate, and to point the students in the general areas of what they should be discussing. However, the instructor needs to be careful to allow the students to properly interact during this component and let their thoughts be heard. During this discussion, student involvement and thought needs to be fostered as much as possible. Approximately 15 minutes was allotted for this discussion.

There are several possible areas that may be addressed in the post-activity discussion. The first is how the students reacted to the moles. Students should be asked to identify, consider, and elaborate on how they responded to their problematic teammates. This is something they likely have yet to consider. If the students fail to contemplate their thoughts and actions, they will lose many of the benefits of the overall activity. It is only through understanding their own thoughts and actions that they will be able to recognize their reactions and make the proper behavioral adjustments when they encounter similar situations in the future.

Ultimately, the discussion should revolve around two central topics. The first is how each student should react to teammates when they are acting improperly. Secondly, each student should learn to self-identify when they are becoming one of the detrimental teammates as conveyed by the moles. When working with problematic team members, the first step is to consciously recognize them. Many students stated that during this activity they noticed these problematic members. However, it wasn't until after the activity and the discussion that they consciously thought about these individuals and their behavior, and how the team could achieve a change in behavior, or work around it. In future team activities, students should be alert for problematic behaviors, such as those exhibited by the "moles".

Once these problematic behaviors are identified, students should understand how to deal with them. Many students stated that they recognized these behaviors, but chose to ignore them, or worse, decided to join in with the destructive activities of their problematic teammates. These "moles" represented a harmful type of team member students are likely to encounter. Each of these roles should be dealt with in different ways when encountered in groups. It is important for students to recognize how to properly identify and appropriately respond to these team members.

The second major discussion topic is how students should learn to self-identify when they are falling into one of these disruptive roles. There is no such thing as perfect team members. We all have areas where we could improve ourselves with regard to working in a team. A goal of this self-identification exercise is to identify our own tendencies toward disruptive behavior, recognize when we are exhibiting one or more of these behaviors, and how we can change the behavior or prevent it from occurring in the first place.

To start this aspect of the discussion, restate the roles that the moles took and have the students quietly think about times when they exhibited one of these behaviors. The students should not be forced to discuss any of these occurrences. Many will be simply too embarrassed to publicly state their shortcomings. Many students would merely not participate in this discussion component, or would be likely to be only partially honest or forthcoming. This component should represent a period of complete open and honest discussion. The environment should be as friendly and positive as possible to foster a good learning environment. Any aspects which make the students feel uneasy or less than totally forthcoming should be avoided.

VI. STUDENT FEEDBACK

The student reaction to the "moles" activity has been generally very good. Most students were very surprised that the moles were planted in their teams, which is a testament to the acting ability of the students. Many even went so far as to apologize to the moles for getting so upset and frustrated with them during the meeting. Students have also stated that the activity was very enjoyable. This is very important because we believe that students ultimately learn better when they are enjoying themselves.

Following are representative samples of written feedback we have received:

> "When we were actually *trying* to work, it was a pain - but it really helped drive the point home. In your SE career, you're going to have that one person on your team who is going to be the bane of your success; they'll show up late, distract the group, do little if *anything.* Instead of complaining about how annoying these people are to work with, we should have enough experience with them to know how to run a successful group *with* them."

> "The mole activity was an extremely fun day in freshman seminar! I thought it was quite a useful activity because it was a demonstration of the sorts of dynamics one can expect to encounter in a group/team environment, which is critical in our field."

During the subsequent discussion, students described how they worked with these moles. Many would simply ignore these problematic team members. This is typically the case when teams are dealing with the “non-contributors.” Teams generally find it easier to just ignore and forget these members rather than confront them about their lack of effort and unwillingness to contribute. This is very interesting because one of the main problems that our upper level students complain about is team members who do not contribute their fair share of the workload to group projects.

While not often the case, when students did directly address the mole during the activity about his or her problematic tendency, it was typically done in a destructive rather than a constructive manner. Students would often become angry with the mole, resort to confrontational discussions, and finally ignore the problematic team member. Part of the subsequent discussion should be about the proper way to confront a team member about his or her behavior.

Students note that the disruptor "mole" also had a negative effect on the team by bringing the team off topic and keeping them from being productive. However, more than with the other roles, it had the added effect of turning other students into disruptors themselves. In many cases, the wave of disruption would resemble a virus spreading through the team.

Students also found it interesting that even though they recognized the mole and the actions he or she was taking, they never really thought about classifying it. They never really viewed problematic team members as falling into different classifications. Being able to identify the behavior brings with it the benefit of known solutions that the team can use to attempt to correct the non-productive behavior.

VII. FUTURE WORK AND IMPROVEMENTS

Even with the success of the activity, there is room for improvement. One enhancement would be the identification of more “mole” roles. Despite the variety of roles currently used, there are likely others which have yet to be recognized that may represent additional problematic areas for team collaboration. Future instructors are encouraged to identify and share these new roles as they are discovered. Additionally, if instructors adopt this activity for use in classes other than software engineering, they are encouraged to create moles which may better reflect their specific course area.

Monitoring the student activity is another area that we feel has the potential to be highly effective for gauging team collaboration. Currently, it is very difficult to observe teams and their interactions without creating suspicions among the students. Additionally, when an instructor is present or observing any team activities, students generally act differently. This is a problem that may be difficult to overcome. Without witnessing these interactions, the instructor risks missing key points and interactions among the team which would provide interesting points to highlight during the subsequent discussion. This is not as large a problem for our course because instructor observation of team activities happens regularly.

VIII. CONCLUSION

Experiencing disruptive behavior in a team using “moles” is an interesting and innovative activity for helping students learn how to work as part of a team. Many of the aspects of working on a team are far too often overlooked in the field of engineering education. The primary focus of this work was dealing with problematic team members. While the exercise described here was with students in a software engineering course, there is no reason why it cannot be used as-is, or moderately altered, with courses in other disciplines. The activity went very well and has been met with positive student feedback for being both an enjoyable, but also very educational activity.

***Abstract*— The need for teamwork skills has been recognised as one of the key requirements for engineering graduates by industries world-wide, including in China. A pilot on teamwork training was conducted in a joint degree programme between a leading British university and a top Chinese university in 2011. This paper attempts to evaluate the effectiveness of this cooperative learning practice to Chinese engineering students and to identify the gap between the declarative knowledge and the skill-based outcomes. This evaluation focuses on the open-ended and qualitative items in students' expectations agreements, team function evaluation forms, peer ratings, and questionnaires. The data collected were analysed using descriptive statistics, with class observation and informal interview responses also being discussed. This qualitative study provides a good supplement to the previous quantitative findings and contributes to understanding by displaying how students perceived a Cooperative Learning practice in a mainland Chinese context, and how they reacted to the experience. It also provides an insight into the underlying cultural considerations behind the team behaviour. Instructors can design and improve team tasks for Chinese students based on these findings.**

Keywords — Cooperative Learning; teamwork; peer rating; evaluation; effectiveness; Chinese engineering students;

I. INTRODUCTION

Teamwork skills have been recognised as one of the key skills required for engineering graduates by industries world-wide, including in China. Every year a large number of engineering students graduate in China and, with the rapidly rising influence of China in the global economy, how to effectively teach technical teamwork to Chinese engineering students needs to be studied urgently, especially as most of the teamwork training in China is undertaken in after-class activities rather than in an academic setting.

A pilot practice on teamwork training was conducted in a joint degree programme between a leading British university and a top Chinese university in 2011 [1]. This programme aims to mix the best of teaching approaches from China and the UK, and it includes more emphasis on professional skills than is usual in other Chinese degree programmes. In the experiment, many successful Cooperative Learning (CL) practices from the West [2] were used in the Personal Development Plan (PDP) module that takes team working as one of its key teaching objectives. Students were asked to complete a task in groups with the basic teamwork concepts and skills being introduced at the beginning; they were encouraged to improve their team performance during the process by drafting and signing the experiment agreement and filling the mid-term evaluation form. At the end of the task, students rated the team performance of the team members including themselves. The detailed strategies can be found in one previous paper [1], and the experiment results had been analysed in another paper [3].

However, an important aspect is how effective the teaching of these skills is, evaluated by how well the students learn the skills. This paper attempts to evaluate the effectiveness of this Cooperative Learning practice to Chinese engineering students and to identify the gap between the declarative knowledge and the skill-based outcomes. It was noted that students' skills that inform their team behaviour are influenced more by their inherited practices and cultural norms than the declarative knowledge learned at the beginning. Many interesting results found in the class observation are also analysed.

II. RELATED RESEARCH

Many studies report successful practice in classroom-based teaching of team work, the most popular being to assign group projects in technical modules [2, 4]. Researchers often comment on the teacher-controlled factors that influence students' team experience [5, 6], and many computer systems have been developed to help the process of group formation, administration and teamwork assessment [7-11]. Some researchers reviewed the peer assessment of group work [12], and some educators modified the peer rating instrument and procedure to enhance the consistency, reliability, and validity of the assessment [13, 14].

However, other researchers and educators argue that teamwork skills cannot be learned through *ad hoc* project experience without teaching; it is a learned skill, and should be taught, practised and assessed as other academic skills [15-17].

However, a teaching strategy can only succeed when it facilitates students' learning. Many educators shed light on students' response to the cooperative learning arrangement

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

and their perspectives on how teamwork can best be learned [18, 19].

III. Methodology

This qualitative study aims to evaluate the effectiveness of the tested CL approach in mainland Chinese context as a supplement to the previous quantitative findings [3].

Data for evaluation was collected from four main sources: students' expectation agreements, team function evaluation forms, peer ratings, and questionnaires; class observation and informal interview responses were also considered.

The data was analysed using inductive text analysis and descriptive statistics. The responses were coded using open coding [20] to label each response with simple words and phrases. Common key words and phrases were identified and organised into clusters.

IV. Evaluation Results

This section will mainly evaluate how the experiment strategies and mechanisms achieved their teaching objectives and learning outcomes; and whether students understood and performed what we wanted them to do.

A. Instruction of Teamwork Skills

It is agreed that students cannot gain team skills by just working in groups [21]. They are not born to know teamwork skills, and these skills must be taught deliberately with as other academic skills. However, technical modules often have tight schedules plus a large amount of teaching content and the instructors do not have enough training on teamwork teaching, so the most common situation is that students are allocated into groups to complete an assignment but are not given any instruction on how to work in groups.

In the experimental PDP class that takes teamwork skills as one of its main objectives, a brief introduction to these skills was given at the beginning. This included team effectiveness, team development stages, assertive communication skills, social skills, interpersonal skills, and conflict resolution skills. Other skills, like interviewing, questioning, exchanging ideas, giving advice, defending oneself, and summarizing information, are introduced and practised in later PDP tasks throughout the whole undergraduate period.

However, because of the time limitation, it is only possible to schedule a two-hour lecture to set up the PDP task and give basic knowledge of teamwork skills. According to the questionnaire results, students found that the instruction is not enough: 90% of the students in the experiment wanted the instructor to check work and progress at least once a week. It is also noted that there is a gap between declarative knowledge and skill-based outcomes: 60% students found "*little help*" in having instructor guidance for improving team effectiveness - "*students feel that the skills and guidance is very useful, but often forget to use, or do not know how to use, the skills in practice*".

Declarative knowledge is easy to learn, but skills are difficult to acquire. Students found the knowledge and skills were very useful, but often forgot or did not know how to use them in practice. They also expressed the desire for more specific practice and instruction during the process.

Because of time constraints, the skills had only been introduced but not been practised to any extent within the class. It is suggested that more time be allocated so students can do more exercises to practice skills within class, such as brainstorming skills, decision-making skills, group-meeting skills, conflict-resolution skills, listening skills, clear-expression skills, summarizing skills, and assertive communication skills. Different forms can be used for this practice - including lectures, tutorials, workshops, and clinic sessions.

B. Team Expectations Agreement

After the introduction of team skills, students were asked to work out an expectation agreement for their teams. They were expected to list the rules and expectations they agreed as a team to adopt. Everyone signed the sheet to indicate their agreement and intention to fulfil them. They were told that the expectations were for their use and benefit; if they made the list thorough without being unrealistic, they would give themselves the best chance.

Western cultures place emphasis upon rules, laws, equity and contracts that should be applied in all situations, irrespective of personal relationships. However it is very different in the Chinese culture, which puts more emphasis on relationships instead of rules: people have obligations to those they know personally, and each situation is treated differently [22]. Chinese people are usually motivated to complete tasks because of a sense of personal loyalty and attachment to others in the group, but are not compelled by rules [22]. Therefore the following questions were addressed: (i) is there any resistance from students in making and following rules and expectations; (ii) do they know how to make rules; and (iii) what kind of rules will they make.

The result was very inspiring: all the 24 groups took it seriously and worked out a detailed expectation agreement. This indicated that students were concerned to improve team effectiveness using rules and intended to use the skills and knowledge they learned to drive their behaviour.

The expectations they listed can be grouped into six categories: (i) meetings, (ii) decision making, (iii) leadership, (iv) discussion, (v) interpersonal and conflict resolution, and (vi) project management.

1) Meetings

Most of the groups expected all members to attend meetings on time, ask for leave if they could not attend, concentrate on tasks, and maintain focus during the meeting. One group had even more concrete meeting rules: they decided the frequency and duration of meetings, and stated that there was zero tolerance for lateness of 10 minutes and above: "*Have a meeting twice a week; no one can be 10 minutes late; meeting time should be limited to 30 minutes*".

The expectations were more about discipline, but no group mentioned having an agenda and capturing action items. Students were not used to making meeting agendas and minutes so this meeting skill should be taught and practised more.

This could be explained by the *polychromic time rhythm* valued by Asian people, who change plans and deadlines frequently and consider schedules as goals rather than as imperatives [23]. However this fluidity does not help coping with time pressure and raising work efficiency in groups so that there is a need for Chinese students to learn how to make and follow meeting agendas and project plans.

2) Decision making

Eleven of the 24 groups agreed on the decision making method: eight groups chose majority rule voting for the best, and three groups decided on consensus instead of majority rule. Chinese people normally vote for majority to show democracy when making decisions as it is an easy way to reach a final decision but not the best way. People in collectivist cultures are disposed to subordinate their personal interests to collective goals [24]: the majority's interests and choice are often perceived as the collective interest. However the majority decision may not be the best solution as it stops alternative discussion and hinders group synergy. Sometimes the real situation with majority voting is that with majority voting the minority may in fact impose a decision on the majority. They pretend to ask "*we are all agreed on this, right?*" to suppress dissension. Only the brave members will speak out against that, but normally in order to save face to both themselves and others, Chinese people will keep silent to avoid confrontation to maintain the group harmony. However, CL encourages different ideas, constructive conflicts and discussions to reach a consensus that surpasses the sum of individuals'. Students should be aware of the benefit of the consensus approach, and practise how to make a consensus within a group.

3) Leadership

From students' statements, it was clear that they preferred sole leadership, and interestingly they liked to use the word "*obey*" to describe the action they took in response to the leader's orders and arrangements. People depended on a good leader to lead them to success. It was believed that obeying the leader's order was the most efficient route to success with no doubts or different ideas being encouraged. Only one group expected shared leadership and confirmed the accountability of each member.

In many Asian cultures, leadership is more about management of people than management of work [25]. A good leader acts as a moral example who receives high-level loyalty and devotion from team members. Personalities rather than work-related competence are more likely to be the criteria for leadership [22]. Team members need to follow the leader's order and arrangement. In addition, influenced by Confucius' value of unequal relationships, people need a leader to maintain group harmony and stability. Without a leader, the group does not know how to work. This is quite different from the shared leadership advocated by CL [26]: each member has a job to do and the team does not have a formal leader.

4) Discussion

In the discussion category, students encouraged different opinions, creative ideas, active participation, good listening skills, and critical remarks in a constructive, respectful, and polite way. This indicated that students became aware of professional communication skills and welcomed open and fruitful discussion by giving constructive feedback.

5) Interpersonal and conflict resolution

Students agreed on the following aspects in interpersonal relations and conflict resolution: willingness to know each other; showing respect and care to each other; trusting others; being open-hearted, honest, considerate, tolerate, modest, and helpful; avoiding blaming others or attacking them; dealing with anger, insults and disagreements peacefully; and correcting mistakes immediately. A few groups expected no arguments and avoided conflicts.

CL emphasises "*face-to-face promotive interaction*" to challenge each other's conclusions and reasoning [26] and encourages constructive conflicts, which involve disagreements over thoughts and different views on how to work further [27]. Chinese students in a collectivist culture are traditionally perceived to value the harmonious relationship within the group [28]. They are more emotionally controlled, and prefer indirect communication [22]. Because of the strong emphasis on harmony and face in the collectivist culture, Chinese people are not encouraged to speak out, to question or to criticise. In order to save face, speakers often become very defensive after expressing their opinions. If other people put up different views or disagreements, they feel humiliated so that constructive conflicts turn into affective conflicts, involving personal friction, rivalries, and clashing personalities [29]. Affective conflicts are destructive to productivity and also a threat to group harmony. Therefore, when the problem is approached in different ways, people often choose to avoid it, bypassing the topic of conflict, or being "*obliging*", or asking for mediation from a high-status individual [29].

Though the Chinese students in this experiment showed desire for open discussion and different ideas, they were very careful in coping with differences by controlling emotions and using majority voting to solve conflicts. However the awareness of the concept to relate professionally and maturely to different ideas and feedbacks was something they had learnt.

6) Project management

Some groups also listed expectations on project management: they expected members to follow the project schedule, take care of equipment, reduce expense, and divide work fairly.

Some of the expectations were not concrete. Some listed the general objectives of team work: cooperate with others, work efficiently, build an effective communication mechanism, have a good leader; and be creative. Some propagandised team spirit: be united, confident, full of passion, and optimistic, never be selfish, put the team's interests first and create a harmonious atmosphere. These slogan expectations were not realistic: they do not actually tell team members how to achieve goals and what to do. But this reflected that traditional Chinese teamwork training is focused on the cultivation of a collective spirit instead of skill-based practice. Collective teamwork advocates maintaining collective interests by sacrificing personal interests.

C. Evaluation of Progress Towards an Effective Team

Students were asked to evaluate, against the intended learning outcomes, how well their team functioned in the middle of the task and to list changes they all agreed to make. This step reinforced students' team knowledge, and initiated voluntary improvement through evaluation.

The most common problem reported by nine groups is that members were not well-prepared for meetings. The second biggest problem (eight groups) is the lack of good listening skills: constantly interrupting each other or talking in pairs without listening.

Chinese people are not encouraged to speak out or to question, so do they know how to evaluate? This mid-term evaluation was intended to teach evaluation skills and problem-solving skills. Students need to learn how to evaluate based on behaviour instead of attitude, and be able to make concrete and specific work plans to solve problems. In general, students' evaluation was effective, and their problem-solving plans were specific and practical.

Regarding the problem of late attendance for meetings, some groups worked out very specific rules: (i) everyone attend the meeting five minutes early; (ii) circulate the meeting time three days beforehand; iii) get everyone to confirm they can make it and can come on time.

Regarding the problem of no preparation for meetings, some of the rules were also concrete: (i) before the meeting, the monitor will tell everyone the topic of the meeting, so members could think about it and work out their own thoughts and constructive solutions; (ii) each member should summarise their own opinions [1] in general before group discussion; (iii) prepare fully individually before the meeting to make brainstorming effective.

Regarding the team role problem, some groups requested that: (i) the coordinator takes more responsibility in the detailed task; (ii) to combine the roles of monitor, sceptic and checker to one role because they found there was not an absolute boundary between the three roles; (iii) to divide the work into roles as well as specific tasks; (iv) to elect a person to be responsible for the whole work; and (v) to establish a supervisory mechanism.

D. Peer Rating

How to assess teamwork and individual contributions has always been an issue for instructors when marking group work. Among various evaluation mechanisms, peer rating has been found the most effective one to get insight into individual contribution and performance. Many peer rating systems and schemes have been developed [12]. The evaluation schemes can be grouped into two approaches: one is a qualitative approach to assess "*team citizenship*"; and the other assesses the contribution and effort invested by each team member to the final product [30] [31].

We adopted the peer rating system used by Oakley and colleagues [2], which emphasises how people contribute cooperatively to team goals, but not on their academic ability for their own individual work. Working together with others to develop synergy is very important. This reinforces the training of teamwork skills to meet the learning outcomes.

This system sets up a behaviour anchored criteria (the behavioural characteristics of good teamwork), and explains the meanings of the rating list ranging from "*excellent*" to "*no show*" in terms of individual team performance. However the peer rating was still based on a subjective judgement of observable performance and effort. The validity, reliability and objectiveness of the rating are areas that need to be considered.

1) Do they understand the rating criteria?

Students were asked to rate team members including themselves using the rating words (excellent, very good…no show), and were also asked to give justifying commentary. We investigate these commentaries to see how they understood the rating criteria and how they made the judgement. Students' commentary included the following topics:

- Listed what each member did in the task, for example: shoot the video; direct the show; act in the play; make PowerPoint slides; edit the video; organise meetings; put forward a proposal and revise our plan; look after for the equipment; search information.
- How each member fulfilled their work: are they a good director/editor/actor/leader/checker; can they shoot video in high quality; can they make good presentation slides or write a good script.
- Their team performance: did they attend all meetings, but did not contribute much; did they finish their own work and help others; did they have lots of good/creative/amazing ideas and advice; were they a good listener; did they share ideas with us; were they absent for some meetings/activities; did they point out problems and help to solve them; did they need more courage to intervene; were they punctual and well-prepared; were they sometimes late and contributed very little.
- General appraisal: were they active, creative, full of passion, careful, easy-going, enthusiastic, generous, hard-working, or talented; did they have an open mind; were they technically good, diligent, earnest, selfless, efficient, or humorous; did they devote a lot to the work.

This study demonstrated that students understood the rating criteria, and they inclined to rate each other based on their general judgement of a person, which also includes their contribution and ability. However, some commentary did not justify the ratings. One example is shown in Table I: all the commentaries were good, but the ratings were different.

[1] Some people might not have conveyed their ideas clearly and systematically before.

It was also noted that students were very generous in giving good ratings ("*excellent*" and "*very good*"). Within the 134 sample students there were 44 students who gave all the team members "*excellent*" ratings, and 15 students who gave all the team members "*very good*" ratings.

Some people might argue that this does not reflect reality, giving everyone the same mark or the full mark. The reason for this phenomenon might be that people do not want to offend others even though the marking is anonymous.

2) Consistency of the marking

The overall rating is generally consistent. However we also found differences in rating to a team member: some members found her work was fine and satisfactory, while others felt she did little (Table II).

There is another example: one student rated a team member "satisfactory" with commentary "*He played a role in the advertisement, but he did not make many suggestions for the advertisement.*", while the others rated him "excellent" or "very good" with comments "*good actor, share ideas, good skills in video editing*".

3) Can students rate themselves and others objectively?

It has often been doubted whether self-rating is objective: people may over-rate or under-rate themselves. A previous statistical test showed that there was no significant difference between self-rating and average peer rating for individuals ($Z=-1.509$, $Sig.=p=0.131>0.05$). This indicated that the Chinese students in the experiment did not over-rate or under-rate themselves when evaluating their team working.

In a previous survey, when students were asked whether they would evaluate members' work including themselves objectively, (i) 60% reported "*Yes*"; (ii) 27.5% of them chose "*No, avoid to make some group members too embarrassed*"; (iii) 7.5% said they would evaluate themselves highly; and (iv) 5% said they would evaluate themselves harshly.

Interestingly any inconsistent rating (normally a lower rating) often came from the student themself, which means students often underrate themselves. For example, one student rated himself "satisfactory" with comments "*As the coordinator, I should carry more load and take more responsibilities*", while others rated him "excellent" and "very good". We found that students were often modest in self commentary: "*I should pay more attention to the task*"; "*Just perform ordinary, have potential to improve*". This is in keeping with the modest characteristics of Chinese people. Confucius told people to do self-questioning and self-examination before a conflict or problem, instead of blaming others. Therefore if the team does not perform well, they often blame themselves.

4) Did they give marks using the same grading scales?

It is true that students often have different understanding of the grading scales. Some people are generous in giving high marks while some are very mean and strict in rating. It was found that in one group, all the others rated group members with "*excellent*" or "*very good*", but one member rated others all with "*satisfactory*". Making the rating criteria more particular might help reduce the marking difference.

TABLE I. COMMENTARIES DO NOT JUSTIFY RATINGS - EXAMPLE

A	Very good	Helped the team work effectively and made the ppt
B	Very good	Came up with good ideas about the ad
C	Satisfactory	Made the video well
D	Satisfactory	Came up with ideas and acted well
E	Satisfactory	Acted as the main character in the video perfectly

TABLE II. DIFFERENT RATING FOR THE SAME PERSON

A	ordinary	a little careless (*This is self rating.*)
B	deficient	She had done nearly nothing
C	satisfactory	compliant
D	satisfactory	She could finish her job.
E	satisfactory	Can complete the task in time, and have her own opinions.
F	superficial	I don't know what she has really done

E. Team Roles and Individual Contribution

Through class observation and final presentation questions, it was found that students got used to single-leader groups even though they were assigned different roles immediately after the groups were formed: the coordinator or the monitor was often considered as the sole leader. The task was often parcelled out into parts and each member did one part. Students only completed and took responsibility for their part of the academic task, but did not care about others' work or undertake other responsibilities for the team. Therefore, getting them to perform the other roles (such as Checker, Sceptic) seems like a vain hope.

Members did not normally understand each other's contributions. For example, students did not know what software was used to edit the video and how it worked except for the one who made the video. Others cannot present the work if they were not assigned to make the presentation slides.

During the final presentation, one group made several typographical mistakes (Beijing Duke instead of Beijing Duck) in their slides. When the Checker and Sceptic were asked whether they checked the slides, they shook their heads and looked at a third person who made the slides. This implied that they thought this was the responsibility of the one who made the slides, but not theirs. In another group, when they were asked about the meaning of a sentence in the slides ("*Wish you a fair wind*" in a kite advert), nobody in the group could answer and all explained that the one who made the slides was sick and did not show up!

V. STUDENTS' FEEDBACK

Students are the best judge as to whether a teaching approach is effective or not. This section mainly examines the perspectives of students towards this team training practice and their suggestions.

A survey was conducted after the experiment and the results had been analysed in a previous paper [32]. 52.5% of the experiment students reported "*very satisfied with the team experience in the PDP task*", and 35% of them stated "*somewhat satisfied*". Students in the experiment group reported a higher satisfaction with the team experience (3.35[2])

[2] A Likert five-point scale was used to calculate the satisfaction mark for each response from "very satisfied" (4) to "very dissatisfied" (0)

than the non-experiment students (3.17). More experiment students (97.4%) felt the group coursework helped them learn teamwork skills than the non-experiment students (87.5%). This team training practice was acknowledged and welcomed by the students overall.

A. Attitude toward future group work

81.6% students preferred to work in groups in future coursework projects. The reasons they preferred group work are summarised in Table IIII.

B. What they learn from the project?

Students learned a lot from the project: it brought challenges to their inherited and cultural views. Details are shown in Table IV.

One student explained their new understanding about values and leadership: *"I learn that each member's value is equal. We should respect each other, even though there is a relationship between a leader and team members."* This contradicts the traditional monopolistic leadership in China and respects equal opportunity of expression.

C. The Biggest Problem Students Found in the Process of the Group Work

Students also listed the biggest problems they found in the process of the group work (Table V). These problems need be studied and illustrated when delivering team skills training in the future.

D. Suggestions to Teamwork Training

Some students thought this PDP task (advertisement video making) is very good and recommend more group coursework like this. About one quarter of the students expressed their demand for more group coursework, projects, exercises and activities. They wanted more opportunities to practise team working. One student even suggested reducing or stopping traditional individual assignments and having more group coursework.

Some students recommended designing more group coursework with a lot of originality. Some suggested training team skills in playing interesting games, which will make the communication and cooperation more natural and effective. Some students asked for more time and space for the team project. When talking about the method of forming, they gave some suggestions: (i) allocate students from different classes into a group; (ii) let students choose their own groups; (iii) let different students form a group every time.

Many students wanted more training on team skills: (i) set up a course to train team skills; (ii) teach more useful team knowledge and skills; (iii) give more specific advice and examples; (iv) have more interaction between students and instructor. One student stated: "*If time permitted, I hope the teacher or instructor can talk with each group individually, or the person individually, which is better, but I think they might not have that much time.*"

TABLE III. REASONS WHY TO CHOOSE GROUP WORKS IN THE FUTURE

Group work can help to develop teamwork skills, and interpersonal skills.
Teamwork is important and interesting.
It is a pleasure to work together with others, and they can learn a lot from each other.
Group members share ideas and help with each other to improve together.
Group work is more efficient and time-saving; it makes the hard technical tasks easier to accomplish.
Nobody is good at everything, and teamwork gathers all the powers together.

TABLE IV. WHAT THE STUDENTS LEARNED FROM THE PROJECT, PREPARING THEM FOR REAL LIFE

Teamwork makes life more efficient and interesting, and we can make more friends.
It helps me to have team spirit, and be more responsible.
Respect other's opinion in a team.
Cooperation helps us do work more easily and make the result better.
Learning to get along with others is important.
Everyone has their advantages; we should believe others and let them do what they are good at.
Communicate with other team members;
Listen to others' advices;
Control our temper when we have different opinions;
Give other people opportunity to express their opinions;
The proper way to express our ideas and give feedbacks to others' ideas;
Be considerate of feelings of others; never be authoritarian and rigor to others;
Compromising with others;
Make agenda before meetings;
Make plan before work;
How to lead a group;
Actually learn more academically.

TABLE V. THE BIGGEST TEAM PROBLEMS STUDENTS FOUND

Time management problems;
Lack of inspiration and creative ideas;
Lack of work enthusiasm;
Uneven distribution of work;
Group parceled the work into parts, and members only did their part of work individually;
Some people did less and took advantage of others when they found the others can do more;
Some people did not fullfill their responsibilities in team because they were too lazy, or only concentrated on their own studies, or were busy with other things;
Some members finished their work late;
Difficulty to find a common meeting time because everyone had their own arrangement;
Do not have enough time to communicate with each other;
Group leader did not show the leadership at some key point;
Different people have different ideas, and it is difficult to reach an agreement or consensus;
Some people did not listen to other's opinion carefully or seriously during discussion;
Some people did not express their own opinions but just agree with others' opinions;
Some people attended meetings late;
How to relate with strange members at the first meeting;
How to break the ice when all members keep silent in the meeting.
Some members were monopolistic and bossy;
Some members were academically weak and did not want to try their best to contribute.

VI. CONCLUSION AND FUTURE WORK

This CL practice is a pilot attempt to Chinese engineering students. It brought a positive attitude to team work to the students and most of the students were satisfied with the team experience, and wanted more training and practice on team skills.

It was found that most of the experiment strategies and mechanisms achieved their teaching objectives and learning outcomes. Students generally understood and performed what we wanted them to do. However we also identified a gap between the declarative knowledge and the skill-based outcomes. The transfer from knowledge to skills needs more practice and exercises. Furthermore, the inherited practices and cultural norms also have a big influence on team behaviour.

This CL practice is generally effective in team work training, though some mechanisms were not suitable to the Chinese students and appropriate changes and modifications are required. Students also gave many useful suggestions to the future work. This qualitative study has been a good supplementary to the previous quantitative findings, and gives a good understanding on how Chinese engineering students react in a CL practice.

***Abstract*—While the improvement of computer science students' communication skills has frequently been called for in the literature, employers continue to feel that recent graduates are not equipped with the writing, speaking, and teaming skills essential in the 21st century workplace. One problem with previous approaches is that they often teach communication skills in dedicated courses rather than integrating them into technical classes across the curriculum. In this paper, we report on a multi-institutional faculty team's efforts to integrate communication skills into mid-level data structures and algorithms courses as part of a larger NSF-funded project to enact integrated reform throughout computer science/software engineering curricula. We present an outline of assignments designed to develop communication skills (writing, speaking, reading, listening, and teaming) intertwined with technical skills, and discuss our preliminary efforts to assess these efforts. Our work reflects a general approach to incorporate communication activities *within the computer science curricula* and to help students learn and communicate technical content in academic and professional settings.**

Keywords— Data Structures, Algorithms, Communication Skills.

I. Introduction

Based upon years of experience in industry, coupled with direct contact with students in academia, we can emphatically state the obvious: most computer science students do not know how to communicate well. The technical skills new employees possess are potentially lost due to an inability to effectively articulate a coherent design, idea, or plan [1]. Even students who land their dream job often have difficulty working as part of a team or presenting ideas, either orally or in writing, to peers, management, or customers. These difficulties lead to frustration and an inability to make a difference in their field.

For many computer science students, communication curricula are part of their general liberal arts education and are typically focused on the social sciences and humanities. As a result, students are often not learning and practicing relevant communication skills (writing, speaking, and teaming) *in their discipline*, and often do not see the importance of developing those skills. Frequently they imagine the typical computer science job as sitting in an isolated cubicle, trying to build the latest video game or killer app.

As part of a National Science Foundation CPATH grant, we teamed up with academics and professionals, including communication-across-the-curriculum specialists from the United States and abroad, to address this gap [2]. By having a consistent thread of communication instruction for students throughout their computer science education, ranging from introductory Computer Science to Software Engineering and Capstone courses, the emphasis on integrating communication skills (reading, writing, listening, speaking, and teaming) with technical content becomes a primary curricular feature. With this approach, students not only acquire the technical and analytical capabilities they need, but are also able to communicate effectively and excel in their field.

This paper focuses on our work with integrating communication skills into *data structures and algorithms* courses, early in the curricula (typically after CS1). Two years were spent designing assignments to expose students to both technical concepts learned in class and the related communications skills necessary to provide coherent, complete, and professional deliverables. Faculty members from four institutions, including a communication specialist, were involved in creating and implementing this new curriculum, evaluating its effectiveness, and refining assignments to make them available to colleagues at other institutions.

Here we offer related work in Section II, and describe the participating institutions in Section III. Section IV presents the different assignment paradigms that were implemented to address different communication skills. Finally, Section V presents some reflections, preliminary evaluations, concluding thoughts and potential future directions.

II. Related Work

A number of universities have attempted to create courses for their majors that deal exclusively with communication skills. Northwest Missouri State University addresses the issue of oral communication skills for their computer science undergraduates through a seminar course [3]. Denison University introduces communication skills to computer science and mathematics students through a jointly led lab [4], focusing on the improvement of their oral communication skills. The University of Toronto created a new course entitled "Communication Skills for Computer Scientists" [5]. Still, as noted previously, rather than integrating communication skills within existing computer science courses, these institutions focus on the creation of a separate course that works solely on students' writing, speaking, and interpersonal communications.

More relevant to our project, Hartman introduced writing skills into a data structures course, specifically in assignments dealing with analysis of algorithms [6]. Based on accreditation guidelines, Beard et al. identified the soft-skills most sought by

FIE'13, October 23-26, 2013, Oklahoma City, Oklahoma, USA.

employers, and created a model for producing and evaluating relevant activities [7]. However, the curriculum was designed around accounting courses and not traditional computer science. Falkner et al. present a theoretical framework for assisting instructors with integrating communication skills in the introductory computer science courses (i.e., CS1/CS2) [8]. They provide some guiding principles and methodologies that can be incorporated early in the computer science curricula, along with initial feedback from students.

A broad view of communication skills, including writing, speaking, and teamwork, has also been supported in several studies. Gruba and Sondergaard report on the use of a conference run by the students in a computer science course so that they can work on their communication skills as well as learn technical content[9]. Students were tasked with the responsibility to create, host, and participate in a public research conference, offering opportunities for a wide range of communication activities in a real-world setting. In a 2006 paper, Hoffman et al. describe activities at Quinnipiac University to capitalize on the potential for communication tasks to help students "write to learn" technical content, as well as to communicate that learning [10].

A caution on curricular redesign is provided by Cilleirs, who found a discrepancy between instructor and student perceptions of the value of communication, particularly writing, activities [11]. The study suggests that while students perceive academic writing activities as beneficial in the construction of a report, many times the actual activities used by instructors are not perceived by students as being useful. Such cautions are essential to consider when integrating communication assignments to fulfill technical content learning.

III. INSTITUTIONAL CONTEXTS

In what follows, we describe each of our institutional contexts: overall demographics, the computer science curriculum, and the place of data structures and algorithms within that curriculum.

Miami University

Miami University, located in Oxford, OH, is a mid-sized public University stressing a balance between research and teaching. The Department of Computer Science and Software Engineering has about 300 undergraduate majors and 20 Masters' students, with a typical class size from 20 to 40. The data structures course is the third programming course, while the algorithms course is generally taken by upper classmen.

North Carolina State University

North Carolina State University, located in Raleigh, NC, is a large, public research-oriented institution. The computer science department has about 600 undergraduate majors and roughly the same number of graduate students. Except for the CS1 course, a multi-section lecture/lab combination with 30 students per section, a typical core undergraduate class has from 60 to over 100 students. Class size presents a special challenge to an instructor who wants to introduce communication skills. As at Miami, the data structures course is the third in a sequence of Java-based programming courses.

Tennessee Technological University

Tennessee Technological University (TTU), located in Cookeville, TN, is classified as a medium-sized, public, rural university, with a computer science enrollment of over 300 students, primarily undergraduates. Most students come into the program with little programming experience, having had no access to computer science classes in high school. At TTU, the data structures and algorithms course is second in the introductory sequence of C++ courses, with class size ranging from 40 to 70 students.

IV. ASSIGNMENT PARADIGMS FOR COMMUNICATION SKILLS

This project defines *communication* in terms of five modes: reading, writing, listening, speaking, and teaming. While data structures and algorithms courses feature considerable technical content, at the core they require students to design solutions (specific data structures or algorithmic approaches) to fit particular computing problems. This design element and the implementation of the design quite naturally lead to a wide variety of communication activities that mirror the types of communication students will need to do in the workplace; thus, the real-world element adds value to these tasks and is often highly motivating for students.

In the following sections we discuss various paradigms or overarching categories that we utilized to incorporate communication skills within a data structures and algorithms course. For each paradigm, we present a brief description of the work-place or professional scenario for the particular communication skills, as well as offer assignment examples. One will note that many of the concepts we implemented are applicable to courses other than data structures.

All of the assignment frameworks described in this paper and detailed descriptions of the assignments (as well as others) can be found at http://cs-comm.lib.muohio.edu/.

A. Program Design: Reading and Writing

Designing and implementing a program is probably the most common assignment (across all institutions) for students. They are given a problem to be solved, and they are responsible for designing, building and testing their solution. With this type of assignment, we incorporate two communication skills: reading and writing.

The *reading* skill is manifested in giving the students a task that requires them to do research. For example, in one assignment, we require students to implement a random number generator, a topic not covered in their textbook, and thus requires they search the literature – a situation they will encounter many times in the workplace. The particular goal is not important; the assignment template is constructed in such a way that the the appropriate communication skills are independent of the data structures concepts being introduced (e.g., stacks or queues) and thus can easily be adapted by other instructors to their own assignments.

The *writing* skill is integrated into the assignment by having the students design an application from scratch. To provide some guidance, a design template is provided that includes three parts for the students to populate: pseudo-code;

design decisions; and design issues/notes. The students limit their design document to no more than two pages (relieving some of the grading workload), and are required to submit coherent, grammatically correct, well-written text. A key concept the students must understand is that in the workplace, an employee's ability to convey their ideas in written form is important at many levels: conveying design decisions to their peers, presenting ideas to project managers, and presenting potentially transformative ideas to upper management.

B. Omitting Details: Listening and Writing

In the workplace, not only must software engineers be able to read technical material and write coherently, but they also must listen well. Customers will sit down with the problem solvers to talk about their problem(s), and it is up to the developer to listen and ask appropriate questions.

In the *listening skills* paradigm, assignments are handed out in paper form or posted on the class website, where class time is spent reviewing the assignment and answering questions. To integrate listening exercises, the assignment explanation includes two *verbal requirements* that cannot be found in the written description – the discussion of a feature that the program needs to accomplish is omitted. Because the students are told upfront that some of the required features of the assignment will be given verbally, and cannot be found anywhere in the written documentation that was distributed, the students listen carefully to the program specifications and ask questions about what they just heard.

C. Collaborative Design: Teaming, Reading, Writing, Speaking and Listening

The ability to work in a team is arguably the most important communication skill. Most software engineering projects involve multiple people, from business analysts to designers, coders, testers, managers, and customers. The ability to communicate both internally (i.e., within your company) as well as externally (i.e., with your customer) is vital to the success of a project.

This paradigm can incorporate all five of the communication skills: reading, writing, teaming, speaking, and listening. The reading and writing skills occur through the same avenues as mentioned previously. However, because the initial design is done as a team, students can view and analyze other students' interpretations of the assignment (i.e., what they read), as well as see and comprehend other students' design ideas (i.e., through their writings).

We present two examples of the collaborative-design paradigm, used at two different universities. Both involve team effort toward writing a design and giving an (optional) presentation of it. Each student, working individually, is then required to implement a design, not necessarily the one proposed by their own team. These examples can be adapted to many practically-motivated situations in which the data structure(s) to be used are not explicitly given.

Example 1

The students explore the idea of using queues to create a simulator, such as an airport runway or a car wash.

The initial design is done as a team exercise, with some minimal time given during class for team meetings, followed by individual implementations of their chosen design. By working together, students will learn different approaches for creating a design from other members of their team. The first deliverable, an initial design document, is submitted for a grade about one week after receiving the assignment. This requires students to craft a design before implementing a program – combatting the common tendency to create a design as an afterthought.

After the teams have submitted their design document, one class period is spent on 5-7 minute design presentations. This exercise incorporates speaking and reinforces listening in a different way. To get a grade for their presentation, each student must present some aspect of their team's design. This is a light introduction to public speaking, as each student only gets about 1-2 minutes to talk. In addition, because students are standing in the front of the class with their team, it is less intimidating as they have a support group for answering any questions from the class. Listening is reinforced because students are permitted to use any design they want for their actual implementation, so by listening and paying attention to other teams' designs, they may find a design choice they prefer better than their own. While not a gradable aspect of the assignment, it is definitely motivating to the students to know that they can use another team's design.

After working as a team on an initial design document (and presentation), the students are then on their own to actually implement a solution. And, as mentioned above, they can choose to use their team's design, another team's design, or their own individual design.

Example 2

The students explore an approach to searching and replacing data in a text file as motivated by the following situation: Suppose that the only strings you are allowed to replace are words – contiguous strings with no embedded spaces or punctuation. A situation like this might occur if you want to rename variables in a program.

As in the previous example, there are two phases: a team design followed by individual implementation. Because this assignment is more complex – non-trivial interaction between data structures and more design decisions – the allotted time for the design document is three weeks, with an additional week for preparing the presentation. Team dynamics thus becomes a more prominent factor. An additional feature in this assignment is a test plan, submitted along with the design. In the workplace, developers and testers must often communicate about designs that will integrate a new feature (e.g., the word search/replace added to an editor). A test plan is a critical aspect of the communication between a requirements engineer and the designer. It ensures that each understands the expected behavior of the software under a variety of circumstances

D. Justifying Choices: Reflecting and Writing

As teachers, we hope our students learn from their mistakes and apply their knowledge to solving new problems. As we use exams to gauge students' understanding of course material, programming assignments are intended to see if they can apply what they have learned in the construction of a piece of software.

After students have crafted designs as members of a team and read (or heard presentations of) the designs submitted by others, their learning can be further enhanced if they are challenged to compose a design document individually. For this task to be successful, it is important that the instructor evaluate the design *before* an implementation (if any) is submitted. Students are, in effect, being asked to make judgments about their own work and that of others and to apply these judgments to their subsequent work. For instance, in our examples, students are successful when they understand the pros and cons of different data structures. Reflection on prior experience with communication skills, particularly writing, but also speaking, is essential for continued improvement of these skills in the workplace. Naturally the proposed paradigm is applicable in any context where students have had opportunity to interact with the work (writing or speaking) of their peers.

E. Experimental Comparison: Writing

The choice of an appropriate data structure or algorithm is often based on carefully crafted experiments using relevant problem instances. Students can be asked to apply competing algorithms (or data structures) to large instances of the same problem, drawn from both real and randomly generated data. In one example assignment, students are asked to compare six different algorithms for counting the number of occurrences of each word in a text. The assignment provides a collection of large text files, drawn from articles and books, and a generator for random text files with various characteristics. The writing component of this assignment is the creation of a report that outlines the scope of the experiment (algorithms and instances used), the results obtained and the interpretations thereof (e.g., does theoretical analysis predict actual run-time?). Creating useful and evocative charts – difficult even for experienced writers – is an important component of this type of assignment.

F. Creative Endeavors: Reading, Writing, Teaming and Speaking

In addition to the traditional classroom modes of gauging students' communication skills, students can demonstrate various communication skills through creative endeavors. Exercises include using media such as blogs and wikis to allow students to implement someone else's design (reading and comprehension) or communicate within their team (writing and teaming).

In one example, large class size makes it infeasible to assign individual (i.e., non-team) design assignments. Thus, a twist on the design presentations is employed using YouTube. Students are directed to post a video, limited to three minutes, containing a discussion of their design. Advantages of this approach include: (1) allowing students to work on their speaking skills in a non-intimidating environment; (2) prompting students to learn how to use a popular media website; and (3) allowing instructors to watch the design presentations at their leisure in a short amount of time.

G. Organization and Clarity Through Proofs: Writing

In one institution's theoretically-oriented algorithms course, we assigned problems as much for the writing challenge as well as the technical challenge. Correctness proofs and problem reductions tend to work well: such proofs frequently address a single concept, allowing the student to better focus on a well-written proof. The nature of many proofs dictate a natural template for students once they have solved the problem, and this structure simplifies the problem of providing feedback. It is easy to identify and comment on a failure to mention the crucial point, or to build steps of the proof in a logical and complete progression.

NP-Hardness reductions provide a particularly good example of how proofs can be effectively used to develop writing skills. The central element of such a proof is that of reducing one problem to another in polynomial time, i.e., to show that a polynomial-time algorithm for problem A implies one for problem B. To make this main idea more accessible to students we ask them to think of the reduction in terms of an implementation: we suppose the existence of a (black-box) implementation of an algorithm for A and ask them to design an algorithm for B using it. Given carefully chosen problem-pairs (Partition to Sum of Subsets being a good place to start), even the weaker students can usually grasp the idea.

The more challenging part of this exercise, one that involves communication skills, is for students to prove that the reduction is correct. They need to prove two different results (that the proposed transformation never results in either false positives or false negatives). Within each proof direction, the student will need to clearly state the central point and support it with arguments – not technically difficult, but challenging for the writer to lay out clearly. The writer must avoid conflating distinct concepts (leading to lack of clarity); leaving out one of the two arguments altogether; or failing to properly structure one or both of the arguments (e.g., neglecting to explain what they are proving). Providing clear, useful feedback is usually a simple task: the almost mandatory structure of the solution allows the grader to easily identify problems with the writing and explain why these problems inhibit clarity.

V. REFLECTION AND EVALUATION

While systematic evaluation of the success of our curricular and pedagogical efforts was not always possible, we offer in this section a combination of reflection, evaluation, and student impressions (from survey data) as a starting point for revision of our assignments. We structure this section around the particular communication modes and tasks we implemented.

A. Reflection and Writing Activities

Design and Experimental Comparison Documents. Design documents are pervasive throughout the curriculum and in the workplace. Data structures and algorithms courses often present the first situation where design focuses on more than the implementation of a simple algorithm or a single C++/Java class. Among the design documents submitted (for Example 2, Section IV.C), most lacked a good overview, consisting primarily of detailed pseudo-code and/or detailed UML. These students had learned UML in a previous course but had only limited exposure to high-level pseudo-code. Writing a well-organized overview is the most important, and apparently the most lacking, skill. One could use examples of excellent work from a previous semester – one student came up with a professional quality document – as models, provided that the assignments were not too similar. Models addressing the appropriate level of competence are harder to craft or find in the literature.

The experimental comparison assignment imposed a challenge not normally encountered in the curriculum, yet extremely important in the workplace: presenting data in the form of tables and charts with explanations. The primary issue with the students' charts was scaling: lines frequently ended up on top of each other. Tables were often hard to read; they did not line up properly or presented far too much detail. In explanations of the data there were two issues: misguided explanations (technical) and poorly organized blow-by-blow descriptions (writing). Future uses of similar assignments might be preceded by examples from the literature, where both good and bad examples of data presentation abound.

Proof-based Exercises. In the proof assignments there was a core set of writing-related problems that reflect specific problem types in the student's general writing ability. Examples include:

Failure to explain premise (poor writing structure): The average student frequently fails to explain what they are proving. Presenting a clear thesis is necessary in good writing; in identifying this problem we hope to help students organize their thoughts and lay a proper foundation for their writing.

Excessive use of notation (poor presentation): Students confuse "proof" with "algebra," apparently believing the latter is mandatory in the former. We emphasize that notation should be used only to facilitate understanding (as short-hand for concepts too cumbersome to write in prose): a proof without Greek symbols is acceptable. Making students aware of overuse of notation forces them to focus on clarity and on the use of appropriate tools.

Failure to connect ideas (poor logical presentation): Students often make logical jumps or fail to explain connections they have correctly made in their own minds. This problem becomes easier to both spot and explain in proofs than essay-based writing, allowing us to provide useful feedback.

Superfluous statements (problems with concise writing): It is not unusual for a student to attempt to say the right thing by way of saying everything. Again, in a mathematical proof it is generally easy to spot irrelevant comments and provide useful feedback.

The above observations about proofs are based on an upper-level algorithms class, but the ideas apply also to data structures classes that incorporate smaller proofs into project assignments. For example, students may be asked to prove assertions related to the correctness or runtime of a program.

B. Reflections on Speaking Activities

On the whole, both the formal in-class presentations and less-formal, student-made videos were successful in helping with speaking skills. For the collaborative design assignment most groups gave what appeared to be well-rehearsed presentations, given either by one group member or several. Almost all presentations adhered to the time limit (imposed in Example 2 of Section IV.C), allowing for a lively question and answer period.

We found that most of the students enjoyed the YouTube *speaking* exercise and were sometimes very creative in the process. Submissions ranged from voice-narrated computer animation to a "60 Minutes" television show parody. The ease of using video equipment, usually embedded in their laptops, made this a fun and easy assignment for the students and an effective vehicle for improving communication skills.

C. Reflections on Teaming Activities

In capstone courses, teams are often based on a set of complex criteria (e.g. Layton et al. [12]) but this approach is unnecessarily time-consuming for our purposes. In our case, team assignments were based on a ranking of students with respect to performance earlier in the semester, using one of two strategies to form groups: (1) including a range of student ranks in each group; or (2) grouping students by rank [13].

In using strategy (1), we hoped that weaker students would learn from stronger ones. This outcome was observed directly in a few cases. Of 18 teams of size three or four students, most appeared cohesive (based on student peer evaluations and instructor observation). However, three of the teams had one member who contributed little or nothing and another team had a member who was completely unable to contact the other three, and therefore ended up doing the assignment alone.

One of the authors had used strategy (1) in an earlier semester, but switched to strategy (2) based on the work of Braught et al. [13]. The justification is that a group of good students will be driven to produce even more, while a group of poor students will realize that they need to step up if they want to succeed. After making this change in team dynamics, the instructor noticed superior work from the top students – they reached out and tried interesting ideas – while most members of the bottom groups actually contributed to their team's efforts, sometimes with surprisingly good results. One disadvantage of the latter approach, observed in a context requiring more complex tasks, is that the poor students make little, if any, progress.

All communication skill assignments presented grading challenges. We relied solely on peer ratings for assessment of teamwork. Speaking was only lightly graded: any reasonable attempt resulted in credit. Thus, most of the grading burden focused on writing. One of the authors advertised a rough breakdown to the students (10 points for each of several aspects), but was then faced with the difficulty of deciding between, say, a 4 and a 7; furthermore, each such decision had to be justified. A more reasonable approach would be a simple checklist of items each worth only 1 or 2 points, such as "a table that summarizes data effectively." This would obviate the need for justification and allow the instructor to focus instead on constructive feedback: positive encouragement and suggestions for improvement.

D. Students' Reflections on Communication Activities

While logistics and a lack of resources precluded comprehensive assessment of this project, we did conduct an assessment of student perceptions of their communication skills before and after a team design assignment in one course – see Section IV-C. Students were given an attitude survey at the beginning and end of the semester; 32 out of 61 students participated. The questions asked students to rate their ability in each of the following: (a) *reading* technical specifications, including assignments, documentation, etc.; (b) *writing* technical documents, including descriptions of algorithms and experimental results, designs, etc.; (c) giving audience appropriate presentations (*speaking*); and (d) working effectively with a team of peers to accomplish a common goal (*teaming*). Ratings ranged from very good (5) to very poor (1).

On average, the students rated themselves more positively at the end of the semester in three of the four categories: the average scores increased from 4.09±0.13 to 4.25 ±0.13 for reading, 3.50±0.12 to 3.75±0.11 for writing and 3.66±0.14 to 3.78±0.14 for speaking. (The ±'s here indicate standard error.) Teaming was a different story: there the average rating dropped from 4.19±0.13 to 4.16±0.12. Students were more confident about their teaming ability at the beginning of the semester than about any other skill. The lack of improvement might reflect the fact that nine students (in the sample of 32), who rated themselves more poorly at the end, were predominantly ones whose teams fared badly. The presence of carefully designed and positively regarded team assignments in the second semester Java course and an emphasis on pair programming in the introductory course could explain the initial high confidence in teaming ability. Clearly more careful attention could be paid to the teaming aspect of our proposed assignments.

Prior experiences in these skills were elicited with the prompt, "Please list the courses (including CSC 316) and/or industry settings (e.g., co-ops) in which you practiced [reading, writing, speaking or teaming skills listed in detail]." Only 21 of the 32 students reported having done reading in CS1 even though the prompt specifically mentioned "assignment specifications." The number increased to 31 for CS2. Prior writing experience was reported by 5 for CS1 and 23 for CS2. Teaming went from 8 in CS1 (pair programming is a part of that course) to 27 in CS2, where teams of four or five are now standard. The significant prior (presumably positive) teaming experience explains the beginning-of-semester confidence (and later drop thereof) with respect to that skill. As expected, there were only a few reports of speaking experience in CS1 and CS2 – 10 in the latter. But nine additional students reported speaking experience in industry, English courses and/or other CS courses. Clearly, prior experience was a significant factor in the better than average initial confidence ratings of students for four of the communication skills.

VI. CONCLUSIONS AND FUTURE WORK

The central point of the work described here is to bridge the gap between CS1 courses, where communication activities are typically low-stakes, and software engineering and capstone courses, where communication is a major part of course content. We address this transition via a collection of assignment paradigms that can be used to seamlessly integrate communication skills with technical content.

The activities we describe are only starting points for integrating communication skills into the computer science curriculum, generally, and data structures and algorithms courses, specifically. We do acknowledge (and have experienced) that large class sizes, last-minute teaching assignments, and skeptical students (and colleagues) are challenges to this work. However, we strongly feel that inducing students to develop the communication skills required of professionals *along with the technical content of these courses* is well worth the time and effort.

In future semesters, we imagine several possible directions:

- *Tracking actual improvement in communication skills as the semester progresses and/or in follow-on courses*. There was an attempt to match the pre/post attitude survey in the course at one institution with another attitude survey in the capstone course, but there was no comparative *evaluation of actual communication skills*. Even the attitude survey did not allow for adequate comparison between students that were exposed to the above-mentioned assignments and students who were not; the questions were not coordinated and it could not be determined how many students (if any) took both surveys.
- *Evaluating the impact of communication assignments on technical skills*. There is a legitimate concern that these assignments require additional class time and/or reduce the portion of a student's grade dependent on technical competence. Anecdotal evidence suggests that increased emphasis on communication skills neither decreases nor increases technical competence. A more rigorous assessment of this observation would be useful.
- *Using professional-quality examples of work demonstrating the communication skills*. High-quality student work from previous semesters (anonymized) could serve this purpose. Speaking and teaming present difficult challenges. In case of the former, industry advisers have suggested use of examples provided by them; the process of developing a functioning team would probably have to be taught and supervised by a specialist, as is done at one of our institutions.

Let's do it OR *Deal with it*: Teamwork in Project-based Learning

Ya Zhou, Yao Hu, Liquan Dong, Ming liu, Yuejin Zhao, Qun Hao
School of Opto-Electronics, Beijing Institute of Technology, Beijing, China
Email: zhouya@bit.edu.cn

***Abstract*—Project-based course is based on teamwork and most of work is done and presented as a team. Team grouping rule is one of the most important issues. In project-based experimental course *Optoelectronic Instrument Experiments* (OIE), several different rules were attempted, each of which produced complaints by some students. After several trials of different grouping rule, we realized that there is no perfect rule which can satisfy everyone. Instead of changing the rule, trying to find a way to persuade the students to accept and support their group willingly might be a better solution. In this semester, the project teams are entirely determined by lot and several teamwork inspirational approaches are introduced to inspire team spirit in the course. Our purpose is to find a way to make student learn the interpersonal skill of working in team. Let's do it, not just deal with it inactively.**

Keywords—Project-based learning, engineering-involved courses, Teamwork

I. INTRODUCTION

The necessity of restoring the balance between practice and science in higher education has long been acknowledged in educational literature, which is now even more pertinent to engineering education. The situation is similar in Chinese undergraduate education.

To educate students how to learn rather than teaching them specific techniques, contemporary engineering education should focus more explicitly on skills including problem-solving, communication, teamwork and leadership skills. As engineering educators, the engineer in education field whose products are students, we view quality teaching of undergraduates as being on par with other scholarly responsibilities and achievements. Equipping students with a range of important professional skills, such as project management, teamwork and cross-cultural communication can be achieved in a carefully managed open ended project course[1]. Project-based learning dealing with key aspects of product design and realization has been acknowledged by many academic institutions as an appropriate means in the training of adaptable, reliable and responsive engineering students[2]. In 2009, a 12-week-long project-based experimental course Optoelectronic Instrument Experiments (OIE) was launched at the School of Opto-Electronics, Beijing Institute of Technology[3]. Our purpose is to help students to improve their engineering practical and personal skills as well as their team collaboration.

Collaboration is one of the most treasured attributes for a qualified contemporary engineer. That's the reason why teamwork is emphasized in OIE course. However, initial resistance to team-based approaches from individual students is quite common and students are not born knowing how to work effectively in teams[4-6]. According to the survey that was conducted at the end of each academic year among all the students who had taken the OIE course, some of the students complained that the grouping rule and the team assessment manner was unfair. Instead of changing the rule, trying to find a way to persuade the students to accept and support their group willingly might be a better solution. In this semester, the project teams are entirely determined by lot and several teamwork inspirational approaches are introduced to inspire team spirit in the course. In this paper, we will give the detail of our tryout and analyses.

II. TEAMWORK PEDAGOGY AND ISSUES IN OIE

A. OIE: The Project-based Course

OIE is a lecture-lab course which aims to familiarize students with the principal ideas of optoelectronic apparatus design and train students to apply the knowledge to identifying, analyzing and solving problems in optoelectronic system construction. We try to expose the students to "real" engineering early. After some brief general topics on optoelectronic instruments and introduction to several successful design examples, the students are assigned to teams and each team chooses one project to implement in twelve weeks. Through the mini simulative "Cycle of Professional Practice"[7], students will learn how to integrate the knowledge and techniques they have learned previously, and use different kinds of components and devices to construct an optoelectronic instrument.

The main difference from the other project-based courses is that the OIE course is compulsory, which means every student must take this course. In our opinion, students are the products of their college. Elite education may help several excellent students to achieve huge success, but we prefer to the results that all the students turn to be qualified products. All the students who are majoring in Measurement & Control Technology and Instruments have to gain the OIE credit to get their bachelor degree. We are trying our best to impel them to be prepared for the real engineering environment they have to throw themselves into soon.

B. Teamwork Pedagogy and Issues

In order to work in modern team-based environments, students must develop the interpersonal skills of teamwork. That's the reason why teamwork is emphasized in the course. The teamwork pedagogies in OIE are summarized as following:

1) Instructor Team: The OIE course has a 6-member instructor team, including full professors, associate professors

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

and lecturers. Lectures in the beginning weeks are given by different teachers, each being adept at one specific aspect such as optical design, mechanical structure or image processing. While they are working as consultants/ advisers/ supervisors in the course, it simulates a team of experts helping the students. This special pedagogy proved to be attractive to all types of students and met to the needs and issues of the broader community.

2) Team Assessment: In the grading phase the teamwork is underscored reasonably. At the end of the course, each student is to hand in their own final project report and a mutual assessment form on which each student should grade his teammates and himself in both technical contribution and collaboration. After the teachers mark all the reports and the average score given by his teammates are calculated, along with the competitive examination estimation, each student has three scores: report score, mutual assessment score and competitive examination team score. The final score of the course is determined by the three factors. The grade of each student is influenced by the team score, that is, if the team does not work well, the team member, no matter how outstanding his personal capabilities are, will suffer a lower grade.

The OIE course has been carried out four academic years. The experience of this course has led to insights in teaching style design, especially with respect to engineering-involved courses. It also helped us find several unsolved issues, most of them involved in team grouping rules.

In the OIE course, there are two alternative team grouping rules: free combination and assigned team manner. Free combination is preferred by some active students because they want to work with classmates who share the same interests and are at a similar competence level. But some introverted students might be ignored or underestimated by their classmates. Furthermore, it could induce initial competence gaps between the teams and the gap will widen as projects progress, which is definitely not what we desire since we view OIE not only a course for professional skill training but a chance for building confidence in engineering field. Assigned team manner was applied in OIE since engineers rarely have the opportunity of choosing their team colleagues in practice. We want to expose the student to a real engineering environment and let them deal with it. Unfortunately but understandably, this assigned grouping approach produced complaints by several students and the repellent mood did reduce the team spirit.

III. WHAT'S NEW THIS SEMESTER

The OIE course is compulsory, which means every student must take this course. Willing or not, students had to work their project out as a team under certain grouping rule. In order to minimize the gap among students' groups and try to ensure that they are in the similar beginning level, several different assigned rules were attempted in OIE: according to the student's academic records in previous courses, according to the level of student's activity, or the teachers' impression. Each of them produced complaints by several students.

We believe in the power of teamwork and we insist that it should be taken into account in grading a project-based course. We also are aware that students could learn more and be more creative with less repellent and conflicting moods. After several trials of different grouping rule, we realized that there is no perfect rule which can satisfy everyone. Instead of changing rule, trying to find a way to persuade the students to accept and support their group willingly might be a better solution.

In this semester, the project teams are entirely determined by lot and several teamwork inspirational approaches are introduced to inspire team spirit in the course at the beginning of the class. Our purpose is to find a way to make student learn the interpersonal skill of working in team. Let's do it, not just deal with it inactively.

A. Team Grouping

The first class of OIE is arranged for team grouping. In this semester, the students are grouped "providentially". Some poker cards with funny pictures are prepared before, the total number of which equals to number of the students who have signed up for the OIE course. Every student is asked to draw a card from the poker card pile when he enters the classroom. Just when they enjoy the funny view on their cards and become curious what it is for, the grouping rule is announced. The students who got the same suits and numbers are grouped as a team.

Most of students do not "hate" any of their classmates. They just do not like the feeling of being assigned. The project teams are entirely determined by the cards they choose by themselves, which could induce less conflicting mood even the teammates are not who they are expecting.

After the announcement of grouping rule, the students are given about five minutes to find their teammates, name their team and elect a team leader. Then after five more minutes' preparation, each team is required to give a 5-minute speech in front of the class and the instructor team. The speech is supposed to include the following information: the brief introduction to each team member; the most remarkable personality of each member; the origin of their team title; the expectation of the course; and at least one strong point that exceed other teams. All members of the team should take a role in the speech.

The team grouping class works as the icebreaker as well. Most Chinese students are reticent and lack of the courage to express themselves. Usually contradictory in teamwork stems from poor communication and misunderstanding. The first work they do together is naming their own team and finding their strong points, which is helpful to familiarize them with each other quickly and build the initiatory team spirit. Furthermore, the joint speech also can help students to begin to practice oral presentation which is one of engineering skills the OIE course aims to help the students to gain.

B. Team Spirit

One of the major missions for project-based course OIE is to teach the students to work together with good team spirit which is about supporting their team, respecting others and most of all encouraging their team mates. What we do for inspiring the team spirits of the students this semester is to give them more pressure.

In OIE course, after the students are grouped into several engineering teams, each group is required to choose a project from about fifteen available ones each of which comes from real engineering projects or is a simplification of teachers' research. That is what they will devote to as a team in the following twelve weeks. They are given about a week for analyzing problems to be resolved, investigating information, generating alternative solutions, disassembling and modularizing assignment, and dividing work among the group. Then in the following week, the students (as a team) should present their project plans to the teachers who are in charge of the course and also some invited faculties who have rich experience in engineering research. They are to present the analysis, their conception and design of the assigned projects, and the project budget. The teachers ask questions, give advice and approve budgets, then decide whether the team and their plan are ready to be implemented or not. The team whose project plan fails to pass the teachers' evaluation has to redo all the preparation and presentation.

This semester, during the project plan approving phase, we were more strict to and even a little more critical of the students team and their project plan on purpose, especially on some issues which seemed due to insufficient team communication, such as assignment modularizing and work dividing. Most of the teams failed the first round and had to redo project plan and the presentation. During the process, the team member united much closely and the team spirit or team cohesion were strengthened effectively. The greater the external force adds, the more solid the structure is. It seems true in OIE course.

C. Benefit Distribution in Teamwork

In real engineering environment, teamwork is not only about implementing the project, solving the problem and completing the work, but also about distributing the profit. We try to expose the students to "real" engineering early, benefit distribution must be involved.

In a project-based course, the most direct benefit to the students is their scores. As we mentioned, in the grading phase of OIE, the teamwork was underscored reasonably. The final score of the course was determined by final mutual assessment score and competitive examination team score, which can also be counted as a kind of profit distribution. This semester, we are attempting to bring the rule of distribution according to work into the whole process of the project. The OIE has intensive classes. In each class every team is given a certain amount of credits and asked to distribute the credits to each team member according to what he have done this time before the class is dismissed. If everyone works hard equally in this class, each will earn the average credits. Otherwise the one who makes more technical contribution and collaboration will get higher scores. These scores from each class will form the daily credit of each team member.

At the end of this semester, we plan to give every team a credit package according to the final competitive examination. Every team member will get his final score by dividing the whole package in proportion to their daily credit. The superior team will earn a bigger package and the hardest worker gain the highest final score.

Our purpose is to let the student realize and understand the benefit distribution in real engineering team, as well as to inspire the students to further efforts. So far, the daily credit assessment does drive the student to invest more energy in their projects.

IV. Discussion and Future Work

Since the capability to work in teams has become a key requirement on engineering graduates, education not only embraces technical competence but also necessitates interpersonal skills. In this paper, we give several of our new tryouts and the analysis on teamwork training in the project-based course OIE. The outcome of these new trials should be criticized by the students.

At the beginning and the end of each academic year, surveys constructed based on several aspects(such as the course organization, the teachers' team, the pedagogy, and the expectation of the course, etc.) are conducted among all the students who have taken the OIE course. Besides the regular surveys, this year each respondent is asked to give a self-evaluation on their teamwork skill before and after taking the course. According to the preliminary statistics, about 75.44% participant think that the course is helpful to improve their teamwork skill and their self-awareness of being a team-member, while 14.04% of them feel it is useless and 10.53% feel the course hurts their self-confidence in collaboration. We are working on the further data collation and analysis. Hit or miss, we will give our investigations further.

Department of Mechanical, Industrial, and Manufacturing Engineering
University of Toledo
Toledo, OH 43606, USA

***Abstract*—To maintain competitive advantages in today's global market, US companies are challenging higher education institutions to bridge competency gaps between industry workforce needs and what is provided by engineering education programs. To meet this challenge, the Mechanical Engineering program at the University of Cincinnati proposes the EXPLORES (Experiential and Problem-based Learning within Opportunities for Real-world Engineering Settings) model where students from freshman year onwards are exposed to real-world industrial problems that have a direct bearing on fundamental engineering concepts. The EXPLORES model is implemented in a learner-centered, knowledge-centered, assessment-centered, and community-centered student learning environment. Although inclusion of real-world industrial problems into engineering curriculum is not a new invention, the EXPLORES model is unique in the following aspects: (1) the problems span multiple courses so students need to have the ability to synthesize knowledge acquired from different courses in order to develop complete solutions; (2) industry partners are an integral part of the education process by providing problem design, periodic feedback, and expert solution; and (3) an on-line virtual company framework is used to facilitate information sharing and motivate student learning.**

Keywords—problem based learning; industrial problems; learning environment, manufacturing processes; engineering statistics

I. INTRODUCTION

Traditionally, engineering students are taught in a classroom setting with the instructor explaining various concepts and deriving the appropriate mathematical relationships. The instructor may also present some applications of these concepts. However, students may not really appreciate the true learning of these concepts unless they are tied to a real-world industrial problem that has a direct bearing on the concepts. Tying the teaching of a concept to the student actually participating in the application of this concept in an industrial setting may result in lifelong retention of the concept [1-3]. In addition, an optimal solution to a larger industrial problem requires appropriate synthesis and adaptation of multiple concepts in a discipline or across disciplines in a comprehensive manner. Currently available curricula at most engineering institutions do not include a systematic study of real-world problems, although some organize problems disparately among different courses. The present practice hinders the development of common understanding among students to integrate concepts from different courses to solve larger real-world problems. Because prevailing engineering education pedagogies do not target real-world problem solving in a comprehensive manner, our graduates need to go through a substantial period of after-hire training before they can contribute to their employers.

The EXPLORES (Experiential and Problem-based Learning within Opportunities for Real-world Engineering Settings) model is proposed to bridge competency gaps between industry workforce needs and what is provided by engineering education programs. It is implemented in a learner-centered, knowledge-centered, assessment-centered, and community-centered student learning environment, as shown in Fig. 1. Specifically, real-world industrial problems are identified that can be broken down into sub-problems and mapped to a selected set of key concepts taught in clusters of core courses in the Mechanical Engineering curriculum. These case problems are presented under a virtual company framework. Students post their work in the virtual company repository during different stages of the learning process. Their solutions and procedures are then viewed by the instructor, industry partners, and other students who provide periodical feedback. Industry experts would then meet with students to discuss the pros and cons of the solutions from a real-world perspective. The efficacy of the EXPLORES model is being evaluated in two pre-junior courses; namely, Manufacturing Processes and Engineering Statistical Methods.

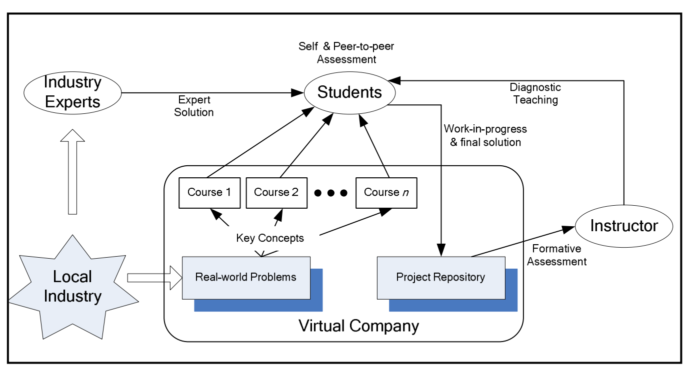

Fig. 1. A learner-centered, knowledge-centered, assessment-centered, and community-centered student learning enivornment.

II. Scientific and Educational Feasibility

The academic community has long recognized that individuals have a variety of learning styles and preferences for receiving and processing information [4]. Research has demonstrated that traditional methods used to teach students are not congruent with many individuals' preferred method for receiving information [5]. In engineering, we have seen that undergraduate education has failed to provide instruction in a manner that is engaging and relevant to large numbers of students [6]. While the explanation given for years was that these students were simply not suited to engineering, other educational leaders have suggested that our traditional educational paradigm has failed significant numbers of students [7, 8]. To meet this challenge in engineering education, we should remember that students are driven by passion, curiosity, engagement, and dreams; and thus we should focus on the environment in which they learn [9]. In fact, Jamieson and Lohmann [10] pointed out that "engineering education innovation is about designing effective learning environments."

The EXPLORES model is rooted in the problem-based learning (PBL) pedagogy while emphasizing the development of a learning environment that is conducive to knowledge acquisition and retention. A few recent studies showed that integrated approach of PBL pedagogy and online delivery model enhanced students' learning attitudes [11], better prepared students for applying the knowledge learned in the classroom [12], and provided a coherent and comprehensive learning environment [13, 14]. These evidences support the presentation of real-world industrial problems using a virtual company framework. Students will have a better understanding of the industrial environment, why they are learning Mechanical Engineering, and how they can apply what they learned to solve problems that have a direct bearing on company missions.

III. Expected Outcome And Evaluation Plan

The expected benefit of this project is that by unifying engineering education with industrial reality, undergraduates will be better educated in applying theory to real-world problems; thus allowing every stakeholder to maximize their return on investment in the education process. In addition, corporations will have better qualified applicants for their job openings, and faculty will have better awareness of the needs of corporate America, thus building an infrastructure of partnerships and networks for both education and research.

The project evaluation will be conducted by the University of Cincinnati's Evaluation Services Center (UCESC). Both quantitative and qualitative methods will be used in conducting formative and summative evaluations. Formative evaluation is meant to track the progress of the project and implement improvements within the duration of the two-year project period. Summative evaluation will be conducted to determine the extent of project success that will be measured in terms of students' outcomes. The major participants in this evaluation are the pre-junior engineering college students participating in two pilot courses implementing the EXPLORES model. The program theory is: students who experienced the EXPLORES model in learning the chosen engineering courses will be more motivated to learn and will manifest better critical thinking skills and greater applied engineering knowledge and skills needed by the industry compared with similar students who were trained with the same courses but were in traditional classrooms.

IV. Importance to the Education Community

To the best of our knowledge, no one has previously attempted to frame a curriculum around a corporate structure and actively involve industrial partners in engineering education. We focus on mapping a few key concepts in each course to projects based on real-world industrial problems. In-depth coverage of these key concepts and their application to real-world problems supports learning with understanding, which is important for the development of expertise [4]. In addition, students will see the usefulness of the key concepts and can apply them to solve problems that have a direct impact to local industry. They will feel that they are contributing to the community and thus are motivated to learn [15-17]. Making industrial partners an integral part of the education process can demonstrate to students what expertise looks like while providing a non-intrusive feedback mechanism. Students can learn to assess their own work as well as the work of their peers; and thus help everyone learn more effectively [18].

V. Project Status and Preliminary Result

This project started in May 2012. The initial focus was on developing the web-based virtual company (current website address http://uc-star.info/v1.9.uc-star.info, version number may change and an official site will be created once the virtual company is fully developed). The company was named STAR Corp. Technical Center. It has two departments; namely, Manufacturing (corresponding to the Manufacturing Processes course) and Quality Assurance (corresponding to the Engineering Statistical Methods course). There are three types of users, summarized as follows:

- *Engineers*. They are students who will be working on projects pertinent to the courses that they are taking.
- *Directors*. They are course instructors who will assign projects to the engineers, monitor project progress, and assess the performance of the engineers.
- *Consultants*. They are industrial experts who will provide feedback to the engineers.

Industrial case problems are currently being developed. These problems will be presented as projects in appropriate departments of the virtual company and assigned to engineers. Students in the Manufacturing Processes and Engineering Statistical Methods courses will be working on these projects starting Fall 2013 and Spring 2014, respectively. Their performance will be compared to that of the students taking traditional courses without implementing the EXPLORES model. The performance data of these traditional course students are currently being collected (Manufacturing Processes in Spring 2013 and Engineering Statistical Methods in Fall 2013).

ACKNOWLEDGMENT

The research is supported by the National Science Foundation under Grant No. 1141120. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

***Abstract*— It is essential to prepare students with knowledge and skills in area of business analytics (BA) which will help business to process data, find patterns and relations, develop insights from past transactions, and make prediction. We develop hands-on labs to teach business analytics to students in Computer Science, Information Technology, and Software Engineering disciplines. Our hands-on labs can be adopted in courses such as database systems, data warehousing, data mining, etc. We use enterprise BA tools including MS SQL Server Business Intelligence and Cognos 10 platforms, which are essential to increase student interests, improve student learning, and enhance student confidence. Our hands-on labs contain three parts with one is built upon another: 1) Data integration; 2) Data Warehouse; and 3) Business analytics.**

Keywords— business analytics, hands-on learning, data analytics

I. INTRODUCTION

An increased number of businesses are using computerized system to gain competitive advantages and make decision, given continuous large amount of data collected from consumers, employees, suppliers, competitors and product inventory. McKinsey's research [1] says there will be a shortage of talent necessary for organization to take advantage of big data. "By 2018, the United States alone could face a shortage of 140,000 to 190,000 people with deep analytical skills as well as 1.5 million managers and analysts with the know-how to use the analysis of big data to make effective decisions."

In observation of this demand, we have developed a series of new hands-on labs on data analytics with real-world and business relevance. Student will first experience generation of data mart and Extract, Transform and Load (ETL) processes in data integration part. ETL is important because it lifts data from transactional systems to operational data stores, data warehouses, and BA platforms. In the part of data warehouse, students will exercise with data warehousing, data dimension, cube and online analytical processing (OLAP). Students create, edit, import, export, and deploy cube models over the relational warehouse schema to perform deeper multi-dimensional analysis across multiple business variables and large data sets. Students also use optimization techniques from cube to improve the performance of online analytical processing (OLAP) queries. In the part of business analytics, students will be taught data mining and artificial intelligence (AI) concepts and algorithms which are then used in decision making. Students use data mining models (clustering, associations, classification, and prediction) to gain business insights. Students also experience rich presentation components, visual analysis of data mining results and interactive tools. BA helps students to apply techniques to assist decision making in business relevant fields.

The innovation of our hands on labs on business analytics lies in engagement of students into enterprise products with real-world business settings, exploration of efficacy of BA as an inter-disciplinary field, and sharpening student skills by data sets with real-world relevance. Examples of skills include:

- Being able to exploring data to discover new relationships and patterns (data mining)
- Being able to explain why a certain result occurred (statistical analysis, quantitative analysis)
- Being able to evaluate previous and alternative decisions (A/B testing, multivariate testing)
- Being able to predict future trends (predictive modeling, predictive analytics)

Being able to visually analyze data (computational modeling, human computer interaction, and graphics)

II. HANDS-ON LABS ON BUSINESS ANALYTICS

Hands-on learning approaches engage students actively and thoughtfully in learning [2]. Students in a hands-on science program remember the material better, feel a sense of accomplishment when the task is completed, and are able to transfer that experience easier to other learning situations [3]. These benefits are achieved because "more than one method of learning is accessed" in hands-on learning and "the information has a better chance of being stored in the memory for useful retrieval" [3]. Naturally, the best teaching method is to offer interactive exercises based on problem solving. Resources and hands-on labs are lacking in the area of business analytics although they are important in preparing needed skills for future workforce. We developed the following hands-on labs in BA.

A. Labs on Data Integration, Transformation, and Loading

Students first create a data mart as a repository for data to be used as a source for business analytics. The data can come from various resources such as online transactional processing (OLTP) systems, XML files or databases. The data marts are architected using either a star schema or snowflake schema. The data marts are not much useful for decision making until they contain enough useful data. Students will then change

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

location of data by copying it from the OLTP databases or other locations into the data mart, which is called data integration. They will also be required to transform the data from the format required by OLTP to the format required by the data mart if data sources are heterogeneous. Foreign key values will be verified during load of the data, which enables implementation of data mart without foreign key constraints. Figure 1 shows a data flow that loads a table to a data mart.

Learning outcomes:

Students will be able to understand incomplete and heterogeneous nature of data sources. They will be able to create a data mart by data integration, transformation, and loading services.

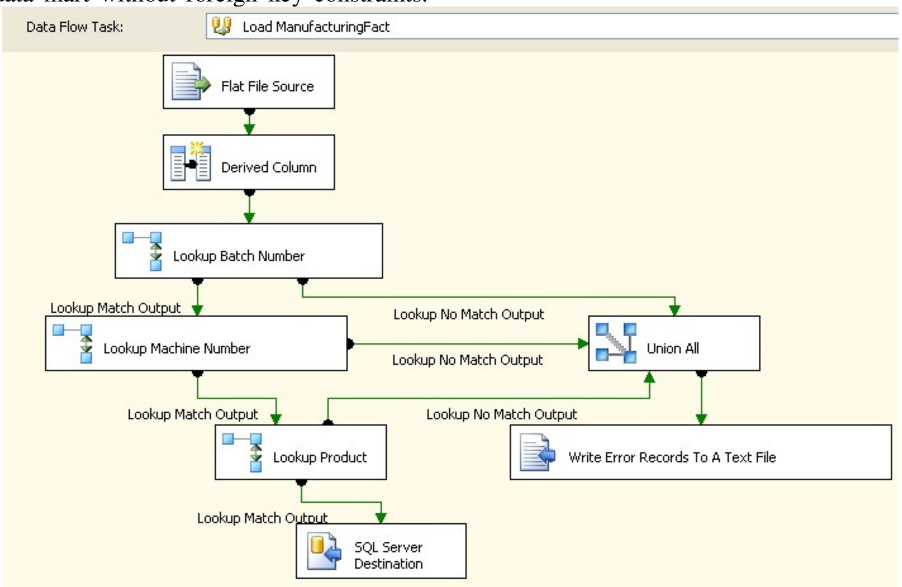

Figure 1 Load data into a data mart

B. Labs on Business Analytics

In these labs students need to access the data mart to populate and update the information in the OLAP cube which has measures, dimensions and attributes. Measures provide the actual information that the users of our cubes are interested in. Dimensions allow students to slice and dice the measures in the cube until they find the meaningful business relevance hidden among all of the numbers. Dimensions provide understandable phrases in business language to define what may be cryptic in a transactional database system. Students have a variety of dimension such as time in their cube to measure groups to perform meaningful analysis on the cube. Additionally, students will also include information discovered by data mining algorithms in their cubes.

Students will also apply data mining algorithms to discover patterns and business relevant results out of their data mart. Data mining allows them to utilize computer power to combine huge amount of data to find meaningful information. The data mining algorithms include classification, regression, association, sequence analysis, and probability predictions. Figure 2 shows how to use decision trees to predict and analyze data using SQL server Business Intelligence Development Studio.

Learning outcomes:

Students will be able to gain business related information by dimensions of data. They will also be able to mine information using related data mining algorithms.

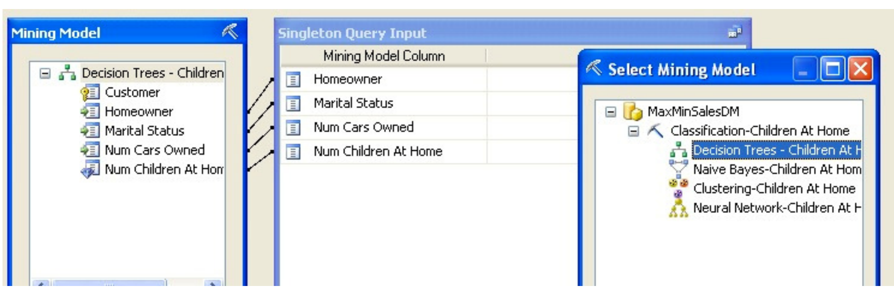

Figure 2 Employ a data mining model for business analytics

C. Labs on Reporting and Delivery of Business Analytics

In the business analytics world, the report is king. Reporting services enables both developers and users to create report. Students devliver reports to demonstrate results of their analysis of data sources. Figure 3 shows an examples of report in the form of interactive dashboard. In this report, students are trying to where and why products are the most frequently returned, and that have the biggest impact on the company's profit. This example comes from one of IBM Cognos Business Intelligence Examples [5].

Learning outcomes:
Students will be able to create a report and interactive dashboard, which supports business related decision making.

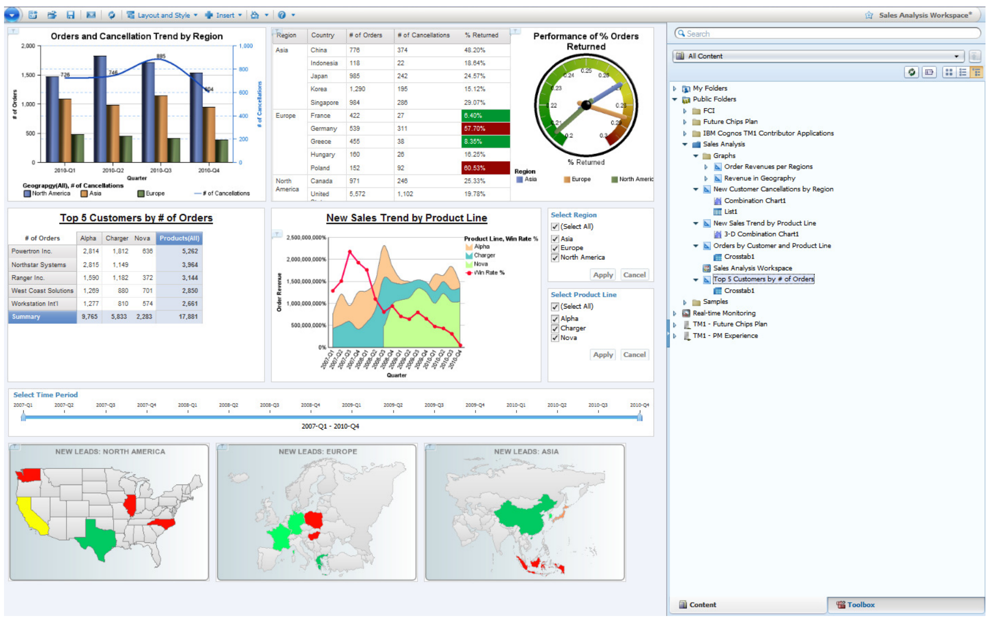

Figure 3 Interactive sales analysis dashboard

III. CONCLUSION AND FUTURE WORKS

These new hands-on labs on business analytics promotes students' learning interest in big data analytics and improves their learning by practices. We received positive feedback when we used them in fall 2012. Their feedbacks manifest a promising effect of the developed labs in helping students with practicing the "learning by doing" methodology, engaging students in learning and interacting with big data. We are current working with local companies for more real-world relevant projects such as Smart Grid in order to bridge hands-on learning with project-based learning (PBL). The PBL will ensure deeper understanding over content coverage. In PBL, complex problem solving skills are developed rather than learning skills in isolation [4].
We will also explore and develop more hands-on labs on business analytics using Open Source Software such as Hadoop, STORM. Meanwhile, we will make dataset that we used available to academic community.

Abstract— **This work-in-progress paper presents an approach to authentic learning of mobile security through real-world-scenario case studies. Five sets of case studies are being developed to cover the state-of-the-art of mobile security knowledge and practices. Some of the developed case studies are being implemented in related courses and the preliminary feedback is positive.**

Keywords- Authentic Learning, Case Study, Mobile Security

I. Introduction

Owing to their ultra-portability, enriched functionality, and ease of use, smart mobile devices, such as Android and iOS based smartphones and tablets, play more and more important roles in many aspects of our society. Users increasingly use their mobile devices to access to the wealth of information available on the Internet, to store sensitive data, to communicate and entertain, and to process many of their daily tasks. These, however, also attract attackers to extend their targets to mobile platforms, resulting in a rapidly increasing number of mobile threats and a growing sophistication of mobile attacks [1-4]. In this work, we use the notion of mobile security to cover the topics of security and privacy issues, attacks, and defenses involved in the use of smart mobile devices. The mobile security is at the intersection of wireless communication, mobile computing, and computer security; and has its unique characteristics, such as introducing new and unique mobile security threats. Few existing security courses cover the full spectrum of mobile security topics; in addition, dedicated courses and effective materials on mobile security are sparse. This calls for efforts to promote mobile security education and to foster qualified mobile security professionals.

This work-in-progress paper presents an approach to authentic learning of mobile security through real-world-scenario case studies. Authentic learning situates students in learning contexts where they encounter activities that involve problems and investigations reflective of those they are likely to face in their real world professional contexts [5, 6]. A recent report pointed out that rather than only teaching students abstract concepts and assigning students abstract exercises, engaging students in real-world settings will benefit student effective learning in security education [7]. In this work, we approach to authentic learning of mobile security via the design of learning materials into real-world scenario cases, and take advantage of mobile device as the authentic learning platform, which will also help create a portable and affordable security-learning tool.

Courses focused on mobile security remain sparse in most computing curricula. Tague offered a mobile security course at the Carnegie Mellon University [8, 9]; however, it was a project-based course that provided students with topics for discuss and explore. In contrast, our work emphasizes on learning mobile security through real-world case analysis and hands-on experience, and we develop the materials for the learning. The application of Android in the education of various computer science subjects is obtaining increasing interests. For example, Andrus and Nieh [10] developed a series of five Android kernel programming projects and an Android virtual laboratory to teach an introductory operating system course; Kurkovsky [11] used mobile game development as a motivational tool to engage students early in the curriculum; and Loveland [12] described the use of Google Android mobile platform and Google's Web Toolkit to provide students with experience in designing and implementing user interfaces for mobile and web applications. The above works showed that the use of Android engaged students' interests in learning and improved effectiveness. Our work focuses on using Android to promote the study of mobile security and we directly use mobile devices and applications for security analysis and practice.

II. Case Study Design

To implement the authentic learning for mobile security, this work employs the following strategies in the development of the case studies, including: 1) connecting the abstract security concepts to real-world mobile security cases so that students can better understand the concepts and can work more actively and effectively with facts and realistic problems; 2) designing each case from both of the attack and defense perspectives so that students can gain more insights and can design better defense solutions via the experience with actual attacks; 3) infusing hands-on practices in the course of case studies and designing most of the practices in such a way that they can be performed on mobile devices directly; 4) encouraging students to identify for themselves the mobile security issues; and 5) providing students with opportunity of reflection in action so that they can learn how and when to use particular strategies for problem solving. Following the above

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

strategies, we are developing five sets of case studies, including:

- Mobile Malware. Case studies that 1) discuss the mobile malware attacking strategies and demonstrate instances of real-world Android malware; and 2) discuss the defense methods and instruct on practicing defense solutions.
- Secure Mobile Coding. Case studies that 1) use code examples to demonstrate the security weakness or unsecure coding patterns in the development of different Android app components, including *Activity*, *Intent*, *Service*, *Content Provider*, and *Broadcast Receiver*; and 2) discuss the best practices for improving the security of the Android app coding, such as using explicit *Intent Filter* to avoid *Intent* spoofing.
- Cryptography on Mobile Devices. Case studies that 1) discuss how to utilize the built-in cryptography mechanisms (e.g., SSL or VPN settings) to improve the security of data in device (database storage, shared memory, shared preferences, internal and external storage), on Cloud, or in the course of network communications; and 2) discuss how to program with Android/Java cryptography libraries to enhance the security of mobile apps.
- Access Control. Case studies that 1) discuss the Android permission model, including its basic concepts, use cases, weaknesses, and enhancements; and 2) discuss other access control and authentication mechanisms for mobile devices and application, including single sign-on and two-factor authentication.
- Mobile Privacy. Case studies that demonstrate the leakage of privacy-related data from mobile devices and communications (e.g., location information, user behavior and usage patterns), and discuss the configurations and best practices for mobile privacy enhancement.

As an example, the set of mobile malware case studies consists of an introductory case study and a set of individual malware case studies. The introductory case study summarizes the state-of-the-art mobile malware research (e.g., [13, 14]) and the malware reports from leading mobile security companies. Each individual malware case study introduces a family of real-world mobile malware, covering the topics of the attackers' incentives (e.g., Premium Calls/SMS or Information Stealing), attacking strategies (e.g., repackaging or update attacks), and existing defense solutions. It is observed that the number of new instances and variants of existing mobile malware families increases rapidly, but the number of new malware families grows rather slowly [14]. We will prepare for each case study at least one real instance of mobile malware in the family so that students can experience the actual attacks in a sandbox environment (i.e., an Android emulator on a virtual machine with experimental settings and data) and analyze the malicious behaviors and features. Each individual malware case study will also instruct student on practicing defense methods. Current mobile malware defense methods include app analysis (static/dynamic/permission analysis), configuration of system security settings, watchdogs, and user education. As the mobile malware evolves, the introductory case study will be updated and new cases will be developed and added into our individual malware case study set.

Fig. 1. Work Flow of a Premium SMS Android Trojan App in Our Mobile Malware Case Studies. (① the Trojan app is downloaded and installed on the victime's device; ② when the Trojan app is activated by the victim, it sends a notification with the victim's information to the hacker; ③ the hacker sends the commands to the Trojan app to ④ send SMS to premium numbers or send Ad SMS to others; and ⑤ the trojan app clears messaging history.)

Fig. 1 illustrates the work flow of an instance of Android Trojan in one of our individual malware case studies. The Trojan app pretends itself as an Asian Gourmet Android app, performs command and control communication with the hacker, and stealthily sends short messages (SMS) to premium numbers or advertisements to others. In the defense practices, students will be instructed on developing an Android SMS Monitoring App, which monitors the messaging actions in the background and sends notifications to users when suspicious messaging are detected. Note that in the latest version of Android 4.2 (Jelly Bean), Google provides similar kinds of control of premium SMS to enhance the Android security.

III. Conclusion

This work-in-progress paper presents an approach to authentic learning of mobile security through real-world-scenario case studies. We describe our strategies in developing the five sets of mobile security case studies and present more detail design of the set of mobile malware case studies.

Some of the developed case studies are being implemented in CS mobile security class and IT wireless security class. The preliminary feedback from students is positive. Students have gained hands-on real world experiences on mobile security with Android mobile devices, which also greatly promoted students' self-efficacy and confidence in their mobile security learning.

In the future work, we will continue to improve the design of the case studies, complete the case study development, and conduct extensive evaluations.

ACKNOWLEDGMENT

Developing a remote release mechanism in support of unmanned aerial systems: A comparison of two separate approaches in freshman engineering design.

I.K. Dabipi & J. Bryan Burrows-McElwain
University of Maryland Eastern Shore, ikdabipi@umes.edu, jbburrowsmcelwain@umes.edu

Abstract- **As restrictions on operating small unmanned aerial systems (sUAS) in the United States national airspace system (NAS) have compounded university researchers in this discipline have had to react by developing increasingly more novel ways to collect remote sensing data. Current restrictions by the Federal Aviation Administration (FAA) require universities to apply for a Certificate of Authorization (COA) to operate any remote control device for the purposes of research. Previously, many universities operated under Advisory Circular (AC) 91-57 (for model aircraft operators). University research does not fall under this circular and therefore, alternative methods of gathering aerial images in support of the universities remote sensing projects needed to be explored.**

The freshman engineering design course at the University of Maryland Eastern Shore is a multidisciplinary and collaborative effort between the Engineering Program and Aviation Sciences Program faculty. Introductory engineering design process theory is taught by engineering faculty while students engage in an experiential exercise in problem solving with the Aviation faculty serving the role of a client with a specific problem that needs to be remedied.

This paper outlines the freshmen engineering design process from the introduction of the initial problem statement, mid-term review and final product delivery of a remote release system for a non-powered glider sensor system. The aviation faculty serving as the client is involved with the class from initial team selection to evaluation of the final product and student's presentation abilities.

Students were asked to design a remote release system that would support the deployment of the client's glider platform from an existing kite lifting device. The freshman design class was divided into two groups and asked to design systems that would meet the clients design criteria. The authors present an in depth comparison of design approaches, execution and lessons learned. Group leadership dynamics are considered.

Index Terms – Remote release, sUAS, engineering design.

INTRODUCTION

One of the issues confronting learning environments is the ability to integrate diversity of approach both in teaching and learning modalities. With the freshman engineering course we have attempted to use the diverse faculty in the department (engineering and aviation sciences programs' faculty), to structure projects that advance engineering principles as well as proof of concept in its application to the aviation program.

The benefit for students is that they are able to engage the faculty both as clients and instructors that result in a variety of learning modes. For this project, the class size was large enough to be divided into two groups. This provided the faculty an opportunity to study the students' applications of engineering principles as well as the approach to finding solutions given the same problem. Engineering design concepts with emphasis on various aspects of planning, developing and product design via hands-on approach was the key to this course experience. It also enhanced the students' communication skills and teamwork. Product visualization utilizing computer software such as word processing, PowerPoint, and spreadsheet enhanced the students' ability to collaborate in defining, developing, and designing a working prototype. Students learned the components of product development such as brainstorming, time allocation, project management, alternative designs, and cost constraints.

Furthermore, the students in the class engaged in teamwork in a multidisciplinary environment such that the reality of cooperation in a global economy became a lesson realized early in their freshman engineering year in college. With a dynamic marketplace, graduates need to be able to interact effectively in diverse fields. One important goal of multidisciplinary design is to identify the many solutions needed to solve a single problem while keeping in mind the many differing objectives of the overall project [2]. A multidisciplinary approach to engineering design is valuable in that it asks that students make certain that, "…advances in performance,… technology, or discipline(s), must be much more highly integrated than in the past" [1]. Students partaking in the engineering exercise are forced to confront concepts outside of their normal field of expertise in the short span of a semester and make decisions on a cost and design schedule.

CUSTOMER REQUIREMENTS AND CONSTRAINTS

Client Requirement: Design a remote release device that can successfully deploy a model airplane from a kite with a minimum altitude of 300 feet.

Constraints included:

The model airplane being released from the specified altitude and gliding unassisted to the earth.

The kite system does not interfere with the flight or path of the released airplane.

Students can predict, with relative precision, the flight path of the released aircraft.

TEAM PROJECT EVALUATION

Student leaders were selected using a selection survey tool. Group members met to determine team responsibilities and areas of specialization. The group decided to break the team tasks into the following categories:

- Picavet
- Kite
- Remote Release System
- Model Airplane

All other tasks such as group reports, purchasing items, and aiding other teams were shared by all members of the group.

Students were required to keep a weekly log, make periodic reports to the course instructor and propose a tentative timeline to the client that would be compared to the actual timeline and schedule at the end of the semester.

.

INNOVATIVE DESIGN

After researching kite based imaging platforms, students determined that a picavet system would provide a stable mounting system for the robotic release system. Students constructed the "T" type picavet out of string, eye screws and wood (Figure 1.)

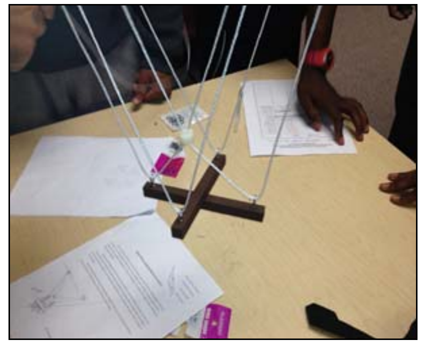

FIGURE 1. Group 2 Picavet system

The remote controlled robotic arm was attached to the picavet which would then hold and eventually release the glide (Figure 2).

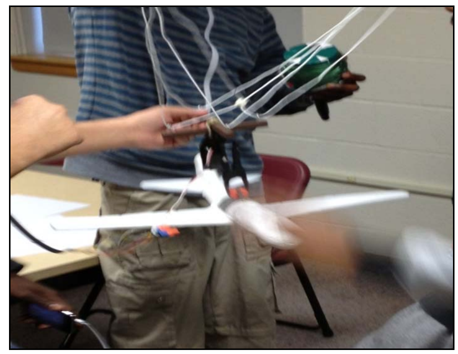

FIGURE 2. Group 2 release system with glider

Group 1 went with a different approach. They utilized the off-the-shelf items shown in figure 5 below to remotely release the system via a RC servo unit.

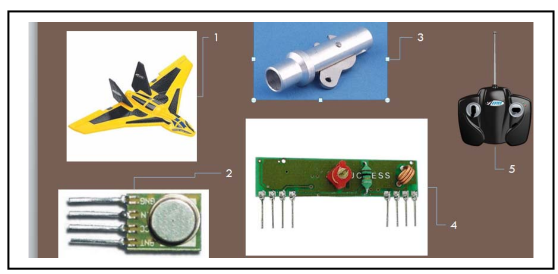

Figure 3. Cannibalized parts for Group 1

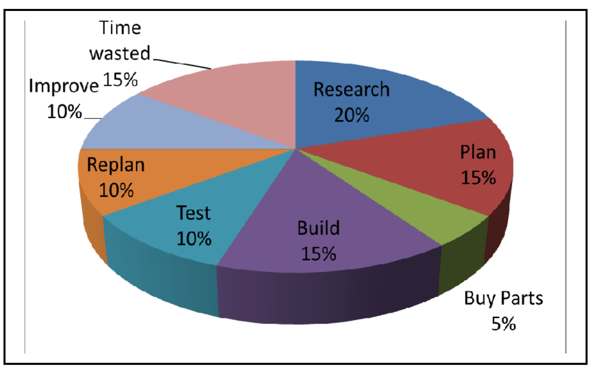
The kite integration group from group 2 was focused on stability issues with launching the system and determining how best to attach the system to the string line (Figure 4).

FIGURE 4. Kite system

FINAL TIME USAGE BREAKDOWN

In the end, less time was spent (Figure 14) on research and planning then expected by both groups. The build time was consistent with early predictions but less time was spent on testing (originally planned for 15%). Re-planning, improvements and time wasted was reported comprising over a third (35%) of project time.



In their final report to the faculty and client, the students identified the following challenges they encountered during the design process:

- Communication Issues
- Conflict with deciding on a design system
- Wasn't able to find a cheap car to use for the original solution
- Delayed Shipments
- The wire attached to the Picavet system was too heavy for the kite.
- The string was damaged accidently by a group member.
- The robotic arm broke due to faulty connection to the kite and had to be repaired.
- How to measure the altitude of the kite.

Overall, the project was a success. The challenges of time, resources and limited subject knowledge required students to brainstorm and react whenever a new challenge arose. Students reported that working in a team environment was extremely difficult. Regardless, they were proud of the project outcome and indicated that they had a great sense of accomplishment considering the constraints, limitations and challenges. The analysis of the leadership qualities and level of students' cooperation will be provided in the oral presentation of this paper.

ACKNOWLEDGMENTS

The authors would like to acknowledge Mr. Geoff Bland and Mr. Ted Miles of NASA Goddard's Wallops Island, VA site for their voluntary contribution of expertise and guidance in the department's remote sensing initiatives.

***Abstract*—We report on the experience of teaching an industry-validated course on Artificial Intelligence in Computer Games within the Simulation and Game Design department at a two-year community college during a 16-week semester. The course format used a blended learning just-in-time teaching approach, which included active learning programming exercises and one-on-one student interactions. Moskal's Attitudes Toward Computer Science survey showed a positive and significant increase in students in both interest (W(10) = 25, p = 0.011) and professional (W(10) = 49.5, p = 0.037) constructs. The Felder-Soloman Index of Learning Styles (n = 14) failed to identify any statistically significant differences in learning styles when compared to a four-year CS1 class. In the final class evaluation, 8 out of 13 students (62%) strongly or very strongly preferred the blended learning approach. We validated this course through four semi-structured interviews with game companies. The interview results suggest that companies are strongly favorable to the course content and structure. The results of this work serve as a template that community colleges can adopt for their curriculum.**

I. Introduction

Community college students face a unique set of challenges that differ in many ways from those of traditional four-year University college students. A significant number of community college students enter their programs lacking study skills and the academic maturity needed to handle more rigorous, self-directed approaches used in traditional colleges [1]. Many of these students have responsibilities outside of school, placing further demands on their time and financial resources. For these students, community colleges must serve as a critical bridge between academia and industry and provide them with a practical and industry-focused education that prepares them for the workforce. At the end of a two-year program, students are expected to have sufficient training so that they can be placed into entry-level positions in their respective fields immediately after graduation. Given these student and instructional differences, we believe that educators should not tacitly assume that pedagogical approaches and experiences that have been successful in traditional institutions can be applied with equal success at the community college level; these approaches must be once again validated in a two-year setting.

Students in community colleges typically restrict themselves to a focused curriculum that emphasizes skills practical for industry. As such, community colleges must make continual efforts to ensure that their courses are relevant and useful to the industry jobs students are seeking. This task cannot be accomplished in isolation, and can only be successful when academia and industry collaborate in curriculum design. We argue that this collaboration must occur not only at the program level, but also at the individual course level, so that each course itself is validated as being appropriate to the types of skills that industry demands.

It is with this understanding that we report on the experience of teaching an elective, pilot course on Artificial Intelligence (AI) in Computer Games within the Simulation and Game Design curriculum at a two-year community college during the 16-week Fall 2012 semester. An advisory committee comprised of both academic and industry members identified the following three criteria for success: 1) to evaluate if teaching computational thinking through game design can positively increase attitudes about Computer Science; 2) to assess student reactions to a blended learning classroom experience; and 3) to validate whether the learning objectives of the course are relevant and useful to industry.

The course format used a blended learning approach, which consisted of discussions, in-class active learning programming exercises, and one-on-one student interactions with the instructor.[1] We minimized the use of formal lecture; when necessary, we delivered lecture content using a just-in-time teaching approach [2] to address observed student difficulties. The course content can be summarized as five weeks of learning the Python programming language through a game context that emphasized algorithmic thinking, with the remaining semester time spent on AI for games topics.

To evaluate instructional compatibility with pedagogical techniques used in four-year institutions, students completed the Felder-Soloman Index of Learning Styles (ILS) questionnaire [3] ($n = 14$). To identify changes in student attitudes, students completed the Moskal's Attitudes Toward Computer Science survey [4] ($n = 10$) twice during the semester. To determine whether our blended learning classroom approach was well-received, students completed a final evaluation ($n = 13$) with 5-point Likert-item questions. Finally, to validate our course, we performed semi-structured interviews with four local game companies.

The results of this work serve as a template for community colleges considering the adoption of specific pedagogical approaches in the classroom or for colleges who wish to adopt a prepared, industry-validated AI course in its entirety. The results also highlight the effectiveness of using a blended learning approach at the community college level.

[1] We recognize that the definition of blended learning varies widely in the education community. We are less interested in constructing a strict definition, and far more interested in whether or not the techniques are useful to students.

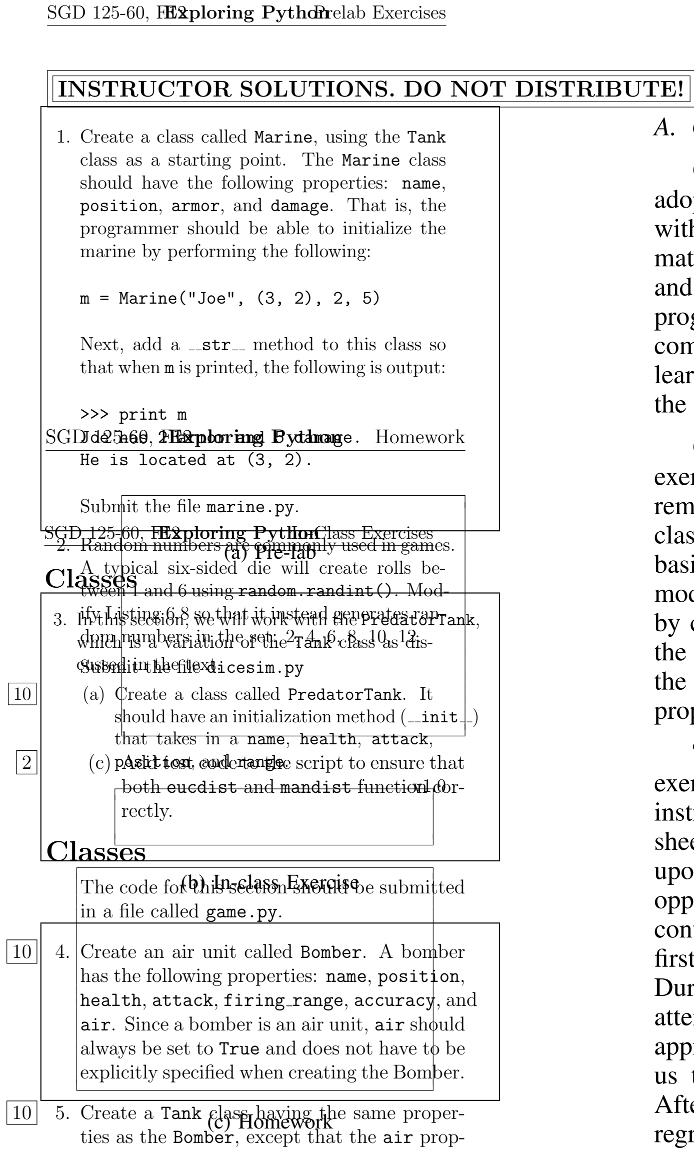

Fig. 1. A representative example of how class assignments carry from pre-lab to homework.

II. Course Syllabus

This 16-week course introduces artificial intelligence concepts with an applied focus in video game development and has been designed to be a part of a two-year community college program. The course is intended to be taught in a lab setting where each student has access to a computer workstation. Upon completion of the course, students should be able to understand the basic concepts, and implement algorithms, for AI in games.

The objective of the course was to teach computational thinking through game programming, so that students could relate theoretical classroom concepts to their existing experiences with playing video games [5]. A secondary objective was to design a modular course structure that can serve as a starting point for other community colleges. In this section, we discuss the specifics of the course format as well as the course topics. The class met once a week for 3 hours in the evening. However, the effective class time, after accounting for three 10-15 minute breaks as well as administrative overhead, was reduced to approximately two hours.

A. *Course Format*

Grounded in Revised Bloom's Taxonomy (RBT) [6], we adopted a just-in-time teaching approach [2] in our course, with some variations: we had less emphasis on web-based materials, integrated the classroom and laboratory sessions, and implemented blended learning by having computer programming tasks as the focal point for all activities. Students completed pre-lab exercises before class, completed active learning sheets in-class, and had a homework assessment on the related material after class.

Our pre-lab exercises were less exploratory. Instead, the exercises explicitly tasked students with surveying the text to remember and understand course material for the associated class session. Because of this, they were graded on a pass/fail basis. For example, the task in Fig. 1a. asks the students to modify an existing piece of code available in their textbook by changing a `Tank` to a `Marine`. To successfully complete the task, the student must rename the file, rename some of the properties, and change a single statement that prints these properties to the screen.

The majority of in-class time was spent completing exercises for the topic, with minimal lecturing from the course instructor [7]. Through the use of modified[2] active learning sheets [8], students completed in-class exercises that built upon the completed pre-lab exercises. Students were offered an opportunity to apply their pre-lab knowledge to new problem contexts, without introducing new material. Students would first attempt to solve the exercises without instructor assistance. During this time, we walked around the room to give individual attention to students as they solved the assigned problems. This approach was essentially an early-alert system that allowed us to quickly assess student understanding of the material. After 5-15 minutes, depending on exercise complexity, we regrouped as a class and together worked toward obtaining a correct solution. With the guidance of the instructor, students analyzed the problems to gain insight into the relationship between pre-lab and in-class material. Here, we provided the rationale for the problem solutions, analyzed tradeoffs and alternative approaches, and discussed how these materials might be applied to games they have played in the past. Continuing the previous example, for the task in Fig. 1b we instructed students to implement an initialization method based on their pre-lab, and performed the aforementioned tasks to explain how this method relates to the programming task as a whole.

After class, students were given a homework assignment that was a continuation of the class topics. The homeworks provided an opportunity to combine the concepts from class in a novel way and in more depth. Because of increased difficulty of homeworks, students were encouraged to work together, but had to submit work individually. Finalizing the ongoing example, for the task in Fig. 1c, we asked students to extend the behavior demonstrated in class by having them create unit types that support both air and ground modes. This required students to modify their existing Tank firing logic because of a constraint that Tanks can only fire on ground units (not shown).

[2]Instead of fill-in-the-blank type responses, our question prompts required students to supply short answers. This style was appropriate to our course format because we did not deliver active learning sheets within a normal lecture as Lau [8].

TABLE I. INDUSTRY VALIDATED SYLLABUS FOR A 16-WEEK SEMESTER AI IN GAMES COURSE

Module	Topic	Learning Objectives
1	Introducing Python	Basic Python syntax and semantics, such as numbers, strings, variables, conditionals, loops, and functions. The list, tuple, and dictionary data structures.
2	Exploring Python	Additional exercises on concepts from the previous module. Classes as a means to organize data. The game loop as building block for all games. Basic random number generation as a means for adding variation in games.
3	Introducing Pygame	Review of classes. Loading sprites and backgrounds; blitting (drawing) objects to the screen. Event handling and keyboard logic.
4-5	Numerical Python	Review of list operations, importing libraries. Converting lists and tuples to `NumPy` arrays. Fundamentals of Newtonian Physics, which include displacement, velocity, and acceleration. Vectors, including Cartesian coordinate systems, plotting, dot products, Euclidean distance, and vector normalization.
6	Movement Algorithms	Review of integer and floating point operations and subtle pitfalls. Additional practice on vector operations implemented using simplified Newtonian Physics model from the previous modules. Game loop updates for updating avatar position. Frame vs. time updates. Seek movement algorithm as a fundamental AI primitive.
7	Pathfinding I	Double-ended queues, and algorithmic costs and tradeoffs for list and double-ended queue operations. Data structures, e.g., stacks and queues implemented using double-ended queues. Static paths, as found older games, implemented through list rotations. Tile graphs as the basic building blocks of two-dimensional world representation.
8	Pathfinding II	Breath-first search implementation using nested lists as a world representation. A simplified edge finding function for locating adjacent nodes. Discussion of generalized search with explored and frontier lists, and choice of distance functions and their effects. Mathematical operations for quantization (translating graph nodes to pixel coordinates and back).
9	Decision Making I	Review of dictionaries and how they can be used to implement Blackboard architectures. Hard-coded decision trees as sequences of conditional statements. Five-state decision tree system involving AI that can fire on the opponent, seek the opponent, find ammo items, find health, and panic when it is out of ammo and low on health.
10	*Practical Midterm Exam*	
11	Decision Making II	Review of Manhattan distance. Multiple mechanisms (references) for accessing unique objects in the context of dictionaries. Visual comparison of decision trees and finite state machines (FSMs). Implementing FSMs in Python using object-oriented programming. Methods as a means to add behavior to classes. FSMs as a technique to modularize AI behavior. Implementation of a schoolyard game of tag through FSM behavior.
12	Learning I	Review of world representations and blackboard architectures. Review of random number generators as a means to emulate intelligence. Artificial stupidity; how games cheat to give the perception of intelligence (for example, fog of war). Implementing finite state machines in a hide and seek game setting.
13	Supporting Technologies I	Technologies that are not directly game AI, but help support games in general. Recasting AI algorithms and demonstrating applicability across domains. Finite state machines as an example of maintaining user states in a chat system. Event-based management in networks, as opposed to games, through the `Twisted` framework.
14	Supporting Technologies II	Continuation of previous module; modifying networking code to implement a text-based online game. Discussed the limitations of AI, and role and need for multiplayer games. The use of AI agents that can act as players.
15	Comprehensive Final Review	Wrap-up of course topics in an interview context. Main take aways and course highlights at a high level. Interviewing techniques for industry positions in entry-level game AI. Application of course topics to general programming careers.
16	*Practical Final Exam*	

Students were evaluated using a midterm and final exam, which had notable differences from evaluations most students were familiar with. To simulate industry settings, all exams were open-book and open-notes, and we allowed the use of the Internet. More importantly, all problems were programming exercises that required students to submit source code within the 3-hour time window. Thus, no multiple choice or fill-in-the-blank questions were employed. Students were notified in advance of the specific subject matter to be evaluated. In much the same way that in-class exercises were built on pre-lab exercises, the exams provided an opportunity to independently demonstrate learning from the in-class exercises. To our knowledge, this exam style is still not widely used in computer science; indeed, at the community college where this course was taught and evaluated, it was the first within the Information Systems department to implement these techniques.

Though many languages have been used for teaching introductory programming [9], we chose Python because of previous successes reported by four-year Universities and high schools, and we expected these reported benefits to apply equally well at the community college level [10], [11]. As presented by Grendel et al. [11], we also considered Python's minimal syntax, dynamic typing, expressive built-in types, and immediate feedback to be positive factors when considering its adoption. Most importantly, Python has an orthogonal design that allowed us to simplify the language, such that advanced language features, including decorators, list comprehensions, and operator overloading, were omitted from the course entirely.

To support game-specific features, the following additional libraries were required: Pygame,[3] for abstracting low-level game engine details (such as graphics, user input, and event management); NumPy,[4] for vector operators; and Twisted,[5] for event-driven networking support. Students used the built-in IDLE editor to write their Python programs, using simple `print` statements when debugging was necessary. All of the software used in the class is open source and therefore freely available to the students for use at home. In short, we offered a general-purpose programming language that was loosely coupled with the underlying game engine library so that the concepts learned in the course could easily transfer to other programming environments.

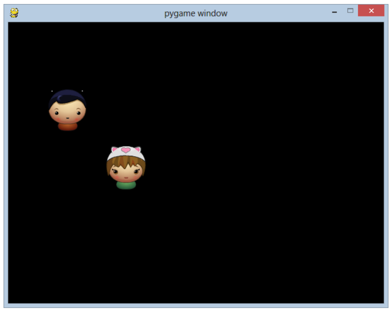

Fig. 2. Students experiment with avatar movement. The boy is controlled using the keyboard by the player and the girl is an AI agent.

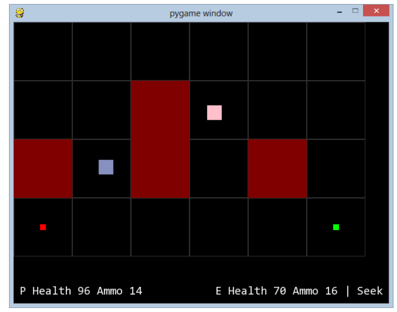

Fig. 3. Students implement a finite state machine in a tile-based world. Colored tiles are obstacles and hiding places for the player. Small red (bottom left) and green (bottom right) rectangles are ammo and health items, respectively, which provide opportunities for the AI to perform additional decision making.

B. Course Topics

The course used two textbooks. The first textbook was Python-specific and introduced the students to the Python programming language from a games perspective and the Pygame framework [12]. Throughout the course, this book was largely used as a reference. The second was an Artificial Intelligence (AI) textbook used in many four-year undergraduate programs [13]. Despite the fact that the AI text was not specifically designed for the community college level,[6] we hoped that its comprehensive coverage would allow students to continue pursuing their interests in game AI well after the completion of the class. As mentioned in Section II-A, class sessions assumed that students had read the text beforehand.

An overview of the topics can be found in Table I. We tried to strike a balance in course topics that satisfied the needs of the industry, but at the same time was appropriate for the capabilities of community college students. We presented traditional computer science algorithms through a game-focused lens. As one example, rather than offer a theoretical coverage of vectors as an abstract mathematical construct, we motivated the need for vector operations as a practical method to simplify AI movement in games programming. As another example, rather than directly cover the concepts of stacks and queues, we motivated the need for these data structures through their use in AI pathfinding, a staple of games. Throughout the course, we emphasized analyzing tradeoffs between different data structures, such as lists, tuples, and dictionaries. Nested lists were found to be most suited to representing a tile-based world; tuples were useful in representing coordinates; and dictionaries were useful in storing agent properties that needed to be accessed by a key (such as a player's health or ammo).

It was important to us that concepts in the course be cumulative because we felt that students could appreciate their efforts if they could tangibly see how their simpler implementations could be reused to develop more complex components. For example, students implemented tuples so that they could implement distance functions. Distance functions were used to implement seek behaviors, which were then used in their implementation of path finding, which is then used within finite state machines to move toward different goals, and so on. Concretely, we began with a simple environment devoid of obstacles and a world representation, as shown in Fig. 2. Students used this environment until Module 7: Pathfinding I (see Table I) as a platform for reinforcing mathematical foundations as well as developing their programming language skills. When the simpler environment representation became insufficient for expressing advanced concepts, students moved to a more complicated representation as shown in Fig. 3. The latter representation provided affordances for discussing more sophisticated topics that required a world model, and was used for the remainder of the course.

[6]The book assumes a moderate knowledge of mathematics. Additional class time may be required to cover these pre-requisites.

III. Methodology

Student data was collected anonymously in full accordance with research protocols at the authors' respective institutions. Students did not receive extra credit for participating in the study. The course consisted of $n = 18$ students (17 male, 1 female), but student data was discarded for students under the age of 18, and for students who did not consent to releasing their data. The course was offered as an elective, and students self-selected to enroll in the course, which is a potential bias.

To identify changes in student attitudes, students completed the Moskal's Attitudes Toward Computer Science survey [4], once immediately before the core AI component of the course and again at the end of the semester. The purpose of this qualitative instrument is to better understand factors that discourage students from pursuing degrees in computer science. The survey measures attitudes across five constructs: confidence, interest, gender, usefulness, and professional. Because of student demographics, the gender construct questions were removed from the survey. To score the survey results, the 4-point Likert-item survey responses are re-coded to a numerical scale which ranges from 1 to 4; negatively phrased questions were reverse coded such that a high score is always a positive attitude. The score for a construct is simply the sum of the responses for that construct.

To reflect on their own learning preferences, students also completed a Felder-Soloman Index of Learning Styles (ILS) questionnaire [3] at the end of the tenth class session. This is a 44-question instrument that can be used to assess preferences on four dimensions: active/reflective (ACT-REF), sensing/intuitive (SEN-INT), visual/verbal (VIS-VRB), and sequential/global (SEQ-GLO). The scoring methodology categorizes students for each of these dimensions ranging through, for example, Strongly Active, Moderately Active,

TABLE II. ATTITUDES TOWARD COMPUTER SCIENCE SURVEY

	Construct							
	Confidence $p = 0.362$		Interest $p = 0.011$		Usefulness $p = 0.172$		Professional $p = 0.037$	
Student	Pre	Post	Pre	Post	Pre	Post	Pre	Post
SA	28	29	36	40	24	24	16	16
SC	28	27	35	38	24	24	13	13
SD	28	29	35	37	21	24	7	16
SE	23	29	30	40	18	24	11	13
SF	20	16	18	22	18	18	10	12

SL	29	29	29	32	22	23	14	12
SP	23	27	25	34	17	21	11	16
SQ	28	28	36	40	24	24	12	15

Balanced, Moderately Reflective, and Strongly Reflective. For this research, we compared the ILS distributions for each dimension against a typical four-year University CS1 program [14], to determine if statistically significant distributional differences exist between two-year and four-year populations.

To evaluate perceptions of the course, students completed a 13-question final evaluation consisting of 5-point Likert-type items. We provided this to the students directly before their final exam.

To validate if the course is relevant and useful to industry, we conducted four semi-structured, in-person interviews with game companies within the Raleigh, North Carolina area. The structure was as follows: a discussion about the course topics, the choice of Python as a programming language, and the blended learning approach of the class. The interviews were conducted over four months, and each session ranged from 1.5 to 3 hours. The first author was both the instructor and interviewer, which may have resulted in social desirability bias.

IV. STUDENT-CENTRIC RESULTS

In this section, we discuss the results of the Moskal's Attitudes Toward Computer Science survey [4], the Felder-Soloman Index of Learning Styles questionnaire [3], and the course evaluation.

A. Attitudes Toward Computer Science

Computer games have been cited as a motivational tool to teach Computer Science concepts [15]. Consequently, we were interested whether students who completed an Artificial Intelligence in Games course would have a positive increase in their attitudes toward Computer Science. Students completed Moskal's Attitudes Toward Computer Science instrument [4] directly before the AI component of the course, and again at the end of the semester. Students were randomly assigned a unique identifier, and the results for students who completed both pre-test and post-test surveys are shown in Table II. A Wilcoxon matched pairs signed-rank test was performed between the two trials, and constructs for students' interests in CS (W(10) = 25, p = 0.011) and students' beliefs about professionals in CS (W(10) = 49.5, p = 0.037) increased significantly.

Since students take many courses during a semester, it should be noted that there are several confounding factors that prevent us from attributing this affect to our course alone. There is also a survivorship bias, in that students who dropped the course before the final survey did not complete both surveys. It is indeed plausible that students who dropped the class had negative attitudinal changes. However, when taking into account the student evaluations, we believe that some component of these positive attitudinal changes were a result of our course.

TABLE III. INDEX OF LEARNING STYLES AGGREGATED SURVEY RESULTS, COMPARING OUR AI CLASS WITH A 4-YEAR CS1 CLASS

	Dimension (A-B)							
	ACT-REF $p = 0.234$		SEN-INT $p = 0.484$		VIS-VRB $p = 0.356$		SEQ-GLO $p = 0.054$	
Preference	AI	CS1	AI	CS1	AI	CS1	AI	CS1
Strong-A	1	13	0	24	4	64	0	8
Moderate-A	3	56	4	53	7	80	3	49
Balanced	7	123	6	101	1	70	6	139
Moderate-B	1	24	2	31	2	28	4	20
Strong-B	2	6	2	13	0	12	1	2

B. Index of Learning Styles

We hypothesized that one of the differences between community college students and traditional University students was that the two student populations have significantly different learning styles, and that these differences can be used to inform the pedagogical approaches in the class. To evaluate this hypothesis, we compared our results against a student population from an Introduction to Computer Science course at a four-year University [14]. Due to the small number of students in our AI class, Fisher's exact test was applied. These results are shown in Table III. We were unable to identify any statistical differences between the two populations, though SEQ-GLO appears to be on the threshold of significance. Thus, as with the CS1 population, a Shapiro-Wilk normality test reveals that, for all dimensions, we were unable to reject student populations as significantly different from normal (all $p > 0.05$). Consequently, our interpretation of this result is that pedagogical approaches that are explicitly based on ILS can potentially be applied with success in community colleges.

C. Student Evaluation

We had 18 students initially enroll, 4 of whom dropped before the final exam. One student did not complete the final evaluation. Though our reports reflect some level of survivorship bias, our course retention rate of 78% is comparable to the Simulation and Game Design program average retention rate (78%).

We expected a progression in student perception of difficulty, with the pre-lab exercises being easiest and the midterm exam being most difficult. Using the Wilcoxon matched pairs signed-rank test, we were unable to find any statistical significance to confirm this expectation. We believe that this is in part due to the small number of students. Qualitatively, we observe a monotonic increase in difficulty between the in-class exercises and the out-of-class homework. Our explanation for this is that students receive help during class from the instructor.

10 out of 13 students (77%) felt that the practical exam format was appropriate or very appropriate and that they would

TABLE IV. STUDENT EVALUATION AGGREGATED RESPONSES

Qn	Question Text	Scale	Likert-item Counts 1	2	3	4	5
Q1	The following question asks you to rate the difficulty of the course materials.	Very Difficult—Very Easy					
	How difficult were the questions for the pre-lab exercises?		–	5	8	–	–
	How difficult were the questions for the in-class exercises?		–	5	5	3	–
	How difficult were the homework assignments?		–	8	4	1	–
	How difficult was the midterm exam?		2	5	5	1	–
Q2	How often did you read the textbook material before coming to class?	Never—All of the Time	1	5	4	3	–
Q3	How often did filling out the in-class exercises cause you to miss important parts of the lecture?	Never—All of the Time	4	4	3	2	–
Q4	The midterm exam was a practical exam. How appropriate was this exam format for this course?	Very Inappropriate—Very Appropriate	–	1	2	4	6
Q5	If given the option, to what degree would you avoid or prefer this exam format for future exams?	Very Strongly Avoid—Very Strongly Prefer	–	–	3	5	5
Q6	During class, the instructor would go to each student to check their progress during in-class exercises. How useful were these one-on-one interactions with the instructor?	Very Useless—Very Useful	–	–	1	2	10
Q7	This course used a blended learning classroom approach. If given the option in your future classes, would you avoid or prefer classes that used this teaching style?	Very Strongly Avoid—Very Strongly Prefer	–	–	5	3	5
Q8	Please indicate your level of agreement with the following statements.	Strongly Disagree—Strongly Agree					
	The in-class exercises encouraged me to attend the lectures.		–	1	1	5	6
	The in-class exercises make the lectures interesting.		–	–	2	7	4
	The in-class exercises helped me better understand the lecture material.		–	1	1	3	8
	The in-class exercises helped me complete the homework.		–	–	2	5	6
	The assigned textbook was a useful resource in the class.		–	3	5	3	2
Q9	This course used the Python programming language for all programming activities. How difficult or easy was it to learn the Python language?	Very Difficult—Very Easy	1	3	4	4	1
Q10	For future programming tasks, how likely would you be to use Python as your preferred language?	Very Unlikely—Very Likely	–	2	3	4	4
Q11	How important do you feel the material in this class is in obtaining an entry-level game developer position in industry?	Not at all Important—Extremely Important	–	–	3	6	4
Q12	Compared to other classes that you have taken at this community college, how would you rate this course?	One of the Worst—One of the Best	–	–	3	1	9
Q13	Overall, how satisfied were you with this course?	Very Dissatisfied—Very Satisfied	–	–	3	3	7

prefer this exam format for future exams. More importantly, 8 out of 13 students (62%) strongly or very strongly preferred the blended learning approach to class. The other 5 out of 13 students (38%) were indifferent, and no students indicated that they would avoid this class format.

12 students (92%) found the one-on-one interactions with the instructor to be useful, despite having only a few minutes of interaction time with the instructor for each exercise. In our opinion, this is because the instructor could quickly steer otherwise perplexed students in the correct direction.

The department allows students to have up to 4 penalty-free absences before being dropped from the course. Of the 13 students who completed the course, 6 absences in total were recorded across all students, and 8 students had perfect attendance. 11 students (85%) agreed or strongly agreed that in-class exercises encouraged them to attend the lectures, reported that the exercises made the lectures interesting, and reported that the exercises helped them complete the homework. Thus, if students did not find class to be useful, we would have expected many more students to have absences.

10 students (77%) believed the class was very or extremely important in obtaining an entry-level game developer position, which shows that students perceive the course as being relevant. 9 students (69%) rated this course as one of the best they have taken at our community college. In general, 10 students (79%) were satisified or very satisfied with the course.

V. INDUSTRY COURSE EVALUATION RESULTS

The selected companies constitute what we believe to be a representative sampling from the diverse types of game studios in the marketplace: Redstorm (RS),[7] for traditional AAA game development; Vicious Cycle (VC),[8] for game engine design; Virtual Heroes (VH),[9] for serious research games; and Spark Plug Games (SP),[10] for mobile and independent game development. Programmers who directly worked with Artificial Intelligence in some capacity within their company evaluated our curriculum and contributed feedback for three measures: selection and ordering of topics, choice of Python as a programming language, and the use of blended learning.

With few exceptions, all four companies found the course topics and topic organization to be appropriate to the game industry. When we designed the course, we envisioned the sections on Supporting Technologies as optional, but all of the interviewed companies felt that this section was necessary to show how game programming concepts can transfer to other programming domains. However, VC felt that Supporting Technologies should only be a single class, using the gained class time on Learning in AI. RS suggested that students should implement a simple, but complete game (such as Asteroids or Pacman), rather than using prototype

[7]http://www.redstorm.com
[8]http://www.viciouscycleinc.com
[9]http://www.virtualheroes.com
[10]http://www.sparkpluggames.com

environments. Decision trees and finite state machines were considered to be an essential topic for all companies, but they differed on the importance of pathfinding. RS suggested that the topics of decision trees and pathfinding be reversed, since pathfinding is a relatively complex topic. Specifically, RS, VC, and VH indicated that all modern game engines support pathfinding, and that breadth-first search could be covered in less detail or abstracted entirely as a result. VC and VH also indicated that the concept of navigation meshes should be presented as an alternative to navigation points.

We were concerned that our course did not make use of an industry game engine, such as Unity.[11] However, the use of Python and Pygame was well-received by all companies. From our interviews, it was clear that companies are less interested in knowledge of particular tools and more interested in students' programming capabilities. For example, RS was interested in whether students understood the thought process behind programming and VH was similarly interested in students who have a base-level knowledge of programming. SP liked Python because it allowed students to focus on concepts, as opposed to focusing on language idiosyncrasies. In terms of entry-level opportunities, RS liked the use of Python because they considered scripting to be a stepping stone into other areas; their entry-level developers begin as scripters. VC entry-level hires also begin in a scripting or support role, and thus found Python to be appropriate. At VH, all entry-level hires start out as generalists, and at SP, their game programmers work on all aspects of the game. Thus, we conclude that teaching through Python is not a significant barrier to entering the game industry, and we recommend that community colleges examine their balance between tool-focused courses and concept courses.

All companies found the blended learning approach to the classroom to parallel the type of work performed in industry. RS liked the interactivity of the course, and how it built on concepts from first principles. VH felt that the course format accurately resembled the way that game programmers solve problems in industry. VC stated that having immediate feedback is valuable, and that the course offered several opportunities to practice debugging code — an essential skill. The practical midterm and final exam formats were also well-received. In general, companies preferred the problem-based learning format to lecture-based learning. In our interviews, we found that companies are interested in what projects students have completed more than the courses they've taken. In particular, SP liked that the course provided students with deliverables that could be discussed during interviews. VH also indicated that it was very important for students to have completed projects when applying for entry-level positions.

VI. Conclusion

While we have shown a positive increase in attitudes within the interest and professional constructs, we are unable to isolate these increases to our course alone. Future replications of this course may mitigate some of these confounding factors. The results of our final class evaluation demonstrate that by having a blended learning approach, no students are marginalized when compared with alternative classroom formats, but a significant number of students stand to have an improved experience. Finally, our industry interviews suggest that game companies prefer a blended learning approach to a traditional lecture because it more closely matches their industry practices.

***Abstract*—The National Science Foundation Industry & University Cooperative Research Center (I/UCRC) program is intended to foster productive collaboration between industry organizations and academia. The focus of the I/UCRC research site herein is on the application of technology within the complex extended enterprise. The center's goal is to conduct research that is of interest to both the industry sponsor and the university partner, with the provision that the industry organization must provide major support to the center. In this paper, we describe the Agile Translation Process (ATP) for complex innovations that was developed at the center. The process meets the constraints of the academic calendar, the knowledge needs and the typical length of stay for a master's student, and the availability constraints of the students. At the same time, the process is designed to provide value to the industry sponsor. Specifically, it describes how the process meets the needs of technology consumers in industry seeking to derive tactical value through the funding of the center. In addition, we demonstrate how to derive research results for technology providers through subsequent activities. We also provide metrics from the center for a period of five years, which show, in particular, the benefit of using the ATP method over the last three years. These metrics provide insights on how to reconcile tactical industry needs with the long-term research and funding goals of academia, while understanding the innovations needed within complex contexts. This case study also provides insights on concurrently meeting the needs of all stakeholders – including industry clients, translational faculty members, adjunct faculty from partner companies, graduate students, and the center's affiliated research faculty – within the constraints of the academic calendar. By using an agile translation process and a set of expanded performance metrics, the center effectively applies research to bring innovation to its industry partners.**

Keywords—collaboration, design, innovation, performance metrics, services science, technology management

I. Innovations for Complex Enterprise Systems

Beginning in early 2004, we looked at hiring patterns within the Information Technology (IT) industry and noticed several emerging trends, including the fact that a significant portion of IT complexity began shifting from *technology development* to *technology use*. These trends are shown through several factors. First, enterprise IT departments became brokers of cloud, social, mobile and information services [1]. Second, there was a significant interest in converting data from these services into actionable intelligence - the *big data opportunity* [2]. Third, hiring by the technology consuming industry overtook that of the technology producing industry. Fourth, budgets for IT maintenance were ballooning due to an increase in the number of technologies needed to manage complex IT service workflows. Thus, the overall focus of the Center's research became the growing gap between technology consumers (government, industry, etc.) and technology providers (including academia). Hence, the Center experimented with alternatives to make the translational process viable within academia.

In this paper, we describe what we term the Agile Translation Process. This process was developed to meet the needs of the student within the constraints of an academic program while meeting the needs of industry, by deriving tactical value through the utilization of the Center as a research partner. Furthermore, we show how to derive *research* results through subsequent activities. Lastly, we provide metrics from the Center for a period of five years. These metrics provide insights on reconciling tactical industry needs with the long-term research and funding goals of academia.

From an industry-university collaboration perspective, we can also ask related questions. How do we as academics and engineers help increase innovation, and diffusion of new ideas? How do we apply the rigor of the latest research to design solutions? How do we show that designed solutions provide value within the context of a complex enterprise? And, finally, how do we overcome any impediments to come up with a cost-effective industry-university capability to accomplish these goals? This case study provides approaches to these questions using the Agile Translation Process that concurrently meets industry-university stakeholder needs. These approaches include: the sharing, use, creation of knowledge and feedback; resourcing of translational projects related to complex systems; and protection of intellectual property while conducting projects.

The context of this study is a specific National Science Foundation Industry/University Cooperative Research Center (I/UCRC) for Experimental Research in Computer Systems (CERCS). This is a multi-university center with

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

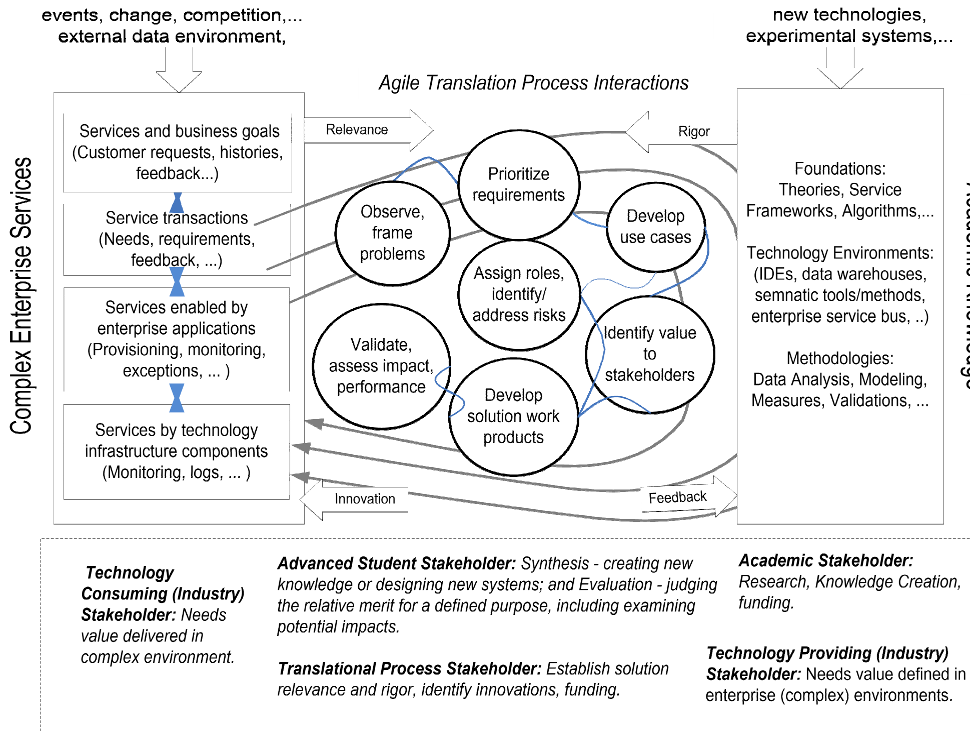

Fig. 1: The contexts of Complex Enterprise Services on the left and Academic Knowledge on the right. The Agile Translational Process (ATP) resources by advanced experiential learning, cycles between Descriptive and Normative research activities as illustrated.

CERCS at Georgia Tech researching technology: hardware, communications and system-level software, and applications. Complementary to this, the CERCS research site at The Ohio State University, the Center for Enterprise Transformation and Innovation (CETI) studies the applications of technology for innovation. The center's goal is to conduct research that is of interest to both the industry and the university, with the provision that the industry organization must provide major support to the center [3]. The simple center structure also provides for the protection and sharing of intellectual property through the Bayh–Dole Act. By emphasizing experimental methods, CERCS promotes the creation of knowledge through the design, implementation, and measurement of large-scale technology and systems.

The specific focus of this case study is the CETI research site and its application of technologies within the extended enterprise.

II. Design Related Concepts

Before presenting our case and performance data, we cover related concepts.

A. Context for Design

It is well established that engineering design requires an understanding of the context for the correct framing of the problem, as well as interdisciplinary approaches to solution development [4]. For example, architectural design is viewed as its own integrated field of study, and compared to other engineering disciplines; it is multi-disciplined since the field seeks integration of electrical, plumbing, lighting and other systems within an overall building design. Capture of contextual knowledge as *design patterns* was also first introduced by the architect Christopher Alexander [5, 6] as a way of making hitherto tacit knowledge explicit. Design patterns were adopted by software engineers, leading to many framework technologies that have improved the development of software. However, far less has been done in integrating interdisciplinary frameworks related to complex enterprise services within the graduate software and systems engineering curricula.

Recent NSF workshops have also looked at the process of introducing design thinking into the engineering curriculum [7, 8]. In addition, advocates of grounded theory provide a systematic methodology in the social sciences involving the discovery of theory through the analysis of data captured in the field [9]. It is mainly used in qualitative research, but is also applicable to quantitative data. These ideas and methods carry forward to bridging the gap between technology consumption (left of Fig. 1) and technology development (right of Fig. 1). Finally, related to technology, engineering research continues to focus primarily on normative theories related to technology while business, such as management information systems, and healthcare focus more on descriptive or operational aspects, leaving a gap to be bridged as described by Christensen [10]. To address this, *design science* [11] emphasizes the need for the information systems researcher to bridge the gap between existing knowledge and the context of use. This is captured in Fig. 1 as the Agile Translation Process (ATP) Interactions discussed later.

B. Complex Enterprise Service Systems

Complex enterprise service systems refer to intra- and inter-enterprise services that collectively enable a business goal. As in [12, 13], we view these as networks (a value chain, supply chain, service value networks) with nodes as agents (humans, organizations, software and hardware) creating, communicating, and consuming information.

C. Living Laboratory

A living laboratory, or sandbox, is an environment that replicates the complexity of real-world enterprise environments. Given the importance of field-based research in innovation, these environments allow problem framing and experimentation to occur as in the real world. This works well if this synthetic environment itself can be embedded in real-world organizations with safeguards in place for privacy and security concerns.

D. Translational Role

While there are many variations across universities, we have kept the role definitions below intentionally simple to make a point. Today the center acts in a translational role to conduct translational activities that are not explicitly identified within universities and their engineering colleges. This role is well recognized in medical schools; within engineering this is often filled in an ad-hoc fashion by appointments that do not fit the translational role and performance requirements. According to Duderstadt, "[t]he strong research focus of many engineering schools has led to a cadre of strong engineering scientists, quite capable of generating new knowledge but relatively inexperienced in applying this knowledge in professional practice" [14].

We illustrate this issue below using the term *role* to identify responsibilities. For a translational role, these responsibilities include: demonstrating the value of research in practice and developing descriptive theories; providing related experiential education in solution-driven contexts and applying research theories and methodological rigor where applicable; providing feedback and identifying intellectual property; developing industry relationships and making interpersonal connections needed for field research. It is insightful to contrast this with the typical academic roles at the other end of the spectrum: developing research theories; providing related education of principles, methods and tools; providing academic administrative services; and developing relationships with federal and industrial research and development labs. Because of the *applied research* component of the translational faculty role, we also distinguish the translational role from the roles of adjunct lecturer and clinical faculty typically filled by professionals from industry to augment teaching resources.

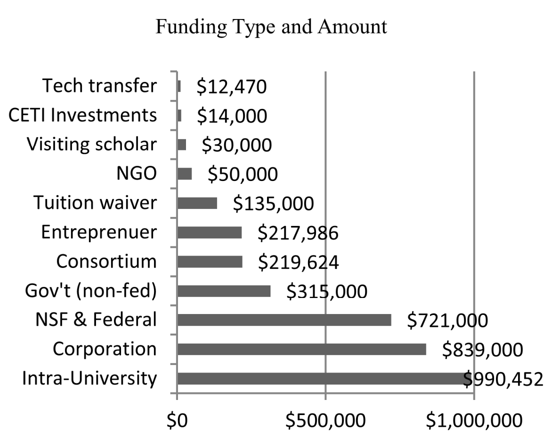

Fig. 2: Funding types and amounts. Total amount is approximately $3.25 million.

III. Agile Translational Processes (ATP)

CETI uses the precise notion of an *Interaction* to bridge technology-consumer context and technology-provider knowledge as illustrated in Fig. 2.

A. Interaction-based Translation Methodology

For the purpose of measurement, we consider the unit of activity to be an Interaction that takes place between consumers and providers. Each Interaction is at the request of a consumer (e.g. a sponsor, student, or academic collaborator) and is provisioned with resources by the center to provide work products of value to the consumer. The request can ask for any type of Interaction, for example: requirements analysis, a project, experiential education, or thesis research. We take the average duration of an Interaction to be an academic term.

Also it is important to note that an Interaction may fall outside the primary I/UCRC mission and be a secondary Interaction. The variation in types of sponsors of Interactions is illustrated in Fig. 2. For example, a project Interaction with the Agriculture department to visualize the transmission of disease may be funded by another federal grant that is not counted as I/UCRC membership revenue for reporting, and is thus a secondary Interaction.

However this type of secondary Interaction would not have happened without the existence of the center and its relevance to sustainability. We therefore list secondary Interactions here to identify the full benefit of the I/UCRC, which is often outside the main / measured intent. We also list secondary Interactions here to identify potential opportunities to establish a sustainable translational center beyond the duration of the I/UCRC. Also, it is important to note that the concept of an Interaction is similar to the previous I/UCRC evaluation methodology followed using *critical events or incidents* in the life of the center from the perspective of the director [15]. The goal of that study was to study management relationships *across* centers. On the other hand, the goal of this study is to analyze events and resulting Interactions *within* a single center.

Agile software engineering bridges customer needs and provider tasks, especially when requirements are uncertain.

From the center perspective, the benefits of combining *agile* and *translation* include: a prescriptive process that is responsive to industry sponsors; an expanded set of internal performance measures across industry engagements; and collaborative resourcing for experiential learning. Thus, by focusing on the details with ATP at the boundary of industry and university, we begin to examine opportunities for increasing the rate of bidirectional idea diffusion.

The ATP is illustrated in the center of Fig. 1. Each Interaction is aligned to academic increments. It consists of the following steps, based on [16]:

1. *Process satisfaction:* Measured by rapid delivery of useful work products, in the midst of changing requirements, even late in development. Work products (see center of Fig. 1) delivered frequently.
2. *Project work products:* Acceptance by the sponsor is the principal measure of progress towards an innovation. This means the sponsor reviews the work products based on value to organization.
3. *Self-organizing teams:* Small teams of one to five students are asked to be responsive to the sponsor. There is regular adaptation to changing circumstances.
4. *Standup presentations:* Made to the sponsor; reviewed by translational faculty.
5. *Sustain development at a constant pace:* For graduate research associates and interns this starts at 20 hours per week, less so for capstone students. Close, weekly cooperation between sponsors and student developers with face-to-face conversations is expected.

Some unique aspects of ATP are important to note here. Industry sponsors approve all work products based on achieving a translational goal; thus the work products are of value to an industry process or product. Each work product contributes incrementally to a final innovation.

A typical master's student is available *only* for four increments; during their first semester, they are taking their mandated core courses. Useful value must result as below:

- Increment 1 (Spring) consists of on boarding in the field with mentoring by professionals, with instruction delivered as an advanced project-oriented course using an enterprise context and curriculum assets. Here, second year group members mentor the first year group members in each team. The course serves to provide needed background on different sponsor companies.
- Increment 2 (Summer) is where students are embedded as industry interns in the enterprise. Enterprise data gathering, model development, and initial problem formulation are the foci of this increment.
- Increment 3 (Fall) sees problem abstraction and solution synthesis along with project deliverables. Thesis research and hypothesis development begin.
- Increment 4 (Spring) consists of analysis and thesis writing for the student, who must defense their research and hypothesis at the end of the increment.

B. Project environment

The environment includes weekly activity tracking, which is kept private to the student and faculty advisor, and a project environment with blogging for team collaboration.

IV. Center Performance and Stakeholder Benefits

The following data are both for primary and secondary Interactions from April, 2007 to March, 2013. These data provide insights into: the primary and secondary Interaction outcomes that are measured from an engineering research perspective in academia; the need for additional translational measures to address translation; and ways the I/UCRC-type structure could provide sustainable translational research.

Over the five-year period CETI has had 85 Sponsors ranging from Fortune 500 companies to small- and medium-sized enterprises. These industry organizations are both technology-using and technology-providing companies, as well as both local and international. Included in the sponsors are other departments across the university and Capstone sponsors. Capstone course projects do not initially involve significant dollar amounts. The center has over fifty master's and doctoral students at any given time. In addition, over five years the center has provided 3,000 students at the undergraduate and graduate levels with experiential learning that generated tuition revenue.

A. Interaction Performance and Related Stakeholder Benefits

The Interaction framework and standard ATP structure presented above allows us now to explicitly state CETI performance, which is discussed next.

1) Interaction Outcomes: As mentioned, all center execution is measured in a standard way as increment-long Interactions. A primary or secondary Interaction can be of different types, can have different types of consumers, providers, sponsors, or resourcing, and can have different outcomes. Outcome types are classified as follows: Academic outcomes and innovation outcomes.

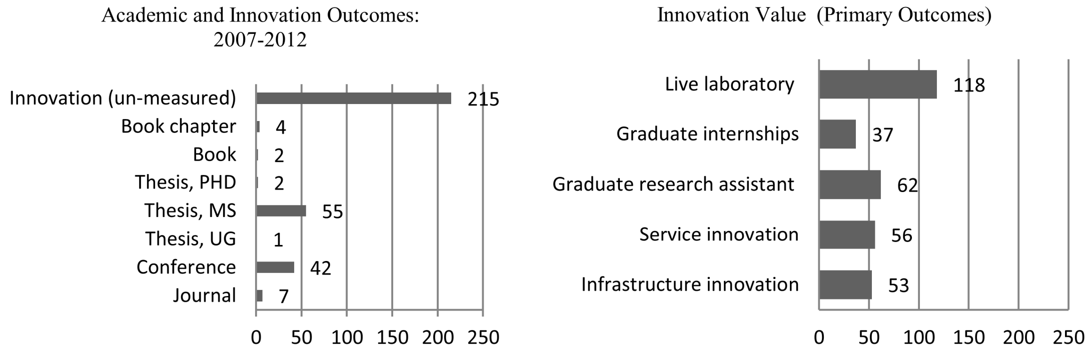

Fig. 3: Overall Interaction outcomes: (a) academic and (b) translational.

Academic outcomes, which are measured for individual researchers, include: journal and conference publications, undergraduate, Masters, and doctoral theses, books, and book chapters. Innovation outcomes, which are typically unmeasured for individual researchers, include: workforce impact, project reports, curriculum assets, software assets, and data assets. As shown in Fig. 3, there were both academic and translational Interactions. There were 113 academic outcomes and 215 innovation outcomes related to projects which are identified in greater detail in Fig. 3(b)Fig. 3. All reported work products were sponsored by consumer or provider stakeholders (see related graphs in Fig. 4).

The center's technology consumers and providers have specific innovation value tied to one or more of the following: Technology Infrastructure, Service Delivery, or Workforce. The rationale related to Workforce innovation is that, through graduate research assistantships and graduate internships, the live laboratory curriculum assets are indirectly used to achieve skills that will diffuse results to industry.

2) Interaction Funding Types: This refers to any organization type that provides funds, including: industry, the government, academic or non-governmental organizations, the university (in terms of fee waivers), visiting scholars, technology transfers, internal CETI funding, intra-university (i.e. other departments within the university). Note that the funds for an Interaction might be from a source that is different from the problem sponsor for an Interaction. For example, a capstone class may provision an Interaction for an entrepreneur, but funds are by tuition. Incidentally, this is the only type of funds not counted in the overall number in Fig. 2. Also, the university support in terms of fee waivers was instrumental in making this program successful.

The overall funds directed to the center are given in Fig. 2. From an NSF perspective, note that the funding from other departments, labeled Intra-OSU, is the highest due to the high level of interdisciplinary collaboration in the center. Also, an I/UCRC brand has far greater impact in fostering and resourcing collaboration than the amount reported as direct I/UCRC funding which is less than a third of the total amount.

3) Interaction Domains: Described in Fig. 4, the sponsor's domain could be a Technology Consumer (in government, finance & insurance etc.), or as a Technology Provider interested in complex system aspects classified as one of: service delivery (e.g. applications of mobile, sensor technologies); technology infrastructure improvement (e.g. applications of cloud computing, Hadoop, etc.); or semantic enterprise architectures and services.

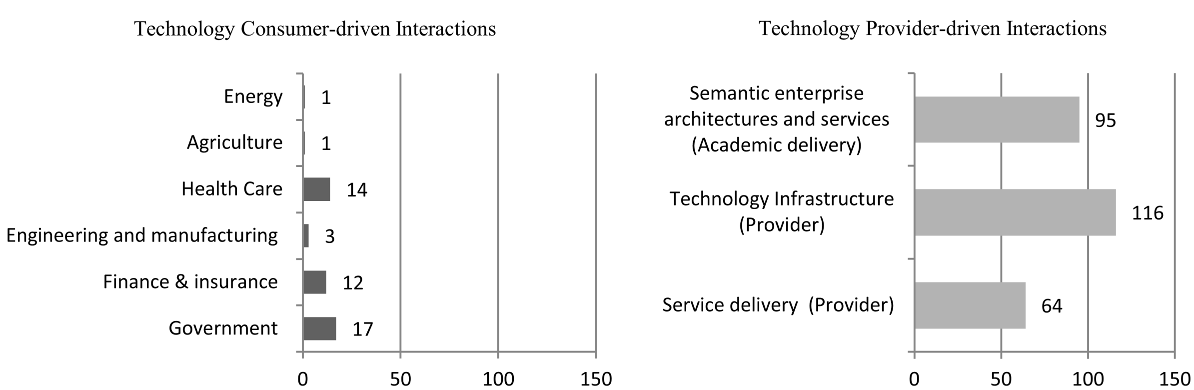

Fig. 4: Interactions and domains of technology providers and technology consumers.

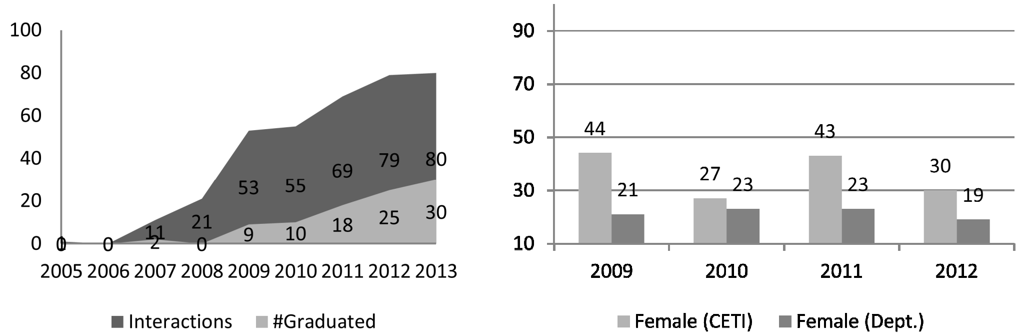

Fig. 5: (a) Advanced student beneficiary numbers (the number of graduate students) and related Interactions. (b) Female students within the CETI sub-population vs. female students within the at-large departmental population.

4) Interaction Resourcing to Achieve Translation Outcomes: Graduate students implement the Interactions using the ATP steps of problem framing, synthesis, and analysis. These are measured as the final project report and work products accepted by the sponsor, a published research paper or thesis, and usable living laboratory curriculum assets, such as case studies that introduce the contextual challenges of problem solving. In addition, the ATP conforms to the students' availability and academic interests and addresses their knowledge gaps. The students also get two to three increments of funding. The knowledge applied is often interdisciplinary. They learn that research ideas may or may not provide value within a complex system whose improvement depends on many factors. The students also learn that the most critical aspects must be identified first, meaning that they must be agile.

5) Interactions versus Graduates: The number of graduate student beneficiaries is related to the Interactions needed to achieve this number in Fig. 5. This provides an idea of the resource intensive nature of advanced experiential learning and the demands on the translational role. While projects were sponsored by industry from the very inception of CETI, we began to link projects and industry sponsorships to the academic increments (e.g. a semester or quarter) and the students' own availabilities and skills only in the third year. Coincidentally, in 2008, the Center's home Department started accepting master's students, thus providing a pool of industry-headed talent with an interest in innovation (see the large increase in Fig. 5. CETI graduates were a fifth of all Masters level graduates over the period. We also note that significant number of female students joined CETI (see in Fig. 5(b)).

6) Interdisciplinary collaboration: As noted earlier, the greatest funding type (Fig. 2) is intra-university funding. This represents over forty faculty from fifteen departments – including public policy, medicine, business, and design – across the university that were actively involved in supervising specific Interactions. Often faculty members started with sponsoring a capstone project, then moved the project to an externally funded grant.

V. Conclusions

The presented case is related to an Agile Translation Process implemented specifically in the CETI I/UCRC research site. The data show that it is possible to impact innovation and research and advance experiential learning in a way that is concurrently beneficial to all stakeholders. We show here how to build a translational structure at the boundary of industry and university through alignment of existing resources. This includes provisioning work through experiential learning courses and funding advanced graduate students. These students, under the guidance of translational faculty, learn how to correctly frame problems, synthesize solutions, and evaluate results in the context of complex enterprise service systems. Such problem-based experience can be time consuming and resource intensive. To overcome the challenges and make this possible, we draw upon agile development principles to address: the translational processes at the boundary of industry and university; the academic calendar constraints; and the needs of stakeholders and challenges.

Acknowledgment

This work was done under the aegis of the Center for Experimental Research in Computer Science at Georgia Tech and The Ohio State University, funded by the National Science Foundation's I/UCRC program (NSF IIP 0753710). Funding was also provided by The Ohio Board of Regents Computer Science Graduate Education program and by NSF CCLI Grant No. 0837555. We wish to acknowledge helpful ideas by CETI students, particularly Andee Peabody, colleagues, members, and sponsors.

Bringing Adjunct Engineering Faculty into the Classroom: Opportunities for Enhancing the Practice

Waddah Akili
Principal, Geotechnical Engineering
3222 Evergreen Rd., Ames, Iowa, 50014, USA,
w.akili@isunet.net

Abstract- **The paper reports on a success story of an adjunct, a practitioner with excellent credentials, who "teamed-up" with a "full-time" faculty, in an attempt to bring-in the "practice" to 4th year students in a *geotechnical/foundation engineering* class. The paper sheds light on this experience, and focuses on the contribution and effectiveness of the adjunct in: course planning, delivery of "practice-related" material, organizing activities and adjunct's ability in engaging students, in and outside the classroom. The positive outcome of this experience has lead other faculty members to follow the same path, i.e., by searching for practitioners - as adjunct faculty- to assist in bringing the practice into the classroom, in partnership with "full-time" faculty**.

Keywords—adjunct faculty, partnership with full-time faculty, bringing the practice into classroom.

THE PROS AND CONS OF ADJUNCTS

There are many reasons for employing adjunct faculty, including: unanticipated increase in enrollment, the start up of new programs, the need for specific expertise, and the replacement of an "on-leave" faculty, are some of the reasons that may necessitate making temporary arrangements to ensure coverage of instruction. Unfortunately, department heads, administrators, and most faculty members, look upon hiring an adjunct faculty as a "stop-gap" measure. Not only that, but there are those skeptics, who are vehemently against employing adjuncts on the grounds that: i) they do not have the teaching skills, ii) are not familiar with rules and regulations that control the day to day academic operations, iii) lack organization skills, iv) do not possess the self-confidence, v) do not have the enthusiasm in comparison to full-time colleagues, and vi) often lack familiarity and depth of insight with course material. Simultaneously, however, there is a growing recognition of the potential contributions that adjuncts and other part-time faculty could make in the teaching arena, provided a thorough search for "the right type" of an adjunct is carried out through proper channels.

Although no firm guidelines on how to search and identify candidates for an adjunct position are available at present; the most common starting point is the unsolicited applications from individuals in industry and consulting firms, seeking part-time work as adjuncts. The motivation often is to supplement their income. There are those that like to do it for other reasons such as: exposure to the academic environment and an interest in working with students, to gain experience in presentation and delivery methods, to take time-out from their daily schedule, or as a stepping stone into a full-time teaching position. In addition, full-time faculty may recommend colleagues, they have known through professional societies or other domains, who may have expressed an interest in working with students. .Some adjuncts could offer linkages for the development of industrial affiliate programs, co-op activities, summer training, and employment opportunities for new graduates. They may also provide ideas for senior design projects, topics for graduate theses, or render help in the establishment of collaborative research programs.

The academic systems in place today have not been fair to adjuncts, in general. The author has known of many "full-time" adjuncts that have been mistreated despite their proven records of being very good teachers.

They are often marginalized by the tenure system, in the sense that their efforts and contributions to the academic process are undervalued [1]. As pointed out by Gosink and Streveler [1], there are ways for recognizing the contributions of adjuncts. Their suggestions have included the following:

- Look into the feasibility and/or the legal aspects of offering 3-5 year contracts to those who have demonstrated their abilities as good teachers.
- Accord appropriate titles, awards & citations, to adjuncts with proven teaching skills, on par with regular faculty.
- Encourage new recruits to take courses towards a degree, or acquire new knowledge, including teaching skills. This is usually done on campus at no cost to the department.
- Encourage experienced instructors to teach new courses to widen their scope and increase their versatility; thus help them get out of "a rut" by developing new potentials.
- Allow those with experience to serve on various academic committees and assign them to undergraduate advising, as is the case with regular faculty.

In summary, if care, recognition, and fair treatment are accorded to adjuncts, their morale, loyalty to the college, as well as their teaching effectiveness, would improve markedly.

REPORTING ON THE EXPERIENCE

At one of the International Universities, a course, *Foundation Engineering*, introduces students to the fundamental concepts and applications of foundation analysis and design with emphasis on methods and applications in the arid and semi-arid soils of the Country in contention, and the Region in general. The prerequisite, *Geotechnical Engineering I*, exposes students to the basics of soil mechanics, including: theoretical background, relevant techniques, and selected applications. The author has always been of the opinion that certain subjects, including *Foundation Engineering*, should be instructed by qualified practitioners; but, if not feasible, then practitioners should be involved in the instructional process, possibly as guest speakers. To proceed with the idea of bringing the practitioner to the classroom, a preliminary plan was drawn, and a search for an expert, preferably with teaching experience, commenced as soon as formal approval was secured. An announcement was dispatched to companies in the Region describing the position, qualifications, and employment-related conditions. It was also stipulated, that the appointment is for one year, renewable for longer periods, depending on outcome & feedback from students and faculty.

The search led to a candidate that had the desired qualifications, and was willing to accept the position, but had no prior teaching experience. However, his skills in lecturing and delivery of teaching materials were put to the test by having him present a seminar on a subject of his choice. Attendees' overall impression was positive; and on that basis, he joined the department as a part-time adjunct faculty. The candidate, a registered professional engineer with experience that stretches over a ten-year period; was particularly suited for the position because of: i) his knowledge and familiarity with the soils and geology of the Region; ii) his direct involvement with the practice in the locale; and iii) being in charge of the geotechnical section in his consulting firm, facilitated getting the right kind of information such as: soil data, case studies, exposure to equipment in-use, and relevant testing procedures. Most important, he was excited, eager and looking forward to bringing-in his experience to the classroom. Initially, different alternatives, on how to proceed with the instruction of *Foundation Engineering*, and in particular, the role/contribution of the adjunct to the process, emerged. The *alternative* agreed upon – and preferred by the adjunct and the full-time instructor - was to work jointly in terms of: planning course material, delivery of subject matter, organizing in-class and out of class activities, and in testing and evaluation It was understood that the adoption of this *alternative* meant that both instructors would be present in the classroom, at the same time, and actively involved in the instructional process: delivering the material in a coordinated manner and engaging students through questions and answers. Both instructors were willing to "do their level best", and pledged to put in the effort required to guarantee success.

In the section that follows, we examine relevant aspects that pertain to: *the role of the adjunct faculty* in this endeavor.

THE ROLE OF THE ADJUNCT FACULTY

In general, *Foundation Engineering* went well and was almost on target! In retrospect, proper planning that preceded course delivery had a lot to do with the success achieved. In all fairness, adjunct's eagerness, commitments, and efforts were instrumental in meeting set goals, and declared objectives, i.e., "bring the practice into the classroom".

On the ***planning*** side, and after a careful review of the syllabus, the adjunct was able to generate the material (design procedures in use, relevant construction and constructability issues, prevalent soil conditions, lessons learned, typical foundation behavior and potential problems in the locale, and a great deal of relevant case studies, statistics, presumptive bearing capacity values, etc.). He was also able to sort it out, stream line it, and diffuse it within the general course outline so that it supplements the various topics as specified in the course chronology. His selections of *case histories* were: relevant, concise, derived from the locale, and addressed timely issues and concerns. He and his colleagues at work were the proponents of the selected *cases.* They were responsible for data acquisition, analysis, the write-up, and the final recommendations. The three selected *field trips* were also based on adjunct's recommendation, who prepared a write-up for each, explaining what would be observed, and how do field observations relate to the specifics in the syllabus

Another aspect that had been planned and fully implemented was ***to cater to different learning styles*** [2]. To promote effective learning, within the context of varied learning styles, the instructors grouped the students, devised activities and tasks that brought the students closer together, and made sure that joint tasks were consistent with course objectives. Therefore, an attempt to create an ***active learning*** environment was pursued in this experiment, despite the fact that traditional teaching methods were dominant and practiced on a wide scale. *Active learning* implies class participation, i.e., the students, the instructors, and the teaching material are intertwined through preconceived learning/teaching activities [3]. Research has shown that what students tend to remember is highly correlated with their level of involvement [4, 5]. This is to say: the higher the level of students' involvement, the greater is their comprehension and the higher is their retention.

On the ***Delivery*** side, the adjunct was always on time, physically present in class with the full-time faculty, the entire semester, ready to contribute and/or express his views at the appropriate moment. He made good use of his "lap top", and often resorted to "Xeroxed" handouts to reduce students' note-taking during the lecture. When his turn came to deliver his part, he was courteous, considerate, and spoke slowly and clearly. His main contribution in every session was to supplement the subject matter, with relevant examples derived from the Region, focusing primarily on the "practice" or the practical side of the topic on hand. For example, when *settlements of shallow foundations* was the theme under consideration; he showed: *settlement plates* being installed and fully operational; an example of the discrepancy between *measured* and *calculated* settlements; guidelines for *tolerable* settlement based on local *building code*; and presented *allowable bearing pressures* in sandy soil based on settlement consideration. He presented valid points and commented on the specifics of the day during the *pause* periods; led the discussion at the end of the session, and answered questions even when improperly phrased! The three case studies he chose to present, during the latter part of the course, were valuable, relevant, and well received. He was extremely helpful during office hours; and the rapport he initiated with students, he was able to sustain throughout the semester. His contributions to the experience can be highlighted as follows:

- His foresight, effort, an abilities as a practicing engineer did enrich the course, made it more relevant, and brought "real" problems into the class room;
- Drawing on his experience as a practicing engineer in the locale, provided students with first-hand information of local soils and their behavior in supporting foundations;
- His ways of responding to questions, engaging students, and encouraging them to come forward with their questions and comments, promoted confidence and community amongst the students;
- The presence of the adjunct faculty in class, side by side with the full-time faculty member, broke the monotony often experienced in traditional lecture room setting, and was instrumental in creating a class room environment, that resembled a professional engineering forum.

. After *Foundation Engineering* was over, and the final course grade was out, a "questionnaire" was sent to those who enrolled in the class seeking their opinions, evaluations, and any comment(s) they may wish to offer. Twenty six out of a total of 30 students returned the "questionnaire" on time! The opinions expressed and comments made were, by and large, positive to say the least. After regrouping, and rephrasing to correct the English language; some of the comments offered by the ex- students, could be summarized as follows:

- The adjunct was easy to approach every time and every where, and was always helpful,
- His input into the course has dramatically improved students' understanding of the material, enlivened the experience, and made the course more meaningful,
- Many students felt that the adjunct was eminently qualified to teach *Foundation Engineering by* himself, should the need arise. On the other hand, many argued that it could not have been delivered as effectively, had it not been for both instructors working together,
- Some students expressed their desire to see similar arrangement be implemented in other courses; with particular reference to design &construction type courses,
- The field trips, planned and conducted by the adjunct, were described as: very useful, particularly in developing an awareness of how soil exploration work is performed.

The experience reported on here was repeated several times; and a number of minor changes, mostly in sequencing teaching material, were since introduced. The experience has gained momentum, and has since been applied to other engineering courses in the same institution.

SUMMARY AND CONCLUDING REMARKS

Properly selected adjunct faculty can enrich an engineering program by bringing their practical experience and introducing relevant practical applications to the classroom. Adjunct faculty members can also provide important linkages for developing joint programs between industry and academic departments, and employment opportunities for graduates. Nevertheless, the position today of adjunct faculty, in most engineering colleges, is tenuous, often marginalized by the tenure system, and their presence on campus is considered as temporary; until replaced by a "full-time" faculty member. The adjuncts, by and large, are extremely capable and in all likelihood, do what we, the "full-time" faculty, could never do, i.e., bring the practical experience into the classroom!

Another arena for the adjunct, who possesses a proven record of practical experience in a specific area, is to "team-up" with a "full-time" faculty, in an attempt to bring in the practical side of the subject into the classroom. This means that two members ("full-time" faculty and the adjunct) share in teaching the class. There are many possibilities on how to "intertwine" teaching material, and merge teaching activities.

This paper reports on a success story of such a merger in a *geotechnical/foundation* class. The success achieved was attributed, in large measure, to proper coordination that preceded course delivery. In this exercise, an experienced practitioner was sought out to supplement the regular lectures offered in an elective course to 4th year civil engineering students. In addition to the practice-related activities brought into the lecture hall; case histories were also introduced by the practitioner, as well as pre-selected field trips, focusing on soil exploration and relevant monitoring and testing procedures.

Students' evaluations, their views, comments and overall impressions (during-and at the end of the course) have been very encouraging to say the least! The positive outcome of this experience has lead other faculty members to follow the same path by searching for practitioners-as adjunct faculty- to assist in bringing-in the practice into the classroom.

Investigating the Attributes and Expectations of Engineering Ph.D.s Working in Industry

Benjamin Ahn, Monica F. Cox, Jeremi London and Jiabin Zhu
School of Engineering Education, Purdue University, West Lafayette, IN, USA
bahn@purdue.edu, mfc@purdue.edu, jslondon@purdue.edu, jiabin.emily.zhu@gmail.com

***Abstract*— Many engineering Ph.D.s are finding career opportunities in industry. Despite the increase in number of Ph.D. engineers working in industry, there is little research on what it takes to be a successful engineering Ph.D. in industry. This study explores the characteristics, and expectations of engineering Ph.D.s by interviewing ten engineering Ph.D.s working in industry. These preliminary findings reveal that responsibilities of engineering Ph.D.s in industry include more than research and development. Among other things, engineering Ph.D.s that work in this sector are expected to communicate effectively and teach others. The characteristics that engineering Ph.D.s need to possess to be successful in industry are also discussed.**

***Keywords*— engineering Ph.D.; industry; attributes; expectations**

I. Introduction

In the past few years, there has been a steady increase in the percentage of engineering Ph.D.s working in industry. According to National Science Board statistics, in 1999, 60.6% of engineering doctorate holders worked in industry (classified as "Profit" companies) [1]. In 2008, this percentage increased to 66% [2]. On the other hand, the percentage of engineering Ph.D.s working in the education sector (including 2-year, 4-year, and precollege institutions) has declined from 31% to 26.6% in the same period [1, 2]. Since 1983, the annual growth rate for employment of engineering Ph.D.s in academia has been declining. The growth rate for employment of engineering Ph.D.s in academia for years of 1983-1993, 1993-2003 and 2003-2008, was 2.54%, 1.95%, and 1.43%, respectively [3]. It is likely that this trend will continue, at least in some foreseeable future, due to the limited number of positions in academia [4] and industry's desire to hire more highly-skilled professionals or recipients of doctoral degrees to help them grow, to compete, and to innovate in this globalized world [5,6].

Since the number of academic positions available to engineering Ph.D.s is lower than the overall demand for such positions and since the majority of engineering Ph.D. graduates will obtain jobs in industry, it is important to investigate the attributes and roles of engineering Ph.D.s in industry. Examining the expectations and important attributes (i.e., knowledge, skills, and characteristics) that engineering Ph.D.s need to possess to work in industry is necessary in order to help future Ph.D.s understand and/or prepare for industrial careers. Moreover, limited empirical studies have been conducted about engineering Ph.D.s in industry. Therefore, this study aims to identify and to examine the important attributes and expectations of engineering Ph.D.s working in industry through a qualitative study.

II. Research Method

A. Data Collection

The data for this study is drawn from interviews within a National Science Foundation project, "An examination of graduate education's role in preparing engineering students for careers in academia and industry". One of the project's goals was to identify the skills, knowledge, and attributes engineering graduate students must have if they are to be successful in academia and industrial careers. To achieve this goal, researchers conducted one-on-one semi structured interviews with 40 engineering Ph.D.s working in industry and academia. All participants were classified according to the employment sector in which they had worked: academia only (17), industry only (10), industry first and then academia (9), and academia first and then industry (4). A 16-item interview protocol was used to examine engineering Ph.D.s' roles and expectations within their work settings, their views on important characteristic and attributes that Ph.D. engineers should possess, their motivations for obtaining a Ph.D.; their perspectives on the added value of getting a Ph.D., their experiences in a doctoral program, and recommendations for doctoral education.

The present study examined ten industry engineering Ph.D.s' responses to the two questions within the 16-item interview protocol. Participants included seven male and three female engineers with five to twenty-five years of experience in industry. In these two questions, participants were asked to identify the most important attributes and characteristics an engineering Ph.D. should possess to be successful in industry and to discuss the expectations of engineering Ph.D.s in their work environment. The insights garnered from this study can help to ensure that graduate schools are preparing its doctoral engineering students to possess the desired attributes and are prepared to meet the expectations of employers for engineering Ph.D. holders.

B. Data Analysis

Members of the research team conducted all ten interviews. The interviews were recorded and later transcribed by an external transcriber. Members of the research team used Atlas.ti, a software program using in qualitative research, to analyze the transcripts. An open coding and constant comparative method were used to study the views of the respondents [7]. In the first phase of data analysis, two transcripts were randomly selected, and each researcher assigned a word (or code) next to a segment(s) of text that best matched the essence of the response. This process involved reading the data multiple times and making memos about phrases and ideas that stood out. All

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

members individually identified and recorded the codes using the software. During research meetings, the team engaged in an auditing process. The team members then discussed the appropriateness of the code assigned to segments of the participants' responses. Codes that were agreed upon among all researchers were recorded in a separate document, which later became the codebook for the study. The research team members were assigned two additional transcripts to analyze. This led to more discussion and the addition of new codes and/or a refinement of existing codes in the codebook (e.g., clarifying existing code definitions and coding rules, including code examples, and indicating when and when not use a code).

In the second phase of the data analysis, inter-rater reliability (IRR) tests were conducted. IRR tests ensure that researchers independently agree on the data sections to be coded and codes to be assigned. One measure of IRR is percent agreement – which is the overall extent to which the individual coders assigned codes that were consistent with they coded the team agree upon during the auditing process [8]. To conduct the IRR analysis in this study, four transcripts were randomly selected. The only restriction on this selection was that the four employment classifications of interest in the larger study (academia only, industry only, industry-to-academia, academia-to-industry) needed to be represented among the four transcripts for the IRR analysis. Responses to the 16 interview questions were randomly selected from the four transcripts and combined to form a "mixed-transcript". The researchers used the final version of the codebook to code individually the mixed transcript. The process involved researchers selecting the codes that they felt best fit the quotes.

The first round of IRR analysis resulted in 75% overall agreement for the responses to the 16 questions. Percent agreement was calculated on an individual basis and across coders. Individual percent agreement was based on the extent to which the codes a researcher's code matched the codes that were determined during an auditing process. Each coder's overall percent agreement was also calculated. The 75% overall agreement is an average of the individual percent agreement values. Although fair coding agreement existed among the researchers, there were three interview questions where all of the coders had a low (less than 75%) percent agreement. The low percent agreement occurred when there were multiple ideas in a sentence or a paragraph and researchers failed to assign all of the codes reflected in the response. Therefore, the research team conducted another round of IRR for these three questions. A different mixed-transcript was generated and used to minimize bias. The IRR for the three questions resulted in overall percent agreement of 79%.

From here, each researcher was assigned a set of interview questions to code across all transcripts. For example, one researcher was responsible for coding all 40 participants' responses to interview questions 1-4. Since the individual researcher was responsible for a set of codes that belonged to their set of interview questions, the coding process was more efficient and accurate. The preliminary findings of this study will be presented in the next section. This will include insights on the responsibilities, expectations, and characteristics of engineering Ph.D.s in industry.

III. Preliminary Findings

A. *The day-to-day responsibilities of an engineering Ph.D.*

During the interviews, engineering Ph.D.s in industry offered in-depth accounts of their work. Industry engineers' work included research-related tasks such as creating new tools to stimulate certain manufacturing processes, developing new techniques to include a new feature in an existing material, investigating faults in an assembly plan, or running experiments and testing hypothesis. Many of the participants mentioned that there is no such thing as a typical workweek; their work was filled with variety. Not all of their day-to-day tasks were research-related. Other examples of tasks included commercializing and keeping valuable projects active within the organization; protecting intellectual property (e.g., dealing with patents, trade secrets, copyrights, non-disclosure agreements, and trade development agreements); managing engineering personnel within the organization; interacting with internal (e.g., engineers, technicians, high level management) and external stakeholders (e.g., customers, and business, engineering, and manufacturing leaders); and developing curricula and teaching classes to improve engineering practice in the company. These findings, which vary by corporation, provide a glimpse of other responsibilities beyond research and development (R&D) for engineering Ph.D. holders who work in industry.

B. *Expectations of others for engineering Ph.D. holders*

There was agreement on what is expected of engineering Ph.D. holders who pursue careers in the industry sector. Many participants emphasized that engineering Ph.D.s are expected to communicate in many ways –speaking, writing, and presenting. The majority of the participants had regular meetings with senior management and customers to provide progress reports on current projects. In these meetings, engineers must be able to communicate ideas or procedures effectively and clearly to technical and non-technical audiences. Furthermore, the participants strongly emphasized that oral communication encompass more than presentations but also involves the vital collaboration between engineers and other stakeholders such that meaningful exchanges can occur (in both directions).

Engineering Ph.D. holders are also expected to demonstrate strong technical skills, innovation skills, leadership skills, and problem-solving skills and to provide hands-on support to their colleagues. Innovation skills include coming up with different and new ideas that the company can pursue. Leadership skills include collaborating with a diverse team of people and delivering a project on time within budget. Problem solving skills include the ability to break down problems, to ask the right questions, to find intermediate steps, and to develop sound hypotheses to reach solutions. Moreover, doctorate-holding engineers, with their in-depth technical knowledge, are expected to teach and to develop technical competencies in others. Furthermore, Ph.D. engineers are expected to be able to see the "big picture", which means that they need to possess understandings of how their work will impact the company and the community at large.

C. Characteristics of engineering Ph.D. holders

Characteristics identified by engineering Ph.D. holders in industry included being curious, adaptable, flexible, able to think ahead and broadly, able to and/or willing to learn new knowledge, and ethical. Participants highlighted that these characteristics are necessary to complete the responsibilities of an engineering Ph.D. holder in industry. Participants discussed being curious and willing to learn new knowledge as important characteristics that are useful when transforming theory into practical products that can drive and deliver upon a corporation's needs. Furthermore, participants asserted that the ability to use tools to predict possible outcomes and implications at a corporation are very important characteristics. They said similar things about the importance of being able to determine how research results provide valuable findings for the company regarding what to pursue in the future. Finally, integrity was identified as the most important characteristic an engineering Ph.D. holder should possess. One participant's relates to engineers' interactions with customers and stakeholders. Engineering Ph.D. holders are expected to report findings to relevant stakeholders. In this reporting process, it is essential to present both the successes and failures of their work, to provide a complete picture of this work, and to discuss next steps for moving forward.

IV. Discussion

A preliminary analysis of the results shows that engineering Ph.D. holders. in industry are expected to be resourceful, to commercialize products, to communicate with internal and external stakeholders, and to engage in business practices. Key characteristics of engineering Ph.D. holders include leadership skills, integrity, being adaptable to a work environment, being willing to acquire deep and broad knowledge, and possessing abilities to think ahead.

The findings from the study contribute to the literature in a number of ways. First, this study did not restrict participants to Ph.D. holders in industry who were only conducting research. Unlike previous research that examined Ph.D.s holders whose primary work role was research [9], this study included any engineering Ph.D. holder working in industry, regardless of role. This sampling criterion provided unbiased views and wider understandings of engineers' roles and expectations in industry. Second, unlike studies that examined the characteristics of the workplace and workers thorough pre-defined variables [9,10], this exploratory study investigated the nature of responsibilities, expectations and characteristics of engineering Ph.D. holders, thereby capturing the comprehensive picture of working engineers' characteristics in industry. Finally, this study explored Ph.D. holders from industry whose discipline was in engineering, hence adding value to the small body of literature that currently consists on research on Ph.D.s in the life and physical science disciplines only [9,10].

V. Implications and future work

The findings of this study present a description of what it is like to be an engineering Ph.D. in industry. Such insights are useful to engineering Ph.D.s that are considering career paths in this employment sector. Additionally, this study has the potential to reveal how graduate schools can collaborate with companies to educate future engineering Ph.D. students who possess the attributes and skills identified in this study. As part of the future work, more interview transcripts will be analyzed to continue to build and to identify important abilities for engineering Ph.D.s across specific engineering disciplines (i.e., mechanical, chemical, and electrical), across various career stages (i.e., early-career or late-career), and across different employment sectors (i.e., industry, academia, government). Furthermore, an assessment tool that measures the important attributes to work in industry (as identified by the interviewees) for engineering Ph.D.s will be developed. This assessment can inform present and future engineers of their current strengths and weaknesses in the needed attributes for a career in industry.

Grading by Experience Points: An Example from Computer Ethics

Edward Gehringer, Barry Peddycord III
Department of Computer Science
North Carolina State University

{efg, bwpeddyc}@ncsu.edu

***Abstract*—In most of education, courses are graded based on percentages—a certain percentage is required for each letter grade. Students often see this as a negative, in which they can only lose points, not gain points, and put their class average at risk with each new assignment. This contrasts with the world of online gaming, where they gain "experience points" from each new activity, and their score monotonically increases toward a desired goal. In Fall 2012, the lead author switched to grading by experience points in his Ethics in Computing class. Students earned points for a variety of activities, mainly performing ethical analyses of various issues related to computing, and participating in debates on ethics-related topics. The students appreciated the ability to earn extra points by performing extra activities. But they were less likely to complete analyses after signing up to do them than were students in a traditionally-graded class. At semester's end, the number of peer reviews increased, as students strove to top off their point total. The grade distribution was bimodal, with clusters at both ends (A+ and F). Students' greatest concern was rapid grading turnaround, so they would know where they stood in the class at all times.**

Keywords—gamification, experience points, XP, computer ethics, assessment *(key words)*

I. Introduction

In most of education, courses are graded based on percentages—a certain percentage is required for each letter grade. Students often see this as a negative, in which they can only lose points, not gain points, and each new assignment puts their class average at risk. This contrasts with the world of online gaming, where one only gains, never loses, "experience points" from each new activity, causing their score to increase monotonically toward a desired goal.

In the last two or three years, several instructors have moved to grading by experience points (XP). The strategy was showcased by Lee Sheldon in his 2012 book, *The Multiplayer Classroom: Designing Coursework as a Game* [1]. It offers a way to motivate students in almost any course, without the need to design actual games to teach different units of the course material. It seemed appropriate for our Ethics in Computing course, which is not always a favorite among our technically oriented students. We thought it might boost the level of student interest and engagement.

II. Motivation

The motivation for using experience points stems from a number of shortcomings of more traditional, percentage-based grading schemes. In such schemes, a finite number of potential points are set at the outset of the course, and students strive to obtain 100% of the potential points. Because the number of points is fixed, it can be difficult for students to recover after poor performance on a single, heavily-weighted assignment.

When assignments are weighted heavily, students are under intense pressure to perform well [9] on them. An unintended corollary is to incentivize behavior that does not adequately promote learning [4]. To gain insight into how students are prioritizing their time and energy, listen to questions that students ask about assignments, e.g., How many pages should the essay be? Or, will the exam be mostly multiple choice or mostly essay? The guiding principle from this insight is that *high-stakes assessment incentivizes performance over learning*.

Gamification [3] is used in business and education to reward positive behavior. In the context of the classroom, gamification would be used to incentivize student actions associated with learning. By setting a goal and allowing students to choose their own way to reach that goal, it allows students more agency in the tasks they perform. The hope is that because they define their own tasks, they will choose those those in which they take a personal interest, rather than performing them simply "for the grade." One of the simplest ways to gamify a course is to grade it by a monotonically increasing number of *experience points*, rather than weights and percentages for each assignment.

The principal detriment of percentage-based grading is that it is difficult for students to recover from mistakes. In the event of failure, experience points are more forgiving than percentages. This is desirable, since failure can serve as an excellent learning experience. While percentage grades equate success with near-perfect performance, experience points can reward deep and thorough learning.

In addition to reducing the pressure on students, points can also be used to reward socially positive activities that not only advance the learning of the individual, but also improve the learning experience for the rest of the class [5]. Students can be awarded points for holding study sessions, office hours, or participating in peer reviews. In this way, students help with the logistics of the course, improve the experience for their peers, and absorb the positive message that teaching others is a valid approach to demonstrating mastery of course material. One manifestation of peer teaching in computer science is pair programming, which is often used to facilitate a transfer of skills between students [2].

III. Implementation

Our Ethics in Computing course is a one-hour course required for all Computer Science students. Students were awarded points for each activity in the class:

- weekly quizzes over the reading material for the class (each worth 50 points maximum),
- ethical analyses (done alone or in pairs, each worth 400 points maximum),
- peer reviews of other students' ethical analyses (each worth 50 points maximum),
- evaluations of one's partners' contribution to an ethical analysis (each worth 50 points), and
- in-class debates (each worth 200 points maximum).

Except for partner evaluations, all activities were graded in some way, and the students' points were scaled by the grade they received. For example, if they scored 80% on a weekly quiz, they earned $50 \times 80\% = 40$ points. For evaluating their partner, they received the full 50 points automatically. This provided an incentive to do the ethical analyses in pairs, since one could earn an easy 50 points just by filling out the partner survey. Some students asked if teams of more than two would be allowed. We decided that students could work in larger teams, but regardless of how many were on a team, the maximum score earned by all team members would be 400 x 2 = 800. So each student on a 3-member team could earn only 800/3 = 266 2/3 points, even if (s)he got a perfect score on the analysis. Of course, they could earn 100 more points for evaluating both of their partners, but even so, the maximum point total was less than for a solo or 2-member analysis. Only 6 out of 174 analyses during the semester were written by 3-member teams; all the rest had solo or pair authors.

The course Web site specified grading thresholds like this: "To get an A in the class requires 2600 points; a B requires 2300 points, etc." The meaning of "etc." was intentionally left vague because this was the instructor's first time grading by experience points, and he wanted the flexibility to adjust cutoffs if necessary to achieve a "reasonable" grade distribution. In any case, if students needed to earn extra points to reach their desired grade, they would merely need to perform additional activities, like analyzing more issues, or

Fig. 1. Signup sheet for ethical-analysis topics

reviewing analyses done by other students. The A threshold was set so that students who (i) took all the weekly quizzes, (ii) did three ethical analyses during the semester, (iii) and two reviews per analysis, and (iv) participated in two debates, and received an average of 93% on all their work, would collect just enough points for an A. However, students were permitted to do as many as six analyses (there were six two-week analysis rounds during the semester), and also to participate in extra debates if space was available. They could thus "make up for" poor performance on other assignments, or for missing those assignments altogether. In effect, all work was treated as if it was "extra credit," counting for a particular number of points. No one needed special permission to do extra work.

Ethical analyses were reviewed by a combination of peer review and instructor/TA review. The process is similar to the practice that we earlier described for writing sections for a student-authored wiki textbook [8]. Using our Expertiza system [6,7], students first select a topic from a list presented by the instructor. Students are allowed to sign up individually (Figure 1) or in pairs, but usually, only one student or team will be allowed to sign up for each topic. This is to ensure that all the topics will chosen by someone. Students then write up their work in a Google doc (ultimately to be included in a Google site) and submit the link to Expertiza. Other students review it using a rubric that asks them to comment and rate approximately ten aspects of the work. The student authors then have an opportunity to respond to their reviewers (also using a rubric). Based upon reviewers' comments, they revise their work. Their final submission is again assessed by their peer reviewers. The instructor and TA review the work and assign the final grade, but are often influenced by the reports of peer reviewers.

To give students an incentive to do careful reviews, the instructor and TA "metareviewed" the reviews done by the students. We looked over all the reviews done by the student during a particular round of ethical analyses, and scored the student's *average* review on a scale from 1– to 3+. (This was faster than assigning a score to each review.) The 1– to 3+ scale was translated to points (1– = 10 points; 3+ = 50 points), and the student was awarded this many experience points for each review done in this round (Figure 2).

IV. Results

As it turned out, the most common grade in the course was A+. The A+ threshold was set at 97/93 of the A threshold, or 2712 points (typical university cutoffs are 97 for an A+, 93 for an A). More than 1/4 of the students (21 out of 77) received an A+. Some of them were very excited about the course. Five students wrote the maximum 6 ethical analyses, and five of these 6 earned an A+ in the course. Of the A+ students, 8 of them participated in at least 3 debates (one took part in 4 debates). These students accumulated 2782 to 3694 experience points. However, there was more than one path to an A+. One of our A+ students wrote only one analysis and received almost 60% of his points for reviewing.

The second most common grade in the course would have been F—if we had extrapolated the grading scale linearly (2600 for an A, 2300 for a B, 2000 for a C, 1700 for a D). Fifteen students accumulated fewer than 1600 XP, with totals that ranged from 152 to 1586. Figure 3 shows the grades that would have been awarded without any "curve." To avoid failing a large number of students (in an ethics course nonetheless!), we loosened the scale so that only 1600 points were needed for a C and 900 for a D. With these cutoffs, there were only 5 Fs. But this meant that an A required nearly three times as many points as a D; on Sheldon's scale [1], by contrast, an A can be earned with only 50% more points than a D.

The idea that grading was based just on points meant that we could not really require students to complete any course activity. According to the syllabus, all students were compelled to participate in two debates. However, there was no way to enforce this requirement, since students could instead earn points for writing or reviewing extra ethical analyses. Even among the A+ students, 7 of them failed to do

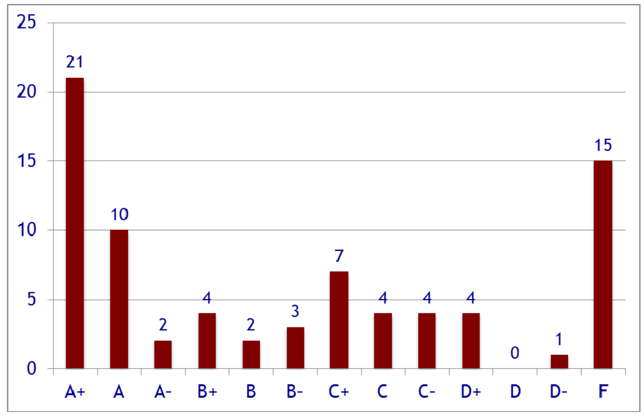

Fig. 3. Grade distribution with unadjusted grading scale

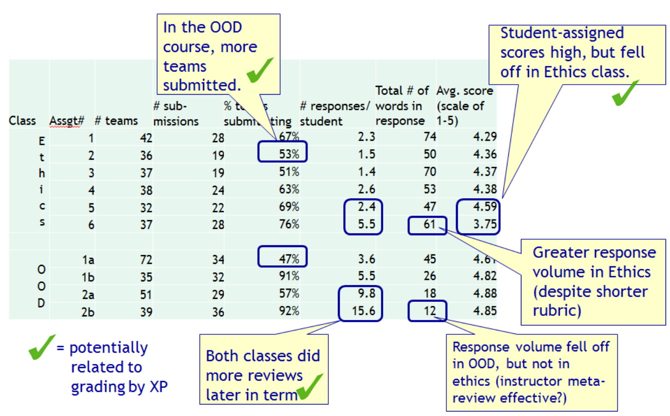
two debates; one of them didn't do any. In future semesters, we will consider making debates an achievement that all students must attain in order to pass the course.

Figure 4 compares the results in the ethics course with the results in the author's other Fall 2012 course, a course in object-oriented design, which was not graded by experience points. The column marked "% of teams submitting" refers to the percentage of teams that chose a topic and then followed through with a submission. In the ethics class, about 2/3 of the teams submitted an analysis of their chosen topic in the first round of ethical analyses. This percentage declined slightly in the next few rounds, then rose as the end of the course approached and opportunities for procrastination evaporated. In the OOD course, students were required to submit a wiki chapter for either assignment 1a or 1b, and again for either 2a or 2b. The percentage actually submitting in the OOD class was lower than the ethics course in the "a" rounds, but much higher in the "b" rounds. This may be a manifestation of the fact that the ethics students feel less pressure to do any particular assignment, since there are always other ways to earn points. This is especially true early in the semester, when the other opportunities are numerous.

Now look at the row titled, "# responses/student". This is the number of reviews done per student for the submissions in



Class	Assgt#	# teams	# sub-missions	% t[illegible]s submi[illegible]ting	# responses/ student	Total # of words in response	Avg. score (scale of 1-5)

Fig. 4. Comparison of peer reviewing in ethics and another course

the different rounds. Note that it rises in both classes as the end of the semester approaches. This is probably a consequence of the fact that students in the OOD class could earn extra credit for doing extra reviews (though there was a cap on the amount of extra credit that could be earned in this way). Thus, students in both classes were incentivized by earning extra points for extra reviews, and this inducement seemed to grow as the semester wound down and the other opportunities for earning credit dried up.

The next column tells how many words of prose were included in reviews submitted by the students. Note that this is much higher in the ethics class than in the OOD class. However, the OOD class was using a much more detailed rubric than the ethics class (18 criteria vs. 6). Thus, it took reviewers longer to rate the OOD submissions on the required criteria, which seemed to subtract from the energy that the student reviewers invested in writing prose. It is probably also true that student authors derived more guidance from the more detailed rubric, so prose comments were somewhat less necessary.

The volume of prose comments falls off sharply toward the end of the semester in the OOD class, but not in the ethics class. This is likely due to the fact that students (rather than instructors) were serving as metareviewers in the OOD class. Students tend to be much less demanding of the reviewers that they rate than the instructor/TA would be. This suggests that instructor/TA metareviewing served to "keep the ethics students honest," doing reviews that were just as careful at the end of the semester as at the beginning.

On the other hand, when one looks at the average score assigned by the reviewers (on a Likert scale of 1 to 5), it falls off sharply at the end of the semester in the ethics class, but not in the OOD class. This suggests that perhaps the quality of ethical analyses fell at the end, with students attempting to earn points via quantity rather than quality of submitted work. However, if one compares the average score awarded (by the instructor and TA) to analyses in round 6 (75.3) with the average score in round 5 (76.2), there isn't much difference. So it's not clear that quality did fall. Of course, one would hope to see quality increase from one round to the next, but we didn't see that happen.

A. Student Responses

Students were surveyed on their reaction to the review process and grading by experience points. Results are shown in Table 1. Students were most positive (4.02 on a Likert scale of 1 to 5) on having the chance to do extra work to achieve the grade they desired. They were least positive (2.11 on a scale of 5) on the grading process giving them a clear indication of where they stood. As one student put it,

> "I believe this system could really work..the problem was this semester is that the grading was unacceptably late. I can't even describe how infuriating this was as a student. I didn't even start knowing what my XP points were until mid November."

TABLE I. RESULTS FROM STUDENT SURVEY

Survey Question (Likert scale of 1 = strongly disagree to 5 = strongly agree)	**Average** (*n* = 44)
1. I had trouble understanding what was expected of me in writing an ethical analysis.	3.36
2. I put a lot of effort into writing my ethical analyses for the Ethics in Computing	3.83
3. The material I read in order to write my ethical analyses gave me new insight into the topic I was writing on.	3.57
4. The ethical analyses I wrote would be credible entries for an undergraduate textbook	2.81
5. I am proud of my contributions to the Ethics site.	3.34
6. Having students write analyses for an ethics Web site in a course like CSC 379 is a good idea.	3.05
7. I clearly understood what was expected of me in reviewing an ethical analysis.	2.95
8. The analyses I read that were authored by other students gave me new insight into the material they covered.	3.21
9. I read the content of the ethical analyses more critically than I read the content of other textbooks I have used.	2.98
10. I often questioned the information and ideas in the ethical analyses I read..	3.29
11. I tried to decide if I agreed with the ethical analyses when I read them.	3.76
12. When I read the ethical analyses I considered what other opinions and ideas might exist on the topic.	3.67
13. As I read, I often thought about my own ideas and opinions on the topic.	3.83
14. I looked to see if the claims made in the ethical analsyes were well supported.	3.57
15. When I read the ethical analyses, I often thought about information that seemed to be missing or what else could be included.	3.48
16. The reviews I received helped me to improve my work.	2.95
17. The scores assigned by the reviewers were fair.	3.07
18. There was too much rating required for this class.	3.55
19. I had trouble determining how to carry out the assigned activities in Expertiza.	3.33
20. Grading by experience points (XP) motivated me to work more on this course.	2.83
21. Grading by XP motivated me to write more than the required number of ethical analyses.	3.40
22. Grading by XP gave me a clearer idea of where I stood in the course"	2.11
23. I appreciated being able to do more work to earn the extra points that I needed to achieve a certain grade	4.02

This can be attributed to two factors, one logistical and one inherent to the review process. Early in the semester, the course staff *was* slow in posting grades. Ethical Analysis 1 grades were not finalized until after Ethical Analysis 2 was due. In part, this reflects the large amount of work required to write up the topics (52 topics for rounds 1 and 2). It should get easier in the future; next time, we can use a revision of this year's topic descriptions. However, it also reflects the time needed to take the submissions through the required rounds of review. The final review deadline was 11 days after submission, and final grading/metareviewing could not start until after that deadline. In later rounds, we caught up and were posting final grades within a week of the final review deadline.

Complaints about the speed of grading were the most frequent prose comment (10 out of 44 respondents). Next most frequent (8 respondents) were favorable reactions to grading by XP:

> "I think it is an interesting and novel idea. Perhaps the greatest benefit is I could participate in as many debates, ethical analyses, and reviews available and not be required to perform any one task. This allowed me to strengthen my skills in an area of my choosing. However, I did have to spend some time deciphering the allocation and accumulation of my experience points."

We thought our grading scheme was simple, but not all students agreed. The third most frequent comment (6 respondents) said it was hard to figure out:

> "Grading by XP gave me no idea about where in the class I stood or how well I was doing the entire semester. I still have no idea how well I've done this semester because the system was so convoluted and hard to figure out."

Some students (4 respondents) thought the course was too much work:

> "Also please assign less work for a 1 credit hour course, its not helpful to have a course that counts for so little of my time take up so much of it. A passing grade for this course should be out of 1600 not 2600 by my estimate of the workload appropriate for a 1-hour course."

Two students thought the system rewarded quantity, not quality:

> "Grading by XP encourages quantity of work, not quality. I didn't care if i got a C on an assignment, because if I got enough C's I would have well over an A."

V. Conclusion

In 2012, we switched to grading by experience points in our Ethics in Computing course. The course has often been plagued by low attendance. We wanted an approach that would make students delve into the very relevant and often very interesting issues of law, public policy, and personal morality. The change was successful in many respects. It did motivate a large number of students to go beyond what was required. Nearly a quarter of the class earned a grade of A+. These students, by and large, wrote more ethical analyses, and participated in more debates, than any student had in previous classes. Some of them told us how much they enjoyed the debates. Students in the 77-member class submitted a total of 174 ethical analyses, on about 150 different topics. This, too, is more topics than we had been able to cover in any previous running of the class.

On the other hand, a significant fraction of the students thought that the class was too much work for one credit. Many students did less than was expected. Even after curving, 10 students received Ds or Fs. This too was a much higher number than in previous semesters. Activity rose markedly near the end of the semester, as student strove to earn the points that they needed for the next higher grade. However, the quality of the ethical analyses was not as high as desired. This may indicate that many students thought it was better to write many analyses, rather than write a fewer number of good analyses. On the other hand, the quality of peer reviews remained high, probably reflecting the effort that the instructor and TA were investing in assessing the reviews and rewarding good quality.

The most important lesson learned is that speed of feedback is critical in motivating students. The peer-review process makes it difficult to finalize grades quickly. But scores should be recorded almost immediately after the final review deadline. Students need a single location where they can go to view the number of points they have accumulated thus far. There is ample opportunity for us to improve the ethical analyses by (i) using good analyses from this semester as examples for later students, and (ii) assigning some students to improve this semester's analyses in specific ways identified by the instructor. As time goes along, the analyses should only get better. This will show the students what a good analysis looks like, and motivate them to do work of similar quality.

Acknowledgments

We acknowledge the efforts of Shea McIntee, the teaching assistant in Ethics in Computing in 2012-13, and Dr. David Wright, the instructor in Spring 2013, who also assisted with the course the previous fall. We also acknowledge the National Science Foundation's support of the Expertiza system, which was used to peer-review the ethical analyses.

***Abstract*— The development of ethical awareness and ethical reasoning is a critical part of engineering education. Appropriate assessments are needed to determine if the educational interventions are effective in developing these skills. Although there are measures to assess general moral reasoning (e.g., DIT2), they do not take into consideration the peculiarities of handling ethical situations in engineering rather than ethical situations in general. In addition, because most undergraduates learn to apply ethical reasoning to engineering through design courses that are taught in teams, it is important to understand the team ethical climate. To address this need, our research team is developing instruments to assess both individual moral reasoning and team ethical climate in an engineering context. As part of the validation efforts, we have conducted individual interviews and team observations to triangulate data from other sources and aid in data interpretation. In this work-in-progress research paper we present an overview of the instruments and our qualitative study design including our interview protocol and analysis approach. At the FIE conference, we will present initial findings from the analyses and discuss how these results are being used to validate and/or modify both the individual engineering ethical reasoning and team climate instruments being developed.**

***Keywords*— engineering ethics; assessment; qualitative study**

I. Introduction

The need for understanding and enhancing engineering students' ethical development has been the subject of numerous publications and has been embedded in ABET criteria. Engineers in today's global society are interacting with ever more of the world's peoples and cultures. These interactions are introducing greater social and ethical complexity to the profession than has been incorporated previously and are raising the importance of practicing engineers becoming capable ethical decision makers and contributors to ethical team climates. As engineering educators, we are responsible for helping to develop these ethical decision-making and productive team climate skills in our students so they might transfer them into the profession.

Although measures such as the Defining Issues Test, Version 2 (DIT2) have been designed to assess general moral development [1], they do not address the peculiarities of handling ethical situations in engineering. In addition, because most undergraduates learn to apply ethical reasoning to engineering through design courses that are taught in teams, knowledge of the interaction between individual ethical development and the team climate, as well as individual and team factors, is vital to design effective learning environments. To address these needs, we are collaborating with three other universities, Illinois Institute of Technology (IIT), Lehigh University, and Michigan Technological University (MTU), to develop instruments that reliably and validly measure individual ethical reasoning (Engineering Ethical Reasoning Instrument or EERI) and team ethical climate (Team Ethical Climate Survey, or TECS), from which we will study multilevel effects of both the individual and team data using hierarchical linear modeling (HLM). This study has been approved by the university's Institutional Review Board (IRB).

As part of the validation efforts of both the EERI and the TECS, we have been conducting individual interviews and team observations at each of the four partner institutions. The interview and observational data not only supplement self-report measures by aiding in data interpretation and suggesting further areas of study but also triangulate data from other sources to contribute to instrument validation [2]. The four university partners all have undergraduate engineering programs with multidisciplinary teams which were the focus of the study: the IPRO program at IIT, the Integrated Product Design (IPD) at Lehigh University, the Enterprise Program at MTU, and the EPICS program at Purdue University.

After conducting a total of 57 interviews and numerous observations within the four programs, we have begun analysis of the interview data using a typological analysis approach [3-4]. In this work-in-progress research paper we present an overview of the instruments and our qualitative study design including our interview protocol and analysis approach.

II. Description of Instruments

In the sections below, we provide an overview of the instruments, including a description of their structure and their underlying foundations. We also describe current statistical validation approaches.

A. *Engineering Ethical Reasoning Instrument (EERI)*

Similar to the DIT2, the EERI uses three fundamental schemas which are based on Kohlberg's moral development phases (originally called "stages") in which individuals increase in ethical decision making from purely self-centered responses to dilemmas to (ideally) highly empathic and contextually oriented choices [5-7] as a foundation to measure ethical development in an engineering context. These schema are: pre-conventional (focusing on personal interest and encompassing Kohlberg's stages 2 and 3), conventional

This work was made possible by a grant from the National Science Foundation (DUE-112374). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the authors and do not necessarily reflect the views of the National Science Foundation.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

(emphasizing maintaining norms, stage 4), and post-conventional thinking (displaying agile perspective-taking, ability to appeal to ideals that are shareable and non-exclusive, and expectations for full reciprocity between laws and the individual, stages 5 and 6).

The EERI has been developed over the course of several years and undergone a number of changes in scenario construction and in item and scale development [8]. We began with eight scenarios, and we are using six of those in its current form. These scenarios involve dilemmas that students might reasonably expect to encounter on a student project team. Similar to the DIT2, students are asked explicitly what action they would take in the given situation. An example scenario with the decision question is as follows:

Your student design team has designed a new Soap Box Derby car that allows children with physical and cognitive disabilities to race by allowing an adult to ride in a backseat and maintain full control of the car. Based on suggestions from the adults, you have added spring tension to the child's steering wheel in front in order to simulate the feeling of driving and make the child's experience more realistic and fun. The child will not have the ability to control the car, only the illusion of control. Before the first test run with an adult and a 14-year-old child onboard you hear the child's parent tell the child to "be careful" and to "drive safely." The parent turns to you, explains that because of a cognitive disability the child likely won't understand the difference anyway, and asks you to tell the child that the front steering wheel is actually functional. The request that you lie to the child would take advantage of the child's disability and it creates the possibility that the child would feel responsible if they were to lose the race or have an accident. Would you lie to the child? __Yes __Can't decide __No

Following their recording of their individual decision, students are next asked to rate the importance of a series of items in making their decision. In its current form, students rate 14 items in terms of importance with five response alternatives: great, much, some, little, or no. The instructions for the ranking of students' top 4 items were: "Consider the 14 issues you rated above and rank which issues are the most important." This rating and ranking process follows the format of the DIT2. Therefore, like the DIT2, it is the ranked items that determine individual students' ethical reasoning schema phase ("score").

A number of statistical analyses of the EERI are being conducted to determine if there is a correlation with year and major, as well as other external measures such as the DIT2 and peer evaluation data. The statistical measures are also being utilized to inform the reduction of the instrument, if possible, to contain only four or five scenarios with 12 items each.

B. *Team Ethical Climate Survey (TECS)*

The TECS is a new instrument adapted from Victor and Cullen's team Ethical Climate Questionnaire (ECQ) [9] for the student project context. The ECQ consists of five scales: caring, law and code, rules, instrumental, and independence. The TECS also includes items intended to measure the caring, law and code, and rules dimensions, as well as exploring dimensions of friendship, personal morality, self-interest, team interest, shared ethics model, interdisciplinary ethics, rule-orientation, and how the team responds under pressure. In the TECS, students are asked to respond to 59 items as they relate to their project team in the Enterprise, EPICS, IPD or IPRO program using a Likert scale (Strongly Disagree-Disagree-Neither Agree nor Disagree, Agree, Strongly Agree).

Validation of the TECS includes item and factor analyses. In addition, scoring methods are being developed to provide scores for the individual scales, as well as an overall score.

III. USE OF INTERVIEWS AND OBSERVATIONS IN VALIDATION

In addition to the quantitative validation efforts, we have conducted observation and interviews at the four collaborative university programs. Our semi-structured interviews provide access to unanticipated aspects of ethical decision making and team ethical climate by enabling participants to add comments that explain their experiences and/or that they believe are relevant but may not be requested directly in a structured interview. These comments provide access to team members' meaning and sense making of ethical processes. These processes include the point at which individuals or teams consider possible ethical challenges through engineering team members' resolution and explanations of ethical decisions. Furthermore, observational data provide access to details of team processes that may not be expressed in, or consciously processed enough for, more traditional interviews.

A. *Interview and Observation Protocol*

The interview protocol was developed to probe aspects from both the EERI and the TECS. Therefore, it includes questions that elicit information about how the participant prioritizes issues related to both their individual and team decision-making. We also explore general team processes and the student's perceived role to provide context on how the individual operates within the team. Overarching questions that are explored include:

- How would you characterize your team interactions as a whole?
- What is important to or valued by your team? What are your team's priorities?
- What is your role on the team? Do you feel like you belong? Are your viewpoints listened to?
- How and when are decisions made by your team? Who was involved in those decisions?
- Do you feel as though any of these decisions or your team work involved ethical considerations?
- How do you define ethics? How do you make ethical decisions?
- Does your team seem concerned about professional codes and/or rules/laws?
- Does your team share a common understanding of "right and wrong"?

Observations of team meetings were also made in order to provide context for the interviewer and help identify participants for the interviews. Observations were guided by a general observation protocol, with other interesting interactions being noted where appropriate. Several examples of the observation protocol include:

- What seems most important to the team at this time? What did you observe that made you answer in the way you did?
- Were there decisions made during team meetings? What were the decisions about? Who made the decisions?
- Did you observe interactions or language centered on how a decision or design aspect might affect individual team members?
- Did you observe interactions or language that centered on how team processes and deliverables align with moral or ethical stances that are up for discussion, shared and malleable, and/or act as appeals to ideals for human existence?

IV. Analysis and Conclusion

After conducting a total of 57 interviews and numerous observations within the four multi-disciplinary programs, we have begun analysis of the interview data using a typological analysis approach [3-4]. Initial codes were generated from the TECS scales (e.g., friendship, rules, shared ethical model) and the schema of the EERI (e.g., personal interest, maintaining norms, post-conventional). As the researchers analyze this interview data, any themes or ideas that seem prevalent across respondents will be considered and additional codes will be added throughout the analysis. We will compare and contrast findings emerging from data with interdisciplinary research to uncover regular patterns of discourse (messages and interactions), team norms for ethical decision making procedures, and other aspects that are part of team processes. In addition, we will review the participant's TECS and EERI instrument responses to how well they align with their scores on the instruments. We will also determine if the there are aspects of the experiences which are not currently reflected in the EERI and TECS. At the FIE conference, we will present preliminary results of our analysis and how it has informed our validation of and/or changes to the instruments.

Acknowledgment

We would like to acknowledge work of Craig Titus in developing the EERI, as well as our collaborators at our partner institutions: Alan Mead, Kemp Ellington, Jill May, and Danny Gandara at Illinois Institute of Technology; Mary Raber at Michigan Technological University, and John Ochs and Lisa Getzler-Linn at Lehigh University.

Ethics in Engineering Education: A Literature Review

Jehan Abu Hamad, Maram Hasanain, Mahmoud Abdulwahed, Rashid Al-Ammari*
College of Engineering, Qatar University, Doha, Qatar

** Corresponding Author: m.abdulwahed@qu.edu.qa*

***Abstract*— Engineering Ethics is an important topic to be developed in engineering education curriculum. Despite its importance, ethics is not much investigated in engineering education as compared to other disciplines, in particular medicine or biology education. In this paper, a comprehensive review of engineering ethics is provided. The review covers three main topics: 1) Attributes of ethical engineers, 2) Content, logistics and pedagogy of engineering ethics, and 3) Assessment of engineering ethics. A particular focus is given to the Defining Issues Test (DIT) and the Engineering and Science Issues Test (ESIT) that is considered a promising instrument to assess moral judgment development of science and engineering students. Final remarks will conclude the paper.**

Keywords*— *Engineering Ethics, Ethics Assessment, Ethics Pedagogy

I. Introduction And Definitions

Recent advances in engineering complexity requires engineering graduates who are able to handle interrelated technical, social, human, and complex issues [1]–[2]. The engineering profession mission requires the engineer to contribute to human welfare by reshaping the social, economic and legal contexts [3]–[4]. Hence, engineering profession is not only about the application of technical knowledge, but it is also about the application of technical knowledge in an ethical manner. Engineering ethics is taught to engineering students as a practical academic discipline that deals with real life situations, whereas an engineer's responsibilities are more complex than ever. Therefore, the professional responsibilities are introduced through these ethics to prepare the students for real life ethical dilemmas [5]. Ermer and VanderLeest [6] define engineering ethics in accordance to Martin and Schinzinger [7] as "the study of the moral problems confronted by individuals and organizations involved in engineering". Another definition of engineering ethics was proposed by Li and Fu [8] as a field which "*consists of the responsibilities and rights of those engaged in engineering, and also their desirable ideals and personal commitments*". They add, ethics "*is the study of the decisions, policies, and values that are morally desirable in engineering practice and research*".

Engineering ethics education plays a significant role in the formation and reshaping of the engineer's ethics. Possible objectives for ethical instruction in engineering education have been reported in the literature. Newberry [1] in accordance to [9] highlighted some of these objectives as follows: "i) stimulate the ethical imagination of students, ii) help students recognize ethical issues, iii) help students analyze key ethical concepts and principles, iv) help students deal with ambiguity, v) encourage students to take ethics seriously, vi) increase student sensitivity to ethical issues, vii) increase student knowledge of relevant standards, viii) improve ethical judgment, and ix) increase ethical will-power".

II. Attributes of an Ethical Engineer

The engineering profession positions the engineer in numerous ambiguous or conflicting situations of various types; a common example is facing ethical dilemmas. In order to tackle ethical dilemmas, the engineer should possess the necessary ethical skills and attributes. Li and Fu [8] highlighted a set of skills an ethical engineer should hold present in [10]. An ethical engineer should have the skill to: define ethics issues, identify relevant socio technical systems, understand different perspectives, identify and recognize value conflicts, identify constraints, identify and assess decisions (in terms of: barriers, consequences and defensibility), engage in ethical reasoned negotiations and finally, revise plans/actions/options.

Reasoning and critical judgment skills are essential for engineers while handling ethical situations. Steneck [11] highlighted that engineers should posses ethical reasoning skills, and should be able to understand the interrelation between technology and society.

Another ethical engineer's profile and set of ethical attributes were suggested by Devon [12]; these are: competency, cognizance, democratic information flows, democratic product design and development teams, a service orientation, diversity, cooperativeness, creativity and project management skills. These attributes act as guidelines for the engagement process of the engineer with other individuals. The understanding and application of such eliminates the reliance on individual ethics. Competency includes the engineer's realization of a product that achieves the goals of money making, protection of infrastructure and the protection of the country. An important attribute is cognizance, i.e. an engineer should have a full understanding of the implications of the decisions and designs they propose. Open democratic information flows includes the respect flowing between the participants while sharing information.

978-1-4673-5261-1/13/$31.00 ©2013 IEEE

Development teams and product design processes must be aimed towards achieving technology of the people, for the people and by the people. An ethical engineer should value diversity and avoid stereotyping. Cooperativeness is essential and without such cooperation the productivity of an unsafe product or decisions becomes a potential risk. New creative innovative ideas are demanded by an ethical engineer. Finally, an ethical engineer should possess project management skills. Knowing what expertise and duties are required, and knowing how to assign and manage them is necessary.

A significant portion of the skills and attributes of an ethical engineer are related to morality. Several moral models have been conducted. The paper proposed by Illingworth [13] in reference to [14] summarized the Four Component Model (FCM) of Morality:

1) *Moral sensitivity (interpreting the situation as moral).*
2) *Moral judgment (judging which of the available actions are most justified).*
3) *Moral motivation (prioritizing the moral over other significant concerns).*
4) *Moral character (being able to construct and implement actions that service the moral choice)*

Based on the literature review conducted in this area [8], [10]-[14]; an optimum model of the ethical engineer was created.

An ethical engineer should have the skills to identify an ethical dilemma and all the constraints related to such dilemma. He/she should communicate effectively with other team members to assess barriers and any possible consequences. Negotiation skills are required when team members decide upon a final ethical decision. Skills of reasoning and understanding of the relationship between both engineering and the society, and technology and society are also essential. Understanding also includes the understanding of different diverse perspectives. An ethical engineer should be competent and service oriented. The identification and recognition of value conflicts is necessary. The exchange of information between colleagues in a democratic form is also a required skill. Part of being an ethical engineer is related to moral sensitivity, judgment, motivation and character. Being creative and having strong project management skills is a must for an ethical engineer. Finally, an ethical engineer should have the skill to revise plans/actions/options.

III. Mechanisms of the Provision of Engineering Ethics Education

Several concerns were raised regarding the engineering ethics education; does it really influence the ethical skills as planned, what is the most suitable and effective approach to teach ethics. Numerous research studies were conducted in this field [3], [5], [8]–[9], [11], [13], [18]–[19]. Stand-alone ethics courses are the most common mechanism, but the introduction of engineering ethics in technical courses is highly recommended [9]. Throughout this review, the delivery methods noticed revolved around three main methods: 1- standalone courses, 2- embedded courses, and 3- team taught courses.

A. Standalone Courses Approach

As suggested by Li and Fu[8]; a standalone course is an independent course usually taught by one professor, not necessarily a professional in ethics. It is also easy to select what topics should be covered. Engineering ethics can be conducted through: standalone ethics courses within engineering or standalone ethics courses from outside engineering [1], [5], [18]. Stephan [5] suggested some "Credit-Hour-Friendly ways of teaching ethics" that were such as "Politics and Ethics of Engineering". A disadvantage of such approach is that it overcrowds the engineering curriculum which is already crowded [20].

B. Embedded Courses Approach

An embedded approach includes the introduction of ethics in different engineering core courses. This is accomplished by incorporating an ethical component or module into actual engineering courses [8]. It includes the integration of ethics content in all technical courses [1], [5], [18]. A series of contextualized activates are used to perform the integration of ethics into the engineering curriculum. This integration is considered an advantage for such approach [20]. An example of an integrative course that includes both technical and non-technical ethics mentioned in [5] was adopted in Drexel School. To further emphasize on the "across curriculum/embedded" approach, the College of Engineering at the University of Michigan adopted this approach for teaching engineering ethics along with the issues of communication, teamwork and environment [11]. The high dependency of the course on the willingness of the faculty member to address ethics decisions in his/her course is considered are the main disadvantage of such approach [8].

C. Team Teaching Approach

Team teaching approach delivers a course which is taught by a team of multidisciplinary professors [21]–[22]. Such approach gives the students that advantage of learning form the diverse expertise of both the engineering professors and the philosophy professors. The main difficulty of such approach is related to finding highly motivated and qualified engineering professors to deliver such course [8].

Some examples of the approaches used to teach engineering ethics in the undergraduate level are: "Segments in Introduction to engineering courses, Segments in Senior Seminars, Segments in Capstone Design Courses, Pervasive Approach, Integrated Humanities Courses, and Stand-alone Courses" [15]. A new approach for teaching engineering ethics is expected to include guidance by experts in making ethical decisions, harmonizing the ethics with the engineering curriculum and finally strongly demonstrating that ethics is an integral component in all engineering practices [19].

IV. Pedagogy

Several researches have been made to define the paramount methods to deliver the curriculum of engineering ethics. The review conducted resulted in numerous delivery approaches such as case studies, ccollaborative/challenge games and role plays, debates and group discussions, presentations, codes of ethics, online instruction, multimedia packages, videos and simulation, and traditional teaching methods [3], [8]–[9], [16], [23]–[30].

A. Case Studies

The best method to teach engineering ethics as mentioned in [9] is by using several case studies, e.g. disasters cases. The cases used are cases which are more likely to be encountered in real life situations. Using case studies provides a framework which engages the students in problem solving themes; they also can become a platform for peer to peer learning and experiences exchange. During such cases, the students train their moral imagination as a result of the holistic effect the case approach has [16]. Case studies force students to draw the line between acceptable and unacceptable actions and behaviors [9]. Involving students in case studies strengthens their ethical reasoning skills [23]. Such method provides the exchange of experiences between students and faculty [16]. Some examples of utilized case studies are: Challenger launch decision, BART case [8]; The Hyatt Kansas walkway collapse, West Gate Bridge, and the Thredbo disaster [23].

B. *Collaborative/Challenge Games and Role Plays in Ethics Education*

Practical understanding of ethical issues, specially the concept of responsibility, can be attained by designing collaborative games [26]. Skills of negotiation, strategic planning, public speaking, and evidence presenting are some of the skills games provide the students with. The "Engineering Ethics Challenge Game" as mentioned by Carpenter [27] involves a large number of ethical cases. Students get involved in without losing interest or feeling bored. Teamwork skills, ethical reasoning and problem solving skills are developed during such game. Such games provide an excellent chance for group discussions and emphasize on teamwork and collaboration between students [8]. Lloyd and de Poel [26] highlighted that games with their competitive environments provide students an informative experience in the management of open ended situations.

C. *Debates and Group Discussions*

An approach to improve the engineering ethics education is to involve the engineers in debates that aim to develop the uses of technology [3]. Such debates improve the ethical reasoning skills of students and the exchange of information and opinions. Debates focus on the idea of respecting other opposing opinions. While debating, students have the chance to fully analyze an ethical situation from all its aspects, i.e. design, technical and statistical considerations [24].

D. *Utilization of Online Instruction*

Loui [28] suggested that online educational technologies used in teaching engineering ethics have many benefits over traditional educational technologies. It opens the space for communication between students with each other and between the students and instructors [30]. Archiving of class sessions is one main advantage of such method. Access via the Internet to course resources is possible by this type of instruction [28].

E. *Utilization of Codes of Ethics*

Schmaltz [24] highlighted that the introduction to existing codes of ethics will increase the students level of knowledge and comprehension. Implicit social contract between society and professionals is also achieved. Being aware of the codes of ethics helps the students understand the professional societies role [23]. Stern and Russell [29] suggested a module to teach engineering ethics more effectively. In this module, students work on developing their own code-of ethics; Once developed, they compare them to established codes by engineering societies.

F. *Other Methods and Approaches*

Multimedia packages, videos and simulation provide an interactive learning framework for students [8]. The use of presentations as a method to teach engineering ethics is recommended by Bowden [23]. During presentations, students with their peers have the chance to discuss their viewpoints and draw conclusions. Group work and cooperation among students is achieved when preparing and giving presentations [28]–[29]. Traditional Methods including exams, reports, quizzes, assignments, etc. are still used in which analytical skills are used and measured [24]. The previous methods are summarized in the table below.

TABLE I. ENGINEERING ETHICS INSTRUCTIONAL METHODS AND OUTCOMES

Instructional Method	Expected Outcome
Case Studies	• Strengthen the ethical reasoning [23] • Engagement in life time ethical concerns [23] • Encountering of real life situations [9]. • Drawing the line between acceptable and unacceptable actions and behaviors [9]. • Engage students in problem solving themes [16]. • Exchange of experiences [16]. • Awareness of harmful practices [24] • Demonstration of ethical issues [25].
Collaborative/Challenge Games and Role Plays	• Practical understanding of ethical issues (responsibility) [26] • Teamwork [27]. • Ethical reasoning [27]. • Negotiation, strategic planning, public speaking, and evidence presenting [26]. • Group discussion [8]..
Debates and Group Discussions	• Exchange opinions and respect others opinion [3]. • Improve the ethical reasoning skills • Analyze ethical situations from all its aspects [24].
Presentations	• Discuss viewpoints and draw conclusions [23]. • Cooperation among students [28].. • Groupwork [29]..
Traditional Methods (Exams, reports, quizzes, assignments, etc)	• Application of analytical skills [24]. • Groupwork [29]..
Codes of Ethics	• Increase the level of knowledge and comprehension [24].. • Understand the professional societies role [23] • Understanding of class-wide codes of engineering ethics [29].
Online instruction	• Communication [28] ,[30]. • Production of documents, drawings, and other artifacts [28] • Train the students moral imagination [16]. • Prompt Feedback [28] • Archiving of class sessions [28]. • Management of open ended situations [26] • Access via the Internet to special resources [28]..
Multimedia packages, videos and simulation	• Interactive framework [8].

In this section, an overview of the most common methods of engineering ethics instruction has been provided. The next section provides more details on the contents deployed in these methods. Examples of where these methods are applied are also mentioned.

V. CONTENT

The content of the curriculum must provide the knowledge and skills the future engineer needs to face the ethical challenges of today's world [8]. It should increase student's knowledge of relevant ethical standards. The curriculum must be designed improve the ethical judgment and ethical willpower of students [9]. The main ethical issues taught in US engineering schools are enumerated in [23]: Public safety and welfare, risk and informed consent, health and environment, representation of data, whistle-blowing issues, conflict of interest, accountability to clients, plagiarism or giving due credit, quality control, confidentiality, gift giving and bribes, employee relations and discrimination. Many methods of teaching engineering ethics were reviewed in the previous chapter. This section focuses on the content of two main engineering ethics educational pedagogies, online instructions and games/role plays.

A. Online Instruction

Instruction using the internet (web-based instruction) bridges cultural gaps and distances between both students and instructors [31]. Several reviews have been made and the following are three examples of applied web-based instruction [11], [30], [32]. Simulator for Engineering Ethics Education (SEEE):

As reviewed from Chung and Alfred [30], the SEEE is an online interactive simulator for engineering ethics education. The students are placed in scenarios which involve several ethical dilemmas, where they have to solve in a first perspective manner. During the first perspective scenarios, the students are obliged to perform an action rather than only observing the situation. The action includes playing the role of an agent and making serious decisions regarding the collection of more evidence, raising of ethical issues, and finally how to best support their ethical concerns**.**

The SEEE has four modes of operation:

a) Instructional mode: "fundamental information about engineering ethics, rules of practice, and professional obligations."

b) Training mode: "specific scenario segments involving the recognition and response to the engineering ethics subjects presented in the instructional mode."

c) Scenario mode: "complete first person perspective scenarios involving different types of possible engineering ethics situations."

d) Evaluation mode: "provide users with an objective means of assessing the level of the user's knowledge."

Comparison was made between the SEEE method and the "conventional web based engineering ethics education resource". A 32% improvement in instructional effectiveness was noticed compared to the conventional web resources [30]

1) Responsible Engineering Forum (REF@UM):

The forum was developed by the University of Michigan, it aimed to engage engineering faculty members in the teaching of engineering ethics in engineering classes. The structure of the REF@UM website is as follows:

a) Main content: divided into four sections (4 levels of ethics introductory courses)

b) Course sections: resources specifically designed to support teaching at each of the four levels (readings, links to other sites, interactive materials, and assignments)

c) Separate, password-protected section: materials specifically for faculty

d) Additional links: to locate other ethics sites, career information, professional societies, codes, journals, and case studies [11].

2) Websites for ethical engagement

A website developed by Imperial College London for the purpose of ethics engagement.

The website was developed in the form of an online ethics advisor. The three main aspects are:

a) A search tool: from which the user can get statistics and specific references to codes of conducts to ethical questions or problems.

b) A polling element: so that users can give their view on ethical matters.

c) A forum: for people to discuss any ethical issues they may have.

B. Games/Role Plays

Skills of negotiation, strategic planning, public speaking, and evidence presenting are some of the skills games provide the students with. These games with their competitive environments provide students an informative experience in the management of open ended situations [26]. The Engineering Ethics Challenge and the Delta Design Game are examples of these games.

1) Engineering Ethics Challenge (EEC):

University of South Florida developed the EEC to encourage teamwork, experience exchange and responses to ethical dilemmas. The EEC game includes questions based on ethical situations. A typical class is divided into 6 groups. Each group has a name. Ethical situations are assigned for each group. Each group develops EEC questions based on these situations. They also develop multiple choice responses. The responses are formulated in a PowerPoint presentation. To begin, a group presents their questions and several responses to all the class. The rest of the groups are asked to discuss the question and choose one of the responses. An expert, usually the class moderator, is given the scoring of the responses made by the remaining groups. The performance of the presenting group is criticized based on their presentation skills, communication skills, their understanding of the codes of ethics and the clarity of their responses. Based on this critique, the playing group makes their move on the EEC board and another group makes their presentation. The group which moves the furthest is the winning group [27].

2) Delta Design Game (DDG):

The Delft University of Technology developed such game to train students for a full design process including all types of ethical dilemmas. In this game a group of multidisciplinary designers work together to design and construct a building which is suitable and at the same time attractive for inhabitants of DeltaP company. This game is used mostly in business sectors. The same idea can be applied with the undergraduate students in which seven groups each consisting of 4 to 6 students. The game is played for almost 3 hours where students propose solutions and start discussing their proposals. Judgments are made concerning the trust of the "rule of thumb" guidelines given. Several conflicts will arise during the game and the students will try to come up with the optimum solution to solve these conflicts [26].

Developing an engineering ethics education approach and applying it is not enough. An assessment of the developed approaches must be constructed to assess the effectiveness of the engineering ethics educational treatment. The following section covers the assessment instruments used to evaluate the effectiveness of ethics educational approaches.

VI. Assessment

Several research studies have tried to examine the effectiveness of ethics education offered for engineering students in higher education institutes. As an example on existing attempts is a recent large-scale study covering engineering undergraduate students from 18 higher education institutes in the U.S [33]. The study aimed to provide descriptive data to aid the process of identifying ethics education practices that most effectively promote ethical development of engineering undergraduates. The data was collected using two main tools; the first is the "Student Engineering Ethical Development (SEED)" survey which was developed by the research team [33]. The survey included 152 items targeting the following measurements: Students' characteristics, ethics related curricular and co-curricular experiences, two constructs of ethical development, which are knowledge of ethics and ethical behavior. The second tool utilized was the Defining Issues Test Version 2 (DIT-2), which is a well-established test used to assess moral judgment/reasoning development [34]. The study has shown that the DIT-2 results are consistent with national norms of DIT-2 measurements. In addition, the authors pointed out that students' knowledge of ethics was 'surprisingly low' [33].

Other studies attempted to use DIT-2 to measure engineering students' moral judgment. A study conducted by May and Luth has utilized DIT-2 in assessing engineering students' moral judgment. They planned this study to investigate the impact of ethics education on enhancing a number of ethical outcomes [35]. Moreover, the authors of the study developed a survey to measure the five remaining outcomes which are: Students' knowledge of responsible conduct of research (RCR) and four positive psychological outcomes including: perspective-taking, moral efficacy, moral courage, and moral meaningfulness. The DIT-2 and survey were conducted in a pre- and post-test experiment design. A main result reported by the authors is that no significant difference was found in students' moral judgment measured by DIT-2 before and after exposure to an ethics course [35]. Drake and others [36] also used DIT-2 to test and compare the effectiveness of two approaches to ethics education by relying on measuring development of moral reasoning in engineering students. The experiment was conducted following a pre- and post-test with a control group experiment design. The experimental group was composed of engineering students where some are exposed to a full course on ethics education and others are exposed to a course with a module on ethics during the semester. As with the previous study, no significant difference was detected in moral reasoning of engineering students before and after exposure to ethics education [36].

Referring back to the discussed studies it can be noticed that moral judgment/reasoning has been widely examined in studies that attempted to measure effectiveness of ethics education for engineering students. Such studies have utilized the well-know DIT test to measure moral reasoning of students. A brief discussion on DIT and DIT-2 test is provided next.

A. DIT-2

The DIT-2 is the second version of the DIT that is widely used to measure individuals' moral reasoning [36]. Moral judgment can be described as "the ability to apply general moral principles to particular situations" [37] it is widely recognized as an important element of ethics education [1], [9], [37]–[38]. The validity of the DIT test has been established by 30 years of testing by many measures, one measure is its sensitivity to the effect of educational interventions [36], [14], [39] cited in [37]. Developers of DIT-2 have provided significant theoretical refinement of the framework underlying the DIT allowing for a more accurate test of moral judgment [37]. The DIT-2 assumes that three moral schemas may be active in the individual's mind in the same time [40] which are; preconventional that can be described as personal narrow interest, conventional characterized as appeal to duty and maintenance of existing social order and postconventional which includes the search for moral ideals and how the ideal social order must be [40]. The test consists of a set of 5 moral dilemmas in social context [33], each stated in one paragraph. Each dilemma is followed by twelve questions corresponding to "different ways to judge what is important for making a decision about the dilemma" [33]. Participants are required to state the importance of each question in taking the decision, and then rank the four most important questions. Reading the test dilemmas and the DIT questions activate moral schemas [40]. When the participant encounters a test question that activates a preferred schema and makes sense, that question is rated and ranked as being of high importance in formulating the moral decision. On the other hand, encountering a question that does not make sense or does not activate a preferred schema, the question receives a low rating [40].

B. DIT-2 in engineering context and the ESIT

Developers of the DIT-2 and other experts in ethics education have identified the usefulness and need for profession-specific assessment tools [41]–[42]. Similar suggestions were reported by Drake et al. [36] deploying the DIT-2 to measure moral reasoning. Based on the test results, no significant difference was detected in moral reasoning of engineering students before and after exposure to a stand-alone ethics course. Similarly, a recent study [35] has found that measuring moral judgment using DIT-2, moral reasoning did not increase as a function of the ethics education conditions. Drake et al. [36] suggested that a general measure of moral judgment such as DIT-2 may not reflect the discipline-specific judgment needed in professional settings such as the case with engineering practice. In a follow up study [37], researchers have hypothesized that these results are due to the fact that DIT-2 tests engineering and science students on general dilemmas that student may not relate to. Borenstein et al. [37] were encouraged to develop The Engineering and Science Issues Test (ESIT) that was designed to follow the structure of DIT-2. A major difference is that the dilemmas in ESIT are drawn from engineering and science contexts rather than a general social context [37]. Such test is assumed to be more sensitive to the impact of professional ethics education on engineering and science students. ESIT was tested by administration to engineering students before and after exposure to a stand-alone course of ethics education. Results have demonstrated significant development in moral reasoning measured by the ESIT due to ethics instruction [37]. The ESIT seems to be a promising tool to measure moral reasoning development for engineering students as pointed out by [35].

VII. Barriers/Constraints that Impede the Effectiveness of Engineering Ethics Education

Integrating engineering ethics into the technical courses of the engineering curriculum is faced by several difficulties and oppositions [43]. Difficulties and oppositions are produced by the teaching faculty, students, the engineering ethics curricula and other constraints. The fact that engineering ethics includes many areas related to attitudes, values and behavior makes it uncomfortable for many engineering faculty members to teach, especially that some of these values have religious overtones [6]. Also, faculty members feel that they don't have formal training in ethics [43] and they don't possess the background skills and education for teaching ethics [1]. These non-supportive attitudes highly affect the success of ethics delivery to students.

Students identify engineering ethics as a non-quantified area of study, i.e. subjective. They perceive it as the softer side of engineering which in their opinion is less interesting [6]. In addition, concrete and specific concepts are preferred by many engineering students over general and abstract concepts taught in engineering ethics [6]. "Philosophy is not practical" is a common pre-concept the engineering students have. Since engineering ethics is related to philosophy (from the students point of view) they believe that engineering ethics is little useful for the engineering field [6]. What's most difficult is the emotional engagement of the students. Newberry [1] reports that the students end of year surveys returned that the ethics course is the least interesting, least useful, most trivial. They also mentioned that ethics is irrelevant, it is common sense, waste of time and effort when studied. This is considered as a main barrier.

Engineering ethics curricula also impede the effectiveness of the engineering ethics education. Engineering ethics is somehow difficult to integrate with the technical engineering topics [6]. In addition, the engineering curriculum is already overcrowded and there is not enough time to include ethics in [43] [44]. The issue of crowded engineering curriculum has been also a barrier to include other topics and activities for another set of essential skills, such as entrepreneurship [45][46], research based learning [47], meaningful mathematics [48], experiential and project based learning approaches [49] [50], continuous assessment and effective feedback provision [51][52], etc. Other constraints related to time, money, role complexity and potentially conflicting interests and commitments are also noted [43].

VIII. CONCLUSION

The paper at hand aimed to demonstrate the results of an extensive literature review on engineering ethics and engineering ethics education. It revealed the importance of engineering ethics in the engineering profession. Pedagogical approaches along with the content of these approaches were reviewed ranging from regular, well-established approaches to the more modern approaches utilizing web and computerised resources. Several assessment methods were reviewed and documented. Most of these assessment methods utilized the well-established DIT-2 to measure moral reasoning of students as moral reasoning is a major element targeted by ethics education. The DIT-2 has shown questionable results in assessment of engineering ethics education as it assesses students' moral reasoning in general contexts that may have not been influenced by the engineering ethics education. Thus, the need for a contextualized assessment instrument for the engineering specific settings is noted and resulted in the development of instruments such as the ESIT which has shown promising results. The paper also highlighted barriers impeding the effectiveness of engineering ethics education.

***Abstract*— Each year thousands of new engineers join the workforce and face novel issues raised by radical technological advances. Concurrently, changing societal responses to new technologies introduce novel conflicts in research and development that challenge the scope of established professional codes of ethics. These issues create a critical demand for new approaches for developing moral reasoning for ethical decision-making. Our multidisciplinary team of engineering, communication, and ethics educators has developed and tested a novel pedagogical framework of Scaffolded, Integrated, and Reflexive Analysis (SIRA) of ethics cases to enhance development of moral reasoning that extends beyond case-based analyses. Implemented as a series of two-week cyber-enabled learning modules, with cases from several engineering disciplines, this theory-based, data-driven, cyber-enabled framework for ethics education has applicability across a broad spectrum of disciplines and provides engineering educators with limited ethics training a tested framework and set of resources and modules to adapt and use in their own disciplines. In this paper, we discuss our work in progress on the SIRA framework, its implementation, and our assessment of changes in moral reasoning and student satisfaction when utilizing this model.**

***Keywords*— engineering ethics; moral reasoning; principlism; reflexivity; scaffold; cyber-enabled learning modules**

I. Introduction

Rapid technological advances, coupled with evolving societal and environmental challenges, introduce unprecedented ethical issues for engineers. This dynamic landscape creates a critical need for ethics education that provides engineers with the conceptual tools to understand and resolve emerging ethical problems not yet addressed in professional codes. To address this need our multidisciplinary team of researchers in engineering, philosophy, communication, and engineering education has developed a novel pedagogical framework to develop moral reasoning in engineering students. Implemented as a series of 2-week cyber-enabled learning modules with cases from several engineering disciplines, this theory-based, data-driven framework has broad applicability and provides engineering educators with limited ethics training a tested framework and set of resources to adapt for use in their disciplines. In this paper we introduce this *SIRA framework*, and discuss its development, assessment, and implementation in a cyber-enabled context.

II. The SIRA Framework

Our novel pedagogical framework involves a coherent approach that is scaffolded, integrated, and includes reflexive analysis (SIRA) of ethics cases to provide effective development of moral reasoning. Grounded in the ethical principlism familiar in medical ethics [1], the framework challenges students to use higher-level reasoning in their analysis of ethical issues through structured learning modules that invite and facilitate integrated dialogue and reflexive and reflective analysis about professional codes of ethics and moral principles. Called *Reflexive Principlism*, this approach uses four core moral principles – autonomy, non-maleficence, beneficence, and justice – as a guiding framework for moral decision-making within engineering ethics, and serves as a backdrop against which to evaluate codes of ethics [1]. Integrated within this framework are well-storied narratives, high levels of interactivity using moderated discussions and facilitated debates, and cases with complex content [e.g., 2,3] implemented on an established learning cyber-infrastructure. The core elements of the approach are discussed below.

A. Scaffolded Learning

Scaffolding refers to the tools and resources provided to the learner to support the developmental learning process [4], supporting the learner in the early stages of complex problem solving by providing high levels of structure, and becoming less prevalent as the learner develops skill and confidence [5]. Hard scaffolds are consistent structures such as glossaries, expert information, and textual guides designed with anticipated obstacles to learning in mind. Soft scaffolds are "dynamic, situation-specific" types of support provided by instructors and are tailored to individual needs [6].

B. Integrated Method

We extend the principlist approach [1,7] by using an integrated method to appeal to the core principles throughout the learning modules. Principlism provides guiding moral principles that are independent of particular situations, and has individuals apply them *in situ* and *reflected* against the details of specific contexts. The principlist approach pushes beyond

application of codes to a richer level of reasoning regarding value assumptions in specific contexts [1]. Each integrated module includes a case study of an ethical issue in an engineering context involving a variety of stakeholder perspectives, including the subjective (self), the imagined (role play), actual persons (stories), professional (codes), and experts (reporting). Grounded in this approach and each specific case, the pedagogical framework leads students through: (a) identification of relevant facts and stakeholders, contextual issues, core ethical principles and moral assumptions; (b) reflexive analysis comparing ethical principles and professional codes; and (c) analysis of key ethical elements using critical thinking, prioritization, and justification of the four principles to arrive at a defensible decision.

C. *Reflexivity Analysis*
