In the first experiment, conducted with undergraduate students who were taking the Computer Organization course, there were 102 students in the pre-test, 93 students in the post-test and 32 students in the practical class. Among all possible combinations, two scenarios were highlighted: (1) 23 students

who participated in the two tests and in the practical class; and (2) 52 students who took both tests and did not participate in the practical class.

Figure 3 shows the grades obtained by the students in pre-test and the post-test, considering both scenarios. The best results can be observed for Scenario 1, where students scored 165 points in pre-test, and 205 in post-test, showing a 24% improvement. Students in Scenario 2 scored 443 points in pre-test and 476 in post-test, showing a significantly smaller improvement of 7%.

Figure 3. Scores per test in Experiment 1.

In the methodology used to analyze the results, firstly the difference between the grades of the students in the pre-test and the post-test was tested in order to observe if they follow a normal distribution. The normality test must be done to guide the choice of the test applied to compare the scenarios and to prove the influence of the Amnesia in the learning process.

The normality test used was the Shapiro Wilk test [13]. For Scenario 1, it was concluded that the differences did not follow a normal distribution (p -value = 0.01613) and for Scenario 2 the differences followed a normal distribution (p -value = 0.1595).

As the first scenario did not follow a normal distribution, a non-parametric test was used in order to test the difference between the two groups (pre-test and post-test) in each scenario, and the Friedman test [3] was chosen. This test compares evaluation methods considering dependent samples, and in this case the dependent samples are the results obtained in the pre-test and the post-test.

The result obtained when the Friedman test was run in Scenario 1 is a p -value equal to 0.001063, leading to a rejection of the equality of the groups. As the post-test grades are higher than in the pre-test, it can be affirmed that Amnesia improves the student's performance.

For Scenario 2, the Friedman test resulted in a p -value equal to 0.1011, leading to a value that did not reject the equality of the groups. In other words, the groups are statistically equals and the performance of the students in the post-test is the same to the pre-test.

Figure 4 shows a better analysis concerning the evolution obtained in each scenario. Figure 4a illustrates the evolution of knowledge obtained in Scenario 1 and it can be observed that the median score was improved, including a greater distribution of hits per student in post-test and eliminating the

outlier present in pre-test.. Figure 4b shows the progress of knowledge obtained in Scenario 2 and it can be observed that the median of the pre-test was almost the same as the post-test and values were more concentrated near the median. Considering this, the adoption of the Amnesia learning object in this experiment positively influenced the consolidation of knowledge obtained by the students.

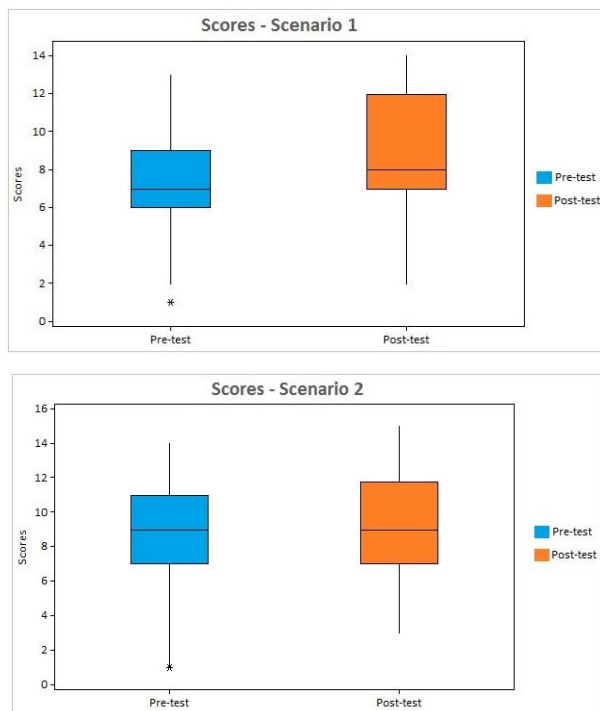

Figure 4. a) Scores in Scenario 1, Experiment 1; b) Scores in Scenario 2, Experiment 1.

Figure 5 and Figure 6 show the scores per subject in Scenarios 1 and 2, respectively. For most subjects, the students' knowledge developed in Scenario 1 increased, except for mapping functions and replacement policies. When this data is compared to data from Scenario 2, it can be observed that among the subjects that had a decrease in performance, mapping functions and replacement policies are also present.

Figure 5. Scores per subject in Scenario 1, Experiment 1.

Figure 6. Scores per subject in Scenario 2, Experiment 1.

This information is important, showing that a decrease in performance is not related to the use of Amnesia. However, when investigating possible causes of this decrease, it was concluded that there was a lack of emphasis in these subjects in the practical class using the learning object.

Still comparing Scenarios 1 and 2 from Figure 5 and Figure 6, students using Amnesia considerably improved their performance in the subjects of motivation/concepts, multilevel and unified/split caches. As in this case the students participated in constructing their own knowledge, there was a larger concern regarding their understanding of concepts and exercises involved, which justifies their higher performance. The subjects on multilevel and unified/split caches demand complex concepts of cache memory architectures, and using the Amnesia learning object makes it easier to understand due to its practical simulation.

In the second experiment, conducted with MSc/PhD students, 15 students took part in the pre-test, post-test and the practical class. The practical class had a higher emphasis on the subjects of mapping functions and replacement policies due to the results in Experiment 1.

Figure 7 shows that the scores in the post-test were higher than in Experiment 1. Students scored 52 points in the pre-test and 135 points in the post-test, which was an improvement of 160%. The knowledge evolution obtained can be observed by the improved median score in the post-test, including a greater score per student.

Figure 7. Scores per test in Experiment 2.

Figure 8 shows the scores per subject. Considering this, we noticed that knowledge was improved for all the subjects. Another important point to be highlighted is that even though the students in the experiments had not studied cache memory concepts for a while, the result was very positive.

Students' interest in the subject was noticeably better when using the Amnesia object, as they focused on the sequence of exercises and therefore consolidated more knowledge of each one, which justifies the significant improvement in learning. Furthermore, it could be argued that the adjustment made between Experiments 1 and 2 regarding mapping functions and replacement policies was also positive.

Figure 8. Scores per subject in Experiment 2.

Students were advised to do not answer the questions they were not sure, in both experiments. Therefore, another positive aspect concerning the two experiments was observed: the significantly fewer number of questions left blank in the post-test by students who participated in the practical class.

Figure 9 shows that the number of questions left blank by students in Scenario 1 of Experiment 1 was 57 in the pre-test, while in the post-test there were 28, which was about 50% less. Students in Experiment 2 left 96 questions blank in the pre-test, and 32 in the post-test, approximately 66% less. However, students in Scenario 2 Experiment 1, who did not take the practical class, left 100 questions blank in the pre-test and then 95 in the post-test, only 5% less. Taking this into account, the importance of the practical class can be highlighted when using the Amnesia learning object.

Figure 9. Number of questions left blank.

To emphasize the relevance of a practical class using a learning object, we analyzed the relation between the number of questions that were left blank in the pre-test and that were

answered correctly in the post-test. Figure 10 shows this relation considering both experiments and the topic Unified/Split, which had only one question in pre-test and also in post-test.

Considering the 23 participants in Scenario 1 of Experiment 1, 11 students correctly answered the question of this topic in the post-test, among which 8 had left the question blank in the pre-test (Goals). For Scenario 2 of Experiment 1, considering the 52 participants, 25 students correctly answered the question of this topic in the post-test, whereas 13 were participants who had left the question in the pre-test blank (Goals). For Experiment 2, considering 15 participants, 11 students correctly answered, among 9 who had left the question in the pre-test blank (Goals).

In terms of percentage, it can be observed that in Scenario 1, Experiment 1 and in Experiment 2, 73% and 82% of the students that were involved in the practical class were able to correctly answer the questions in the post-test that were left blank in the pre-test respectively. In Scenario 2, this value is 52%, which shows the importance of the practical class using a learning object.

Figure 10. Number of questions left blank in pre-test and correct answers in post-test (Goals) per subject Unified / Split.

B. Evaluating Students' Attitudes

The first experiment conducted with undergraduate students had 32 participants. 37% were in doubt whether they would use Amnesia again in the future or not. 38.24% had sound knowledge of the subject before using the learning object. After using it, 97.06% said they would use the object again, and 88.24% felt confident with its results, 58.82% stated that their knowledge on the subject had improved and 29.41% said it had improved significantly. Furthermore, 85.29% of the students considered the subject more interesting after using Amnesia and 73.53% claimed they were motivated to use other learning objects in the future.

In the second experiment, carried out with MSc/PhD students, there were 14 participants. 57.14% of them already had sound knowledge on the subject before using the object and 92.86% stated that they had improved their knowledge significantly on the subject. While using the object, 71.43% felt confident with its results and 100% considered the subject more interesting and claimed they would use the object again. 78.57% said they were more motivated to use other learning objects again.

It is worth mentioning that the interest in using Amnesia again, as well as other learning objects, is a consequence of the importance of the practical class in the knowledge construction process.

VI. CONCLUSIONS AND FUTURE WORK

This paper presented the cache memory module of the Amnesia learning object. Its use as a support mechanism of the teaching and learning process was discussed, considering the memory hierarchy contents taught in Computer Organization courses.

In general, it could be observed that the simulation of cache memory theory concepts of helped students to learn, as discussed in Section V-A.

As the Amnesia object stimulates students' interaction, it was possible to hold their attention in class and they were able to construct their own knowledge. This makes the understanding of concepts and exercises easier for them. These conclusions can be supported by the 24% of the undergraduate students in Experiment 1 who improved their knowledge using Amnesia, compared to 7% who did not use it, and also by the 160% higher score reached by the graduate students in Experiment 2.

Furthermore, based on the Amnesia's object evaluation described in Section V-B, the high interest in using Amnesia (as well as other learning objects) again provides evidence on the importance of practical class in the students' knowledge construction process.

As future work, we point out the need of conducting a more complete evaluation of Amnesia. New experiments are being set up aiming to improve the evaluation methods. Moreover, new functionalities are being developed, tested and implemented on the object to make it easier to use.

The Amnesia learning object is available in the MERLOT LOR: <http://www.merlot.org/merlot/viewMaterial.htm?id=929863>.

How Should We Estimate a Missing Exam Score?

Abstract—In core engineering courses, instructors administer multiple examinations as major assessments of students' learning. When a student is unable to take an exam, the instructor must estimate the missing exam score in order to calculate the student's course grade. Using exam score data from multiple offerings of two large engineering courses, we compared the accuracy of several methods to estimate an exam score, including linear regression methods. The standard error of regression of the ordinary least squares (OLS) regression model was consistently about 0.5. For final exam scores, the standard errors of linear models with equal weights were nearly the same as the standard errors of the OLS regression models. For other exam scores, the equal weight model was somewhat less accurate. The results of this study provide practical guidance to instructors who need to estimate missing exam scores.

Keywords—examination, grading, assessment

I. INTRODUCTION

In large engineering courses that I (the first author) have taught, with hundreds of students, I usually schedule three examinations plus a comprehensive final examination. For the first three exams, I return exam papers to students within two or three days of the exam date. When a student misses an exam for illness or some other commitment, I try to give the same exam to the student on the next day, but for a prolonged illness, that solution is not possible. It would be unfair to give the student the same exam after papers had been returned, because the student would be able to obtain correct answers from other students during the interim time. Creating a makeup exam that has exactly the same difficulty as the missed exam would be impossible. How should I estimate the student's missing exam score, which I need to calculate the student's course grade?

There appears to be no previous research on estimating a score on an exam. In this study, building on the literature on imputing missing data, we investigate methods to estimate an exam score, using combinations of other exam scores as predictor variables.

Statisticians have developed several methods to impute missing data [1, 2]. In *mean imputation*, a missing value is estimated by the average of the other values of the variable. With mean imputation, if a student misses the second exam, the average of other students' scores on the second exam would be used. Mean imputation seems unfair because a student's academic performance would be determined by the performance of other students. In *interpolation imputation*, which is appropriate for time-series data, a missing value is

interpolated between neighboring values. With interpolation, a student's missing score on the second exam would be determined by fitting a line through the student's scores on the first and third exams. Although interpolation has the advantage of using the student's own scores, it does not use all of the student's scores. The practice of substituting the student's final exam score for the lowest exam score [3], in this case the missing exam score, has the same disadvantage.

In *regression imputation*, a missing value is estimated with a multivariate linear regression, using other variables as predictors. In a regression analysis, the variables are sometimes normalized so that each variable has a mean of 0 and a standard deviation of 1. Normalization of exam scores enables us to combine data on exams with different scale ranges and different levels of difficulty. For example, if the mean score is 72 and the standard deviation is 15, then a raw score of 69 is replaced by a normalized score of $(69 - 72)/15 = -0.20$. To estimate the normalized score on the third exam, a linear regression would determine coefficients $\beta_1, \beta_2, \beta_4$, to produce an estimate e_3^* of the normalized score on the third exam, using the normalized scores e_1 and e_2 on the first and second exams and e_4 on the final exam as predictor variables:

$$e_3^* = \beta_1 e_1 + \beta_2 e_2 + \beta_4 e_4$$

The *ordinary least squares regression* (OLS) calculates the β coefficients to minimize the sum of the squares of the residuals, i.e., the differences between the predicted scores and the actual scores.

Rather than OLS regression, I (the first author) have historically used a linear combination with fixed weights (β coefficients). To estimate the normalized score on the third exam, I used the equation above with $\beta_1 = \beta_2 = 0.25$ and $\beta_4 = 0.50$. Although I did not have any theoretical reasons for choosing these weights, the estimation with fixed weights was simple to calculate, easy to explain to students, and more "transparent" than an OLS regression: I simply disclosed the mean and standard deviation of the score on each exam. In the sequel, we call the linear combination with $\beta_1 = \beta_2 = 0.25$ and $\beta_4 = 0.50$ the *historical model* for estimating an exam score. Note that using the final exam score alone to estimate the third exam score corresponds to setting $\beta_1 = \beta_2 = 0$ and $\beta_4 = 1$.

Dawes [4] suggested that equally weighting the predictor variables produces better estimates than expert-chosen weights. To estimate the score on the third exam, Dawes would use the equation above with $\beta_1 = \beta_2 = \beta_4 = 1/3$. We call the linear

combination with equal weights the *equal weight model*. We can use the equal weight model to estimate any exam score.

Some instructors estimate a missing exam score by averaging the student's raw scores on all other exams. If all raw scores use the same scale, say 0 to 100, and they have the same mean and standard deviation, then calculating the straight average of the raw scores is equivalent to applying the equal weight model. For other methods of estimating student academic performance, see [5].

In this study we address the question of how the well OLS regression, the historical model, and the equal weight model estimate students' actual exam scores in engineering courses. To compare the quality of the estimates produced by these three different methods, we use data from actual offerings of core engineering courses with large enrollments.

II. METHODS

We gathered raw exam score data from multiple offerings of two core engineering courses taught each semester at the University of Illinois at Urbana-Champaign: ECE 110, Introduction to Electrical and Computer Engineering, and TAM 335, Introductory Fluid Mechanics. ECE 110 is a substantial, four-credit course with lectures and a design laboratory. The course covers electrical and electronic circuits, digital logic, and digital information systems. ECE 110 is required for first-year students who plan to major in electrical engineering or in computer engineering, and it is required for second-year students majoring in general engineering. TAM 335 is also a lecture-laboratory course that covers conservation, energy, and momentum principles via control volumes; the Navier-Stokes equation; laminar and turbulent boundary layers; and closed-conduit flow and open-channel flow. TAM 335 is required for third-year students majoring in agricultural engineering, in civil engineering, in engineering mechanics, and in general engineering.

In the table below, we summarize the semesters from which we obtained exam score data in ECE 110 and TAM 335. The data were completely blinded: they included no names of any students. Neither of the authors of this paper was involved in teaching these courses in these semesters. To develop the linear models, we used only data from the students with complete records, i.e., students who had taken all of the exams.

TABLE I. SUMMARY OF COURSES WITH DATA

Course Number	Semester	Total Enrollment	Students with complete records
ECE 110	Spring 2014	437	437
ECE 110	Fall 2013	416	416
ECE 110	Spring 2013	399	399
ECE 110	Fall 2012	352	339
ECE 110	Spring 2012	411	398
TAM 335	Fall 2014	213	206
TAM 335	Spring 2014	144	135
TAM 335	Fall 2013	218	204

Since Spring 2013, students who missed an ECE 110 exam were given a makeup exam. As a consequence, we have

complete records for all ECE 110 students for three semesters. In the Fall 2013 and Fall 2014 offerings of TAM 335, there was more than one version for most of the first three exams; students who sat in adjacent seats received different versions of each exam. For each student in TAM 335, we calculated each normalized exam score based on the version that the student took. Using Shapiro-Wilks test for normality, we concluded that the distributions of exam scores within each version were not normal. We used Levene's test to assess the equality of variances between different versions of the same exam because Levene's test is not as sensitive to normality as the F test. Based on the p -values of Levene's test (with significance level 0.05), we determined that the variances of exam scores from different versions were not significantly different. For Fall 2014, the p -values were above 0.70 for all three exams. For Fall 2013, the p -values were above 0.28 for all exams.

Using the statistical software package R, version 3.1.2 GUI 1.65 Mavericks build (6833), we calculated the coefficients for the OLS regression models for each exam in each course offering. For example, for ECE 110 in Spring 2014, we obtained the following OLS regression models for the estimates of the normalized exam scores e_1^* , e_2^* , e_3^* , and final exam score e_4^* , using the other exam scores e_1 , e_2 , e_3 , e_4 as predictor variables:

$$e_1^* = 0.21 e_2 + 0.04 e_3 + 0.56 e_4$$

$$e_2^* = 0.21 e_1 + 0.15 e_3 + 0.47 e_4$$

$$e_3^* = 0.05 e_1 + 0.19 e_2 + 0.47 e_4$$

$$e_4^* = 0.39 e_1 + 0.33 e_2 + 0.26 e_3$$

Notice that the coefficient of e_3 in the equation for e_1^* is relatively small, and the coefficient of e_1 in the equation for e_3^* is also small. The scores on these two exams were not highly correlated because they covered different kinds of material and required significantly different skills.

III. RESULTS

To measure the quality of the OLS, equal weight, and historical weight models, we calculated the standard error of regression for each estimated exam score for each of the three models. The standard error is the standard deviation of the predicted errors of a regression line. In the table below, we report the standard error for each model for estimating the score for each exam. A smaller standard error indicates higher accuracy. See Table II. We also found that using the final exam alone to estimate any of the first three exams always had a larger standard error than both the equal weight and the historical models. The standard errors for estimating scores using only the final exam were between 0.66 and 0.84.

IV. DISCUSSION

The standard error can be used to construct a confidence interval for the estimate. For example, suppose the standard error for the third exam is 0.60. If the standard deviation of the raw scores on third exam is 15 points, then we expect that the true score is within $0.60 \times 15 = 9$ points of the estimate with a confidence of 68%.

TABLE II. STANDARD ERRORS OF MODELS

Course	Semester	Standard Error			
		Exam	OLS	Equal	Historical
ECE 110	Spring 2014	Final	0.46	0.47	
		Exam 1	0.50	0.60	0.60
		Exam 2	0.50	0.59	0.59
		Exam 3	0.50	0.68	0.68
ECE 110	Fall 2013	Final	0.50	0.57	
		Exam 1	0.50	0.66	0.67
		Exam 2	0.49	0.54	0.57
		Exam 3	0.50	0.63	0.62
ECE 110	Spring 2013	Final	0.49	0.52	
		Exam 1	0.49	0.66	0.67
		Exam 2	0.50	0.62	0.62
		Exam 3	0.50	0.67	0.67
ECE 110	Fall 2012	Final	0.47	0.49	
		Exam 1	0.48	0.72	0.72
		Exam 2	0.49	0.56	0.56
		Exam 3	0.50	0.61	0.60
ECE 110	Spring 2012	Final	0.47	0.50	
		Exam 1	0.48	0.72	0.73
		Exam 2	0.50	0.64	0.66
		Exam 3	0.50	0.62	0.60
TAM 335	Fall 2014	Final	0.48	0.60	
		Exam 1	0.43	0.72	0.72
		Exam 2	0.46	0.67	0.69
		Exam 3	0.48	0.65	0.66
TAM 335	Spring 2014	Final	0.50	0.55	
		Exam 1	0.45	0.71	0.71
		Exam 2	0.46	0.70	0.70
		Exam 3	0.44	0.68	0.70
TAM 335	Fall 2013	Final	0.53	0.57	
		Exam 1	0.48	0.69	0.70
		Exam 2	0.48	0.67	0.69
		Exam 3	0.47	0.70	0.72

From the table of standard errors, we observe that the calculated standard errors for the Ordinary Least Squares models range from 0.43 to 0.53. The ordinary least squares model is always slightly more accurate than the equal weight model and historical weight model. This result is expected because the ordinary least squares model finds the linear model that minimizes the sum of the squared residuals.

The standard errors for the equal weight model and historical weight model are always within 0.03 of each other. This finding suggests that the equal weight model and historical model predicted very similar exam scores for our samples. We recommend that instructors use the equal weight model instead of the historical model to estimate missing exam scores. The theoretical reasoning behind the equal weight model is derived from Dawes [4]. As suggested by Dawes [4], we found that the equal weight model is almost as accurate as the OLS model in estimating final exam scores: for final exams, the standard errors of the two models are generally

close. An instructor could use the equal weight model to estimate students' final exam scores. The instructor could then offer students the option to use the estimated scores in calculating their course grades if they do not want to take the final exam. As an instructor, however, I (the first author) almost never excuse a student from a final exam, however, because students learn from repeated testing [5].

V. FUTURE WORK

To check the robustness of our findings, we plan to gather exam score data from other technical courses with large enrollments. Some courses schedule only two exams before a final exam. In these courses, if a student misses an exam, the missing score would be estimated from the scores on only two other exams. We will compare the quality of estimates from two other exams with estimates in courses that have three other exams. In addition, we will examine other models such as equal weight models in which the weights do not sum to one and models that use raw scores instead of normalized scores.

VI. CONCLUSIONS

When circumstances such as a medical emergency prevent a student from taking an exam, the instructor can use the student's scores on other exams to estimate the score that the student would have earned on the exam. From our empirical study, we conclude that the equal weight model is almost as accurate as the OLS regression model, especially for estimating the final exam score. Both linear models are always more accurate than using the final exam score alone as the estimate. Further, the equal weight model can be easily explained to students. Instructors are thus justified in using the equal weight model to estimate a missing exam score when they calculate a course grade.

ACKNOWLEDGMENTS

Richard Keane and Christopher Schmitz shared exam score data from the courses that they taught. Chi-Fang Wu provided advice on the statistical analyses. Natascha Trellinger helped us interpret our results.

How to Take Into Account a Student's Degree of Certainty When Evaluating the Test Results

Abstract—To more adequately gauge the student's knowledge, it is desirable to take into account not only whether the student's answers on the test are correct or nor, but also how confident the students are in their answers. For example, a situation when a student gives a wrong answer, but understands his/her lack of knowledge on this topic, is not as harmful as the situation when the student is absolutely confident in his/her wrong answer. In this paper, we use the general decision making theory to describe the best way to take into account the student's degree of certainty when evaluating the test results.

I. INTRODUCTION

A. Need to take into account the student's degree of certainty

On a usual test, a student provides answers to several questions, and the resulting grade depends on whether these answers are correct.

However, this approach does not take into account how confident the students is in his/her answer.

In real life situations, when a person needs to make a decision, it may happen that a person does not know the correct answer – but it is not so bad if this person realizes that his knowledge is weak on this subject. In this case, he/she may consult an expert and come up with a correct decision. The situation is much worse if a decision maker is absolutely confident in his/her wrong decision.

For example, we do not expect our medical doctor to be perfect, but what we do expect is that when the doctor is not sure, he/she knows that his/her knowledge of this particular medical situation is lacking, and either consults a specialist him/herself or advises the patient to consult a specialist.

From this viewpoint, when gauging the student's level of knowledge, it is desirable:

- to explicitly ask the student how confident he/she is in the corresponding answer, and
- to take this degree of confidence into account when evaluating the resulting grade.

Some tests already solicit these confidence degrees from the students; see, e.g., [4], [6], [8], [9]; see also [3], [8].

B. How can we take the student's degree of certainty into account?

Once we have the student's degrees of confidence in different answers, how should we combine these degrees of confidence into a single overall grade?

As of now, the existing combination rules are semi-heuristic. It is therefore desirable to come up with well-justified rules for such combination.

C. What we do in this paper

In this paper, we propose to use decision making theory to come up with a combination rule that adequately describes the effect of possible uncertainty and/or wrong answers on the possible decisions.

For that, we emulate a real-life decision making situation, when the decision is made by a group of specialists including the current student. In this setting, we estimate the expected contribution of this student's knowledge to the quality of the resulting decision.

II. HOW TO TAKE INTO ACCOUNT A STUDENT'S DEGREE OF CERTAINTY WHEN EVALUATING THE TEST RESULTS: CASE OF ONE QUESTION WITH TWO ALTERNATIVES

A. Need to describe how decisions are made: reminder

A natural idea to gauge student's uncertain knowledge is to analyze how this uncertainty affects the decisions. To be able to perform this analysis, we need to describe what is a reasonable way to make a decision based on the opinion of several uncertain (and independent) experts.

Decision making under uncertainty: general case. According to decision theory, decisions made by a rational agent can be described as follows:

- to each possible situation, we assign a numerical value called its *utility*, and
- we select an action for which the expected value of utility is the largest possible;

see, e.g., [1], [5], [7], [10].

B. Let us start with the simplest simplified case

Let us start our analysis with the simplest case, in which:

- we only have one question and
- for this question, there are only two possible alternatives A_1 and A_2 .

Let P_1 be the student's degree of confidence in the answer A_1 . Since we assumed that there are only two possible answers,

the student's degree of confidence in the other answer A_2 is equal to $P_2 = 1 - P_1$.

To gauge the effect of the student's answer on the resulting decision, let us assume that for each of the two alternatives A_1 and A_2 , we know the optimal action.

For example, we have two possible medical diagnoses, and for each of these diagnoses, we know an optimal treatment.

Let $u_{i,j}$ be the utility corresponding to the case when

- the actual situation is A_i and
- we use the action which is optimal for the alternative A_j .

In these terms, the fact that the action corresponding to A_1 is optimal for the situation A_1 means that $u_{1,1} > u_{1,2}$; similarly, we get $u_{2,2} > u_{2,1}$.

If we know the probabilities p_1 and $p_2 = 1 - p_1$ of both situations, then we select the action corresponding to A_1 if its expected utility is larger, i.e., if

$$p_1 \cdot u_{1,1} + (1 - p_1) \cdot u_{2,1} \geq p_1 \cdot u_{1,2} + (1 - p_1) \cdot u_{2,2},$$

i.e., equivalently, if

$$p_1 \geq t \stackrel{\text{def}}{=} \frac{u_{2,2} - u_{2,1}}{(u_{1,1} - u_{1,2}) + (u_{2,2} - u_{2,1})}. \quad (1)$$

If the actual situation is A_1 , then the optimal action is the one corresponding to A_1 . Thus, the above inequality describes when the optimal action will be applied – when our degree of confidence in A_1 exceeds the above-described threshold t .

C. How to estimate the probabilities of different alternatives under expert uncertainty

Let us denote the number of experts by n . Let us assume that for each expert k , we know this expert's degree of confidence (subjective probability) $p_{1,k}$ in alternative A_1 , and his/her degree of confidence $p_{2,k} = 1 - p_{1,k}$ in alternative A_2 .

In general, we do not have prior reasons to believe that some experts are more knowledgeable than others, so we assume that all n experts are equally probable to be right:

$$P(k\text{-th expert is right}) = \frac{1}{n}.$$

Thus, by the law of complete probability, we have

$$p_1 = \text{Prob}(A_1 \text{ is the actual alternative}) =$$

$$\sum_{k=1}^n P(k\text{-th expert is right}) \cdot P(A_1 | k\text{-th expert is right}),$$

hence

$$p_1 = \frac{1}{n} \cdot \sum_{k=1}^n p_{1,k}. \quad (2)$$

D. How to estimate the student's contribution to the correct decision

We started with the average of the probabilities of n experts. Once we add the student as a new expert, with probabilities $p_{1,n+1} = P_1$ and $p_{2,n+1} = P_2$, the probability p_1 changes to the new value

$$p'_1 = \frac{1}{n+1} \cdot \sum_{k=1}^{n+1} p_{1,k} = \frac{n}{n+1} \cdot p_1 + \frac{1}{n+1} \cdot P_1. \quad (3)$$

For large n , this addition is small, so in most cases, it does not change the decision. However:

- sometimes, the increase in the estimated probability p_1 will help us switch from the wrong decision to the correct one, and
- sometimes, vice versa, the new estimate will be smaller than the original one and thus, because of the addition of the student's opinion, the group will switch from the correct to the wrong decision.

According to the general decision theory ideas, the student's contribution can be gauged as the expected utility caused by the corresponding change, i.e., as the probability of the positive change times the gain minus the probability of the negative loss times the corresponding loss.

The probability of a gain is equal to the probability that $p_1 < t$ but $p'_1 \geq t$. Due to (3), the inequality $p'_1 \geq t$ is equivalent to

$$p_1 \geq t + \frac{1}{n} \cdot t - \frac{1}{n} \cdot P_1.$$

Thus, the probability of the gain is equal to the probability that the previous estimate p_1 is in the interval

$$\left[t + \frac{1}{n} \cdot t - \frac{1}{n} \cdot P_1, t \right].$$

For large n , this interval is narrow, so this probability can be estimated as the probability density $\rho(t)$ of the probability corresponding to p_1 times the width

$$\frac{1}{n} \cdot P_1 - \frac{1}{n} \cdot t$$

of this interval. Thus, this probability is a linear function of P_1 .

Similarly, the probability of the loss is also a linear function of P_1 and hence, the expected utility also linearly depends on P_1 .

E. How to gauge student's knowledge: analysis of the problem

The appropriate measure should be a linear function of the student's degree of certainty P_1 . So, if we originally assign:

- N points to a student who is absolutely confident in the correct answer and
- 0 points to a student who is absolutely confident in the wrong answer,

then the number of points assigned in general should be a linear function of P_1 that is:

- equal to N when $P_1 = 1$, and
- equal to 0 when $P_1 = 0$.

One can check that the only linear function with this property is the function $N \cdot P_1$. Thus, we arrive at the following recommendation:

F. How to gauge student's knowledge: the resulting recommendation

When a student supplies his/her degree of confidence P_1 in the answer A_1 (and, correspondingly, the degree of confidence $P_2 = 1 - P_1$ in the answer A_2), then we should give the student:

- $N \cdot P_1$ points if A_1 is the correct answer, and
- $N \cdot P_2$ points if A_2 is the correct answer,

where N is the number of points that the student would get for an absolutely correct answer with confidence 1.

G. Discussion

Let us show that if we follow the above recommendation, then we assign different numbers of grades in two situations that we wanted to distinguish:

- the bad situation in which a student is absolutely confident in the wrong answer $p_1 = 0$ and $p_2 = 1$, and
- a not-so-bad situation when a student is ignorant but understands his or her ignorance and assigns the degree of confidences $p_1 = p_2 = 0.5$ to both possible answers.

Indeed:

- In the first (bad) situation, the student gets the smallest number of points: 0.
- In the second, not-so-bad situation, the student gets $N \cdot 0.5$ points, which is more than 0.

Comment. Of course, if we assign the points this way, the fact that someone with no knowledge can get 50% means that we need to appropriately change the thresholds for A, B, and C grades.

III. GENERAL CASE

A. What if a question has several possible answers: analysis of the problem

In general, a question can have several possible answers corresponding to several alternatives. Let us denote these alternatives by A_1, \dots, A_s .

In this case, a student assigns, to each of these alternatives A_i , his/her degree of certainty P_i . Since we know that exactly one of the given s alternatives is true, these probabilities should add up to 1: $\sum_{i=1}^s P_i = 1$.

How does adding this student's knowledge change the decision of n experts? Similarly to the previous case:

- it may be that previously, the experts selected a wrong alternative, and the student's knowledge can help select the correct alternative A_1 ;
- it also may be that the experts selected the correct alternative, but the addition of the student's statement will lead to the selection of a wrong alternative.

Let us describe this in detail.

Similarly to the case of two alternative, we can conclude that a group of experts selects an action corresponding to the alternative A_{i_0} if the corresponding expected utility is larger than the expected utility of selecting any other action, i.e., if

$$\left(\sum_{j=1}^s p_j \cdot u_{i_0,j} \right) - \left(\sum_{j=1}^s p_j \cdot u_{i,j} \right) \geq 0 \quad (4)$$

for all i , where p_i is the estimate of the probability that the i -th alternative A_i is true. Similarly to the case of two alternatives, we conclude that

$$p_i = \frac{1}{n} \cdot \sum_{k=1}^n p_{i,k},$$

where n is the number of experts and $p_{i,k}$ is the estimate of the probability of the i -th alternative A_i made by the k -th expert.

When we add, to n original experts, the student as a new expert, with $p_{i,n+1} = P_i$, then the probabilities p_i change to new values

$$p'_i = \frac{1}{n+1} \cdot \sum_{k=1}^{n+1} p_{i,k} = \frac{n}{n+1} \cdot p_i + \frac{1}{n+1} \cdot P_i.$$

Thus, the left-hand side of the inequality (4) has a change which is linear in terms of the degrees P_1, \dots, P_s .

For each case when the addition of the student as a new expert changes the inequality between two expected utilities, the corresponding interval of possible values of the difference is small and thus, the resulting utility is proportional to the linear function of P_i – and is, thus, linear as well.

The probability of each such change is very small, so the probability that the addition of a student can change two or more inequalities – i.e., that two changes can occur at the same time – can be estimated as the product of these two (or more) small numbers and can, therefore, be safely ignored.

In this approximation, the overall utility can be obtained by adding the probabilities of all such cases and is, therefore, also a linear function of the probabilities P_i :

$$u = u_0 + \sum_{i=1}^s a_i \cdot P_i.$$

Let c be the index of the correct answer, then this formula can be reformulated as

$$u = u_0 + u_c \cdot P_c + \sum_{i \neq c} a_i \cdot P_i. \quad (5)$$

Usually, there are no a priori reasons why one incorrect answer is better than another incorrect answer. So, it is natural to assume that the utility c_i corresponding to each incorrect

answer A_i is the same. Let us denote this common value of the utility by f . Then, the above formula (5) takes the form

$$u = u_0 + u_c \cdot P_c + f \cdot \sum_{i \neq c} P_i. \quad (6)$$

Since the degrees P_i add up to 1, we have

$$P_c + \sum_{i \neq c} P_i = 1,$$

hence

$$\sum_{i \neq c} P_i = 1 - P_c,$$

and the formula (6) takes the form

$$u = u_0 + u_c \cdot P_c + f \cdot (1 - P_c).$$

Thus, the utility is a linear function of the student's degree of confidence P_c in the correct answer.

Let us denote by N the number of points that we assign to a correct answer in which the student is fully confident ($P_c = 1$). Naturally, a student gets 0 points when he or she is fully confident in the wrong answer (i.e., $P_i = 1$ for some $i \neq c$ and thus, $P_c = 0$). Thus, the desired linear function should be equal to N when $P_c = 1$ and to 0 when $P_c = 0$. There is only one such linear function: $N \cdot P_c$. So, we arrive at the following recommendation.

B. What if there are several possible answers: the resulting recommendation

Let A_1, \dots, A_s be possible answers, out of which only one answer A_c is correct. Let N denote the number of points that a student would get for a correct answer in which he or she is absolutely confident.

During the test, the student assigns, to each possible answer A_i , his/her degree of confidence P_i that this answer is correct. These degrees must add up to 1: $\sum_{i=1}^s P_i = 1$.

Our analysis shows that for this, we give the student $N \cdot P_c$ points, where P_c is the student's degree of confidence in the correct answer.

C. How do we combine grades corresponding to different problems?

In the above text, we describe how to assign number of points to a *single* question. Namely:

- Our idea was to assign the number of points which is proportional to the gain in expected utility that the student's answer can bring in a real decision making situation.
- Our analysis has shown that this expected utility is proportional to the probability P_1 of the correct answer.
- Thus, our recommendation is to assign the number of points proportional to the probability of the correct answer.

Real-life tests usually have *several* questions.

- In the traditional setting, a student provides answers to each of these questions.
- In the new setting, for each question, the student also provides us with his/her degrees of confidence in different possible answers to this question.

How do we gauge the student knowledge level based on all this information?

A natural idea is – similarly to the case of a single question – to use, as the measure of the student's knowledge, the expected utility that the student's answers can bring in a real decision making situation. Let us show how this idea can be applied.

The general decision making situation means selecting a decision for each of the problems. For example, on a medical exam, a student may be asked several questions describing different patients.

Usually, different questions on the test are independent from each other. It is known (see, e.g., [2]) that if a decision problem consists of several independent decisions, then the utility of each combination of selections is equal to the sum of the corresponding utilities.

We know the utility corresponding to each question – this is the value that we used as a recommended grade for this particular question. Thus, the overall grade for the test should be equal to the sum of the grades corresponding to individual questions.

Hence, we arrive at the following recommendation.

IV. RESULTING RECOMMENDATION

Let us consider a test with T questions $q_1, \dots, q_t, \dots, q_T$. For each question q_t , a student is given several possible answers $A_{t,1}, A_{t,2}, \dots$. For each question q_t , we know the number of points N_t corresponding to the answer which is correct and for which the student has a full confidence.

The student is required, for each question q_t and for each possible answer $A_{t,i}$, to provide his/her degree of confidence $P_{t,i}$ that this particular answer is correct. For each question q_t , these probabilities should add up to 1: $P_{t,1} + P_{t,2} + \dots = 1$.

To estimate the student's level of knowledge, we need to know, for each question q_t , the correct answer; let us denote this correct answer by $A_{t,c(t)}$. Then:

- for each question q_t , we give the student $P_{t,c(t)} \cdot N_t$ points;
- as an overall grade g , i.e., as a measure of overall student knowledge, we take the sum of the points given for individual problems: $g = \sum_{t=1}^T P_{t,c(t)} \cdot N_t$.

Abstract—This paper introduces an alternative to singular performance measures through the creation of a scaled index incorporating a variety of performance factors indicating overall student success as well as the creation of similar sub-indices for performances in the particular areas of math, English, and science. These indices have been used in two studies based on nationally representative college student data: the Sustainability and Gender in Engineering (SaGE) and the Outreach Programs and Science Career Intentions (OPSCI) projects. The Academic Performance Index (API) is a scale constructed out of students' weighted high school GPA, available standardized test scores (ACT/SAT), AP test scores (if any), highest levels of various high school coursework taken, and college credit hours earned prior to enrolling in college. Importantly, the API uses *any and all* available data in these domains, which can be up to 42 different indicators for an individual student in the case of the SaGE project. This index shows less bias regarding race and gender, when compared with commonly-used standardized tests scores. Additionally, this item is psychometrically better at indicating variation across students' performance.

Keywords—API; academic performance; measurements; controls

I. INTRODUCTION

Measures of academic performance are used in decisions about college admission and scholarships. Prior academic performance is also regularly used in educational studies to control for an individual's level of academic preparation, either overall or in particular subject areas. Many of these studies use a single measure, such as SAT/ACT standardized tests or Grade Point Averages (GPAs). However, there can be issues of consistency in the use of these measures. Standardized tests scores depend on a single performance in a testing environment that may not give an accurate picture of students' content knowledge or academic preparation. Additionally, GPA can vary significantly by school, district or state in the calculation of credit for scores earned in courses at different levels (e.g. college preparatory, advanced, Honors, or Advanced

Placement/International Baccalaureate) as well as the scores themselves. For example, in the state of South Carolina, each final grade in a course receives a distinct score on the GPA metric based on the Uniform Grading Policy implemented in 2006 (e.g. 94 in a college preparatory class corresponds to a 4.125 GPA, while a 95 corresponds to a 4.250, and a 94 in an AP course corresponds to a 5.125 GPA) [1]. However, in Indiana, the grading policy uses a more traditional +/- grading scale where an "A" is equivalent to a 4.0 and an "A-" is equivalent to a 3.667 [2]. Such variation can reduce the validity of GPA measures as controls or measurements of academic performance. Moreover, the traditionally used performance measures have been shown to be biased against historically-underrepresented groups in engineering – women and racial/ethnic minorities. With this focus, we present a more robust method of calculating academic performance that shows less bias.

II. BIAS OF TRADITIONAL MEASURES

Research has shown that traditional measures of scholastic achievement like the SAT or ACT required for college admissions show bias against women and underrepresented minorities [3-5]. Typically, test creators come from upper middle-class to upper class families. Because of homogenous backgrounds, items they put on these tests show bias towards language and culture that is associated to higher socioeconomic status [6]. Often, this bias directly affects underrepresented groups. The use of tests scores for college admissions is problematic because it creates barriers for entry based on unjust and factors favoring men, whites, and the affluent [4]. This trend has been noted by Haycock & Gerald [7, p. 7]: "...the 50 flagship universities now look less and less like America—and more and more like 'gated communities of higher education.'" Further (p. 5): "...the highest achieving students from high income families—those who earned top grades, completed the full battery of college prep courses, and took AP courses as well—are nearly four times more likely than low-income students with exactly the same level of academic

accomplishment to end up in a highly selective university.” In addition, standardized tests have not been shown to be particularly correlated with college performance [8]. Nonetheless, these measures continue to create barriers for underrepresented students to succeed in disciplines like engineering that require high admissions criteria.

Additionally, while average performance on standardized tests has increased for both men and women over time, a small but persistent gender gap favors men on both the SAT and ACT. The primary purpose of the SAT is to measure students’ potential for academic success in college. The current test, revised in March 2005, includes Critical Reading, Math, and Writing all scored on a range of 200 to 800 [9]. On the SAT, the largest gender gap is seen on the math section of the exam across all races/ethnicities and socioeconomic statuses. While, on the SAT math section, men outscore women across all of these demographics, Asian American, Hispanic, and white men have a gender advantage twice as large as that of their African American peers [10]. There is also a smaller advantage on the verbal section of the SAT as well. Some studies show that this advantage is on average 30 to 50 points [11]. Although, in general, the difference is small, and the distributions of male and female performance are overlapping, these differences can still have a significant impact on admissions and scholarships offered to students [12]. The average difference between males and females on the Math portion of the SAT has remained unchanged for over 35 years, despite the large increase in the number of females entering fields that require mathematics [13].

Similar to the SAT, the ACT is meant to predict first-year college grades. Unlike the SAT, the ACT questions are linked to curriculum and test students in English, math, reading, and science with a score for each subject area and total composite score ranging from 1 to 36. On the ACT, men have moderately higher composite scores, and there are gender differences on the individual sections. Men, on average, perform better on the math and science sections, whereas women perform better on the English and reading section of the ACT. While ACT scores have improved for Asian American and white test takers from 1995 to 2007, scores for African American and Hispanic students have either remained the same or declined. Additionally, Asian American and white students have outscored their peers on the math section over this period [10].

Several explanations have been offered for these persistent differences on standardized tests like the SAT and ACT, including test bias, purported biological gender differences, test anxiety (linked to stereotype threat), peer relationships, and differences in course taking [14,15]. However, recent trends point to self-selection as a reason for gender differences. Since 2002, all high school students in Colorado and Illinois are required to take the ACT. In both states, the male advantage on the composite scores has disappeared and a slight female advantage has emerged. Similarly in Maine, all students are required to take the SAT since 2007. These testing results have shown a reversal in the gender gap for the verbal section and a reduction in the math advantage for men from 38 points in 2006 to 12 points in 2007 [10].

Also, students on average are earning higher GPAs in high school with women performing slightly better than men. This trend does not reflect enrollment in easier coursework; in fact, women earn more credits than men in high school math and science and have a higher combined GPA in these courses [16]. Men still outscore women in the NAEP assessment in math, but only by a small margin. However, students’ family income level has a significant impact on student performance in these areas and the gap is not significantly decreasing [10]. With these potential biases in traditional measures of academic performance in mind, the Academic Performance Index (API) was created from a number of indicators to reduce bias and more accurately control for prior student preparation.

III. DATA FOR ACADEMIC PERFORMANCE INDEX

The two data sets used as examples in the construction of the API comes from two nationally representative surveys administered in two different contexts for separate research projects. The Sustainability and Gender in Engineering (SaGE) survey was administered in required, introductory English courses in Fall 2011 to collect data from a representative sample of engineering and non-engineering students (engineering.purdue.edu/ENE/Research/SaGE_survey_Godwin_2014). Drawing from a stratified, random sample of colleges and universities across the United States taken from the National Center for Education Statistics (NCES), the survey study collected data from 6,772 students attending 50 different 2- and 4-year post-secondary institutions. The SaGE survey included questions on high school science and math experiences, science enrollment and achievement (courses taken, grades, AP test scores, etc.) as well as their career goals, family characteristics and support, attitudes about sustainability, science and engineering, and demographic information.

Multiple aspects of validity and reliability of the SaGE instrument were assessed. To ensure content validity, hypotheses generated from a survey of NSTA members as well as from an open-ended survey of 82 first-year engineering and 41 non-engineering majors were included as items in the survey. Questions were further refined based on feedback from evaluators and the results of pilot-testing in a first-year freshman engineering course. An in-person pilot of the survey and focus groups were conducted with first-year freshmen engineering students. Thus, each item of the survey was further examined for face and content validity. Stability reliability of the items used in this analysis was assessed by a test-retest study of 62 students, with an acceptable-to-good average Pearson's correlation of 0.725 [17].

The Outreach Programs and Science Career Intentions (OPSCI) survey was administered in the fall of 2013 to incoming students at U.S. institutions of higher education that participated the Science, Technology, Engineering, and Mathematics Talent Expansion Programs (STEP) funded by the National Science Foundation. This program supports initiatives geared toward increasing the number of students receiving associate's or bachelor's degrees in STEM fields. The survey was administered in freshman English courses, typically required as a general education credit, to gain a representative sample of both STEM and non-STEM students at each

participating university. These responses included 23 four-year institutions and 4 two-year institutions. In total, 15,847 students completed and returned surveys.

Several items on the OPSCI survey were identical with an already developed and successfully used instrument, the “Persistence Research in Science and Engineering” (PRiSE - NSF GSE 062444) survey. Other questions were created specifically for the OPSCI survey by the project team. The OPSCI survey was pilot tested with students at a Southern university to ensure construct validity and to ascertain the time it took for survey completion. Test-retest reliability of the survey was established by administering the survey to 57 students at that same university twice in an interval of about two weeks. For continuous variables, the Pearson correlation coefficient serving as a measure of stability reliability had an overall mean of 0.73.

IV. CONSTRUCTION OF ACADEMIC PERFORMANCE INDEX

In each data set, a normalized API was created from the variety of performance measures to capture the wide spectrum of prior academic preparation into a single measure. Students’ self-reported many indicators on both the SaGE and OPSCI surveys including the math courses they took in high school (e.g. Algebra I, Geometry, Statistics, Trigonometry, etc.); the highest score earned on the SAT and ACT (total and individual sections); the high school science courses taken (e.g. Physical Science, Environmental Science, Earth Science, 1st Biology, 2nd Biology, 1st Chemistry, 2nd Chemistry, 1st Physics, 2nd Physics) as well as their most advanced math and English courses; the course level at which these courses were taken (e.g. regular, honors, AP, IB, other advanced); the year the courses were taken in high school; the final grade (e.g. A+, A, A-, etc.); and the AP exam scores for any AP tests taken. One difference between the two data sets is that the OPSCI survey did *not* ask students to report on the highest course level for English. (This resulted in the API-English having a higher mean and smaller standard deviation for OPSCI than for SaGE.)

First, the data were cleaned to remove any irregular student responses on the hand written SAT and ACT scores. Section scores below 200 or above 800 for the SAT and below 1 or above 36 for the ACT (all impossible) were removed. Additionally, total SAT scores below 600 and above 2400 were removed along with scores that did not conform to the ten point interval scoring scale for a total of 112 removed responses on SaGE (1.65% of the total respondents) and 444 responses on OPSCI (2.8% of the total respondents).

The data were normalized on a uniform 0 to 1 scale for each variable included in the index. For example, students’ science grades (reported in letter grades) were initially made numeric on a 4.0 GPA scale. Then, an “A” in a course (4.0) was interpreted as a one on the normalized scale, a “B” (3.0) corresponded to a 0.75, etc. Each of these scales was weighted by the level of course taken. For regular courses, students received no grade bump, for honors and advanced courses students received a 0.5 GPA increase, and for AP/IB courses

students received a 1.0 GPA increase consistent with GPA weighting for post-secondary students in the U.S. [1,2]. This weighting helped to reduce the inconsistencies typically seen in student’s GPAs from different high schools across the U.S., as discussed previously, by putting ALL students on the same GPA scale.

To obtain the most comprehensive amount of data and allow for simple comparisons across students, an overall SAT score and SAT section scores were created. Some students reported only the SAT, only the ACT, or both, or neither. We collected the available data and converted the highest scores into the SAT scale. For example, if a student did not report an overall SAT score, but reported individual section scores, these were summed to find the total. A similar process was used to combine ACT section scores into composite scores. The conversions of the ACT writing and math sections was a simple translation of the scores into the SAT scales [19]. For the ACT reading (ACTR) and English sections (ACTE), the concordance model appearing as (1) was used to combine these scores based on a conversion provided in an Education Testing Service (administrators of the SAT) report [20]:

$$SAT\ I\ Verbal = 7.52*ACTR + 8.76*ACTE + 156 \quad (1)$$

For students with only partially reported sections, each section was converted into an SAT scale using an ACT-to-SAT concordance [18] and the total score was left blank. Finally, all SAT scales were re-scaled from 0 to 1.

Once each of these data transformations was accomplished, an index for total performance, math performance, science performance, and English performance was created from any and all available data (on a case-by-case basis) using R [21]. For example, if a score was available for a given variable, then that score was added to a running total and the denominator (weight for the mean) was increased by one to appropriately incorporate that response for the index; otherwise, if there was a non-response on that question, the value was not added and the count remained the same for that student in the data set. Thus, the total performance index includes all available academic performance data reported by each student. Each of the subsections in math, science, and English was constructed in an analogous manner and includes the relevant information reported by students in each of those topical areas.

Some differences in the nature of the questions asked on the SaGE and OPSCI surveys resulted in a different construction of the API and subscales. Namely, the OPSCI survey did not ask for the level at which students took English courses, so a weighted GPA was not calculated for those courses. The result is that we would expect the AI-English index from OPSCI to have a higher mean and smaller standard deviation (which was, indeed, found – See Table I). Additionally, OPSCI not only asked for the highest level of math taken and the list of math courses taken, but asked specifically about students’ Pre-calculus and Calculus course taking. This fact means that for some students, their API-Math component might actually be weighted heavier because of additional details included about these class experiences.

TABLE I. COMPARISONS OF ACADEMIC PERFORMANCE INDICES BETWEEN SAGE AND OPSCI SURVEYS

Survey	Mean	Median	Std. Dev.
<i>API-Total</i>			
SaGE	0.54	0.56	0.19
OPSCI	0.69	0.69	0.12
<i>API-English</i>			
SaGE	0.48	0.46	0.21
OPSCI	0.77	0.75	0.13
<i>API-Math</i>			
SaGE	0.43	0.42	0.22
OPSCI	0.62	0.62	0.16
<i>API-Science</i>			
SaGE	0.56	0.57	0.18
OPSCI	0.67	0.70	0.14

The API-Science is very similar between the two data sets on the types of data collected, except that OPSCI did not collect information about students' Environmental Science courses. Additionally, a larger proportion of the students in the SaGE dataset attended two-year institutions (1548 out of 6772 or 22.9% of the sample) compared to the OPSCI dataset (2361 out of 15,847 or 14.9%). These differences could result in lower averages for the SaGE aggregate numbers on the four API measures presented in Table I.

Other minor differences include that OPSCI asked students about their Engineering and Computer Science course experience in high school. This difference affected the composition of the indices by including additional course information, but does not inherently suggest a significant difference in interpretation. OPSCI also asked for AP scores on Environmental Science and Computer Science. However, the OPSCI data set reported fewer than 200 students taking these classes in high school, or about 1% of the total population. Therefore, with the exception of English, we expect the index to be equivalent across to the two data sets.

V. EVALUATION OF THE ACADEMIC PERFORMANCE INDEX

The resulting indices combine a variety of academic performance and preparation information into a single index for both the SaGE and OPSCI data.

For the SaGE data, the API has a median of 0.56, mean of 0.54, and standard deviation of 0.19 with 5259 responses. The skew (-0.47) and excess kurtosis (0.03) indicate a fairly normal distribution that is slightly skewed negatively which is reasonable for a student population that has been admitted into a college or university. For the OPSCI data, the API has a median of 0.69, mean of 0.69, and standard deviation of 0.12 with 15,403 responses. The skew and excess kurtosis were -0.50 and 0.88, respectively indicating an almost normal distribution (slight negative skew and more peaked distribution

than Gaussian), similar to the SaGE data. Table I shows a comparison of the means and standard deviations of the indices from both SaGE and OPSCI. The results show the OPSCI with higher means and smaller standard deviations across all the indices. For English (and its contribution to the total index), the absence of a course level is a significant contributor to this difference. In addition, the OPSCI survey was administered only at four-year colleges and universities. As SaGE was administered in both four-year and two-year institutions it includes students with significantly different demographic backgrounds and academic preparation [22]. Thus, we are not surprised that the data which only includes students at four-year institutions to have higher academic performance indices.

When examining the relative bias of standardized tests in the SaGE data, the SAT math section and writing section show gender differences with the math section having a higher average for men, whereas the writing section has a higher average for women (see Table II). The ACT math and science sections have significantly higher averages for men than for women. In examining the performance indices in the areas of math, science, and English, only the API-Math shows gender differences. This result is not surprising since the API-Math index is created from standardized tests scores as well as high school course taking. However, when comparing the API-Math index with the SAT math section, the gender difference observed in the performance index is *smaller* than the difference seen in SAT math scores ($t(1023) = 1.87, p = 0.006, d = 0.11$). The API-Math is also significantly *less* biased against women than are the ACT math test scores ($t(1396) = 6.37, p = 0.006, d = 1.09$). While all of these indicators that may be used to control for prior academic performance show some gender differences, the developed API show significantly less differences between men and women than traditional standardized test scores. The fact that the API shows less bias while being constructed out of several factors, including those which show greater bias, is likely due sampling a students'

TABLE II. COMPARISONS OF THE ACADEMIC PERFORMANCE INDEX TO TRADITIONAL SAT/ACT SCORES BY GENDER – MEASURES WITH SIGNIFICANT DIFFERENCES

Standardized Measures	Women Mean	Men Mean	Significance ^a	Effect Size ^b
SAT Math (scale 200-800)	596	624	**	0.03
SAT Writing (scale 200-800)	596	556	***	0.06
ACT Math (scale 1-36)	23	25	***	0.04
ACT Science (scale 1-36)	23	25	***	0.03
API-Math (scale 0-1)	0.42	0.44	***	0.004

a. ** represents a p-value of statistical significance between 0.01 and 0.001, and *** a statistical significance of less than 0.001.

b. Effect size for Welch's t-test were calculated by using Cohen's *d* with 0.1, 0.3, and 0.5 indicating small, medium, and large effects, respectively.

TABLE III. COMPARISONS OF THE ACADEMIC PERFORMANCE INDEX TO TRADITIONAL SAT/ACT SCORES BY RACE – MEASURES WITH SIGNIFICANT DIFFERENCES

Standardized Measures	URM Students Mean	White Students Mean	Significance ^c	Effect Size ^d
SAT Total (scale 600-2400)	1611	1685	*	0.03
ACT Total (scale 1-36)	23	24	***	0.03
SAT Critical Reading (scale 200-800)	551	587	***	0.06
SAT Critical Writing (scale 200-800)	547	584	****	0.06
ACT Math (scale 1-36)	23	24	**	0.03
ACT English (scale 1-36)	23	25	**	0.04
ACT Science (scale 1-36)	23	24	***	0.04
ACT Reading (scale 1-36)	23	25	***	0.06
API (scale 0-1)	0.51	0.55	***	0.004

c. ** represents a p-value of statistical significance between 0.01 and 0.001, and *** a statistical significance of less than 0.001.

d. Effect size for Welch's t-test were calculated by using Cohen's *d* with 0.1, 0.3, and 0.5 indicating small, medium, and large effects, respectively.

performance across several domains, which will tend to “average out” testing bias on individual scores.

Additionally, the standardized tests in the SaGE data showed bias against underrepresented students. Students were grouped into either majority (white) or underrepresented minority (URM, consisting of self-reported racial groups: Black, American Indian or Alaskan Native, and Native Hawaiian or Pacific Islander. Note: Asian students are overrepresented in engineering and were not included in the URM measure [23]). White students had significantly higher averages on total SAT and ACT tests as well as higher averages on SAT Critical Reading, ACT science, and ACT Reading sections. The overall API measure also showed significant differences for underrepresented minorities (see Table III). When the difference for the overall SAT was compared to the API, a significant difference was found between the two measures ($t(1947) = 3.21, p = 0.0013, d = 0.23$). The API was not significantly different when compared with overall ACT scores ($t(4457) = -0.20, p = 0.84, d = 0.001$). These comparisons indicate that the API measure is no worse

and may even be less biased against URM students than traditional SAT/ACT scores.

Another advantage of using a performance index in controlling for or understanding students' prior academic performance is in utilizing the majority of data provided by students on self-report surveys can be included. For example, in the SaGE data only 954 out of 6,772 respondents reported a total SAT score, and 1651 reported a total ACT score. However, 1356 students reported individual sections scores on the SAT while 1669 students reported section scores on the ACT resulting in 2130 total SAT scores and 3320 total ACT scores when these measures were summed. By combining this information along with high school course taking, AP scores, and student performance, the API is estimated for 5,259 out of 6,772 total respondents. This technique uses the available data rather than resorting to missing data methods. While some forms of missing data methods, like multiple imputation, are highly robust and valid for handling these types of missingness, the efficiency of these methods are low for the extreme missingness of student-reported standardized test

scores (85.9% missing SAT scores). Our approach to this method used a variety of data sources to triangulate student academic performance without having to deal with the decisions involved in dealing with missing data methods in these kinds of extreme cases.

This approach allows for a comprehensive understanding of students' prior academic performance. Having more data incorporated allows the "data to speak for itself," instead of relying on unproven assumptions and weak correlations. It is also parsimonious, by allowing for the construction of simpler models with more easily interpretable results than those requiring complex data manipulations or numerous collinear controls within a model. In these cases, the standard errors of the affected predictors tend to be large and the Type II error rate may increase in the testing of various hypotheses. Redundant data (with independent variables that correlate highly with one another) can result in the over-fitting of a regression model. Such "high noise" models are less statistically robust and may not reliably predict the outcome across numerous samples drawn from the same statistical population.

The API subsections of math, science, and English also allow for a comparison of students' performances in specific areas in a more nuanced way than an overall performance measure, like standardized test scores or GPAs, could provide. For example, a student could be mediocre in their academic performance overall, but excellent in math. This is typical of many engineering students who score, on average, higher on the math sections of standardized tests than on the critical reading sections. The average math score of admitted students for the top 50 engineering schools in 2009 was 764 for SAT math sections and 655 for critical reading [24]. While overall performance is a useful indicator of prior academic performance, a closer examination of domain-specific performance can indicate differential effects of certain classroom performances on outcomes of interest. Use of the academic performance index

The API has been used as a control for prior academic performance in several published studies. For example, in a paper from the SaGE data set, published in the January 2014 issue of the *Journal of Engineering Education* [25], API-Math was used as a control in a logistic regression model predicting students' engineering career intentions as a binary dependent variable that was primarily concerned with students' sustainability-related outcome expectations (p. 146). This estimate had an odds ratio of 3.60 ($p < 0.001$) in predicting engineering choice and was the largest estimator within the included controls for the outcome of interest. API-Math and API-English were also included as controls in a logistic regression model predicting students' interest in an engineering career from sustainability issues that they wished to address in their career (p. 148). API-Math had an odds ratio of 7.58 for engineering choice ($p < 0.001$), and API-English had an odds ratio of 0.37 for engineering choice ($p < 0.001$). These results show that the API-Math has strong predictive power for outcomes of interest to engineering educators like students' choice of engineering as a career. Having a higher score on API-English reduced the odds of choosing an engineering career in college by over one-third. Additionally, these results

are a proof of concept in the use of the API and API subscales as controls in larger regression models.

This index was also used in a large block regression model predicting students' engineering choice in college based on background factors, critical engineering agency, career expectations, direct influences on student career choices, and students' experiences within their high school science classrooms as presented at the 2014 *American Educational Research Association Annual Meeting* [26]. This model revealed that students' prior academic performance (API) was non-significant in predicting students' engineering choice when a variety of other hypothesized independent variables about students' attitudes, self-beliefs, and pedagogical experiences were added.

This index has also been used with the OPSCI survey with similarly successful results. In a model of physics identity, the way in which a student describes themselves as a "physics person," as an outcome, API-Science was not a significant predictor because of co-linearity with high-school physics grades which were also included in the model. However, both API-Math ($\beta = 0.10, p < 0.001$) and API-English ($\beta = -0.04, p < 0.001$) were significant control predictors of physics identity [26]. Work currently underway has also successfully used these APIs as independent variables in regression models predicting interdisciplinary affinity – a construct measuring students' interdisciplinary interest and self-efficacy.

VI. IMPLICATIONS

The API and related subscales offer an alternative method for accounting for students' prior academic performance over traditional, singular measures of standardized test scores and high school GPA. These typical measures have shown bias against underrepresented groups and may skew findings in statistical modeling. The API and related subscales are less biased against these groups than other measures of performance. Additionally, this measure is a more robust accounting of academic performance than single, often highly collinear variables in a model. This method captures the maximum amount of information on student self-reported measures which are a typical way of gathering such data. Self-reported academic performance reduces the difficulty of obtaining student data under FERPA guidelines, but we acknowledge that it is not without limitations. Students' self-reported measure may be less accurate or more positive than actual student academic performance data from transcripts. However, normalizing all reported information together may mitigate some of the concerns.

Additionally, these data can be used as benchmarking tools to compare other students' prior academic performance with nationally representative values of college students' prior academic performance. Often, conducting a study with large-scale data is not feasible because of time and money restrictions. These data offer a picture of how students in studies with less variation may compare to a national sample of students in colleges across the U.S. The average values for the SaGE dataset are 0.46 for two-year institution students and 0.56 for four-year institution students. The average values for the OPSCI dataset are 0.62 for two-year institution students

and 0.70 for four-year institution students. These data are only nationally representative of *college-enrolled* students. This limitation would make comparisons to other groups (e.g. pre-college students or students who did not enroll in college) unfair.

Future studies using the API should include an external validation study of the measure by correlating students' self-reported API with actual high school performance and college grades. We would be interested in examining if the API and related subscales are better predictors of college performance than other measures.

While this method does provide opportunities to account for bias in traditional performance measures and to normalize prior academic performance across students from different schools, it does not address the root issues surrounding standardized testing procedures or the use of these scores in important decisions like college admittance or scholarship awards. This approach to providing a more robust and less biased estimate for prior academic performance works within the current system of national measurements rather than offering alternatives. Until the inequities in American society can be addressed, many minority students will be less likely than white students to attend well-financed, generously-staffed elementary and secondary schools, and many women will have the challenges of taking tests that under-measure their performance potential, and women of color will encounter the compounding of both of these issues. The use of this measure addresses the symptoms of measuring unequal educational opportunities with "standardized" assessment methods but does not change the underlying causes for bias in the evaluation of students. While we argue that the use of this measure is a step forward toward making research-based and less biased education and policy decisions, we acknowledge the long journey ahead to make education and access to engineering opportunities equitable for *all* students. The biggest issue in standardized testing is not the participating student population, but lies in how standardized tests are used to exclude specific groups from higher educational opportunities.

VII. CONCLUSIONS

In conclusion, we have delineated the process of developing the API for two large, nationally representative data sets. The API and related subscales have proven to be a successful way to control for prior academic performance in several published studies. In this paper, we demonstrated that the API and related subscales are a less biased estimate of prior academic performance than standardized tests scores for underrepresented groups in engineering such as women and minorities. This approach to operationalizing students' prior academic performance reduces the risk of Type II error in regression models by combining multiple collinear variables into a single measure and it maximizes the use of students' self-reported performance information.

ACKNOWLEDGMENT

The authors would like to thank the participants of the Sustainability and Gender in Engineering and the Outreach Programs and Science Career Intentions surveys for providing the data used in this paper.

Abstract—Over the past three years, we have been studying how automated evaluation of student mind maps (when compared to an expert map) shows student learning for a variety of metrics. The goal of this work is to build a system that would then allow students to evaluate their understanding of the terminology in a respective field. The weakness of our studies, so far, is that our focus group to study these metrics consists of a single course in the field of Computer Engineering, and though this class has been used over multiple years to demonstrate the feasibility of our approach in a longitudinal study, a broader study needs to be done. In this work, we show how our current metrics perform across three additional fields; specifically, we have collaborated with instructors in speech pathology, communications, and political science (in addition to our traditional class in computer engineering). We then use our methodology to determine if these courses and a term long mind map exercise have similar results than previously reported and are these results evidence of student learning. Our results show that our existing metrics have similar results for one of the three new courses. However, in the two other courses, the data shows no evidence of learning based on the mind map exercise. Each of the instructors of these courses describes their experience with the activity. Additionally, we evaluate the construction of the expert maps in each course to understand if there is a graph-based structural reason why the results might be different. We conclude by suggesting our methodology is good for courses where terminology is clearly defined and is used and studied throughout the semester, and describe some future directions for this research.

I. INTRODUCTION

The overall goal of this research is to investigate if machines can help provide students with feedback on their learning using mind maps. Mind maps are simple visual drawings that includes terms of interest (which we will call nodes) and lines connecting these terms (which we will call edges). We use the terms nodes and edges as they are common terms in for describing components of a graph, which is a structure under study in a mathematical field called graph theory. Based on this, we are examining if graph theory and

related algorithms can help us evaluate a student's mind map. This evaluation is achieved by comparing a criterion map to the students map, where the criterion map is the original mind map created by an expert (instructor). The criterion map determines the number of words and their connectivity.

To achieve this, we have proposed and studied a number of metrics in previous publications ([1], [2], and [3]) in terms of finding a set of metrics that show if a student is learning. The weakness in these works is that they have focused on a single course (Digital Systems Design) within a single major (Computer Engineering), and even though the results for some of our metrics (two in particular) have shown promising trends over each year of data collection, the bigger question is if our methodology shows similar trends over a range of courses.

The goal of this paper, then, is to present a broader range of courses and apply the same experimental method and evaluation to see how these metrics show learning. Specifically, we have enlisted the help of three instructors in speech pathology, communication, and political science and implemented our experimental method on some of their courses. The data collected over a semester in each of these courses was then analyzed using two of our most promising metrics, and the results are evaluated in this paper. In particular, we found that our favorite metric (a match metric) performed well in one case (speech pathology), showed some indication of learning in a second class (political science), and showed little evidence of learning in the third class (communication).

After presenting the methodology, a brief introduction to the metrics, and the results, we provide each instructors perspective on experiment, mind map activity, and their respective results. This discussion provides us with a conversational explanation for our results, and additionally, we look at aspects of the criterion maps to see if there is any difference that can further explain why in two out of four cases our preferred metric seems to be capturing student learning. This work provides us with one recommendation that our methodology

seems to be applicable to courses that introduce terminology with clear definitions and that terms are used throughout the semester. For courses that do not fit this model, we suggest some future work that might allow our techniques to be useful to students in their learning process.

The remainder of this paper is organized as follows: section II provides a background on mind maps and research into their use as measurement artifacts. Section III describes our methodology and measurement metrics. Section IV presents the results for two of our measurement metrics for the 4 courses we used in 2012/13, and describes these results in some details. Section V provides the three new course bases with a more personal description of their experience with the experiment and their respective results. Section VI discusses our overall results and concludes the paper.

II. MIND MAPS AS MEASURABLE ARTIFACTS

Fig. 1. Example of a mind map on the relationship between mind maps and graphs

Mind maps are simple visual representations of terminology and simple one-to-one relationships [4]. Mind maps [5] are a visual representation that are used in a number of settings including a Class Assessment Techniques (CATs) [6] which allows teachers to evaluate student understanding in class and provide feedback. Figure 1 shows an example mind map that expresses the main author's understanding of mind maps and how they relate to mathematical graphs. The words/concepts that are in a mind map are the nodes of a graph (circled bubbles), and the connecting lines between these words are edges of a graph.

There is continued interest in mind maps as a pedagogical tool that can help structure learning [7] as well as a vast and rich data set that can provide other insights [8]. Mind mapping tools are readily available and the technique is used in an wide number of areas. In our past studies we have provided background on mind maps in scoring. An updated one for mind maps includes:

- comparing the scores on tests to the technique [9]
- having two independent experts score (sometimes with a rubric) the mind map on a scale two times with one week delay and compare correlation of ratings [10]
- using structures and frameworks to identify redundancies and troubling portion of a map [11]
- using a large data-set of mind maps for deep fact finding of interrelated topics [12]

The type of mind maps we use in this study are called closed, which means they have a limited set of words (nodes) [13]. Our scoring technique that uses criterion maps is called *comparison with a criterion map* [14].

III. EXPERIMENT AND MEASUREMENT METRICS

To perform automatic feedback from mind maps to help students learn a field's vocabulary, our focus has been on semester long experiments that evaluate student mind maps with various metrics. In this work, we continue this experimental setup, but for a broader range of courses. In this section, we will describe the experimental setup and the measurement metrics that we have found to be most useful in showing that students have learned.

A. Experimental Method

We start with the assumption that *most* students learn about a particular area (course) over a semester, and this learning includes a better understanding of the technical vocabulary and terms as related to a class topic/field. Nation [15], Coxhead [16], and Chung *et. al.* [17] discuss the relevance of technical vocabulary in a field and quantify that their are approximately 5% technical, field-based the words used in related publications. However, the technical vocabulary is not necessarily the most important learning objective, and in terms of emphasis and assessment, the vocabulary might be a periphery outcome.

To measure the relevance of the vocabulary we will use Wiggins and McTighe's simple taxonomy [18]:

- 1) worth being familiar with
- 2) important to know and do
- 3) enduring understanding

where the importance of the learning objective is more important as the number increases. Each of our instructors in this experiment will give their courses technical vocabulary a 1, 2, or 3 rating depending on how important it is to their respective course and students.

The experiment is a semester based longitudinal experiment. First, the instructor picks twenty terms (closed mind map) that they then use to create the criterion map (expert map). Next, the students are briefly taught how to make a mind map using an example that is not part of their class. For example, a list of countries is provided and the instructor shows how different mind maps could be created depending on the context; for example, countries organized by trading partners versus geographical location versus immigration paths will each make a very different mind map. Then over the semester the students will be given the 20 terms (unorganized) and will create an in class mind map.

In terms of controls, we have attempted to control the following:

- Each in class activity is kept to 10 minutes
- There are twenty terms to create a mind map and those terms stay the same each time
- The activity is done at least twice, but preferably three or more times spread somewhat evenly throughout the semester

Students create their mind maps on paper, and therefore, the mind maps need to be electronically encoded to allow the measurement metrics to be calculated. This process takes some time, but until we have a flexible electronic tool this is part of our methodology. The conversion of paper mind maps is done once the semester is completed and grades have been submitted. Research consent forms are opened and students that gave permission for their mind maps to be included in the experiment are kept and non-participants mind maps are shredded and removed from the data set.

Once the criterion maps and the student mind maps have been converted into an electronic format, we run our data analysis tools to generate the respective metrics as will be presented in the results section.

B. Metrics to Measure Mind Maps

In our past papers ([1], [2], and [3]) our goal has been examining different metrics that measure how similar the criterion map is to a student mind map. Over these studies, we have found two metrics that seem to strongly show differences and a third one that is pretty good at showing graph similarities. In this work, we will use one of the strong metrics (the second metric was being evaluated) and the okay metric; these metrics are called *match metric* and *RGF-distance*, which we will describe below. These two metrics are the best performing metrics in our 2013 paper [2], which has additional description of why these metrics seem to better capture similarities and differences as related to learning.

The *match metric* is an edge by edge comparison between the student mind map and the criterion map. The nodes in our graphs are uniquely identified by a label (the term written in the bubble), and this allows us to compare the two graphs in linear time. During this comparison a number of statistics are recorded about the differences including missing nodes (*MissN*), extra edges (*ExtraE*), and matching edges (*MatchE*) where the comparison is the student map as compared to the criterion map. The *match metric* is a combination of these statistics:

$$MatchMetric = \frac{MatchE}{MissN + ExtraE + MatchE} \quad (1)$$

This equation results in a number between 0 and 1. The number is interpreted where as it approaches 1 indicates there is more similarity between the two graphs.

The second metric is *RGF-distance*. This metric is a little more complicated and relies on what are called, graphlets, which, are “a connected network with a small number of nodes” [19] and these small graphs are non-isomorphic induced subgraphs of a larger graph. Figure 2 shows all the graphlets of size 2, 3, and 4.

The existence of graphlets is used to analyze the structure of a graph. The procedure developed by Przulj *et. al.* [19] is to search for all graphlets of size 3, 4, and 5 in a given graph. Based on the count of each type of graphlet, a signature is constructed in the form (g1, g2, g3, g4, g5, g6, g7, g8, ..., g28, g29), where g1 is number of the first type of graphlet of size 3 shown in figure 2 and g29 is the count for the last graphlet of size 5. This signature can be compared to another graphs' signature to get a measure of similarity, and Przulj

2-node graphlets

3-node graphlets

4-node graphlets

Fig. 2. Graphlets of size 2, 3, and 4

et. al. used their technique to compare graphs representing biological structures such as proteins.

RGF-distance is a measure of the difference in frequency of graphlets of g1, g2, g3, ..., g28, and g29 appearing in the two graphs being compared. A tool called GraphCrunch II will calculate this metric, and as this value approaches 0 the more similar the two compared graphs are, however, this is an approximate measure since the specific labels of the nodes are not used.

IV. RESULTS

In this section, we show the results for all four courses (computer engineering, communication, speech pathology, and political science) for both metrics (Match Metric and RGF-distance). Additionally, we provide a table that summarizes some of the differences in each courses experimentation, some parameters of each criterion map, and a percentage of metric results that align with evidence of learning. Our key assumption in this exploration is that we assume that on average the students are learning the technical vocabulary in the course as the course proceeds and if a metric is capturing this in the mind maps we should see the majority of the the students metrics trend a certain way (towards 1 from 0 for the *match metric* and towards 1 from larger numbers for the *RGF-distance*).

Table I includes a summary of a number of pieces of data for our experiments. Column 1 shows the course area. Columns 2 and 3 report the percentage of students included in the experiment that have a measured metric (RGF-distance and Match Metric, respectively) that trends better in a student's final mind map as compared to their initial mind map (for example, the match metric would be closer to 1 in an upward trend and the RGF-distance metric would be closer to 0 in a downward trend). Column 4 shows the number of students that gave permission to be included in the experiment and participated in all the mind map activities, and column 5 shows how many mind map activities were performed for the

TABLE I. DETAILS FOR EACH COURSE EXPERIMENT

Course Area	Metric Summary		Experimental Parameters		Criterion Map	
	Percent improved Match Metric	Percent improved RGF-distance	Population	Mind Map Activities	Average Degree	Density
Computer Engineering	100%	69%	32	3	2.85	0.30
Communication	27%	73%	51	4	0.95	0.10
Speech Pathology	91%	59%	34	3	1.68	0.18
Political Science	55%	57%	42	2	2.95	0.31

respective course. Finally, columns 6 and 7 report the average degree and density of the criterion mind map and these graph parameters will be used to describe differences in the criterion map.

Figure 3 shows each of the four courses and includes students metric if they participated in all the mind map activities. In terms of our assumption of learning, we hope to see an upward trend (from values of 0 towards values of 1) for the match metric. We see this upward trend in two cases - computer engineering and communication. Since there are many students in each of these courses, the data is a little noisy and is hard to interpret, but the summary of the “Percent Improved Match Metric” in Table I suggests that these 2 upward trending courses are clearly showing student learning. Conversely, both the graph and the summary data show that the communication course is not trending upwardly. The political science course is not showing clear results, and unfortunately since only two data points (mind map activities) were performed it is hard to make strong conclusions from this result.

Figure 4 shows each of the four courses and includes students metric if they participated in all the mind map activities. In terms of our assumption of learning, we hope to see a downward trend (from values tending towards 1) for the RGF-distance metric. The results here are much less pronounced compared to the match metric, and the summary data in Table I for “Percent improved RGF-distance” shows that all courses have over 50% of the students demonstrating improvement. On closer examination of the results, it is clear that RGF-distance and its estimation of graph similarity is a poor comparison metric since there can be false positives. For this reason we used these results to look at creating a new metric that mixes graphlets with the match metric in our paper [3].

We performed additional analysis on this data set including evaluating our previous experimental graph metrics and checking if there is any correlation between grades and the metrics. As reported previously with computer engineering and with these new courses, we saw little correlation between grades and any of our measurement metrics. No other metrics seemed to show trending as match metric and RGF-distance metric have.

V. INSTRUCTOR EXPERIENCES AND DISCUSSION

In this section, each of the three instructors (additional courses beyond our traditional computer engineering course) provide their experiences with the mind map activity and the respective results for their class.

A. Amber Franklin - SPA 334 Clinical Phonetics and Articulation Disorders

Clinical Phonetics and Articulation Disorders (SPA 334) is a required junior level class for students majoring in the department of Speech Pathology and Audiology. The majority of majors in this department plan to apply to graduate schools where they will be trained as Speech-Language Pathologists or Audiologist. The SPA 334 course addresses the fundamental aspects of phonetic transcription and articulatory phonetics. Students are taught to transcribe spoken English using the International Phonetic Alphabet. Other topics include English dialectal variation, and clinical phonetics as it applies to normal speech development and articulation disorders. The course quizzes and exams assess knowledge of terms and concepts as well as phonetic transcription ability, which is an applied skill. Some students excel in conceptual knowledge but do not perform well in transcription tasks. The mind map exercise corresponds to the conceptual and technical information taught but does not address the applied skill of phonetic transcription, which constitutes a significant portion of students’ final grades. This distinction may partially explain why there was no correlation between mind map performance and final grades. The terminology as a learning outcome is rated as “2 -important to know and do” based on the taxonomy discussed earlier.

The SPA 443 course builds gradually on a foundation of terms and concepts. Each quiz in the course is cumulative, thereby encouraging students to retain information introduced earlier in the semester. Twelve of the 20 concepts on the list were introduced before the midterm (2nd data point) and the remaining eight concepts were introduced after the midterm. Additionally, several of the terms introduced before the midterm were revisited in the second half of the semester and linked explicitly to new concepts. It is likely that the cumulative nature of the course was reflected in the improved match metric and decreased RGF distance over time. The students understood that their maps were going to be compared to my criterion map once the course was done. However, they also knew that mind map performance would not affect their course grade, making this a very low-stakes activity. The students demonstrated focused attention when generating mind maps at each time point in the semester. I believe the low-stakes nature of the activity facilitated student engagement and allowed them to interact with the material in an authentic way rather than worrying about the “right answers.” The technical vocabulary in this course is rated as “2-important to know and do” based on section III-A.

I observed several differences in the visual representations of student maps. One map was arranged in two distinct columns. Terms within a column were connected using curved

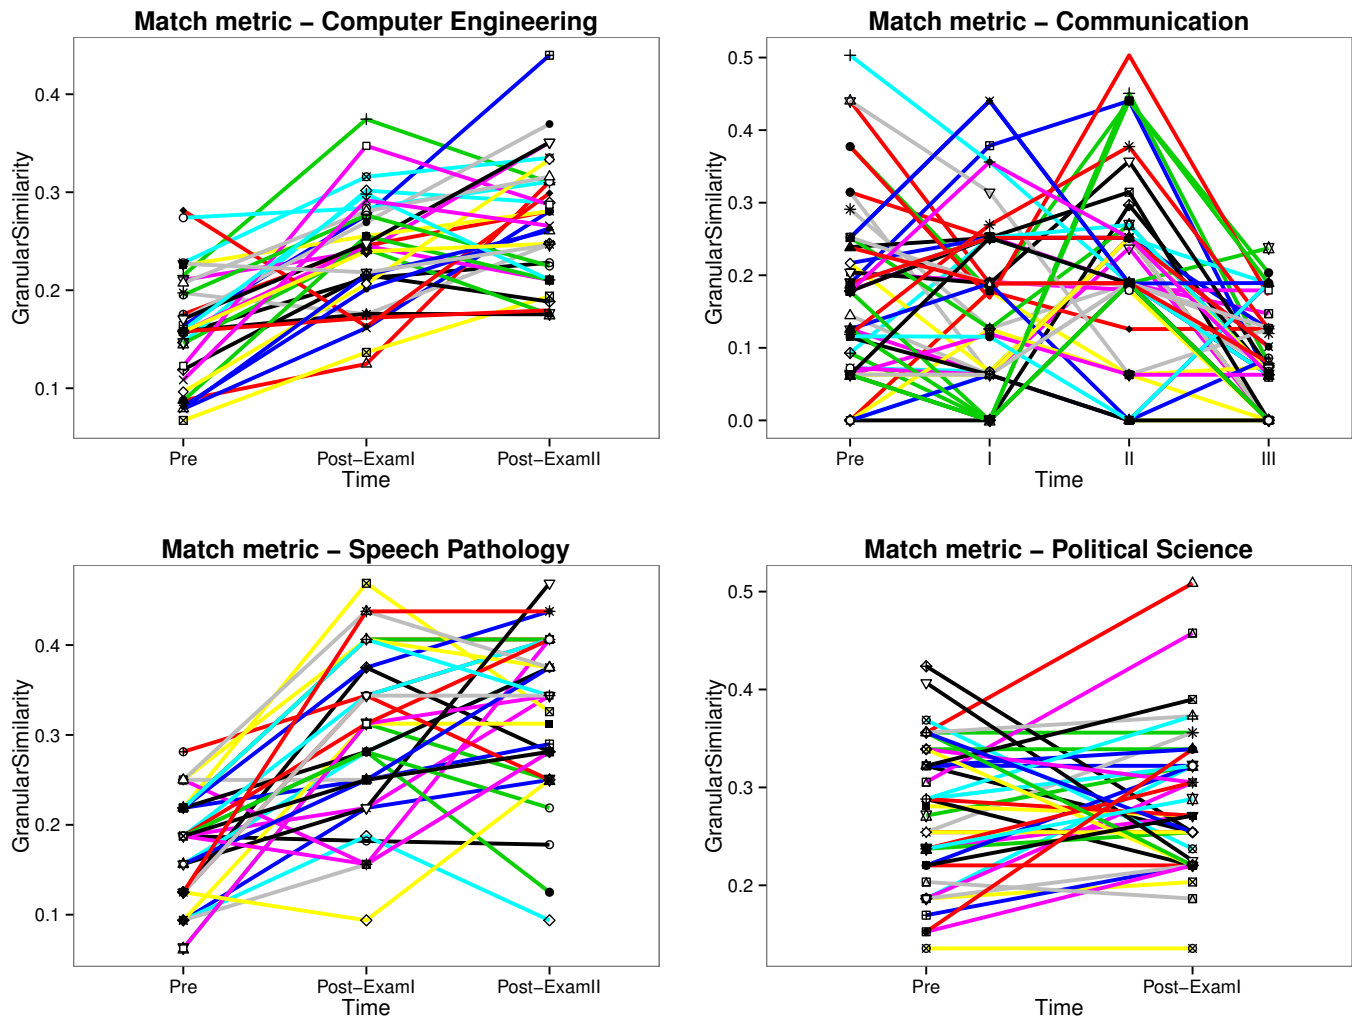

Fig. 3. Match Metric results for each of the four courses

lines and terms between columns were connected with straight lines. Other maps demonstrated a hierarchical structure, with a key concept at the top of the page and related concepts branching below it. Several other maps had a central concept in the center of the page with related terms and concepts branching like spokes from the center. Students were given a general example of a mind map at the beginning of the semester. However, they were not given specific directions regarding the visual structure of the map (e.g. "Start with a key concept in the middle of the page"). The electronic encoding of the maps removes the visual texture from the students' paper representations. Though not within the scope of the present study, I found it interesting to consider how the variation in written map representation may further reflect students' conceptual knowledge.

B. Walter Vanderbush - POL 101 Politics and National Issues

Political Science 101 is a course that fulfills a Liberal Arts social science requirement at Miami but does not count toward the political science major or minor. The primary goal of the course then is not to prepare students with the conceptual knowledge and analytical skills necessary in upper

level political science classes, but rather to expose those who major in Engineering, Accounting, or Zoology to social scientific analysis of political issues and debates. In this version of the course, just over half of the students were in their first year of college; only one of the students was a political science major, and one other student was majoring in public administration, which is housed within the political science department.

Before the first map exercise, I did an exercise on the board with a list of countries and attributes, suggesting various ways that one might link them depending on the context. The concepts chosen for the mind map assessment range from democracy, capitalism, and freedom (which all students will have some familiarity with on day one of the semester) to pluralism, libertarianism, and judicial review (which students may have heard before but were not universally likely to fully understand) and a couple of concepts that only students following politics pretty closely were likely to have familiarity with (self-deportation, e.g.). Over the course of the semester, the expectation was that the relatively unfamiliar concepts would become familiar. On the other hand, the definitions of the familiar ones such as democracy and freedom are

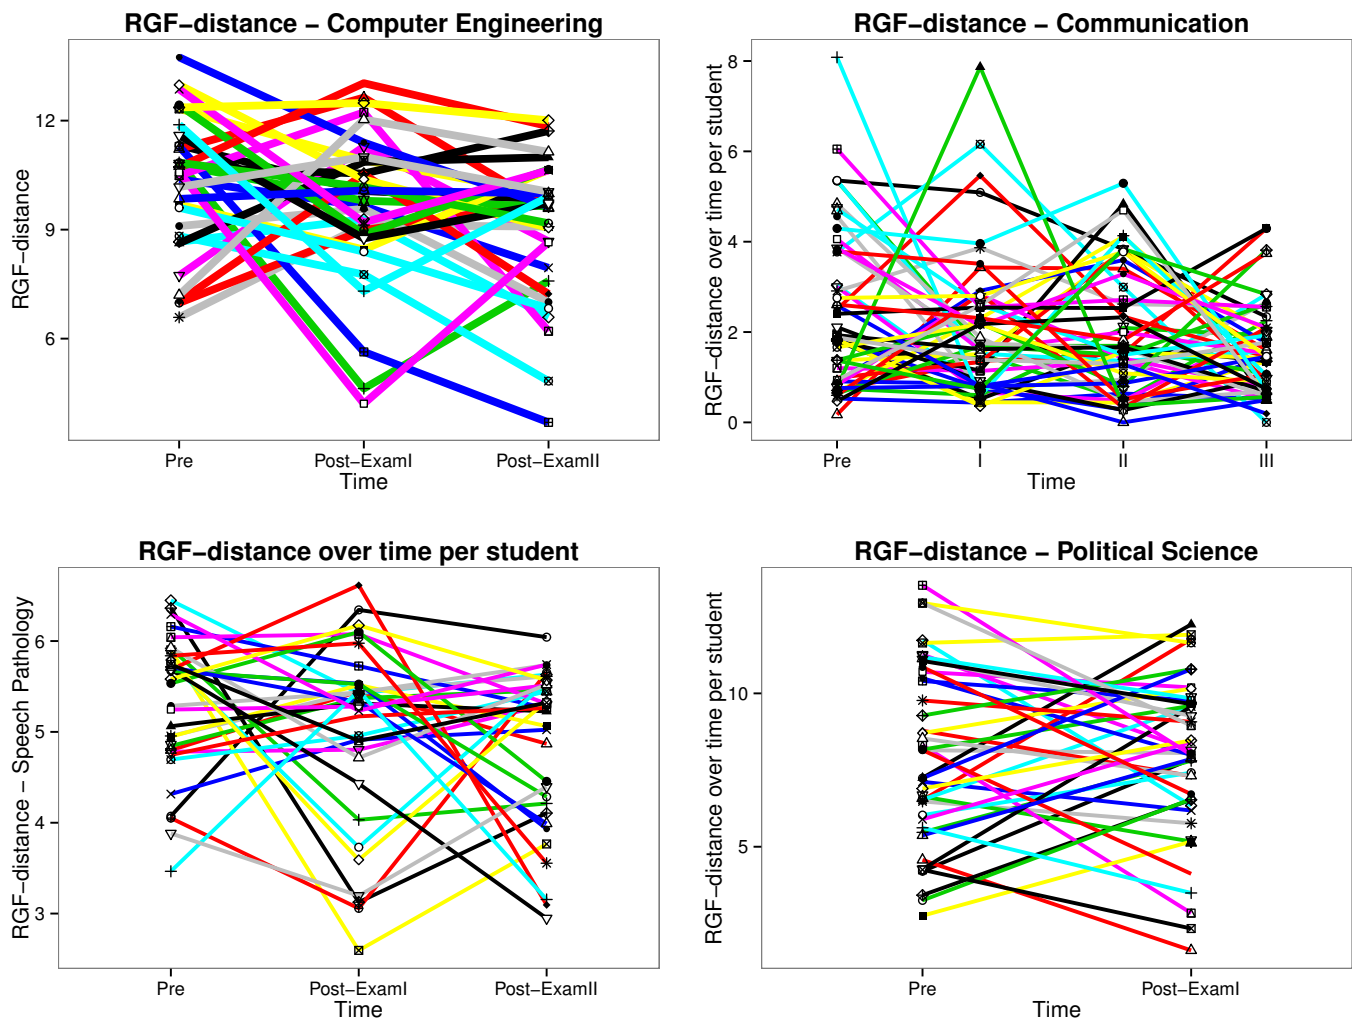

Fig. 4. Match Metric results for each of the four courses

challenged throughout the semester, as students are asked to think of them as contested concepts. To take another concept, separation of powers, one lesson students should learn during the semester is that some democracies have explicit separation of powers such as are laid out in the US Constitution, but other democracies do not see that sort of separation as necessary. On his or her mind map, a student is likely to have made a clear link between separation of powers and democracy at the beginning of the semester, thinking that all democracies had the separation of powers like the U.S., but by the end of the class might reasonably still make that link or might decide not to. The terminology as a learning outcome is rated as “2-important to know and do” based on the taxonomy discussed in section III-A.

I expect that the mix of concepts contributed to the mixed results for the metrics in this study. I tried to make the list reflect the variety of discussions that the class would have during the course of the semester. To that end, there were big philosophical concepts such as democracy, freedom, and individualism; traditional political science concepts such as pluralism, separation of powers, and judicial review; and reflecting some of the contemporary policy debates, terrorism,

American exceptionalism, and even self-deportation. The second of those groups is the closest to the idea of a technical vocabulary that made up a larger percentage of lists in other classes studied here. In a course intended to prepare students for more advanced political science classes, that technical vocabulary would have been more central. This initial use of mind maps, as well as pre-course discussions with my colleagues did lead me to think more about the ways that my twenty concepts might be interrelated. My criteria map tended to make more linkages than those of nearly all of my students. Many of them seemed to look for 2 or 3 strong relationships before moving on to the next concept. In my “expert” map, several concepts had five or six connecting lines, and others even more.

C. Julie Semlak - COM 135 Introduction to Public Expression and Critical Inquiry

The communication course used for this study, an introduction to communication theories course, is a survey course intended to provide communication majors with a foundation of metatheoretical issues, as well as a survey of communication theories they may encounter throughout their studies. The

terms used for this study were metatheoretical terms exploring the philosophy of theory development. Although these terms are utilized and reinforced throughout the semester, they are emphasized much more at the beginning of the course, and were likely most salient to students Post-Exam One, as these terms are the primary focus of exam one. Although the terms do appear on exam two and three, the content emphasized for these exams is specific to the individual theories taught during the semester.

Before students completed the mind map activity for this project, I introduced the definition of mind maps, and as a class we generated a mind map on the board, using pizza as the topic, and the word at the center of my sample mind map. I think this example prompted many of my student to want to put one of the concepts they had to work with at the center of their mind maps, which lead to some frustration when I told them they could choose any of the 20 words for the center. Similar to Dr. Franklin, although I also emphasized this activity was not graded, many students were concerned about completing their map correctly, and asked me if their mind map was correct. Also, after the second data point, several students asked to compare their second map to their first map. Those who did compare remarked at how different their respective maps were, and commented on the errors they had made in their data-point one map. The technical vocabulary in this course is rated as “1-worth being familiar with” based on the ratings in III-A.

When using mind maps as a pedagogical tool, one should take into account the overall goals of the course. The communication course used for this study’s goals focus on students being introduced to a variety of communication theories, students being able to apply individual concepts or theorems from individual theories to their experiences, and to identify the advantages and disadvantages of specific theories. While these skills are important for effective communication, they are skills, which are often assessed different from knowledge or understanding. When considering mind maps as a pedagogical tool, the overall intent of the course should be considered, as mind maps may not be the best assessment tool for a skills-based course.

VI. DISCUSSION AND CONCLUSION

From our results and discussions we find that our study, which expanded the number of classes studied with automated mind map evaluation, shows that there are more details in achieving a successful automated feedback metric(s) for students. In particular, from this study we can see how the nature of the ideas, words, and concepts used within the CAT has significant impact on the quality of the results. Second, this study provides further evidence that our best metric *match metric*, because of its more direct comparative feature, is still the best metric we have to analyze students maps and provide detailed feedback of what they are and aren’t connecting as compared to the expert.

Our mixed results on the *match-metric* groups the four courses into two sets. In one set, which includes computer engineering and speech pathology, the chosen words for the CAT have very clear definitions and relationships to other words, and these terms are introduced and used throughout the class. Conversely, in the other set, which includes political

science and communication, the words used either do not have clear definitions that are to be developed over time, or the terms themselves are introduced early and are used sparingly throughout the term. It makes sense that the first set when analyzed by our metrics shows student improvement because the terms are easier to classify and continually used over the semester, which follows the experimental design. Therefore, if courses have terms that are clearly defined and consistently used then this methodology seems strongly applicable.

Still with the second set, we wonder if there is still potential for automated feedback. In particular, we think the methodology has potential for those courses where term definitions and relationships to other terms is more ambiguous. In this case, our match metric could be used to find similarity over a set of experts and learners. For example, instead of a single criterion map, one could imagine a number of instructors creating maps and similarly students creating mind maps. In addition to these maps, the creator might write a paragraph or two describing why they created the map the way they did. With this database of mind maps, we could run a comparison to a new map and provide that student with a weighted match and show why and how the map they created relates to other learners and experts. This might even be a more meaningful form of feedback than a simpler yes/no response that indicates if you’re making a particular mind map relationship.

Looking back at table I the last two columns looked at some simple graph properties for the criterion map. In particular, another question we have is should the words in the criterion map be selected in such a way to manipulate the density or degree of a graph. In simpler language, if the criterion map is simpler (as in less connections between words) is that better for our automatic feedback methodology compared to a more heavily connected criterion graph. Our results, are unclear at this time, but we believe this is an interesting direction to pursue, where, currently, we hypothesize that a simpler graph will produce better results, but too simple a graph might be detrimental. A follow on question for this hypothesis, is how does an instructor create a criterion map that is appropriate for this methodology, and we leave this as future work.

Overall, in this study we took our early ideas on automatic feedback for student created mind maps to a larger and more diverse set of classes. This study concludes that our approach seems to be useful for courses that use a set of terms that are clearly defined and are used throughout the class. Our future work will focus on refining these techniques by focusing on how to create the criterion map, which in turn determines the subset of terms that will be used in the exercise. The summary data and mind maps are included in a compressed file and can be downloaded at: www.users.miamioh.edu/jamiespa/data_sets/fie_2015_mind_map_data.zip.

mvaughan@utep.edu

Abstract— Identifying and tapping into what is intrinsically motivating has been touted as a key to true learning. Educators, therefore, are attempting to focus on instructional tools that tap into intrinsic motivation in order to excite students about learning and encourage them to become self-taught, lifelong learners. Finding the optimal tools to produce intrinsic motivation, however, can be challenging. Since what is intrinsically motivating is individualistic and can be challenging to identify for instructors, a course at The University of Texas at El Paso (UTEP) has been redesigned in an attempt to better align with what motivates students in the program. In order to create a paradigm shift in engineering education and focus on what students find motivating, Engineering Leadership (E-Lead) students at UTEP stepped up to help take ownership of, not only their own education, but also the education of future students. Under the assumption that students understand what motivates their peers best, the current Introduction to Engineering Leadership course has been developed and taught by second year Engineering Leadership students. Held once a week for three hours, this zero credit course is required for all students interested in the Bachelor of Science in Engineering Leadership at UTEP

Keywords—engineering leadership, first year course, innovation, intrinsic motivation, student taught course, curriculum development

I. INTRODUCTION

Intrinsic motivation has been noted to be a fundamental key to education in today's society. Institutions have been required to adjust to the technological era in which we are living today; hence their teaching methods are being modified to meet the company's expectations of the graduating students. As a result, educators are being encouraged to find new and innovative ways to inspire their students to take ownership of their education and to be intrinsically motivated to continue with their studies.

According to a research conducted at the University of Rochester, intrinsic motivation is defined as the drive to do something for one's own comfort [1]. The goal of numerous professors around the world is to get their pupils to motivate themselves and each other to become life-long learners. In an attempt to achieve this goal The University of Texas at El Paso (UTEP) has redesigned one of their seminar courses for the

Bachelor of Science in Engineering Leadership (E-Lead), which seeks to empower their students to turn their ideas into reality.

In order to develop a new curriculum for this seminar, a group of second year students from the program, alongside several UTEP faculty members, worked with Franklin W. Olin College of Engineering in an effort to redesign the course and its objectives. The goal of the course was to create an immersive learning environment that was also social, relatable, and inspiring to the instructors and the students. In order to achieve that goal, the second year students, also known as Mavericks, were given the opportunity to act as instructors for the course. The curriculum that was developed aimed its attention on three major aspects: leadership identity development, innovative thinking, and hands on skills, which were taught in a studio environment with collective and individual activities.

As a result of this experience, the hypothesis is that the Mavericks and incoming students would be intrinsically motivated to directly impact the Engineering Leadership program. Intrinsic motivation would be enhanced in the Mavericks through mentoring the incoming class during this teaching and curriculum development opportunity. Due to this student centric peer-taught course, student retention in the course (and therefore the program) would also improve. If this course instruction method proves effective, this pattern of allowing a group of students to redesign and teach the course each year will be maintained for future incoming classes.

II. BACKGROUND

In developing The University of Texas at El Paso's Bachelor of Science in Engineering Leadership (BSEL), a blend of effective leadership development philosophy and innovative pedagogy was sought. To this end, a partnership was strategically formed with the Franklin W. Olin College of Engineering for its progressive pedagogical approaches to teaching engineering. Although the program seeks to develop itself by learning from the collective knowledge and experience of these institutions, it also seeks to create its own identity and set of values appropriate for its student population while using a pedagogical approach that is transferrable.

A. Motivation

To begin mentoring incoming students in the style of learning expected during their BSEL and to start building intrinsic motivation in them, an Introduction to Engineering Leadership course was first developed and piloted in the fall of 2013. Unfortunately, having relied too heavily on traditional teaching styles, a lack of structure and synthesis of all of the subjects rendered the class unsuccessful. Retention rates in the course were poor and most students had strong negative feedback on the course. Several students, however, provided viable suggestions for modifying the course in their feedback. In an effort to improve on the shortcomings of the first class and develop leadership skills and motivation in students, the Engineering Leadership faculty decided to cede a majority of the control of the class to the students for the following fall 2014 course. This included curriculum design and the teaching of the course.

These second year students, also called Mavericks, worked closely with Engineering Leadership faculty, as well as faculty from Franklin W. Olin College of Engineering (Needham, MA), throughout the summer in order to develop curriculum for the incoming cohort of students in the fall of 2014. Upon being given the opportunity, the a group of Mavericks were hired to work closely with faculty to identify the three main focus areas they wished to address in the course as well an overall goal for the course. One of the major objectives set by the Mavericks while developing the curriculum was to indirectly create intrinsic motivation for the incoming students to take charge of their own education - meaning that they would be able to motivate themselves and have an intrinsic reward when their goals were achieved.

B. Pedagogical Approach

Engineering Leadership's pedagogical approach is the result of close collaborative efforts with Olin College. Olin is a small, private engineering-only college with a progressive perspective on engineering education with an admission rate of 16.8%[2]. In contrast, the University of Texas at El Paso, with an admission rate of 99.8%[3], is an urban, commuter based, and minority-serving university [4]. Questions were raised as to how translatable would the Olin pedagogical approach would be to a completely different institutional setting.

A method commonly employed in Engineering Leadership program to build intrinsic motivation is experience-based learning [5]. As such, students in the program are often placed in situations where they are encouraged to take a leadership role or actively participate in a group that is working on a project designed by the faculty but where the students are able to pick a topic of their interest. This approach to education is evident even in the classroom, where students are encouraged to take initiative and an active role in their education. Using a flipped classroom approach, or one in which students are tasked with learning the material on their own and are given an opportunity to synthesize and apply it in the classroom, is one of the many ways the program pushes the student to become intrinsically motivated.

III. METHODS

In order to start building the intrinsic motivation of the students mentioned earlier, the methods employed in this research relied heavily on the development and assessment of students' motivation. To this end, a process to craft the curriculum for the course and an assessment plan was developed. The Mavericks got together with three of the faculty members who designed the pilot course and started from scratch a new plan with different objectives and a more innovative initiative. The curriculum's main objective was to create activities that will allow the students to expand their creativity with an ample margin for decision-making were they would be able to choose topics of their interest, this way they would develop intrinsic motivation to finish the course and continue on the program.

A. Curriculum Development

During the summer, Mavericks collaborated with faculty to work through a series of curriculum development workshops. The goal of the workshops was to allow the Mavericks to develop an improved, student-driven introductory. Engineering Leadership and Olin College faculty facilitated the workshop to teach pedagogy as needed and ensure adequate scope for the course and that assessment measures were appropriate. Over the course of two workshops, the Mavericks took their past experience in the pilot introductory course and worked with the faculty to develop the new curriculum.

The first of these workshops was specifically focused on the curriculum for the new introductory course. The Mavericks, along with the faculty, first outlined the strengths and weaknesses of the pilot course. To isolate key themes, individual strengths and weaknesses were written on sticky notes and then grouped. Mavericks then took the emerging themes and brainstormed methods for maintaining or improving each part of the pilot version of the course. Taking a step back, the Mavericks and faculty also worked to generate a list of the key skills with which the degree, as a whole, should equip students. These broad skills were distilled down to the fundamental skills that the incoming students would need in order to lay a foundation for excellence in the E-Lead program. The key skills that remained became the new focus of the introductory course: leadership identity development, innovative thinking, and hands on skills.

To further develop the curriculum, Mavericks brainstormed ways to provide incoming students experiences through with to grow in the three focus areas. These ideas were grouped into three different categories: needs development, can be implemented, and blue-sky ideas. The Mavericks then took the ideas, especially the blue-sky ideas, and worked on making them into implementable ideas. Blue-sky ideas were the creative ideas in which the possibility of implementation was not a limit. From there, the two main projects for the course were developed. The first was the Identity Sculpture (focused on leadership identity development) and the second was the

Entrepreneurship Project (focused on the innovative thinking and business acumen).

As an engineering *leadership* degree, leadership identity development was a key skill to develop in the incoming students. To help students begin to articulate their own identity, the Identity Sculpture project focused on identity development and the use of common tools. To complete this project, students were instructed to create a sculpture of their choosing that they believe best tells the story of who they are and who they want to become. During the creation of their sculpture, students were trained on how to use tools in the machine shop and were required to manufacture at least one part of their statue in the machine shop. In the Entrepreneurship Project, students were introduced to innovative thinking, teaming, and business skills while developing a product prototype and pitch for their own small startup company. (Additional details on other course activities provided in the Results.)

Having ideas for the two main projects for the course, the Mavericks then considered the reactions of at an important stakeholder: the students who would be taking the course. To do this, hypothetical student profiles were created, using the current demographics of UTEP and Engineering Leadership population. With these profiles, the Mavericks assessed how each student might react to and feel in the new course. This activity helped the Mavericks better identify ways to enhance the learning environment for a broad range of students and further refine the course projects and activities. By the end of the first workshop, the backbone of the new course was established but still needed to be better connected to the overarching goals of the Engineering Leadership degree plan.

In a second workshop, Mavericks worked with the entire Engineering Leadership faculty to connect the goals of the course to the goals of the degree. The Mavericks presented the curriculum developed to this point and the faculty gave feedback to help further advance the curriculum. Once the curriculum was finalized and classes started, the Mavericks were presented with different challenges that limited some of the activities and lessons that were planned, this caused the curriculum to evolve as the course went, but thought out it maintained its main purpose and overall structure.

Although the Mavericks were more successful in relating to the students in the course, they did lack the authority and experience in being a professor and had no upperclassmen to seek assistance from. Although progress was made, future iterations of the course should ensure that the leadership abilities of student instructors is passed down in order to perpetuate the continuous improvement of the course. In fact, the intent for this course is that each year, the students that took the course the prior year would become the new Mavericks. Lessons learned by the student-instructors the prior year would be handed down, creating a cyclic pattern of leadership in the program. In addition, this is hoped to maintain a relevant and ever evolving culture in the Engineering Leadership program. Each summer, a group of students finishing their first year in Engineering Leadership will be hired to repeat this process of iterating on the course design and content before taking

responsibility for teaching the course to the new incoming students.

B. Interviews and Observations

To assess achievements and the deficiencies of the course, interviews were completed with each of the Mavericks at the end of the course by a faculty member in the Engineering Leadership program (also an author of the paper) not overseeing the course. The interviews were a blend of open-ended and structured questions requesting students rate their agreement to a given statement based on an ordinal scale from 1 to 5, with 1 being strongly disagree and 5 being strongly agree. Each Maverick was individually interviewed at the conclusion of the course for approximately 30-45 min. Questions in the interview covered the following topics:

- Demographic data: age, gender, year in college, and role in the course.
- Course design, classroom setting, and meeting time
- Likes and dislikes about the course
- Leadership development in the 3 C's

IV. RESULTS

As a result of being empowered by the faculty in the Engineering Education and Leadership department at UTEP, the Mavericks were able to experience the other side of education and overhaul the Introduction to Engineering Leadership course. By reflecting on their own experience in the pilot course the prior school year, the Mavericks were able to identify the strengths and weaknesses of the previous course design. They then developed the new introductory experience for the incoming Engineering Leadership students. Following the completion of the course development and subsequent instruction of the course in the fall of 2014, the Mavericks were interviewed as described above. In addition, observations about the response of the incoming cohort of students are also shared.

A. Participant Demographics

a) *Demographic data was collected for each of the Mavericks interviewed "Table 1".*

TABLE I. MAVERICKS DEMOGRAPHIC DATA

Gender	Number	Average Age	Ethnicity	Classification
M	3	20.0(0.0)	2 Hispanic, 1 Caucasian	2 nd year students E-Lead
F	3	19.33(0.58)	3 Hispanic	2 nd year students E-Lead
Total	6	19.67(0.52)	5 Hispanic, 1 Caucasian	2nd year students E-Lead

B. Introduction to Engineering Leadership Course Outline

The semester was split into three main leadership development goals, which were leadership identity development, hands on skills, and innovative thinking. Using these goals, course content was laid out to fit the development of these skills. To help in the implementation of these skills, two main projects were created for the course. These projects were designed to touch on at least one of the main course goals. The rest of the course was structured around these two projects and smaller activities were chosen to supplement what the students were learning to be able to use those skills for their projects. For leadership identity development, a group project was created that would allow students to further their understanding of themselves and start viewing who they were as leaders. This project included the creation of a identity sculpture that helped them learn about themselves and each other. The Mavericks were also able to learn more about the students and create a more comfortable environment than would be more difficult to reach with a regular college professor. After the students were encouraged to learn more about each other, the transition began from the individual to the group. Small group activities and discussions were integrated that would introduce the topics of group work and leadership. These topics prepared the students to begin to get comfortable with group work since the second project was a group project. The second project was chosen to the innovative thinking part of the course and also ties in the hands on skills. Students were put in groups in order to come up with a new and innovative product for which they had to have a prototype by the end of the course. Instructional time and discussions were used to develop innovative thinking in the students. Smaller activities and projects, like machine shop and circuit building, were also introduced to develop hands on skills that could be implemented in the major project.

5	Innovative Thinking	Introduce the students to innovative thinking	Second project introduction: improve on an object that already exists
6	Identity Development	Reflect on Project One and the Course	Project 1 Reflection Discussion
7	Young Entrepreneurs	Introduce Entrepreneurship and its role in Engineering	Professional sales pitches on their up and coming ideas
8	Leaders Have Fun	Help students apply a couple of group dynamics understanding, and have fun!	Lego Mindstorm robotics development
9	Hands-on Skills	Students will understand the basics of circuits	Students will use breadboards to make a circuit with a LED that blinked at faster or slower rates depending on temperature.
10	Hands-on Skills	Introduce machine shop	Complete requirements to enter machine shop and use tools.
11	Innovative Thinking Application	Understand how to apply an innovative mindset	Group discussion on previous war, tech, and everyday products: how have they evolved? Why?
12		Address final concerns and last minute adjustments to project two	Last Minute Feedback Session
13	Communication Skills, Identity Development	Present final Project and give an understanding of the skills and knowledge they have gained	Final Project Presentation
14	Reflection	Get feedback from students about the course and their experience	Course Evaluation

TABLE II. ACTIVITIES AND DISCUSSION TOPICS FOR REDESIGNED COURSE

Week	Course Goal	Outcome Statement	Course Activity
1	Leadership Identity Development	Show students how their identity is going to be developed along their college life and beyond.	Identity Sculpture - students designed a sculpture that they believe best tells the story of who they are and who they want to become.
2	Group Dynamics	Gain insight to the overall "personality" of a team.	Lecture and discussion about leadership through TV and movie clips
3	Leadership Introduction	Demonstrate to students what leadership truly means, and how great leaders achieve greatness.	Discussion and group activity on past 'leaders'
4	Invention and Innovation	Understand the difference between invention and innovation	Group discussion on various everyday items

Using the methods described above, the Mavericks developed the materials outlined in Table 2. A required zero-credit course for all students pursuing the Bachelor of Science in Engineering leadership, the class met on Friday afternoons from 3-5pm in a studio style setting with movable tables and chairs and ample whiteboard space. On an average week, the Mavericks met twice with the teaching team: once to prepare the material for the week and again to receive feedback from the supervising faculty member. While all Mavericks attended the class each week, smaller sub-teams shared primary material delivery responsibilities in order to share the teaching and perpetration load.

Summarized in Table 2, specific activities were designed to enhance leadership identity development in the three C's, innovative thinking, and hands-on skills.

To develop *Character*, the primary activity was an 'Identity Sculpture'. For this project, incoming students had to reflect on their own personality and identify what made them unique. They then were to create a statue to visually communicate who they are and who they want to become to their peers. These sculptures not only helped the students learn more about themselves, but they also served as an icebreaker at the

beginning of the course. To follow up on this exercise, students also took the Myers-Briggs Type Indicator (MBTI) self-assessment to help them discover and better express the type of person they identify with and want to be, as well as possible strengths and weaknesses.⁶ MBTI results were also used in pairing students when doing group work. Since group projects were more about further personal identity development rather than outcomes focused, students were paired with others of the same MBTI personality type hoping to make them comfortable in a group setting and allow them to see their own personality type mirrored in their peers. When working on group projects, student interactions and habits were closely observed to see their interactions with others in a group setting. Each group also had at least one Maverick with the same MBTI personality type as the incoming students to help in facilitating discussion. Students were also encouraged to interact with the Mavericks that were teaching the course in social settings. The frequency and depth of these social interactions were monitored consistently. Mavericks also kept track of their individual growth, confidence, and ability to relate to their audience and communicate information. Through this character and identity development process, students were to become more self-aware in order to become better leaders.

The *Capacity* of the students was also developed in and outside of the classroom. Students were given opportunities through the program to be part of extracurricular and volunteer activities. In these volunteering opportunities, the students got to expand their leadership skills by being part of running Innovation Session, an event to introduce high school students to the degree. In order to track the students involvement, Mavericks checked which students were attending Innovation Sessions, were involved in student organizations, had a job, or where participating in other activities. The main group project that was designed for the course was also designed to improve student capacity. Relying on the skills students had learned throughout the course, the final project they were given was to apply these skills in a project that made them think about different areas of new product design and development. Being given control of the class allowed the Mavericks to also grow with the students taking the class. Mavericks had to learn to manage their regular course schedules and prepare for the course.

Opportunities to expand their *Competence* were offered through the lessons given in class and the projects were a reflection of what the students were learning. However, Competence was rather tricky to measure mainly due to the fact that it encompasses more than just technical knowledge. To a greater extent, competence is demonstrated when students are able to take what they have learned and apply it in a tangential application in another course, at work or at home. One semester was insufficient to fully understand how much they grew in their learning and in what areas they subsequently applied this knowledge.

Besides the two main projects, smaller activities and projects were created alongside the main projects to help students connect what they were learning to real applications and practice the *hands-on* skills necessary for completing the

major course projects and equip them for future Engineering Leadership courses. These activities included, but were not limited to, working in the machine shop and building circuits. The students could then take those skills and use them to create items for their sculptures or build their product for the final project. In order to successfully teach the course, Mavericks developed their individual capacity as leaders by going through these different topics and gain the skills necessary to teach to the incoming students. While the class itself encouraged students to gain a variety of competencies, from presentation skills to business practices and engineering principles, student teachers too had to become educated on pedagogical practices as well as the material in the course.

While the lessons given to the students introduced the idea of innovative thinking, the true measure was the final Entrepreneurship Project. The objective of the project was to take an already existing product and/or materials and bring new value by creating an entirely new purpose for it. The idea was that the new product must solve a current issue using products/materials of their choice, given those materials were not originally intended to solve the issue. The students were paired in teams and given the freedom to choose anything they would like to use and the project was left very open ended to allow for creativity. This idea of not being told specifically what to do or specifically what to deliver was discomfoting to the students. They were expecting to be told what they had to deliver, but that does not capture the process of innovatively thinking and producing. Over the course of the project and the class time they became more comfortable with the idea of owning their own project and delivering something that would be completely different and presented differently than their peers. This helped encompass the notion that being innovative involves overcoming the fear of doing something different and better.

C. Observed Impact on Incoming Students

While the primary focus on leadership development in this research was focused on the Mavericks, leadership growth was also observed in the students taking the course in the areas of character and capacity (competence was more difficult to observe as the time limit of one semester did not allow for observation of the students applying their gained competence in a tangential application). At the beginning, the expectations for the course, as voiced by the incoming students, was that of "concern", "uncertainty" or expecting "traditional lecture". However, the majority were surprised by their experience and pleased with the outcome. One of the trends observed was the incoming students consistently commenting about the "welcoming environment" in the course. This seemed to indicate a growth in *Character* for some students. For example, several shy students that never talked in class were making jokes with their peers and the student-teachers. As one student shared, "This class has really helped me break out of my shell and open up." For students who claimed it was hard for them to meet new people, they felt that they were able to quickly made friends and were thankful for the introductory course. One student, on the other hand, claimed, "I got along with my classmates but not really made friends. It is not something that

I can easily manage.” It appears that as a result of the course structure and environment, a majority of the students showed greater confidence in themselves, increased efforts in the course, and elevated interaction with student teachers and peers; this improved their team dynamics during group participations. These results will require further study.

The *Capacity* of the incoming students was observed based on their change in involvement throughout the class. From the beginning, incoming student involvement ranged from being highly involved on campus (as members of student organizations for example) to having little or no involvement outside of the classroom. In an effort to build community, the Mavericks consistently invited the students to organized social events, such as going to a movie, playing Frisbee, or going out to eat. Often, one or more faculty members also attended these extracurricular events. Participation in the after class hangouts was optional. Most students, once they attended an after class hangout, were regular attenders with few new students joining the hangouts later in the semester.

Incoming students in the Intro to E-Lead course also demonstrated growing leadership capacity and personal ownership of the Engineering Leadership program. During the semester, Mavericks held recruitment events, called Innovation Sessions, at local high schools. These three hour Innovations Sessions required continuous development, iteration, and improvement by the students running them in order to create an effective method of spreading awareness about engineering, engaging with the high school students, and provide future college students an opportunity to learn about the Engineering Leadership degree. Though not a requirement of the course, several first year students volunteered to help host the Innovation Sessions and took responsibility for leading portions of the day. These first year students had to presenting material, organizing activities, and interacting with the high school students. In fact, of the first year students that volunteered, none had previous history of being highly involved on campus. Many of these students however remained engaged and active in the Engineering Leadership program and continued to volunteer to the end of the semester. A preliminary review of current enrollment in the second course in the BSEL degree plan taught in the spring of 2015, shows a trend indicating that students that attended these organized social events often also volunteered and were more likely to remain in the program. Every student who attended socials went on to become a part of the next course (16 out of the 25 that continued the E-Lead course sequence participated in these social events). It was observed that community produced a willingness to step into leadership positions in incoming students. They also developed an understanding of the importance of their leadership development and the importance of inspiring the next group of incoming students.

D. Maverick Leadership Development

Although allowing Mavericks to teach incoming students was a step forward in the development of their leadership, the student instructors did lack the educational experience and authority that is often given a faculty member. This, at times, took away from the credibility of the class, as the enrolled

students often questioned Maverick credentials, and inquired as to the experiences that qualified them to teach the course, especially in the area of leadership. On the other hand, the student instructors were seen as ‘experienced peers’ who were able to connect on a deeper level and provide feedback to the incoming student. This allowed them to share relevant experiences in addition to technical information; such as mistakes that second year students made so incoming students would not have to repeat the same mistakes. Allowing student to be instructors seemed to encourage the incoming students to become more engaged in the classroom activities due to the fact that the student instructors were able to better relate to the incoming students. In the future, an improved balance of faculty involvement could help to lend credibility to the Mavericks while also mainlining the incoming student’s perspective of them as experienced peers.

E. Retention Rates

The student retention rate – measured as the number of students to complete the course that were enrolled as of the university census day – in the Engineering Leadership program as a result of the redesigned introductory course was 92% (Table 4). This was higher than the retention rate when it was piloted the year prior (60%). An even greater number of students were retained from the first class day in the redesigned course (70%) than in the pilot course (30%).

TABLE III. STUDENT RETENTION

Number of Students	2013	2014
Number of Students at First Day of Class	50	34
Number of Students Enrolled at Census Day	25	26
Number of Students that Completed the Course	15	24
Retention Rate	60%	92%

The resulting improvement in retention rates (from 60% in 2013 to 92% in 2014) of the first semester of the Engineering Leadership program is largely attributed to the improved community and course designed by the Mavericks. Based on feedback from the Mavericks, the pilot year took much more effort and time to build community amongst the students as well as with the faculty. When the Mavericks were given the opportunity to teach the Introduction to Engineering Leadership course, they developed relationships with the incoming students and created a safe, inviting, and friendly environment that bridged the gap between the incoming students and faculty. As a result, the incoming students in the redesigned introductory course benefitted from the program in ways that were not present the year before and the Engineering Leadership retention rate greatly improved. To date, several of the incoming students continue to come by the Engineering Leadership department on free time and say hello to faculty, student-teachers, and other students from their course. It is also prudent to note that this retention rate may have been influenced by the fact that this course and the program was in its inaugural year and this may have also influenced the differences in retention as the popularity of the program was still growing.

However, most efforts to promote the program did not occur until the second year was well underway. Therefore, initial recruitment of students in the redesigned course mimicked those of the pilot course.

V. DISCUSSION

A. Curriculum Outcomes

Overall, students felt that they were able to achieve strong improvements in their leadership skills and knowledge. In particular, due to their unfamiliarity with curriculum design and any new material to be covered in the course, Mavericks developed the ability to learn thing on their own and then communicate that information to their peers. Not only did they learn about different engineering fields and create the interdisciplinary connections for themselves, but they also had to communicate this knowledge to the incoming students. Further, they not only learned basic theory of leadership, they also applied it. The position these student instructors were put in required them to become leaders - becoming more responsible, accountable, and meticulous. The Mavericks had to prepare content before classes, be ready to deliver content, and answer questions. These second year students also became role models and mentors for the new incoming students, guiding them through their first year of college. This experience helped develop a higher understanding for the Mavericks of what it takes to lead and effectively develop future leaders.

B. Study Limitations

As this research covers a single course, a single redesign iteration, and a single group of six student-teachers, one major limitation of this research is its small sample size. An additional limitation is that a subset of the Mavericks and faculty member that did the interviews are co-authors on this paper and therefore some objectivity in the reporting is lost. Further, the students teaching the redesigned course, while second year students in E-Lead, were third year students by credit. Therefore, it will be interesting to see if the above trends continue with the next group of student-teachers that will be second year students both in the program and by credit hours. Further, no formal interviews were completed with incoming students, but informal interviews and observations were completed throughout the semester to record their experiences. Future iterations of this research should include interviews of the both the incoming students and the current student teachers. However, this research demonstrated the feasibility and effectiveness of allowing students to develop their leadership skills through taking on the role of instructor in an introductory engineering course.

VI. CONCLUSION

In the fall of 2013, an Introduction to Engineering Leadership course was piloted with the inaugural class of students in the Engineering Leadership Program. After getting numerous ideas for improvements to the course for the following 2014 year, these same students were hired to take

over the redesign and implementation of a new Introduction to Engineering Leadership Course. This redesign effort by students not only resulted in a new curriculum for the E-Lead program, but also improved the course by increasing the feeling of community for incoming students and thereby increased. More importantly, this experience of being placed in the curriculum development driver seat, also served to help the student-teachers develop intrinsic motivation in themselves and in the incoming class. The mavericks also agreed that the experience helped them increase their innovative problem solving and thinking skills and develop their identity. Overall, this research demonstrated the feasibility and effectiveness of allowing students to become intrinsically motivated by taking on the role of instructor in an introductory engineering course.

ACKNOWLEDGMENT

Special thanks to Dr. Scott Starks, Dr. Shane Walker, and Dr. Jessica Townsend for conducting the planning workshops of the course. *The Olin-UTEP Partnership for Change: Adoption and Adaptation of Innovative Practices for 21st Century Engineering* project, is supported by a grant from the U.S. Department of Education through the Minority Science and Engineering Improvement Program (MSEIP), UTEP Award #P120A140066 and the Argosy Foundation.

Abstract— Engineering and Society, a course designed for first-year engineering (FYE) students and non-majors, was introduced in spring 2011 and most recently (F2014) became part of the required FYE core curricula. In addition to traditional elements of an FYE course such as the study of engineering disciplines and a team-based design project, students explore the various ways non-technical factors influence the development and integration of technology within our society, aligning with many of the learning outcomes specified by ABET General Criterion 3. Student outcomes were measured with a relatively simple pre-test/post-test study that uses a self-constructed on-line survey. Relative to the control group, students who enrolled in the course showed significantly greater gains in self-confidence, most notably with respect to engineering problem solving and design; sense of fit within the engineering profession; and understanding of the broad nature of engineering, including the importance of creativity, ethics, and societal influences to engineering design and decision making. Changes in academic self-confidence and satisfaction with the decision to study engineering were somewhat mixed, yet students in the course expressed a significant increase in their confidence of remaining in an engineering major throughout college, while students in the control group expressed a slight but not significant decline.

Keywords—First year engineering course, science-technology-society, student attitudes)

I. INTRODUCTION

Engineering and Society is a course designed for first-year engineering (FYE) students with a small number of seats open to interested non-majors (NM). The course was developed and implemented at Clarkson University, a small, technologically-focused research university comprised of three schools – Engineering, Arts and Sciences, and Business. Prior to its introduction all FYE students were enrolled in a 2-course sequence in Calculus, Physics, and Chemistry, two humanities/social science/writing courses, and a two-credit computing course. Now, approximately half of all incoming FYE students delay Physics I, largely by virtue of their performance on a pre-enrollment math readiness exam. These students are scheduled into a fall section of Engineering and Society, while the remaining FYE cohort enrolls in spring semester. Students receive credit toward university-established Common Experience course requirements in communication, technology, and science-technology-society [1].

In addition to meeting curricular requirements for the university, Engineering and Society strives to enhance the first year experience for engineering students by engaging them with engineering faculty and the field of engineering in general. The broad goal of the enhanced experience is to improve students' overall understanding of the field of engineering and, ultimately, their own identity and sense of fit within the scholarship and profession of engineering. These efforts go hand in hand with other curricular efforts to improve engagement and retention of first and second-year engineering students at the University [2, 3]. National retention data for engineering education indicate that 40 to 50% of all students who enroll in engineering programs either leave engineering or the university entirely before graduation, and that roughly half of that attrition happens after the first year [4-7]. Engineering student retention at Clarkson University is slightly above the national average, with roughly 10% to 15% of FYE students changing their majors or leaving the university entirely after the first year.

Contrary to popular belief, academic difficulty is not the main reason students leave engineering [8, 9]. Several studies have investigated factors that contribute to student attrition from undergraduate engineering degree programs and the findings have indicated that, while academic ability often plays a role, the reasons students leave engineering are actually much more complex and include students' background, lack of peer group support, loss of confidence, lack of motivation, poor teaching practices and/or inaccessible faculty, the competitive culture of the programs, class size, and poor fit within the institution [e.g., 10-14]. In fact, with respect to women and minority students in particular, the science and engineering gap may have more to do with perceptions and beliefs than with academic achievement levels [15-19]. For a thorough literature review on engineering retention and the individual and institutional factors that contribute to student attrition, see [9, 19].

An effort has been underway since the mid-1990's to increase participation in engineering by attracting a more diverse group of students [20]. Framing engineering concepts, studies, and careers within a broader context to demonstrate societal relevance is one way to dispel negative perceptions of engineering among women and minorities, who are shown to be more sensitive to the broader context of engineering design

[21] and are generally drawn to the careers that involve working with and helping people and communities [16, 18, 22]. Similarly, adapting evidence-based, student-centered teaching and learning strategies, known for improving student learning, achievement, and knowledge retention [23-27], may engage a broader range of students in the learning process [28, 29]. Other efforts to improve retention include unifying programs to minimize compartmentalization [30, 31], and broadening the curriculum to better prepare students with 21st century skills [32]. At the freshman level, introductory courses have been developed to bridge the gap between students' perceptions and expectations of engineering and engineering curricula, as well as dispel many of the generalizations students carry with them into the start of their engineering degree [4, 6, 7, 14]. Use of collaborative and project-based learning [4, 6] and supportive pedagogies [4], were shown to improve retention of students within engineering paths, particularly students from underrepresented groups such as women and minorities [4, 6]. These findings support the assumptions of a GE foundation report [33], which proposes that student success in the quantitative disciplines relies on three factors: engagement (interest), capacity (content mastery), and continuity (institutional support). In fact, the importance of student attitudes, engagement, and feelings of self-efficacy to their academic motivation and success is well documented [13, 34-36]. A relatively small number of studies have investigated the relationship between these phenomena specifically for engineering students [e.g., 13, 19]. Building on these findings, a better understanding of the effectiveness of learning experiences on student attitudes, values, self-confidence, and sense of fit within engineering will help us move forward with strategies to support student engagement and success.

This paper provides a descriptive case study analysis of the new Engineering and Society course outcomes, including those aligned with ABET criteria as well as our objectives related to improving students' understanding of and attitudes toward engineering. We have specifically looked at the changes in students' feelings of self-confidence, self-efficacy, and sense of fit within engineering, as they progress through the one-semester course. The course content and pedagogical approach, briefly summarized, highlight the importance of student engagement, specifically in learning activities that demonstrate the broad and complex nature of engineering, to achieving the intended course outcomes. Although our findings are constrained to the student population at our relatively small research university, the course's value is indeed demonstrated with a combination of summative and cumulative assessment results, with recommendations for future research.

II. COURSE CONTENT AND PEDAGOGY

Although it has elements typical of an FYE course including a survey of the origins and characteristics of various engineering disciplines and the engineering profession, as well as a hands-on design project, Engineering and Society uniquely focuses on the non-technical aspects of engineering and addresses the connections between engineering, technology, and society. When synthesized in this manner, engineering ethics and engineering design content/experience naturally dovetail with the technology and society content. Our

approach, supported by the work of, for example, [37], [38], and [7], allows us to introduce FYE students to engineering topics and content from a perspective that aligns with many of the learning outcomes specified by ABET (Accreditation Board for Engineering and Technology, Inc.) General Criterion 3 [39]. The course allows us to address societal context and contemporary issues alongside engineering topics in a manner that, unlike most of the rest of the engineering curriculum, emphasizes the former. In particular the role of societal forces shaping technology is emphasized; while most students broadly accept the notion that our society has been shaped by the development and implementation of various technologies, the role of societal forces in shaping technology, and the complex interplay between engineering, social science, business and economics, are generally less apparent.

Core learning objectives of the course meet the needs of a technology-focused engineering class as well as a science, technology and society (STS) course within the University's common curriculum requirements [1]. Learning outcomes are shown in Table 1 with reference to ABET Criterion 3 program outcomes. With the STS focus of this class as well as the in-depth analysis requirements, many of ABET's program outcomes are addressed. Most notably, the course addresses at length and in various contexts the topics of engineering design [ABET 3(c)], ethics [ABET 3(f)], impacts of engineering solutions in a global/societal context [3(h)] and contemporary issues [3(j)]. As shown in Table 1, students are assessed on their ability to engage in course activities and to successfully demonstrate their understanding of concepts orally and in writing.

TABLE I. COURSE LEARNING OUTCOMES AND ABET CRITERIA

Course Learning Outcome – Students will demonstrate:	ABET ^a	Assessment
An understanding of and an ability to use the engineering design process.	a, b, c	design project
An understanding of value systems and ethics and be able to relate these concepts to professional problems.	f	HW, exams
The ability to recognize and analyze environmental, social, political, ethical, health and safety, and sustainability considerations and impacts of engineering design.	c, f, h, j	HW, discussion, exams
An appreciation of the need for critical assessment of the sources of information, including computational tools, used to solve engineering design problems.	c	HW, discussion, design project
An understanding of the major engineering disciplines and be able to identify the core scientific disciplines underlying these. They will demonstrate an understanding of how the engineering profession intersects with the sciences and mathematics.	d	HW, exams
The ability to effectively communicate their ideas in written and oral formats.	g	class activities, design project

^aABET criteria c: (a) an ability to apply knowledge of mathematics, science, and engineering; (b) an ability to design and conduct experiments, as well as to analyze and interpret data; (d) an ability to function on multidisciplinary teams; (e) an ability to identify, formulate, and solve engineering problems; (g) an ability to communicate effectively; (h) the broad education necessary to understand the impact of engineering solutions in a global, economic, environmental, and societal context; (i) a recognition of the need for, and an ability to engage in life-long learning; (j) a knowledge of contemporary issues; (k) an ability to use the techniques, skills, and modern engineering tools necessary for engineering practice.

Engineering and Society has been offered each semester since the initial one-section pilot in Spring 2011, and has most recently (Fall 2014) become a required course for all FYE students (roughly 500/year). Eight to ten closely-coordinated sections are offered each semester by a team of three to four instructors, who have adapted many evidence-based, student-centered instructional practices [23] in an effort to engage students in a non-traditional learning experience. Course topics align with the following categories: (i) The Engineering Professions; (ii) The History of Engineering and Technology; (iii) The Design Process; (iv) Value Systems and Engineering Ethics; and (v) Engineering and Society. Topic (iii) is covered largely through a semester-long team-based design project challenge, which students accomplish primarily outside of class time. Past projects have included the construction of a prosthetic arm [40], a bench-scale solar water heater, a bench-scale wind turbine, and a portable pedestrian bridge [41].

The majority of class time is spent on topics (iv) and (v). Students explore various concepts and case studies through extensive readings (primary texts include [42] and excerpts from [43-45], as well as supplemental assignments related to current events), interactive class discussions and activities, and written composition. Students practice role play, risk assessment, and value conflict resolution; they debate the benefits and risks associated with emergent technologies and conceptualize creative approaches to inherently safe and sustainable designs; and they approach ethical dilemmas through the lens of different ethical theories and from the perspective of various stakeholders, applying ethical problem solving techniques to analyze decisions associated with a number of historical and contemporary case studies. For an in-depth description of course structure and content see [2] and [46].

III. COURSE OUTCOMES

Course level outcomes assessment focuses on ABET General Criteria 3(c), (f) and (h). Summative assessments are conducted annually using student design project deliverables [ABET 3(c)] and specific exam questions that target [3(f)] and [3(h)]. Scoring rubrics are used for the design projects and specific criteria are used to grade the exam questions. Data collected since Spring 2012 demonstrate that students consistently meet expectations for these key outcomes and, by extension, for the course. The most recent analysis in Spring 2014 indicates that, for ABET 3(c), design, students are meeting (94.9%) or exceeding (37.7%) expectations; for ABET 3(f), ethics, students are meeting (89.3%) or exceeding (44.3%) expectations; and for ABET 3(h), societal context, students are meeting (86.4%) or exceeding (34.3%) expectations. Anecdotally, by inviting students at the freshman level to consider the complexities of ethical and societal questions in relation to engineering decision making and design, our intent is to equip them with skills that they will continue to use as they revisit these ideas throughout their undergraduate education, which is quite different from the traditional path that provides them with a first exposure to engineering ethics, for example, in their upper level design classes. Our hope is that, as upper classmen, they will draw on these experiences to

develop a deeper appreciation of the intricate relationship between engineering and society.

IV. STUDENT OUTCOMES:

UNDERSTANDING OF AND ATTITUDES TOWARD ENGINEERING

A. Methods

Student understanding of and attitudes toward engineering were measured with a relatively simple pre-test/post-test study that uses an online survey to elicit a combination of Likert-type and open-ended responses from students enrolled in the course. Students in the course ('treatment') are administered surveys at the beginning and end of each semester. Pre- and post-surveys are administered simultaneously in fall semesters to a control group consisting of freshman engineering students enrolled in Physics I (Introduction to Physics) who, by virtue of their schedules, are not enrolled in Engineering and Society. The anonymous questionnaires are coded to enable matching of pre/post student responses. All components of the survey procedures have been approved by Clarkson University's Institutional Review Board (IRB).

The questionnaire we use was developed as part of this project. Most of the attitude items were adapted from existing questionnaires [47-50], while original items were created to measure course objectives related to students' understanding of the breadth of engineering and interactions with society. The questionnaire contains 22 items that use a Likert-type format with five options ranging from strongly disagree (1) to strongly agree (5). The items are specifically intended to measure students':

1. Self-confidence (general performance, within engineering problem solving and design, and team work)
2. Confidence in the engineering curriculum
3. Satisfaction with the decision to study engineering
4. Comfort level or "fit" within engineering
5. Understanding of the broad nature of engineering and engineering problem solving (creativity, teamwork, ethics, and society context)

The post-survey contains 4 additional Likert-type items that ask students to broadly self-assess the degree to which the course has helped them learn about engineering and design, as well as 10 mixed-format questions that provide formative feedback for adjusting the course pedagogy. The complete survey is available from the author.

Student response data collected over seven academic semesters, fall 2011 through fall 2014, have been pooled by semester for analysis, yielding three sample groups: fall semester treatment (n=500), spring semester treatment (n=221), and fall semester control (n=735). Students in the course were separated into the two treatment groups to enable a more realistic comparison between treatment and control groups (using fall only), and also to enable us to investigate potential variations between the fall and spring student cohorts. By way of design, many students in the fall control group were part of the spring treatment group; as of yet there has been no

effort to identify these students for special analysis, although this has been identified as an area for future research.

All data were compiled into Excel and analyzed through different methods within SPSS (Statistical Package for the Social Sciences). Likert-type rating scales were converted to numerical values (1 to 5) according to a predetermined preferred direction of response in order to calculate summated rating totals for each item. Items were subsequently grouped into the five topics or categories defined above, and average mean responses for each student were calculated as simple means based on their responses to each item in the category. Post-pre changes in student responses for each cohort were analyzed by comparing students' matched pre/post average mean scores using the Wilcoxon signed rank test, a nonparametric statistical procedure equivalent to the paired-sample Student t-test. Between-group comparisons (fall treatment vs. fall control; fall treatment vs. spring treatment) were analyzed by comparing post-pre differences using the Mann-Whitney U Test.

B. Quantitative Outcomes – Results and Discussion

The pre/post matching procedure resulted in sample sizes of 500 (fall treatment), 221 (spring treatment), and 735 (control). Results are summarized in Table II and Figure 1. Figure 1 shows pre and post mean values for each of the five above categories, for the fall treatment and control groups. Table II presents a more detailed look at mean student responses on the post survey (ranging from 1 to 5), and the post-pre differences, for the five categories and for a few selected items within each category, for all three student cohorts. Also shown are the significance level of between-groups comparisons, which were performed between the fall treatment v. control, and fall v. spring treatment groups. Bold values in the table indicate a significant difference ($\alpha=0.05$) between the pre and post survey mean response, or between the pre/post change of the two comparison groups, respectively. Parenthesis indicate negative post-pre changes, within-group, and post-pre changes for the fall treatment group that were less than (if positive) or greater than (if negative) the control; that is, parenthesis indicate changes in the treatment group that were 'worse' than changes in the control.

In general, there were significant pre/post improvements in responses from students enrolled in the course to items relating to students' *self-confidence*, *sense of fit within the engineering profession*, and *understanding of the broad nature of engineering and engineering problem solving*. These changes were significantly more positive than the control group, who declined significantly in all three of these categories overall. In particular, after taking the course students felt more confident about problem solving and team work, a stronger sense of 'belonging' in an engineering career, and a better understanding of the role of ethics and societal factors to engineering design and decision making. While the control group showed similar gains on some of these items, overall the changes were much more pronounced and widespread among the students who took the course. Also, while the emphasis of the comparison is between the control group and the fall treatment group, these changes were generally consistent

Fig. 1. Pre/post changes in student responses (scale of 1 to 5) to the 5 question categories, fall treatment group vs. control. Gains were significant for treatment group, and significantly greater than control, in 'Self-Confidence', 'Fit with Eng. Prof.', and 'Understanding'. Both groups showed significant decline in 'Conf. in Eng. Curriculum'. Treatment group showed significant decline and control a significant increase in 'Sat. to Study Eng.' Details provided in Table II.

among students enrolled in the course in both fall and spring semesters, at least in terms of the students' increase in self-confidence and understanding of engineering problem solving (Table II). Unlike the fall treatment group, students in the spring cohort did not indicate that they increased their feelings of fitting in with the engineering profession, with their overall post mean response remaining roughly stable, and lower than the post-mean for the fall treatment group, over the course of the semester. Thus, it appears that students' appreciation for the broad nature of engineering problem solving, and their feelings of self-confidence, are more malleable in general than their sense of belonging within the engineering profession. Another possible explanation for the significant changes in fall semester among both treatment (positive) and control (negative) groups compared to the relatively stable response in the spring is the idea that first semester freshmen are adapting to change at many levels, academically and socially, as they integrate into university life. This is certainly a phenomenon that warrants further study, yet the findings here of the positive influence the Engineering and Society course had on students' understanding of engineering problem solving, self-confidence, and – for fall semester – students' sense of fit within engineering, bodes well for the course.

Results for the remaining two categories are somewhat mixed. Students in both the fall treatment and control groups expressed a roughly equivalent, significant decline in their *confidence levels with respect to the engineering curriculum*. This decline in academic self-confidence was noted in an earlier study [46] and was posited to reflect a combination of students' overconfidence when first arriving on campus (pre-scores were on the order of 4.2-4.4 for these questions) followed by the realization, after first semester, of the difficulty level of these courses. The lack of change in academic self-confidence among the spring cohort seems to confirm this hypothesis, although this, too, warrants future investigation. Moreover, while both fall groups showed a drop in confidence

TABLE II. STUDENT RESPONSES TO PRE/POST ATTITUDE SURVEY

	Fall Treatment		Control		Fall v. Control	Spring Treatment		Fall v. Spring
	Mean Post	Post-Pre ^b	Mean Post	Post-Pre ^b	Mann-Whitney P ^c	Mean Post	Post-Pre ^b	Mann-Whitney P

^aThese negatively worded items have been reverse-scored for analysis.

^b**Bold** values indicate that pre/post gains for this student group, or differences between designated groups, are significant. Parenthetical values () indicate a negative pre/post change. **Bold** values are significant:

* $\alpha=0.05$

** $\alpha=0.01$

*** $\alpha=0.001$

^cP-values in parenthesis indicate that post-pre changes for fall treatment group were less than (if positive) or greater than (if negative) control.

in math/chemistry (2 questions combined), the drop was greater among students in the course, which makes sense given that students are enrolled in the fall semester of Engineering and Society because of their lower performance on pre-enrollment math readiness exams. Students in spring semester showed a slight but significant increase in their confidence in math and chemistry, again confirming the suspicion that freshmen in general may come to university with inflated confidence in their academic abilities, and that confidence is swiftly thwarted during their first semester as they experience the difficulty of university-level courses. Such misconceptions of introductory engineering courses have been found by others [e.g. 51, 52]. However, as shown in Table II, confidence specifically in *engineering* courses dropped for the control group but remained level for students in the course, both fall and spring semesters. These findings suggest that, by engaging with engineering faculty and educational opportunities related specifically to engineering, students' confidence in their ability to study engineering may be preserved.

Finally, as shown in both Figure 1 and Table II, *satisfaction with the decision to study engineering* declined significantly among students in both fall and spring treatment cohorts, and increased significantly among the control group. This finding may partially result from inflated satisfaction levels at the beginning of the semester among the fall treatment group (pre response mean was 4.3), since the post scores at the end of fall semester were essentially the same for both treatment and control. Also, although responses continued to decline throughout the spring, post values were still relatively high at 4.0. Both fall groups showed equivalent declines in response rates to the individual item 'satisfaction to study engineering' (no change in spring), still with high post values despite the decline (4.3). There is also some level of inconsistency among the results for individual items in this category. For example, students in the fall treatment group simultaneously expressed an increase in their confidence about staying in engineering, and an increase in exploring other non-engineering majors (item negatively worded and reverse scored). This

inconsistency was also present, although not as pronounced, for the spring treatment group. These inconsistent responses may be an artifact of the detrimental effects of a negatively worded survey item noted by others [53, 54].

Nevertheless, despite inconsistencies among this particular group of questions, the results clearly indicate that in general, both the treatment and control student cohorts finished out their semester with relatively high levels of satisfaction with their decision to study engineering, and – most importantly – students in the fall semester course were significantly more inclined to stay in engineering than students in the control group. This result, together with the finding discussed previously regarding the stable confidence of students enrolled in the course toward succeeding in their engineering coursework, indicates overall that the course is having a positive impact overall on students' attitudes toward engineering.

C. Self-assessed Course Impacts

Student responses to questions on the post survey that asked them to self-assess the impacts of the course on their attitudes generally confirmed the positive pre/post changes described above with respect to their improved understanding of engineering. After taking the course, 86% of the students agreed or strongly agreed that they have a better understanding of what engineering is (mean=4.2); 90% agreed/strongly agreed that the course helped improve their understanding of the engineering design process (mean=4.2); and 75.2% strongly agreed/agreed that the course helped improve their understanding of the differences between the various engineering disciplines (mean=3.9).

Students responded overwhelmingly positive to the classroom format, with 371 out of 488 students (76%) selecting 'activities/discussions' as their preferred learning environment, as opposed to 117 selecting 'lecture'. A total of 723 FYE students provided qualitative feedback regarding the most valuable aspects of the course. Since we first began collecting information, students have consistently cited most frequently their experiences with the design project (297 students) and teamwork (136 students) as most valuable. They also appreciate learning about the relationship between ethics and engineering (136 students) and the exposure to engineering in general, the various disciplines, the real-life case studies, and the relationship between engineering and societal factors (323). Students appreciated 'learning how things are connected [with engineering];' 'applying things we learned to real scenarios (role play and design project);' and that the course 'changed my perception about engineering.' Students consistently write that the course helps them 'think differently about the world' and 'see the bigger picture.' One student wrote that through the course, they were 'able to notice connections among the way we got to where we are today and how to analyze where we need to go from here.'

In the words of one student: "I think the course overall was valuable because it teaches you that as you become an engineer you will not just be developing products but also playing a role in society development. It helps show that you have a responsibility to society as an engineer to create products that

will not only be beneficial but also be safe." Taken as a whole, the qualitative feedback supports the value of exposing students at the freshman level to engineering 'in context', as found by the work of Kilgore et al. [21].

V. CONCLUSIONS AND FUTURE WORK

A course has been developed for first year engineering majors that engages students with engineering faculty and the field of engineering in general. Students explore engineering through an STS lens that uniquely focuses on the non-technical aspects of engineering and addresses the connections between engineering, technology, and society. The course content aligns with many of the learning outcomes specified by ABET General Criterion 3, most notably 3(c), 3(f), 3(h), and 3(j). Course instructors have used a variety of evidence-based, student-centered instructional techniques to create a supportive, inviting, and engaging learning environment. Aside from satisfying ABET criteria, a major goal of the course is to improve students' attitudes toward and understanding of the broad field of engineering, and their sense of belonging within engineering studies and careers. Results from a relatively simple pre-test/post-test survey study administered over seven semesters show that, relative to a control group, students in the course experience positive changes in their self-confidence regarding problem solving and teamwork, their sense of fit within engineering, and their understanding of the broad nature of engineering, including the importance of creativity, ethics, and societal factors to engineering decision making and engineering design. Although the findings regarding students' academic self-confidence and satisfaction with their decision to study engineering are somewhat mixed, students in the course have relatively stable confidence levels toward their ability to succeed in their engineering courses, and indicate a clear positive trend in their confidence about keeping their engineering major throughout college. The study has uncovered a general decline in academic confidence among freshman students in the fall semester, which seems to be pervasive among both the study and control groups and is not present in spring.

Future work will include a closer look at qualitative results collected from the study, to better elucidate the decline in academic self-confidence as well as the conflicting findings noted in this paper regarding the change in students' levels of satisfaction with their decision to study engineering. We also hope to work toward a more consistent survey administration methodology that will include testing each incoming freshman engineering student at three points: prior to enrollment, and following fall and spring semesters. This will be possible now that the course is required as part of the regular freshman engineering curriculum. As this methodology is developed, the survey will undergo major revisions as we attempt to create more detailed questions that probe nuances that may be connected with students' identity as an engineer, sense of fit within engineering studies and careers, and their intent to continue with studies in their engineering major. Simultaneously, a system will be developed to engage a subset of freshmen in focus group interviews following their participation in the course. We hope that future research will garner findings that will both (1) deepen our understanding of

the nature of our own students and the impacts of the course on their own sense of belonging; and (2) enable us to broaden our findings to a more generalizable population.

Assessing Student Views of Traditional, Free, and Interactive Modifications for an Introductory Networking Course

Patrick Seeling

Department of Computer Science
Central Michigan University
Mount Pleasant, MI 48859
pseeling@ieee.org

Abstract—Common questions faced by instructors in their course designs are how to incorporate interactive technologies to increase student motivation as well as limiting the costs associated with education, contributed predominantly through course textbooks. We describe two course changes from a baseline scenario for a networking course, which aim at making the course no-cost using public domain content or, alternatively, focus on making the course highly interactive. We find that course cost benefits were offset by shortcomings in the open-source material replacing the textbook, but that the additional course costs of an interactive course are offset by increased course and learning perceptions reported by students. The focus on instructional interactivity, however, left the hands-on components up to students, with a potentially negative impact on the perceived quality of instruction.

Index Terms—Computer science education, Communication engineering education, student perceptions

I. INTRODUCTION

The interconnected world of today requires a thorough education of students in different fields, such as engineering and computer science, to attain at least a basic level of mastery concerning underlying mechanisms at play. In turn, introductory networking concepts oftentimes are integrated into the curriculum in a dispersed manner or covered in a dedicated course. This paper explores the self-reported student perceptions for such an initial “funnel” course. Independent of their selection of several specialization areas within the Information Technology (IT) track offered by the Department of Computer Science at Central Michigan University, students are required to take the introductory course in communications networks. As the IT track offers a more hands-on approach to the underlying concepts, students typically experience a combination of lectured content and hands-on networking exercises. Common choices that educators preparing these types of courses face are (i) the affordability of materials to students, especially when considering institutions with high ratios of financial aid receiving students as well as (ii) the fashion in which courses are delivered when considering an in-classroom setting. For three consecutive semesters, we evaluated student progression through this introductory sophomore-level course. We gathered the student feedback

employing anonymous survey instruments at the beginning, middle, and end of each considered semester targeting how student perceptions about the course focus changed over time with modifications from (i) traditional over (ii) no-cost to (iii) interactive, but not “flipped.” The remainder of this paper continues with a description of the underlying changes between semesters on a high level and the survey instrument. We follow in Section III with a discussion of dominant findings before we conclude in Section IV.

II. IMPLEMENTATION

Throughout the three semesters under evaluation, we performed several modifications to the course’s instructional methodology, which reflect some common choices faced by today’s educators:

- The baseline semester featured a traditional course setup, delivered employing a standard networking textbook paired with hands-on instructional laboratory units as part of the class meeting times.
- The first change was a replacement of the traditional textbook with an open-source book, which was supplemented with materials and hands-on instructional laboratory units as part of the class meeting times, i.e., the focus was on a no-cost course.
- The second change combined a traditional textbook paired with classroom response systems for feedback (“clickers,” which students had to purchase) and laboratory units now performed as homework, i.e., the focus was on increased interactivity resulting in significant costs for required course materials.

The accessible Kurose/Ross textbook [1] was adapted for the course and typically, each chapter in the textbook was flanked by a hands-on experience for students, related homework problems, and a quiz administered through the Learning Management System (LMS). For the interactive class, all quizzing (graded and ungraded) was performed using the clickers [2], with immediate feedback to foster resolution of wrongly retained answers. Throughout each course offering, announcements within the LMS and in-class were used in the beginning (first two week time frame), middle (after

the first mid-term examination), and end of the semester (before the final examination) to make students aware of the anonymous survey. The survey itself was modeled after the one presented in [3], combining persistence in engineering [4] and motivational tendencies [5], with questions presented in Table I.

III. RESULTS

We performed a multi-variate analysis on the 86 total responses we received for survey items incorporating persistence in engineering and motivational components, with an overview of results for all semesters provided in Table II. Throughout, we consider a two-factor design (semester or instruction mode \times time within) and employ significance levels of $\alpha=0.05$ in the univariate analyses of variance (ANOVA). Due to space limitations, we focus our discussion on (i) program continuation or persistence, (ii) quality of instruction, (iii) perceived course value and enjoyment, and (iv) self-perceived learning, which are items that were found to exhibit the highest significance by semester, time within a semester, and the interaction of both. We furthermore note that in some cases, significant variability differences exist between groups, which in an overarching manner can be explained through the survey feedback rate differences throughout semesters.

We initially note that the persistence of students to continue taking courses within the discipline exhibits a significant difference by semester. Students in the traditional course setting indicated the lowest level of continued interest ($M=2.06$, $SD=0.79$), followed by the free semester ($M=4.35$, $SD=0.88$), while the highest interest in the program was indicated in for the interactive instruction group ($M=4.7$, $SD=0.68$). These results indicate a significant main effect with $F(2, 83)=108.51$, $p<.001$, $\eta_p^2=.723$. Students overall indicated as they progressed throughout the semester in the traditional and interactive course formats an increasing likelihood of remaining with the department's programs, while a slight reduction can be observed for the free course approach. The interaction between these semester and surveying time factors was also found to be significant $F(4, 77)=7.99$, $p<.001$, $\eta_p^2=.3$. We note that effect sizes indicate that a larger contribution stems from the overall instruction mode (semester), which exhibits a large effect size, while the time during a semester features a medium effect size. Comparing the joint effects, we again note a larger effect size.

Next, we evaluate the perceived instruction quality, which was found to exhibit a significant main effect by semester $F(2, 83)=18.44$, $p<.001$, $\eta_p^2=.308$ and is illustrated in Fig. 1a. We note that while variances between groups vary significantly, a Welch evaluation of means indicates significance ($p<.001$). Specifically, students in the traditional course rated the instructional quality highest ($M=4.58$, $SD=0.61$), followed by the interactive group ($M=3.39$, $SD=1.03$), and trailed by the free course ($M=3.2$, $SD=1.20$). As indicated, this finding is corroborated by the large effect size. As all three course variations were taught in the same manner with the

outlined adjustments, it seems that the overall student perception leans towards employment of the traditional textbook and lecture style combining slides and whiteboard together with instructor-guided hands-on exercises. However, we did not find a considerable main effect for the time within the semester $F(2, 83)=.444$, $p=.643$, $\eta_p^2=.011$ or the interaction of both $F(4, 77)=1.78$, $p=.141$, $\eta_p^2=.085$. This indicates that students overall perceived the instructional quality highest in the traditional textbook-based lecture paired with hands-on laboratory settings most, while the free textbook approach did not meet student instructional needs. The interactive course format falls somewhere in the middle and results could be interpreted in the context of laboratory units being conducted in a self-guided manner, which might overload students not familiar with self-scheduling. Indeed, an additional evaluation indicates that student ratings by semester for the homework difficulties show a significant main effect with an effect size approaching medium $F(2, 83)=3.811$, $p=.026$, $\eta_p^2=.084$.

We noticed a significant main effect between the semesters when students were to value the course $F(2, 83)=12.514$, $p<.001$, $\eta_p^2=.232$ with a medium effect size. While a Levene test indicates variances between groups vary significantly, a Welch evaluation of means indicates significance ($p<.001$). Students in the traditional course overall indicated the lowest perceived value ($M=3.18$, $SD=1.16$), followed by the free course format ($M=4.1$, $SD=0.79$). Students in the interactive class, however, exhibited the highest level of appreciation for the course with the lowest deviation of ratings ($M=4.18$, $SD=0.53$). While no significant main effect was determinable for within a semester $F(2, 83)=.42$, $p=.658$, $\eta_p^2=.010$, the evaluation of the interaction indicates a significant main effect $F(4, 77)=3.823$, $p=.007$, $\eta_p^2=.166$. (We note that for the combination of semesters and times within, the variances are non-homogeneous.) The overall differences become more apparent when viewed graphically, as in Fig. 1b. While students in the interactive course agree to the course being worthwhile on a stable level, students in the free course reduced their course rating over the time of the semester. The traditional course students increased their class valuation towards the middle of the semester and kept their rating afterwards on the same level. Some of this increased valuation could be attributed to the increased hands-on practices in the laboratory times. Some problems became apparent with the free course text selection, which students mentioned in class. Amongst those referenced were writing styles, illustrations, and spelling errors. In turn, the increased usage of the free text with generated slides could be a significant contributor to the lower ratings.

When asked if they enjoyed the course, students in the traditional setting provided the best marks ($M=4.15$, $SD=0.62$) followed by the interactive course delivery ($M=3.76$, $SD=0.94$) and the free format ($M=3.5$, $SD=1.15$). With a significant main effect $F(2, 83)=3.643$, $p=.03$, $\eta_p^2=.081$, this indicates that overall, students enjoyed the course, but the delivery format

Fig. 1. Visual representation of means observed for quality of instruction, considering the course worthwhile, and self-perceived learning.

and potential problems with materials can have a significant impact. This result has to be regarded with caution, however, as the variability difference between groups is significant. While the traditional and interactive course versions remain at a fairly stable level, the free course shows a continuous slide of student course enjoyment as surveyed. When the time within a semester is considered, however, we do not observe significant differences $F(2, 83)=1.324, p=.272, \eta_p^2=.031$, which indicates the initial observation is corroborated on a steady level during semesters. The interaction main effect, in turn, can be explained by this individual course format's content problems can be regarded as culprits for the reduced ratings $F(4, 77)=3.104, p=.020, \eta_p^2=.139$.

Finally, we describe the self-perceived learning as reported by students in the survey, illustrated in Fig. 1c. An increase can be noted from traditional ($M=3.67, SD=0.99$) over free ($M=3.9, SD=1.02$) to interactive ($M=4.15, SD=0.67$) course formats. The visible order can be noted by semester, which, however only approaches significance $F(2, 83)=2.463, p=.091, \eta_p^2=.056$. Due to a lack of variance homogeneity, a Welch test was employed to confirm ($p=.074$). The significant main effect within the semesters $F(2, 83)=6.491, p=.002, \eta_p^2=.135$ showcases how student rating progress throughout the semester from (i) high to (ii) reduced and return to (iii) higher for the course versions. We note, however, that due to in-between group variability, we corroborated our observation with a Kruskal-Wallis H test, which showed a statistically significant difference, $\chi^2(2)=12.374, p=.002$. This finding is further corroborated by the significant interaction main effect $F(4, 77)=4.679, p=.002, \eta_p^2=.196$, noting that again inter-group variability is significant.

We note in conclusion that the individual submission for the Spring 2014 semester could be a significant outlier, potentially submitted by a student that was fully dissatisfied with the course and/or grade earned during the semester. In turn, response number variations significantly impact the between-group variabilities and assumptions for ANOVA, which, however, can be considered more a call for caution in the interpretation of results rather than their invalidation [7].

IV. CONCLUSION

We find that overall, student responses vary greatly with the course implementation, but less within a semester. The interactive course results in the highest motivation to continue with the department's offerings while students report challenging lectures and reading assignments. Their valuation of the course as worthwhile and enjoyable can be seen as a result of the right challenge level, see, e.g., [6]. Compared to the free textbook offering with material shortcomings and the traditional textbook-only approach, we note that a replacement of the designated supervised laboratory time with the increased in-lecture activities results in a higher level of the students' need to keep up with materials and self-organize (based on general feedback we received). Thus, we conclude that a traditional, edited textbook can aid to keep learners abreast in self-studying, while adding interactivity and immediate resolution of misconceptions significantly fosters the perceived value of the course offering by helping to balance challenge levels for learners. Future works will investigate supplemental video instructions to help students in the initial phases of assignments and replacing the current traditional textbook in the interactive course with another free or low-cost alternative.

TABLE I
OVERVIEW OF THE EMPLOYED SURVEY FOR A SUBSET OF THE PERSISTENCE IN ENGINEERING [4] AND MOTIVATIONAL TENDENCIES [5] SURVEYS
BASED ON LIKERT-TYPE QUESTIONS.

Item	Text
1	I want to continue taking Computer Science courses.
2	After graduation I want to become a computer scientist or IT professional.
3	I think that I am doing well in this course.
4	I have good math skills.
5	I have good science knowledge.
6	I am good at applying math and science to real world problems.
7	I like working in teams.
8	I perform well on teams.
9	Creative thinking is one of my strengths.
10	I am skilled at solving problems that can have multiple solutions.
11	Math skills are important for computer scientists and IT professionals.
12	Science knowledge is important for computer scientists and IT professionals.
13	An ability to apply math and science principles to real-world problems is important for computer scientists and IT professionals.
14	An ability to perform on teams is important for computer scientists and IT professionals.
15	The quality of instruction by faculty is good.
16	There are enough opportunities to interact with faculty.
17	The computer facilities at the IT sites are good.
18	The classroom facilities are good.
19	The library services are good.
20	The academic advising is good.
21	I feel stressed about the course load for this class.
22	This is an enjoyable course.
23	I learn a lot in this course.
24	The team projects require a lot of effort.

A Pedagogical Model for Introducing 3D Printing Technology in a Freshman Level Course Based on a Classic Instructional Design Theory

Pit Ho Patrio Chiu, King Wai Chiu Lai, Tsz Ki Frankie Fan, and Shuk Han Cheng
City University of Hong Kong
Hong Kong SAR

Abstract—This paper presents a seven-step pedagogical model for introducing 3D printing technology to students with different levels of technological literacy in a freshman level course. The model was derived from a classic instructional design theory on the development of intellectual skills, the Conditions of Learning, with consideration of the technical requirements of 3D printers. It aimed to tackle the practical problems arose when course instructors adopted 3D printing as learning activities in classes, such as the diversity of students' technical backgrounds, the low throughput of 3D printers and the difficulty in integrating 3D printing into learning task. The model was piloted for two years in a General Education course under the engineering domain that opened to all freshmen. Most of the students had no prior experience in 3D printing and all of them agreed that they have had a good understanding of the technology after completed the course. They reported that the learning task supported the development of their innovative ideas and enhanced their learning motivations. However, their perceptions of the workload vary.

Keywords—3D Printing; Educational technology; Pedagogy

I. INTRODUCTION

3D printing technology, also known as rapid prototyping technology, is identified as one of the key emerging educational technologies to support student learning and to stimulate innovations. The technology is likely to have a major influence on higher education [1-3] in the coming years. It is even being heralded as “Industrial Revolution 2.0” [4]. While the technology is not new to the higher education community, academics have been using 3D printers (or rapid prototyping machines) for more than 20 years in research and teaching. However such equipment is very expensive and is usually housed in department or research laboratories. It is often available only to students in certain professional disciplines [5,6], wide adoption of 3D printing technology across disciplines as teaching and learning activity is rare. In the recent year, the cost of the 3D printers dropped significantly and the higher education community is eager to integrate the now inexpensive technology into regular classes for enhancing student learning. Instructors begin to incorporate 3D printing technology in their courses [7-9], but very often they encountered practical problems during the implementation, such as students may have different levels of CAD and 3D printing technology knowledge, the slow printing speed and low throughput of 3D printers which handicapped the adoption of the technology in large class, and no proven teaching

strategy in adopting 3D printing in learning task. These pedagogical and technical issues can hold back the adoption of the technology and discourage passionate teachers from developing innovations in teaching. Thus a working pedagogical model is needed for instructors to integrate 3D printing into their courses.

II. ISSUES IN ADOPTING 3D PRINTING TECHNOLOGY IN LEARNING TASK

Issues in adopting 3D printing in learning activities have been reported by early adopters [7-8,10]. Also course leaders who wished to incorporate the technology into their courses at City University of Hong Kong have been consulted and their practical concerns during the instructional design process are documented. In general, issues related to adopting 3D printing in learning task can be grouped into two categories:

1) *Students' diverse technical backgrounds*: Students from different disciplines who enrolled in the same course poses a challenge to the instructor in adopting 3D printing technology in class. Although it is reasonable to assume the majority of students do not have any hands-on experiences on using 3D printers, as the technology is still not widely available to general public, some students do possess a higher level of technological literacy to begin using the technology, such technical skill in CAD and proficiency in comprehending 3D objects. These skill sets can be acquired by students during their studies in high schools, through technical courses offered by vocational colleges, or by self-learning before entering University. This group of “advanced” students may find that the introductory materials of the 3D printing technology are redundant knowledge and may lose motivation in learning. On the other hand, this fundamental knowledge (refer to skill in CAD and comprehension of 3D objects) is essential for the rest of the class to learn and use the technology.

2) *Low throughput*: As the majority of the 3D printers are using additive manufacturing process, the sequential deposition of materials limited the printing speed, resulted in low throughput. For example, it is commonly to find that a 5 x 5 x 5 inch object requires at least 10 hours of printing time and another hour for post processing (removing supportive material). It basically consumed a day's work on printing just one item. Using the same formula, a 25-student class will take 25 working days to accommodate all student works for

sequential printing. It is not cost effective to support teaching in this way, thus limited the adoption of 3D printing technology in large class. Purchasing additional 3D printers can certainly increase the throughput if budget and space were available. 3D printer manufacturers attempt to increase the overall speed by putting multiple printing heads in one 3D printer and extrude building material simultaneously, however most of 3D printers available on the market at affordable price are still single-head model. This technical barrier is unlikely to be solved completely, thus the pedagogical model has to work around this issue.

III. THE PEDAGOGICAL MODEL

A pedagogical model for integrating 3D printing into learning task is developed. It is derived from a classic instructional design theory, the Conditions of Learning by Robert Gagne [11], with consideration of 3D printers' throughput and students' differences in technological literacy.

A. The Conditions of Learning

Gagne's theoretical framework is based on the development of student's intellectual skills and is first used for military training purpose in the 60s' [12]. Since then it has been applied to the design of instruction in different domains [13]. According to the theory, Nine Instructional Events are the basis of instruction design. Each instructional event corresponds to a specific cognitive process. The nine-event provides the necessary conditions for learning in any discipline. Table I shows the Nine Instructional Events and the corresponding cognitive process.

TABLE I. NINE INSTRUCTIONAL EVENTS AND THE CORRESPONDING COGNITIVE PROCESS OF THE INSTRUCTIONAL DESIGN THEORY: THE CONDITIONS OF LEARNING [11]

	Instructional Event	Cognitive Process
1.	Gaining attention	Attention: Alertness
2.	Informing learner of the objective: activating motivation	Expectancy
3.	Stimulating recall of prior knowledge	Retrieval to working memory
4.	Presenting the stimulus material	Selective perception
5.	Providing learning guidance	Encoding: Entry to long term memory storage
6.	Eliciting performance	Responding
7.	Providing feedback	Reinforcement
8.	Assessing performance	Retrieval
9.	Enhancing retention and transfer	Generalization

B. Pedagogical Model for Introducing 3D Printing Technology

Although the theoretical framework of the Conditions of Learning can be applied to all aspects of learning, including 3D printing, practical implementation issues have to be addressed. A seven-step pedagogical model is developed based on the theoretical framework with practical solutions to address the two aforementioned problems in adopting 3D printing

technology in learning task. Staff requirements for the model are the course instructor, tutors (senior year students) with 3D printing skills and a laboratory manager (technician) to provide technical support and feedbacks. These are typical resource available to a freshman level course with laboratory session. The pedagogical model is described below and its association with the Nine Instructional Events and the cognitive processes is presented in Table II step-by-step.

- First (Step 1) students are grouped into team-of -three to -six followed by (Step 2) an introductory seminar on 3D printing technology conducted by the instructor or the laboratory manager. The adoption of collaborative learning in the model is proven to be effective in enhancing creativity [14-16] and also enable large class to adopt the technology. The two steps correspond to the cognitive processes of attention and expectancy. Students are alerted about the use of 3D printing in their learning tasks. It stimulates their motivation and also informs them the expectancy of the performance to be achieved in the course.
- Then (Step 3) each team is coached by a senior year student, who acts as tutor in class, on creating printable 3D designs using CAD. "Advanced" students with good technical background in CAD within the team can help to teach other teammates, providing additional peer learning element in the learning process. This step corresponds to the retrieval, selective perception and encoding processes. The action of demonstrating CAD by the tutors helps students to recall any prior knowledge or subordinate skills to their working memory, setting up their mindsets to receive the stimulus material. The new knowledge then can be encoded and transferred to students' long term memory.
- Afterward (Step 4), students work together to create their own team designs within a specific time period (i.e. two weeks). These collaborative learning approaches help to draw out expertise from students with different backgrounds and contribute to the design. While science and engineering students can lead the technical aspect of the product, art students can advise on the outlook design and business students can contribute to the marketing feasibility. Whenever they encounter technical difficulty (Step 5), they can visit the on-duty tutors who are stationed in the 3D printing laboratory for troubleshooting their design problems and also to conduct a preliminary design rules check (DRC) as a formative assessment of their designs. Students with weak technical skills can receive extra help from the tutors, by repeating Step 4 to 5, and to catch up with the rest of the class referenced to the Mastery Learning approach [17]. This self-learning process provides flexibility to suit individual student's learning style and need. Step 4 to 5 correspond to the cognitive process of encoding, responding, and reinforcement. Encoding of new knowledge to long term memory continues in this step, but instead of learning under the instructions of tutors, students collaboratively work and learn together. The

shift from passive to active learning is particular important for students to create innovative designs. To ensure students develop in the right direction, their performances are elicited according to the DRC. This timely feedback helps students to gauge their works and allow them to improve on their designs and reinforce their learning.

- Students then (Step 6) submit their final designs to the laboratory manager by the end of the design period for a detail DRC and receive technical feedbacks from him. Multiple designs then combine together (Step 7) into one design file for printing simultaneously. The batch printing eases the pressure on long printing time, as compared to serial printing. Finally students receive the printed objects and conduct a summative assessment on their designs in physical form under the guidance of instructor (cognitive processes: retrieval and generalization). Students receive an overall evaluation of their works and appraisal in a formal way. It enhances the retention of their newly acquired

knowledge and enables them to apply/transfer the intellectual skills to future projects.

The proposed model not only adopted the classic instructional theory in designing learning task using 3D printing technology, it also provides the flexibility to accommodate different settings and budgets (for 3D printers) and can be scaled up with class size. As the laboratory manager can select suitable 3D printers based on the resource available, such as professional 3D printer versus desktop model, the only requirement is to have a sufficient building volume that can print multiple student designed items (combined into one object) all together. Low cost, desktop version, 3D printers with build volume larger than 12 x 10 x 10 inch are available on the market. Additionally the course instructor can adjust the student team size to meet the resource requirement. The model can easily accommodate a 60-student class by dividing them in to 12 team-of-five. Six items, each with a size of 4 x 5 x 4 inch, can be printed in one batch and only two batches of printing are needed (approximately 2 days of printing time). However the maximum item size that each team can use is dictated by the 3D printer's building volume.

TABLE II. PEDAGOGICAL MODEL FOR INTRODUCING 3D PRINTING TECHNOLOGIES

	Pedagogical Model	Nine Instructional Events	Cognitive Process	Staff Involve	Remark
Step 1	Instructor explains the adoption of 3D printing technology in learning task and groups all students into team-of -three to - six.	1. Gaining attention	Attention: Alertness	Instructor	Collaborative learning approach is proven to be effective in enhancing creativity and also it enables the adoption of the technology in large class size
Step 2	Instructor explains the objectives of the learning task and conduct a brief introductory seminar on 3D printing technologies	2. Informing learner of the objective: activating motivation	Expectancy	Instructor and Laboratory Manager (optional)	Activate students' motivation using real examples and applications
Step 3	Tutors coach individual team on creating printable 3D designs using CAD	3. Stimulating recall of prior knowledge 4. Presenting the stimulus material 5. Providing learning guidance	Retrieval to working memory Selective perception Encoding: Entry to long term memory storage	Tutors	"Advanced" student within the team can help to coach his/her teammate
Step 4	Students create/revise their own designs in computer lab at school or at home		Encoding: Entry to long term memory storage		Self-learning approach to provide flexibility to suit individual student's learning style and need
Step 5 (Repeat step 4 if need)	Whenever students encounter technical difficulty, they can visit the on-duty tutors for troubleshooting their design problems and also conduct a preliminary design rules check (DRC)	5. Providing learning guidance 6. Eliciting performance 7. Providing feedback	Encoding: Entry to long term memory storage Responding Reinforcement	Tutors	Students with weak technical skills can receive extra help from the tutors and to catch up with the rest of the class (the Mastery Learning approach)
Step 6	Students submit their final designs for a detail DRC and receive technical feedback from the laboratory manager	8. Assessing performance	Retrieval	Laboratory Manager	
Step 7	Laboratory manager combines multiple designs into one file for printing Students receive the 3D objects and assess the products with the instructor	9. Enhancing retention and transfer	Generalization	Laboratory Manager and Instructor	The batch printing eases the pressure on long printing time, as compared to serial printing

IV. IMPLEMENTATION

The pedagogical model was piloted for two years (2013/14 and 2014/15) in a General Education course, GE1324 Creating Your Smart Home, under the engineering domain that opened to all freshmen at City University of Hong Kong. The course aimed to introduce students a creative approach to smart living and to inspire students to adopt technology innovatively for a healthier and more environmental friendly living environment. It was taught by an academic staff from the department of Mechanical and Biomedical Engineering. In the year 2013/14 and 2014/15, there was 89 and 28 student enrolment respectively. About half of the class came from the College of Science and Engineering and the other half is from different Colleges and Schools (Table III) in both years. Thus it created a learning environment with diverse student backgrounds, similar to the issue #1 mentioned in section II, to evaluate the pedagogical model. The key assessment task was to develop a concept of a smart home appliance and to visualize the idea by building a prototype using 3D printing technology followed by a final presentation. The assessment weighted 35% of the course grade. Approximately 15% of student work hour was dedicated to learn and use the technology for their prototype development. Students were grouped into team-of -five to -six and only one design per team is allowed. They were expected to complete their CAD designs within two weeks of time. The maximum object build size for each team was 4 x 4 x 4 inch. The allowed build volume was sufficient for printing scale prototypes for presenting and demonstrating their designs/ideas. The course instructor followed the seven-step pedagogical model for introducing 3D printing technologies to students during the tutorial sessions, in parallel with the lecture sessions where subject contents were taught. Five tutors and a laboratory manager provided the technical support during the 3D printing tutorial sessions. Three packages of CAD software, Tinkercad, SolidWorks and Rhino 4.0, were available to students. Most of them selected the cloud version of Tinkercad, an easy to use 3D CAD design tool that was available online. A Stratasys Fortus 400mc 3D printer from the Gateway Education Laboratory [18] was used to print all the items. Every six designs were combined in one file for batch printing.

TABLE III. GE1324 STUDENT ACADEMIC BACKGROUND

	2013/14		2014/15	
College of Business	21	(24%)	10	(36%)
College of Liberal Arts & Social Science	14	(16%)	2	(7%)
College of Science & Engineering	42	(47%)	15	(54%)
School of Energy and Environment	7	(8%)	0	(0%)
School of Creative Media	4	(4%)	0	(0%)
School of Law	1	(1%)	0	(0%)
Exchange student	0	(0%)	1	(4%)
Total	89	(100%)	28	(100%)

V. STUDENT FEEDBACKS

Quantitative feedbacks from two questionnaires and qualitative feedback were obtained from students at the end of the course to evaluate the effectiveness of the pedagogical model.

The first quantitative feedback is an institutional Teaching and Learning Questionnaire (TLQ). It is a 7-point Likert-type questionnaire to gather student feedbacks on the overall course teaching and learning experience. TLQ was sent to all GE1324 students with 51% and 43% response rate in the 2013/14 and 2014/15 classes. Results of the learning experience from GE1324 TLQ are compared to the University Norm in the respective year (69,490 responses in 2013/14 and 66,954 responses in 2014/15, both with 48% response rate). Results are summarized in Table IV.

TABLE IV. GE1324 TEACHING AND LEARNING QUESTIONNAIRE DATA COMPARED TO THE UNIVERSITY NORM*

Item		2013/14			2014/15		
		GE 1324	U Norm	% Diff	GE 1324	U Norm	% Diff
TLQ1	I found the learning experience well designed.	5.60	5.58	0.4%	5.83	5.62	3.7%
TLQ2	I was encouraged to be creative/innovation.	5.98	5.47	9.3%	6.17	5.50	12.2%
TLQ3	I was encouraged to think critically	5.60	5.56	0.7%	6.00	5.60	7.1%
TLQ4	I found the course difficult.	4.93	4.93	0.0%	4.58	4.95	-7.5%
TLQ5	Overall, I consider the learning experience provided by the teacher in this course as valuable	5.71	5.69	0.4%	5.83	5.73	1.7%

*7-Point Likert Scale: 1 (Strongly Disagree) to 7 (Strongly Agree)

The second quantitative feedback is a 3D Printing Experience Survey (3D-PES) specifically designed to seek each team's collective perspective on the use of the 3D printing technology in class, that included learning and usage experiences. It is a 5-point Likert type questionnaire and each team is allowed to provide only one response. The 3D-PES was administered only to the 2014/15 class and all 5 teams have responded to the survey. Four out of the five teams indicated they have no prior experience in 3D printing technology and one student reported that he has less than 6 month experience in using the technology. Results are shown in Table V.

TABLE V. 3D PRINTING EXPERIENCE SURVEY*

	Item		Mean	Std Dev
Learning Experience	ES1	After completing the course, I have a good understanding of the 3D printing technology	4.2	0.40
	ES2	The use of 3D printing technology in the course supported the development of my innovative idea	4.4	0.49
	ES3	The use of 3D printing technology in the course enhanced my learning motivation	4.4	0.49
Usage Experience	ES4	After completing the course, I am comfortable in using the CAD software to design a simple 3D object	4.4	0.49
	ES5	Workload related in using 3D printer/CAD software in the course is appropriate	4.2	0.75
	ES6	Support from the GE Lab staff/tutors in using 3D printer/CAD software is appropriate	4.6	0.49

	Item		Mean	Std Dev
	ES7	The overall learning experience related to the use of 3D printing technology is well designed	4.6	0.49

*5-Point Likert Scale: 1 (Strongly Disagree) to 5 (Strongly Agree)

Qualitative feedbacks from students are obtained through an anonymous online platform and are summarized into three categories: 1) Learning experience; 2) Usage; and 3) Area for Improvement. Six statements are identified:

Category 1) Learning experience

- *The course provide a chance for students to use the 3D printing technology and learn to design their 3D objects by using online software, it is a really useful experiences to students as some of them may not have an opportunity to touch those things in their 3/4 years university life.*
- *Earning the experience to have lab visit, and do 3D model drawing and printing.*
- *Amazing experience to use this technology.*

Category 2) Usage

- *The software for 3D model development is easy to use.*
- *The product is printed as expected.*

Category 3) Area for improvement

- *Something may be too difficult for other areas' students to learn (e.g. BBA/CLASS)* because it involves technical things in the course.*

*(BBA = Bachelor of Business Administration; CLASS = College of Liberal Arts and Social Sciences)

VI. DISCUSSION

From the TLQ results, it is evident that students believed the course provided a good learning experience for them to be creative/innovation (TLQ2). The score in this item is significantly higher than the University Norm by 9.3% and 12.2% in the two years, while other items are on par with the Norm. It is an encouraging result that students agreed with the course aim that a creative/innovative learning environment was provided to them. Since the TLQ is an institutional instrument that provided an indication of the overall learning experience of the course, which involved lecture, tutorial, 3D printing task and other hands-on activities, the higher that Norm score on innovation was an integrated result of all the learning tasks of the course. While task related to 3D printing consisted of 15% of student work hour, one can suggest that the 3D printing pedagogical model has contributed to the development of student innovations. This assumption is supported by the 3D-PES and qualitative feedback (Category 1) and is discussed subsequently.

The team responses from the 3D-PES indeed provided a clear indication of student learning experience specifically on 3D printing from their perspectives. They overwhelming agreed that the adoption of 3D printing technology in the learning task supported the development of their innovative ideas (ES2) and enhanced their learning motivation (ES3). They indicated that they had good understanding of the technology after completing the course (ES1) and have received positive learning experience on using 3D printing in

learning task (ES7). Students also explained in written form that they have received a very good learning experience in using the 3D printing technology (Qualitative feedback - Category 1). As for the usage experience, students also agreed that the CAD software was easy to use under the coaching of tutors (ES4 & ES6), supported by their qualitative feedback (Category 2). However, students' perceptions on workload related to the learning task vary (ES5) with a high standard deviation value (0.75). This result agreed with the qualitative feedback (Category 3) where student pointed out that technical material was more difficult for art and business students to learn as compared to science and engineering students. It is reasonable to assume that students outside the science and engineering areas, whom have weaker technical backgrounds in general, may require more study hours to master the technical skills.

Overall, students provided very positive comments on their 3D printing technology learning experience under the piloted pedagogical model. They have learnt to use the technology in a relatively short period of time with good results. It is believed that the collaborative learning approach helped students in learning the new technology effectively. The complex 3D printing learning task, for intellectual skill, was introduced to students in a teaching sequence corresponded to the well-established Nine Instructional Events proven to be successful. A portion of the learning steps in the model relied on student's ability in self-learning and their own initiatives to seek assistance; at the same time, this approach provided the flexibility for students with lower level of technological literacy to catch up and mastery the skills. Nevertheless, students' own learning motivation and willingness in spending efforts in learning were always the vital keys for their successes, and the piloted model provided a good and supportive learning environment for them.

The piloted pedagogical model essentially provided structured instructional steps that can be easily adopted to different settings and course contents. It provided a practical solution to scale up the technology adoption in a large class, by using the collaborative learning approach, forming teams and relying on batch printing, and handled the teaching challenge of having students with diverse backgrounds through the self-learning and mastery learning approaches. The instructional steps of the model helped students to clearly identify their objectives and guided them to reach the learning outcomes step-by-step.

VII. CONCLUSIONS AND FUTURE WORK

A seven-step pedagogical model for introducing 3D printing technology based on the classic instructional design theory, the Conditions of Learning, was developed. The model adopted the collaborating learning, self-learning and mastery learning approaches to tackle the two major practical issues, students with different levels of technological literacy and low 3D printer throughput. The pedagogical model was applied to a freshman level General Education course for two years. Students' feedbacks were analyzed and the results shown that the model has supported the development of their creative ideas with good learning and usage experiences. However,

students had different perspectives on workload in learning the technology.

To further study the effectiveness of the pedagogical model across disciplines, courses in different subject areas should be considered. Comparison of results from different General Education and major courses can reveal the disciplinary dependency of the model. Furthermore, student profile has not been considered in the current study, it is valuable to evaluate whether the model has the same pedagogical effect to all students in terms of gender, major and level of study in the future.

Outcomes of Accepting or Declining Advanced Placement Calculus Credit

Karen De Urquidi, Dina Verdin, Stephen Hoffmann, Matthew W. Ohland

Engineering Education
Purdue University
West Lafayette, Indiana

Abstract— Students who qualify for Calculus credit via the Advanced Placement (AP) exam often have the choice of accepting the credit, and starting in Calculus II or III, or declining the credit, and retaking Calculus I in a university setting. This study investigates and reports success metrics for students who make a choice of accepting or declining AP Calculus credit. The 2014 College Board National Report states when compared to similar peers, students who receive a score of 3 or higher in an AP exam tend to earn higher college grade point averages (GPAs), have higher graduation rates, and have the opportunity to take more discipline course work in college. This report is based on all the AP courses offered by College Board. It is not certain what the outcomes are for an individual course, i.e. AP Calculus, or how the markers of success translate to engineering students and engineering programs. By analyzing 3,600 engineering students academic records from Fall 2012 and 2013 (i.e. gender, ethnicity, residency, grade received in Calculus I course, AP Calculus exam score, High School GPA, SAT/ACT Math and Verbal score), this study seeks to describe patterns of success in students' subsequent Calculus courses from those who accepted AP Calculus credit, skipping Calculus I, as opposed to those who did not accept their AP Calculus credit and took Calculus I. Students ask for recommendations from their first year engineering advisors on whether to retake Calculus I in college or accept their AP Calculus credit, which consists of a score of 4 or 5 at this university. As research in this specific topic is absent, advisors in a first year engineering program must advise in the absence of concrete data. This paper offers insight based upon previous student academic records, which may inform advisors and incoming first year students on whether or not to accept AP Calculus credit.

Keywords—Engineering Education; mathematics; calculus; engineering students; qualifications

I. INTRODUCTION

While much research has been done showing who has access to Advanced Placement (AP) Calculus classes and the benefits associated with enrolling in them [1][2][3][4], little research has been done to look at the consequences of the choice to accept or decline credit for one or more calculus classes for those who qualify. Some of these students retake the course they received credit for, whereas others move on to the next course in sequence. Typically, incoming students seek counsel from their advisors on whether to retake Calculus I in college or accept their AP Calculus AB credit. University policies vary in what AP score qualifies a student to receive college credit- many offer credit for a score of 3 or higher

[5][6], whereas more selective institutions require a score of 4 or 5, or do not offer credit based on the AP at all [7]. Currently, advisors in the FYE program at Purdue University offer advice based on anecdotes and prior experience with students. This study seeks to identify key factors that may predict students' success in the first Calculus course by analyzing 3,600 engineering students academic records, some of whom accepted AP Calculus AB credit, skipping the introductory Calculus course, while others did not accept it and took the introductory course. We studied academic records for the Fall 2012 and Fall 2013 cohorts of First-Year Engineering students who enroll at Purdue University who qualify for credit in either Calculus I or both Calculus I & II. The data drawn from academic records includes gender, ethnicity, residency, AP Calculus exam score, high school GPA, SAT math and verbal scores, first math course taken at Purdue, and the grade received in that course. These data were chosen for their relevance in observing any racial or gender biases in advising or outcomes and based on relevance of these variables in earlier studies [8][9][10]. By evaluating these data from First-Year Engineering students, we hope to better equip advisors to inform incoming students about whether they should accept or reject the AP Calculus credit for which they qualify.

II. BACKGROUND

Previous research highlights the significant impact AP courses have on a student's academic trajectory (i.e. college grade point average and graduation rates) by focusing only on students who accepted their AP credits [1]. There has been little research focused on the outcome of students who reject AP credits and retake the introductory course.

Research has shown that students who take AP courses in high school have an academic advantage over those who do not [2][11][12]. In the admissions process, universities have traditionally used Advanced Placement (AP) courses as determining factors for academic success. The 2014 College Board National Report states that when compared to similar peers, students who receive a score of 3 or higher on an AP exam tend to earn higher college grade point averages (GPAs), have higher graduation rates, and have the opportunity to take more discipline course work in college [4]. The Advanced Placement Calculus AB curriculum in high school is designed to be equivalent to a first-semester college course. A student passing the AP Calculus AB exam with a score of three or higher is considered to be capable of passing Calculus I as a college freshman[13]. When compared to non-AP students,

those who scored a 3 or higher perform better in college courses within their disciplines as opposed to those who took introductory courses[13] . Yet the report does not separate AP courses, rather it pertains to AP courses and test scores in the aggregate. A longitudinal study conducted on students with AP credits at Georgia Tech revealed an association between AP score, college GPA, and graduation rate. Across the cohort of students being studied, those who did not complete any AP exams graduated at a rate of 72.7 percent, while the graduation rate increased 8.9 percentage points for students who took one or more AP exams regardless of scores [14].

First semester GPA has been shown to be a good predictor of graduation success. Budny, et al. concluded that for engineering students, the first semester math grade can be used as a predictor of graduation success, in place of the entire first semester GPA [15]. Therefore, placing students in the correct first math course may be critical to their success. This study will look at what the best placement is for a student to be successful in their first math class while obtaining as much college credit upon arrival as is prudent to accept.

III. DESCRIPTIVE STATISTICS

A. Eligibility to Receive Credit

Data from two Fall cohorts (Fall 2012 and Fall 2013) of incoming First-Year Engineering students were collected. This data included both performance and demographic data. Race/ethnicity, gender, and residency were demographic factors, and high school GPA, SAT scores (verbal and math), AP Calculus AB or BC scores, and grade in first math class taken were performance data. Of the approximately 2800 students entering in Fall of 2012 and 2013, just over 1300 had received a 4 or higher on the AP Calculus AB or BC test, giving them a choice on whether or not to accept college credit for their AP score. Breakdowns of these scores by gender are shown in Figures 1 and 2.

As seen in the graphs, gender differences are slight. Females appear to have more scores in the lower AB and BC levels compared to males. When a t-test was run, the difference in means was significant, but with only a 0.37 difference in the actual mean AP scores. Means for both male and female were between 4 and 5, using a scale from 1-7 with values of 6 and 7 representing BC scores 4 and 5. An F test was done and showed no difference in variances for the two samples. A proportion test on the two distributions showed no significant difference.

B. Choosing to Receive Credit

We next looked at the choices made by the students as to whether or not to accept the AP credit received. At Purdue, credit for Calculus I or II is only given for a score of 4 or 5. Scoring a 4 or 5 on the AP AB test gives a student possible credit for Calculus I. For a 4 or 5 on the AP BC test, students

Fig. 1. AP Calculus AB Scores by Gender, Fall 2012 and 2013

Fig. 2. AP Calculus BC Scores by Gender, Fall 2012 and 2013

can receive credit for both Calculus I and Calculus II, if desired. Those who took the AP BC test also receive an AB subscore. A 4 or 5 on this subscore will allow them to receive credit for Calculus I. Table 1 shows the breakdown of how potential credit was chosen for those students entering in the fall of 2012 and 2013 aggregated, disaggregated by AP score. The data are further disaggregated by gender and race/ethnicity. White and international students were aggregated as these populations tend to be privileged. Black and Hispanic students were aggregated as underrepresented minorities for comparison purposes. Due to low numbers, American Indian/Alaskan Native, Native Hawaiian/Other Pacific Islander, 2 or more races, and unknown groups were not included in the breakout groups. Asian populations were not used in either breakout category.

TABLE I. CHOICE BY AP SCORE FOR ENTERING 2012 AND 2013

# STUDENTS	NO CREDIT TAKEN	HALF CREDIT TAKEN	ALL CREDIT TAKEN
BC 5	25 (6%)	94 (24%)	268 (70%)
WHITE/INT'L Female	4	18	41
BLACK/HISP. Female	2	2	1
WHITE/INT'L Male	14	60	171
BLACK/ HISP. Male	2	4	11
BC 4	14 (10%)	73 (54%)	49 (36%)
WHITE/INT'L Female	2	19	14
BLACK/HISP. Female	0	1	0
WHITE/INT'L Male	9	39	25
BLACK/ HISP. Male	0	2	2
AB 5	86 (30%)	----	201 (70%)
WHITE/INT'L Female	29	----	63
BLACK/HISP. Female	0	----	0
WHITE/INT'L Male	94	----	223
BLACK/ HISP. Male	1	----	11
AB 4	169 (50%)	----	171 (50%)
WHITE/INT'L Female	42	----	35
BLACK/HISP. Female	0	----	1
WHITE/INT'L Male	108	----	108
BLACK/ HISP. Male	5	----	4

The column for 'half credit taken' only applies to students who had BC scores of 4 or 5. They had the choice to either take credit for both calculus classes, just one class, and no credit at all.

For students who received a score of 5 on the BC test, credit for both Calculus I and II was available. Overall, close to 70 percent of those students took credit for both courses and started in Calculus III at the university. Of the remaining 30 percent, only 6 percent chose to retake both courses in the university and not receive any credit for math. These ratios are also seen in the gender and race splits, with the exception of black/Hispanic females. For this group, only 20 percent took the credit and the remainder was split evenly between no credit and half credit. Although the sample size is small, this might be explained by the fact that this group is the minority group in both race/ethnicity and gender, and therefore may have less confidence in their ability to succeed at the university level (regardless of their actual ability to succeed).

Students who received a 4 on the BC test also had the choice of taking all, half, or none of the credit afforded them by their AP score. For this group overall, the majority (54 percent) chose to only take half of the credit offered. Just over a third chose to take all of the credit, and similar to BC 5, only 10 percent started out in Calculus I, not accepting any credit. Due to the fact that these students did not score the maximum on the BC test, they may have felt that they should not accept all the credit but start in a class that would partially be a review

for them. The only subgroup not following this breakdown were the Black/Hispanic males. Everyone in that group took at least some of the credit offered. The sample size was small, so it is difficult to assert that this represents a general trend in those populations.

Students receiving the highest possible score on the AB test followed a similar path to the BC 5 students. Two-thirds chose to take the credit for Calculus I and start in Calculus II, with one-third repeating the Calculus I course. These students did not have the choice to only take half of the credit. Considering that they received the highest score possible on the test, it is again reasonable that the majority chose to take the credit instead of repeating the course. The one subgroup who didn't follow this split was again the black/Hispanic males. A full 92 percent of this group took the credit for Calculus I, with only one student retaking Calculus I. Given the fact that this subgroup is more likely to be socioeconomically disadvantaged, the decision could in part have been made with financial reasons involved. As there were no black/Hispanic females to compare the trend with, this is only a possible idea to explain the discrepancy.

As with students receiving a 4 on the BC test, students who received a 4 on the AB test were a bit less likely to take the credit with half choosing to take the credit and half deciding to retake the class. The white/int'l females were a bit less likely to take the credit, again possibly due to confidence.

C. Grades in First Math Class

After looking into the choices made by the students, we looked at the grades received in the first math class taken at the university. As mentioned earlier, grade in the first math class correlates with student graduation, therefore it is important that a student does well in that first class. After the choice was made by the student, grades in the first math class are shown in Figures 3 through Figure 7 below for each group of students that had a choice to make.

Figure 3 shows the grade distribution of Calculus 1 grades for students who either did not take the AP Calculus exam or did not earn a 4 or 5 on the exam. All of these students were required to begin in Calculus 1. The average grade for these students was a 2.44 (C) and the median score was a 2.3.

As would be expected, students who came in with credit for both Calculus I and II by receiving a 4 or 5 on the BC test, performed well at all levels, whether retaking the class or accepting the credit and moving on. Very few of these students earned grades below a C- , the minimum grade to proceed in the math sequence and the first-year engineering curriculum. Based only on this descriptive data and given the fact that students who scored a 4 or 5 on the BC test did well in whichever math class they decided to begin in, it would be safe to tell students who make a 4 or 5 on the BC test to take all of the credit for which they are eligible, unless there are mitigating circumstances. The fraction of students earning each grade does not seem to be a function of whether half or all eligible credit is accepted. If these students are particularly concerned about earning a high grade in their first math course, the grade distribution for the students in this group that accept no credit is particularly favorable.

Fig. 3. Grades in first calculus class for students without AP Calculus credit (Fall 2012 & 2013)

Fig. 4. Grades in first calculus class for students with a BC score 5 (Fall 2012 & 2013)

Fig. 5. Grades in first calculus class for students with a BC score 4 (Fall 2012 & 2013)

For students earning a 4 or 5 on the AB test had the choice to start in Calculus II or retake Calculus I. The data as shown in the graph below for students with an AB 5 score appears to a distribution that favors high grades in Calculus I, whereas the distribution of grades in Calculus II appears to be a normal distribution centered on a grade of B. Therefore, accepting the credit would seem to be reasonable in the absence of mitigating circumstances for students most concerned with making forward progress, whereas students concerned about maintaining a high GPA should be advised to retake Calculus I. The importance of the grade in the first math course documented in the literature may support the latter recommendation to retake Calculus I even for students with an AB score of 5. There is very little likelihood of receiving below a C- in Calculus II.

IV. REGRESSION ANALYSIS

A. Predicting the Choice to Accept Credit

SAS 9.4 was used to run systematic, stepwise regression analysis on the data. The first analysis was designed to identify factors affecting the choice made by the students to accept or decline AP credit for calculus. For entering and exiting variables, a significance level of 0.15 was used in the model. Research has shown this to be the best level for identifying and retaining significant covariates in regression [16]. For students who scored a 4 on the AP AB test, the significant factors were high school GPA ($p=.0567$) and verbal SAT score ($p=.0837$). Yet these two factors explain only 3 percent of the variation in choice and no other factors were significant. The relevant factors were different for students who scored a 5 on the AB test. Here, the only significant factor in their decision was their math SAT score ($p=.1406$). Again, the explanatory power was low; less than 1 percent of the variation was explained.

For BC students who scored a 4, the only significant factor in the choice was gender ($p=.1313$), explaining 3 percent of the variation. While this might be explained by research that women are less confident in math than men [17][18], this same effect was not found for students with an AB score of 4. Finally, for students who scored the highest possible score of 5 on the AP BC exam, the significant factors in their decision on how much credit to accept proved to be high school GPA ($p=.0088$) and math SAT score ($p=.0220$), explaining only 4 percent of the variation. This last relationship seems to indicate that the highest academic performers accept the credit and students whose GPAs and math SAT scores are lower are more likely to choose to retake at least one Calculus course.

The regression was run again, pooling the data and treating AP score as a continuous variable. The model for choice included two significant factors. These were AP score ($p<0.0001$) and math SAT score ($p=0.0015$). These two factors accounted for 7.5 percent of the variance in choice.

B. Predicting the Grade in the First Math Class

Next, another systematic stepwise regression analysis modeled the grade in the first math class, using the same factors used earlier but adding choice (all, half, or none) as a new factor in the regression (with values of 0, 1, and 2). At first the regression was separated by first calculus class taken, and then the data was pooled into one group. For Calculus I, the factors affecting the math grade were AP score ($p<0.0001$), math SAT score ($p=0.0166$), and gender ($p=0.0297$). All of these factors were significant and together accounted for almost 11 percent of the variation in math grade.

For grades in Calculus II, gender dropped from the model but choice was significant. The significant factors were choice ($p=0.0479$), AP score ($p<0.0001$), and math SAT score ($p=0.0001$). These three factors together accounted for 12.5 percent of the variation in grade in Calculus II.

Grades in Calculus III were significantly affected by AP score ($p=0.0115$) and math SAT score ($p=0.0012$), consistent with the high-performing factors affecting the choice to accept credit for Calculus II. These two factors accounted for 9 percent of the grade variation.

First Math Grade by AB 5

Fig. 6. Grades in first calculus class for students with an AB score 5 (Fall 2012 and 2013)

First Math Grade by AB 4

Fig. 7. Grades in first calculus class for students with an AB score 4 (Fall 2012 and 2013)

For students who received a 4 on the AB test, the choice was split evenly between whether or not to take the credit for Calculus I. The grade distributions for these students are shown in Figure 6. At this level of AP, both grade distributions are normal, but the average grade is a bit lower for students. This may suggest that AB students who retake Calculus I are overconfident and underperform their ability, resulting in a grade distribution that is very similar to students who take Calculus II. Thus, the advising in this case might be that students who retake Calculus I should be cautioned to complete all their work and study to ensure they receive a higher grade. Students who are either focused on making rapid progress toward their degree or who will not keep up with the work if they are not challenged should proceed into Calculus II. Particularly because this choice seems ambiguous, we looked closer into all the student factors we had to see if there were any statistically significant factors that may affect the math grade based upon a student's choice.

When the data were pooled and calculus level was coded as an independent variable, the model for grade in the first math class had three significant factors: AP score ($p < 0.0001$), math SAT score ($p < 0.0001$), and calculus level ($p < 0.0001$). All three of these factors were significant and together explained over 12.5 percent of the variation in math grade. Whereas AP score and math SAT score correlate positively with math grade, Calculus level has a negative correlation. The parameter estimate for calculus level was -0.3139, so for every increase in calculus level, students would expect to see their grade lowered by 0.3 of a letter grade. All other factors in every model run were positively correlated with both choice and math grade.

V. CONCLUSIONS

Females tended to have slightly lower scores on the AP Calculus test, which may be due to self-efficacy and confidence issues more than ability issues. When looking at the choices made by the students to accept or decline the AP credit for which they qualified, 70 percent of students who earned the top BC score of 5 chose to receive all credit for which they qualified. The only exceptions to this trend came for the black/Hispanic females who received a BC 5. Only 20 percent of them accepted full credit, with 40% taking half credit. This may again be a result of confidence issues for females, but more research needs to be done to back up that claim. For black/Hispanic males who scored an AB 5, 92 percent chose to receive full credit, as compared to 70 percent overall. This choice may be the result of socioeconomic factors, but more research would need to be done on this issue.

For students who scored a 4 on either the AB or BC test, the percentages who chose to accept all credit declined to around 50 percent. It may be that the fact that they didn't earn the top grade kept them from accepting full credit, thinking they still needed to learn some of the material.

The effect of the choice made was shown in graphs of grades in the first math class taken. For students who received a 4 or 5 on the BC test, the grades in calculus 2 and 3 were equivalent. Taking all of the qualifying credit would appear to be advantageous. Students who received the top AB score did well in either class but if a student needs to keep a high GPA, retaking Calculus I gives them a better chance at an A. There is little chance they would not receive credit for Calculus II if they enrolled, however. For students who received an AB 4, the chance of receiving a D or F in Calculus II goes up, but the grades in Calculus I are also lower than might be expected for a student who could have accepted credit for it. Overconfidence or boredom may come into play in this case.

Regression analysis was run to find the significant factors in both choice and in math grade. The math SAT was a significant factor for students who scored a 5 on either AB or BC. Choice was affected by different factors for those who received a score of 4. For BC 4 students, gender was significant as was mentioned earlier with the black/Hispanic female population. For AB 4 students both GPA and SAT verbal were significant. This may be representative of harder working students who believed that their hard work would allow them to succeed in an upper level course.

When the regression analysis was run with math grade as the dependent variable, AP score was a significant factor in all three calculus levels. The SAT math score was also significant for those who took Calculus I or II. Choice was significant only for those who started in Calculus II, and gender was a significant factor only in those who chose to retake Calculus I. Advisors should use this information to especially help students who are thinking of beginning in Calculus II as that appears to be the place where lower grades have been earned.

Abstract— The assessment process *in* engineering courses is an arduous task. It requires a lot of effort from teachers. In Mathematics and Physics courses, there are additional issues related to the evaluation of questions with numerical and symbolic answers. In this project, an on-line dynamic assessment system called *TecEval* was developed. It is a web platform that can be accessed via desktop and mobile browsers. This system enables the management of mathematical equations, and it can randomize the order of the questions and the values of the coefficients in them within certain parameters. Consequently, every student will have to answer a different test every time he/she uses the platform. *TecEval* allows professors to generate dynamic tests for engineering courses, which are graded automatically. *TecEval* can create tests with 4 types of questions: i) numerical questions, where the answer is a predetermined number, ii) multiple choice questions (including multiple answers), iii) dynamic questions, where the response is based on a equation, and iv) dynamic-equation questions, where the response is a mathematical equation that may contain dynamic variables. During the evaluation process *TecEval* performed successfully with students and it obtained positive comments from surveys applied to professors.

Keywords— *Assessment process, eLearning tests, Online evaluation, Object oriented Architecture, Virtual learning environments.*

I. INTRODUCTION

Thanks to the development of technology, it is more frequent to find tests or exams that are applied on computers or mobile devices. In this kind of exams, it is common to find question catalogues with static questions and static answers, mostly with multiple choices. Although in some occasions the question order can change each time the exam is opened, static question catalogues makes student evaluation more difficult to determine. The main issue with this static catalogue is that the student knowledge is not always congruent with the grade generated by the system. This is caused by a variety of reasons. One of them is that students can get the right answers by using

a trial-error method (after several attempts to answer), or the presented question has been seen before and the answer is already known (even without knowing the justification for it) [1].

In Mathematics and Physics this problem is even greater due to numerical and symbolic resolution in problems. Questions with multiple choices also have the inconvenient that the student might choose the correct answer by guessing, without following the appropriate procedure to solve the problem.

To overcome these difficulties, this paper proposes the development of an online dynamic evaluation system that provides suitable handling of mathematical equations. In this system the order of questions changes each time an exam is presented and the equation coefficients may also change according to certain parameters, in such a way that each student has a different exam each time he/she accesses the system.

The main goal of this project is therefore to design an online system, called *TecEval*, which allows:

- Elaborating, managing and applying different kinds of questions that can be graded automatically in exams, including open questions.
- Making the writing of mathematical symbols easier.
- Including dynamic questions (algorithmically).
- Generating statistics for the teacher and for the system improvement.

In addition, the system has to be Mobile/tablet friendly and compatible with Android or iOS.

This project is innovative because it permits accessing the resources (questions and exams) not only from a computer, but also from mobile devices with the most common operative

systems. On the other hand, *TecEval* considers both content management by the teacher and statistical analysis of the content use by the students (few current systems offer this last functionality). This feature can help teachers to adjust their contents based on students' performance and necessities that may appear. *TecEval* uses trees for the computational representation of mathematical expressions [2].

II. RELATED WORK

As related work, four commercial tools were analyzed.

- A. *MyMathLab* [3]. This is an application developed by *Pearson Publishing*. This tool provides students additional online resources to improve their learning, but questions and materials are restricted only to textbook content. There is functionality so that the teacher can create their own independent resources. However, the price of the license is already included in the cost of the textbook, i.e. when a textbook is purchased, it contains an access code to create an account on the Web application.
- B. *Aleks*[4]. This application was developed by McGraw Hill. The content of materials ranges from elementary mathematical concepts to advanced undergraduate topics. It provides different types of feedback (hints and explanations). *Aleks* has an interesting feature that provides practice exercises in the application. The functionality is called "worksheets", which generates a pdf for printing with a series of exercises. *Aleks* is a robust application to practice and learn mathematical themes. However, this system does not include sophisticated assessment tools and lacks an appropriate functionality for the teacher, because their approach is to link it to other products (textbooks) where the main goal is learning, not assessing.
- C. *Hawkes* [5]. *Hawkes* is a desktop tool that runs on Windows platforms and for some courses on Mac platform. *Hawkes* was developed by the company *Hawkes Learning Systems*. Although this platform has no graphical tools it provides appropriate calculation tools and functionality to display answers in the form of equations. *Hawkes* presents on its web page a case study with 14 US universities, where a improvement in students' grades, savings in the cost of the course, and a study on the relation between classwork and work time out of class are reported.

- D. *ReadyMath* [6]. The *ReadyMath* application was developed by *iLearn* and *Ed2Go* companies and it is only available in English. The focus of this application is to support mathematics learning for undergraduate students. If a question is not answered correctly the system provides students an easier question. On the other hand, if the question has been answered correctly *ReadyMath* delivers a question with a higher difficulty level. The application displays immediate feedback to students showing the correct solution for wrong answers.

Additionally, it is also convenient to mention that some major publishers have provided robust online systems to their textbooks in order to enrich their learning resources. Most of them include tools to assess and give online feedback to students and to deliver performance statistics for teachers. Examples are: *Connect*, *WebAssign*, *MasteringPhysics* and *CengageNOW*, among others ([7], [8], [9], [10]). Nevertheless, the formats or syntaxes provided to write mathematical equations are usually rather limited, so students have first to learn how to write down their results in the system before solving the problem. Therefore, it can happen that even if the answer is mathematically correct, the system considers it as wrong. This could produce an unwanted and counterproductive effect on students, who could become confused and disappointed because they do not can find the origin of their mistakes.

Due to the fact that the main objective of the commercial tools or systems presented above is to support learning themes contained in the textbooks provided by these editorials, they do not include functionality for student assessment or only provide rather basic versions to this purpose. Nor are teachers allowed to create their own questions that are aligned to the particular curriculum or knowledge they want to evaluate. On the other hand, these systems do not always provide functionality to create diverse kinds of questions that teachers consider the most appropriate (multiple choice, open, etc.).

III. PROCESS

The development of the project was divided into 6 big steps, shown in figure 1: 1) definition of the characteristics and requirements of the system, 2) development of the system software, 3) elaboration of questions of diverse types, 4) testing of the system with teachers and students, 5) results gathering and analysis, and 6) discussion and conclusions.

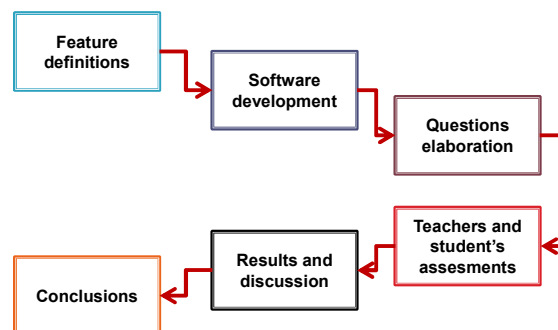

Figure 1. Main Phases of the project

A. Definition of TecEval's features

To define the characteristics and requirements of the system, several work sessions with expert teachers on Mathematics and Physics were organized. The main characteristics that were identified in these meetings are described next.

Services

It was defined that the system had to provide services to four types or main users:

- *Administrator*
- *User teacher*
- *Author teacher*
- *Student*

The *Administrator* takes care of the basic catalogues and information of the academic department (School, departments, semesters, assignments, topics, teachers and groups), and also of the security module for access control.

The *User teacher* functionality includes the management of his/her account to modify data, create exams, reopen exams and obtain reports.

The *Author teacher* has the option to add more questions, sections and themes to the course, in addition to the functionality of a User Teacher.

The *Student* has the functionality to select an exam already created, configured and activated by the teacher, to answer questions and to consult grades from current and past academic terms.

Types of questions

It was requested that *TecEval* should be able to create the following types of questions.

1. **Numerical questions:** This refers to questions whose answer is a number that is calculated from a specific formula, and lies within a given range of values.
2. **Multiple choice questions:** This refers to questions where the right answer or answers must be selected from multiple options. These options are provided when the question is designed. The question may have more than one correct answer. In this later case the level of difficulty of the question increases.
3. **Dynamic questions:** This refers to questions that depend on a formula whose variables can take values within certain specific ranges. In this way, each time a user solves a problem the value or values of the question change in a dynamic way within the specific range, although the formula for the general solution remains the same.
4. **Dynamic-equation questions:** This refers to questions whose answer is a mathematical equation. It has the additional possibility of posing questions including variables that can take values in certain ranges. These variables can change

dynamically. This possibility includes up to four dynamic variables.

A very important requisite of the system is that it has to be capable of grading questions of any kind automatically. Nevertheless, it also includes the option of allowing the teacher to manually grade questions whenever he/she may consider there were other possible answers.

Tools for representing equations

It was identified the necessity of having a tool to represent mathematical equations in two ways:

- A. Visual representation: It was required a visual representation of the equation for Web and tablets in a clear and elegant way, as shown in Figure 2. A control was defined that would allow teachers and students to write equations from a web browser (Desktop and tablets) [11]

$$\int_1^3 \sqrt{\frac{2x^9+1}{x^2+9}} dx \quad (1)$$

Figure 2. Example of the representation of a complex equation.

- B. Computational representation: In mathematical equations there is a problem when there are multiple equivalent ways of representing the same answer. For example: $3x + 2$ equals $2 + 3x$. Therefore, it has been established the necessity of generating a tree for the equation based on a lexicographic analyzer (it is a program that receives as input the source of another program (string) code and produces an output consisting of tokens or symbols), with the following rules:

- The priority order for basic operations is: addition, subtraction, multiplication and division.
- Fractions are transformed into divisions.
- Parenthesis, braces and brackets are deleted, and when appropriate, they're expressed in a multiplication form.

B. Software Development

During the investigation process to develop a computational platform for the automatic evaluation of exams, using the requirements described before, several difficulties and challenges were found. Among them the following are distinguished:

- a) *The functionality to evaluate automatically questions for Physics and Mathematics assignments.* In the case of

Physics a parser had to be used to allow answer computing based on formulas created by the teacher, which contains dynamic variables that change for each student. In the case of Mathematics the system should evaluate if a mathematical expression corresponds to a correct or to an incorrect answer.

b) *The challenge of creating a scalable platform that could be used from desktop computers, tablets, and/or a web browser.*

c) *The development of user-interfaces that are attractive to students and teachers alike.* They are interfaces designed to allow writing mathematical symbols in a practical form. Instructors can create questions and exams easily. The format for students is equally easy to use. The system can be used in both web and Android and iOS tablets.

TecEval's Platform consists of 3 main components (Fig. 3):

- Core:* Shared classes generated with EMF on Rails and Database
- Service Providers:* Spring MVC Web application and Service Server where all functionality and business rules exists.
- Clients:* Web and mobile browser using the services and business rules from the Service Server. Only UI/UX functionality exists here. More clients can be added over time.

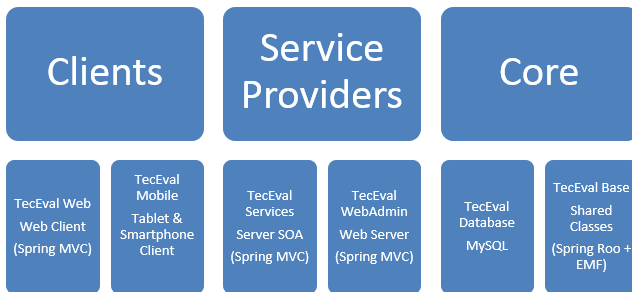

Figure 3. *TecEval's platform components.*

One of the core processes in *TecEval* is to get a mathematical expression from a web control and to save it as a tree data structure [11]. The process is done following the steps (Fig 4):

- Enter the mathematical expression in the web application.*
- Using Javascript the expression and the image of the expression are sent to TecEvalServices.*
- The image is saved in the server.*
- The expression is translated to MathML.*
- The MathML expression is translated in a tree.*
- The tree is saved to the database.*

The tools, models and technologies used in the development of *TecEval* were: Modelling with Unified Modelling Language (UML), Object-oriented language (Java) in a Service Oriented Architecture (SOA), EMF on Rails,

Spring MVC, Security Aspects, Web Technologies (HTML5, CSS, Javascript + JQuery), MathML, Mathematical Equations representation trees and regular expressions.

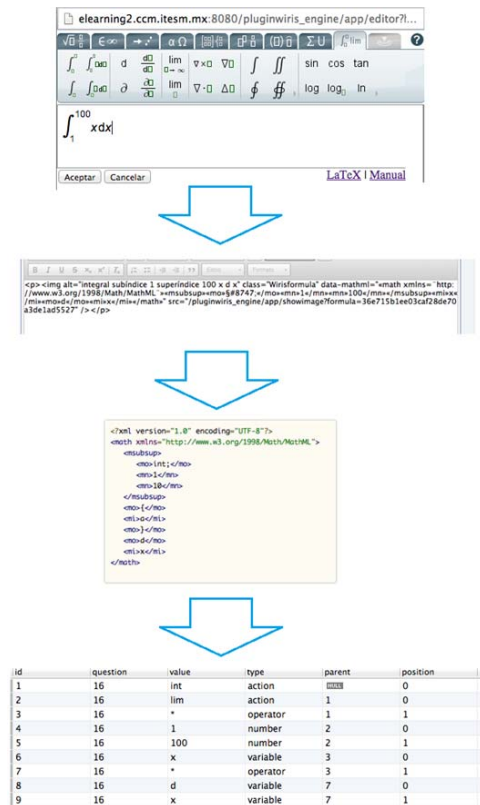

Figure 4. Workflow of a simple equation from the web application to the database.

Finally *TecEval* Services implements a 3-way security system to avoid reading or saving questions and answers without authorization [12].

IV. *TECEVAL* MAIN INTERFACES

The main interfaces of *TecEval* are presented next.

A. SYSTEM ACCESS

Students and teachers can access the system in the site (Fig. 5): <http://elnovus.ccm.itesm.mx:8181/TecEval/>

Figure 5. System login interface

When entering the username and password, *TecEval* activates the allowed functionality that corresponds to the type of user.

B. ADMINISTRATOR INTERFACE

In Figure 6 the administrator user view is shown. The administrator controls the Access to users, in addition to the functionalities described in section III.

Figure 6. Administrator interface example

The administrator also has the functionality of updating (Adding, removing, changing, and consulting) the following catalogues: institutions, schools or divisions, departments, terms, assignments, topics and groups.

Additionally, the administrator is responsible for the security module with the following specific functionalities: creating new users with any role, blocking/unblocking user accesses, consulting user information (except their passwords), and activating/deactivating users.

C. QUESTION CREATION

As it was mentioned in section III, *TecEval* allows the creation of different types of questions. These are briefly described next.

Numerical questions. In these questions the result is a number. *TecEval* allows defining a value range for the correct answer. In figure 7 an example is shown.

Figure 7. Example of a numerical type question.

Multiple-choice questions. When designing a multiple-choice question there are two modalities: questions with just one right answer or questions with more than one right answer. The system indicates to users the corresponding modality: for the one right answer modality *TecEval* displays small empty circles preceding the question options, while for a question

with more than one right answer the system displays small squares. In figure 8 an example of this kind of question is shown.

Figure 8. Example of a multiple-choice question

Dynamic questions. This kind of questions is particularly useful for Physics-like problems, in which up to 4 parameters in a given formula change each time a student enters the system, displaying problems with different data. The parameters take values randomly within certain specified ranges and the answer is a numerical value. In figure 9 an example of this question is shown.

Figure 9. Example of a dynamic question.

Dynamic-equation questions. The answer for these questions is a mathematical equation. The system allows teachers and students to write mathematical symbols in an easy way. This is accomplished using the WIRIS equation editor [13]. Teachers may represent the answers up to three different ways and the system can grade them automatically. In this kind of questions it's possible to change up to 4 parameters, so they appear in a different way to each student each time an exam is presented. In Figure 10 an example is shown.

Figure 10. Example of a Dynamic-equation question.

D. EXAM CREATION

A model to facilitate the teacher the creation of exam was developed based on questions previously created by other teachers. Exams are organized by assignment and topic. The functionality is described below.

To create an exam its name, timespan to solve it, the corresponding course, and the topic(s) that the exam covers have to be defined. The teacher is allowed to define whether the student can see or not the correct answers at the end of the exam, the number of allowed attempts to solve it, and the question order. The teacher can also indicate some general instructions and select the appropriate questions the exam will contain. This selection can be done in several forms:

- From a tree of previously created questions, the root is taken to add questions and create the exam.
- From a list of questions previously created.
- The teacher can create questions during the allowed timespan assigned to solve the exam.
- The teacher can ask the system to randomly select questions previously created.

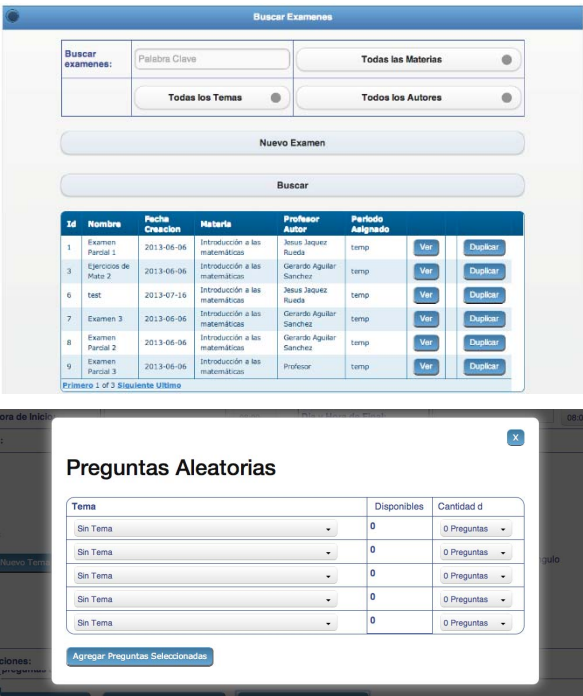

Figure 11. Example of an exam creation.

In Fig. 11 an example of an exam creation is shown.

The questions and exams created by a teacher can be shared with other colleagues. However a teacher cannot directly edit questions or exams created by another teacher in the main database. For this purpose, he/she should first create a copy of the selected resources in a new entry and afterwards edit and adequate them to his/her courses.

E. SOLVING EXAMS

To answer an exam, the student must enter the assignment section and select the exam that he/she has to solve. In the test *TecEval* displays the time given and the number of attempts that the student has to solve it. The student has the option to hide the chronometer during the exam. Due to the structure of *TecEval*, the writing of Mathematical symbols is simple for the student. In case of disconnection, the system registers the precise place where the student left the test at that moment, and *TecEval* will allow him/her to continue solving the exam just in that place. The interface for solving exams is illustrated in figure 12.

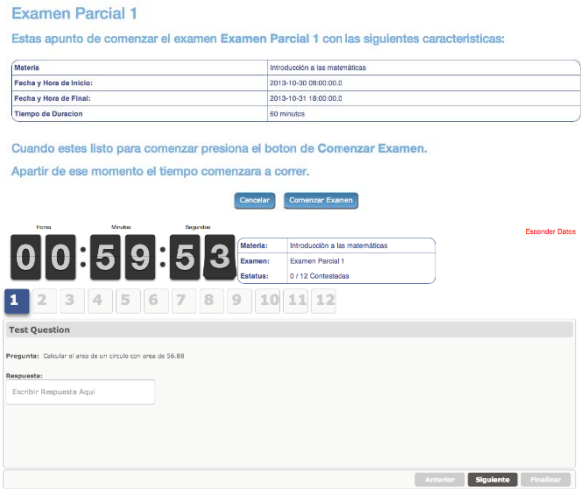

Figure 12. Student interface during an exam.

F. SCORES

The teacher can consult the students' grades by question, exam, group, student, or topic, as seen in figure 13. This allows them to provide appropriate feedback to students. On the other hand, the system also allows students to consult their performance immediately after completing the exam and check their grades in previous exams. Additionally, the head of the department can monitor student performance by assignment or group. All these reports can be downloaded in PDF format.

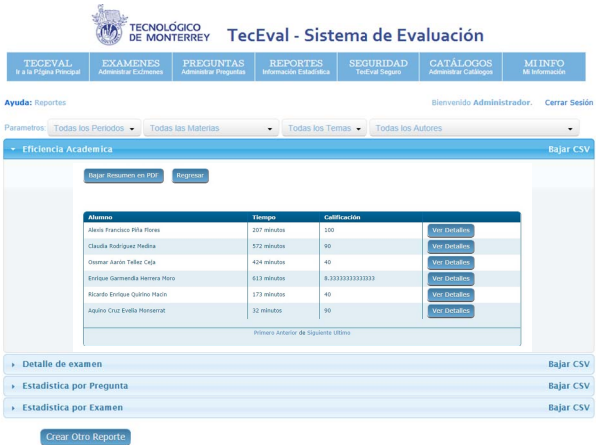

Figure 13. Example of the interface to consult grades

V. EVALUATION, RESULTS AND DISCUSSION

Testing sessions for the system were carried out during two weeks in the January-May 2014 term, where 9 teachers of Physics, Mathematics and Computing used the system in their courses. During this period some adjustments and improvements to *TecEval* emerged. In general, the perception on *TecEval* provided by teachers was good. Indeed, most professors found it easy to use this system (88%), and 89% of them felt that the system would be useful in their academic areas. On the other hand, 67% of them stated they would use *TecEval* in their courses, while the remaining 33% indicated that they would also use it once it incorporates some suggested modifications. Additionally, the results for specific questions of a survey applied to teachers regarding the functionality of the system are presented in Fig. 14.

Figure 14. Results of the survey questionnaire applied to teachers

Tests were also conducted with 26 students of the Engineering area during the same term. Students worked in assignments of their courses using *TecEval*. After the assignment, they were asked to answer a survey questionnaire. The corresponding results are presented in figure 15. In general, the perception of the students was good: 62% said that it was easy to use the application, and 64% said that it was easy to do assignments and tests in *TecEval*. A comparison of opinions between doing exams in *TecEval* against doing them elsewhere resulted to be divided: 31% of the students think it is better, 31% think it is worse, and the remaining 38% had a neutral opinion. Finally, we found that 73% of the students and the teachers said that the platform has a nice design and it was easy to use, and some students even asked for a smartphone version of *TecEval*.

An additional feature of the system is the possibility of including open questions to be graded automatically. Although the kind of questions included so far in *TecEval* were designed for Mathematics and Physics, the system can also be adapted to be used in other disciplines.

Figure 15. Results obtained in the students' perception questionnaire

Finally, the following points describe the main advantages and disadvantages of *TecEval*:

A. Advantages for teachers

Creation and management of appropriate questions and exams that correspond to specific curricular material. The teacher can add his own questions, share quizzes and questions with other teachers, and carry out analysis and evaluation of students' performance.

B. Advantages for students

It is an additional tool to self-evaluation for curricular material. Students can access the exams through mobile devices, with optimal security measures.

C. Possible disadvantages

Server failures would affect the presentation of the quizzes.

V. CONCLUSIONS

TecEval system allows the creation of diverse types of questions and tests in engineering areas that need an appropriate mathematical notation, in a simple way for the teacher. The system allows teachers to design their own questions according to the learning needs of their students. Writing mathematical symbols is simple for both teacher and students, even for complicated formulae and specialized mathematical symbols. The system also permits adding figures to complement the questions.

In a test of the system performance both, teachers and students, expressed a favorable opinion on the usability of *TecEval* when compared to other assessment systems.

Additionally, *TecEval* allows the collaboration and synergy between colleagues of the same or different areas, who can share both questions and exams. It has also a great flexibility in content management. An important feature of the system is that it can be accessed via web or from tablets. The system can deliver appropriate statistics that facilitate the administration of the course, and also can provide teachers and students with timely and group feedback. This feedback leads to a better learning of subject topics. Finally, it is important to note that *TecEval* also permits users to carry out searches by subject and

group. As future work, more tests of the system will be conducted with students and teachers of Mathematics and Physics courses in order to improve its performance.

VI. ACKNOWLEDGMENTS

This project was supported by *Fondo Novus 2013* grant of Tecnológico de Monterrey. The authors want to thank the following persons: Dr. Linda Medina-Herrera, Dr. Andrés González-Nucamendi, Dr. Jaime Castro Pérez, Dr. Rosa María García Castelán, MSc Marlene Aguilar Ábalo and Dr. Víctor Francisco Robledo Rella from the Physics and Mathematics Department of Mexico City Campus; Dr. Gerardo Javier Alanis Funes from the Computer Department; and Héctor Alberto Rueda Zárate, Alejandro Cárdenas Ovando and David Escobar Castillejos for their participation in the testing process.

Abstract—This Work In Progress describes a NSF funded project to revise/simplify our research instruments used to measure ethical development of engineering undergraduates and make them useful for practical applications. Results of this project will provide a way for institutions, programs, and faculty to assess the impact of ethics initiatives at the, course, co-curricular, or single intervention level. As such, it has the potential to transform the way in which undergraduate engineering education is delivered by allowing individual institutions, programs, and faculty to assess and improve on their own ethics initiatives. In this paper we describe the method for reducing the full instrument to a more practical tool and initial steps at pilot testing.

Keywords—ethics, assessment, moral reasoning

I. INTRODUCTION (HEADING 1)

The work described in this paper is an outgrowth of the Survey of Engineering Ethical Development (SEED) project. Here we describe the refinement of the SEED survey to a tool that is more practical for use in assessing the impact of individual curricular or co-curricular interventions. Development of the SEED-PA (Survey of Engineering Ethical Development – Practical Assessment) is guided by four goals: Goal 1: create a practical instrument for assessing individual ethics initiatives (SEED-PA); Goal 2: use the SEED-PA to conduct four separate studies addressing important research questions and demonstrating the utility of the instrument; Goal 3: develop the SEED-PA User's Guide to assist in research design, administration, data analysis, and interpretation of results; Goal 4: broadly disseminate the SEED-PA instrument and the SEED-PA User's Guide.

To date, the researchers have created the SEED-PA (Goal 1) and pilot tested the instrument at our four institutions (Goal 2). The researchers have also begun to work on a User's Guide (Goal 3) including documenting the process for online administration, describing how the survey can be adjusted to measure what was taught in a course, and explaining how student data can be used to understand how students interpret faculty interventions. The researchers have also addressed limitations of what can be evaluated given that we are not using controlled experimental conditions in this analysis.

Overall, the SEED-PA will be a useful tool for assessing learning and evaluating innovations related to students' ethical development. The project spans multiple institutions and involves the creation and adaptation of an assessment tool that may contribute to our understanding of engineering students' ethical development. Thus, it will allow the researchers to learn how new strategies for ethics instruction are transferred to diverse settings and how they impact student learning. Finally, the researchers expect to bring about the widespread adoption and implementation of the SEED-PA. Thus, the user's guide will be designed in such a way to assist the community in transferring its use.

II. THE SEED INSTRUMENT AND THE SEED-PA

A. The SEED Instrument

The focus of the 2010 SEED study was to assess the state of ethical education in engineering programs nation-wide. Consequently, it included 227 items related to students' past and current experiences with ethics interventions in and out of

the classroom. Results from the SEED survey and the instrument have been published elsewhere [1-5].

B. Reframing the SEED into the SEED-PA

The first step in reframing the SEED instrument into the SEED-PA instrument was to remove all items not related to the new purpose of testing the efficacy of a single ethics instruction or intervention. These included the majority of items serving as explanatory variables, including past curricular and co-curricular experiences, specific engineering major, and high school grade point average.

The next step in reframing was to test a new set of items intended to measure whether students' pro-social and anti-social behaviors were pre-planned or spontaneous. In order to do so, we conducted three pilot test sessions with 24 undergraduate engineering students at a doctorate-granting, very high research institution. Each session was 50 minutes and all participants received a \$20 Amazon.com gift certificate as an incentive. The test functioned in an iterative manner, with each group viewing and being asked about a set of items which were then rewritten based upon their feedback and tested with a subsequent group. The final versions of the altered items are shown in Table I.

Two other items were tested related to students' potential reluctance to cheat or potential to ignore reluctant thoughts. These items were ultimately discarded when students could neither appropriately interpret the provided items nor suggest suitable alternate language.

The final step in reframing was to create two instruments which could be used in tandem and be administered prior to and after an ethics intervention. Items measuring demographics were removed from the post-intervention survey because data are collected on the first instrument and because the two response sets are intended to be merged together by a unique identifier. For most items the language was simply adjusted from plans and intentions in the pre-intervention survey to actual experiences and behaviors in the post survey. We also created items to measure students' satisfaction with and perception of value of the intervention just experienced, as well as a measure of the types of pedagogy they perceived were used, which was intended to be matched against the instructor's description of the actual pedagogical techniques. A comparison of the initial SEED instrument to the SEED-PA pre- and post-intervention surveys is provided in Tables II and III.

TABLE I. COMPARISON OF SEED AND SEED-PA PRO-SOCIAL AND ANTI-SOCIAL ITEM WORDING

Pre-Intervention Survey	Post-Intervention Survey
Do you intend to volunteer for a service project during the current term? <ul style="list-style-type: none"> Yes No 	During the past term were you part of any volunteer service projects? <ul style="list-style-type: none"> Yes No
How will you figure out the details of volunteering? <ul style="list-style-type: none"> I already have a plan for how I will volunteer I don't have a plan yet, but figure one out ahead of time I won't have a plan, I'll just volunteer when an opportunity arises 	Did you create a plan for volunteering for a service project? <ul style="list-style-type: none"> Yes, I had a plan ahead of time for how I would volunteer No, I just volunteered when the opportunity arose
Do you intend to cheat on homework (in any course, not just this one) during the current term? <ul style="list-style-type: none"> Yes No 	During the past term, how often did you cheat on homework? <ul style="list-style-type: none"> Every time I had a homework assignment Almost every time I had a homework assignment About half of the times I had a homework assignment A few of the times I had a homework assignment One time Never
How will you figure out how to cheat? <ul style="list-style-type: none"> I already have a plan for how to cheat I don't have a plan yet, but will figure one out ahead of time I won't have a plan, I'll just cheat when an opportunity arises 	Did you create a plan for cheating? <ul style="list-style-type: none"> Yes, I had a plan ahead of time for how I would cheat No, I just cheated when the opportunity arose

III. RESULTS OF SEED-PA FROM PILOT STUDIES

Over the course of a single academic year, four pilot studies were conducted as part of the development of the SEED-PA instrument. Two schools participated in the survey – School A and School B. Three sets of data from School A (Spring 2013, Fall 2013, and Spring 2014) and one set from School B (Fall 2013) are presented here. A total of 35 students were surveyed at School A and 26 at School B. Respondents from School A were enrolled in a senior level course on ethics in civil engineering, while students from School B were enrolled in a first-year engineering course. For each set of data, both a pre- and post-intervention survey were administered.

Explanatory Variables			
	SEED		SEED-PA
<i>Formal Curricular Experiences:</i> <ul style="list-style-type: none"> • Nine pedagogical methods by seven settings in which they might have occurred • For the most influential experience, an item about Bloom's Taxonomy and an item about likelihood of that experience influencing a future decision • An item about overall satisfaction with ethics instruction 	66 items	<i>Formal Curricular Experiences:</i> <ul style="list-style-type: none"> • Items about overall satisfaction with ethics instruction to date and the importance of professional ethics to engineering education • Items about the specific ethics intervention: satisfaction with instruction, value of instruction, type of pedagogical method experienced, and perception of value when used to confront future professional ethical dilemma 	Pre-survey: 2 items Post-survey: 1 item
<i>Co-Curricular Experiences</i> For each of five engineering activities (e.g. engineering design team, professional engineering student society) and ten non-engineering activities (e.g. student government, varsity athletics), items measuring: <ul style="list-style-type: none"> • Frequency of participation • Status as an elected or appointed leader • Participation in volunteer service sponsored by the group 	45 items	<i>Co-curricular Experiences</i> A multiple-response item about participation in a range of student organizations	1 item
<i>Student Characteristics</i> Class level, transfer status, age, gender, citizenship, race, ethnicity, full-time/part-time status, specific engineering major, final high school grade point average, current college grade point average, primary language, political orientation	13 items	<i>Student Characteristics</i> Class level, transfer status, age, gender, citizenship, race, ethnicity, full-time/part-time status, current college grade point average, primary language, political orientation	Pre-survey: 11 items Post-survey: None

Outcome Variables			
<i>Knowledge of Ethics</i> Ethics questions from Fundamentals of Engineering Exam	5 items	<i>Knowledge of Ethics</i> Ethics questions from Fundamentals of Engineering Exam	5 items
<i>Ethical Reasoning</i> DIT2 Scores calculated by the Center for the Study of Ethical Development including P score, N2 score, Personal Interest score, Maintaining Norms score [6]	85 items	<i>Ethical Reasoning</i> DIT2 Scores calculated by the Center for the Study of Ethical Development including P score, N2 score, Personal Interest score, Maintaining Norms score [6]	85 items
<i>Pro-social ethical behavior</i> Items about course-taking due to a community service component, participating in K-12 outreach, and participation involunteer service	5 items	<i>Pro-social ethical behavior</i> Items about participation in volunteer service in college and high school, intent to volunteer in the current term, plan for accomplishing volunteer service Items about participation in volunteer service in past term and creation of plan for accomplishing volunteer service.	Pre-survey: 4 items Post-survey: 2 items
<i>Anti-social Ethical Behavior</i> Items about frequency of cheating in high school and college	8 items	<i>Anti-social Ethical Behavior</i> Items about frequency of cheating in college and high school, intent to cheat in the current term, plan for accomplishing cheating Items about cheating in past term and creation of a plan for cheating	Pre-survey: 4 items Post-survey: 2 items

Over the course of the four pilot studies it was clear that the response rate varied considerably depending on what incentives were used. We attempted several pilot studies without incentives in relatively large courses at two universities other than School A and B. In both cases, the lack of incentives resulted in low response rates. The response rate for the pre-intervention tests was 3-10%, causing us to cancel the post-intervention tests as there would be insufficient data to analyze. At School A two incentive strategies were used. In the first case, we offered respondents a chance to win a \$100 Amazon.com™ gift card if they completed the pre-intervention test and an added \$20 Amazon.com™ gift card if they completed the post-intervention test. In this case the pre-intervention response rate was 50% and the post-intervention response rate was 86% for a net response rate of 43%. For the second intervention strategy, respondents were told that

participation in the SEED-PA pilot study was required for course credit. In this case, the pre- and post-intervention response rate was 100%, resulting in a net response rate of 100%. Finally the pilot study at School B used a different incentive strategy. Respondents were given two bonus points on the final exam if they completed both the pre- and post-intervention SEED-PA instruments. In this case the pre-intervention response rate was 85% and the post-intervention response rate was 52% for a net response rate of 44%. From these data it seems apparent that students are unlikely to complete the SEED-PA unless some form of incentive is provided. This incentive need not be financial, as the School A and School B pilot tests resulted in good response rates with promises of course credit or extra credit.

B. Explanatory Variables Other Than Demographics

For formal curricular experiences both School A and B respondents viewed the importance of ethics instruction as "Important" with a total of 50% of respondents choosing this response. Responses differed between the two institutions with respect to satisfaction with prior ethics interventions. School A students reported that "I haven't had any" (65%) while School B students were generally "Satisfied" (58%). From the post-test survey we are able to determine what pedagogy students experienced in formal curricular settings. From this multi-response item we can discern that respondents from School B indicated "Presentation by a professor", "Movie or film", and "Small groups or class discussion". School A respondents indicated similar experiences, but rather than a movie or film indicated that they experienced a "Presentation by a speaker".

C. Outcome Variables

Outcome variables are grouped into three categories: knowledge of ethics, ethical reasoning, and ethical behavior. Results from the knowledge of ethic items were compared for both pre-test and post-test surveys using a paired sample t-test with a 95 percent confidence interval. For the School B respondents only one item showed a significant difference between the pre- and post-test results, while for the School A respondents there were no significant differences in the before and after results. Thus we can conclude that there is no apparent change in the ethics knowledge of the participants as measured by the SEED-PA from pre- to post-intervention regardless of the nature of the intervention. This lack of significance may well be due to the fact that the sample sizes for the pilot studies were relatively small.

Ethical reasoning was measured using the DIT2 questionnaire and resulted in four scores that define an individual's moral reasoning capacity: N2 score, P score, Personal interest score, and Maintaining norms score [6]. No significant differences were found between the pre- and post-test survey results for any of the four scores with respect to either the School A or School B respondents.

Ethical behavior was assessed using pro-social and anti-social items focused on either volunteering or cheating. No statistically significant differences were observed in respondents self-reported pro-social or anti-social behaviors.

IV. CONCLUSIONS

From an analysis of four pilot studies at two institutions, the following conclusions about the SEED-PA instrument can be offered:

- We have generated a simplified and specific instrument (SEED-PA) from a larger research tested instrument (SEED) for measurement of ethical development in engineering undergraduates.
- Use of an incentive is necessary to assure sufficient response rate to the instrument for data analysis. However, the incentive need not be financial as academic incentives were found to provide sufficient response rates.
- The SEED-PA was unable to find significant differences in any of the measured outcome variables which may be a result of the short time interval between pre- and post-intervention or the relatively small sample sizes of the pilot tests.

ACKNOWLEDGMENT

We thank the students who graciously completed the pilot instrument described in this paper and the faculty and staff who supported its distribution.

Abstract—Today's educational systems require students to recall and apply major concepts from study material to perform competently in assessments. Crucial to achieving this is practice and self-assessment through questions. The crafting of such questions can be time consuming for teachers while questions from external sources, e.g. assessment books, might not be tailored to suit students' study materials. As such, we present RevUP: an automated system for Gap-Fill Question Generation (GFQG) from educational texts. Example GFQs generated by RevUP from a high-school biology textbook are as follows.

- *Endocrine signals generated by the hypothalamus regulate hormone secretion by the _____.*
(a) posterior pituitary (b) anterior pituitary
(c) thyroid gland (d) pineal gland

Our system factors the problem of generating good questions into 3 parts:

- 1) Selecting topically important sentences to ask about
- 2) Identifying which part of the resulting sentence to choose as the gap
- 3) Crafting effective distractors to be part of the set of options to confuse the learner

The immediate advantage of this service is that it provides the tools that make it easy for teachers to quickly generate and edit questions for pop quizzes and worksheets from their lecture notes. In the paper, we will provide a detailed description of the methodology used to generate questions. We will also provide preliminary usability statistics from high school students where they qualified the usability and the negative aspects of the application.

I. INTRODUCTION

Knowledge acquisition is central to educational systems today. This requires a student to be able to recall and apply major concepts from study material to perform competently in assessments. Crucial to this is practice and self-assessment through questions. Questioning has been found to be an effective method of helping students learn better [1]. However, such questions are not easily accessible to students leading them to solely depend on teachers for practice material. On the other hand, continued crafting of varied questions is extremely time consuming [2]. Furthermore, learners are increasingly moving from the traditional classroom setting to an independent learning setting online [3]. The Internet is a treasure trove of texts, some of which could match the educational needs of students.

However, much of these texts do not come with instructional content that conventional classroom material provide. Here, there is a need for leveraging upon online educational texts to provide practice material for students.

Automatic Question Generation (AQG) shows promise for both these use-cases. AQG can provide extra practice material to students, for self-assessment to help reinforce concepts learnt during lessons. On the other hand, AQG can assist teachers in the laborious task of setting questions which could help free time and resources. Furthermore, AQG can be valuable in generating questions from arbitrary text for online learners.

However, most contemporary AQG systems have focused on generating grammatically and syntactically correct questions with little attention given to the semantics and educational relevance of the questions. To overcome these problems, we built a system, harnessing cutting edge computer science techniques, for automatic Gap-Fill Question Generation (GFQG) from educational texts such as lecture notes. In this Work-In-Progress paper, we will first provide a description of the application and examples of some questions generated by the system. This will be followed by a high-level description of the methodology used to generate questions. Finally, we will provide results of a very preliminary evaluation with 15 students where we requested participants to rate the questions generated by the system, the negative aspects of the application and ideas to improve the application. The study validates the promise of the system and also provides a set of future directions to pursue for the completion of the system.

II. SYSTEM DESCRIPTION

Our system generates gap-fill multiple choice questions from educational texts such as lecture notes. Example questions generated by our system from a high school biology textbook are as follows. The correct answers are in bold.

- 1) Endocrine signals generated by the hypothalamus regulate hormone secretion by the _____.
(a) posterior pituitary **(b) anterior pituitary**
(c) thyroid gland (d) pineal gland
- 2) _____ also use their hydrolytic enzymes to recycle the cells own organic material, a process called autophagy.

- (a) Endosomes (b) Organelles
(c) **Lysosomes** (d) Golgi Apparatus
- 3) Ribosomes facilitate the specific coupling of tRNA anticodons with mRNA codons during _____.
(a) DNA Replication (b) DNA Synthesis
(c) RNA Splicing (d) **protein synthesis**
- 4) NaCl diffusing from the ascending limb helps maintain a high osmolarity in the interstitial fluid of the _____.
(a) juxtamedullary nephron (b) **renal medulla**
(c) collecting duct (d) peritubular capillary

Throughout this paper, we will refer to the question sentence as the *sentence*. The correct answer to the blank in the sentence will be referred to as the *gap*. The wrong options will be referred to as *distractors*.

III. METHODOLOGY

Our system factors the problem of generating educationally relevant gap-fill multiple choice questions from educational texts into 3 parts:

- 1) **Sentence Selection:** Selecting coherent and important sentences from the text to ask about
- 2) **Gap Selection:** Identifying which part of the resulting sentence to choose as the gap. The gap essentially represents the concept being tested
- 3) **Distractor Selection:** Crafting effective distractors to be part of the set of options to confuse the learner to ensure that he has a good grasp of the concept being tested

Our system builds upon and proposes accurate techniques spanning the fields of Artificial Intelligence, Machine Learning and Natural Language Processing to solve each of the above-mentioned problems. We do not delve into the details of the algorithms used but a high-level description of the methods used are provided in the following subsections.

A. Sentence Selection

Here, we aim to select sentences that are coherent (express a few core ideas) and contain important information. Such a task requires domain knowledge. As such, we trained a neural network based topic model to discover concepts and topics from a high school biology textbook ???. These topics and concepts served as the basis for selecting important and coherent sentences.

Since the topics and concepts discovered were biology-related, questions generated by our system, as described in this paper, will be biology related. However, extension to other subject domains is trivial and only text covering most of the key concepts is required.

B. Gap Selection

We found that selecting an educationally relevant gap was one that depended on qualitative human judgement. As such, we collected human judgements (good/bad) on about 1200

gaps through the Amazon Mechanical Turk platform. This data was used to train a machine learning model. The specific model chosen was a Gaussian Kernel Support Vector Machine. After training, the machine learning model was able to distinguish between good and bad gaps. Validation of the model yielded an accuracy of 81% ??.

C. Distractor Selection

Our method selects distractors that fulfill the following properties best.

- *Semantic Similarity:* Distractors need to be similar in meaning to the gap. To do so, we use the word2vec tool. Word2vec learns and obtain distributed representations of words, from input texts, in a vector space which spatially encodes the semantic information of these words. As such, to find semantically similar distractors, we search for words that are closest to the gap in the vector space ??. To train the word2vec, we used texts from Wikipedia.
- *Syntactic Similarity:* Distractors that often look similar to the gap can be good. For e.g., t-phase is probably as good distractor for g-phase. We captured such syntactic similarities by computing the Dice Coefficient for the gap-phrase and each candidate distractor ??.
- *Contextual Fit:* Distractors need to fit into the question sentence. To do so, we used a language model to calculate the probability of a candidate distractor occurring in the question ??. The higher the probability, the greater the context fit.

IV. PRELIMINARY STUDIES

In this section, we will provide and analyse some preliminary statistics we have collected using the proposed system with students. The goal of the preliminary study is to provide metrics that could provide insights into the effectiveness of the system and also its efficacy in fulfilling students' needs.

A high school biology, *Campbell Biology, 9th Edition* textbook was used as the domain knowledge for the question generation system in the experiments. **15** students from NUS High School, whom had taken at least 4 years of high school biology, were recruited for the study. The students were aged between 15 and 18. We requested all the students to complete 3 main tasks. The description for each task and the results are presented in following paragraphs.

A. Question Rating

In the first task, our goal was to assess the educational relevance of the questions generated by our system. To do so, each student was tasked to provide us with a high school biology text of his/her choice. A list of questions were generated for each text and the students were asked to rate each question on a scale of 0 to 3. A cascade rating scheme was used as illustrated in Table I. From the texts that the **15** students sent, **495** questions were collectively generated. Figure 1 shows the number of questions that belongs to each rating band.

In terms of sentence and gap selection, our system performed

Rating	Requirements
0	Sentence is bad; Does not matter whether gap and distractors are good or bad.
1	Sentence is good, gap is bad; Does not matter whether distractors are good or bad.
2	Sentence and gap are good but distractors are bad.
3	Sentence, gap and distractors are all good.

TABLE I. QUESTION RATING SCHEME

Fig. 1. Number of questions in each rating band

very well. 94% of sentences 87% of gaps were considered good. However, this was not the case of distractor selection where only 60% of the distractors were considered good. This can be mainly attributed to the fact that our algorithm, in its current state, is not able to reject distractors that could be correct answers to the question. More work is needed to build complete the question generation system.

B. Efficacy of System

The students were also posed the following question: "Do you think these questions serve as an effective memory tool to help you remember concepts learnt from notes". The aim of this question was to gain an understanding on how effective students perceive this tool to be. We found that **14** out of the **15** students answered "Yes" to the above question. The student who said "No" felt that the questions should require more critical-thinking. Nevertheless, this result is encouraging and serves as a reaffirmation of our approach.

C. Improvements

In the final task, students were posed the following question: "Do you have any suggested improvements?". our aim was to gather information on certain improvements students wanted to see in our final system to focus our efforts on the right areas.

- **Better Distractors:** One of the main concerns was the lack of good distractors. Apart from the fact that certain distractors were correct answers to the question, students expressed a need for more "confusing" distractors.

- **Question Variety:** On the other hand, a few students noted that there were repetitive questions tested on the same key concept. As such, we have to look into ways on increasing the variety of the questions generated. The re-wording of questions to make them more comprehensible to the reader was also proposed. We also hope to look into generating questions that test higher order thinking skills.
- **Tuning Difficulty:** Another interesting suggestion brought up included the addition of a feature to tune the difficulty of questions.

V. CONCLUSION

In this paper, we presented the preliminary version of our proposed automatic question generation system for student self-assessment by leveraging . The immediate advantage of this service is that it provides the tools that make it easy for teachers to quickly generate and edit questions for pop quizzes and worksheets from their lecture notes. These questions, as compared to those from practice books, etc. would be more relevant to the notes uploaded. Preliminary testing was also done with students. First, the quality of the questions generated was assessed. 94% of the question sentences, 87% of the gaps and 60% of the distractors were considered to be educationally relevant. Second, we found that 14 out of the 15 students surveyed found the system to be effective in helping to reinforce concepts. Finally, we gained insights into improvements they want to see implemented in the final system. The results obtained have been encouraging have given us clarity on the direction to be henceforth pursued.

VI. FUTURE WORK

To complete the system, we would be working on the improvements suggested by the students surveyed. Thereafter, we would like to take a more teacher-centric approach to the system. We feel that it would be useful if our system could pinpoint the certain topics that students make the most errors in, based on their answers to the auto-generated questions. This would allow tutors to re-emphasise those concepts in class whilst enabling students to focus on the concepts that they lack knowledge in. Furthermore, studies with teacher-participants to assess the effectiveness of our system could be useful. We also plan to assess how the system can contribute to preparing students for examinations.

Pluggable Reputation Systems for Peer Review: a Web-Service Approach

Yang Song, Zhewei Hu, Edward F. Gehringer

Department of Computer Science
North Carolina State University
Raleigh, NC, U.S.
[ysong8, zhu6, efg]@ncsu.edu

Abstract—Peer review has long been used in education to provide students more timely feedback and allow them to learn from each other's work. In large courses and MOOCs, there is also interest in having students determine, or help determine, their classmates' grades. This requires a way to tell which peer reviewers' scores are credible. This can be done by comparing scores assigned by different reviewers with each other, and with scores that the instructor would have assigned. For this reason, several *reputation systems* have been designed; but until now, they have not been compared with each other, so we have no information about which performs best. To make the reputation algorithms pluggable for different peer-review system, we are carrying out a project to develop a reputation web service. This paper compares two reputation algorithms, each of which has two versions, and reports on our efforts to make them "pluggable," so they can easily be adopted by different peer-review systems. Toward this end, we have defined a Peer-Review Markup Language (PRML), which is a generic schema for data sharing among different peer-review systems.

Keywords—educational peer review; reputation system; web service

I. INTRODUCTION

Online peer-review systems are now in common use in higher education. They free the instructor and course staff from having to provide personally all the feedback that students receive on their work [1]. However, if we want to assure that all students receive competent feedback, or even use peer-assigned grades, we need a way to judge which peer reviewers are most credible. The solution is to use a *reputation system* [2]. Reputation systems may take various factors into account:

- Does a reviewer assign scores that are similar to scores assigned by the instructor (on work that they both grade)?
- Does a reviewer assign scores that match those assigned by other reviewers?
- Does the reviewer assign different scores to different work?
- How competent has the reviewer been on other work done for the class?

Any or all of this information may be factored into a reviewer's reputation. Not only does this help us determine what grade to award student authors; it also helps students see how effective they are as reviewers.

In the past, with small size classes, reputation systems were seen as an ancillary function of peer-review systems. However, in a large class they are essential, and in a MOOC, they are indispensable [3]. There is simply no other way to assess large volumes of work that cannot be automatically graded.

The same reputation algorithm can be used by many different peer-review systems. We have a multi-campus NSF-funded project to develop web services for peer review. Our project will develop pluggable reputation systems that can be deployed in many different peer-review systems. These reputation systems can assign grades calculated as a linear combination of student-assigned grades, with competent reviewers' scores weighted more heavily.

Once reputation systems have been deployed as web services, peer-review researchers will be able to use them to calculate scores on assignments, both past and present (past data can be used to tune the algorithms). This will yield the following benefits: (1) peer-review systems that lack reputation systems may use one of ours without coding it in their system; (2) instructors will be able to experiment with different reputation systems for their own classes, without implementing them locally; and (3) the information that we gather from this experimentation will help us recommend reputation systems appropriate for different kinds of assignments and courses.

II. ALGORITHMS SUPPORTED

Inputs of reputation algorithms vary, but a common way to represent review scores is to use an adjacency matrix. In this matrix, each row represents an artifact and each column represents a reviewer. The values of the matrix are the scores given to each artifact by each reviewer. Reputation algorithms use the matrix to generate two quantities: the reputation values for each reviewer and the weighted grades for each artifact.

It would be simplest to assign reputations based on agreement with expert (instructor) grades. But, in practice, instructor grades are not always available, so reputation algorithms need to calculate reviewer reputations and weighted scores for artifacts recursively till they reach convergence.

To give a precise definition of the algorithms supported in our web service, let a be an artifact; A be the set of all the artifacts; r be a reviewer; R be the set of all the reviewers; g_a^r

This project is sponsored by the National Science Foundation, on grant DUE 1432347.

be the grade that r assigned to a ; R_r be the set of artifacts reviewed by r ; A_a be the set of reviewers who have reviewed a ; W_r be the weight for reviewer r ; G_{expert}^a be the expert grade for artifact a ; $G_{predict}^a$ be the grade that the algorithm predicts for artifact a based on current reputations; and G^a be the temporal grade for artifact a in the algorithm.

In the Hamer algorithm (we call it Hamer-peer in this paper) [4], $G_{predict}^a$ is the weighted average of the grades assigned to a :

$$G_{predict}^a = \sum_{r \in A_a} g_r^a \times W_r / \sum_{r \in A_a} W_r \quad (1)$$

$G_{predict}^a$ is then used to update the reviewers' weights since the expert grades are not considered available: $G^a = G_{predict}^a$.

The variances in the scores assigned by each reviewer are calculated based on how close their grades are to the predicted weighted grades:

$$\Delta_r = \sum_{a \in R_r} (G^a - g_r^a)^2 / |R_r| \quad (2)$$

With the Δ_r for all the $r \in R$, we can tell whether a reviewer's variance is higher or lower than average:

$$W_r' = \text{mean} \Delta_r / \Delta_r \quad (3)$$

So the higher W_r' is for $r \in R$, the "better" a reviewer r is. The range for W_r' is $(0, \infty)$.

To avoid having the reviewers with higher W_r' "dominate" the grade aggregation, Hamer used a "log-damping" approach to calculate the W_r :

$$W_r = \begin{cases} 2 + \log(W_r' - 1) & W_r' > 2 \\ W_r' & W_r' \leq 2 \end{cases} \quad (4)$$

W_r and $G_{predict}^a$ are calculated iteratively till they converge.

However, if expert grades are available, it is unnecessary to calculate $G_{predict}^a$; instead, G_{expert}^a can be used as G^a : $G^a = G_{expert}^a$. With this modification, we can use similar processes to derive an implementation of the Hamer-peer algorithm with expert grades (Hamer-expert). The difference is that this algorithm does not need to be run multiple times because G^a does not change from one round to the next.

The ranges for both Hamer-peer and Hamer-expert are $(0, \infty)$. If a review's reputation score is greater than 1, this reviewer is considered to be above average.

In contrast to the Hamer algorithms, the reputation range calculated by the Lauw algorithm (we call it Lauw-peer in this paper) [5] is $[0, 1]$. A reputation score close to 1 means the reviewer is credible.

The main difference between the Hamer-peer and the Lauw-peer algorithm is that the Lauw-peer algorithm keeps track of the reviewer's leniency ("bias"), which can be either positive or negative. A positive leniency indicates the reviewer tends to give higher scores than average.

Let l_r be the leniency of r . After $G_{predict}^a$ is calculated for each $a \in A$, l_r can be updated:

$$l_r = \sum_{a \in R_r} (G^a - g_r^a) / g_r^a / |R_r| \quad (5)$$

The difference between (2) and (5) is that in the Lauw-peer algorithm, the variance is not squared, which results in higher reputation scores for the weak reviewer. More results and analysis are provided in section 4.

Similar to the Hamer-expert algorithm, if expert grades are available, a new algorithm (Lauw-expert) can be defined by using G_{expert}^a as G^a . This algorithm also does not need to be run recursively because expert grades are already available.

III. DESIGN OF THE WEB SERVICE AND PRML

A. Design of reputation web service

Our web service is designed to make different reputation algorithms available for peer-review systems. As in any web service, the inputs and outputs will follow a pre-defined format. Our design goals were to—

- minimize data transactions;
- minimize the effort needed to plug the web service into the clients;
- minimize the knowledge that the web services need to have about the clients.

Fortunately, no personal information needs to be passed to the web service; personal IDs and names are not needed for calculating reputations. The web service can keep track of each reviewer using the primary keys from the clients, or a one-way hash, for example. Nor does the web service need to store any information used to calculate the reputations. However, client systems may choose to allow it to save anonymized score information to, for example, calculate reputations for a whole semester, or to make it available in a learning-analytic database.

To make use of all the algorithms provided by our web service, client systems simply need to implement a web-service interface module for their systems. This module will (1) transform and send data to the web service and (2) receive the reputation data and use it in calculating grades. We are open to helping potential clients to implement this module. Since this interface is on the clients' end, clients can set up security rules to guarantee data integrity and security. The clients will be able to adapt this web service interface module to make use of our other web services (such as visualization and rubric improvement).

The data that the web service receives from the pluggable interfaces will be in a common format, regardless of how the client systems represent it. A common format also simplifies the design of reputation web services, because they do not need to have any knowledge of the development languages, the designs and the purposes of the client systems.

B. Design of PRML

In order to interface this reputation web service to a wide variety of peer-review systems, we have defined a Peer-Review Markup Language (PRML). This language will provide a standard format for representing data structures common to peer-review systems, such as assignments, users, rubrics, and reviews. It will allow different peer-review systems to interface to our reputation web service (and our other web services) without needing to change their databases.

PRML is a generic data schema for collecting and sharing numeric and textual data. The reputation web service uses only a subset of PRML. The full PRML contains other entities, such as textual feedback provided by students. This paper only presents the portion of PRML used for reputation services.

PRML is an JSON-based markup language which encapsulates data and metadata generated by peer-review tasks. The entities of data used in the reputation web service are clients, assignments, tasks, reviewers, reviewed entities and scores. Each of these is explained in Table I.^a

IV. DATA SET AND EXPERIMENTAL RESULTS

The data set that we used in experiments was generated in CSC 517 (Object-Oriented Design and Development) at NC State University in 2014. This is a graduate-level course, which peer-reviews two programming and three writing assignments. All of these are team assignments with 2- to 4-member teams. In the review phase, students select artifacts to review. Peer reviews are done using the Expertiza system [6], which is a system developed to review student-generated course content. In the peer-review phases for each assignment, reviewers were asked to fill out a review rubric. They were expected to give textual feedback and Likert-scale scores for the various rubric criteria.

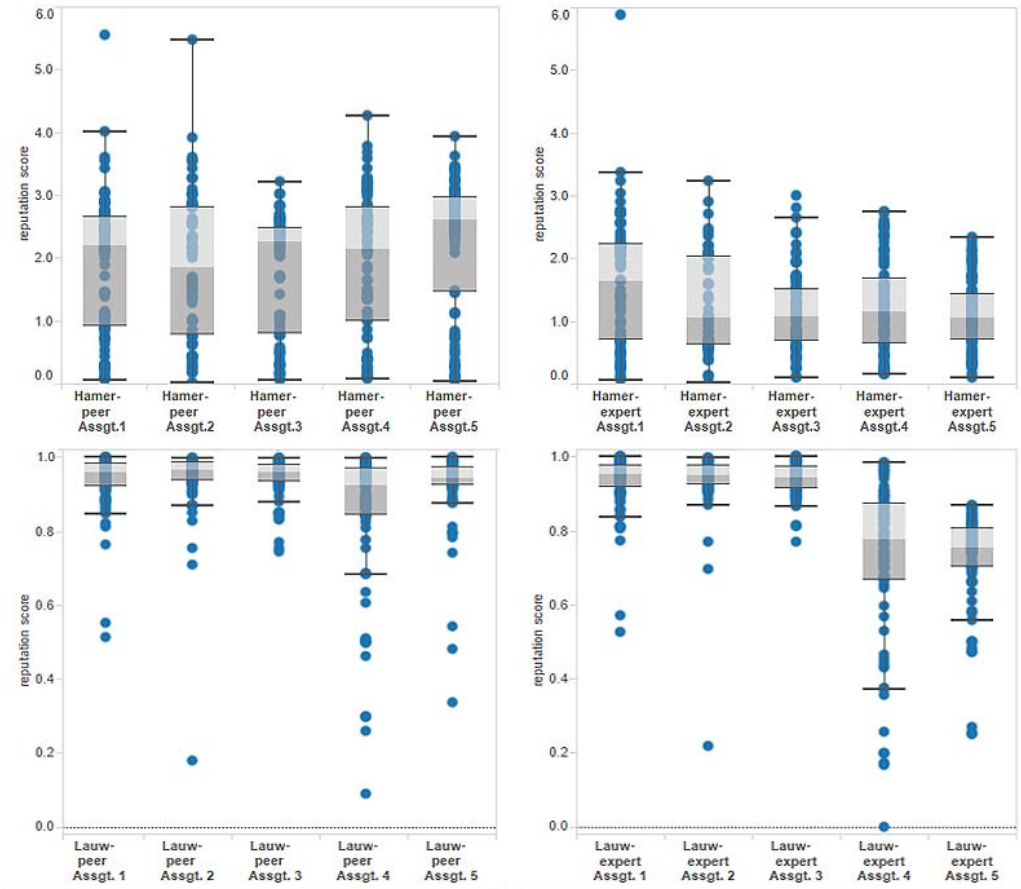

Fig. 1. Distribution of reputation scores calculated by each algorithm.

TABLE I. ENTITIES NEED BY THE REPUTATION WEB SERVICE

Entity name	Explanation
Client	A client system that uses the reputation web service.
Assignment	An assignment is what an instructor creates to prompt students to create artifacts.
Task	A task is an activity within an assignment. To incorporate peer-review systems that support multiple rounds of reviews, we consider each round as a task, and the web service calculates reputations for each task instead of for each assignment.
Reviewer	A user who submits one or more reviews for the current task.
Reviewed entity	The reviewed entity in the current task can be an essay, a video, a program, etc. Since we do not do content analysis in the reputation web service, we only need identifiers for the entities.
Score	The mapping table between reviewers and reviewed entities. Each instance represents a peer-review record, consisting of {reviewer, reviewed_entities, task, score assigned}. The instances of this entity should also contain the expert grades if they are available.

a. Class diagram of these categories can be found in : <http://www4.ncsu.edu/~ysong8/FIE2015/class%20diagram.jpg>.

Example of PRML can be found in:

<http://www4.ncsu.edu/~ysong8/FIE2015/json%20sample.xml>.

Fig. 2. Distribution of reputation scores calculated by each algorithm. We sampled 33 students (s1-s33) from assignment 1. The barchart shows the reputations calculated by Hamer-peer and Hamer-expert algorithms, with scale on the left side; the line chart shows the reputations calculated by Lauw-peer and Lauw-expert algorithm, with scale on the right.

Eighty-four students finished the course, and 2852 peer reviews were collected. We used the peer-review scores and computed aggregated scores on a 0-to-100 scale. Some of the artifacts received more than 100 because of bonus points, but bonus points are ignored in our experiments.

The web-service code calculated reputations for all students. Fig. 1. shows the distribution of all reviewers' reputation for all the assignments. The distribution of the reputation scores show that the Hamer algorithms have wider ranges, and that weak reviewers can receive reputation scores which are close to 0. By contrast, the Lauw algorithms give decent reputation scores to most of the students, but accord less weight to peer grades from credible reviewers.

One question that may interest instructors on client systems is, Do the reputation algorithms give consistent results? To answer this question we sampled 1/3 of students from assignment 1. Their reputations are presented in Fig. 2. It shows that even though the ranges of those algorithms vary, the result are consistent: the reviewers found to be credible by one algorithm are also deemed credible by the other algorithms. This is because all the algorithms are based on the degree of consistency between the scores given by one reviewer versus the scores given by the other reviewers on the same artifact. Another observation from Fig. 2 is that the students who received reputation scores close to 1 from the Hamer algorithms (meaning peer reviews skills are average) may receive 90% reputation scores from both Lauw algorithms, which shows that Lauw's tends to give higher reputation scores.

Another piece of information that the instructors using the client systems may want to know is, Which algorithm works best for my course? Since in this case the experts grades are available, the client can calculate the cosine values between the predicted weighted grades and expert grades for each assignment. We sample three assignments from the data set, namely assgt. 1 (writing a wiki page) assgt. 3 (writing a design document) and assgt. 5 (programming). We also computed the

TABLE II. COSINES BETWEEN PREDICTED AND EXPERT GRADES

		Hamer-peer	Hamer-expert	Lauw-peer	Lauw-expert
Assgt. 1	<i>Cosine</i>	0.999	0.999	0.999	0.999
	<i>Overall bias</i>	1.627	-0.773	1.082	-0.755
	<i>Max. absolute bias</i>	7.9	12.2	15.6	12.1
Assgt. 3	<i>Cosine</i>	0.997	0.997	0.997	0.997
	<i>Overall bias</i>	4.824	3.210	2.533	2.405
	<i>Max. absolute bias</i>	23.8	22.5	22.6	22.5
Assgt. 5	<i>Cosine</i>	0.999	0.999	0.998	0.998
	<i>Overall bias</i>	-16.583	-16.489	-18.539	-18.022
	<i>Max. absolute bias</i>	23.2	23.5	26.9	26.3

overall bias and maximum bias of predicted grades, relative to expert grades. The result is shown in Table II.

All the algorithms perform well on assignment 1: the Hamer-peer algorithm has the lowest maximum absolute bias and the Lauw-peer algorithm has the lowest overall bias. This indicates, from the instructor's perspective, if there are further assignments of this kind, expert grading may not be necessary. From assgt. 3, the overall bias is a little bit higher, but the max. absolute bias is very high (more than 20). This indicates that for future similar courses, the instructor can trust most students' peer grading, but should be aware that the students may give inflated grades. Therefore spot-checking is necessary. For assgt. 5, however, overall bias is quite low, as the students gave grades at least 16 points lower than expert grades. This may because either more training is needed, or the review rubric is inadequate. The results on assgt. 5 also suggest that for future courses of this kind, the instructor cannot trust the students' grades; expert grades are still necessary.

V. CONCLUSION

Reputation systems are a necessary part of peer-review systems, especially when they are used by large classes. We have designed a reputation web service which makes reputation systems "pluggable" into any peer-review system. It provides several algorithms that allow client system users to test different reputation algorithms without the need of implementing them locally. Instructors using the client systems can use reputation scores as weights in aggregating student-assigned scores into grades for each artifact.

The reputation web service is based on our Peer-Review Markup Language (PRML), which is designed as a generic schema for sharing peer-review based educational data. PRML isn't just useful for communicating with web services; it also facilitates development of more advanced peer-review systems by giving the community a common language for talking about peer review. With the plug-in interfaces that support PRML, researchers can also (1) share data with each other, and (2) build a centralized data repository. This means that, PRML can serve as a bridge to bring together isolated peer-review systems into a single research community.

Abstract—In addition to the domain and pedagogic knowledge required to design the laboratory experience, the development and maintenance of the current generation of remote laboratories typically requires a relatively high degree of technical expertise. This has resulted in long development timelines, a lack of engagement from teachers, and limited exploration of new laboratories. This paper explores the feasibility and requirements of a laboratory architecture that simplifies the development of remotely accessed laboratories. The intent is that a non-expert user with limited technical knowledge (typically a STEM teacher) can readily configure an experiment so that it is able to be both monitored and controlled remotely. The solution incorporates a dynamic interface that can detect and configure components automatically. We believe that the result will be a much wider and more rapid exploration of possible remotely accessed experiments - in much the same way that science teachers readily explore variations in hands-on laboratory experiments.

I. INTRODUCTION

Laboratory environments have always been essential components in the education of Science and Engineering. They enhance learning through the direct exploration of a student's field of study and develop the experimental skills and methodologies required for the practice of those fields. Whilst rarely intended as a direct alternative for conventional hands-on laboratories, remote laboratories have garnered increasing interest as an additional resource due to the opportunity they provide for more flexible access [1], sharing of facilities and for augmentation of the student interaction with the equipment.

Unfortunately, the current generation of remote laboratories require a high degree of technical expertise and dedicated resources to develop, deploy and maintain. Some attempts have been made to create flexible architectures or streamline the creation of remote laboratories (see, for example, [2], [3], [4]), these generally still require a degree of customisation that is beyond a typical teacher. This has resulted in long development timelines, a lack of engagement from teachers, and limited explorations of new laboratories. These difficulties ultimately affect the viability of remote laboratories as a cost effective alternate laboratory experiences. However, allowing teachers to create, deploy and maintain remote laboratories with minimal assistance and technical expertise at a low cost will promote new remote laboratory endeavours and innovations.

To solve this problem, we have designed and implemented of a remote laboratory architecture that would allow non-expert users to quickly create their own remotely accessible experiments with ease. The motivation of this solution is

to provide teachers with the ability to quickly create and share remote laboratory experiments with their colleagues and students with a goal of building a community of practice where people can share their designs and creations. The simplicity and ease of use of this solution would also allow teachers to design remotely accessible experiment rigs that would keep up with new content and the changing syllabi that existing remote laboratories cannot cover or support.

The paper is organised as follows: Chapter 2 presents the background and literature review of remote laboratories and existing architectures. Chapter 3 introduces the proposed remote laboratory architecture design and implementation. Chapter 4 discusses and analyses the feasibility and results of the architecture, and Chapter 5 concludes the paper.

II. BACKGROUND

A. Remote Laboratories

Laboratories are an important aspect of education, in particularly with Science and Engineering. It enhances the learning of students, whilst allowing them to develop experimental skills and methodologies in their respective field of study. Although the right to education is universally recognised, limitations in the resources quite often exist in the form of a lack of funding or support to procure equipment and facilities. Concerns for a cost effective solution increases as a result of (claims/reports) that laboratory utilisation can be quite low, despite a lack of evidence to the fact (see, for example [5]). The emergence of remote labs offers a feasible solution to these issues by the cross-institutional sharing of resources to offset costs and labour. With further improvements made to current generation architecture and design, as is the aim of this paper, remote laboratories become an increasingly viable and attractive alternative [1].

Remote laboratories first appeared in the Engineering Education literature in the mid 1990's[6] and have developed considerably over the last two decades. These systems allow students and teachers to conduct scientific investigations using real lab apparatus via the Internet. This enables students and teachers from different organisations to access a wider range of equipment that would be too expensive or difficult for the individual schools to support. These remote laboratories are usually set up with cameras, data acquisition instrumentation and switching mechanisms to its allow users the ability to control and monitor experiments through either a web based or native application.

B. Benefits and Opportunities

Unlike conventional lab sessions, access to remote experiments can be 24 hours, 7 days a week. This allows students the flexibility to carry out experiments during their own time as well as repeating experiments for better understanding and clarifying doubtful measurements. In turn, it supports autonomous learning and enhances the educational values of the laboratory.

Remote laboratories have the potential to serve as assistive technology[7], allowing students with disabilities to complete experiments without being physically present in a laboratory. This also applies for students who are taking distance education or remote courses.

Although most groups developing and researching in this field acknowledge that this form of laboratory is not expected to replace traditional physical laboratories [8], remote laboratories do however present valid alternatives for some laboratories and serve as useful complements to others[9].

C. Existing Architectures of Remote Laboratories

Over the last decade, numerous remote laboratories have been created with varying architectures and technologies. In earlier iterations, remote labs were often accessed via remote desktop software such as Windows Remote Desktop or Log-MeIn. Although this method served its purpose, allowing users to access the experiment, it raised issues with scheduling, reliability and scalability.

With the emergence of web development, remote labs have gradually leaned towards web applications. Although there are many different implementations, most web-based remote labs have adopted the 3-tier web architecture[5]. This architecture consists of the application client which the users accesses, the lab server which manages the experiment and apparatus, and a service broker which manages the communication between the application client and the lab server. The 3-tier web architecture can be recognised in several different remote lab systems such as the Labshare Sahara Project, Ciclope[10] and MIT iLabs[11].

1) User Management: Remote laboratory architectures are designed to support multiple experiments and rigs. With multiple experiments and multiple users, there is a need for user and access management. The management of end users allow an organisation to administrate the users, assign their identities, credentials and grant them authorisation to specific resources[12]. For example, the UTS Remote Labs which uses the Sahara framework, currently utilised both the Australian Access Federation (AAF) and an internal university LDAP to authenticate users with their university credentials (even if they are from other Australian universities). Within the application, administrators have the ability to control the authorisation levels and access rights of the individual users.

2) Scheduling: Remote laboratories benefit from scheduling schemes to manage access to resources for concurrent users. The easiest approach is the implementation of a queue that allow users to wait for their turn to access the remote laboratory. This method however is inefficient with larger user populations and would cause strain and unfairness amongst the users. The best suited scheduling schemes are based upon

the consideration of varying factors including the number of concurrent users, the available resources, the average duration of each usage and the availability of the resource.

Sahara has a hybrid scheduling scheme which allows users to make reservations for predefined periods on time on a given date. It also allows users to enter a priority queue for the current or next time allocation if it has not already been reserved by another user[13].

3) Hardware: Remote laboratory architectures rely on certain hardware to control and broker the experiments' inputs and outputs. Microcontrollers such as the Arduino, PIC controller and Raspberry Pi are commonly used in prototyping and building remote lab experiments[14] [15] [16]. These microcontrollers are used to manage the lab equipment and components, whilst also serving as a connection to the Internet. They are also capable of hosting the remote lab interface[16], allowing the remote lab system to be an all-in-one architecture (although this is not a scalable approach). With some remote labs, the microcontrollers are used to program and interface with actual lab equipment such as oscilloscopes and function generators[7] or even FPGA boards[17] [18]. In other cases, the microcontrollers are a part of a dedicated experiment rig, where the sensors and circuits are directly controlled by it as seen in [14].

These devices usually require an intermediate level of programming knowledge to operate which most STEM teachers do not have. The management and setup of the hardware and physical components of a remote laboratory experiment would likely be done by technicians. Beyond the hardware, they would also need specialised software to be developed and hosted, which would require software engineers and developers. The sheer complexity of creating remote laboratory experiment is high and tend to require many different types of expertise.

4) Current Trends and Challenges: A common problem among existing remote laboratories is that they only offer stand-alone solutions, with limited or no capability to co-operate with other platforms. There are similar systems and architectures but most of these solutions are developed as special or ad hoc solutions with varying technologies and standards[9]. The lack of standardisation, portability, scalability and interoperability between different solutions is a current major challenge for remote laboratories. This is likely due to the lack of proper software design, in both the client and server side as well as a lack of communication and collaboration between institutions when it came down to development[19].

However, interoperability between multiple remote laboratory architectures has been attempted for Sahara, iLabs and WebLab-Deusto as seen in [20], in which the goal was to allow users of one institution to use federated remote labs developed for other frameworks. This endeavour has shown great potential and presents further opportunities for resource sharing as well as the possibility for standardisation, reusability and scalability.

Accessibility is also a major concern. Providing easy access to remote laboratories from developing countries (where computer access is limited and bandwidth is constrained) is a major challenge as well as a worthy goal, as remote laboratories are

expected to be facilitators to get access to resources otherwise unavailable[12].

Furthermore, the deployment of a remote laboratory can be complex and require a high level technical knowledge. As a result non-expert users such as STEM teachers would require professional assistance to create an experiment which would result in high cost and development times. Making remote laboratories easily deployable, allowing instructors and students to connect experiments to the Internet is another challenge. This challenge is addressed to both the software and hardware of the remote laboratory architecture as it usually requires both software engineering skills and an understanding for circuits to build setup an experiment.

There have been attempts to make the creation of remote laboratories easier for non-expert users through a variety of architectures and approaches. Unlike the previously mentioned Sahara, iLabs and WebLab-Deusto architectures, the architectures/platforms proposed in [15] and [21] are lightweight solutions that aims to allow users to easily to connect their experiment rigs to the Internet. However, these architectures do not consider the entire process of creating a remote laboratory experiment without technical assistance and extra programming. They also, do not consider the context and environment of which the rigs will be hosted, which overlooks the issue of connectivity to the Internet over a strict network.

From the review of previous works and the literature involving remote laboratories, it is clear to see that most remote laboratory architectures are designed to be one-off solutions that do not allow of change or evolution. The development of remote laboratories tend to be complex and costly, which in turns causes long development timelines. Furthermore, we cannot expect the teachers and other non-technical people to be able to use the existing architectures as they all require technicians, designers or developers to create and maintain the different components from the hardware to the end user interfaces. This shows that there is a definite need for a remote laboratory deployment architecture designed for non-expert users that would simplify the process of creating remote laboratory experiments.

III. DESIGN AND IMPLEMENTATION

By analysing the architectures and platforms discussed in Chapter 2, we have designed a smart, modular and low cost architecture intended for non-expert users to be able to easily setup, deploy and share their own remote laboratory experiments. This chapter discusses in detail, the design and implementation of our proposed architecture.

In regards to the design and implementation, we have approached the issue in a highly Agile and exploratory manner. Throughout the duration of the project we have defined and developed the architecture by researching existing technologies, creating prototypes and improving said prototype incrementally. This implementation of the solution was done with the purpose of piloting it to potential users in the near future so that it can be assessed for feasibility.

A. Requirements

The designed and implemented remote laboratory platform is oriented to the needs of STEM teachers in a secondary

school or university context.

The defined users for this platform are:

- Lab owner: Typically a teacher or instructor, this user sets up and configures the remote laboratory experiment. We are making the assumption that the lab owner has little to no technical abilities in terms of programming and remote laboratories.
- Lab user: Typically a student, this is the end-user of the remote laboratory experiments.

Existing implementations of remote laboratories are complex and require a high level of technical understanding to create and maintain. Through the analysis of existing remote laboratory architectures and in conjunction with leading researchers in the field, we were able to define the requirements for a non-expert friendly remote laboratory deployment architecture. This remote laboratory architecture aims to provide an optimally flexible and dynamic solution, which enables non-expert users to implement remotely accessible experiments with minimal technical expertise and without any coding whilst maintaining a low cost.

To cater to lab owners with limited technical knowledge, an architecture that does not require additional programming or complex circuit building is required. This was achieved with a hardware platform and a software solution. In regards to the hardware, we have created dynamic platform which utilises smart "slave modules" that are programmed to be plug and play and self configuring. These slave modules are plugged into a "rig controller" which acts as the central hub for all slave modules and handles the communication between the rig and the Internet. Additionally, we have also designed a software platform to allow the lab owner to easily configure their hardware and design their remote laboratory experiment interface online via a web browser. The software platform is also used to host the experiment interfaces for lab users to access.

To create a remote laboratory experiment using the proposed architecture, the lab owner would be required to do the following:

- 1) Power up the rig controller device and ensure it is connected to the Internet (via WiFi or Ethernet).
- 2) Go online to <https://remotelab.club> and login using their university credentials through the Australian Access Federation or after creating an account manually.
- 3) Register and configure their rig controller.
 - a) Click "Register New Rig Controller" and find their pending rig controller.
 - b) Sync the rig controller by clicking sync button on the web interface and holding down the sync button on the rig controller for 5 seconds.
 - c) Once synced and confirmed, configure the following:
 - Title
 - Description
 - Type (Publish Only or Interactive)
 - Sharing setting (Public or Private)
 - Password (optional)

- 4) Plug slave modules into the rig controller and connect any additional components to the slave modules if needed.
- 5) Using the User Interface Designer on the web interface, design the experiment interface by dragging and dropping widgets onto the canvas. Widgets can then be configured to be bound to a specific slave modules.
- 6) Once satisfied with their remote lab experiment setup, the lab owner can publish it and allow lab users to access it.

The workflow was derived by identifying and assessing the technical abilities of the expected lab owners to create an optimal user experience where there would be minimal complex steps like programming their own logic or editing configuration files on a Linux shell. The process of creating a remote laboratory was significantly simplified as the traditional steps of programming backend logic and designing user interfaces are encapsulated into basic forms and drag and drop interfaces on a user friendly web application.

B. Technical Design

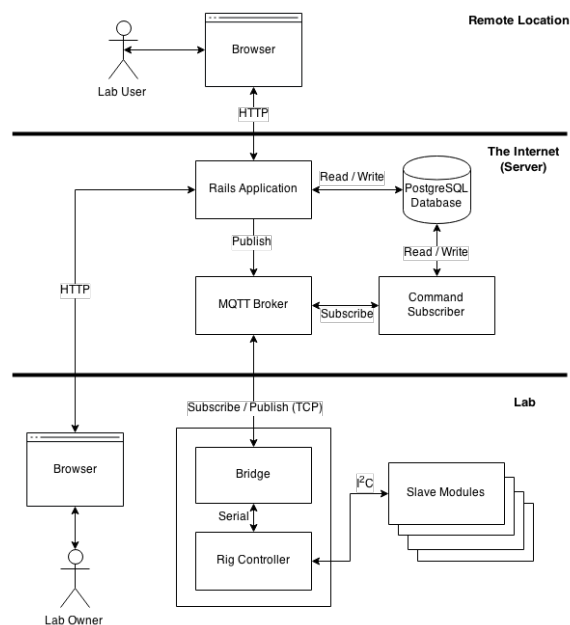

Fig. 1. Technical Overview of Architecture

Our approach adopts an adaptation of the commonly used three-tier architecture which consists of the hardware, a server and some middleware (see Figure 1). To remove the complex step of deploying and maintaining a local server to host the management logic and application of the remote laboratory platform, we have designed our platform to work with a dedicated server on the cloud. Furthermore, the difficulty of the hardware design of an experiment rig is decreased with the proposed "plug and play" platform using defined slave modules.

This section will in detail elaborate on both the hardware and software designs and development of the proposed architecture.

The hardware platform of the proposed architecture consists of a rig controller and a variety of different slave modules.

Note that the implementation of the hardware platform of this architecture was done with the intention that it would be later be implemented on custom printed circuit boards.

C. Rig Controller

The rig controller is the central component of the hardware platform which manages connected slave modules and is the intermediary entity between the hardware and the server. It is based on the Arduino Yn which has an ATmega32u4 AVR microcontroller, an Atheros AR9331 processor which supports OpenWrt Linux and has on board WiFi and Ethernet capabilities. This board was chosen over the other typical boards such as the Arduino Uno or Raspberry Pi because it would remove the need for a dedicated computer to run the communications to the server, but instead have it built into the rig controller. This removes several layers of complexity and reduces the required components which are commonly seen in other architectures.

The rig controller handles the following:

- Manages connected slave modules.
 - Dynamically allocates the slave module addresses (this is discussed in detail in Section III-E).
 - Keeps a record of the slave modules metadata (address, type and status).
- Receive requests from connected slave modules and executes them.
- Receive commands from the server and executes them.
- Send data to the server.

D. Slave Modules

The slave modules are based on the Arduino Uno which has an ATmega328 AVR microcontroller. The idea of slave modules arisen during the analysis of the hardware of existing remote laboratory approaches. Most architectures have either custom designed devices for specific rigs or were made up of a large array of components which would require in-depth knowledge or assistance from experts to build. To avert from this issue, a variety of production ready "plug and play" modules that would be sufficient for most of experiment scenarios was introduced.

During the implementation of the slave modules, we were able to generalise and refactor the underlying logic and functions that make up the base of a slave module into a basic Arduino library and template. This allowed for rapid development of new slave modules which would only require the developer to program the specific functionality revolving around the sensor or component and not have to worry about the communication between devices. Extending the list of available slave modules in the future would be a simple task of copying the base slave class, adding to the list of commands which are callable by the rig controller and editing the configuration variables which determine the type and required pins on the Arduino. This process would be simple for most components that do not require highly complex or convoluted systems.

E. I²C Bus

Communication between the rig controller and the slave modules relies on a master-to-slaves I²C serial bus. By using an I²C serial bus we were able to create the "plug and play" behaviour for the slave modules. The I²C serial bus can handle up to 128 addresses where the rig controller has a fixed address of 1.

The rig controller dynamically allocates addresses for newly connected slave modules (similar to the one proposed in [22]). When a slave module is plugged into the rig controller, on setup, it would request the next available address from the rig controller and registers itself with that address.

The messages that are transmitted between devices as byte streams through the I²C serial bus, we had to use to a special message format consisting of delimited values and ending with a tab character.

`< address >:< command >:< value > \t`

Fig. 2. Message format used during I²C communication

F. Middleware (Bridge)

Running on the OpenWrt Linux environment of the Arduino Yun is the bridge application which consists of a serial service, subscriber service and a publisher. The bridge software is a multi-service application written in Python using the Twisted library which is widely used for communication and protocol management. The application is automatically started when the rig controller is turned on and the Linux environment starts up and runs in the background as a daemon process.

1) *Serial Service*: The serial service reads the byte stream from the serial port with the baud rate of 9600. This component of the application collects the messages from the rig controller which come in the same format mentioned above in Figure 2 and parses it into a Python dictionary (hash table) and executes to appropriate functions. The serial service can call the publisher mechanism to send messages to the server. Furthermore, just as it receives messages from the rig controller through the serial port, the serial service also sends messages back to the rig controller the same way.

2) *Subscriber Service*: The subscriber service of the bridge application, is a TCP client that listens to the MQTT broker of our remote laboratory platform. It subscribes to the "rigs/ < rigHash > /#" topic, where rigHash is the preset rig controller identifier set by the server when the devices are registered and synced. When the service receives a message, it would intelligently parse the topic to determine the required actions to take and use the message value appropriate. In most case, the subscriber server would call the serial service to pass commands to the rig controllers which in turn would pass it to the slaves.

3) *Publisher*: The publisher is a service that is used in the bridge application to communicate back with the server via the MQTT broker. When called, it sends messages with a specified topic which is usually in the "rails/ < rigHash >" topic, where rigHash is the rig controller identifier.

G. Server

One of the major concerns whilst designing and implementing this architecture was the "push to a remote server" approach opposed to the more traditional hosting of a server locally. We pursued the push approach because the context of which the remote laboratory experiment is set up is of great importance as we have to consider the network limitations and firewall restrictions of schools and universities.

In the first stage of development we used API endpoints, which we would POST commands to and regularly poll for new commands. This approach had caused a lot of latency and was an inefficient approach. The API was replaced with a WebSockets server which allows the bridge application to make a TCP connection to it and communicate. This approach was better than the previous, however it also had its limitations as there was a lack of channels and required complex parsing to determine messages and commands. Finally we decided to use a Mosquitto broker to handle communication between the hardware and the software on the server. Mosquitto is an open source MQTT broker that is supported on a variety of operating systems and is easily installed.

MQTT gave us the option to use topics as endpoints, whilst having a similar behaviour as if there was a hard connection to the server with the subscriber services. As previously mentioned in the details of the serial and subscriber services, we used specific topics to handle the communication between the hardware and the server. Commonly used topics consists of the following and their subsets; "rigs/ < rigHash > /#" and "rails/ < rigHash >". Running on the same server as the MQTT broker is a subscriber process which listens to "rails/ < rigHash > /#" topics and executes the requested commands just as the subscriber service on the bridge application.

H. Web Application

Running on the same server (for now) as the Mosquitto broker, is the Ruby on Rails application which is used by the lab owner for hardware configurations and user interface/experience design of their experiment rig and by the lab users to access published experiments. The application uses a PostgreSQL database, served with NginX and is hosted on an Amazon Web Services instance based in Sydney, Australia.

1) *Rig Management*: As mentioned Section ??, one of the steps to register and setup a rig controller requires it to be synced with the user's account on the web application. When the lab owner enters the new rig controller registration page, they will see a list of pending rig controllers that have not been synced yet. Given to the option to ping the rig controller from the web interface (which flashes an LED on the rig controller), the lab owner will be able to find their rig controller on the pending list. Once found, the lab owner can sync it by holding down the sync button on the hardware after initialising the syncing process on the web interface. The rig controller is then recorded in the database and presented on the web application for the lab owner to configure, design and publish their remote laboratory experiment.

2) *User Interface Designer*: Interfacing the hardware with a graphical user interface would usually require a significant

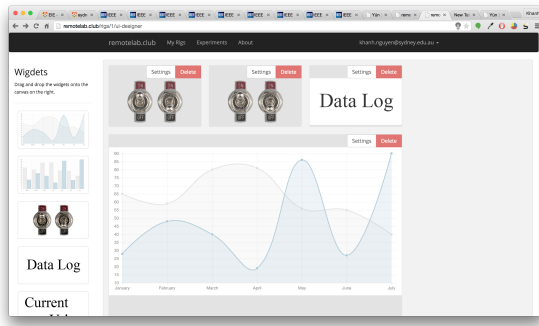

Fig. 3. User Interface Designer

amount of time and resources which in would turn incur a large cost. We have implemented and integrated an easy to use, drag and drop User Interface Designer tool into the web application. This tool allows the lab owner to drag and drop predefined widgets onto a canvas and bind them to slave modules inputs and outputs.

There are two types of widgets:

- Generic widgets are designed to work with most, if not all slave modules. These are usually simple display, graphing or switching widgets which can be bound to slave modules' input or outputs.
- Specialised widgets which were designed to only work with a certain slave module to bring out extra functionality that is not possible with generic widgets.

Once the lab owner is satisfied with the design of their user interface and the configurations of the widgets and slaves, they can save it and publish the remote laboratory experiment.

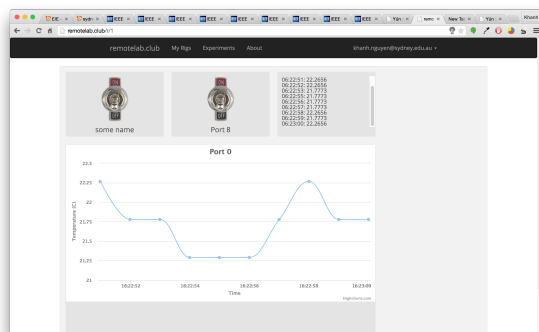

Fig. 4. Experiment rig end-user interface

3) *Experiment Sessions:* When a lab user accesses a published remote laboratory experiment, they will be presented with the user interface that the lab owner had designed. Within the browser they will be able to see the live data from the components and interact with the experiment (if the rig is interactive).

Previously in other architectures and frameworks, the end user interface of a remote laboratory rig is usually implemented using Java applets or with polling AJAX calls with HTML and JavaScript. Both of these approaches have become inefficient

and outdated in light of the recent development of the new web technologies such HTML5 and WebSockets. Our implementation of the experiment session uses HTML5 and Server Sent Events to update the data dynamically without the need for AJAX polling or Java Applets.

When the lab user access an experiment on the web application, the browser immediately subscribes to a channel which received messages from the Rails controllers. When messages are sent to the browser, the JavaScript will automatically update the content on the page. Furthermore, if given a the option, the lab user can also interact with the experiment which triggers AJAX POST requests to the server side which would relay the command to the rig controller.

IV. ANALYSIS

A. Benefits

The discussed architecture allows non-expert users such as teachers and students to easily design and build lightweight remote laboratory experiments at a low cost. The plug and play nature of the architecture along with the software to design and configure it allows lab owners to rapidly build their experiment rigs and easily design an online interface for their remote lab experiment.

The cost of a rig controller would be \$50 and a slave module would cost on an average of \$10 depending on the type of sensor. This means that it is possible to create a minimalistic remote laboratory experiment with a minimum of cost of \$60 using this architecture. This is relatively low compared to the high end remote laboratories developed by universities as those usually require specialised equipment and long development times. By reducing the costs and time to build remote laboratories, this architecture provides an alternate approach to remote laboratory prototyping and development at the cost of quality, extensiveness and robustness. Doing so, this architecture would allow teachers and students to easily explore and innovate with remote laboratories.

The communication logic between the rig controller and the server was designed to be portable and extensible such that it can easily be altered to work with other data storing services and APIs such as Firebase or Twilio.

B. Issues and Problems

The current implementation of this architecture uses the Arduino Yun as the rig controller and multiple Arduino Unos for the slave modules. However, this architecture requires the rig controller and slave modules to be off-the-shelf products for lab owners to easily acquire. As this architecture is targeted at non-expert users with limited technical knowledge, it is not feasible to expect them to be able to build their own rig controller and slave modules.

Furthermore, this architecture can be restrictive as the lab owners are limited to the available slave modules. If a lab owner wants to use their own sensors or hardware, then it would require them to use the base slave module which would require some basic understanding of the Arduino.

The robustness and reliability of the architecture can also be a potential problem due to its restrictive nature and its heavy

dependency on the pre-programmed logic and connection to the server to operate. The architecture also requires an uninterrupted power supply to continually operate, which may be hard to guarantee depending on the individual's circumstances and environment.

C. Comparison to existing architectures

This architecture is comparable to two other existing remote laboratory systems, ISES [21] and the easily deployable low-cost remote lab platform [15] developed by Campos et al. Both of these architectures emphasise a "plug and play" functionality however both have drawbacks in regards to cost and ease of use.

Similarly to Campos' design, our architecture provides a low cost and lightweight solution using inexpensive micro-controllers. However, Campos' architecture requires technical staff to assist teachers in setting up and deploying a remote laboratory experiment. The remote laboratory interfaces are hosted on a micro server which requires port forwarding or similar network configurations. In contrast, our architecture allows teachers to deploy on any network that is connected to the Internet without further configurations.

ISES, on the other hand, presents a high quality plug and play solution with the use of modules that connect via PCI. The consequence of such a high quality product is the high cost as the main PCI board can cost up to \$1500 and individual modules average around \$100. The high cost of platform would not be desirable for non-expert users to use on their own without assistance. Much like other traditional architectures and Campos' platform, ISES also hosts the end user interface or application onboard which would again require further configurations of the network that it is connected.

Furthermore both of these architectures offer software solutions to configure and setup the end user interfaces for the remote laboratory experiments. However unlike the interface designer offered in our architecture, both ISES and Campos' solution require additional programming of the web interfaces. This, again would be undesirable for users who have experience in web development and programming.

V. CONCLUSION

In this paper, we have presented the problems in existing remote laboratory architectures through the review of previous work. We found that the creation of remote laboratories have always required high costs and technical expertise which causes stagnation and inflexibility as existing architectures are difficult to change and evolve. We proposed an architecture that removes these limitations, enabling users of all technical proficiencies to design, build and share their own remote laboratory experiments.

The proposed architecture innovates upon and differentiates itself from any existing solutions as it successfully removes a number of complex processes and requirements seen in the traditional architectures. This was done by simplifying, encapsulating and removing the steps and requirements into basic and user friendly workflows. Furthermore, with the use of technologies such as I²C communication, MQTT, HTML5, and JavaScript this solution provides a lightweight and modular

platform which allows non-technical users to be able to easily connect their experiments to the Internet. The cost and resources required to set up a remote laboratory experiment using this architecture is tremendously lower compared to currently existing high-end alternatives which presents new opportunities for innovation and further explorations into remote laboratory endeavours.

Future lines of work should focus on:

- Increasing the robustness and reliability by adding logic and state checks to the rig controller.
- Removing the restrictiveness caused by limiting the architecture to the slave modules by developing more generic modules which would support existing components and equipment.
- Improving the online platform by adding more functionality to provide lab owners a better experience when configuring and designing their remote laboratory experiments.
- Developing dedicated boards for the rig controller and slave modules and moving away from the prototyping Arduino boards.

Student-Constructed Concept Maps for Active Learning in a Foundational Undergraduate Engineering Course

Ning Fang

Department of Engineering Education
Utah State University
Logan, Utah, USA
ning.fang@usu.edu

Abstract—As a graphical pedagogical tool for knowledge organization, representation, and elicitation, concept mapping has been widely employed to improve student conceptual knowledge and understanding in a variety of academic disciplines. In the traditional approach to concept mapping, the instructor develops concept maps and then shows them in lectures. This work-in-progress study takes a non-traditional, active learning approach, in which students (rather than the instructor) construct their own concept maps in engineering dynamics, a foundational sophomore-year undergraduate engineering course. This paper provides representative examples of student-constructed concept maps. These maps were collected from a total of 165 engineering undergraduates who took an engineering dynamics course in one of two recent semesters: Semester A (94 students) and Semester B (71 students). Questionnaire surveys including both Likert-type and open-ended questions were administered at the end of each semester. The results show that 37% of the students rated their experience with developing their own concept maps “positive” or “highly positive,” and that 44% of the students “agreed” or “strongly agreed” that developing their own concept maps improved their conceptual understanding. Representative student comments are also provided in this paper.

Keywords—*student-constructed concept maps; active learning; engineering dynamics*

I. INTRODUCTION

Concept maps are a graphical pedagogical tool for knowledge organization, representation, and elicitation. Since Joseph Novak and his colleagues developed the technique of concept mapping [1], concept maps have been widely employed to improve student conceptual knowledge and understanding in a variety of academic disciplines [2-6]. For example, Egelhoff, Podoll, and Tarhini [5] developed a concept map for teaching a Mechanics of Materials course. Ellis, Rudnitsky, and Silverstein [6] developed two concept maps for teaching a Continuum Mechanics I course.

Educational research has been conducted to assess and evaluate the effectiveness of using concept maps to teach and

learn important subjects [7, 8]. For example, Horton, McConney, Gallo, Woods, Senn, and Hamelin [7] conducted a meta-analysis of 19 studies in various science disciplines and found that concept mapping had generally medium-positive effects on students’ academic achievement. Most recently, Nesbit and Adesope [8] conducted a meta-analysis of 55 studies that involved 5,818 students from Grade 4 to postsecondary in science, psychology, statistics, and nursing. They concluded that concept mapping was effective in achieving knowledge retention and transfer [8].

In the traditional approach to concept mapping, it is common for the instructor to develop concept maps and then show them in lectures. Students learn concepts by watching the instructor-constructed concept map and listening to the instructor’s explanations [5, 6, 9]. This traditional way is still passive because students are not fully and actively engaged in the learning process. Moreover, there are many different ways to organize a variety of concepts on a concept map. The concept map developed by the instructor might not be the only map that is technically correct and logically reasonable. In other words, the traditional approach to concept mapping does not provide students an opportunity to assimilate or represent the content in a graphical way.

This work-in-progress study promotes and fosters active learning by providing students opportunities to construct their own concept maps in engineering dynamics, a foundational sophomore-year undergraduate engineering course. The course is required in many undergraduate engineering programs, such as mechanical, aerospace, civil, biological, and biomedical engineering programs. The course covers a broad spectrum of foundational concepts, e.g., displacement, velocity, acceleration, force, moment, mass momentum of inertia, work, energy, impulse, momentum, and vibration [10, 11]. Because of the numerous concepts involved, many students have difficulty seeing connections and relationships among different concepts and fail to see the “big picture” of engineering dynamics [6, 9, 12].

This paper describes how students were offered opportunities to construct their own concept maps in engineering dynamics in two recent semesters: Semester A (94

This material is based upon work supported by the National Science Foundation under Grant No. DUE 1244700.

students) and Semester B (71 students). Representative examples of student-constructed concept maps are provided. Questionnaire surveys including both Likert-type and open-ended questions were administrated at the end of each semester in order to answer the following research question:

What were students' attitudes toward and experiences with constructing their own concept maps in engineering dynamics?

The scope of this work-in-progress study is limited in using questionnaire surveys to assess students' attitudes and experiences with concept mapping. A detailed assessment of the quality of student-constructed concept maps is beyond the scope of this study and will be addressed in future work.

II. STUDENT-CONSTRUCTED CONCEPT MAPS

A. Offering Students Opportunities to Construct Their Own Concept Maps

The students who recently took an engineering dynamics course in either Semester A or Semester B were offered opportunities to construct their own concept maps. The author of this paper was the instructor of the course in both semesters.

At the beginning of each 16-week semester, the instructor explained to the students what concept maps are, showed the students example concept maps, and taught them how to use a free online software program, IHMC Cmap Tools (<http://cmap.ihmc.us>), to draw a concept map. The students were encouraged to download the free online software to their own computers, so they could use it to draw and modify their concept maps.

At the end of each learning topic (i.e., each textbook chapter), the students were asked to construct their own concept maps and submit their maps to the instructor. Excellent student-constructed concept maps were shared in the class, so all students could learn from each other.

B. Learning Topics Covered in Engineering Dynamics

Each student participant developed a concept map for each of the following eight learning topics in engineering dynamics:

- Kinematics of a Particle
- Kinetics of a Particle: Force and Acceleration
- Kinetics of a Particle: Work and Energy
- Kinetics of a Particle: Impulse and Momentum
- Planar Kinematics of a Rigid Body
- Planar Kinetics of a Rigid Body: Force and Acceleration
- Planar Kinetics of a Rigid Body: Work and Energy
- Planar Kinetics of a Rigid Body: Impulse and Momentum

Each learning topic contains many concepts. For example, the "Kinetics of a Particle: Force and Acceleration" learning topic involves Newton's Second Law, rectangular coordinates, normal and tangential coordinates, and cylindrical coordinates. Throughout the semester, each student participant constructed a total of eight concept maps, covering all the above eight learning topics.

III. RESULTS AND ANALYSIS OF QUESTIONNAIRE SURVEYS

A. Student Participants

A total of 165 students in two semesters participated in the present study. They all signed the Informed Consent letter approved by an Institutional Review Board. Table I shows student demographics in terms of gender. The vast majority (89.7%) of the students were males, while female students accounted for 10.3% only.

Table II shows student demographics in terms of major. The majority of the students were either mechanical and aerospace engineering (MAE, 52.7%) or civil and environmental engineering (CEE, 22.4%) majors. Less than 25% were biological engineering or other majors.

B. Questionnaire Surveys

Questionnaire surveys were administrated at the end of each semester. The surveys include both Likert-type and open-ended questions, for example:

1. Please rate your overall experience with developing your own concept maps: 1) highly negative; 2) negative; 3) neutral; 4) positive; 5) highly positive
2. On average, the time that you spent on developing your own concept maps, including thinking about it and then drawing it with hands or a computer, was 1) < 10 minutes; 2) 10-20 minutes; 3) 20-30 minutes; 4) 30-40 minutes; 5) > 40 minutes for each map
3. Overall, the concept maps helped improve your conceptual understanding of dynamics concepts, laws, and principles as well as their relationships: 1) strongly disagree; 2) disagree; 3) neutral; 4) agree; 5) strongly agree
4. Please describe in detail how the concept maps helped, or did not help, with your conceptual understanding of dynamics concepts, laws, and principles as well as their relationships.

TABLE I. STUDENT DEMOGRAPHICS: GENDER

Semester	Male	Female
Semester A (n = 94)	84 (89.4%)	10 (10.6%)
Semester B (n = 71)	64 (90.1%)	7 (9.9%)
Semesters A and B (n = 165)	148 (89.7%)	17 (10.3%)

TABLE II. STUDENT DEMOGRAPHICS: MAJOR

Semester	MAE	CEE	BE	Other
Semester A (n = 94)	53 (56.4%)	16 (17.0%)	12 (12.8%)	13 (13.8%)
Semester B (n = 71)	34 (47.9%)	21 (29.6%)	11 (15.5%)	5 (7.0%)
Semesters A and B (n = 165)	87 (52.7%)	37 (22.4%)	23 (13.9%)	18 (10.9%)

C. Results and Analysis

As representative examples, Figs. 1 and 2 (see the next page) show two original concept maps constructed by two students on “Kinetics of a Particle: Force and Acceleration” and “Kinetics of a Particle: Work and Energy,” respectively. The two students employed different font sizes on their maps.

In Fig. 1, the student starts from Newton’s Second Law and indicates clearly that it can be applied in three forms using rectangular coordinates, cylindrical coordinates, and normal and tangential coordinates. All three forms can be analyzed through free-body and kinetic diagrams. The student also includes important equations on his concept map.

In Fig. 2, the student places “Work of a Force” in the central position of his concept map. This central concept is linked with three other concepts: power, Conservation of Energy, and the Principle of Work and Energy. The map also clearly shows how the “Work of a Force” concept is associated with other concepts using either equations or linking words.

Tables III-V summarizes student responses to three Likert-type questions employed in the questionnaire surveys. As seen from these tables, among 165 student participants, 37% had “positive” or “highly positive” experiences with developing their own concept maps, 45% spent more than 20 minutes on average in developing each concept map, 44% “agreed” or “strongly agreed” that developing concept maps improved their conceptual understanding. Representative student comments are provided below:

“It help me to put my mind in order. It help me to understand much better because I had to read the chapter before to do the concept map. So when I was reading, I was learning at same time.”

“I was able to spend quality time developing and understanding how each concept connected to other concepts in the chapter and this helped me formulate ideas of practical and academic applications of the content.”

“First of all it made me go back to review the entire chapter after we had finished learning it in class. It also helped me build bridges for which equation can be used in each situation.”

“They helped by piecing together how everything worked together and how it all fit.”

“The concept maps helped me to organize my thoughts about each chapter. It made it so I could see how each all the different concepts, laws, and principles fit together in the big picture.”

IV. LIMITATIONS AND FUTURE WORK

The primary limitation of this work-in-progress study lies in that it has not focused on a detailed assessment of the quality of student-constructed concept maps. Because the study involved 156 students and each student developed eight maps, a total of 1,248 concept maps have been generated from this study. Assessing the quality of each map will take a significant amount of time and effort. Because there are many different ways to organize concepts on a concept map, a detailed rubric will need to be developed to assess the quality of student-cons-

TABLE III. STUDENTS’ OVERALL EXPERIENCE WITH DEVELOPING THEIR OWN CONCEPT MAPS

Semester	Highly Negative	Negative	Neutral	Positive	Highly Positive
Semester A (n = 94)	8%	20%	36%	32%	4%
Semester B (n = 71)	2%	10%	48%	35%	4%
Semesters A and B (n = 165)	5%	16%	41%	33%	4%

TABLE IV. THE AVERAGE TIME STUDENTS SPENT IN DEVELOPING EACH CONCEPT MAP

Semester	< 10 Min.	10-20 Min.	20-30 Min.	30-40 Min.	> 40 Min.
Semester A (n = 94)	32%	34%	20%	12%	2%
Semester B (n = 71)	10%	31%	32%	18%	8%
Semesters A and B (n = 165)	22%	33%	25%	15%	5%

TABLE V. DEVELOPING CONCEPT MAPS IMPROVES STUDENTS’ CONCEPTUAL UNDERSTANDING

Semester	Strongly Disagree	Dis-agree	Neu-tral	Agree	Strongly Agree
Semester A (n = 94)	10%	21%	29%	35%	5%
Semester B (n = 71)	5%	17%	28%	44%	6%
Semesters A and B (n = 165)	8%	19%	28%	39%	5%

tructed concept maps [13, 14]. The development and implementation of this assessment rubric will be a future work.

V. CONCLUDING REMARKS

This paper has described a non-traditional approach to concept mapping, in which students (rather than the instructor) construct their own concept maps in engineering dynamics, a foundational sophomore-year undergraduate engineering course. As students must develop their own concept maps, this non-traditional approach promotes active learning, creativity, and critical thinking. A total of 165 students who took an engineering dynamics course in two recent semesters have participated in this study. The results of questionnaire surveys show that 37% of the students rated their experience with developing their own concept maps “positive” or “highly positive,” and that 44% “agreed” or “strongly agreed” that developing their own concept maps improved their conceptual understanding.

Abstract—Scientists, business analysts, and others in a growing number of fields are trying to cope with the vast amount of data being generated. The lack of software that can efficiently process large data sets hinders insight into complex relationships. One of the most important concepts in learning how to construct efficient code is time complexity analysis with Big-O notation. Students often find time complexity difficult to learn and too abstract to apply in any meaningful way. Common instructional methods consist of a combination of mathematics and intuitive analysis which are often too cumbersome for practical application or cannot be extended to complex algorithms. Unfortunately, there are few tools available for teaching time complexity that students find concrete, straightforward, and applicable to real problems. In this paper, we present O-Charts, a first step in the development of a practical toolkit for teaching and applying time complexity analysis. O-Charts allow the systematic analysis of deeply nested loops where the use of control variables makes the number of executions difficult to define, calculate, and explain. We report initial results and our plans for future work.

I. INTRODUCTION

As the size of data sets continues to grow, constructing code capable of efficiently processing large amounts of data is increasingly important. A significant part of teaching students how to build efficient code is analyzing algorithm time complexity using Big-O notation. Although extremely important to an increasing number of fields outside of computer science, algorithm efficiency using Big-O notation is rarely taught before a third computer science course. Even during a third course, students often find time analysis difficult to learn and too abstract to apply.

There are few resources available for teaching time analysis in a manner that students find understandable and applicable. Most instructional techniques currently consist of mathematical approaches, intuitive approaches, or a hybrid of mathematics and intuition. The problems associated with current instructional techniques first become evident when asking students to evaluate an algorithm with deeply nested loops where the number and use of control variables obscure a direct analysis. Theoretical approaches for analyzing code with these complex loops require a high level of mathematical preparedness and, even for the mathematically literate, quickly become too cumbersome to develop or communicate in a practical setting. Intuitive approaches and rules-of-thumb are limited to cases where the efficiency can be quickly deduced or where the control variables are used in a straightforward

manner. Hybrid approaches often lack a bridge that cohesively connects the mathematics to intuition.

This work-in-progress introduces O-Charts, our first step in developing a comprehensive and practical toolkit for calculating algorithm time efficiency. O-Charts allow students to methodically analyze code with loops where the efficiency is obscured by the number and use of control variables. O-Charts were successfully employed as a teaching tool in a third semester data structures course to help analyze deeply nested loops with multiple control variables. Students were tracked for their performance on selected test questions and then surveyed at the end of the course. Initial results indicate a step forward in making time analysis more concrete and easier to apply. We plan to use the technique presented here as a starting point in the development of tools tailored for each algorithm type that students find difficult to analyze. This toolkit will make teaching time complexity more targeted and will provide a way of introducing those concepts earlier in the curriculum.

The remainder of the paper is organized as follows. A brief introduction to Big-O is first presented followed by a survey of related work. Next, we present O-Charts. We then describe how O-Charts were used in a third semester data structures course and how we measured student achievement. Finally, future work is presented.

II. BACKGROUND

Quantifying completion times is one of the first steps in analyzing algorithm efficiency. Computer scientists often compare the growth rate of completion times to establish a relative ordering among algorithms [3]. This ordering is based on the number of times that the most time consuming operation (basic operation) is executed and allows algorithm comparisons to be generalized across multiple machines. Of primary importance is an algorithm's upper bound and lower bound. Big-O notation is used for describing the asymptotic upper bound and Big-Omega (Ω) is used for describing the asymptotic lower bound. Big-Theta (Θ) is used to denote an asymptotically tight bound. There are additional classifications depending on the level of desired specificity. We do not consider classifications other than Big-O in this initial attempt since the upper bound is the focus of most algorithm analysis in early computing courses.

Listing 1. Nested loops with a time complexity of $O(n^5)$.

```

1   for(int i = 0; i < n; i++)
2       for(int j = 0; j < i * i; j++)
3           for(int k = 0; k < j; k++)
4               sum = sum + 1;

```

Listing 2. Nested loops with a time complexity of $O(n^7)$.

```

1   for(int i = 0; i < n; i++)
2       for(int j = 0; j < i; j++)
3           for(int k = 0; k < j * i; k++)
4               for(int m = i; m < j * k; m++)
5                   temp = i * j + k * m;

```

A. Summation Notation

The run time of loops is often represented and solved with summation notation. For simple nested loops, students may be able to quickly derive and solve summations. However, as the number of nests and control variables increase or become less direct, quickly deriving and solving summations becomes more difficult. For example, the time complexity for the nested loops in Listing 1 would be found solving

$$\sum_{i=0}^{n-1} \sum_{j=0}^{i^2-1} \sum_{k=0}^{j-1} 2 \quad (1)$$

in terms of n where the constant was derived from the observation that the inner most loop consists of two operations (assignment and addition). For simplicity, we assume each operation takes a single time unit to complete and that all loop setup costs are ignored. A summation similar to that shown in Equation (1) may prove intimidating and difficult for students just being introduced to time analysis. As nests become deeper and variable use less direct, an increasing amount of mathematical maturity is necessary. For example, a time analysis of the nested loops in Listing 2 would require solving

$$\sum_{i=0}^{n-1} \sum_{j=0}^{i-1} \sum_{k=0}^{ji-1} \sum_{m=i}^{jk-1} 4. \quad (2)$$

If students do not have the necessary level of mathematical maturity, solving deeply nested summations requires that an instructor (or employer if in an industry setting) spend time constantly refreshing math skills. Even if the student has a solid background in mathematics, mistakes in applying appropriate rules and identities can significantly alter results. Furthermore, once the final derivation is found a student or employee may have difficulty articulating their findings to other programmers or managers that may not have the same level of mathematical literacy.

B. Rules-of-Thumb and Intuitive Analysis

Mathematics form the foundation of algorithm analysis and are an important part of a computer scientist's education.

However, many data structures instructors spend little time on mathematics and quickly follow any theoretical approaches with simple rules-of-thumb and intuitive analysis. Rules-of-thumb attempt to give simple guidance to quickly analyze frequently occurring code constructs. Rules-of-thumb found in a popular data structures book [3] and used in our data structures course include 1) the running time of a *for* loop is at most the running time of the statements inside the loop multiplied by the number of iterations, 2) nested loops should be analyzed inside-out where the total running time of a statement inside a group of nested loops is the running time of the statement multiplied by the product of all loop sizes, 3) consecutive statements are added, and 4) the time required for an *if/else* statement is never more than the running time of the test plus the most time consuming branch.

Intuitive analysis simplifies the process further. Often, this type of analysis attempts to eliminate all operations that do not contribute to the leading term of the Big-O formulation. For example, an intuitive analysis of an array search may be similar to the following:

In the worst case, the element being searched for may be the last element or not in the array. Therefore, the search may have to include every element in the array and this results in a run time of $O(n)$.

Rules-of-thumb and intuitive methods greatly simplify analysis for instructors, students, and professionals. However, these are difficult to extend to code segments that are more complicated. Using rules-of-thumb for the code in Listing 2 requires calculating the number of iterations of the basic operation which reduces to solving the summation in Equation 2. Intuitive analysis for the same set of loops is, at best, difficult and, at worst, nonexistent. Instructors, students, and professionals using traditional methods must choose between complicated mathematics and oversimplified rules. Neither approach may be appropriate given the background of the analyst or the ones with which the analyst may need to communicate.

III. RELATED WORK

There has been little progress in developing concrete methods to help students understand and apply time complexity. The progress has been so slow that Rouso [2] argues in favor of a new paradigm. Another approach is to better understand why students find Big-O challenging and then change how time complexity is presented according to student needs. Parker and Lewis [1] conducted student interviews and found that students struggle because of both the mathematical function involved in the analysis and the technique employed to solve the analysis. They also found that students feel more comfortable with tangible and concrete analysis methods. O-Charts support this finding by visually bridging the gap between mathematics and intuitive analysis with a concrete, systematic approach.

IV. O-CHARTS

O-Charts are visual tools for methodically analyzing nested loops. To analyze sections of code, O-Charts allow the analyst to substitute inner loop variables with outer loop variables. First, a small chart representing expanded Big-O notation is

Fig. 1. Steps in determining the time complexity for the nested loops shown in Listing 2 with O-Charts.

drawn with each control variable listed under a single blank. Because the same format will continue throughout analysis, this approach encourages consistency among multiple control variables and eventually to additional code segments. Second, the control variable for each nested loop is systematically replaced with an outer loop variable until all of the variables can be rewritten in terms of the outermost control variable. Third, the terms are combined to find the overall upper bound.

A. Example

We now illustrate how O-Charts can be used to analyze the deeply nested loop in Listing 2. In the example presented here, O-Charts are used to realize the complex multiplicative effects of deeply nested loops without summations. Figure 1 shows the process which is described step-by-step below:

- **Step 1:** Big-O notation is extended to include each control variable and a space for the time of the basic operation. The basic operation has a constant time of 4 (one time unit for each assignment, multiplication, and addition on line 5 in Listing 2) and is listed in the chart.
- **Step 2:** The basic operation is executed m times in the inner most loop. The loop with m is executed $(j \cdot k) - i$

times and this expression replaces all occurrences of m in the chart.

- **Step 3:** The next outermost loop (Listing 2, line 3) iterates k times. The loop with k is executed $j \cdot i$ times and the expression $j \cdot i$ replaces all occurrences of k in the chart.
- **Step 4:** The next outermost loop (Listing 2, line 2) iterates i times. All occurrences of j in the chart are replaced with i .
- **Step 5:** The outermost loop (Listing 2, line 1) iterates n times. The variable n replaces all occurrences of i . All variables in the loops and listed in the chart during Step 1 are now in terms of n . The total number of executions for each variable can be written in the blanks in terms of n .
- **Step 6:** Multiplications are performed and finalized in Big-O notation.

V. EXPERIMENTAL USE AND RESULTS

O-Charts were used in one section of a third semester data structures course at Western Carolina University. Students entering the course had either limited or no experience in time analysis. Big-O was first presented with summation notation, second with O-Charts, and third with intuitive analysis. O-Charts were presented between the two techniques because they are less complicated than summation notation but more detailed than intuitive analysis.

Student use of O-Charts was evaluated by both quantitative and qualitative methods. Quantitative evidence was gathered by evaluating performance on selected test questions that asked students to use O-Charts to derive the time complexity. 85 percent of students correctly analyzed the loops in Listing 1 as having an upper bound of $O(n^5)$. 53 percent of students correctly analyzed the loops in Listing 2 as having an upper bound of $O(n^7)$.

Qualitative evidence was gathered by anonymously surveying the students. Thirteen students completed the survey that included the following questions:

Question 1: *If someone asked you to find the worst case time complexity for a section of code, would you rather use summation notation or the chart method? Why?*

Question 2: *If someone asked you to explain the worst case time complexity for a section of code to someone else, which method (summation notation or the chart method) do you think would help you explain it more effectively? Why?*

One survey was discarded because the responses were unclear but the remaining results were overwhelmingly in favor of O-Charts. All students preferred O-Charts to analyze code segments (Question 1). According to the written responses from the survey, the charts were

- *Easier to visualize*
- *Simpler and less math intensive*
- *More straightforward and obvious to solve*

Nine of the twelve students would prefer to use O-Charts to explain the analysis to others instead of summation notation (Question 2). The students responded that the chart method

- *Breaks down each loop separately*
- *Isn't as confusing*
- *Easier to understand how each for loop relates to the others*

Although most of the students preferred using O-Charts to explain their analysis to others, three thought summation notation was the preferred method. Students that preferred summation notation believed that the mathematical approaches are more detailed, relate directly to the code, and may appeal to a more mathematically literate audience.

We also asked students to rate how easy each of the two methods were to use from 1 (easy) to 5 (difficult). The O-Charts averaged 1.9 and summations averaged 3.9. The distribution for each type of analysis on the easy to difficult scale is shown in Figure 2.

VI. DISCUSSION

Results indicate that O-Charts worked well for the specific types of loops described here and shown in Listings 1 and 2. Student satisfaction was higher for O-Charts than for summation notation. This is an important finding considering that the simplicity of O-Charts allowed the instructor to efficiently present loops that were more deeply nested than the loops presented with summation notation. We recommend using O-Charts between the mathematical and intuitive approach since this order introduces students to both the theoretical and intuitive approaches with decreasing granularity. Not only does this order provide a cohesive bridge between the traditional methods, it also fits the approach of following mathematics with intuition already used by many instructors.

In the code examples here (Listing 1 and 2), only a single set of nested loop is considered. O-Charts can be extended to larger sections of code that include multiple nested loop segments. As students progress in the analysis, they simply construct a chart for each consecutive statement and then sum the individual chart results.

Although effective, O-Charts represent an initial attempt and should be further refined. Improvements include capturing more code constructs, such as searching and sorting algorithms, that students find difficult to analyze. Additionally, O-Charts should be flexible enough to express more algorithm classes (Ω , Θ , etc.).

VII. CONCLUSION AND FUTURE WORK

In this work-in-progress, we have presented our first steps in building an effective toolkit for teaching and applying time complexity. Students performed well when analyzing deeply nested loops. They also reported feeling more comfortable using and applying O-Charts than mathematical techniques. For instructors, O-Charts fill a gap when transitioning from mathematical techniques to intuitive analysis.

There are many avenues for future work. First, we only tracked student performance on O-Charts. In the next phase of

Fig. 2. Students rated O-Charts (top) and summation notation (bottom) from easy to difficult. Each column represents the number of students for a given rating. The results reveal that the students found O-Charts much easier to use than summation notation.

research, we would like to more directly compare summation notation, O-Charts, and intuitive analysis techniques on the same segment of code. Second, we would like to experiment with a more thorough introduction to time analysis earlier in the curriculum. The quick and systematic approach presented here make O-Charts a viable possibility for the early introduction of time complexity. Third, more algorithm classes should be included. Finally, more code constructs which present problems for students, including advanced searching and sorting techniques, need to be identified so that O-Charts can be altered appropriately or additional tools developed.

Abstract— Universities collect qualitative and quantitative feedback from students upon course completion in order to improve course quality and students' learning experience. Combining program-wide and module-specific questions, universities collect feedback from students on three main aspects of a course namely, teaching style, content, and learning experience. The feedback is collected through both qualitative comments and quantitative scores. Current methods for analyzing the student course evaluations are manual and majorly focus on quantitative feedback and fall short of an in-depth exploration of qualitative feedback. In this paper, we develop student feedback mining system (SFMS) which applies text analytics and opinion mining approach to provide instructors a quantified and exhaustive analysis of the qualitative feedback from students and avail insights on their teaching practices and this in turn will lead to improved student learning.

Keywords—Student feedback, education data mining, topics, sentiments, text analytics, clustering.

I. INTRODUCTION

Universities employ various formal and informal methods to collect and analyse feedback from students in order to enhance the quality of teaching and learning. Many institutions have implemented evaluation surveys which combine "program-wide" questions and "module-specific" questions that enable comparisons to be made across the institution whilst allowing flexibility for individual modules [4]. These surveys provide valuable feedback that helps course designers towards improving teaching style, course content and assessment design, and overall student learning [2][3]. The feedback must be analysed and interpreted with great care so that action, and ultimately improvement, can result from feedback process [1].

Students provide feedback in two distinct forms namely quantitative (numerical) ratings for questions and qualitative comments related to teaching, content and learning [5]. The teaching component refers to instructors' interaction, delivery style, ability to motivate students, out of class support, etc. The content refers to course details such as concepts, lecture notes, labs, exams, projects, etc. The learning refers to students learning experience such as understanding concepts, developing skills, applying skills acquired, etc. Analysing and evaluating this qualitative data to help us make better sense of student feedback on instruction and curriculum.

Current methods for analysing student course evaluations are manual and majorly focus on the quantitative feedback [17] [18]. More often, an analysis of student feedback falls short of an in-depth exploration of a qualitative feedback [32], thereby limiting instructors to the numerical scores and a human understanding of a sample of the feedback, which abstracts collective sentiments for individual components of courses. The question is to how to help the faculty to better digest such large amounts of comments and discover the gaps in the course delivery.

Going forward, a more useful approach will be to map the students' qualitative feedback in the form of topics and sentiments towards the three major components namely teaching, content and learning. Figure 1 shows the problem setup. The input data is a set of students' comments given for an information systems curriculum undergraduate course, IS304, process modelling and solution blueprinting.

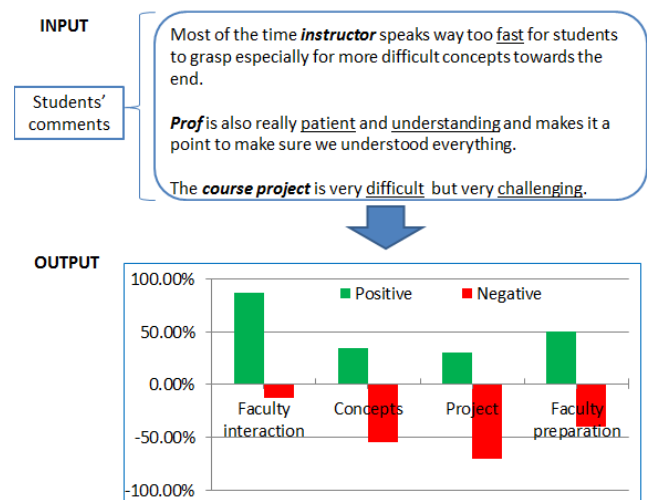

Fig. 1. Sample comments from students for an information systems curriculum undergraduate course. Bolded words are the topics and underlined words are the sentiment words.

With such data, an instructor can only get an overall impression of the course and not the deeper insights. It is infeasible to go over all the comments for deeper analysis. In contrast, an output such as topic based summary on sentiments as shown in Figure 1 provides a detailed analysis. A **topic** refers to an aspect of the course such as concepts, delivery style, understanding, lab, faculty interaction, skills, learning,

etc., and **sentiment** refers to positive or negative experience with the corresponding topic. Figure 1 shows the topics such as “concepts” and “project”, and sentiment words such as “patient”, “understanding”, “challenging”, etc. The overall sentiment for *professor* is positive, while the sentiment on *concepts* is negative. Extracting individual topics and sentiments automatically provides instructors and curriculum managers a data-driven approach for improving teaching and learning. Decisions can be made while constructing future cycles of course delivery to maintain or improve components as per feedback and measure the impacts.

In this paper, we provide automated techniques to diagnose textual feedback. The main challenge with this task is the textual nature of comments which are expressed in natural language. Furthermore, the feedback topics and sentiments are embedded within the text. Opinion mining, topic extraction and NLP techniques [8] [15] [16] from the text analytics and linguistics research are widely popular for mining users’ comments in social media. Sentiment mining techniques are widely used for product review mining in consumer business world [9] [12]. We leverage these techniques for building the student feedback mining system (SFMS). SFMS applies data mining, text mining and opinion mining techniques on qualitative comments to extract topics and sentiments on courses aiding in generating quantitative visuals to support a deeper analysis.

We evaluated SFMS using student feedback provided by the students for undergraduate core courses taught at the School of Information Systems, Singapore Management University collected for two semesters on seven courses. Information Systems is classified under science and technology education (all engineering courses as classified under this) by Ministry of Education, Singapore. The evaluation is conducted in two phases; quality of the topic extraction and quality of the sentiment extraction. Our experiments show that SFMS system provided meaningful clusters of comments and aspect words for topic extraction task and precision of 80.1% for sentiment extraction task.

The paper will be structured as follows. Section II will review the key background of text analytics techniques and opinion mining problem. Section III will be devoted to literature review and will primarily focus on describing the current research done in the field of student feedback analysis. Section IV describes our system in detail for topic and sentiment extraction from students’ comments. Section V describes our dataset and pre-processing of data. In section VI, we focus on experiments, results, discussions and pointing some interesting future directions of our work, and we conclude in section VII.

II. BACKGROUND

Text mining and natural language processing techniques are useful for opinion mining research. Therefore, we first provide a brief description of few text analytics techniques that are key components to our system, followed by the background of opinion mining research.

A. Text Analytics Techniques

Text analytics or text mining is a knowledge discovery technique that provides computational intelligence [12] [19] through devising of patterns and trends. The techniques comprise of multidisciplinary fields, such as information retrieval, extraction, text analysis, natural language processing, and data mining. Text mining techniques enable to identify similarities between text attributes [12]. Some of the natural language issues that should be considered during text mining are tokenization, stop word lists, etc.

Stop word removal: Most frequently used words in English are useless in Text mining. For example “has”, “if”, “and”, “on” etc. Such words are called stop words. Stop words are language specific functional words which carry no information and therefore removed from the documents during data pre-processing stage. Parts of Speech such as pronouns, prepositions, conjunctions are defined in stop word list¹.

Tokenization: Tokenization deals with the splitting of text into units during data pre-processing. Text can be tokenized into paragraphs, sentences, phrases and single words. The delimiters used in this process vary with data sets.

Stemming: This method is used to find out the root/stem of a word. Words are stemmed using the Porter Stemming algorithm [31], which returns the root form of a word. For instance, the word “progression” is stemmed as “progress” and “progress*” is formed as part of the query. However, in our preliminary experiments we observed that, stemming impairs our results. Therefore, we do not use stemming.

Document Representation: In order to score the similarity between two documents, we need to first adopt a vector space representation of a document where each document is evaluated as a term-frequency (TF) vector [18] and inverse document frequency (IDF) [18]. TF-IDF is a statistical measure or weight often used in information retrieval and text mining to evaluate how important a word or term is to a document in a collection or corpus. Term frequency is the number of occurrence of a term in a document. The information that is captured by term frequency tells how salient a word is within a given document. Document frequency on the other hand can be interpreted as an indicator of informativeness. Inverse document frequency is used to scale down the term frequency of terms with high total number of occurrences in the collection. Both these measures aids in generating the aspects or topics for a comment in our case. One way to combine a word’s term frequency and inverse document frequency into single weight is a TF-IDF. Finally, each document in the dataset is represented as a document-term matrix.

Document similarity score: The similarity score between two documents determines the co-occurrence of a primary topic between two documents to cluster them together. We compute this score by computing the cosine angle between them [18] which are modeled as vectors in a vector space.

¹ www.ranks.nl/resources/stopwords.html

Agglomerative Clustering: Clustering algorithms are exploratory data analysis tools that have proved to be essential for gaining valuable insights on various aspects and relationships of the underlying textual data [16]. Agglomerative algorithms find the clusters by initially assigning each object to its own cluster and then repeatedly merging pairs of clusters until either the desired number of clusters has been obtained or all the objects have been merged into a single cluster leading to a complete agglomerative tree. The key step in these algorithms is the method, also referred to as clustering function, used to identify pairs of clusters to be merged iteratively.

B. Opinion Mining

Opinions are central to almost all human activities and are key influencers of our decision making process. Opinion mining is a well-studied research topic for the past ten years mainly focusing on opinion extraction, sentiment classification, opinion summarization and applications in real world. Opinion mining found its roots in many real-life applications and several application-oriented research studies have been published.

Figure 2 shows the architecture of opinion mining. Opinion mining architecture takes users' comments as inputs to generate sentiment analysis visualizations as outputs that can aid the decision makers in decision making process. The text processing component handles data cleansing and processing issues. In next subsections, we briefly explain the main components of the architecture namely, topic extraction, sentiment classification and opinion summarization.

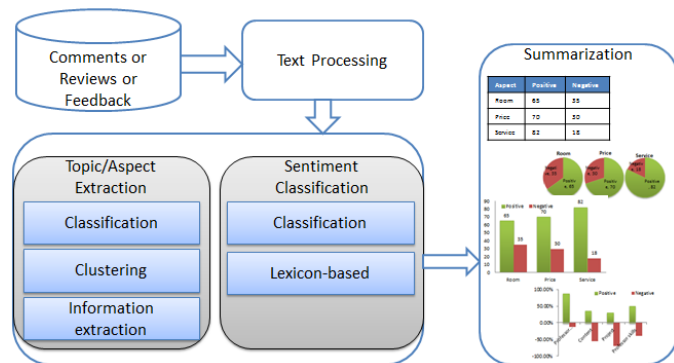

Fig. 2. Opinion mining architecture.

C. Topic Extraction

Opinion extraction aims at automatically finding attitudes or opinions about specific targets, such as named entities, consumer products or public events [8] [15]. An opinion without its target being identified is of limited use [9]. For many applications opinion extraction is insufficient, and a fine-grained opinion mining and analysis such as topic or aspect extraction is highly effective [9] [10]. "The iPhone's call quality is good, but its battery life is short" evaluates two aspects, call quality and battery life. Hu and Liu used a data mining algorithm that finds explicit aspect expressions that are nouns and noun phrases from a large number of reviews in a given domain [9]. Jiang et al. proposed how a dependency

parser was used to generate a set of aspect dependent features for classification [15]. Many algorithms based on supervised learning have been proposed in the past for information extraction [14]. Clustering based feature extraction techniques are implemented by some research works [6] [7]. Beil et al. designed clustering technique on the basis of frequent pattern mining [7]. Lu et al. proposed clustering based technique for discovering aspects from users' comments [6]. Inspired by these works, we use agglomerative clustering to group comments into clusters based on their cosine similarity.

D. Sentiment Classification

Sentiment classification aims at classifying the data into positive or negative polarities [12] using supervised methods or unsupervised methods. Similar to opinion extraction, fine grained sentiment analysis is desired as it is highly effective to understand the pulse of the consumers at feature level. The task of sentiment target detection [9] aims at extracting the sentiment targets in the reviews using multiple heuristic techniques. Pang et al. examined several supervised machine learning methods like SVM and Bayes classification for sentiment classification of movie reviews and showed that classifiers performed poorly on sentences as sentences contains less information [12].

Lexicon methods are based on sentiment words and phrases which are instrumental to sentiment analysis for obvious reasons [8]. A list of such words and phrases is called a sentiment lexicon (or opinion lexicon). Over the years, researchers have designed numerous algorithms to compile such lexicons; SentiWordNet [11] and Sentiment lexicon [9]. Our system generates sentiment for each topic using classification approach.

E. Opinion Summarization

Summarization is a study that attempts to generate a concise and digestible summary of a large number of opinions [8]. Current research aims at two types of summarization: aspect-based summarization and non-aspect-based summarization. Aspect-based summarization divides input texts into aspects, which are also called features, and generates summaries of each aspect [9] [13]. A common form of summary is based on aspects and is called aspect-based opinion summary (or feature-based opinion summary) [8] [9].

III. RELATED WORK

Traditionally, universities collected written feedback from students regarding the course taught and the professor's engagement in order to assist the development of the course through future cycles. Pedagogical theory of student feedback describes the need for interpreting students' perceptions and sentiments for overall teaching evaluation and improvements [33]. Donovan et al. [17] found that online student feedback comments were longer and that they were more formative in nature than the traditional written feedback. Moreover, online feedback received longer and half as many (54% or more) comments as traditional written comments. This highlights the importance of collecting online comments. However, manually reading and analyzing these online comments takes a lot of time and hence the need for an automated feedback system

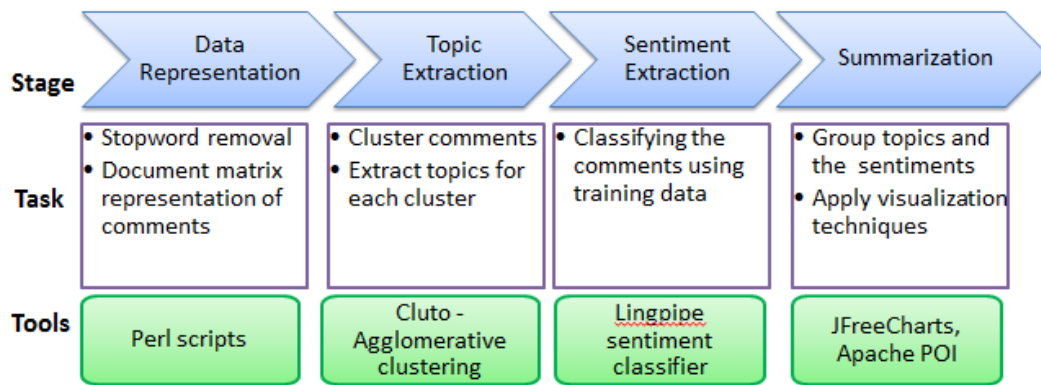

Fig. 3. SFMS system architecture

which automates feedback collection and analysis, allowing a visual analysis of opinions or sentiments on different aspects of the course.

In existing research on educational data mining, the more prominent forms of analysis are with Apriori algorithms, decision trees and clustering algorithms [18] with most research being done on association pattern mining to find links between opinions on courses and professors in order to better cater to students, enhance their grades, prevent drop-out or transfers and improve the overall degree experience. Altrabsheh et al. devised a system to analyze sentiments in real time to provide real-time intervention in the classroom. Their experiments yielded the conclusion that Support Vector Machines and Complement Naïve Bayes produced the most accurate results while learning sentiment [19]. Hajizadeh et al. experimented on student feedback to analyze whether or not a student would retake the course [20] indicating sentiment opinions about the course. Rashid et al. used generalized sequential pattern mining and association rule mining with 87% accuracy to analyze opinion words from student feedback while stopping short of sentiment classification upon identification of the opinion words [21]. Gamon et al. took another approach for analyzing sentiment in free flowing text – as is with student feedback as well – by building a system, Pulse, that brought together algorithms that clustered topics and classified sentiments with intuitive visualization to allow a deeper analysis of customer feedback and sentiment on special topics [22].

Qualitative research in education suggests that student feedback is not only important for course improvement; it also allows universities to align their courses to international accreditation standards in the avenue of quality control and assurance of universities [23]. The actual use of the analyzed data is also a subject for research where researchers have tried to tie feedback to changes in teaching, grading and self-evaluation for professors. Yao et al. found that professors do indeed care about student feedback and used discretion in using formative comments in modifying their teaching. Despite variations in the ultimate use of the feedback collected, they found that sentiments towards student feedback ranged from neutral to positive, indicating the usefulness of collecting feedback [24].

Given course codes and students' comments as inputs, the goal of our project is to develop a system that can extract and

visualize the topics and sentiments on courses. In the next section, we explain the details of SFMS system.

IV. STUDENT FEEDBACK MINING SYSTEM (SFMS)

In this section, we describe the architecture of SFMS (depicted in Figure 3), which basically follows the opinion mining architecture shown in Figure 2. The first layer in the architecture shows the main stages of the system. Second layer depicts the key tasks in each stage. The third layer depicts the tools or techniques used to accomplish the tasks in each stage.

The system consists of four main stages as shown in Figure 3. In first stage, a dense matrix of comments is generated after preprocessing the data. In second stage, the comments are clustered based on their primary common topic. In third stage, sentiment of each comment is extracted, and finally in the fourth stage, topics and sentiments are aggregated for comprehensive reporting. SFMS system is developed in Java platform.

The system initiates with the course codes and corresponding comments as inputs and executes all the stages to generate visual analysis reports. For example, “The course project is very difficult but very challenging” is a comment for a course code, IS203. We explain each stage in detail in the subsequent sections.

A. Data Representation

In data representation stage, first, all terms are extracted from input comments using tokenization by space. Second, stop words are removed from each comment using the stopwords list. Document representation is shown in Figure 4.

	Feature	Value	Feature	Value	Feature	Value
1	pace	1.000000	time	1.000000	uploaded	1.000000
2	sometimes	2.000000	require	1.000000	meet	1.000000
3	students	1.000000	sometimes	1.000000	factor	1.000000
4	meet	1.000000	teams	1.000000	factor	1.000000
5	ridiculous	1.000000	is480	1.000000	grades	1.000000
6	students	2.000000	especially	1.000000	understand	1.000000

Fig. 4. Document representation matrix (document – term – value). Each row represents comment. Feature represents word or term and value represents frequency of a term in the document. Due to space constraints only three features for sample comments are depicted.

In order to calculate the similarity between two comments, we need to transform the free-flowing text in the comment into a numerical matrix as shown in Figure 4. Each row denotes a comment, and each cell in that row is occupied by a single word (or feature) from that comment together with its term frequency (log or square root).

Such data representation would assist in judging the importance of each word in a comment and therefore measuring the similarity between comments. To generate the document term matrix, we use perl scripts. Our interface takes the comments and stopword list as inputs and generates document matrix.

B. Topic Extraction

A topic is the subject or target of a student's comment. For example, given the comment, "The course project is very difficult but very challenging", "project" is the topic of the comment. In topic extraction phase, the objective is to breakdown all the comments by topics such as teaching, content, learning etc. To achieve this, the first task is to cluster the comments using clustering algorithms and specific clustering functions.

Various clustering criterion measures such as I_1 , E_2 , H_2 etc., are available for measuring the clustering similarity [29]. These schemes differ on how the similarity between the individual objects in various clusters is combined to determine the similarity between the clusters themselves. Table I provides the notation for the formulae and Table II provides the formulae for selected clustering functions.

TABLE I. NOTATION

S : collection of documents
$S_1, S_2, \dots S_k$: set of document of k -th cluster
k : number of clusters
$n_1, n_2, \dots n_k$: number of docs of corresponding clusters
C_r : centroid vector of r -th cluster
C : the centroid vector of the entire collection
d_i, d_j : i -th and j -th documents
D : the composite vector of the entire docs

TABLE II. MATHEMATICAL FORMULAE FOR CLUSTERING CRITERION [29]

Criterion	Formula
I_1	$Maximize(I_1) = \sum_{r=1}^k n_r \left(\frac{1}{n_r^2} \sum_{d_i, d_j \in S_r} \cos(d_i, d_j) \right)$
I_2	$Maximize(I_2) = \sum_{r=1}^k \sum_{d \in S_r} \cos(d_i, C_r)$
E_1	$Minimize(E_1) = \sum_{r=1}^k n_r \cos(C_r, C)$
H_1	$Maximize(H_1) = \frac{I_1}{E_1}$
H_2	$Maximize(H_2) = \frac{I_2}{E_1}$

I_1 : This function tries to maximize the intra cluster similarity between the elements of a cluster.

I_2 : This function also tries to maximize the intra cluster similarity between the elements of a cluster. The only difference between I_1 and I_2 is that while calculating I_2 we must take the square root of the function.

E_1 : This function divides the intra-cluster similarity with inter cluster similarity.

H_1 : This is a hybrid function to maximize I_1/E_1 .

H_2 : This is a hybrid function trying to maximize I_2/E_1 .

To cluster the comments, we use agglomerative clustering algorithm, and the tool we use is Cluto clustering library [25]. Similar comments will be grouped together by the clustering algorithm. The top words in the cluster represent the topic of the cluster. The examples are demonstrated in our experiments section.

Once clusters are generated, the second task is to extract topics for the clusters. In this context, the topics are the high frequency words that appear in each cluster. For example, the words like *project*, *time*, *practice* etc., are some of the high frequency words that represent the cluster with comments related to topic, *project*. However, the label for the cluster should be manually provided to generate a meaningful representation for a cluster. We developed an interface that accepts users' inputs for the cluster labels and the system uses them for subsequent phases.

Mostly student comments refer to a single topic, but there are few instances that they may span across many topics in a single comment. A comment with multiple topics is not a focus of our work and we leave it to future work.

C. Sentiment Extraction

Discovering the sentiment of each comment provides the user with an analysis of collective sentiments against each topic or each cluster in the entire collection. Sentiment refers to the positivity or negativity of a given comment. For example, given the comment, "The course project is very difficult but very challenging", the sentiment is "negative".

In this phase, the objective is to find the overall positive or negative sentiment for a given comment. We propose a classification based approach for this task and therefore created a training set for the training the classifier. For this purpose, we use LingPipe Language Identification Classifier [26] which adopts the classification approach to sentiment analysis using a sentence-level logical regression classifier. It deconstructs each comment sentence into n-grams, or number of words evaluated at a time while processing the sentiment of the comment. We have chosen to use bi-grams for sentiment extraction task. We use bi-grams as they aid in processing negating phrases such as "not good".

Using bi-grams, LingPipe evaluates two words at a time before assigning an overall sentiment to the comment. This allows evaluation of double negatives which allow a better evaluation of sentiment. The classifier learns the natural distribution of characters in the language model of a training

data set and then assigns a sentiment probability to each evaluated bi-gram according to a probability distribution. Eventually leading to an aggregated final sentiment for each comment evaluated. Agarwal et al. [30] evaluated the use of three categories of sentiment for basic polarity in sentiment – negative, positive and neutral, but found that the results were better with strict polarity between positive and negative only. In our preliminary studies, we observed that the students’ comments are mostly negative or positive. We leave neutral component for future exploration.

D. Summarization

Summarization is the final stage where the goal is to provide user friendly summaries of the quantitative results obtained from the previous phases. Once the comments have been clustered into topics and the sentiment for each cluster is known, we categorize the comments by course. Therefore, each course has its own set of k clusters with their individual comments annotated with a sentiment. Essentially, the courses serve as high level category or a curriculum level summarization. In contrast, individual comments serve as course level summarization. Visualization charts use the topics, sentiments and course codes as inputs. The charts are generated using JFreeCharts [27] and inserted into Microsoft Excel files that are created and manipulated using Apache POI libraries [28] for enabling users with easy analysis. We adopt the charts similar to feature-based sentiment summaries by Hu et al. [13].

V. DATASET

We use dataset of feedback comments given by students attending courses offered by the School of Information Systems at Singapore Management University for the academic year 2013-14. These comments are collected at two feedback cycles, midterm and end-term, and span across two semesters. In total, seven courses are evaluated, yielding 5,341 comments for evaluation.

In our data analysis, we noticed that some students provide “NA” or “Nil” comments. In order to avoid noise in the results, we removed comments with less than 10 characters. This allows us to focus on those comments which would yield a constructive view on topics being discussed and their respective sentiments. Finally, we have 3,144 comments for our experiments.

VI. EXPERIMENTS

We first explain experiment setup followed by the results.

A. Experiment Setup

We developed SFMS as a desktop application with simple graphical interface. Recall that our first stage of SFMS system is to generate document representation in matrix format. To generate the document term matrix, we use *doc2mat* perl scripts provided in the Cluto library [25] and Figure 5 shows the GUI for data representation stage. The UI takes the comments and stop word list as inputs and generates document matrix in a given location. We observed that words such as “students”, “course” etc. that occur very frequently in the

dataset generate noise and impact the quality of customers. Therefore, these words are added to the current stopword list.

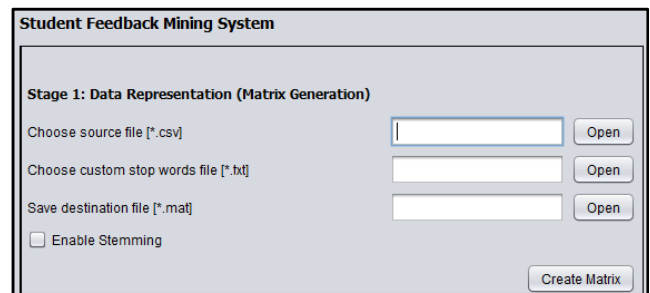

Fig. 5. SFMS System UI: Data Representation Stage.

Cluto API is an easy-to-use platform that combines a variety of different clustering algorithms. We use vcluster (agglomerative) in the toolkit to generate clusters. Cluto provides three row models; log, MAXTF and square root. All our experiments are based on agglomerative clustering with cosine similarity and log model. We set number of clusters to 10 after some preliminary experiments. For sentiment classification, we use Lingpipe [26] which provides a sentence based logistic regression classifier for sentiment classification.

B. Topic Extracion Results

We first present quantitative results on clusters followed by qualitative analysis of topics generated. Recall that Cluto provides multiple clustering functions to determine clusters as described in Section IV. Figure 6 depicts the GUI for cluster generation.

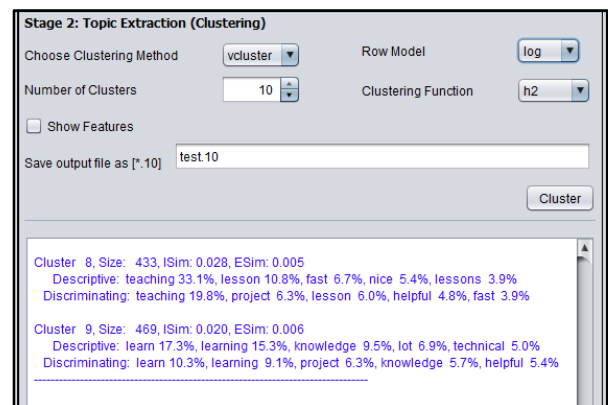

Fig. 6. SFMS System UI: Topic Extraction Stage (Clustering task).

The UI allows users to choose cluster methods, term frequency measures, count of clusters, and clustering functions to generate clusters. Various clustering criterion measures such as I_1 , E_2 , H_2 etc., are available for measuring the clustering similarity [29] as described in Section IV. SFMS calls Cluto API with the user inputs and performs clustering. For our preliminary experiments, we tested with multiple combinations. However, we present only the results from the selected combinations that provide better performance. We use *Purity* (the higher the better) and *Entropy* (the lower the better) to evaluate the performance of clustering algorithm in topic extraction phase [8]. From our results, we observed that the clustering function, H_2 provides Purity of 93.4%, which is

slightly higher than other clustering functions and Entropy of 0.214. Therefore, we use H_2 for subsequent experiments. We now present the qualitative analysis of topics generated by clustering task. Using H_2 , the comments are clustered and the top features of each cluster are as shown in Table IV.

TABLE III. TEN CLUSTERS WITH TOP WORDS AND HUMAN ALIAS (H_2)

Cluster #	Top frequency words	Alias
0	approachable, friendly, enthusiastic, consultation, help	Faculty interaction
1	helpful, feedback, concepts, understanding, encouraging, help	Faculty feedback
2	patient, knowledgeable, passionate, responsible, fun	Faculty preparation
3	project, heavy, time, requirements, lot	Project
4	time, assignment, sql, labs, php	Assignments
5	challenging, lab, test, project, exercises	Labs
6	excel, future, skills, real, applicable	Skills
7	understand, concepts, help, questions, explain	Concepts understanding
8	teaching, lesson, fast, nice, lessons	Classroom delivery
9	learn, learning, knowledge, lot, technical	Learning experience

Each cluster has distinguishing or determining features or words which determine the topic of the cluster. We notice that all clusters are very coherent and meaningful except clusters 4 and 5 which both refer to labs. This is one of the drawbacks of clusters as it is unsupervised. To improve the quality, one approach is to exploit the questions together with the comments and we leave it to future work on improving the quality of the clusters. SFMS system provides an UI to users to provide *Alias* or *labels* for each cluster as shown in Figure 7. Once aliases are provided, the comments are also categorized by course codes. This categorization aids in generating user friendly visual reports.

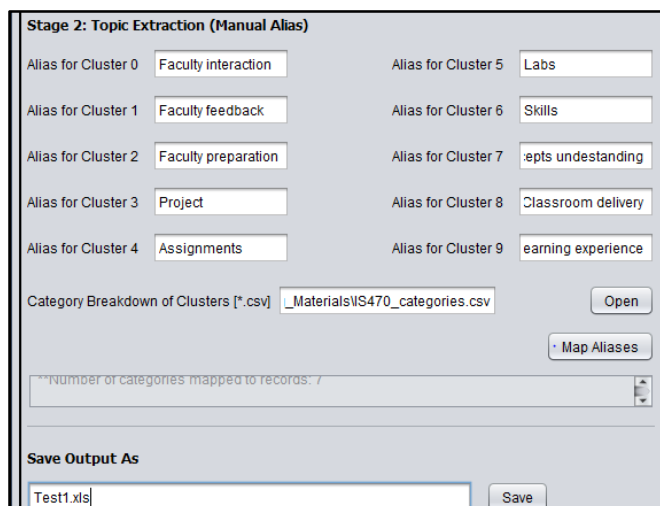

Fig. 7. SFMS System UI: Topic Extraction Stage (Human labeling task).

C. Sentiment Extraction Results

In the sentiment extraction phase, we use human labeling for training the data and evaluating SFMS. Lingpipe uses logistic regression and we evaluated the effect of domain knowledge on the training of sentiment classifier. Figure 8

shows UI for sentiment classification. The UI allows users to provide training data to SFMS to train the classifier.

Fig. 8. SFMS System UI: Sentiment Extraction Stage.

We used log regression model trained on Internet Movie Database (IMDB) domain and education domain. Sample comments and the corresponding sentiment classification results are depicted in Table II. We observe that training the classifier on education domain gives best results instead of the standard (IMDB) dataset provided by Pang et al [6].

TABLE IV. SAMPLE COMMENTS AND COMPARISON OF BOTH DOMAINS FOR SENTIMENT CLASSIFICATION TASK

Function	IMDB	Education
very knowledgeable, patient and easygoing	-ive	+ive
sometime he went through the concepts a bit too fast for us to grasp.	+ive	-ive
always concern for student and willing to help weaker student	-ive	+ive
Asks challenging questions to get us to think deeper.	+ive	-ive

Table II shows some example comments and the corresponding sentiment labels generated by SFMS when trained on IMDB and education domain. In our analysis, we observed that low precision for IMDB domain is due to false positives. In contrast, the classification approach labeled it as positive. Overall, the sentiment extraction phase with education domain training has a precision of 80.1%, which is significantly higher than IMDB trained classifier.

D. Feedback Summarization Results

Topics and sentiments generated by previous phases are used for reporting using JFreeCharts [27].

Fig. 9. Integrated visualization of topics and sentiments for seven courses in Information systems curriculum. Excel sheet generated by SFMS.

Figure 9 shows the integrated reporting view of student feedback which can be useful for curriculum designers and management. To categorize the results, course codes are used for generating reports. It has the clusters information as well as reports for every course in our dataset. Figure 10 provides deeper analysis for the course instructors on various aspects of the course.

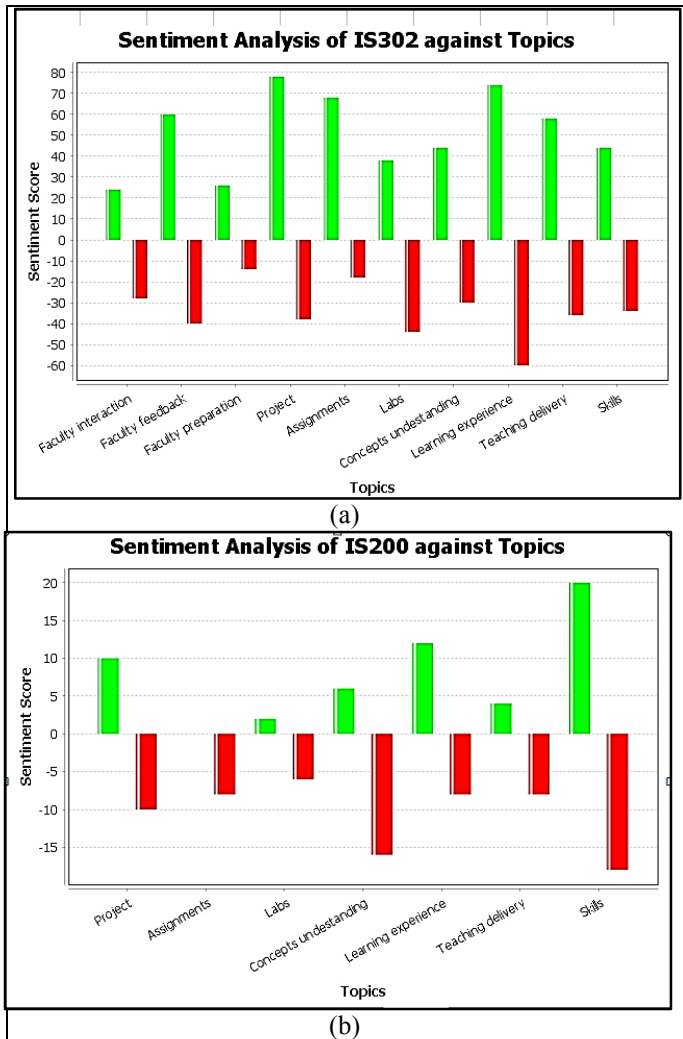

Fig. 10. Visualization of topics and sentiments for Information systems course codes. (a). Course code, IS302 - Information security & trust.(b). Course code, IS200 - Software Foundations.

We observe that the students provides comments on aspects such as project, labs, skills, etc. of IS200 (IS software foundations) course, which is programmatic in nature. However, the faculty feedback and interaction is not of their concern. In contrast, for IS302 (Information security & trust) course which is less programmatic in nature, but with an open research project, the students are concerned with the faculty feedback and interaction. We observe the negative sentiments are also quite high. Therefore, there is a need for the faculty to plan for some changes in the project or consultation sessions. For example, faulty may provide additional consultation hours or online discussion forums. For IS200, faculty may provide some extra tutorials to improve student learning experience.

E. Discussions and Future Work

One major limitation of Cluto is that, each comment can only belong to one cluster. This means that even though a single comment can span multiple topics, it will be clustered under the primary topic – or the topic with most of its discriminating significant words similar to those in the comment, as judged by the clustering function. Topic models such as LDA can be explored to overcome this limitation which we leave it to future work. Similarly, exploring sentence based topic-sentiment is an interesting future work. Currently, SFMS can only take in a single-level categorization for distribution of clusters. Other categories such as term, year, school, faculty, etc., can provide detailed analysis. Future iterations of the development of this system could create dynamic hierarchies of categories that will allow users and analysts to drill down dynamically into topics and sentiments by each level for deeper analysis. Secondly, SFMS offers a sentiment score for each topic being discussed by students but does not go deeper to signify what the actual comments spoke about. Faculty might want to retrieve the comments interactively for further analysis. Lastly, students often leave suggestions for professors regarding delivery, content, interactions and so on. Since these relate strongly to each of the topics being analyzed, each topic and its respective sentiment can also have a highlighted set of suggestive comments to take the system one step forward from descriptive analytics to actionable insights.

VII. CONCLUSION

In this paper, aspect or topic based sentiment mining techniques are evaluated in order to build a desktop-based solution to analyze topics and their sentiments from student generated feedback in universities. We found that agglomerative clustering with cosine similarity using a hybrid approach generates coherent clusters for topic extraction task. Further, using a logistical regression algorithm, which is trained on education domain, extracts sentiments on comments with higher accuracy compared to the classifier trained on movies domain. Free flowing textual data like student feedback in an education context can be therefore analyzed automatically in order to gather a deeper understanding and facilitate the stakeholders in course improvement cycles.

Preparing ECE Students for Research Career in Nanotechnology via Track Program

Maher E. Rizkalla^{1,2} and Mangilal Agarwal²

¹Department of Electrical and Computer Engineering

²Integrated Nanosystems Development Institute (INDI)

Indiana University-Purdue University Indianapolis, Indianapolis, Indiana

Abstract— This paper details the research participation of undergraduate students from the freshman to the senior year. Four courses were designated to prepare students for a nanotechnology research career. New modes of instructions leading to research participation followed in this curriculum have been reported. This covers integration of knowledge, just in time approach, and project portfolio based curriculum. Courses developed in this track emphasize research and applications in health sciences and renewable energy areas. The structure of the track program was presented before with emphasis on the senior level courses of the track. The work in this paper, however, emphasizes research participation in nanotechnology of the junior students within the electrical engineering, computer engineering, and mechanical engineering disciplines. The multidisciplinary components in nanotechnology research topics were attractive to students to work in team. The topics covered in this course included nanotechnology applications in diabetes, cancer research, and neurosciences. Lecture materials were all from up-to-date research papers, and can be altered with the course updates. Students registered for this course were required to emphasize two research topics seven week each, and prepare research posters in a research day where industrial representatives are invited to participate in the discussions with students. Students who completed this course were interested to continue with nanotechnology individual research and get enrolled in upper level courses.

The course starts with introducing students to the nanotechnology applications in various fields, including environment, society, consumer electronics, computers, health sciences, optics, electromagnetics, energy, and medical imaging. The course then introduces students to research issues emphasizing health sciences and renewable energy. Students will be required to expand their research to cover in depth one or two research issues that fall within their interests. In the research projects, students work in team, two students/team, and assignment is given to each to share the contribution of the project.

Submitted on April 27th, 2015. The authors are with the School of Engineering and Technology at Indiana University Purdue University Indianapolis. The project was partially funded by the NSF NUE program grant 1042110.

Dr. Maher Rizkalla is a Professor & Associate Chair of Department of Electrical and Computer Engineering and Member of Integrated Nanosystems Development Institute (INDI) at IUPUI, 723W Michigan St. Indianapolis, IN 46202 USA (email:mrizkall@iupui.edu)

Dr. Mangilal Agarwal is a Associate Director for Research Development and Director of Integrated Nanosystems Development Institute (INDI) at IUPUI.

The course was assessed with student satisfaction, and the objectives and the outcomes of the course were met.

Index Terms—undergraduate track, research career in nanotechnology, undergraduate research projects, multidisciplinary, innovation.

I. INTRODUCTION

Engineering major is considered in many disciplines as applied sciences where math and sciences knowledge are applied into real engineering products. Near 25% of engineering curriculum is covered from Math and Sciences course. Big emphases on the engineering programs are invested in mathematical and computer models, a very important element in engineering research. This emphasis assists undergraduate students with integrating knowledge from math and sciences into engineering system modeling. These systems may range from the device level to the system level. Classroom engineering instructions provide engineering students with research tools, including hands on practical models, mathematics models, and computer models. Software engineering is an integral component in the EE, CmpE, and ME curricula. These tools equip engineering students with research foundation. Undergraduates at Indiana University Purdue University Indianapolis (IUPUI) team up with graduate mentors, to explore research hypothesis in various areas.

At IUPUI, undergraduate students are engaged in research at early stages in the curriculum via individual research courses, multidisciplinary research courses, and industrial based research/design courses. Undergraduate research has become a part of the educational culture. They are given plenty of opportunities to apply math and sciences into engineering curricula.

Undergraduate research opportunities at IUPUI lie on the faculty research expertise. One of the research areas emphasized in the past 5 years was nanotechnology, where engineering and sciences faculty members integrating their efforts towards new engineering/science applications. Research topics range from bioengineering/biosensors, solid state nanotechnology and molecular devices, and nanomaterials. There are two areas of concentration

emphasized by the Integrated Nanosystems Development Institute (INDI) group with the IUPUI campus. These are the health sciences, and the renewable energy. Our dedicated faculty and research resources on campus have led to the success of this emphasis. The collaboration of the IU Medical School has added to the future potential of this institute.

In 2010, the team of engineering from ECE and ME together with INDI received an NSF NUE grant leading to the development of a track program within ECE and ME programs, taking the students for nanotechnology road from the sophomore year to the senior year. Educational outcomes from this track program have been presented elsewhere [1-5]. Unlike the other STEM programs that combine math and sciences into K-12 education [6-8], this development features a multidisciplinary area where a nanotechnology theme is the focus that let participation from ME, ECE, BME, Chemistry, and Physics all into the same program.

II. ABOUT THE NANOTECHNOLOGY TRACK

The team of faculty from engineering and sciences has provided innovative educational opportunities in nanotechnology. With the collaboration with INDI, important features of this program have been integrated into the curricula. This included lab-based curricula; strong linkages to existing undergraduate research programs; technical and research courses; and integrated Themed Learning Communities (TLCs) in nanotechnology. Students pursuing the nanotechnology track will have lectures and laboratory research experiences to prepare them to enter the global workforce and to become leaders of research and development in industry, business, and academia in the emerging era of nanotechnology. The nanotechnology track was designed in a way that will not exceed the plan of study (P.O.S) credit hours meeting the minimum credit hours needed for the ECE or ME degrees. Students may choose four within the allowable elective list “tech electives, EE electives, ME electives, CmpE electives, math/science electives, and free electives [9] of their programs.

Students are prepared for the nanotechnology track via freshman engineering courses where TLC “Theme Learning Community” where cohort of 15 students are taking freshman courses emphasizing the future applications of nanotechnology. Some projects in the problem solving freshman course are pursued where some mathematical background are emphasized. The students pursuing this track must have gone through the TLC experience at the freshman year.

The following gives a brief description of each course under the nanotechnology track program.

A. *Introduction to Nanotechnology and Applications 3 credits*

The course aims to help students understand the scale of nanotechnology, identify materials used in nanotechnology, evaluate forces acting in nanomaterials, describe electronic and mechanical behaviors on the nanometer scale, and

describe applications in industries and life sciences. Nano-versus micro-technology in the evaluation of potential risks and benefits will be covered with emphasis on their societal impact.

B. *Nanosystems Materials and Measurements (Lab-based Course) 3 Credits*

The course introduces students to statistical process control, optical microscopy (light propagation, Snell’s law, mirrors, prisms, lenses and beam-splitters, etc), scanning electron microscopy, atomic force microscopy, scanning tunneling microscopy (STM), near-field microscopy, transmission electron microscopy, surface roughness and step profilers, roughness step testing (RST), and reflectometry, and ellipsometry. Nanosystem measurement laboratory is associated with the course.

C. *Nanosystems Principles 3 Credits*

This course introduces students to the principles and applications of nanosystems, including: nanoscale materials, processes, and devices. It also provides students with a basic understanding of the tools and approaches that are used for the measurement and characterization of nanosystems and for their modeling and simulation. Moreover, the course covers the applications of nanosystems in a wide range of industries: information technology, energy, medicine, and consumer goods.

D. *Nanosystems Processes and Devices (Lab-based Course) 3 Credits*

This course introduces students to processes and devices associated with integrated nanosystems. “Integrated Nanosystems” refers to systems which consist of integrated micro-, meso-, and/or macro-scale parts and their core components in nanoscale materials, processes, and devices. The course focuses on the theory and operation of select electronics, electromechanical, and biomedical devices which are used for information technology, sensing, medical, and other applications. The lectures will be complemented by hands-on laboratory experience.

E. *Research*

Students are encouraged to pursue research during their undergraduate studies. During the sophomore year, the students are divided into teams to work with faculty mentors, who assign a literature search on a given nanotechnology research topic. During the junior year the students will pursue a research project with their faculty mentor on an assigned research topic. The first course in this track prepares students for a research career in nanotechnology.

III. THE SOPHOMORE COURSE

ECE495/ME397: Intro to Nanotechnology and Applications (3 credit hours)

Required Course for nanotechnology track:

A. Bulletin Description

The course introduces students to the scale of nanotechnology, materials used in nanotechnology, forces acting in nanomaterials, electronic and mechanical behaviors on the nanometer scale, and applications in industries and life sciences. Nano-versus micro-technology in the evaluation of potential risks and benefits will be covered with emphasis on their impact on society.

B. Prerequisite or co-requisite

ECE 204 (for ME major); ECE270 and ECE201 (for ECE major)

C. Prerequisites by topic

TABLE I
COURSE OUTLINE

Lecture #	Conversion from Gaussian and CGS EMU to SI ^a
1-3	Introduction to nanotechnology: Perspectives and businesses, and infrastructure
4	Nanotechnology products
5	Nanotechnology standards
6	Environmental, Health and Safety Aspects of Nanotechnology
7-8	Nanotechnology manufacturing: (tools, molecular assembly, quantum metrology)
9-12	Nano electronics (band structure, conductors, semiconductors, device strategies, CNT, Nano devices and single electron tunneling, and molecular wires). Design approach for device characteristics
13-16	Nano-optics (interaction of light with matter & Nano-perspective, surface Plasmon, Quantum dots, Nano photonics, fabrication and applications). High efficient quantum dot solar cells, design approach.
17-21	Nano magnetism (introduction, Nano magnetic materials, physical properties, magnetic Nano-structures, and Nano magnetism applications)
22-26	Medical nanotechnology: medical breakthroughs, nanoparticles and Nano capsulation, and stimulating Tissues and functions
27	Term Paper discussions
28	Students' presentation

Semiconductor devices (pn-junction diodes, BJTs, MOSFETs), digital logic (Boolean functions, logic building blocks, and finite state machines).

D. Textbook

Gabor L Hornyak, John J Moore, Harry F. Tobbals, and Joydeeo Dutta, "**Fundamentals of Nanotechnology**" CRC 2009. ISBN # 978-1-4200-4803-290000

E. Goals

Introduce students to the nanotechnology area in various applications, and providing them with research hypothesis as applied to nanotechnology materials and devices. The course was structured to provide a number of research areas that are suited for the engineering discipline.

F. Outcomes

After the successful completion of this course, a student should be able to:

- 1) Describe the status of nanotechnology infrastructure and products in the USA in instrumentation, devices, materials, and applications. [a,b,c,d] .

TABLE 2
ABET CATEGORY

Engineering domain	Credits	Percentage
Science	2	67
Design	1	33

- 2) Compare Nanotechnology to microtechnology issues. [c,e,k].
- 3) Demonstrate knowledge of Nanotechnology standards, tools, and nanomanufacturing (a, c).
- 4) Explain the features of nanoscale electronics [b, c]. Communicate team project or team research term paper work through oral presentation, and technical report (b, c)

IV. EVALUATION METHODS

Midterm exams and a comprehensive final exam. Homework assignments and term paper presentation.

V. SAMPLE RESEARCH PROJECTS

A. Non-Invasive Diabetes Monitoring Devices

Monitoring glucose levels using nanotechnology devices "smart Tattoo" that can detect glucose molecules in the absence of enzymes. This emits a florescent color that correlated to the level of glucose. The sensor is based on a plant-sugar-binding protein.

Students studied the current technologies of monitoring glucose levels, and the promising solutions to the invasive issue by allowing new types of nan-invasive blood glucose sensing devices that can utilize other bodily fluids in addition to blood. The research project covers the electrochemical reaction using diffusible or immobilized mediator to transfer the electrons from the glucose oxidase to the electrode. With the use of nanotechnology, however, the electrode is able to perform direct electron transfer utilizing organic conducting materials. This allows for implantable, continuous monitoring devices.

B. Nanotechnology in Bone Regeneration

This research explores how nanotechnology has begun to impact this future field. There have been many unanswered

questions there nanotechnology can potential contribute to such important medical fields. Current technology have limited available quantities, inability to possess the same properties as bone, provoking immune system response, infection transmission, and cost. The research also focuses on how advancements in nanotechnology can be applied towards various tissue-engineering strategies. Students study more in regenerative medicine with the development of nanostructures and biomaterials with potential clinical implications. The studies included scaffolds that are biocompatible, extracellular matrix (ECM) in cartilage cells to produce bone, synthetic bio-scaffolds.

C. Nontechnology Applications for Cancer Detection and Treatment

Research covers new technology for screening for cancer detection from benefiting of biomarkers in tissue and fluids. Quantum dots are a way that enables the simultaneous detection of multiple markers. They are nanoparticles that emit light of different colors depending on their size. The photoluminescence signals from antibody-coated quantum dots can be used to screen different types of cancer. The different colored dots can be attached to antibodies for cancer biomarkers to allow oncologists to discriminate cancerous and healthy cells by the spectrum of light they sea. Carbon nanotubes are a type of nanodevices for biomarker detection. Therefore, biomarker screening can help in cancer detection. Cancerous cells may also absorb the nanocarriers to bring drugs into the cells. The research deals with the methodology of treatment and diagnosis.

D. Molecular Nano-Communications

This research studies the nanoparticles and nanowires based sensors since they are utilized in FET devices. The nanowire FET may be converted into nanowire nanosensors for pH sensing.

E. Nanotechnology Based SOC

System on Chip is an area where integrated sensor system can be implemented on board for different sensing functions. Some of the designed systems are applied to health care, while others for renewable energy.

VI. RESULTS AND DISCUSSION

A. Motivation

The course motivates undergraduate students who are pursuing a career in nanotechnology or sometimes a research career. Since the course is a sophomore course, introducing students to research hypothesis, and teach them how to search to find research activities that have been introduced into this research issues, means of approaching solutions, and limitations of various approaches, the courses gained popularities within the ECE and ME departments. The team work and the multidisciplinary aspects of the projects have enhanced students' motivations into the research.

B. Research Outcomes

At the end of the semester, four poster papers were presented in a poster research day on campus, where industry representatives and faculty members from School of Sciences, Engineering, and others have attended and had exchanged research ideas with the students.

C. Research Integration

Student contribution was limited to the mathematical models, software development, and simulations. Students had lab tours to the microscopy center on campus and had discussions with the research scientists running these equipment.

D. Feedback

The students' feedback on the course contents in the different areas and the research components of the course. All students have reposted very high satisfactory results in all questions regarding the course materials, research topics, course preparation on future research, and their expectation with the course multidisciplinary aspects, the team work, and poster presentations.

VII. CONCLUSION

The new research course developed at the sophomore year has enhanced the students' interests in pursuing a future career in nanotechnology. Majority of students are progressing more of nanotechnology courses in their junior and senior years. The new course provides integration of knowledge from math and sciences, and various components from ME, ECE, and BME. The knowledge learned in this course may also assist students with other areas such as DSP, Medical devices, communications, and instrumentations. In addition, the research apparatus involved in this research will assist students in integrated circuit design for both digital and analog applications.

ACKNOWLEDGMENT

The authors will like to acknowledge the NSF NUE program grant 1042110. Acknowledgements are also due to Mr. Vinay Kumar Suryadevara for his assistance with this paper.

Curriculum Driven Classroom Design

Kerry Milligan and Adam K. Fontecchio, Ph.D.

College of Engineering

Drexel University

Philadelphia, Pennsylvania

kmm567@drexel.edu, fontecchio@drexel.edu

Abstract— Classrooms and learning environments are almost as diverse as the curriculum that is taught in them. However, one thing that almost all classrooms have in common is that they are designed before the curriculum is developed. This leads to the design of common, generalized learning environments. These generalizations can lead to inconveniences in the classrooms, which cause deficiencies in learning. This problem is particularly true in engineering, where curriculum can be lecture based, design based, or project based. The goal with this project is to design a classroom and lab to fit the needs of specific undergraduate engineering curriculum. Allowing the classroom design to be driven by the curriculum that will eventually be taught there will result in a more efficient and effective learning environment. Current freshman engineering students in the existing labs were surveyed, and next year's freshman engineering students in the new lab will be surveyed to collect data about their experiences in the current learning environment. When the classroom construction is complete, a comparative analysis of the classroom dynamics both of the old and new classrooms will take place in order to determine the success of the work.

Keywords—*curriculum based design; engineering design; classroom; engineering lab (key words)*

I. INTRODUCTION AND BACKGROUND

Drexel University's College of Engineering consists of five departments, and approximately 3,800 undergraduate students. As part of the freshman year curriculum, all engineering students take a series of Freshman Engineering Design courses (ENGR 101, 102, and 103). This sequence of courses follows a structured to free-design model. ENGR 101 consists of a single engineering project, where students have set parameters and guidelines to follow. In ENGR 102, students have two different projects to choose from. In these projects, there are still parameters and guidelines, however, there is more freedom and creative design incorporated. For the last course of the sequence, ENGR 103, students complete their freshman design project. Students are presented with a free-design project where they can choose from a list of existing projects, or work to create their own design project.

Many undergraduate college engineering programs have a freshman design project as part of their first year engineering curriculum. These design projects are pivotal in providing a complete learning experience for freshmen in their first year of engineering, as they provide a first-hand view of the engineering design process [1 - 4]. In order to for students to

complete their projects, they go through an extensive design and construction process. This process is often completed in basic, standard engineering labs, which do not always provide a suitable or efficient working environment for these students [5]. Without a work space that is conducive to intensive design projects, students are not always able to complete their projects efficiently or to the highest quality. One way this problem can be solved is by designing these engineering labs and classrooms to accommodate curriculum requirements.

There have been a few instances in which universities have addressed this problem by designing learning environments focused on housing specific curricula. The University of Colorado at Boulder's Integrated Teaching & Learning Laboratory (ITLL) supports a first-year engineering design course with its curriculum-driven designed lab. This lab has received the Bernard M. Gordon Prize for Innovation in Engineering and Technology Education in 2008 [6, 7]. The Olin College of Engineering in Needham, MA conducted an interesting experiment to kick-start their program. Olin's main academic facility, The Academic Center, was constructed only after a year of curriculum development and testing. This allowed for the curriculum to influence the design of the facility, resulting in a much more dynamic environment [8, 9]. Drexel University's College of Engineering is currently able to perform similar experiment in which a new freshman engineering lab will be based on the curriculum that will be taught there.

The process for the current project consists of three phases: implementing a curriculum with no lab space, to then having a pre-existing lab space, to finally having a custom designed lab space where the curriculum will be taught. During the winter and spring terms of 2014, Drexel University's College of Engineering piloted a section of new curriculum involving the design and construction of Rube Goldberg machines. This section of students, who were enrolled in the second and third courses of Drexel's Freshman Engineering Design sequence (ENGR 102 & 103), was broken up into 14 groups of approximately 3 people each. Each group was tasked with designing and building a Rube Goldberg machine with between 25 and 30 events. An "event" in a machine is defined as an interaction between two unique objects in which energy is transferred from one object to the other. Fig. 1 shows an image of the machine designed and constructed by one of the groups. These individual Rube Goldberg modules were then linked together to form one long chain of energy transfers totaling approximately 315 events. This new curriculum was

implemented with no change in the classroom or lab space, which caused several problems. The original space was not outfitted to support such a large-scale design project. With little space in the lab to construct the machines, and a far distance from the lab to the machine shop, a new space had to be utilized for the project. A large, empty office space was found to be used as the machine construction zone, which was located adjacent to the machine shop. Further adjustments had to be made throughout the process to better suit the students' needs for the design project.

Fig. 1. Example twenty-nine event Rube Goldberg Machine from Spring term 2014 pilot section. Machine begins at top right, near wind-chimes, and ends at left near rubber duck. Events travel along multiple levels, traveling both upwards and downwards. Machine is approximately 1m wide by 1m deep, and 1.5m tall.

A revised version of this same project was rolled out as a new ENGR 101 project for all entering freshman engineers beginning the fall term of 2014. Approximately 900 freshmen engineers participated in this new curriculum as the first course of their Freshman Design sequence. Groups of three students each were tasked with constructing a six-event Rube Goldberg machine that fits on a two-foot by three-foot platform. These individual machines were then linked together in chains of either eight or sixteen to form a section-wide machine.

As the curriculum was developed, a student's perspective provided input on factors that could help enhance the students' learning experiences. At the same time, a new freshman engineering lab space was being designed for opening in the fall term of 2015. Drexel University's 3101 Market St. building is undergoing a renovation, which will house this new freshman engineering lab, along with other new research facilities. This new lab will be the home for the Rube Goldberg curriculum, creating a unique opportunity to design and develop the curriculum and the lab concurrently. Working on both projects at the same time exposed the connections between the two, and the benefits of designing each with the other in mind. By making decisions about the classroom layout and design with the specifics of the curriculum in mind, the resulting classroom should lend itself to a more efficient and exciting learning environment.

II. METHODS

In order to begin the design of the lab space based on the curriculum, a baseline layout was first used to get an idea for the room requirements. Fig. 2 shows the baseline layout that was originally planned by the architects working on the renovation. This shows the large lab space divided into two areas by a hanging room divider. On each side of the divider sit 10 work benches with 20 stools (shown at the top of the figure), 6 lab desks with 36 chairs (shown in the middle of each room), 2 project tables (large squares toward the bottom of the figure), and one instructor desk (shown between the two project tables). The room divider provides the opportunity to separate the space, allowing the room to be more suitable for smaller class sizes when needed. The un-shown room to the right of the figure is the university's Machine Shop, creating an ideal situation for collaboration between the two rooms.

However, the layout of this room shows some design aspects that could make working on an intensive design project such as the Rube Goldberg module difficult. Some of these inefficiencies include the separation of the work benches from the Machine Shop and project tables, static furniture, and the lack of room for placing the Rube Goldberg machines.

Fig. 2. Baseline layout of new freshman engineering lab [10]. Notice the workbenches and stools located at the top of the figure. Below them, student lab desks are shown six students to a table, which encourages collaboration. Toward the bottom of the figure notice the two square project tables, along with instructor stations.

In addition to foreseeing problems that may occur with the layout for the new Rube Goldberg curriculum, problems from the pilot project that took place in the 2013-2014 school year were also considered. The major problem that was encountered by students working on this project during the Spring term of 2014 was the lack of designated space to construct their machines in the engineering lab. Furthermore, once a space was found for a construction zone, the groups built their projects exclusively by themselves, with not much interaction between groups. It is important for there to be a specific area of the new lab reserved for the building of the machines. Additionally, this work space should be open and inclusive of all groups working on the project. This will spark collaboration among the groups, leading to a more cohesive and successful machine.

After previous experience and the dynamics of students in the classroom were reflected on, adjustments to the layout of the room were considered in order to improve efficiency. AutoCAD was used to rearrange the furniture into new

possible formations. One example of these changes is shown in Fig. 3, below. 3D models of the new lab space were also created, using Google SketchUp to get a better idea of what the room would look like once construction is complete. A perspective view within the model is shown in Fig. 5 below.

As construction on the new lab space began, analysis of students was underway. The first class of freshman engineering students was enrolled in the new Rube Goldberg curriculum in the Fall term of 2014. This class was held in existing engineering labs on campus. Sociometric badges were utilized to record student dynamics within the lab. The students were also surveyed at the end of the term to gather qualitative responses as to how they felt the lab space suited their needs during the project. Data of this nature will continue to be collected during the Spring term of 2015, the Fall term of 2015, and the Spring term of 2016. A comparison of this data will result in a determination of the current success of the project, and lead to further improvements and adjustments of the layout.

III. RESULTS AND DISCUSSION

One new possible classroom layout was designed with the current considerations and analysis in mind. The resulting layout takes into consideration all of the problems encountered in the Methods section. Fig. 3 depicts this new layout after making all of the changes. One of the changes that was made is the location of the furniture within the room. The workbenches, now shown at the top and bottom on the right of the figure, were moved to be in closer proximity to the Machine Shop. This would reduce traffic between the workbenches and the Machine Shop, creating a more efficient environment. Between the two sets of workbenches are the project tables. These project tables were reworked to be useful for both the existing curriculum, and the new curriculum, reducing the amount of space and new furniture needed. This is detailed further in Fig. 4.

The remaining lab tables were positioned on the opposite side of the lab. Positioning the lab tables further away from the Machine Shop will also reduce the noise from the machines in the main room. Placing the furniture in this layout creates two distinct areas in the lab: a work space, and an instructional space. This type of formation fits well with the needs of design projects, such as the ones that will be taught in this lab.

Fig. 3. Layout of new freshman engineering lab with modifications [10]. Student lab desks are now situated on the left side of the figure, creating an

instructional zone. On the right of the figure lie the student workbenches and project tables, creating a work and construction zone. The instructor stations are positioned between the two zones to provide a view of both sides of the lab space.

Once the new lab space was reorganized based on efficiency for design projects, the specifics of the Rube Goldberg machine module were considered to further accommodate the room. One of the problems encountered in the baseline layout was that there was no place for students to connect their machines to form one long chain of events. To accommodate this, the existing Winter term furniture (project tables) was redesigned to include spaces for the machines to be linked together. These square, 8' x 8' project tables are needed for the Winter term curriculum, and therefore need a designated space in the lab. Making modifications to these tables allows them to remain in the lab year-round, and eliminates the need to purchase new furniture for the Fall term curriculum.

As seen in Fig. 4 below, two project tables will be used together to create a platform for sixteen individual group machines. The specific layout of the machines had to be designed purposely for several reasons. The first and main restriction on the design of the layout was that students need to be able to have easy access to their machines in order to re-set them or make adjustments. By lining the machines along the outside of the platform, students will easily be able to adjust and re-set their machines when necessary. Another restriction was that the layout of the two tables needed to be the same, or a mirror image of each other. This allows for single-section classes to run their combined machine with eight groups, and for double-section classes to run their combined machine with sixteen groups. Working on the specifics of the classroom and furniture will better integrate the curriculum with the space it is taught in.

Fig. 4. Project table layout for new module incorporating existing furniture. Notice the "U"-shape design, allowing access to all machines within the chain. The mirror image layout (1 through 8 is mirror image of 9 through 16) allows for single- or double-section machines to be assembled.

However, there are drawbacks to this newly reworked design. Rearranging the furniture in this layout eliminates the possibility of dividing the space into two separate, complete classrooms. This would be an inconvenience for when having smaller class sizes is preferred. It is, on the other hand, a more convenient layout for large design projects, such as ones that are done in the third class of the Freshman Engineering Design sequence (ENGR 103).

After reviewing these considerations, it was decided that the most important feature of the room be the capacity to take on different forms. This led to the reworking of the electrical and furniture plans to allow the furniture in the room to be dynamic, movable, and yet still connected almost anywhere in the room. This plan allows for different layout testing, and adjustment based on the type of project that is taking place in the room during a certain term.

Flexibility both within the room and among the rooms themselves is the key factor to take away. The adjacent storage area and parts room with a distribution window allow for project materials to flow into and out of storage and the lab space with ease. These rooms make transitions within and between projects much more convenient. Furniture flexibility was achieved by utilizing non-stationary furniture, and outfitting the space with capabilities to connect the furniture to power and data in many different configurations. The room divider and garage-style doors connecting the lab to adjacent resources allow the space to become totally open or closed off as necessary.

IV. CONCLUSION

The new layout, which was based on the curriculum being taught in the classroom, was finalized and presented to the architects and faculty. Upon review, it was decided that the infrastructure and utilities would be installed so as to incorporate the multiple layouts such that the room can be rearranged between terms to accommodate the multiple modes of educational delivery. This reconfigurable layout was designed with an extensive engineering design project in mind, and therefore should be a great fit for the Spring term design project in ENGR 103. A screenshot of the 3D model drawn in Google SketchUp is shown in Figure 5. Once the classroom is constructed and furnished, planned future work, detailed below, will help to determine the success of the project.

Fig. 5. Perspective view in 3D model of lab. Lab desks with computer screens for each group are shown. White board exists both on shown side and opposite side, allowing all students to view board. Instructor station (shown at bottom right of figure) has view of both instructional zone and construction zone.

In order to determine whether or not this model for designing classrooms and lab spaces is beneficial, data must be collected. For Academic Year 15-16, the original layout will be

deployed for the Fall and Winter terms, and the new layout for the Spring term provides an opportunity to study the reconfigurable nature of the room. The dynamics of the students in the classroom can be observed both during the Fall/Winter and the Spring in the new lab space. Things to look for when observing the students will include: which places they walk to most often, the distance from their start and end points, how each part of the classroom is being used, where the most collaboration takes place, and how often the two sides of the classroom are divided. Comparing the way students move differently in each layout will provide quantitative data as to whether or not this model was a success.

Additionally, surveying students and faculty who teach and work in the room will provide qualitative feedback. The survey should include questions regarding the benefits and deficiencies of each classroom layout (particularly regarding the use of the space for different project types). Feedback and suggestions can be used to further determine how to most efficiently arrange the space.

ACKNOWLEDGMENT

Thank you to Drexel University's Students Tackling Advanced Research (STAR) program for providing the opportunity to work on this project, to Coscia Moos Architecture for providing me with architectural drawings, and to Sociometric Solutions, Inc. for sociometric badges.

Rubrics for Assessment Item Difficulty in Engineering Courses

Shilpi Banerjee, N.J.Rao, Chandrashekar Ramanathan
International Institute of Information Technology, Bangalore
Email: shilpi.banerjee@iiitb.org, njraoiisc@gmail.com, rc@iiitb.ac.in

Abstract—A course in Engineering programs is designed and conducted to facilitate students to acquire a set of competencies to meet a subset of Program Outcomes(Graduate Attributes) identified by the accreditation agency. Formative and summative assessments, if in alignment with the competencies, enable the instructor to guide the students to learn well, and to measure the level of attainment of competencies. The difficulty levels of the assessment items are a measure of mastery of the competencies. Well defined difficulty rubrics provide guidelines to the instructor to prepare assessment items with stated difficulty levels. Several difficulty rubrics which are learner dependent or independent, subject specific or non-specific and score-based or score-independent to characterize the difficulty level are reported in the literature.

This paper presents a set of learner-independent and score-independent difficulty rubrics. The parameters that characterize these rubrics are arranged in a hierarchy. The nodal parameters are content, task and structure (stimulus) of assessment items. The leaf and atomic parameters are identified in the framework of Anderson-Bloom taxonomy. The parameters for a given assessment item are identified and difficulty is determined by applying weight based and fuzzy logic rule based methods. The efficacy of the proposed item difficulty rubrics is validated by designing different difficulty level items for the course Basics of Digital Systems, and validating the difficulty of the designed items by the subject matter experts.

Index Terms—Assessment, Difficulty, Fuzzy logic, Learner independent

I. INTRODUCTION

Engineering programs are designed and conducted to facilitate students to acquire a set of Program Outcomes identified by the accrediting agency of the country. Each course of an engineering program must formulate competencies that foster attainment of subset of these Program Outcomes. Competencies represent what the students should be able to do at the end of a course as per the instructor. Each competency statement is mapped to one of the cognitive levels and one or more categories of knowledge of Anderson-Bloom's taxonomy[1]. The assessment items associated with a competency are termed to be aligned if they belong to the same or lower cognitive level as that of the competency. Mastery of a competency gained by the student can be evaluated by offering them items of varying difficulty levels.

Here we propose item difficulty rubrics which will help instructor to arrange the available items in three difficulty level categories: easy, medium and hard. The intent is to capture in a gross way how instructors think about difficulty. These rubrics will also enable instructor to design items of three

difficulty levels at each cognitive level. The difficulty levels are not comparable across subjects and cognitive levels. Proposed fuzzy evaluation and weight based model estimates difficulty using an identified set of hierarchically arranged parameters. The designed rubrics are:

- 1) Independent of scores
- 2) Learner independent
- 3) Subject non-specific

While assessment items can be different for oral exams, lab viva, project demonstration and classroom assessment, we restrict our rubrics to items used in fixed duration classroom formative/summative assessments. Following section presents the existing difficulty frameworks and parameters used by each of them, and also a discussion on the characteristics chosen for the proposed difficulty rubrics.

II. LITERATURE REVIEW OF EXISTING DIFFICULTY RUBRICS

Difficulty rubrics have been explored in a variety of scenarios based on the roles of usage, learners, scoring and subjects. Table 1 presents an overview of the existing literature. The usage refers to classroom assessment (CA), intelligent tutoring system (ITS) and computer adaptive testing (CAT). Rubrics have been defined with respect to learners as either learner dependent (LD) or learner independent (LID), score based (SB) or subject matter expert based (SME), and subject specific (SS) or subject non-specific(SNS). It is very clear that majorly used approaches are either learner dependent and/or use students evaluation scores.

There can be various reasons, other than inherent difficulty of an item, because of which a student finds an item difficult. These include the effort involved in processing, student's mental model, motivation, interest, prerequisite knowledge, intelligent quotient and meta-cognitive knowledge. An assessment item, therefore, will be perceived differently by different students with regard to the difficulty level. Quantifying the LD parameters accurately within a span of a semester is a challenge. Also, the measures of the LD parameters for one batch of students may not be applicable to another batch of students[15]. *We consider here learner independent parameters by focusing on inherent difficulty of assessments items while designing the rubric by assuming that all the students have required prerequisite knowledge.*

Each of the approaches listed in Table 1 gives qualitative and quantitative measures for item difficulty, apriori or post assess-

Approaches	Usage	LD	LID		Score Based	SME Based
			SS	SNS		
Concept/Ontology/Knowledge map[6][7][8][9]	ITS, CAT		✓	✓		✓
Rasch models(IRT,LLTM) [10][11][12]	CAT, CA	✓			✓	
Psychological models [13][14][15]	ITS, CA	✓	✓	✓		✓
Rule based AI techniques [16][17][18]	CAT, CA	✓		✓	✓	

TABLE I
VARIOUS APPROACHES USED FOR ESTIMATING ITEM DIFFICULTY

ment administration. For apriori estimate, difficulty is found out using LD and/or LID parameters. For post assessment difficulty estimation approaches, difficulty of an item is found out by offering it to students and by calculating the proportion of students in class who got the item correct[4]. True score for a student may be different from the evaluation score due to the presence of random and systematic errors in the evaluation (scoring) processes involved[5]. Therefore, difficulty estimate based exclusively on evaluation scores fails to give the actual estimate for item difficulty. *The proposed rubrics aim at estimating difficulty apriori to assessment administration and evaluation.*

Engineering subjects can be descriptive, abstract and or computational. Therefore, every subject has some characteristics that make it different from other subjects. Also, the concerned instructor of a subject may restrict the competencies to lower cognitive levels while some other instructor may want to address higher cognitive levels. Also, items of the same difficulty level for two different subjects may not be comparable. The amount of detailing is more for subject specific approach. On the other hand, generalization of these models across subjects leads to abstraction. There is a clear trade off between generalization and the amount of detailing for these models. *The proposed rubrics are based on subject non-specific parameters, and are applicable to a wide range of engineering courses.*

III. DIFFICULTY AND COGNITIVE LEVELS

Because of the hierarchical nature of cognitive levels, there is a notion among instructors and researchers that items measuring abilities of students for higher cognitive processes are more difficult than items measuring lower cognitive processes. In the literature, there are some experimental evidences to disapprove this hypothesis by proving that difficulty and cognitive processes hierarchies are not necessarily same[19][20][21] based on estimating difficulty level using scores. The validity of this type of differentiation is always in question because of the influence of various random and systematic errors over scores[5]. We have tried to resolve the fuzziness between the terms difficulty hierarchy and cognitive process hierarchy by conducting an experiment for the following hypothesis.

Hypothesis 1: *Assessment items at higher cognitive level are not necessarily of higher difficulty levels than assessment items at lower cognitive levels.*

Fig. 1. Relation between Difficulty and Hierarchy of Cognitive Process

Basics of Digital Systems course was chosen for validating the above hypothesis statement. A large number of assessment instruments for this course were collected from various universities. A subset of assessment items from these assessment instruments was selected for conducting the survey. Each item was tagged with their respective cognitive level as per Anderson-Bloom's taxonomy[1] by pedagogy experts. Twenty eight SME's having two to five years of experience in teaching the same course were selected randomly for taking part in the survey. Each question in the survey had an item pair with items from different cognitive levels.

SME's were asked to make a binary comparison of difficulty level(DL) among each pair of items and mark the items with tags DL_{LOW} and DL_{HIGH} . There were mixed opinions among experts as shown in Figure 1. For some item pairs, few SME's marked item at lower cognitive level as DL_{HIGH} and for some item pairs, item at higher cognitive level was marked as DL_{LOW} . Also for a few item pairs, higher cognitive level item was marked as DL_{HIGH} and lower cognitive item was marked as DL_{LOW} . From the survey, it is clear that cognitive level and difficulty level is not necessarily related which proves our hypothesis that assessment items at higher cognitive level are not necessarily of higher difficulty levels than assessment items at lower cognitive levels. Proposed difficulty rubrics facilitates designing different difficulty level items for each cognitive level.

IV. PROPOSED DIFFICULTY RUBRICS

An analysis of Osterlinds[2] definition of a test item suggests, intrinsic difficulty resides in the content assessed, stimulus and task to be performed. *Content difficulty* is related to various elements of knowledge such as facts, concepts and procedures. *Stimulus difficulty* is related to the manner in which the item is presented to the students which includes words, phrases and information which is packed along with the item. *Task difficulty* refers to the difficulty that the students face when they generate their responses. The content to be assessed is related to the knowledge dimension while task to be performed is related to the cognitive level dimension of Anderson-Bloom taxonomy[1] table which is used as a tool to guide the development of item difficulty rubrics. We have

used content, task and structure as nodal parameters for our rubrics. Equation (1) gives difficulty(D) for assessment item.

$$D_{\text{item}} = D_{\text{task}} + D_{\text{content}} + D_{\text{stimulus}} \quad (1)$$

The cognitive dimension of taxonomy table consists of the cognitive processes and categories of knowledge. The cognitive processes are the updated versions of Blooms categories and they include, hierarchically, Create, Evaluate, Analyze, Apply, Understand, and Remember. The categories of knowledge include Factual, Conceptual, Procedural and Meta-cognitive. Taxonomy Table was created with six cognitive levels as columns and four categories of knowledge as rows. From a survey of existing assessment instrument for fixed duration classroom assessments, it was observed that assessment items from analyze, evaluate and create cognitive levels were not included for such assessments. Also, it is difficult to assess meta-cognitive knowledge for such assessments[3]. Based on our observation about the cognitive level and knowledge category for assessment items, we have designed our difficulty rubric for three cognitive levels(Remember, Understand, Apply) and three knowledge categories(Factual, Conceptual, Procedural). Each knowledge element can be assessed for one or more cognitive levels. Therefore, the resultant difficulty rubrics is defined for {remember-factual, remember-conceptual, remember-procedural, understand-conceptual, understand-procedural, apply-procedural} cells. Following is a discussion on three nodal parameters of difficulty considered for our rubric.

A. Task Difficulty

Task difficulty for an item comprises of any one of the cognitive levels: remember, understand and apply.

$$D_{\text{task}} = \{D_R, D_U, D_A\} \quad (2)$$

- 1) **Remember:** When the objective of assessment item is to assess retention of the instruction material in much the same form as it was taught/ delivered, the relevant cognitive level is remember. The associated sub cognitive processes are recognizing(TC_{R_1}) and recalling(TC_{R_2})[1]. Recognize cognitive process have more number of cues as compared to recall cognitive process as assessment items associated with recognize cognitive process are selective type. The cue for such items is in the form of list of answers. Memory is organized as chunks which can be considered as basic interconnected units. Connection between two chunks is called as association. When something in our current environment is strongly associated with a chunk in our memory, it spreads activation to that chunk. Because of available cues for recognize items, activation is spread fast to memory chunks in case of recognize cognitive process as compared to recall[23]. Therefore, recognize assessment items are easier as compared to recall assessment items. The difficulty of remember task increases if more amount of data need to be remembered. Number of unknowns(R_1) in an assessment item influences the

difficulty of remember cognitive process. Unknown can be either fact or concept or procedure. The difficulty of remember task is given by D_R .

$$D_R = D_{R_1} + D_{TC_R} \quad (3)$$

$$D_{TC_{R_1}} < D_{TC_{R_2}} \quad (4)$$

- 2) **Understand:** Student should be able to construct meaning from the instructions delivered by the instructor. When the objective of assessment item is to assess transfer of the instruction material, the relevant cognitive level is understand. This cognitive category is closely linked with Conceptual Knowledge. The associated sub cognitive processes are interpreting, exemplifying, classifying, summarizing, inferring, comparing and explaining[1]. Exemplify and classify processes occurs when student links example with a concept or vice versa. Infer involves linking a pattern with appropriate concept. For our rubric, we have assumed that summarize and explain forms the lowest difficulty level. Exemplify, classify and infer cognitive process are considered to be hardest as student need to understand two concepts/procedures for generating their response. The sub cognitive processes for understand cognitive level can be arranged in three groups in increasing difficulty level as TC_{U_1} {summarize, explain}, TC_{U_2} {compare, interpret}, TC_{U_3} {exemplify, classify, infer}.

The difficulty parameter for assessment items belonging to understand cognitive category is number of unknowns(U_1), number of concepts(U_2) and number of conditions(U_3). Students are expected to use some specific resource while giving response for assessment items which is termed as conditions.

$$D_U = D_{U_1} + D_{U_2} + D_{U_3} + D_{TC_U} \quad (5)$$

$$D_{TC_{U_1}} < D_{TC_{U_2}} < D_{TC_{U_3}} \quad (6)$$

- 3) **Apply:** Apply cognitive process involves procedures to perform exercises or solve problems and is closely linked with Procedural Knowledge. The Apply category consists of two cognitive processes: executing(TC_{A_1}) and implementing(TC_{A_2})[1]. In executing processes, there are sequence of steps which are followed in fixed order. Students are more familiar with such tasks. On the other hand, students encounter unfamiliar task for implement processes and they need to select the procedures and their sequence[1].Therefore, implement process is considered to be more difficult as compared to execute process.

The difficulty parameter for assessment items belonging to apply cognitive category is number of unknowns(A_1), number of concepts(A_2), number of procedures(A_3), number of inputs(A_4) and number of conditions(A_5).

$$D_A = D_{A_1} + D_{A_2} + D_{A_3} + D_{A_4} + D_{A_5} + D_{TC_A} \quad (7)$$

$$D_{TC_{A_1}} < D_{TC_{A_2}} \quad (8)$$

B. Content Difficulty

Content difficulty for an item comprises of any one or more knowledge elements: factual, conceptual and procedural.

$$D_{\text{content}} = \{D_F, D_C, D_P, D_F+D_C, D_F+D_P, D_C+D_P, D_F+D_C+D_P\} \quad (9)$$

- 1) **Factual:** It contains the basic elements a student should know to be acquainted with the discipline or to solve any problems in it. The two sub-types of this type of knowledge are knowledge of terminology(KC_{F_1}) and knowledge of specific details and elements(KC_{F_2})[1]. KC_{F_1} is considered to be easier as compared to KC_{F_2} as terminology deals with the vocabulary used for a course while specific details require to produce some specific information about the vocabulary used for a course. For example: the item “what is excitation table?” is easier as compared to “what is the excitation table for D flip flop?”.

$$D_F = D_{KC_F} \quad (10)$$

$$D_{KC_{F_1}} < D_{KC_{F_2}} \quad (11)$$

- 2) **Conceptual:** A concept is an abstract or generic idea generalized from particular instances. A conceptual knowledge element often requires knowledge of many concepts. The three sub-types of this type of knowledge are knowledge of categories and classification(KC_{C_1}), knowledge of principles and generalization(KC_{C_2}) and knowledge of theories, models and structures(KC_{C_3})[1]. KC_{C_2} is composed of KC_{C_1} and KC_{C_3} is composed of KC_{C_2} . Therefore, KC_{C_3} is considered to be more difficult than KC_{C_2} and KC_{C_2} is considered to be more difficult than KC_{C_1} . Some examples of KC_{C_1} are combinational, sequential functions, moore, mealy functions and synchronous, asynchronous functions. Items for KC_{C_2} relate to usage of clock signal for avoiding race around condition and increase in execution speed for asynchronous functions. Items based on digital representation of information represents KC_{C_3} .

$$D_C = D_{KC_C} \quad (12)$$

$$D_{KC_{C_1}} < D_{KC_{C_2}} < D_{KC_{C_3}} \quad (13)$$

- 3) **Procedural:** Procedure is a series of steps/ actions done to accomplish a goal. Knowledge of procedures is referred to as procedural knowledge. Procedures can be predetermined sequence of actions that will lead to correct answer when executed correctly or it can be possible actions which must be sequenced appropriately to solve a problem. The three sub-types of this type of knowledge are knowledge of subject specific skills and algorithms(KC_{P_1}), knowledge of subject specific techniques and methods(KC_{P_2}) and knowledge of criteria for determining when to use appropriate procedures(KC_{P_3})[1]. Fixed order of decisions are taken and the the end result of the procedure is fixed for KC_{P_1} . Order of decisions and end result for the procedure is

not fixed for KC_{P_2} . KC_{P_3} helps in taking decisions for KC_{P_2} based on certain criteria. Therefore, KC_{P_3} is considered to be more difficult than KC_{P_2} and KC_{P_2} is considered to be more difficult than KC_{P_1} .

$$D_P = D_{KC_P} \quad (14)$$

$$D_{KC_{P_1}} < D_{KC_{P_2}} < D_{KC_{P_3}} \quad (15)$$

- 4) **Relationship between Difficulty of Knowledge Elements:** Factual knowledge is required to understand any concept or solve any procedure and they can be considered in isolation which have some value in and of themselves. It is considered to be less difficult as compared to conceptual and procedural knowledge element[1]. Conceptual and procedural knowledge categories cannot be considered independently. There is significant amount of research which discusses that these two types of knowledge are related[22]. There is a causal and bidirectional links between conceptual and procedural knowledge. Conceptual tasks are relatively unfamiliar to students, they need to derive answer from their conceptual knowledge rather than implement a procedure for solving the task. Therefore, conceptual knowledge element is often considered to be more difficult as compared to procedural knowledge element[1].

$$D_C > D_F, D_P > D_F, D_C > D_P \quad (16)$$

C. Stimulus Difficulty

This type of difficulty refers to the difficulty faced by the student to understand and analyze the item statement. Same item can be presented to students in many different ways by changing the type of vocabulary used. The amount of effort in analyzing the item statement increase as the number of deductions(S_1) increases. The difficulty for an item decreases if students are guided with some number of hints(S_2). While attempting the item, often student need to identify certain number of implicit assumptions(S_3) to reach the final solution. More is the number of such implicit assumptions, more is the difficulty.

$$D_{\text{stimulus}} = D_{S_1} + D_{S_2} + D_{S_3} \quad (17)$$

Table II shows difficulty rubrics which indicates difficulty parameters for each cognitive level.

V. ESTIMATION OF DIFFICULTY

In this paper, we have tried to estimate difficulty using proposed difficulty rubrics by following two methods. We have then compared the performance for each of these methods with SME's perspective of item difficulty gathered through a survey.

A. Weight Based Method

The weights(W) given to each of the nodal parameters(content, task, structure) is subject specific. Weights for nodal parameter are decided by SME's by considering the nature of the subject. For example, courses which include various types of computation, maximum weight is given to task

D _{item}	D _{task}	D _{content}	D _{stimulus}
Remember (R_D)	{D _{R₁} , D _{TC_{R₂}} }	{D _{KC_{F₁}} , D _{KC_{F₂}} , D _{KC_{C₁}} , D _{KC_{C₂}} , D _{KC_{C₃}} , D _{KC_{P₁}} , D _{KC_{P₂}} }	{D _{S₁} , D _{S₂} , D _{S₃} }
Understand (U_D)	{D _{U₁} , D _{U₂} , D _{U₃} , D _{TC_{U₁}} , D _{TC_{U₂}} , D _{TC_{U₃}} }	{D _{KC_{C₁}} , D _{KC_{C₂}} , D _{KC_{C₃}} , D _{KC_{P₁}} , D _{KC_{P₂}} }	{D _{S₁} , D _{S₂} , D _{S₃} }
Apply (A_D)	{D _{A₁} , D _{A₂} , D _{A₃} , D _{A₄} , D _{A₅} , D _{TC_{A₁}} , D _{TC_{A₂}} }	{D _{KC_{C₁}} , D _{KC_{C₂}} , D _{KC_{C₃}} , D _{KC_{P₁}} , D _{KC_{P₂}} }	{D _{S₁} , D _{S₂} , D _{S₃} }

TABLE II
DIFFICULTY RUBRICS

difficulty. On the other hand, courses which give more emphasis to organizing and attributing the subject matter, structure difficulty carries maximum weight. Figure 2, 3 and 4 shows the difficulty parameters for remember, understand and apply cognitive levels arranged hierarchically. We have drawn these weight graphs for Basics of Digital Systems course which is focused primarily on design of digital functions. Therefore, we have allotted maximum weight to task parameter.

The weights given to the intermediate level parameters and atomic parameters is subject non-specific. It is based on our discussion in section IV and equations (1) to (17) which mostly consider pedagogical theories to compare difficulty related to each parameter. Each assessment item has content, task and stimulus difficulty. Content can be either factual, conceptual and procedural. Task is a combination of difficulty due to any one item category and the cognitive process difficulty parameters. Stimulus is again combination of stimulus difficulty parameters. Each item has certain number of cognitive process parameters and stimulus parameters in it. Difficulty increases as the number of each of these parameters increases except for the parameter number of hints. Difficulty decreases as number of hints increases. The bold lines in the weight graphs indicate that the weights of leaf parameters need to be combined. The dotted lines indicate the exclusivity of the leaf parameters, that is any one leaf parameter weight which is applicable for the assessment item need to be selected.

Initially, specific knowledge category(KC) and item category(TC) for an item are identified. $R_1, U_1, U_2, U_3, A_1, A_2, A_3, A_4, A_5, S_1, S_2$ and S_3 are related to numbers, each of which has a maximum value. Let $Num_{R_1}, Num_{U_1}, \dots$ be number of parameter present in an assessment item. Let $Max_{R_1}, Max_{U_1}, \dots$ be the maximum number of parameters that can be present in an assessment item. The difficulty is found out using the following equations:

$$N_p = Num_p / Max_p \text{ where } P = R_1, U_1, U_2, \dots, S_3 \quad (18)$$

$$D = W_{KC} + W_{TC} + \sum (N_p * W_p) \text{ where } P = R_1, U_1, U_2, \dots, S_3 \quad (19)$$

where W_{KC} , W_{TC} , W_p denotes weight for knowledge category, task category, cognitive process and stimulus difficulty parameters respectively.

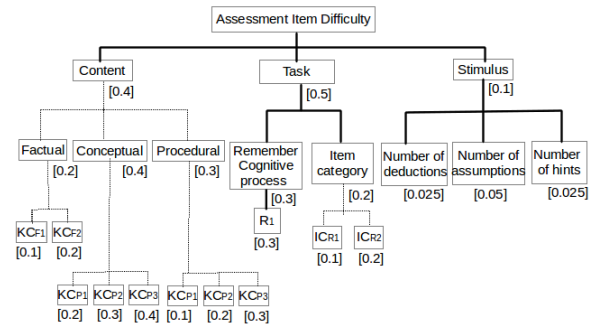

Fig. 2. Weight Vectors for Remember Cognitive Process

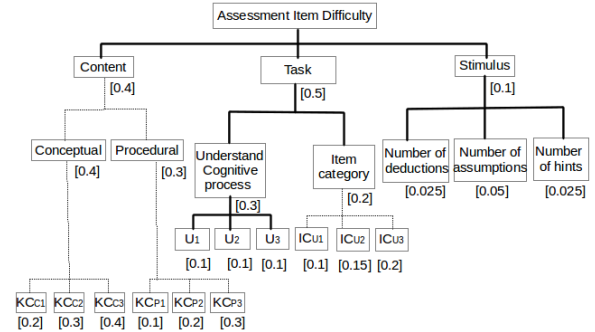

Fig. 3. Weight Vectors for Understand Cognitive Process

Table III shows some examples from {apply-procedural} cell and Table IV shows their difficulty estimation using this method. Difficulty level is easy(1) if the estimated difficulty value is less than 35, it is medium(2) if it is less than 65 and hard(3) if it is more than 65.

Decision making frameworks based entirely on weight is often influenced by SME's view and opinion about the subject matter. Also, it is a challenge to extract the highest count which can be present in items corresponding to each parameter for normalising them. For such vague and imprecise scenarios, fuzzy logic often proves to be a better approach.

B. Fuzzy Logic Rule Based Method

The way instructors think about difficulty is inherently fuzzy. Each instructor may decide different combinations and

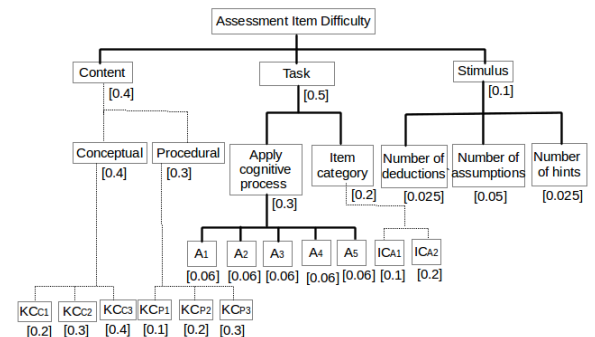

Fig. 4. Weight Vectors for Apply Cognitive Process

AI1	Construct a logic circuit using NAND gates only for the expression $x = A \cdot (B + C)$.
AI2	Design a counter that might be used to simulate the roll of a die in a dice game. Use D flip-flops and a 3-input NAND gate. Draw the corresponding timing diagram.
AI3	Design a simplified traffic-light controller that switches traffic lights on a crossing where a north-south (NS) street intersects an east-west (EW) street. The input to the controller is the WALK button pushed by pedestrians who want to cross the street. The outputs are two signals NS and EW that control the traffic lights in the NS and EW directions. When NS or EW are 0, the red light is on, and when they are 1, the green light is on. When there are no pedestrians, NS=0, EW=1 for a minute, follow by NS=1 and EW=0 for 1 minutes, and so on, when WALK button is pushed, NS and EW both become 0 for a minute when the present minute expires. After that the NS and EW signals continue alerting. For this traffic-light controller: a) Develop a state diagram. (Hint: can be done using 3 states) b) Draw the state transition table. c) Encode the states using minimum number of bits. d) Derive the logic schematic for a sequential circuit which implements the state transition table.

TABLE IV
DIFFICULTY ESTIMATION USING WEIGHT BASED METHOD

values of parameters for easy, medium and hard items. We have used fuzzy logic technique[24] for estimating difficulty by considering proposed difficulty rubrics as shown in Table II. The difficulty parameters for each cognitive process are:

$$R_D = \{KC_F, KC_C, KCP, R_1, TC_R, S_1, S_2, S_3\} \quad (20)$$

$$U_D = \{KC_C, KCP, U_1, U_2, U_3, TC_U, S_1, S_2, S_3\} \quad (21)$$

$$A_D = \{KC_C, KCP, A_1, A_2, A_3, A_4, A_5, TC_R, S_1, S_2, S_3\} \quad (22)$$

- Fuzzy sets:** The domain of the parameters $R_1, U_1, U_2, U_3, A_1, A_2, A_3, A_4, A_5, S_1, S_2$ and S_3 range over set of values. Since the range of values is not clearly defined for easy, medium and hard items, these sets need to be defined as fuzzy sets as shown in Table V. The parameters $KC_F, KC_C, KCP, TC_R, TC_U$ and TC_A have pre fuzzified values which are ordered hierarchically and are given values as shown in Table VI. As discussed in rubrics, sub-knowledge categories and sub-cognitive processes exist for these parameters which are arranged in increasing difficulty level. These sub-parameters are inherently fuzzy. Usually the inputs to fuzzy inference system is given as crisp value. But for certain inputs, such as KC_F, KC_C and KCP , the given values are already fuzzy. Fuzzification process is not required for such input values. Therefore, we have termed them as pre fuzzified sets.
- Membership function:** These are formed by assigning proper range to respective linguistic variables for fuzzy sets: low, medium, high. We have chosen combination of triangular and trapezoidal membership function(μ) for $R_1, U_1, U_2, U_3, A_1, A_2, A_3, A_4, A_5, S_1, S_2$ and S_3 . The membership function for U_2 is built by choosing trapezoidal membership function for each linguistic variable

Fuzzy variables	Low(1)	Medium(2)	High(3)
Number of unknowns(R_1, U_1, A_1)	{1,2}	{1,2,3}	{2,3,4}
Number of concepts(U_2, A_2)	{1...5}	{3...8}	{6...12}
Number of procedures(A_3)	{1...5}	{3...8}	{6...12}
Number of inputs(A_4)	{1,2}	{2,3,4}	{3,4,5}
Number of conditions(U_3, A_5)	{1,2}	{2,3,4}	{3,4,5}
Number of assumptions(S_1)	{1,2}	{2,3,4}	{3,4,5}
Number of deductions(S_2)	{1,2}	{2,3,4}	{3,4,5}
Number of hints(S_3)	{1,2}	{2,3,4}	{3,4,5}

TABLE V

Fuzzy variables	Values	Fuzzy variables	Values
{ KC_F, KC_C }	{1,2}	{ TC_R, TC_R }	{1,2}
{ KC_C, KC_C, KC_C }	{1,2,3}	{ TC_U, TC_U, TC_U }	{1,2,3}
{ KCP, KCP, KCP }	{1,2,3}	{ TC_A, TC_A }	{1,2}

TABLE VI
PREFUZZIFIED SETS

as shown in Figure 5. In a similar way, membership function for other parameters are also built as shown in Table VII. For variables having prefuzzified sets, prefuzzified membership functions are chosen. For pre fuzzified membership function, each term has value 1, 2 or 3 depending upon the pre fuzzified set.

- Fuzzy Rules:** Fuzzy rules are written for combination of values of fuzzy sets. The accuracy of the output estimation increases with the number of rules. For our application of estimating difficulty, rule base needs to be written for all the combinations of R_D, U_D and A_D . Each difficulty parameter for R_D, U_D and A_D can have value {1, 2} or {1, 2, 3} based on their fuzzy and prefuzzified sets. The total number of combination of values for R_D is 2916, U_D is 19683 and A_D is 118098. It is practically in-feasible to design rule base for these many combinations manually. Therefore, we have automatically generated the rule base. The algorithm for the automatic generation of rule base is based upon the intuition that there is a positive correlation between difficulty and the distance of any combination of values to the origin of multidimensional space of difficulty parameters. More is the closeness to the origin, more is the easiness for items. A reasonable approach can be to find sum of fuzzy values of vectors R_D, U_D and A_D for finding

1	2	1	1	1	1	2	1	10	Easy
2	2	2	1	1	3	1	2	14	Medium
2	3	3	1	2	3	1	2	17	Medium
1	3	3	1	2	3	3	3	19	Hard
2	3	3	1	2	3	3	3	20	Hard

TABLE VIII
SAMPLE RULE BASE FOR D_R

the distance from the origin of multidimensional space. The sum of vectors R_D , U_D and A_D is found out with minimum and maximum fuzzy value for each parameter. These sums are denoted as Sum_{min} and Sum_{max} . The difference(D_f) between Sum_{max} and Sum_{min} is used to form three equal categories, one each for every difficulty level. Equation (23) denotes rule base for deciding easy, medium and hard difficulty levels.

$$D = \begin{cases} Easy, & \text{if } Sum < Sum_{min} + D_f/3. \\ Medium, & \text{if } Sum < Sum_{min} + (2 * D_f/3). \\ Hard, & \text{if } Sum \leq Sum_{max}. \end{cases} \quad (23)$$

where Sum is the result of addition of fuzzy values for each parameter. An example rule base generation for R_D for some combinations is as shown in Table VIII.

$$Sum_{max} = 2 + 3 + 3 + 3 + 2 + 3 + 3 + 3 = 22 \quad (24)$$

$$Sum_{min} = 1 + 1 + 1 + 1 + 1 + 1 + 1 + 1 = 8 \quad (25)$$

$$R_D = \begin{cases} Easy, & \text{if } Sum < 13. \\ Medium, & \text{if } Sum < 18. \\ Hard, & \text{if } Sum \leq 22. \end{cases} \quad (26)$$

- 4) **Fuzzy output and Defuzzification:** The output variable is *assessment item difficulty*, which has again three linguistic variables: easy, medium and hard for D_R , D_U and D_A . The degree of membership functions is given by following equations:

$$\mu_F(R_D) = \max[\min[\mu_{K_F}, \mu_{K_C}, \mu_{K_P}, \mu_{R_1}, \mu_{TC_R} \mu_{S_1} \mu_{S_2} \mu_{S_3}]] \quad (27)$$

Fig. 6. Comparison of SME's opinion with Weight Based and Fuzzy Rule Based Method

$$\mu_F(U_D) = \max[\min[\mu_{K_C}, \mu_{K_P}, \mu_{U_1} \dots \mu_{U_3}, \mu_{TC_U} \mu_{S_1} \dots \mu_{S_3}]] \quad (28)$$

$$\mu_F(A_D) = \max[\min[\mu_{K_C}, \mu_{K_P}, \mu_{A_1} \dots \mu_{A_3}, \mu_{TC_A} \mu_{S_1} \dots \mu_{S_3}]] \quad (29)$$

These equations determine an output membership function value for each active rule. After completing the fuzzy decision process, the obtained fuzzy output is converted to a crisp value by applying centroid technique. Difficulty level is easy(1) if the estimated difficulty value is less than 35, it is medium(2) if it is less than 65 and hard(3) if it is more than 65.

VI. PILOT STUDY AND RESULTS

We have conducted a pilot field study with assessment items for Basics of Digital Systems course. Twenty three SME's having two to five years of experience in teaching the same course were selected randomly for taking part in the survey. The assessment items chosen for the survey were selected from question papers from various universities for the same course. We have conducted an experiment for the following hypothesis with 9 items, 3 each from remember, understand and apply cognitive level.

Hypothesis 2: *Fuzzy rule based difficulty estimation using proposed difficulty rubrics correlates better with subject matter expert's perspective of difficulty as compared to weight based difficulty estimation.*

The chosen items were given to SME's to mark them as easy(1), medium(2) and hard(3). The cognitive level information was not revealed to experts. We have estimated the value of difficulty for these 9 items using weight based and fuzzy rule based method. We have then compared the performance of both these methods with SME's opinion as shown in Figure 6. It was observed that fuzzy logic difficulty estimation correlates better with SME's opinion as compared to weight based method which proves our hypothesis. The accuracy of difficulty estimation using weight based method can be improved by modifying weights allotted to difficulty parameters corresponding to task, content and stimulus difficulty.

VII. CONCLUSION AND FUTURE WORK

Rubrics to identify the difficulty level (difficulty rubrics) of an assessment item can greatly facilitate the instructors of engineering courses to aim at and achieve the right level of mastery of learning. Difficulty rubrics that are learner independent, subject non-specific and score-independent will make them easier to use. The estimation of difficulty level of an assessment item is based on three of its aspects: task, content and stimulus. Task difficulty is based on the sub-processes of Blooms six cognitive levels. It should be noted that difficulty level of items at higher cognitive levels are not necessarily higher. However, it is possible to arrange subsets of the sub-processes associated with a cognitive level at different difficulty levels. Therefore, it becomes necessary to address each cognitive level with respect to difficulty level. Difficulty rubrics in this paper are restricted the most dominant cognitive processes, namely, remember, understand and apply.

The number of parameters to be considered to determine the difficulty becomes impressively large. Weight based and fuzzy logic based methods are proposed to make the process of determining the difficulty of an assessment item tractable. The difficulty levels of a given set of items related to the first level course on Digital Systems as determined by these two methods differed from each other, with fuzzy based method giving results closer to the opinions of subject matter experts.

Deeper understanding of engineering concepts is a pre-requisite for applying engineering knowledge and skills in practical and professional situations. Formative and summative assessment designed using wide range of difficulty level assessment items, will facilitate instructors to assess students abilities pertaining to course competencies completely.

Though these rubrics prove to be effective, the precision can be further increased by conducting survey with sufficiently good number of experts and using the survey results as a feedback to the fuzzy model for changes with respect to the membership function and rule base. Also, a training data set with large values may prove to be helpful for the fuzzy model to become more accurate and precise. We also aim to extend this contribution by designing rubrics for analyze, evaluate, create cognitive levels and engineering specific categories of knowledge as proposed by Vincenti[25] namely Fundamental Design Concepts, Criteria and Specifications, Practical Constraints and Design Instrumentalities.

ACKNOWLEDGMENT

The work has been supported by OAES, NIELIT Project for International Institute of Information Technology, Bangalore, India. The authors would like to thank subject matter experts for their help and co-operation in filling the survey questionnaires.

Abstract—‘Flipping the Classroom’ is a well-known effective educational approach which can produce significant learning gains. Students are doing the preliminary cognitive work to gain knowledge and comprehension outside of class, then focusing on the advanced cognitive work on application, analysis, synthesis, and evaluation in class. However, practically its application is quite challenging due to the limited accessible resources on both timing and spatial, especially in teaching engineering courses. In dealing these issues, in this paper we present our initiative works on improving the learning process of undergraduate students by applying this approach, by the use of the key laboratory equipment ‘Analog Discovery’. We applied the AD kit in three levels in teaching various electrical engineering courses: lecture, laboratory and senior design. Moreover, a series of engineering workshops are also developed targeting on various topics, with the direct support with AD kits. The results have shown a significant improvement on students’ learning. The application of AD kit in engineering education can greatly help students’ comprehension on knowledge, facilitate their engineering practice, and inspire their interests and motivation on learning.

Keywords—Analog Discovery Kit, Flipping the Classroom

I. INTRODUCTION

To improve the learning effectiveness in engineering education, diversified theories have been proposed and practiced by educators, among which ‘Flipping the Classroom’ and ‘Experiential Learning’ are two of the most well-known methods.

The ‘Flipping the Classroom’ enables an instructor to provide traditional, low cognitive level, lecture materials in an alternative format outside the classroom, freeing up class time normally used to ‘convey’ information to students [1]. Instruction that used to occur in class was then accessed in advance of class (generally at home), so that students were well prepared and could derive the most benefit from time spent in the face-to-face learning environment. In this scenario, class becomes the place to work through problems, advance concepts, and engage in collaborative learning. Most importantly, all aspects of instruction can be rethought to best maximize the scarcest learning resource – time [2, 3].

On the other hand, Experiential Learning Theory (ELT) provides a holistic model which emphasizes the central role that experience plays in the learning process. The most widely

used learning theory is Kolb’s experiential learning cycle [4-6] as shown in Fig. 1. According to the Kolb’s cycle, the four experiential learning stages are Concrete experience, Reflective observation, Abstract conceptualization and Active experimentation.

Fig. 1. Kolb’s cycle of experiential learning [7].

Practically, one of the major issues in applying these advanced teaching methods in engineering education is the gap between the limited facilities and students’ accessibility of required resources. Especially in teaching electrical engineering courses, the number of expensive equipment and working stations rarely meets the requirements of students, and it is always a trouble for all students to agree on a schedule to work together after class.

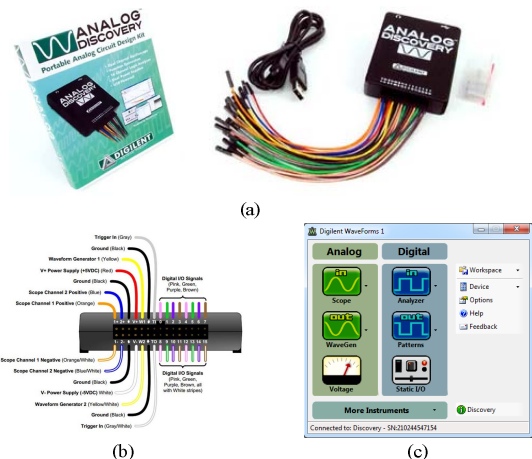

Fig. 2. a) Analog Discovery kit, b) pin-out, and c) interface of ‘Waveform’.

In dealing with these issues, we tried to integrate the Analog Discovery (AD) kit into our teaching practice to undergraduate engineering students. The AD kit is a small (3.2"×2.6"×0.8"), portable and low-cost (\$99 for US student)

Supported by NSF through Howard University.

multifunction instrument that can measure, record and generate analog and digital signals. A PC based free software 'Waveforms' is provided to control all I/O of the AD, by which the kit can be configured to work as all major laboratory instruments including multimeter, function generator, DC power supply and oscilloscope. Fig. 2 shows the AD kit, its pin-out, and the software interface [8]. In short, the AD kit can drive, measure, and visualize, for both analog and digital signals.

The AD kit has been applied in three different levels in teaching various electrical engineering courses: lecture, laboratory and senior design. Moreover, a series of engineering workshops are also developed targeting on various topics, with the direct support with AD kits.

From the beginning, most engineering students in the department are recommended by instructors to play with the AD kit in different courses. A pre-survey is required when they pick up the kit. Then by the end of the semester, students are requested to return the AD kits, or submit the application to keep the AD kit for another semester. Meanwhile they are also requested to complete a post-survey. These data are collected and analyzed for the assessment of AD kit's effectiveness.

Up to date, according to the feedback collected from involved students, the AD kit brought them an unprecedented learning experience on various engineering courses. First of all, the AD kit enables students' engineering practice on anytime and anywhere, but no longer limited in the laboratories. This unique feature has significantly changed many aspects of engineering education. The effectiveness assessment has shown great improvement on teaching outcomes.

The paper is organized as following: Sect. II introduces the methodological approaches applied; Sect. III illustrates typical case studies, Sect. IV presents the effectiveness assessment of proposed educational methods, and Sect. V concludes the whole work.

II. METHODOLOGICAL APPROACHES PROPOSED

The educational practice of integrating the AD kit into engineering curriculum teaching is in three levels: lecture, lab, and senior design, plus a series of workshops.

Level I – Lecture

The Kolb's experiential learning model was applied in teaching engineering courses by using the AD kit. Many engineering courses in the curriculum are suitable for this application, ranges from Basic Circuit Theory, Digital Logic Design, Electronics, to Instrumentation, etc. This different approach from the traditional didactic or demonstrative way now makes the teaching more interactive and the learning is more substantial.

For instance, in teaching the Boolean algebra in Digital Logic Design, originally the instructor will introduce concepts in class first, from 'AND', 'OR' and 'NOT' operations, to symbol of gate, and truth table, etc. Later in the lab (maybe a few days after) these concepts need to be reviewed again, then add up with new contents such as the logic '1' ($\sim +5V$) and '0' (GND), and 74-series ICs using guidelines. Such an exposure to a high

volume of new knowledge is quite challenging to beginners, whereas the separation of theory (lecture) and practice (lab) makes things even worse. Instructor may want to move his class to a laboratory, to give students an instant experience. However not all schools have enough lab stations and equipment to support. The effectiveness of lecturing in laboratory is also questionable.

By using the AD kit now, students' learning and practicing can be seamlessly integrated during regular class hours. In the new 'Experiential Learning' style, every student needs to have the laptop and AD kit properly setup before the class. During the class hours, they are provided with a small breadboard and various IC chips. Right after the instructor's introduction of each logic operation, students will practice and verify the function of a corresponding gate on the breadboard. Undoubtedly such experience is more direct, substantial and inspiring. In this scenario, the instructor can expect the ignition of a warm discussion, whereas students are excited and eager to learn more technical details and advanced contents. In this way their study process as well as the width and depth of their comprehension can be greatly expedited through experimental learning.

A similar example can be found in introducing the propagation delay of logic gates in teaching the same course. In the past this concept was confusing to many students, especially those who have not passed the Electronic course yet. By the use of the AD kit and other basic components, everyone can build a ring oscillator in a few minutes in class, to observe/measure the propagation delay of a single gate on the laptop display. Fig. 3(a) and Fig. 3(b) show the circuit setup and result of a three-inverter ring oscillator.

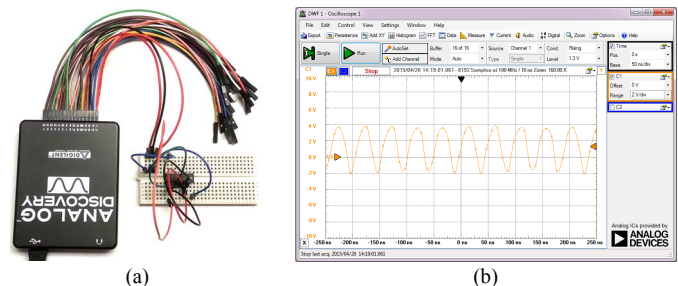

Fig. 3. a) Circuit setup of ring oscillator, and b) output of the ring oscillator.

Moreover, the AD kit offers additional functions that can help students to easily exercise on advanced materials. For instance, now students are using the kit to generate Bode plots in doing homework of Power Electronics and Control System.

A. Level II – Laboratory

The AD kit was applied in practicing the interactive engagement pedagogy 'Flipping the Classroom' in various engineering labs, including Basic Circuit lab, Electronics lab, Digital Logic lab, etc. All experiments were redeveloped with new labs added to support the utilization of AD kit.

One fundamental requirement for applying the 'Flipping the Classroom' in lab teaching is to enable students to finish experiments in advance. Essentially, the AD kit is a complete portable laboratory with all essential equipment for

implementing most basic experiments, which provides the capability to students. In the new teaching style, students were given lab manuals in advance and they requested to finish on their own time with the AD kit before the class.

The regular lab hours were much more enriched with diversified sessions. The students were then asked to first perform a demonstration of their individually. They were then to demonstrate the completeness of their lab work as a team. They needed to setup the circuit, operate and show all measurements or functions. Meanwhile, instructors (and other students) may ask questions to evaluate the performance of each team member. The second session was for questions, answers, and discussions, which provides the students with the opportunity to raise all questions and issues they experienced. After all questions have been addressed, the third session was used to test the students' understanding of the experiment. The third session is different from the first session as it was used to evaluate students' practical skills on implementation. The quiz focused more on testing their comprehension of theories. The fourth session was used to discuss advanced topics. It is also the opportunity for the instructor to expand students' comprehension of related teaching materials in scope and depth. The last session was used to assign of next lab, together with the brief review of major related concepts and tips students should be aware of. This process was repeated until the final project/exam.

With the support from the AD kit, quite a few extra benefits can be derived from the 'Flipping the Classroom' teaching, which are impossible on the past:

- All students are guaranteed of completely 7/24 access to laboratory resources. Instructors are no longer concerning about the participation of every student in the large group due to limited number of lab stations.
- The new teaching style enables students to spend more time on learning, practicing, critical thinking and identifying special questions than merely go through the basic experimental materials quickly in regular lab hours.
- The training to students on team working can be greatly enforced in the new style as well. All team members now have a more flexible schedule to meet, discuss and work together, in classroom, library, or even in Starbucks. Moreover, when time is not a big concern, students are more inclined to learn from each other, share experiences and try to contribute more to the project. To the contrary, these needs are suppressed or skipped in the past when the completion of lab in regular hours is the first priority.
- The instructors are also enabled with more flexibility on lab design while in the past during the lab hours the instructors are always too occupied on dealing with student questions to work on alternative ways of strengthening the teaching performance. In the new style the instructor can concentrate much more than before on improving the learning effectiveness, adding attractive materials, design challenging experiments, etc.

B. Level III – Senior Design

The integration of AD kit in engineering education was

expanded to include the teaching of Senior Design projects. With the kit, students' engineering project practice is no longer limited in the lab but can be anywhere. Fig. 4 illustrate an senior design project example, exoskeleton 'B.T. Suit'. By the use of the kit, student can run on-site test of its functions on extreme conditions anywhere, which will be very inconvenient on the past.

Fig. 4. a) The project suit, and b) demonstration of firethrower [8].

Moreover, the AD kit brings not only the convenience of testing and measurement, but expanded the way students perceive, explore and comprehend the engineering world. For the time being, they are more used to play and learn new stuff with the kit, as the extension of their fingers and eyes. Fig. 5 illustrate a senior design project, wearable device 'Communicare'. Students replaced the heart rate sensor with the AD kit to mimic pulses in different rates in testing the cardiac analytic algorithm they developed.

By the use of the AD kit, students are excited to learn and practice various sensors and integrate into the system. For instance, they tested the features such as the heart rate sensor with the kit, developed the algorithm on microprocessor to analyze the heart rate behavior, and then tested the algorithm by mimicking the signal by using the AD kit.

Fig. 5. Senior design project: wearable device 'Communicare'.

C. Additional Workshops

In addition the AD kit's application on the curriculum teaching, targeted to students' special needs a series of workshops on special topics that are offered from time to time. One example is the recent workshop on 'Microprocessor Arduino and Pulse Width Modulation for Motor and Servo Control'. The workshop was offered to engineering students especially those juniors who are interested in participating in an ongoing project of developing unmanned ground/surface/aerial vehicles. Fig. 6 shows example slides presented during the workshop to introduce the PWM implementation. In general, with the use of AD kit, the effectiveness of a workshop can be always improved. Every participant can practice more interactively with the instructor with directed experience and their questions will be addressed and solved immediately.

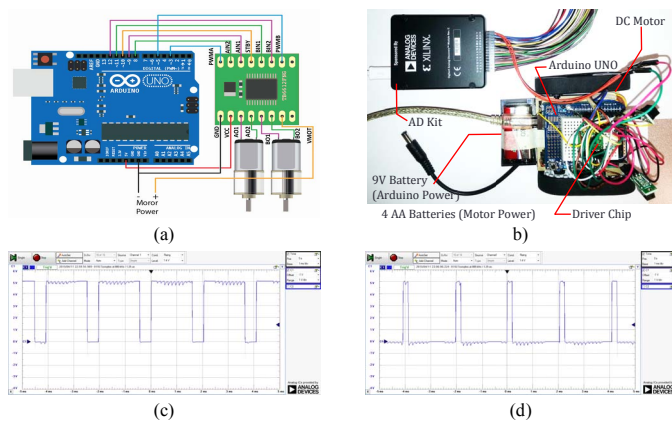

Fig. 6. a) Circuit setup, b) circuit diagram; c) PWM output on 78% duty, and d) PWM output on 10% duty.

III. ASSESSMENT

Diversified methods have been applied to access the effectiveness of this experiment, including pre/post-survey and statistics analysis of students' grades. Officially our application of the AD kit started only one semester ago. The status of this experiment is still in the collection of the first batch of data. However the students' feedback so far has already shown a significant improvement on their learning process. Fig. 7, Fig. 8 and Fig. 9 show students' recognition on the effectiveness of integrating the AD kit into the teaching process, the helpfulness of AD kit on their course learning, and the enhancement of AD kit on their professional, respectively.

Fig. 7. Effectiveness of the intergration of AD kit on teaching.

Fig. 8. The helpfulness on course learning by the use of AD kit.

Fig. 9. The enhancement on professional abilities by the use of AD kit.

IV. CONCLUSION

In this paper the authors have introduced our experience on integrating a portable laboratory device, AD kit into our education practice. In conclusion, by the use of the kit, we successfully applied the 'Flipping the Classroom' method in engineering courses teaching, and the 'Experiential Learning' in engineering lab teaching. Assessment results have shown that such integration can greatly improve students' learning, enhancement their professional abilities development, and inspire and motivate their interests to explore a much wider engineering world.

Teaching Project Management using a Real-World Group Project

Lawrence Collingbourne and Winston K.G. Seah

School of Engineering and Computer Science

Victoria University of Wellington

Wellington, New Zealand

{Lawrence.Collingbourne,Winston.Seah}@ecs.vuw.ac.nz

Abstract—It is well established that an effective pedagogy for project management requires students to get real-world experience. The challenge in providing this when teaching undergraduate engineers is the dichotomy between achieving realism and maintaining sufficient simplicity to make the course tractable. A real-world group technology project at Victoria University of Wellington (VUW) in New Zealand establishes essential non-technical attributes required by the engineering profession while covering key elements of the project management body of knowledge (PMBOK). This paper first shows how the project covers the knowledge required in project management and then presents the results of two years of data collected from students' reflection on their own learning. We have established a pleasing congruence across the years against the specific learning topics of team working skills, communication skills and personal working skills with an improvement in project management skills. A key finding emerging from our analysis is the importance of reinforcement learning and reflective learning. We show a key link between these two learning mechanisms and the project pedagogy. Further analysis shows the link between the project pedagogy and four skill areas acquired. Finally, our research has identified specific areas for us to focus on for subsequent years.

Keywords—project management, real-world project, graduate attributes

I. INTRODUCTION

It is not sufficient to equip engineering undergraduate students with just a technical education. The professional requirements for accreditation of engineering education in New Zealand [1] define more non-technical attributes for graduates than technical attributes. One of the ways Victoria University of Wellington (VUW) addresses non-technical attributes is through a practical application of project management to an environmental technology programme using group work.

Addressing non-technical attributes through project management starts with defining a practical scope and making it relevant to students focused on demonstrating technical prowess. There are several obstacles: project management is met with scepticism from non-practitioners, there is only a vague consensus over what it should be and there is no single model [2]. This is despite, or maybe because, established approaches such as PMBOK [3] and PRINCE2 [4] (the acronym for Projects IN Controlled Environments, which is a de facto process-based method for effective project management), and modern methods such as SCRUM [5] have

been applied to impose conformity and control on their practitioners in the name of professionalism [2][6]. Far from there being consensus, project management models are diverse, with as many as 1,000 in publication [7].

In New Zealand scepticism about formalising approaches resonates with the local culture of using a basic approach and “she’ll be right”. But “she isn’t right” and out-of-control projects continue to reap disaster with as many as one in six organisational change technology projects having 200% cost overruns [8]. Just recently two NZ government IT projects blew out from \$33m to \$163m [9] and from \$71m to “in the range of” \$155m [10] respectively.

Another key challenge is learning and teaching: how to ensure real learning that makes a difference to students’ engineering attributes. It is well established that it is not sufficient merely to ‘teach’ project management [11]; group work [12] and realistic project contexts [13] are essential to learning. Using a group project to achieve non-technical outcomes has to be simple enough to fit within the undergraduate teaching programme yet realistic enough to ensure students acquire skills for employment.

To solve these challenges, at VUW we follow up in-class teaching with a practical project that gives students responsibility for real-world outcomes to develop their learning of non-technical skills. We have found this to be a good pedagogy for grounding the project management teaching, establishing its relevance to the students and enabling them to learn essential non-technical engineering attributes. However, this is not the only approach available, as we discuss next.

II. PEDAGOGICAL ALTERNATIVES

There are a number of pedagogies available for project management. Professional project management development and certification through Project Management Institute (PMI) and PRINCE2 are predominantly based on training courses. These are available from around 2,000 providers worldwide [14][15]. While direct teaching is an important component of learning, it should be supplemented with other teaching methods, such as modelling, simulations, case studies and group projects. How does the use of a real-world group project compare to these?

Using real-world projects to teach construction project management is simply not practical: realism requires a scale that is too large and it takes too long for students to understand

and apply the method [13]. To overcome this, Stanford University uses software modelling tools to enable students to create construction plans that have sufficient detail and completeness to learn important project management concepts first-hand [13]. Important lessons learned include: time-based quantities, intuition for workflow, project monitoring (by plan features) and project fundamentals (also by plan features). Even so, direct experience stops at planning, so lessons to be learned in project execution are at best left to inference from the plan.

Simulations extend the software model into the project execution phase and become tractable as a learning tool in software engineering project management. The University of Stuttgart has developed a software engineering simulation tool used by nine Universities in Austria, Germany and Slovakia to supplement classroom teaching of project management [16]. This enables students to create software development projects and to execute them by simulation, gaining feedback and having the opportunity to change decisions to improve results. A system dynamics tool used at the University of Reading used simulation in an experiment to confirm that students gained better understanding of typical behaviour patterns of software engineering projects and raised their interest in project management [17].

The key limitation of simulations is that they lack real people, having neither a real client with real outcomes nor a real development team. Simulations can have other limitations, e.g. in supporting agile lifecycles or only modelling basic principles. This illustrates that significant investment is needed to get realism from software tools be it models or simulations.

A third alternative used in universities is case studies, through documentation, class discussions and/or by inviting in guest speakers with first-hand knowledge [12][18][19]. These go beyond simple classroom exercises and anecdotes from the lecturer's experience, to use real-world scenarios that students analyse to undertake assignments that they can evaluate from actual outcomes. While this presents more realism, key limitations are that students are learning second-hand and have little opportunity to ground their learning with direct experience. This limits case studies as a means to acquire practical skills [11].

A group project addresses some of the limitations of using modelling, simulation and case studies by enabling students to get first-hand experience of managing a project. This can be combined into an integrated approach, where more mature students manage group projects that teach technical skills [20]. However, it is not a given that group projects address the scope of learning required or provide real-world experience.

III. LEARNING REQUIREMENTS FOR A REAL-WORLD PROJECT

To understand how a real-world project can enable undergraduates to acquire the non-technical attributes specified by the engineering profession, we must first ask what attributes are required, how should they be learned and what scope of project management should be covered?

The seven non-technical graduate attributes defined by the Institution of Professional Engineers New Zealand (IPENZ) [1]

are based on international accord and are itemized in the following list. The VUW project has elements of all of these, which are all part of applying technical skills in professional practice:

1. Assess health, safety, legal and cultural issues of the engineer and society
2. Evaluate the impact of engineering on sustainability and the environment
3. Apply ethical principles to engineering practice
4. Function effectively as an individual and in a team
5. Communicate effectively on complex engineering activities
6. Apply management principles and economic decision making to manage projects
7. Prepare to engage in life-long learning.

The scope of project management as defined by PMBOK [3] includes knowledge areas itemized in the following list. The VUW project has elements of all these areas:

1. Organizational influences: the project environment
2. Project life cycle and processes
3. Management of project:
 - a. Integration
 - b. Scope
 - c. Time
 - d. Cost
 - e. Quality
 - f. Human resources
 - g. Communications
 - h. Risks
 - i. Procurement
 - j. Stakeholders.

Previous research by Ojiako *et al.* [21] identified the project management pedagogy 'dimensions' important to engineering students. These were in-class learning, out-of-class learning (provided through another course at VUW) and acquisition of generic skills (supporting the IPENZ requirements for these).

In another paper [22], the authors identify the key generic or transferable skills as the following:

1. Development of inter-personal skills
2. Experience of self-management
3. Development of critical thinking
4. Development of communication skills with others.

In the next section we show how our real-world project at VUW brings all these threads together to give engineering students a first-hand learning experience in these areas.

IV. THE VUW RIVERWATCH PROGRAMME

Engineering at VUW comprises three majors: electronic and computer system engineering, network engineering and

software engineering. In their third year, undergraduate students take two courses in project management, the first being a taught theory course using lectures, in-class discussions and group work, and the second being practical application of the theory through participation in the RiverWatch programme.

RiverWatch is a multi-year, multi-project programme to develop a technology platform for a voluntary organization called WaiNZ [23] that enables the New Zealand public to become “kaitaki” (Maori term for guardians) of their rivers and streams. Students have developed a website, smartphone applications, unmanned aerial vehicles (UAVs) and water quality data sensors for this purpose. Each year students form teams of five to broaden the base and push the boundaries of the platform with new development projects. The 2014 cohort’s key highlights included developing new iOS, Android and Windows phone apps, prototype water quality measurement devices, a UAV relay network to extend monitoring range and website enhancements. The programme has run for three years.

Students learn professional skills directly through their project work via the following mechanisms:

1. Creating self-organizing project teams [24]
2. Selecting and elaborating client requirements
3. Preparing project initiation documents, covering: requirements, business case, work breakdown structure (WBS) & Gantt chart, risk management, quality plan and communications plan
4. Communicating with the client weekly

5. Maintaining working documents, including team meeting minutes, updated Gantt chart and risk register
6. Presenting team achievement to the client
7. Demonstrating the team product to the client.

As a result of feedback appraisal from 2013, the two project management courses were adjusted to improve learning:

- The RiverWatch programme was introduced during the theory course to improve familiarity with it and the students produced an outline initiation document for the programme as part of that course
- The time available for students to do project initiation at the start of their RiverWatch project was extended by one week in the practical course to reduce risk
- Practical approaches to undertaking risk management were taught in the theory course and applied to the RiverWatch programme
- Communication with project stakeholders was introduced for the first time in the theory course to extend the students’ learning of communication skills
- Writing an individual reflective report.

The RiverWatch project addresses the IPENZ graduate attributes through the direct student experiences shown in Table 1 and addresses the PMBOK knowledge areas as shown in Table 2. The generic or transferable skills identified in the previous section are addressed as shown in Table 3.

The next section presents how we evaluated these learning experiences.

TABLE I. HOW RIVERWATCH ADDRESSES IPENZ GRADUATE ATTRIBUTES

IPENZ Graduate Attribute (3. and 7. Excluded)	RiverWatch Learning Experience
1. Assess health, safety, legal and cultural issues of the engineer and society	1. Comply with VUW laboratory and offsite health and safety requirements during their project 2. Identify project risks as a team and manage them through team meetings 3. Achieve community cultural outcomes with technology products to meet WaiNZ goals
2. Evaluate the impact of engineering on sustainability and the environment	4. Apply technology to enable WaiNZ and the public to improve the sustainability of beef and dairy farming and to protect the river environment in NZ 5. Define the environmental context in the product demonstration and answer client questions
3. Apply ethical principles to engineering practice	4. Apply ethics to client commitments, working together as a team and University requirements
4. Function effectively as an individual and in a team	6. Deliver an individual contribution to a group project with individual accountability to the team and to achieve personal assessment marks 7. Learn about team dynamics, leadership and motivation through teamwork and inter-project collaboration, by making real-world project decisions that result in a usable end product
5. Communicate effectively on complex engineering activities	8. Learn to write specifications and plans the project team can use effectively 9. Take turns to provide a verbal achievement report to the client weekly and get a real-world response back 10. Communicate effectively with the business owner (course lecturer) by producing project and technical documentation in writing and get feedback through assessment 11. Present achievement to the client and business owner in a formal team presentation and answer real-world questions 12. Demonstrate tangible end products to the client and answer real-world questions 13. Submit apps to the app stores for publication 14. Write a reflective end of project report to capture learning from the project experience and receive assessment and feedback
6. Apply management principles and economic decision making to manage projects	15. Work to a project brief the team has created and had reviewed 16. Choose an appropriate project lifecycle and plans and execute them, monitoring actual achievement against real deadlines 17. Produce an outline business case including project costs
7. Prepare to engage in life-long learning.	18. Capture key learning in project closure and produce a personal plan to for its future application and development.

TABLE II. HOW RIVERWATCH ADDRESSES PMBOK KNOWLEDGE AREAS

PMBOK Knowledge Area	RiverWatch Learning Experience
1. Organizational influences: the project environment	1. Work within a programme structured of multi-year stages and sub-projects with dependencies 2. Resolve the relationship between project, programme and organisational goals
2. Project life cycle and processes	3. Understand the organisation of the RiveWatch programme and its communication 4. Apply agile lifecycles in a real-world multi-subproject environment to manage risk
3. Development of critical thinking	
a. Development of critical thinking Integration	5. Integrate mechanisms to manage the project effectively within the RiverWatch programme 6. Apply planning and change control to achieve a real-world product within constraints
b. Scope	7. Collect client requirements accurately and unambiguously 8. Work with the client and proactively elaborate requirements 9. Use a WBS to ensure nothing is omitted or duplicated
c. Time	10. Use a Gantt chart to allocate activities and manage their dependencies and timing 11. Manage real-world resource constraints in the project plan
d. Cost	12. Create a simple business case and project budget
e. Quality	13. Apply quality planning and control to achieve product acceptance and client satisfaction
f. Human resources	14. Assign work, motivate the team, monitor performance, make decisions and manage time
g. Communications	15. Apply taught theory to real client communication, team meetings and presentations
h. Risks	16. Identify, analyse and manage real-world project risks and handle their impact
i. Procurement	17. Budget for, specify and procure engineering components
j. Stakeholders.	18. Manage the expectations of a client, other teams and technical stakeholders.

TABLE III. HOW RIVERWATCH ADDRESSES KEY TRANSFERABLE SKILLS

Transferable skill	RiverWatch Learning Experience
1. Development of inter-personal skills	1. Work with others in a group project and with other teams in a multi-disciplinary environment
2. Experience of self-management	2. Manage own work and motivation to meet the project plan and team commitments
3. Development of critical thinking	3. Research and analyse project requirements and solutions, reflect learning in logbook, write report
4. Development of communications skills with others.	4. Work in a group environment to make decisions, control project interdependencies, present achievement to a client and produce technical and user documentation.

V. EVALUATIONS OF STUDENT LEARNING

At the end of the project management course each student produces an individual reflective report that describes their own evaluation of the project and what they learned from it. There were 40 students in 2013 and 56 students in 2014. This section explains how an analysis of the student reflections on their learning using grounded theory [24] provides an assessment of the pedagogy of the course.

Student learning from their reports was initially coded into specific learning points identified by the students from their project experience, i.e. what they did. Using concurrent data generation and analysis these were then coded into project management skill categories, which was complete when student learning fitted all the categories identified, yielding 618 reflections. This eliminated the trite repetition of textbook theory by verifying each learning point from direct evidence cited in the report, for example, "I found that referencing the plan was useful for drawing attention to forgotten tasks. It was easy for us to focus on the technical implementation, while neglecting components such as presentations and documentation."

Two types of learning emerged from this coding: reinforcement learning and reflective learning. Reinforcement learning is where students applied their learning and gained a positive outcome that reinforced it. Reflective learning is where students failed to gain a positive outcome from a key learning point but through reflection learned from their mistake. For example, some student projects followed their project plans while others did not, with students that did not learning on reflection that more investigation was required to obtain a successful plan. Reflective learning does not indicate poor pedagogy, as learning from making mistakes is a powerful way of learning [26]. However, it indicates where further research into the taught element is required.

The learning was then further coded to understand the type of project experience that drove it in order to see whether the assertions of using a real project made in previous research can be supported from RiverWatch. To do this, each learning point and the evidence for it were examined to determine the generic mechanisms driving the learning point. The results of our analysis and its consistency over two years are presented in the next section. The two graphs of results on the next page are explained the text on the following page.

Fig. 1. Total learning points grouped by the skills shown in TABLE IV.

Fig. 2. Reflective learning points grouped by the skills shown in TABLE IV.

VI. EVALUATION RESULTS

The student learning points from the above evaluation are presented as total learning and reflective learning. The total learning is grouped into four skill areas. Following this, the experiential source of this learning is presented.

A. Total learning points

Fig. 1 summarizes all the learning topics identified from the analysis by the percentage of total students reflecting on them in their final reports in 2013 and 2014. These are grouped into the four skills areas and then ordered from the largest number of topics to the smallest in 2014.

The average number of topics reported by each student in each skills area is shown in Table IV.

TABLE IV. TOTAL LEARNING POINTS IN FOUR SKILLS AREAS

Skill area	2013	2014
Project management skills	2.2	2.6
Team working skills	2.2	2.2
Communication skills	1.3	1.2
Personal working skills	0.7	0.9

The summary of student learning by skill area in Table IV shows the consistency across the two years. It shows that learning transferable skills through the group projects is on par with learning project management skills. Personal motivation dominates the personal working skills.

B. Reflective learning

Fig. 2 summarizes the learning topics identified by the percentage of students reflecting on what they learned from their mistakes. (Reinforcement learning makes up the difference between Figs. 1 and 2).

The total number of reflective learning topics went up from 1.9 in 2013 to 2.2 in 2014, with most topics at one per five students or below.

C. Sources of learning

The experiential sources of the students' learning are shown across the two years for each of the four skill areas in Figs. 3 to 6. This was determined by examining the experiential context of the learning previously analyzed. This addresses the question of how much learning comes from the real-world group project with a real client with programme complexity verses self-learning.

As might be expected, personal working skills have a significant self-learning component. The other key skill areas, especially the transferable skills of communication and team working are predominantly learned from the real group project. Communication and project management skills had a significant real client component. The real-world group project learning has increased in 2014 in all cases except team working, where it is insignificant.

2013 Project Management Sources

2014 Project Management Sources

Fig. 3. Project management skills learning sources 2013 & 2014

2013 Team Working Sources

2014 Team Working Sources

Fig. 4. Team working skills learning sources 2013 & 2014

Fig. 5. Communication skills learning sources 2013 & 2014

Fig. 6. Personal working skills learning sources 2013 & 2014

VII. SIGNIFICANCE OF RESULTS

The evaluation results support the effectiveness of improvements made in 2014 described in section IV. High levels of reflective learning on project initiation and inter-team collaboration in 2013 were significantly reduced in 2014. Reinforcement learning of communication increased in 2014, reflecting its wider application beyond just presentations. Reinforcement learning of risk management doubled and there were fewer changes to project scope resulting in reduced reflective learning from this.

The evaluation of reflective learning also reveals two unexpected regressions in 2014. The first is in team working, where a timetable conflict was introduced by a change to another course that increased reflective learning due to fewer meetings being scheduled.

The second is the increase in reflective learning in project planning. This is dominated in both years by learning the truism that original plans and estimates often don't survive in a real project. Further research is required to identify the cause of this, but it may be due to more detailed planning being practiced in 2014.

A summary of the explanations of the differences in total learning is shown in Table V.

The sources of learning identified show that all four key skill areas acquired through the RiverWatch project derive predominantly from the students' direct experience of group working on a real project with resource constraints, deadlines, hard measures of success, a real client and complex characteristics, such as, stakeholders, inter-dependencies and multiple stages. The amount of self-learning reduced from 16% in 2013 to 10% in 2014. Further research is required to identify the cause of this, and will be part of our future work.

TABLE V. EXPLANATION OF CHANGES IN TOTAL LEARNING

Learning topics	Change between 2013 and 2014
Risk management Project planning Spiral/Agile	These project management topics were all taught more practically in 2014 resulting in an increase in learning
Team roles Inter-team collaboration Pair working	The first topic scored lower in 2014 due to calendar conflicts, while inter-team collaboration saw a reduction in reflective learning and pair working increased
Communication Presentation skills	Communication was taught more broadly in 2014, reducing the focus on presentation skills
Personal motivation	Increased to become a significant learning point issue in 2014, possibly reflecting less mature and overseas students than in the 2013 class
Client role Scope/Change	The class lecturer and tutors played a stronger role in 2014, possibly diluting client focus, but reducing scope change due to problems.

VIII. SUMMARY AND CONCLUSIONS

This paper has shown how teaching project management through a real-world project has addressed the needs of the engineering profession and covered the scope of the project management body of knowledge. The analysis of the students' personal reflection shows the key learning points achieved through the course and indicates where further adjustments will be beneficial.

This analysis corroborates previous research in showing that the generic transferable skills are rated by students as important learning [19][20]. Communication (including presentation skills) is the highest learning topic reflected by both quantity and importance, with team working also significant in the total number of generic transferable skill reflections.

Project management skills are also rated highly, with project planning, project initiation and risk management being the top six important learnings reflected by students.

The research also shows that learning can be improved by focusing on the reflective learning points to enable greater reinforcement learning. Key points to take forward from this are to ensure the reflective learning does not represent over-challenge and to review key topics such as project planning and team working to ensure student motivation is maintained. The precise pedagogy that increased learning from the real-world project in 2014 also needs further research.

We conclude that the use of a real-world project has been a success in addressing the IPENZ non-technical attributes, as reflected in student learning. The students' reflections provide direct evidence of learning from the real-world project, with group working and a real project being the biggest drivers.

Abstract—This study investigated the effect of Google SketchUp on students' learning achievements in spatial visualization. A quasi-experimental with pre-test and post-test design was used to conduct the research. Eighty-four fifth graders from a public elementary school in Taiwan voluntarily participated in the study. Students from different classes were divided into three instructional modules: Google SketchUp (with full features), Google SketchUp (with limited features), and traditional instruction (hand-held objects). Students in each of the three experimental groups were instructed to manipulate various 3D objects that were created by a class teacher. A criterion test was developed to measure students' understanding about basic concepts of spatial visualization. The educational experiment was completed within three weeks. The results showed that Google SketchUp (with full features) was an effective learning tool to support students in developing spatial visualization skills ($F=8.20$, $p < 0.01$).

Keywords— *spatial visualization; open source software; k-12 engineering education*

I. INTRODUCTION

Spatial visualization skills refer to the ability to mentally process and manipulate two-dimensional (2D) or three-dimensional (3D) visual objects [1]. Due to the significance in engineering professions, engineering educators contended that spatial visualization skills were emphasized in all engineering disciplines and not limited to graphic design-related disciplines [2-3]. These skills are particularly important for architectural, manufacturing, and electronic engineers.

With advances of information technology in engineering education, traditional hand-held visual aids in supporting spatial visualization skills have been replaced by 3D multimedia tools. They may provide additional learning opportunities for learners and attract their attention. For example, Christou et al. [4] found that features of 3D multimedia tools motivated students to manipulate virtual visual objects on the computer screen and resulted in better learning outcomes. Similarly, Wu and Shah [5] considered that animations embedded in 3D multimedia tools clearly demonstrated spatial concepts and effectively lowered learners' cognitive learning loads.

Google SketchUp developed by Google Company is a 3D multimedia tool that allows students to design and develop 3D

visual objects. Being open source software, Google SketchUp has been widely used for creating 3D building models in architectural engineering, interior design, and civil engineering [6]. Kurtulus and Uygan [7] and Erkoc and Gecu [8] were pioneers who explored the use of Google SketchUp in mathematics classes. However, even though they employed an experimental method to examine the effect of Google SketchUp on students' geometric learning performances, a major problem was that student participants in these studies were asked to draw 3D models rather than manipulating visual objects. Training students to create visual models in limited time may pose a severe threat to the external validity of experimental design [9].

Therefore, the current study aimed to investigate how elementary school students employed Google SketchUp to support their mathematics learning regarding spatial visualization. An educational experiment was conducted in three fifth-grade classes where 84 student participants manipulated various types of 3D geometric models (computer-based vs. hand-held objects) created by one class instructor. One major research question was as follows: Did significant differences exist on learning achievements in spatial visualization for students manipulating different types of 3D geometric models?

II. RESEARCH METHOD

A. Research Design

A quasi-experimental with pre-test and post-test design was adopted in the study to explore the effect of Google SketchUp on students' learning performances. The independent variable was the type of 3D geometric models manipulated by students. The dependent variable was students' learning achievements in spatial visualization.

Three different treatments were used to investigate Google SketchUp's learning effectiveness. Students in Treatment 1 employed Google SketchUp with full features to manipulate virtual 3D objects. In Treatment 2, one major feature (object transformation) in Google SketchUp was disabled. Students only used limited features in Google SketchUp to manipulate virtual 3D objects. Treatment 3, used as a control group, provided each student with a package of cardboard-made geometric objects to practice spatial visualization skills. One

week before and after the implementation of the study, students received a pre-test and a post-test on spatial visualization.

B. Research Instruments

One mathematics-learning unit regarding geometric objects was selected as the main instructional content. Virtual 3D objects were created in Google SketchUp. These geometric models served as computer-based visual aids that supported students in comprehending important concepts of spatial visualization. A criterion test was developed to measure students' understanding about basic concepts of spatial visualization. The test contained 18 multiple-choice questions. The test items were directly related to these three major constructs: spatial comparison (similar to spatial rotation), spatial measurement, and spatial transformation. For example, one of the test items asked students to compare the surface areas of two given geometric objects. Higher scores in the measurement represented students' higher learning achievements. The score range of the test was between 1 and 18. The Kuder-Richardson 21 (KR-21) coefficient of reliability was calculated as 0.9.

C. Participants

Eighty-four fifth graders from a public elementary school in Taiwan voluntarily participated in the study (Treatment 1: 28; Treatment 2: 29; Treatment 3: 27). Overall, students in Google SketchUp groups had medium-level computer literacy since they received computer knowledge at computer courses.

D. Procedures

The educational experiment lasted for three weeks; in each week, students received various instructional treatments within one hour. In Treatment 1 and 2, the course instructor taught mathematics through oral presentation, demonstrated 3D objects in Google SketchUp, and allowed students to manipulate 3D objects by using five features in Google SketchUp. In Treatment 3, in addition to class lecture, the course instructor also demonstrated hand-held objects and asked students to practice with cardboard-made visual aids.

E. Data Analysis

One-way analysis of variance (ANOVA) was used for data analysis. When the significance value was realized, a post-comparison method was used to compare mean differences among experimental groups. The significance level was set to 0.01 in the study.

III. RESULTS AND DISCUSSIONS

A. Mean Difference Among Groups

Table I summarizes the results of descriptive statistics regarding the pre-test and post-test. Table II reports the ANOVA results for each of the three experimental groups.

TABLE I - SUMMARIES OF PRE-TEST AND POST-TEST RESULTS

Experiment Group	N	Pre-Test		Post-Test	
		Mean	S.D.	Mean	S.D.
Treatment 1	28	6.68	3.50	11.71	4.59

Treatment 2	29	5.48	4.29	7.31	4.45
Treatment 3	27	6.52	4.01	8.96	5.50

TABLE II - ANOVA RESULTS FOR GROUPS

Source	SS	DF	MS	F
Between	259.56	2	129.78	8.20**
Within	1265.71	80	15.82	
Total	1525.27	82		

** $p < 0.01$

Table I shows that students in the three experimental groups all improved their spatial visualization skills after receiving various instructional methods. Compared to the pre-test, students in the Treatment 1 earned more points (mean differences: 5.03) in the post-test. Table II indicates that there was a significant difference among the three experimental groups ($F=8.20$, $p<0.01$). Thus, a post-comparison test was performed to compare mean differences in the post-test. Table III lists the comparison results.

TABLE III - POST-COMPARISON RESULTS

Group	Modified Mean	Post-Comparison
Treatment 1	11.70	T1>T2**, T1>T3**
Treatment 2	7.54	T1>T2**
Treatment 3	8.74	T1>T3**

** $p < 0.01$

The results in Table III showed that a significant difference existed between Treatment 1 and 2 ($p<0.01$) and between Treatment 1 and 3 ($p<0.01$). However, no significant difference was found between Treatment 2 and 3. Therefore, students in Treatment 1 group performed significantly better than the other two groups.

B. Discussions

After the implementation of a three-week experiment, students' spatial visualization skills in three experimental groups were increased through various instructional models. From a starting point (pre-test), students in the Google SketchUp (with full features) group achieved a better learning improvement in the post-test. In contrast, students' post-test performances in Google SketchUp (with limited features) and traditional instruction groups grew by a small margin.

Regarding group comparison, there was a significant difference between Google SketchUp (with full features) and Google SketchUp (with limited features) and between Google SketchUp (with full features) and traditional instruction (hand-held objects). This finding showed that Google SketchUp (with full features) is an effective instructional solution in developing elementary students' spatial visualization skills. While engaging in Google SketchUp (with full features) group, students might use five main features to manipulate virtual 3D objects to obtain full understandings of basic concepts in spatial visualization. The result supported previous research, which reported that 3D multimedia tools could support students in learning mathematics concepts [4].

Even though students with limited features strengthened their knowledge base in the post-test, no significant learning benefits were identified. Their learning performances were lower than those that received traditional instruction (hand-held

objects). In Treatment 2, Google SketchUp lacked one major feature (object transformation) for students to manipulate 3D virtual objects. Limited learning gains resulted from the effect of the computed-based visualization tool being blocked. This phenomenon can be attributed to the role of object transformation being disabled in the Treatment.

Traditional instruction (hand-held objects) served as a comparison group to reflect the function of treatment groups. However, the findings showed that students under traditional instruction still performed well. Although there was no significant difference between Treatment 2 and Treatment 3, students' learning performances in traditional instruction surpassed those in Google SketchUp (with limited features) group. In other words, a learning value indeed exists for physical contact with cardboard-made objects. Manipulating these hand-held objects also supports student learning in spatial visualization [10]. This finding was consistent with past studies that physical objects exhibited a positive effect on students' development of spatial visualization skills [11-12].

IV. CONCLUSION

This study explored the effect of Google SketchUp on students' learning achievements in spatial visualization. Based on the statistical results identified above, the research null hypothesis was rejected. A significant difference in students' learning achievements was found among three experimental groups. Compared to two other groups, students in Google SketchUp (with full features) group achieved a better learning outcome. Therefore, Google SketchUp (with full features) can be an effective learning tool to support students in developing spatial visualization skills.

Even though students in the Google SketchUp (with limited features) group used computers to facilitate their mathematics learning regarding spatial visualization, students' learning outcomes were the lowest among the three experimental groups. From a statistical perspective, Google SketchUp (with limited features) and traditional instruction (hand-held objects) achieved similar learning outcomes. When one major feature (object transformation) was disabled, Google SketchUp might not effectively benefit student in learning fundamental engineering concepts.

Although the study was conducted in a K-12 learning context, the findings of the study may still provide an implication for engineering educators at higher educational institutions. In engineering colleges, when given an opportunity to adopt advanced technologies in classrooms, instructors tend to choose commercial-based software and

spend time developing specific tools for classroom instruction. From the results of our study, Google SketchUp as open source software showed its benefits in engineering learning. While developing visualization-training programs becomes popular in higher education, Google SketchUp may offer an alternative instructional solution to support engineering students in developing spatial visualization skills.

Abstract – In 2007, Borrego published her groundbreaking work “Conceptual difficulties experienced by trained engineers learning educational research methods”[1] that described five conceptual difficulties engineering faculty encountered as they began to learn about rigorous research in engineering education. Since Borrego’s research was published the engineering education departments have been formed and a new generation of engineering education researchers has emerged. These researchers must tackle the same paradigm shift that faced the engineering faculty in Borrego’s study. The research question that guided this study was: “What conceptual hurdles still exist for the new generation of engineering education researchers?” PhD students in Engineering Education were asked to reflect on their conceptual difficulties during the first semester of their PhD courses and write an end-of-semester reflective paper that summarizes their cognitive journey. The summative reflections were coded using Borrego’s conceptual hurdles as a framework. The results of the present study can inform those entering the engineering education research community by highlighting areas that remain problematic and offer strategies that emerging scholars have used to make sense of educational theories and methods.

Index Terms –Conceptual difficulties, Rigorous Research in Engineering Education, Paradigm shift, New Generation of Scholars

INTRODUCTION

In the past two decades research in engineering highlighted the fact that engineers were being educated in a manner that would probably be no longer applicable by the time they exit school [2]–[4]. Hence there was a reported need for innovative approaches to educating engineers aimed at developing adaptive people and organizations

tasked with designing learning experiences to leverage students’ strengths and experiences [5]. Similarly, there were increased calls for a systematic approach to research in engineering education that saw the development of what is now an established engineering education research initiative. Felder, Sheppard and Smith discussed this as “pressures on engineering education to adapt and change that were not going to go away. The impetus for engineering schools and faculty to develop new curriculum structures and improved teaching methods and materials is only likely to grow in the coming years, and the need for high-quality scholarship to assess the new developments and archival venues to chronicle the work will grow concurrently” [6, p. 8]. The main idea behind this initiative was to conduct research aimed at identifying tools capable of defining and transforming learning experiences as well as to provide opportunities for collaboration among engineering and science fields [3], [7]. Radcliffe described this move as “a need for a broader conception of engineering and of engineering research, one that includes the practice of engineering and which takes account of other types of knowledge” [8, p. 263]. Consequently, the important questions of what constituted engineering education research and how this research was to be conducted would eventually emerge.

A. Defining What Constitutes Engineering Education Research

The Rigorous Research in Engineering Education: Creating a Community of Practice (RREE) funded by the National Science Foundation (NSF DUE-0341127) was one of the first programs designed to increase the number of faculty who could conduct high quality engineering education research. The idea behind this project was to bring together a wide array of engineering faculty, educational practitioners and other research scientists through a five day workshop aimed at exposing these engineering faculty to the world of educational research [9]–

[11]. Having an executive committee comprising of members from the American Society for Engineering (ASEE), American Educational Research Association (AERA) Division I and the Professional and Organizational Development Network in Higher Education (POD) “the purpose of the RREE project was to prepare faculty to conduct rigorous research in engineering education” [12, p. 103]. The term “rigorous” as defined by the authors aligned with the National Research Council’s [13] six steps for conducting scientific research which were:

1. Pose significant questions that can be investigated empirically.
2. Link research to relevant theory.
3. Use methods that permit direct investigation of the question.
4. Provide explicit, coherent chain of reasoning.
5. Replicate and generalize across studies.
6. Disclose research to encourage professional scrutiny and critique.

B. Conceptual Difficulties Associated with Conducting Engineering Education Research

The work of Borrego [1, p. 91] based on data collected at the RREE project identified five conceptual difficulties experienced by the participants specifically the engineering faculty, involved in this project as they learned and engaged with the materials presented at the workshops. These were:

1. Framing research with broad appeal – research questions on the “why” and “how” of a phenomena.
2. Grounding research in a theoretical framework – using the theoretical framework as a guide for conducting the research.
3. Fully considering operationalization and measurement constructs – how to determine measurement of constructs outside of their area of expertise.
4. Appreciating qualitative and mixed-methods approaches – how these research approaches can be just as valuable as quantitative approaches.
5. Pursuing interdisciplinary collaboration – the importance of having a diverse group of researchers to foster collaborative work.

However, in 2005 when Borrego collected the data for the “conceptual difficulties” paper, engineering education research was just being “born” as a discipline [7]. One of the conceptual difficulties she describes specifically addresses this state of affairs. “In the absence of individuals trained in both engineering and social science methods, a team of collaborators with diverse disciplinary backgrounds is required to provide the necessary expertise for rigorous engineering education research” [1, p. 95]. Since 2005, engineering education departments have been created based on the recommendations for relevant skills researchers in this field would need to possess [14]. To this end a new generation of engineering education researchers has emerged. However, this new generation of researchers must

tackle the same paradigm shifts that faced the engineering faculty who participated in the RREE – they begin as trained engineers and need to understand the similarities and differences between technical research (dealing largely with the physical world) and educational research (which focuses on human learning and behavior). The purpose of this paper is to investigate, based on the conceptual difficulties identified by Borrego, what conceptual hurdles still exist for the new generation of engineering education researchers.

METHODOLOGY

Research Questions

The research question guiding this study was: “What conceptual difficulties still exist for the new generation of engineering education researchers?”

Participants

The data used for this study were collected from 16 PhD students in the Engineering Education department at a large research intensive University who were enrolled in a one-credit introductory engineering education research seminar in their first semester in the PhD program.

Study Context

The course is aimed at introducing new students to the profession of being an engineering education researcher. The purpose of the course explicitly outlined in the course syllabus discusses the fact that unlike engineering education, other more established disciplines possess areas of research and research methodologies that are well-defined and relatively stable. This being the case, the activities employed in the course centered on providing the new students with the ability to transition into new bodies of knowledge, research methods, jargons and concepts direct related to this new and still emerging field. A requirement of the course was that students, having read the paper by Borrego, were to summarize what engineering education concepts were difficult for them to understand and strategies they used to make sense of the difficult information. To be able to better understand the experience making the paradigm shift, a subgroup of students were invited to further reflect on their journey and be co-authors on this paper. Their reflections serve as case studies that strengthen our understanding what it is like to experience this paradigm shift and what strategies might be used to make the transition.

Data Analysis

The summative reflections written by the students based on the two guiding questions given at the beginning of the course were coded using Borrego’s conceptual hurdles as a framework. The number of instances of the five conceptual hurdles identified by Borrego were noted and examples of each hurdle presented in the following section of this paper.

RESULTS

A. Coding based on conceptual hurdles framework

Of the five categories, theoretical framework and qualitative and mixed-methods approaches were reported as the most problematic areas faced by the students. Illustrated in Table I below, theoretical frameworks were reported 11 times, qualitative and mixed-methods approaches nine times, transferability of results five times, interdisciplinary collaboration twice and operationalization and measurement of constructs once. Much like the participants at the workshop, the new PhD students spoke about difficulties

they experienced writing research questions that would fit this research paradigm, being completely overwhelmed by the idea of a theoretical framework, the uncertainty associated with being able to measure what their new research questions were intended to find, their doubt in the usefulness of qualitative research as well as why they needed to foster collaboration between two seemingly dissimilar fields. Specific examples of these difficulties taken directly from the students' reflection documents are shown in Table II.

TABLE I
NUMBER OF COUNTS FOR CONCEPTUAL DIFFICULTIES REPORTED BY PARTICIPANTS

Conceptual Difficulties	Number of instances
Transferability of results	5
Theoretical Framework	11
Operationalization and measurement of constructs	1
Qualitative and mixed-method approaches	9
Interdisciplinary collaboration	2

TABLE II
EXAMPLES CONCEPTUAL DIFFICULTIES FROM PARTICIPANTS REFLECTION DOCUMENT

Conceptual Difficulties	Examples from participants reflection document
Transferability of results	--While I might see the difficulty in moving away from the scientific closed-form question "yes" or "no," my own initial struggle was writing a research question that truly articulated the knowledge I wished to create or unveil. The challenge was not starting a question with "why" or "how," rather it was the difficulty of capturing the essence of what I wished to discover. -- If we did not ask questions that could be answered empirically, if we did not link the research we are doing to theory, if we did not follow the other characteristics of what is rigorous engineering education research, then how can we ever ensure disciplinary progress?
Theoretical Framework	--The concept of " <i>theoretical framework</i> ", which immediately pulled the ground from under my feet and I started to grapple with an entirely new concept. --When I would read papers I would find myself thinking: "Why are you telling me what framework this is based on? Why can't you just explain what you did and what you found? Why is a 'framework' even important?"
Operationalization and measurement of constructs	--Given my large foundation in ECE courses the utility of the course is contained in the courses name. Such is not the case for me with philosophy. The philosophical underpinnings of why we're engineering software is not something we readily discuss in ECE. Finding utility in these new ideas or some way of applying them to the world I already knew was something I yearned for
Qualitative and mixed-method approaches	--What we perceive as humans is not always what actually happened, so how could we trust this data? We are also not reliable. Personally, if I answered questions one day versus another day, I might respond differently depending on my mood or my experiences just prior to the questions. For these reasons, I was suspicious of qualitative methods and I clung to quantitative ENE research. -- Qualitative studies were not considered true research so the thought of doing qualitative research didn't even cross my mind. I did not believe it had validity (how could a study of 6 people be valid?) nor did I believe it added value to the field.
Interdisciplinary collaboration	--We were three engineers from distinct fields attempting to conduct a qualitative study with First Year Engineering students. We had no experience or expertise with regards to this research at any level. We had our own experiences on which to lean on, but we were pushing ourselves to do more than what we already knew. -- It's not the idea of diverse collaboration that confuses me; instead it's the requirement that one needs technical engineering training to perform engineering education research. I realize that originally engineering educators were trained engineers with an interest in engineering, but people with diverse backgrounds are now entering the field of engineering education

B. Expanded example from Avneet

While reading Borrego's paper, the first conceptual hurdle that I came across was transferability of results. She wrote about how engineering faculty have difficulty understanding the importance of framing research questions that have a broad appeal, because they assume transferability. As I read this section, I found myself perpetually thinking about how that wasn't the case, and in my experience with engineering research, framing a broad research question was imperative to make any sort of contribution to the field. From my research work in the field of aerodynamics, one of the most important lessons that I had learnt was that one needed to research situations that could be commonly reproduced in more pragmatic situations. Even though fluid dynamics theories and experiments are considered easier, and are even taught before at educational institutes, as an aeronautical engineer it was always important for our results to be applicable to compressible fluids (like air). Thus to deal with this difficulty, I drew an analogy between the broader transferability of engineering education research, and my prior experience of moving from incompressible to compressible fluids to make a real impact in the field of work.

Working on engineering education research seemed like a great idea, and I saw how it would help me satiate my inner sense of purpose. However, I was unsure about how most of the research was being carried out. Research always meant numbers to me, one way or another. I just could not see how numbers could be used to understand how students learn, and consequently help them learn. The big turning moment occurred in a professor's office, who is now my advisor. He shared with me one of his projects in which he along with his colleagues studied students solving engineering problems presented in fictional books. There was a clear research question, method, and even big real-world implications, even though it involved absolutely no numbers! This is when I realized the power of qualitative research. I couldn't think of a way in which the aforementioned research study could be carried out by quantitative methods.

C. Expanded example from Juan

To better understand a theoretical framework I mentally compared to it to a protocol in that I see a protocol as a set of agreed-upon general rules that guide practice on a particular field, or toward a particular objective. A protocol, as I interpret it, is not a detailed instruction on *how* to do something thing, but a higher level description or narrative of what the thing *should do* or how it *should look* like. It is for the practitioner to overcome the gaps from description to execution, bringing in her/his own expertise, beliefs, and evidence. In my analogy, the theoretical framework becomes the overarching set of rules, descriptions, and indications that guide the actions of the researchers in order

to help them produce something that other people—and they themselves can make sense of. A framework in this sense serves not only for the researchers to frame and orientate their work, but also for the interested community to look at the finished product, understand the underlying principles and intentions that shaped it, and assess its utility accordingly.

D. Expanded example from Hector

As we were studying the sources of information students used in choosing a major, we looked at their previous experiences, sources of information used, and influence from adults/peers, etc. Throughout discussions within our research group we arrived at this idea that students were motivated in some way to choose engineering, and then to choose a major within engineering. Through the reading assignments of other classes one member found a paper that used Eccle's expectancy value theory. We all looked at the framework and concluded that it sounded very applicable to what we were doing. We felt we ought to ground ourselves in a framework because otherwise we were just conjecturing based on what we had seen in the data. In our classes we were talked to about frameworks. In papers we saw people using frameworks. We knew we used the scientific method as a framework in other engineering work. And here was this framework that fit very nicely into the work we were doing.

Throughout the examination of the data words like 'values' and 'beliefs' would pop up in our research group discussions. When we adopted a theoretical framework that seemed to fit our research study (to the best of our knowledge) the biggest change I remember happening was that our vocabulary changed. We felt more at ease being able to point at something [the theoretical framework] as a way of labeling the phenomena we were observing. Using the framework bolstered our confidence. We were using a tool our community of practice encouraged and endorsed, and the tool made me feel thorough, empirical, objective, more 'scientific'.

DISCUSSION

The coding of the summative reflections (shown in Table I) indicates the three most reported areas of difficulty still perceived by the new PhD students were using a theoretical framework, the issue of qualitative research being a "real approach" to research and transferability of results. This was similar to the group of engineering faculty observed by Borrego in the RREE project. A common theme that was repeated throughout the participants' explanation of strategies they used to deal with the conceptual difficulties they faced while learning about engineering education research in the course was the ability to use their prior engineering knowledge or experiences. Regardless of the difficulty, the students would speak to

another educational experience or aspect of working as an engineer that could relate to the current difficulty.

I. Using a theoretical framework

The participants who discussed theoretical framework being an area they had to wrestle with collectively questioned why this was something they need to use. However, in their reflection document as some the participants described the kinds of “scientific” work they were used to doing it was found that they actually aligned their work with a framework except it was not called a framework at the time. This indicates that the students had a misconception of what the term theoretical framework meant. In discussing strategies used to deal with this difficulty, one of the co-authors described using a theoretical framework in a trial-and-error approach. Not having any idea what a theoretical framework was or how to use it when faced with a new research project in engineering education they “just chose a framework and hoped it would work”. Borrego writes about a similar analogy was made by the facilitators of the RREE workshop when they emphasize that there is no one *correct* theoretical framework just as there is no one correct answer when attempting to solve an engineering design problem. Rather, it is a case of choosing the framework that is most *appropriate*. Another co-author discussed having done technical work in which they did not have to be explicit about a framework “likened it to a having a protocol that governed how a task was to be completed”.

II. On qualitative research approach being “real” research

The participants who attended the RREE workshop expressed a preference for research approaches that were absent of ambiguity and that lessened the possibility of being misconstrued. However, as the RREE participants refined their research questions they reported appreciating the level of depth qualitative approaches provided them. Initially, both the RREE participants and the PhD students in our study found the notion of small cases or conducting research dependent on human interpretation was a culture shock. The PhD students discussed not trusting a qualitative approach primarily on the grounds that perception about an event can change as people reflect or time passes. One student explicitly discussed being “suspicious” of any method that does not allow for the same results to be achieved when the study is replicated by a different researcher. However as they reflected on what benefits a qualitative approach provides, their level of wariness slowly subsided. One co-author described the process of their conversion as the point in time when they really got to read about a research project being conducted using qualitative research methods and came to the realization that the research questions being posed could not have been answered using a purely quantitative approach. Numbers would not provide the data they needed.

III. Transferability of results – framing the research question

Participants spoke about the challenge of wording research questions “just right” in order to uncover what it was they were hoping to find. All the students who raised this concern described this the essence of the difficulty as knowing when they had a question that captured the *purpose* of the research. This difficulty was even further compounded by the fact that they had to be able to answer the question empirically. From questions being too broad to becoming too narrow, these participants discussed being challenged by advisors or professors mechanism whereby they were finally able to come up “acceptable” research questions.

CONCLUSIONS

Based on the research question that guided this study the following important conclusions can be drawn:

Conceptual difficulties identified by Borrego are still an issue for new engineering education PhD students

Ten years after Borrego collected her data, Engineering Education departments are an established reality, and students are able to receive PhDs in Engineering Education. However, based on the results of our study the conceptual difficulties highlighted by Borrego are still prevalent in the new generation of engineering education researchers. This finding has significant implications for the design of current and emerging engineering education programs in that introductory courses for newly admitted students should provide materials necessary for a successful transition to the discipline. Research projects new PhD students engage in their first year of study should also be a good representation of the type of the research that characterizes this field.

Students linked their prior knowledge and experiences to the new information being learned

Interestingly, while it was students’ prior knowledge and experiences that lead to conceptual difficulties in their first exposure to engineering education research, our participants used their previous engineering and scientific knowledge where applicable to make sense of the new material they were learning. The participants spoke of the different analogies they used or how they compared the current information to other educational or social interest in a manner that helped them to understand the new concepts. Documenting and sharing these analogies is the next stage of our work. These results can be shared with others who want to enter EER community to help make sense of this new way of looking at things.

ACKNOWLEDGMENT

Thank you to the Engineering Education PhD students enrolled in the course “Research in Engineering Education”

in Fall 2014 who were so thoughtful in their reflections about their learning.

Apprenticeship of Observation

Implications for the adoption of evidence-based instructional practices

Kari L. Jordan, James J. Pembridge, Heidi M. Steinhauer, Timothy Wilson, Douglas Holton

College of Engineering
Embry-Riddle Aeronautical University
Daytona Beach, FL

Abstract— This work explores the relationship between faculty descriptions of how they currently teach and how they were taught in similar courses during their undergraduate experience in order to understand how faculty choose to adopt evidence-based instructional practices in light of signature pedagogies in engineering education. Twenty-one one-on-one structured interviews were conducted with faculty members in a College of Engineering who teach courses in the first two years of the engineering curriculum. Interviews were analyzed using thematic and axial coding approaches to understand faculty's educational experiences as a student and how this relates to how they currently teach. Findings indicate that the current inclusion of evidence-based practices in undergraduate engineering courses positively relates to the adoption and persistence of usage by engineering educators. By this we can begin to understand the gestalt shifts that lead faculty away from signature pedagogies and towards more progressive and research-based approaches.

Keywords— *Signature pedagogies; faculty beliefs; evidence-based instructional practices*

I. INTRODUCTION

Studies have drawn contrast between teacher-centered and content oriented to student-centered and learning-oriented [1] instructional techniques. Entwistle et al. [1] note intermediate categories ultimately describing developmental trends in thinking and conceptions of teaching (Figure 1). This model identifies that faculty epistemological levels align with a focus on instructional techniques and the focus of their course. A dualistic instructor imparts knowledge to his/her students through teacher-centered and content-oriented instructional methods. As his/her epistemological beliefs advance to a more relativist approach, the instruction becomes more student centered. Regarding this progression, Entwistle et al. [1] assert, “more sophisticated conceptions emerge out of the earlier ones, while retaining certain elements of them.”

For engineering faculty, earlier conceptions such as how they were taught have the potential to influence not only how they teach, but whether they stick to using traditional teaching practices (ex. lecture) or adopt evidence-based instructional practices (EBIPs). Thus, this work seeks to explore the relationship between faculty descriptions of how they currently teach and how they were taught in their fundamental engineering courses. Additionally, this work seeks to

understand how faculty choose to adopt evidence-based instructional practices in light of signature pedagogies in engineering education. Thus, this study explores the following research questions:

1) *How do faculty describe their current general pedagogical practices in comparison to their own learning experience?*

2) *What evidence-based instructional practices occur in faculty teaching that have carried over from their own learning experiences?*

II. SIGNATURE PEDAGOGIES

Throughout the training of those who participate in professional practice, signature pedagogies can be identified across the disciplines from science and engineering to law. Signature pedagogies inform students on how to think, perform, and act and can be recognized as the first thing that comes to mind when thinking about professional preparation in a field [2]. The signature pedagogies of engineering have been recognized to change depending on the context of the course; whether it is an engineering analysis course or a design studio reflects the signature pedagogy. As summarized by Shulman [2], signature pedagogies represent a history and pervasiveness of practice that defines the role of knowledge in a field:

“Signature pedagogies are important precisely because they are pervasive. They implicitly define what counts as knowledge in a field and how things become known. They define how knowledge is analyzed, criticized, accepted, or discarded. They define the functions of expertise in a field, the locus of authority, and the privileges of rank and standing. As we have seen, these pedagogies even determine the architectural design of educational institutions, which in turn serves to perpetuate these approaches.”

Many faculty who teach in higher education rarely receive direct training to teach, instead they rely on an “apprenticeship of observation” where they most often model their own teaching from their prior experiences as a student [2, 3]. In order for faculty to adopt the practices they observed as a student they must be attentive to the process of the practices, be able to repeat the practice, and be motivated to repeat it [4, 5].

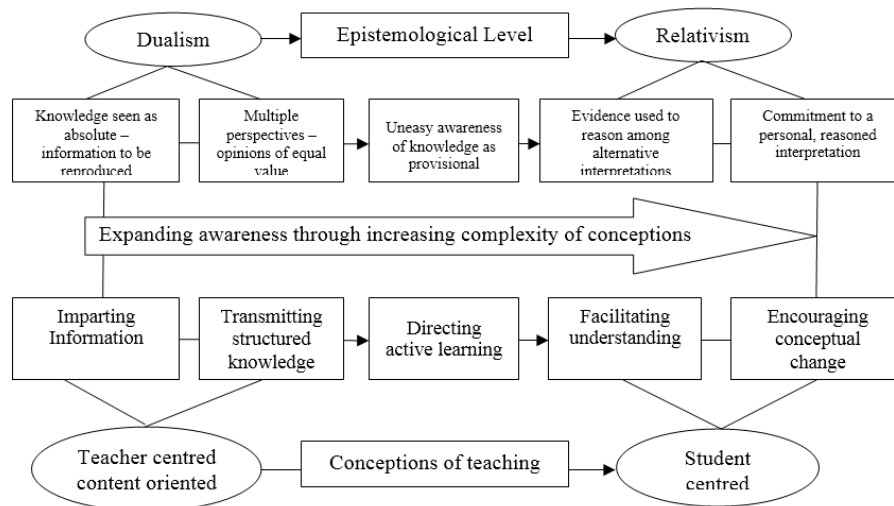

Fig. 1. Developmental trends in thinking and conceptions of teaching [1]

III. BELIF STRUCTURES AND PEDAGOGICAL PRACTICE

In part, signature pedagogies persist because they simplify the practice of professional education. As faculty learn an instructional practice and internalize it, they become more comfortable with its implementation [2]. These practices then begin to imbed themselves into the belief structures of the faculty. Pajares [6] notes that in studies examining teacher beliefs, the construct is not normally clearly defined. He uses the definition provided by Rokeach [3] where he defines beliefs as any simple proposition, conscious or unconscious, inferred from what a person says or does, capable of being proceeded by the phrase ‘I believe that...’. Additionally Rokeach [3] noted that all beliefs have cognitive, affective, and behavioral components. Attitudes are the holistic organization of beliefs around an object or situation. Values are the evaluative, comparative, and judgmental functions of beliefs. Together beliefs, values and attitudes form a person’s belief system [6]. When applied to teaching, these belief structures influence the perceptions faculty have regarding their students, the instructional practice, and how it should be carried out. These beliefs are first structured from their experiences as a student, and later as an instructor based on their in-class experiences, feedback, and interactions with other instructors [5].

Nespor [7] suggested that the structure of beliefs are comprised of four primary features that differentiate beliefs from knowledge. The first is that beliefs contain existential presumptions. One’s belief system contains assumptions regarding the existence or non-existence of an entity like the teacher’s perception of the student’s ability and maturity. These presumptions represent deeply personal beliefs of the physical and social reality and are very difficult to change [6]. The second feature pertains to the alternativity of beliefs. This refers to the conceptualization of an ideal situation as a result of concerns and the recognition of short comings in current realities [7]. The third feature is the role of affective and evaluative qualities. These qualities involve subjective evaluations and feelings that can be distinguished from cognition. This feature differentiates between the knowledge

of a domain and the feelings toward a domain and can directly impact the effort a teacher gives toward teaching a particular subject [7]. The final feature of belief systems is that they are composed of memories and experiences stored in the episodic memory, whereas knowledge is stored semantically. This type of storage provides a quick recall of rich descriptions that can influence faculty practices [7].

Belief structures are primarily characterized by their non-consensuality and unboundedness [7]. The non-consensuality of beliefs refers to the fact that belief systems are debatable, generally inflexible, and unchanging. This makes altering beliefs, and therefore signature pedagogies, a difficult task, requiring a restructuring of the belief system for it to occur, also referred to as a gestalt shift. The unboundedness of belief systems indicates that they are highly variable allowing their inferences to be applied in a wide variety of phenomena and settings [7]. Contrary to belief systems, knowledge systems are capable of being altered given adequate reasoning and their applications are contextually bounded to appropriate applications. Faculty beliefs and the use of their belief structures aids in the development of engineering pedagogical practices by providing a means to deal with the ill-defined nature of the classroom and providing a source of pedagogical practice to pull from that can be quickly accessed.

Within the academic context and environment that faculty function in, faculty frequently encounter ill-defined and deeply entangled problems [7]. By nature of the environment of teaching, faculty have interpersonal contacts and must be able to function on impulse rather than reflection [6]. The use of knowledge to solve these complex and varied problems requires a clear definition of the problem as well as the identification of a multitude of courses of action [7]. Due to the nature of the entangled domain, faculty are ill-equipped to deal with problems through cognitive and information processing strategies alone as they do not work [6]. Instead faculty are required to rely on their belief structures to solve these problems.

Nespor [7] provides a description of how teachers can use their belief structures to deal with ill-defined problems. As belief structures are unbounded, faculty can utilize the quick retrieval of detailed memories and past experiences that have been episodically stored, and apply them to a wide variety of scenarios. These solutions are also relatively immune to contradiction as belief structures are non-consensual and involve the alternativity of the situation being addressed. The use of existential presumptions further stabilizes the problem as it imparts absolute and concrete entities into the ill-defined problem.

The resources available to faculty in their episodic storage consist of memories and experiences throughout their lives. One of the most common sources of these experiences resides in the teachers own experience as a student [8]. As a large portion of the teachers' youth is spent in the classroom observing teachers, they begin to develop beliefs about the practice of teaching. Pajares [6] acknowledges that early experiences, like those in elementary education, are very influential, and beliefs because of these types of experiences are difficult to change. The limitation of this perspective is that students only observe the action of the faculty from the student perspective, and therefore what they learn about teaching is intuitive rather than empirical; it does not represent all of the aspects of teaching. Despite this, data from Lortie's study [8] indicates that faculty realize their current practices reflect those of their teachers. Stice et al. [9] discuss the future of engineering education and the qualification of future teachers, noting that future teachers may not know much about teaching, but will "teach the way they were taught", thus supporting the findings presented by Lortie [8].

If this model persists, then the current engineering pedagogical practices that involve more traditional and dualistic perspectives will persist, limiting the opportunity for the adoption of evidence-based instructional practices. By understanding which evidence-based instructional practices carry over from faculty's own education, further emphasis can be added to those practices that will require a substantial gestalt shift to alter faculty belief structures regarding their implementation.

IV. METHODOLOGY

This study utilizes a qualitative exploratory design. The study explores the relationship between how faculty describe the way they teach and how they were taught in similar undergraduate engineering course. This study will address which evidence-based instructional practices carry over as signature pedagogies and why faculty choose to adopt new evidence-based instructional practices in lieu of signature pedagogies in engineering education.

A. Participants

This study involved twenty-one faculty members who teach core courses within the first two years at a medium-sized, private, primarily undergraduate institution. Participants included both tenure and non-tenure track faculty with varying teaching experiences and course loads (Table I).

Participants had an average of 8 years teaching experience. Of the twenty-one participants, six faculty members taught design courses, eight taught lab courses with major class projects, and seven taught courses involving fundamental engineering theory (ex. Statics).

TABLE I. PROFILES OF PARTICIPATING FACULTY

Academic Rank	Instructor	1
	Adjunct Professor	6
	Visiting Assistant Professor	1
	Assistant Professor	5
	Associate Professor	7
	Professor	1
Sex	Male	12
	Female	9
Course Category	Design	6
	Theory	7
	Lab	8

B. Data Collection

Each of the twenty-one one-on-one interviews were recorded and transcribed. Interviews lasted an average of 62 minutes. The researchers modified Cutler's [10] interview protocol for her assessment of the use of EBIPs (coined *Research-Based Instructional Strategies*, or RBIS, in her work). During each interview faculty members were asked to walk the interviewer through a typical class session in their course, describe the purpose of the course in their own words, and describe what the course was like if they took it during their undergraduate program:

- 1) *What course or courses are you currently teaching?*
 - a) *How many sections?*
 - b) *How long have you been teaching those courses?*
- 2) *Could you please walk me through a typical class session in your course? What does it look like?*
 - a) *In your own words, what is the purpose of the course?*
 - b) *Did you take a course like this in your undergraduate program?*
 - c) *What was the course like when you took it?*

In addition to the questions above, participants completed a survey regarding their use of EBIPs outlined in Table II [14]. Participants were asked to provide a rich description of their implementation of the EBIP if they indicated they currently used it, how they learned about the practice, and why they decided to use that particular strategy. This line of questioning was used to determine whether their decision to use a practice was based on their past learning experience. Interviews were used as the primary source of evidence as the researchers could include additional probing questions that would prompt the participant to provide critical incident descriptions in order to validate the implementation of the EBIP. While video recordings of class room practices were

collected for each of the participants, these observations did not ensure that a currently implemented EBIP would be used that day and provided little insight into the belief structures of the participants in comparison to the in-depth interviews.

TABLE II. EVIDENCE-BASED INSTRUCTIONAL PRACTICES AND DESCRIPTIONS [14]

EBIP	DESCRIPTION
Active Learning	A very general term describing anything course-related that all students in a class session are called upon to do other than simply watching, listening, and taking notes
Collaborative/ Cooperative Learning	Asking students to work together in small groups towards a common goal; A structured form of group work where students pursue common goals while being assessed alone
Think-Pair-Share	Posing a problem or question, having students work on it individually for a short time and then forming pairs and reconciling their solutions. After that, calling on students to share their responses
Inquiry Learning	Introducing a lesson by presenting students with questions, problems, or a set of observations and using these to drive the desired learning
Just-in-Time Teaching	Asking students to individually complete homework assignments a few hours before class, reading through their answers before class, and adjusting the lessons accordingly
Problem-Based Learning	Acting primarily as a facilitator and placing students in self-directed teams to solve open-ended problems that require significant learning of new course material
Concept Tests/Peer Instruction	Asking multiple-choice conceptual questions with distracters (incorrect responses) that reflect common student misconceptions. / A specific way of using Concept Tests in which the instructor poses the conceptual question in class and then shares the distribution of responses with the class. Students form pairs, discuss their answers and vote again.

C. Data Analysis

Interviews were transcribed by an undergraduate research assistant and professional transcription service. The interviews were then coded by the lead researcher, first comparing the participants' description of their course to their description of how they were taught. These learning experiences included any experience a faculty member had as an undergraduate and in graduate school. The described instructional practices were categorized for pedagogical practices through thematic analysis to provide generalized descriptions to compare practices.

The analysis was then examined in-depth for descriptions to categorize their learning experience as an evidence-based instructional practice through the a priori codes identified in Table II. These classifications were then compared to their descriptions of their own teaching practices; providing a point-to-point comparison of the practice. The codes were validated for confirmability through negotiated agreement of two interviews [13].

V. FINDINGS

Each of the participants indicated that they utilized several EBIPs they experienced in previous learning experiences, and secondarily from other sources such as workshops and other professional development opportunities. These findings emphasize that as a result of their prior experiences as a student, faculty develop belief structures that relate to their use of specific pedagogical practices. These belief structures are developed as a result of favorable educational experiences that translate to their own practice or through modifications to practice and improve the experience for their students. Overall student-centered approaches are identified as current signature pedagogies among participants.

A. Student-Centered Learning as Engineering Signature Pedagogy

Faculty members described the courses they currently teach, whether they took a course like it in their undergraduate program, and how the course they teach compares to when they took it as an undergraduate student. Comparing faculty pedagogical practices with their own learning experiences, we find that teaching has moved from traditional teacher-centered lecture style (how they learned), to faculty serving as more of a facilitator, implementing EBIPs (how they teach). Faculty comparisons parallel the stages in the evolution of teaching styles (Figure 2) [14].

Fig. 2. Stages in the evolution of teaching styles. [14]

Stage 1 consists of the course instructor lecturing from the front of class, serving as an authority figure solely delivering material, with minimal instructor-student engagement, as noted in the following interview excerpts:

“He sat at the front of class. Didn’t stand, didn’t walk around, wasn’t engaged, [and] didn’t really give examples. Just kind of went through what the steps of the design process were and then he gave us projects to work it out on our own so it was not engaging at all. I was very turned off by that class.”

“Ok so at [institution], 500 students in a lecture hall, [and] one professor lecturing in the front. The chances of getting a question in or even wanting to ask a question, much lower than if we were to have, say 100 students in a large lecture hall. Also the room, being so much larger, you felt such a far distance from the class. So it’s less personality

connection. In fact the professor, we almost never spoke with him outside of lecture.”

In each of these situations, faculty developed belief structures regarding the level of interaction with faculty and engagement in the course. In these instances these faculty participants perceived their experience negatively; choosing to alter their practice in order align their practice with their own beliefs.

In stage 2 the instructor serves as a demonstrator or coach, incorporating several lecture formats including demonstrations and multimedia presentations. One faculty member in the sample described learning in this way as seen in the following interview excerpts:

“Yeah, it was the same thing: activities, labs, projects. But we were always in teams of two.”

As a result, this faculty member teaches using a similar approach since their belief structure aligned with the positive outcomes of the approach:

“They get the code sheet. Usually they read the first two lines and try to code so you just stop them and tell them to finish reading and then they start coding again and then they make mistakes and we stop them and they fix it and then they get stuck and they raise their hand and then the teaching assistant or me just walks and tries to make them find a solution to the code, again.”

Stage 3 describes how several of the participants in this study currently teach, and how this differs in comparison to how were taught. The model is a learner-centered teaching style where the instructor serves as a facilitator promoting self-regulated learning, as evident in the following interview excerpt:

“I think the whole course is structured around this collaborative learning. We have three projects in which students have to work towards [a] common goal. I had groups of four or five students. Pretty much the entire class is collaborative learning essentially. The students are given the assignment and they’re asked to decide who’s going to be responsible for parts of the project. I basically split them into team leaders, into let’s say the project manager, the engineer, and basically the timekeeper. They have roles in the teams so everybody [is] supposed to have a specific task and we come together as a group to reach a successful final design. As a teacher basically [I’m] making sure that they’re on the right path, the issues they’re having are resolved and assisting them in any way I can.”

Throughout the interviews a common theme emerged: participants self-identified that the signature pedagogies for engineering were focused on student-centered approaches or at least should be. Through their reflection of their own learning experiences, faculty developed beliefs regarding instruction and the necessity for student-centered approaches.

While the findings presented here are associated with faculty descriptions of their own learning experiences, it is important to note that the development of the faculty belief structures were not solely developed as a student. Student-centered instructional approaches were either experienced in one of the courses they took as a student that they chose to adopt because of a desire to increase student engagement, through collaboration with other faculty, and traditional professional development activities. These experiences align with those of Oleson and Hora [5] indicating that a faculty’s prior learning is not the only source of educational training that promotes the usage of certain pedagogical practices. Further, there are broader experiences aligned with their belief structures that support their adoption of pedagogical techniques.

B. Evidence-based instructional practices as signature pedagogies

When examining which evidence-based instructional practices carry over from their learning, there was a common theme of active learning, problem/project-based learning, and inquiry learning. While faculty were not aware of the terminology, which has been recognized in prior studies [9], their descriptions of their own learning experiences identified these EBIPs.

However, in their descriptions of the course they were currently teaching as compared to what it was like when they took it, there was little indication of carry over. Instead much of the carry over about specific EBIPs came from other learning experiences. During the examination of their usage of these practices, faculty were asked “where did you learn about this practice”. The source was recognized from a general perspective of their own educational experience that they could not specifically identify. Instead, it manifested as a norm or belief about the course. For example common responses to this question included:

“I guess my own experiences as a student.”

“I just copied my way of learning.”

“I guess that’s how I learn things, so I figured that’s the way to teach it.”

These statements provide an insight into a belief structure that was developed by the faculty participant when they were a student.

Active learning was the most common EBIP occurring in faculty teaching that carried over from faculty members’

own learning experience. This practice was described as being used where faculty taught theory-based courses. Common signature pedagogies in this context included question-answer periods, discussions, and guided problem solving, as evidenced in the following interview excerpts:

“I would present the students with a topic and have them come out with the answers, and then kind of guide them to an answer.”

“The primary mechanism for me is through discussion.”

“I actually have the students try to solve problems in class. I have them present it up on the board, as they're learning it as they go.”

In design courses, active learning is heavily dependent upon group work, as described in the following interview excerpts:

“Sometimes they have to go out of the way and actually go on the internet and do research. I have them going through groups. The way I implement it is I have them in groups. I have them talk amongst themselves—have them go outside. Sometimes I'll set a class in the library, et cetera and work on it and they come back. Answering their questions, anything that they have, some issues with the problem and stuff.”

“My next activity is [an] impromptu vehicle building activity, so I'm going to give them some stuff and ask them to build something, depending on constraints, cost constraints and item constraints.”

Teamwork and hands-on activities were the primary pedagogies used in lab courses. Faculty described their usage of active learning as having students help each other and “learn by doing” in the following interview excerpts:

“I give them problems and then explain to them, so that they have a moment to think to themselves, and then work with other team members. If they've already completed any [software task], they help their other friends, and so they're actively telling others—I mean it's one thing to know material, but teaching others kind of [reinforces] what you know, so I encourage that as well.

“It could be even, just anything with learning by doing— just going through the tutorial and then trying to apply the tutorial-the lessons from the tutorial to a less scaffolded assignment.

“When the information is presented in different ways and different terminologies are used I will deliberately give them tutorials from different style textbooks and then they are allowed to work with each other.”

Faculty who taught design and lab courses also included aspects of problem-based learning and inquiry learning as a result of their previous learning experience. These courses involved computer programming and semester long design projects. Signature pedagogies can be summarized as facilitating group learning and project-based learning, as noted in the following two interview excerpts from faculty who taught design and lab courses:

Design course:

“I gave them seven to eight different case studies, divided the class into small groups and asked them to look at the case study, brainstorm a solution, look at the NSPE code of ethics, see which code of ethics is violated, which code of ethics they stuck to and what they should have done ideally in that situation, and then I asked them to present their solution to the class, and then the classmates asked them questions.”

Lab course:

“They need to pick up an existing product on the market and to look for the sustainable design solution so they are not just designing an existing product. They need to look for any particular weaknesses of the product and see how to improve it. And so they need to make sure they define their problem and they tell me what problem they have and how they are going to seek the solution to stop the problem and they need to do the cost analysis to demonstrate their design (if it's functional and applicable). And they need to show me the final design so they need to first give me a model based on the current existing product and they also need to show me an improved model based on their problem statement.”

Although several faculty members mentioned using think-pair-share, concept tests, and just-in-time teaching, it was not as a result of these practices carrying over from their previous learning experiences. Instead they were associated with other experiences that included professional development activities, collaborating and observing other faculty, and industry experiences. In many instances, the faculty interviewed in this study had never heard of these practices (Table III).

TABLE III. SOURCES OF ADOPTION OF EVIDENCE-BASED INSTRUCTIONAL PRACTICES

<i>EBIP</i>	<i>Prior Learning</i>	<i>Other Source</i>	<i>Not Adopted</i>
Active Learning	Design Theory Lab		
Collaborative/ Cooperative Learning		Lab Design	Theory
Think-Pair-Share		Lab	Theory Design
Inquiry Learning	Lab Design		Theory
Just-in-Time Teaching		Design	Theory Lab
Problem-Based Learning	Design Lab		Theory
Concept Tests/Peer Instruction		Lab	Design Theory

IV. CONCLUSIONS & IMPLICATIONS

Faculty belief structures have a strong impact on the persistence of educational practice and the ultimate recognition as a signature pedagogy in the field. These practices are initially experienced by faculty through their own experiences as a student, but persist due to their perception and implementation of the practice. Despite a focus on lack of implementation of evidence-based instructional practices utilized in engineering education, there appears to be some movement towards a focus on student-centered teaching across several engineering education course contexts.

While it has been identified by several authors that past experiences as a student are not the only source of inspiration to implement an evidence-based instructional practice, it does represent a first experience that can have a lasting belief in a faculty member's own practice. As more students have positive experiences with these implementations and faculty experience success implementing them, they will have the potential to redefine signature pedagogies in engineering.

Abstract—Work place engineering problems are recognized as being complex and ambiguous. However, most of the problems students are asked to solve during their degree programs are classroom problems. Most studies of ambiguity in problem solving have defined ambiguity as a characteristic of the problems. We are interested in understanding how students interpret engineering problems, either creating or resolving ambiguity during their problem solving process. The research question that guides this study is: How is ambiguity manifested by engineering students as they solve problems? This study is part of a larger project examining engineering students' engineering problem solving across different types of engineering problems. Twenty materials engineering students were asked to solve four materials engineering problems during a think-aloud session. For the analysis, points of ambiguity during the problem-solving process were identified as periods in which the students specifically verbalized uncertainty. The points of ambiguity in the transcript were then analyzed through script analysis. More specifically textual instances of ambiguity were linked with three main periods and situational categories: a) the situation that caused the ambiguity, 2) what happened during the point of ambiguity, and 3) the reaction of the student after reaching the point of ambiguity. Results indicated that students experienced points of ambiguity in both closed- and open-ended problems. Several motifs were common to both types of problems, including confusion over how to use given values, not having necessary content knowledge, lack of self-confidence, and difficulty conceptualizing the problem. The lack of constraints inherent in the open-ended problems also caused additional ambiguity among some students. Our findings show that ambiguity can take many forms and is not just a function of the problem structure. Students reach points of ambiguity (e.g., points where they do not know what to do next), due to many factors. Some of these factors represent aspects of their academic and epistemological development. Our analysis to date suggests that students need more comprehensive training and practice to be prepared in facing problems that reflect the work in engineering practice. We are currently examining the data further to identify patterns in their response to ambiguity, which may help in developing pedagogical strategies and tools to support students' ability to successfully solve engineering problems

Keywords—*ambiguity; qualitative analysis; problem solving*

I. INTRODUCTION

Engineers have been seen as problem solvers, yet the kind of problems students solve in classroom environments are different than what they will face in their professional careers [1,2]. Most classroom exercises involve application of content knowledge in well-defined situations to obtain a single correct solution. Walther and Radcliffe argue that engineering graduates may not have the competencies required for their practice, even though program outcomes are designed to meet the needs of industry [3]. Along similar lines, Atman et al believe engineering education falls short of the goal of adequately preparing students for professional practice [4]. Where the traditionally taught classes permit the efficient delivery of basic content knowledge, they fail to provide an opportunity for the synthesis of knowledge, development of skills, and possibility of finding innovative solutions to engineering problems [8].

Previous research has demonstrated that to promote flexible thinking and to furnish students with skills that will enhance their chance of being successful in their workplace, educational institutions should introduce students to complex, ill-structured and open-ended problems [5-7]. Ill-defined problems are problems with many possible answers [9]. The difficulty of these problems lies in evaluating multiple viable solutions, and choosing the best one. Ill-defined problems require more information to understand the problem than what is provided, have multiple solution paths, may change as new information is acquired, often elicit additional questions, are open-ended, and are complex enough to require collaboration and thinking beyond recall.

In past studies, the difficulty of a problem has always been analyzed as an external factor [10]. According to Schrader most empirical research has considered the degree of ambiguity as a characteristic of the problem independent of the problem solving process (i.e. exogenous to problem solving) [11]. However, the level of ambiguity in the problem that is

acknowledged by the problem-solver is often made implicitly, based on the problem solver's mental models that are brought to bear on the problem. An individual's mental models are derived from a host of factors such as their educational background and experiences. Ambiguity is defined as the decision maker's lack of understanding of the critical parameters or variables in a given problem, and/or the nature of the relationship between variables.

The level of ambiguity endogenous to problem solving is positively correlated with the level of experience. Novices strictly accept the rules until they progressively reach an expert level through experience; proficiency at a subject matter is arrived only after substantial reflective practice. In our initial study of problem solving we witnessed the consequences of being a novice [12]. Students with little or no experience with the problem type and a lack of content knowledge struggled to make decisions to move forward during problem solving. Thus, we undertook this study to answer the research question: How is ambiguity manifested by engineering students as they solve problems? This Work in Progress paper provides some preliminary results of our study.

II. METHODOLOGY

The qualitative study presented in this WIP paper is part of a larger study aiming to understand how students interpret problems, creating ambiguity or unambiguity as part of the problem solving process.

Twenty undergraduate materials science students from a large research university in the southeastern region of the United States participated in the study. Although participation was voluntary, students were required to be materials science students and seniors. The reasoning behind the criteria was to equalize the domain knowledge and level of experience in the subject area. We also wanted to select advanced students in order to examine how they dealt with ambiguity at the end of their degree program.

Data collection included video-recordings of problem-solving through the think aloud method. The think aloud method allows the researchers to gain insight into mental operations and observe the processes underlying the performance of a task in addition to the final product [13]. During the think-aloud sessions, participants were provided with a problem statement on a single page of paper, blank paper to work out their solution, a calculator, and a reference textbook [14].

Students were asked to solve four problems during the think aloud sessions. The problems varied in their complexity and whether they were open- or closed- ended. For this study, we analyzed think aloud data from the more complex closed- and open- ended problems. The two problems are presented in the Appendix.

During think-aloud sessions students were asked to verbalize their thinking process no matter how irrelevant it seemed. The role of one of the researchers was to prompt participants during extended periods of silence. Some of the prompts used were: "What are you thinking now?", "How are you deciding what to do now?". Prompts were never used to provide information to students.

Recordings of the think aloud sessions were transcribed verbatim and transcripts were treated as a data set for the analysis process. Fonteyn et al argue that script analysis allows for the investigation of the types of information that participants attend to during problem solving in terms of their method of structuring the problem, justification of the decisions they make, and their problem-solving plan [15]. Analysis continued with identifying points of ambiguity as periods where students were unsure of how to proceed. Those instances in the transcript were categorized based on the situation that caused the ambiguity, what happened during the point of ambiguity, and the reaction of the student to resolve the ambiguity.

To ensure the distinction between filler words and words that represent ambiguity, we watched the videos a second time and incorporated factors such as the participants' body language and the amount of time they took so that we could differentiate ambiguity words from filler words. For example, the word "hmm..." could be used as either a filler word or as a word indicating ambiguity, depending on the situation.

III. PRELIMINARY FINDINGS

In this study we analyzed three instances of when students dealt with ambiguity: a) the situation that caused the ambiguity, b) what happened during the point of ambiguity, and c) how the student responded to that ambiguity. As an example, Table 1 shows a sample of part of the coding for participant 39.

TABLE I. EXAMPLE OF PART OF THE CODING FOR PARTICIPANT 39.

Problem Type	Participant 39		
	<i>Situation that causes ambiguity</i>	<i>During the point of ambiguity</i>	<i>Reaction of the student after point of ambiguity</i>
Closed-ended Many decisions	Trying to manipulate equations	Cannot solve the problem due to missing initial length	Accessing book for Poisson's ratio and connecting it to strain in different dimensions
Open ended, Many decisions	Revisiting the problem	Failing to solve the problem due to missing information	Making assumptions to move forward

The coded text for the closed-ended many decision problem for this student is:

...Um, I'm just trying to still manipulate, you have this set of 3 values that are equal to each other. You know that the stress is equal to the force over area which is also equal to the modulus times the um, change in length over the original length. (Looking at paper) So what's throwing me off is which values, like before and after values, to plug in for the dimensions.

The solution to this problem does not require knowledge of the length, as the only relevant quantity for the length of the cylinder is the strain. However, because this student knows that strain is defined as change in length over original length, she believes that the initial length is needed as part of the calculation. This point of ambiguity is an example of the student not

understanding the relationship between variables. Eventually the ambiguity is resolved when she accesses the textbook and finds the definition of Poisson's ratio, which then allows her to move forward without knowing the initial length.

The coded text for the closed-ended many decision problem for this student is:

"...I'm just trying to see if I'm missing something in terms of um, maybe that the, the cross-section element is also, it's a, a cube so the 12 feet would apply not only for the length but for the cross-section value, too"

Here again the student is confused over missing information. In this case the problem is open-ended in that the cross-sectional area is not defined in the problem; rather she must select a cross-sectional area on her own. In this case she makes an assumption about the cross-sectional area, which is the correct approach, and is able to continue.

The examples above are for the motif *failing to make connections between different variables and/or between values and variables*, which is one of the primary reasons students faced ambiguity. Fig. 1 shows an example of the categories for this motif. In this figure we can see the patterns of responses that led to ambiguity. For example, three different situations led to the category "cannot solve problem due to missing initial length". Participants demonstrated many different approaches to the problem, some resulting in ambiguity and some resulting in unambiguity. Also we have seen cases where the same situation led to a different ambiguity category, and different situations that led to the same ambiguity category. Examples of these cases are shown in Fig. 2, which is for the motif *misconceptualization of the problem*.

At this preliminary stage of analysis we have identified four motifs that represent major areas of ambiguity: *unclear approach to problem solving*; *misconceptualization of the problem*; *uncertainty over what is being asked*; and *failing to make connections between different variables and/or between values and variables*.

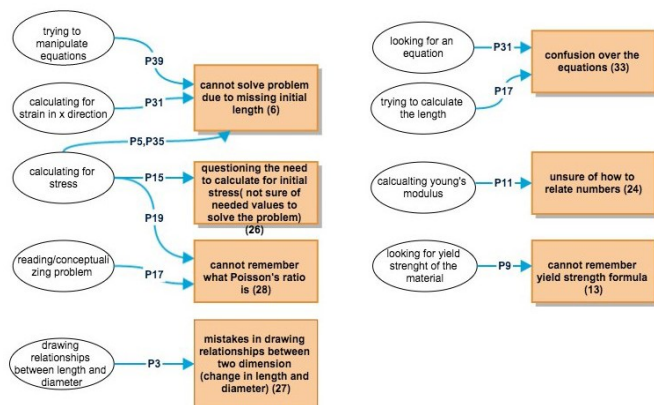

Fig. 1. Codes and categories in the *failing to make connections between different variables and/or between values and variables* motif. White circles are the initial codes and orange boxes are the resulting categories. Px indicates the participant number that had that particular coded text. Numbers in parentheses are a unique identifier associated with each category.

IV. CONCLUSIONS

Our preliminary results to date confirm Shrader et al's assertion that ambiguity is not only a characteristic of a particular problem, but also can be imposed by the problem-solver. This is most clearly seen in the closed-ended problem, which was designed explicitly to avoid ambiguity. An expert could solve it easily in a step-by-step fashion without any need to make assumptions or decide between alternatives. However, the students in our study found many points of ambiguity in this

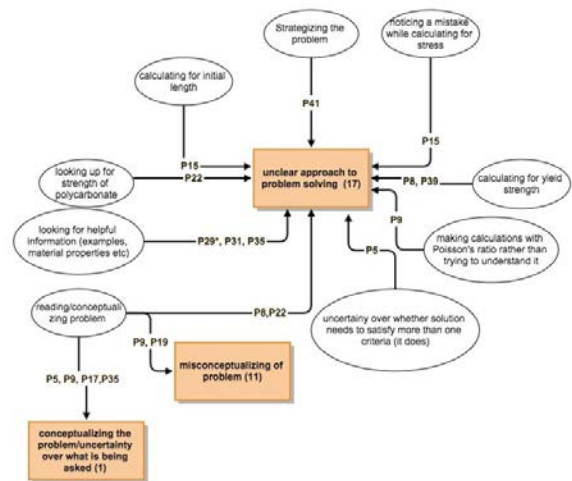

Fig. 2. Examples of different situations leading to the same ambiguity and the same situation leading to different ambiguity for the *misconceptualization of the problem* motif. White circles are the initial codes and orange boxes are the resulting categories. Px indicates the participant number that had that particular coded text. Numbers in parentheses are a unique identifier associated with each category.

problem, as illustrated in Table 1. The open-ended problem also elicited points of ambiguity. In this case, the point of ambiguity shown in Table 1 was a deliberately designed ambiguity, and participant 39 handled it in much the same way we would expect an expert to. However, there were also places in the problem-solving process where students experienced or even created imposed ambiguity where ambiguity was not intended.

A number of factors may be responsible for the ambiguity seen in this study. Lack of content knowledge is clearly one factor. Students who do not have the needed content knowledge will reach a point where they do not know how to proceed. The ambiguity for the closed-ended problem shown in Table 1 is at least in part a result of lack of content knowledge. Once the student was reminded of the definition of Poisson's ratio and how it could be used to calculate strain in directions normal to the applied stress she was able to continue.

Another factor causing ambiguity may be the students' epistemic beliefs. In our previous work [12] we described the problem-solving processes used by students and related those processes to the stages described in the Reflective Judgement Model [16]. In this model, the stages of epistemic beliefs are as follows:

- Pre-reflective: All knowledge is certain and comes from authority.
- Quasi-reflective: Knowledge is uncertain and there is no definitive way to select between competing knowledge claims.
- Reflective: Knowledge is uncertain, but different knowledge claims can be weighed against each other and an appropriate choice made.

We believe that the differences in ambiguity seen in this study may in part reflect different stages of epistemic beliefs. For example, some students had difficulty choosing a material for the open-ended problem. These students could not identify a justification for choosing one material over another, believing that any of several options were equally appropriate. This type of ambiguity is suggestive of a quasi-reflective epistemic belief. A reflective student, faced with the same situation, would be able to justify a choice. In our future work we intend to combine think aloud protocols with additional measures of epistemic beliefs.

Our results, while preliminary, in combination with our previous work have potential implications for engineering education. First, even these fourth year students faced ambiguity due to lack of content knowledge, suggesting a need to use research-based instructional practices to improve learning. Second, in order to become comfortable in dealing with ambiguity students need practice and guidance in solving complex, open-ended problems. However, students are generally not exposed to these types of problems in traditional engineering programs [1-4]. While many programs include design experiences in the freshman and senior years, the problems students are given in the bulk of engineering topics in the middle years are generally closed-ended. In order for students to develop the problem-solving skills needed in engineering practice, traditional classes such as statics, thermodynamics, and kinetics should incorporate authentic, open-ended engineering problems that include ambiguity.

APPENDIX

A. Closed-Ended, Many Decision Problem

A cylindrical piece of polycarbonate with the diameter shown below is subjected to equal and opposed uniaxial forces of 3 kN as shown. With these forces applied will the polycarbonate piece be able to pass through an opening 10.00 mm in diameter without breaking due to the applied stress?

B. Open-Ended, Many Decision Problem

A truss bridge requires 40 members of square cross-section each of which is 12 feet long and experiences its maximum load in tension. The bridge is designed so that the maximum load experienced by each member is 500,000 lbs. You are bidding on the contract to provide these 40 members. The weight of each member cannot exceed 350 lbs as this is the lifting limit of the crane that will be used to construct the bridge. Provide a recommendation as to the specifications for these members and the cost for the job.

Background and demographic factors that influence graduation:

A comparison of six different types of majors

Abstract — How are engineering students different from other students? This study determined which demographic and background variables influenced graduation for engineering students, as well as education, business, psychology, health, and social science students. Once determined, a comparison between disciplines was made to discover if or how engineering students differ from other students. To perform the analysis, logistic regression with backwards elimination was used. The results showed that high school grade point average was a significant influence with respect to graduation for each discipline except psychology and business. A student's American College Test (ACT) English score was a significant and positive variable for both business and engineering majors while ACT math scores were only statistically significant for engineering students. These findings could potentially be used for recruiting as well as retention.

Keywords—graduation factors; engineering; ACT scores; Input-Environment-Output model; logistic regression

I. INTRODUCTION

Multiple studies have declared that engineering students are different from students majoring in other disciplines. Potvin, Tai, and Sadler found measurable differences between science and engineering majors in certain aspects of their backgrounds, such as SAT scores, level of mathematics preparation, and other high school aspects [1]. Another study stated that engineering students are more persistent than other college students when persistence is defined as students who matriculate in engineering and are still enrolled in their eighth semester [2]. However, little information is available about how engineering students are different from other students with respect to factors that influence graduation.

Abundant research has been conducted analyzing only engineering or STEM students and graduation. At least one study has found that both high school GPA and math SAT were positively correlated with graduation rates for each of the six universities tested, along with factors such as gender, ethnicity, and citizenship for some universities [3]. The study used a single pooled model to incorporate all the data, but used dummy variables to compare the results for each institution from an unpooled analyses. Moller-Wong and

Eide, also studying engineering students, reported that students with higher high school rank and ACT math score, among other factors, were more likely to graduate in engineering [4]. On the opposite end, they also found that being African American or having an ACT composite score of 35 or 36 puts a student at risk for not graduating with an engineering degree [4]. French, Immekus, and Oakes determined that high school rank, SAT Math scores, and GPA were related to persistence in engineering [5]. Using slightly different variables, some studies connected persistence and achievement in engineering with students' self-efficacy [6,7].

Scott, Tolson, and Huang, studying math and science majors, discovered that high school rank and combined mathematics and reading SAT scores positively correlated with retention [8]. A separate study sampling business, education, and STEM majors found that “students with higher high school rankings, no matter their race..., gender... or which school district they are coming from, should be encouraged into STEM majors” [9, p. 23].

II. RESEARCH QUESTION AND PURPOSE OF THE STUDY

Using data from Louisiana Tech University, this study aims to identify the demographic and background variables that significantly influence a student's graduation and determine if those factors are different across types of majors. More specifically, the question guiding the research is, “What factors that correlate with graduation are unique to engineering students?”

The purpose of this study is to discover the strongest influences on graduation by category of major. This information can then be used for both recruiting (to identify students who show great potential) and retention (to better design pre-college interventions).

Based on previous studies, it is expected that all categories of majors will show a positive correlation between high school GPA and graduation. Extrapolating from other results already published, such as Moller-Wong and Eide as well as Thompson and Bolin, it is expected that high school

rank will have a strong correlation with graduation for engineering students.

At Louisiana Tech University, as well as many other engineering programs, engineering students must have a certain ACT math score to enroll in non-remedial mathematics classes. Other majors, such as education and psychology, do not have such requirements. Therefore, regarding only engineering students, it is suspected that ACT math and science scores will positively correlate with graduation while neither of these variables will show significance for the other categories of majors. While ACT science scores do not directly affect enrolling in a class, it is likely that engineering students also show an affinity for science.

III. THEORETICAL FRAMEWORK

The theoretical framework guiding the study is Astin's Input-Environment-Outcome (I-E-O) model, which takes into account incoming characteristics of the student as well as environmental variables of the institution or program [10]. The input variables studied include high school GPA; high school rank; Louisiana residency, Math, Science, English, and Reading ACT scores; race; and gender. The different educational environments are engineering programs and five categories of non-engineering programs. Specifically, non-engineering majors will be broken into five separate categories: business related majors, social science/history majors, health related majors, psychology majors, and education majors. The outcome of interest is graduation in any major. We define graduation as a positive outcome if within six years of starting college.

IV. RESEARCH METHODS

Data for this study come from a single source: Louisiana Tech University's academic records, which included demographics and admission information. To analyze the data, logistic regression with backwards elimination is used.

A. Participants

The participants in this study consist of first-time-in-college (FTIC) freshmen who started at Louisiana Tech University in the fall of 2008. This group of students was chosen because a six-year graduation rate is used and 2008 is the most recent cohort with six years of data available. The students were split into six different groups according to the major declared when they began their studies. The first five major categories are reflective of the majors with the largest percentage of bachelor degrees according to the Condition of Education 2014 [11]: psychology, social sciences and history, business, health professions, education. The sixth group is engineering. Engineering students were not contrasted against other math and science majors because of insufficient sample size. Classification of Instructional Programs (CIP) codes were used to determine which majors offered at the university fit under each category. Not all

degree programs at Louisiana Tech fell into one of these categories, notably Mathematics, Physics and Chemistry. The list of specific majors that fall under each major category is given in Appendix A.

UNIV 100 is a university seminar class which all FTIC freshmen are required to take. Enrollment in this course was used to identify FTIC students, so transfer students are not included in the study. In total, 909 students were enrolled in the required class for the fall of 2008 that declared majors within the aforementioned categories. A total of 74 students were in the psychology majors, 84 in education, 91 in social sciences/history, 112 in health-related majors, 184 in business, and 364 in engineering.

The students were followed from the fall of 2008 until the spring of the 2013/2014 school year. This allowed for students to graduate within six years of their initial quarter attended.

B. Descriptive Statistics

As with most universities, at the time of data collection, race, ethnicity, and international status were confounded into one variable. The options were: White, Black/African American, Hispanic, Pacific Islander, Asian American, non-resident alien, and decline to identify. The population of students used in this study are not representative of all college students in the United States. The records indicate that the percentage of students in each race who started at Louisiana Tech majoring in the aforementioned disciplines are as follows: 82% White, 13% Black/African American, 1% Hispanic, and 1% Asian. Less than one percent of students were Pacific Islander. Two percent of the population declined to report a race and 1% of the students were non-resident alien. Unfortunately, cell sizes limited the study to those who reported their race as White or Black/African American. As for gender, forty percent of the students were female and sixty percent were male. A breakdown of percentages for each major group is given in Table I.

TABLE I. SAMPLE BY RACE AND GENDER

Major (Abbreviation)	White	Black	Female	Male
Psychology (Psyc.)	72 %	27 %	69 %	31 %
Social Sciences (S.S.)	79 %	16 %	53 %	47 %
Health (Health)	86 %	13 %	80 %	20 %
Business (Bus.)	83 %	12 %	39 %	61 %
Education (Ed.)	87 %	6 %	56 %	44 %
Engineering (Engr.)	81 %	12 %	15 %	85 %
Total	82 %	13 %	40 %	60 %

To identify differences between major groups, a model was created for each major group. Comprehensive data sets were compiled for each group of students. Each major group had similar average high school rank, high school GPA, and ACT scores with two exceptions – engineering students had a higher ACT Mathematics score and therefore higher ACT composite on average. The detailed information for each discipline's averages are shown in Table II.

TABLE II. GPA, RANK, AND ACT BY MAJOR

Major	GPA	Rank	ACT			
			<i>S</i>	<i>M</i>	<i>E</i>	<i>R</i>
Psyc.	3.28	70	22.9	21.5	24.9	25.1
S.S.	3.27	65	22.5	21.2	22.8	24.4
Health	3.47	44	22.5	21.8	24.0	24.4
Bus.	3.40	61	23.0	22.9	24.2	24.7
Ed.	3.39	65	20.9	22.0	22.2	22.2
Engr.	3.43	60	23.1	25.4	23.4	23.7

As noted, ACT scores rather than SAT scores were used for this study. According to research, high school students from Louisiana have an 80 – 100 percent chance of taking the ACT at least once, and Louisiana Tech University's students are primarily from Louisiana [12, 13]. Furthermore, after reviewing the data for the students in the study it was revealed that a very small percentage of the population had recorded SAT scores.

C. Definition of Graduation

For this study, graduation is defined as graduating from Louisiana Tech University within a six year time period with any undergraduate degree. In the logistic regression model, graduating from Tech was indicated with a 1 and not graduating with a 0.

Although the data for this study came from a single source, multiple files held different pieces of information. These files were merged to obtain all of the variables for each student. Once compiled, a logistic regression analysis with backwards elimination was completed for each cohort to determine the variables which had a statistically significant relationship with graduation. The procedure for backwards elimination involved removing the least significant variable from the model each time until only statistically significant variables remained. After the logistic models were run for each major group, the odds ratio for each statistically significant variable was calculated. The software R Studio was used to perform these operations.

For the purpose of inputting variables into the logistic regression, all symbols or letters were transformed into a numerical value. For example, gender was transformed into binary numbers; 0 for male and 1 for female. Louisiana Residency was transformed as well. If a student was from out of state or out of country, it was indicated with a 0, and a 1

TABLE II. VARIABLES

Variable (Abbreviation)	Range/Values
Sex (Sex)	0=Male 1=Female
Race (Race)	0= White 1= Black/African American
Louisiana Residency (State)	0= Non-Resident 1= Resident
High School Rank (HS Rank)	1 – 533
High School GPA (HSGPA)	1.59 – 4.0
ACT component scores	
Science Score (ACT S)	14 – 36
Mathematics Score (ACT M)	13 – 36
English Score (ACT E)	10 – 36
Reading Score (ACT R)	13 – 36

for students within state. High school rank ranged anywhere from 1 to 533 with 1 being top of the class. High school grade point average ranged from 1.59 to 4.0. Race was separated as seen in the table; again, the values rearranged

into binary numbers for each student. The variables obtained and analyzed in this study are presented in Table III with the abbreviations and range.

V. RESULTS

A snapshot of the initial results when each major had all nine variables left in the model (before backwards elimination) is given in the Table IV as a reference to how variables were eliminated and retained.

Backwards elimination was complete when only statistically significant ($p < 0.1$) variables were left in the model. The final results for each discipline are displayed in Table V. Table V displays the coefficient, odds ratio, confidence intervals, and level of significance for each for each variable included in the final models.

The *odds* of an event (such as graduation) occurring are the ratio of the probabilities of the two outcomes. If for example, a typical student has a 75% chance of graduating, there is a 25% of not graduating, then the odds of graduation are $75\%/25\% = 3$ (sometimes written 3/1, 3:1, or 3 to 1). The typical effect size used with logistic regression is a ratio of the odds of an event occurring under certain conditions compared to the odds of the event occurring under a reference set of conditions. This *odds ratio* represents the percent change in the odds of the event for a one unit increase in the variable. So if a variable has an odds ratio of 2, we would say that the odds of a students with that characteristic are twice that of a similar student without it. In our example, that would make the odds $2 \times 3 = 6$, or 6 to 1 odds, and therefore the probability of graduation $6/7 = 85.7\%$. An odds ratio near unity means the variable has a negligible effect on the outcome.

. $p < 0.1$, * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$

We can interpret odds ratio in a similar way for the given models in Table V. For example, if there is a one unit increase in high school GPA for an engineering student, the odds of graduating only increase by a factor of 2.564. However, if there is a one unit increased in high school GPA for a social science student, the odds of graduating increase

by a factor of 3.535 [14]. The larger the gap between 1 and number given for odds ratio, the more impactful the variable is. The odds ratio is an estimate of effect size. Table V also gives the 95% confidence interval. There is a 95% chance that the true odds ratio is within these limits. The formula for confidence interval is

$$\text{Estimate} \pm \text{Confidence Coefficient} * \text{Standard Error}$$

Confidence intervals can also be used to determine if a variable is or is not statistically significant at $p < 0.05$ level [15]. If the two confidence interval numbers include 1, the variable is not significant at that level. For example, the gender variable for education students has a confidence interval that starts at 1.086 and ends at 7.904; therefore, it is statistically significant because 1 is not included in the span. This is verified by the given p-value.

In the case of psychology majors, no variables were concluded to be significant through the logistic regression; the last variable in the model was high school GPA, but it was not statistically significant, even at $p < 0.1$. Every other discipline showed at least one significant variable. For social sciences, health, education, and engineering students, graduation had a positive and significant relationship with high school GPA. For students within business and engineering majors, ACT English scores were also positive and significant. The results for engineering students also showed that ACT Math was a positively significant variable while ACT Science was a negatively significant variable. The analysis for education also revealed that gender, specifically being a female, was a significant variable.

VI. DISCUSSION

To answer the initial research question, “What factors that correlate with graduation are unique to engineering students at Louisiana Tech University?”, the logistic regression analysis showed that engineering students are the only discipline to have a positive, statistically significant correlation to ACT math scores and a negative, statistically significant correlation to ACT science scores. It was expected that ACT math scores would be a strong influence on graduation for engineering students given previous research and the mathematics involved in obtaining such a degree, but it was not expected that ACT science scores would show a negative relationship with graduation. This may be due to the collinearity of ACT Math and ACT Science. When entered into the model as a lone predictor, ACT Science has a non-significant, yet positive effect.

Surprisingly, high school rank was not a significant variable in terms of graduation for engineering students as some previous research has shown. As expected, almost all models displayed high school GPA as a significant indicator of graduation.

Another unexpected result was ACT English score being a significant variable for both business and engineering majors. Neither of these majors require a large number of English classes in order to graduate nor do they require a

specific score on that portion of the ACT to be admitted to the programs.

A lack of relation between race and graduation is another finding that does not concur with the majority of previous research. However, it is possible this is because race and ACT are confounded. The differences in ACT scores between the two races of students, using the entire sample, can be seen in the table below. The average score for White students in the sample is about three points higher than for Black students on each part of the ACT.

TABLE IV. AVERAGE ACT SCORES BY RACE

Race	Comp.	M	E	R	S
Black	21.5	20.2	21.7	22.5	21.0
White	24.6	23.8	24.9	25.3	24.0

Another issue is the small sample sizes. Only two categories of race were included in the study, White and Black; furthermore, only thirteen percent of the students in the study identified as Black.

Psychology students, according to the model, are not significantly affected by demographic or background variables. However, this discipline did have the smallest sample size ($n=74$) and this may have influenced the results.

A factor that could have been significant to any of the majors in the study, but was not used is the socioeconomic status (SES). Multiple studies have found that low-income students or ones from low SES schools are at a disadvantage in terms of graduating from a postsecondary institution [16, 17]. Unfortunately, the authors did not have access to this data and that variable was not included in the study.

These results could be used to help universities identify students that may need more assistance in order to graduate. The findings of this study could also potentially assist high schools in advising students about career choices.

VII. LIMITATIONS

The primary limitation is that the study only used data from a single institution, and therefore the results cannot be broadly generalized. These particular findings may not translate to other schools. The quality of data used in this study also limits the generalizability. For example, high school rank was only given as a number for each student; it was not possible to calculate the percentile rank. Also, neither SES, marital status, nor number of credits a student obtained before coming to the university were a part of the data available. It is possible that including these variables could produce differing results. Moller-Wong and Eide found that engineering students who were married were less likely to graduate [4]. As for diversity, some students had to be left out of the analysis due to small cell sizes.

As previously mentioned, another limitation within the data is the use of ACT scores. Using college readiness standards, ACT reported that at least 50% of Caucasian and Asian students meet the standard for three of the four subjects while African American students typically struggle

meeting the standards [12]. However, the difference between genders is minimal with female students' averages about two-tenths of a point less than males' composite scores [18].

VIII. CONCLUSION

Using logistic regression, separate analyses were done to determine what factors influence graduation among psychology, social sciences, health, business, education, and engineering students respectively. A total of 909 participants were involved in the study with forty percent being female and sixty percent being male. Concurring with previous research and literature, high school GPA held a significant relationship with graduation for social science, health, education, and engineering majors. Sex was a significant variable for education students. For business majors, ACT English scores were slightly significant while engineering students' graduation positively related to both ACT English and math scores. The main limitation of the study is that the data came from a single university; an analysis using data from multiple institutions would be helpful in determining the generalizability of the results. This study could be useful in helping colleges and universities recruit as well as retain students in engineering.

ACT math scores showed significance in predicting graduation for engineering students, but not other majors studied herein. As ACT math scores are commonly used for math placement, further research is needed on the interactions between math ACT score, math placement, and graduate rates.

Abstract— We present a simple diffraction experiment with Fibonacci gratings as a motivational strategy for students of physics and engineering to learn the potential applications of aperiodic systems. The Fraunhofer diffraction patterns were obtained with the standard equipment present in most undergraduate physics labs and compared with that obtained with conventional periodic gratings. It is shown that Fibonacci gratings produce a splitting of the diffraction orders which positions are related to the Golden mean involved in the Fibonacci sequence. A very good accuracy is obtained between experimental and numerical results.

I. INTRODUCTION

Most of basic Physics courses for science or engineering students include the study of interference and diffraction as fundamental properties of all wave phenomena [1]. This phenomenon appears when light interacts with an obstacle or aperture with a size comparable to its wavelength. It plays an important role, for instance, in image forming systems due to the finite sizes of lenses and other optical components. This fact makes the image of a real point object does not be a point but a diffraction spot whose dimensions limit the resolution of the imaging systems. This includes the diffraction effects caused by the pupil in the human eye.

Even the undoubtedly importance that in many real systems the study of the diffraction of light waves has, it is usually perceived by the students as something of purely academic interest that requires of a complicated mathematical treatment and very specific elements for the observation, such as, monochromatic light sources, apertures, slits of very small size or diffraction gratings. However, nothing is more away from reality either in terms of interest or in the difficulty to make experiments. For this reason, some creative works have been published to increase the interest of students. For example, the tracks of a compact disc [2], the spiral element of a spider orb-web [3], the cells of the onion epidermis [4], and the array of pixels in CCD image sensors or LCD screens [5] are used as diffraction gratings.

In our opinion, other non-conventional aperiodic diffractive objects such as fractals are also very motivating because it is a

way to students to basic research activities [6]. Fibonacci gratings are also one of the most common examples of aperiodic structures exhibiting two incommensurate periods (i.e., it is quasiperiodic) [7]. The ratio of these two periods is equal to an irrational number known as the golden mean. This number has been historically associated with the subjective concepts of equilibrium, harmony, or beauty and can be found profusely in nature [8] and technology [9]. In Physics teaching, some interesting examples where the Fibonacci sequence and the golden mean appears include the study of network of resistors [10] or the coupled-oscillator problem [11].

We present here a simple experiment (from a didactic point of view) to verify the discrete Fourier spectra produced by Fibonacci gratings. The experiment has been developed at the *Escuela Técnica Superior de Ingeniería del Diseño* at the *Universitat Politècnica de València* (Spain) as a new laboratory practice for electronics engineering students, but may be easily reproduced with the standard equipment present in most undergraduate Physics laboratories. For comparison, the diffraction patterns produced by regular periodic gratings are also obtained. We show numerically and experimentally that the diffraction peaks generated by Fibonacci gratings are related to the golden mean.

II. BASIC THEORY

A Fibonacci grating is defined as a set of slits distributed aperiodically according to the following recursive procedure. Starting with two elements (seeds), $F_0 = 0$ and $F_1 = 1$, the Fibonacci numbers $\{F_j\}$ are obtained by the iterative rule and $F_j = F_{j-1} + F_{j-2}$ with $j > 1$, so $F_j = \{0, 1, 1, 2, 3, 5, 8, 13, \dots\}$. The golden mean or golden ratio is defined as the limit of the ratio of two consecutive Fibonacci numbers

$$\varphi = \lim_{j \rightarrow \infty} \left(\frac{F_j}{F_{j-1}} \right). \quad (1)$$

Taking into account that the Fibonacci can be expressed as the sum of the two preceding numbers, it is easy to prove that the above limit results in the transcendental equation

$$\varphi^2 - \varphi - 1 = 0. \quad (2)$$

Solving this equation we obtain $\varphi = \frac{1}{2}(1 + \sqrt{5}) \approx 1.618$.

Figure 1. Fibonacci grating (top) at stage of growth $S=9$ with $F_{10}=55$ slits ($F_9=34$ transparent slits) and the equivalent periodic grating (bottom) with the same number of slits.

In a similar way, a binary Fibonacci sequence can also be generated with two seed elements, $t_0 = \{0\}$ and $t_1 = \{1\}$, and the successive elements of the sequence are obtained as the concatenation of the two previous ones $t_j = \{t_{j-1}t_{j-2}\}$ with $j > 1$, so:

$$\begin{aligned} t_2 &= \{10\}, \\ t_3 &= \{101\}, \\ t_4 &= \{10110\}, \\ t_5 &= \{10110101\}, \\ t_6 &= \{1011010110110\}, \dots \end{aligned} \quad (3)$$

Note for example that t_6 presents $F_6 = 8$ type-1 elements and $F_5 = 5$ type-0 elements, being the total number of elements $F_7 = 13 = 8 + 5$. In general, the Fibonacci sequence at an arbitrary generation level S contains F_S type-1 elements and F_{S-1} type-0 elements, so the total number of elements is $F_{S+1} = F_S + F_{S-1}$. Then, the ratio between the number of type-1 and type-0 elements is $F_{S+1}/F_S \approx \varphi$ when $S \rightarrow \infty$.

With this encoding, a Fibonacci grating at a given generation level, S , can be constructed as a sequence of F_{S+1} slits with the same width a , but defining the transmittance $t_{S,j}$ of the j -th slit as the j -th element of the binary array t_S , where $t_{S,j}=1$ for transparent zones (slits) and $t_{S,j}=0$ for opaque zones. Then, a Fibonacci grating presents F_S transparent slits and F_{S-1} opaque zones aperiodically distributed, as shown in figure 1. In mathematical terms, the transmittance function $T_S(x)$ of a Fibonacci grating of order S is given by

$$T_S(x) = \sum_{j=1}^{F_{S+1}} t_{S,j} \text{rect}\left(\frac{x - a(j-1/2)}{a}\right). \quad (4)$$

The Fraunhofer diffraction pattern is generated at the back focal plane of a lens placed against the grating when a monochromatic plane wave is used as illumination. Within the scalar approximation, the focal irradiance is given by the Fourier transform of the transmittance function [12]

Figure 2. Normalized Fraunhofer irradiance versus the normalized transverse coordinate u for the (a) Fibonacci grating and (b) for the periodic grating shown in Fig. 1.

$$I(x) = \left(\frac{A}{\lambda f}\right)^2 \left| \int_{-\infty}^{\infty} t(x_0) \exp\left(-i \frac{2\pi x x_0}{\lambda f}\right) dx_0 \right|^2, \quad (5)$$

where λ is the wavelength of the light, A is the amplitude of the incident plane wave, and f is the focal length of the lens.

To determine the diffraction properties of Fibonacci gratings, we will obtain analytically the Fraunhofer patterns by replacing in the above equation the transmittance function $t(x)$ by $T_S(x)$ given by equation (3). By using the dimensionless transversal coordinate $u = \frac{ax}{\lambda f}$, equation (5) can be rewritten as

$$I_S(u) = \frac{1}{F_S^2} \left| \sum_{j=1}^{F_{S+1}} t_{S,j} \exp(-i2\pi u j) \right|^2 \text{sinc}^2 u. \quad (6)$$

Note that the above equation has been normalized to have $I_S(0) = 1$.

By using Equation (6) we have computed the Fraunhofer diffraction pattern provided by the Fibonacci represented in Fig. 1 and for comparison purposes the corresponding to a conventional periodic grating. The results are shown in Fig. 2. It can be seen that the main diffraction peaks in both cases coincide. However, the aperiodic distribution of zones according to the Fibonacci sequence produces a symmetrically distributed splitting of the first diffraction order with two irradiance peaks located at $u_I=0.6165$ and $u_{II}=0.3831$. Thus, the ratio of the transverse distances satisfies $u_I/u_{II} \approx \varphi$. Higher diffraction orders with a lower irradiance also appear. However, only the transverse distances associated to the first diffraction order of the Fibonacci grating are related through the generalized golden mean φ .

III. EXPERIMENTAL RESULTS

To experimentally check the above results, the gratings shown in Fig. 1 were built on graphic arts film [13] by using a photoplottter AGFA with 2400 lpi resolution. The basic zone width was $a=50 \mu\text{m}$ in all cases.

Figure 3. Experimental setup: a) collimated laser diode; b) diffraction grating; c) variable density filter, consisting in a couple of linear polarizers (one rotatable); d) thin lens; and e) camera body (CMOS sensor).

Figure 3 shows the setup used in our experiment. We only considered the standard equipment present in most undergraduate Physics laboratories. From left to right, the first element was a light source (a conventional laser diode with a wavelength $\lambda=650$ nm). The laser source was adjusted to provide a plane illumination onto the object grating. Next, a set of two linear polarizers controlled the irradiance level of the registered pattern by in-plane rotating one respect to the other.

The Fraunhofer diffraction patterns were obtained on the back focal plane of a thin lens (focal length 200 mm) and registered with an digital camera (Canon EOS550D, with a 18 Mpx 22.3×14.9 mm sensor). The registered irradiance patterns are shown in Fig. 4. These results are in full agreement with the theoretical predictions in Fig. 2. From the diffraction pattern generated by the periodic grating, a splitting of the first diffraction order is clearly seen in the Fibonacci case. Moreover, the splitted orders are symmetrically distributed around the original position. Furthermore, from a quantitative point of view, it is easy to check that the ratios between their distances to the zero diffraction order follow the relationship presented above. Actually, these distances can be measured to be $x_I=268$ pixels and $x_{II}=166$ pixels in the Fibonacci pattern, following that $x_I/x_{II}=1.614$, which is in good agreement with the theoretical value for $\phi=1.618$.

IV. CONCLUSIONS AND OUTLOOK

We have presented a simple optical method to analyze the Fraunhofer diffraction properties of one-dimensional gratings based on the Fibonacci set. With this method we have shown that optical processing can be performed using the standard equipment available in most undergraduate physics laboratories. In fact, the diffraction patterns can be easily observed and recorded with this setup and measurements of the mathematical properties of the Fibonacci are also possible from experimental results. It is worth to be mentioned that with this method other one-dimensional aperiodic structures, such as the Thue-Morse gratings, can be studied. In our opinion this result could be a strong motivation for the students to go into the field of optical processing in depth.

Figure 4. Experimental Fraunhofer diffraction patterns of a Fibonacci grating ($S=9$) and a equivalent periodic grating shown in Fig. 1. The basic zone width was $a=50$ μm in both cases.

ACKNOWLEDGMENT

The authors would like to thank the Institute of Education Sciences, Universitat Politècnica de València (Spain), for the support of the Teaching Innovation Group, MoMa.

Abstract—In this paper, we propose a Web-based interactive learning environment with a knowledge-based assistant for helping undergraduate students in solving problems on designing digital circuits, focusing the relationship between Boolean algebra and Digital Logic. Particularly, we have addressed problem solving situations that essentially consist of mapping a logic expression into another equivalent, for example, the task of simplifying digital circuits. To do that, we have considered to operate on two symbolic linked representations: Boolean Algebra and Logic, connecting these two representations to a visual one with logic gates. This integration comes from the importance to involve students in three equivalent representations, permitting them to make connections between them. The learning environment contains a knowledge-based assistant that works on a collection of scenarios with several associated problems, where the students are placed in a problem-solving situation. To each problem, there are pedagogical resources needed to provide the students with feedback and knowledge support based on their performance and identified needs. Furthermore, there is an adaptive mechanism that is responsible for how problems should be sequenced or ordered, and even we have designed a switcher mechanism, which permits the students to change from one to another representation. We evaluate our approach by using scenarios and conclude that the system is feasible.

Keywords— *interactive learning environment; multiple representations; Digital Logic; Boolean Algebra*

I. INTRODUCTION

The little motivation and dedication observed in undergraduate students when take courses in foundational formal disciplines of the curriculum of computer science and computer engineering, is causing some difficulties to such students to learn the subjects in those disciplines. Particularly, Mathematical logic and logic digital circuit's courses contain many abstracts concepts and, at the same time, they are strongly related and share the same essence, but often they are not seen on this way. The first one is inherently abstract and the second, frequently, is less abstract, but always more directly referring to concrete situations, for instance: a traffic light design. Here, one important question is on how approximate abstract and concrete approaches in order to help the students to have a unified view between these two abstraction levels.

One alternative to alleviate this problem is to provide those students with software tools that allow them to link concepts and results, that occur, in these two disciplines, appreciating that abstract and concrete aspects may be adequately connected. In fact, in a broad sense, some studies have presented arguments in favor of the use of multiple representations of a given domain knowledge, considering its potential to cause positive effects on the learning process [1]. Additionally, they state that during the learning process, switching among different methods may cause more effective learning [2].

Taking into account the above motivations, questions and discussions, in this paper, we propose a Web-based interactive learning environment for assisting undergraduate students in solving problems on designing digital circuits, focusing the relationship between Boolean algebra and Digital Logic. There are many reasoning tasks associated with digital circuits. Particularly, here we have addressed problem-solving situations on how to design some smaller logic circuits, performing operations on them that consist of mapping a logic expression into another equivalent represented in a symbolic language. For example, it is often the situation in which one need to deal with the task of simplifying digital circuits represented as a boolean expression, where you need to reduce the number of logic gates required to implement it. To approach these problem situations, we have considered operating on two symbolic linked representations: Boolean Algebra and Logic, connecting these two representations to a visual one with logic gates dealing with the basic three types: AND and OR gates and NOT gates (inverters). From the two first representations, we have considered Digital logic with their three basic operators: the AND, the OR and the NOT, expressed in their correspondent notations. Therefore, the suggested integration comes from the importance to involve students in three equivalent representations, permitting them to make connections between them.

The proposed learning environment contains a knowledge-based assistant, with the basic modules of a typical Intelligent

Tutoring System (ITS)[3], including modules, such as: a problem solver, a diagnoser and a pedagogical planner, as well as, a learner model representing cognitive information about a given learner. This assistant works on a collection of scenarios with several associated problems, where the students are placed in a problem-solving situation. To each problem, there are pedagogical resources needed to provide the students with feedback and knowledge support based on their performance and identified needs. Furthermore, there is an adaptive mechanism that is responsible for how problems should be sequenced or ordered, and even we have designed a switcher mechanism, which permits the students to change from one to another representation. A functional view of the proposed assistant may be summarized in four steps as follows:

(i) The assistant to selects and to present to the student a problem from a given scenario;

(ii) The student choices in what representation, between algebra or logic, he prefers to start the problem solving process, and

(iii) As the student is going to operate the logic circuit by repeated application of the rules and laws of boolean algebra or classic logic, according to the choice done to operate;

(iv) To each step, the assistant will create a third view on logic gates: one correspondent digital circuit to that current expression, as well as, this is done to the other symbolic representation.

Alternatively, the step (i) may be changed to one where the student selects and poses a problem to be solved by the assistant. In this case, the system will solve the problem according to the selected symbolic approach, showing step by step of the developed solution, as well as, mapping each yielded step in the other two representations.

Through scenarios with adequate problems coverage, we evaluate the value of the proposed approach and conclude that the assistant is feasible and useful.

The remainder of this paper is organized as follows. Section II presents some background knowledge and discusses some related work. Section III describes the proposed learning environment with its main requirements, its overall architecture, and its main functionality, as well as an illustrative scenario with the main interactions provided by the assistant. Section IV presents an evaluation for the proposed approach, offering comments on the initial results. Finally, section V summarizes our research work, offers conclusions and discusses the next steps to be taken.

II. BACKGROUND KNOWLEDGE AND RELATED WORK

In what follows, we present a brief background knowledge with respect to two kind of knowledge employed in our proposal. Firstly, we provide a brief coverage of digital logic with boolean algebra and propositional logic, that are important

to clarify what we have used in our approach. Secondly, we describe some related work.

A. Boolean Algebra and Propositional Logic

We summarize here some important aspects in Boolean Algebra and Propositional Logic, which serve to clarify what has been directly used in our work. To this end, it is important to remember that we can approach digital logic according to different ways of representations, and in our case we have considered Boolean Algebra, Propositional Logic and Logic Gates. There is a one-to-one correspondence between each two of these three representation ways, as well as, there is a one-to-one correspondence between one of these three representations and its physical implementation using electronic circuits. For instance, Boolean functions are implemented in digital computer circuits, that is, gates. A gate is an electronic device that produces a result based on two or more input values.

Boolean algebra is a kind of algebra that manipulates variables that can take on only two values, typically true and false. It has operations that can be performed on these variables, in such a way that when one combine the variables and operators, yields Boolean expressions. As mentioned earlier, three common Boolean operators are AND, OR, and NOT. As in arithmetic expressions, Boolean operations have rules of precedence, where the NOT operator has highest priority, followed by AND and then OR. There are different ways to manipulate these expressions, for example, reducing one to another that is equivalent, including simplification of a given expression that is not in its simplest form. To perform reduction operations on expressions there are a collection of identities or laws to be applied to the expressions, as for instance in boolean expressions.

Most boolean identities have an AND (product) form as well as an OR (sum) form. In what follows we present some identities using two forms. More information about boolean algebra and digital logic can be found in Gregg [4].

Identity Name	AND Form	OR Form
Identity Law	$1x = x$	$0 + x = x$
Null Law	$0x = 0$	$1 + x = 1$
Idempotent Law	$xx = x$	$x + x = x$
Inverse Law	$x\bar{x} = 0$	$x + \bar{x} = 1$

Fig. 1. Rules 1

Identity Name	AND Form	OR Form
Absorption Law	$x(x+y) = x$	$x + xy = x$
DeMorgan's Law	$\overline{(xy)} = \bar{x} + \bar{y}$	$\overline{(x+y)} = \bar{x}\bar{y}$
Double Complement Law	$\overline{(\bar{x})} = x$	

Fig. 2. Rules 2

Identity Name	AND Form	OR Form
Commutative Law	$xy = yx$	$x+y = y+x$
Associative Law	$(xy)z = x(yz)$	$(x+y)+z = x+(y+z)$
Distributive Law	$x+yz = (x+y)(x+z)$	$x(y+z) = xy+xz$

Fig. 3. Rules 3

The same construct is verified in classical logic with its logical expressions, as well as, is verified in logic gates. The mentioned three ways of representing expressions are equivalents, only having different languages. Therefore, the boolean identities presented above have correspondent, one-to-one, in the other two representations: Propositional Logic and Logic Gates.

B. Related Work

Learning environments with support to multiple representations have been the focus of some studies in the literature. Part of them concentrate on examining the potential benefits of supporting multiple representations by analyzing the main influences on learning process. In particular, Steiner, and M. Stoecklin [5] showed that learners acquire a deep understanding only if they are able to link multiple representations of the same concept and to coordinate between them. At the same time, we have seen computer-based learning environments for propositional logic with focus on solving problems by generating proofs have been considered in some works in the literature. One of them was selected to be discussed here, because it is closely related to the present work. On the other hand, we selected one paper that has invested in multiple representations for a given formal domain.

The work proposed by Rau, Aleven and Rummel [6] shows an Intelligent Tutoring Systems that uses multiple graphical representations as support to teaching mathematical fractions. In this sense, the authors propose that students use self-explanation, aiming to improve the students' comprehension about the relation between the different graphical representations and the symbolic representation. The results indicate that that approach is promising and the use of multiple representations coupled together with better understanding of the relation between them can enrich the teaching of fractions. This approach uses multiple representations with support only to visualization and does not offer a proposition where the student can solve a problem based on different ways.

The work proposed by Lukins, Levicki and Burg [7] shows an ITS to teach students basic concepts of propositional logic and theorem-proving techniques. The work can be summarized with the following contributions: i) an ITS to teach the student how to use truth tables, equivalence rules and inference rules to proof the validity of an argument; ii) a learning mechanism to improve the capacity of the tutoring system in proving theorems. One limitation in this work is that it offers just one representation of this domain. Our approach differs from this mainly on dealing with multiple representations on the knowledge domain.

III. PROPOSED LEARNING ENVIRONMENT

In what follows, we describe the modelling of the proposed domain and we present the architecture of the learning environment, where we highlight the Expert, Student and Pedagogical Modules.

A. Domain Module: Curriculum Structure

A curriculum is composed by a set of pedagogical units, which have a sequencing that will be followed by the tutor to guide the student in their studies. Each one of the three representation languages adopted in our work has an associated curriculum structure. That is, one for boolean algebra, one to logic, and another to logic gates.

In Figure 4, there is an abstract curriculum structure that we have adopted in our approach.

Fig. 4. Curriculum Structure

In this structure, SC stands for Structure of curriculum that is formed by a collection of topics. To each topic is associated to a set of problems, where each problem may be abstractly defined as a triple, as follows:

$P = \langle I, F, Op \rangle$, where I is an initial state of the problem (in this case, an expression), F is the final state or goal (a particular expression), and Op is a set of operators to be applied to the involved expressions.

KS: Knowledge Support, including several resources, for example hints.

Solutions: Set of possible solutions for a particular P .

Representations: Each solution may have more than one representation. The assistant works on three representations: boolean algebra, logic and logic gates.

B. Architecture

The architecture of the proposed system, as in Figure 5, is based on the classic architecture of an intelligent tutoring system involving an expert module, a pedagogical module,

model student and a user interface. The expert module contains the expertise of the system in propositional logic and digital circuit, composed of four sub-modules: Problem solver, Profiler, Solution Reviewer and Diagnoser module. Each sub-module works as a traditional expert system that contains a knowledge base, an inference engine and an explanation module.

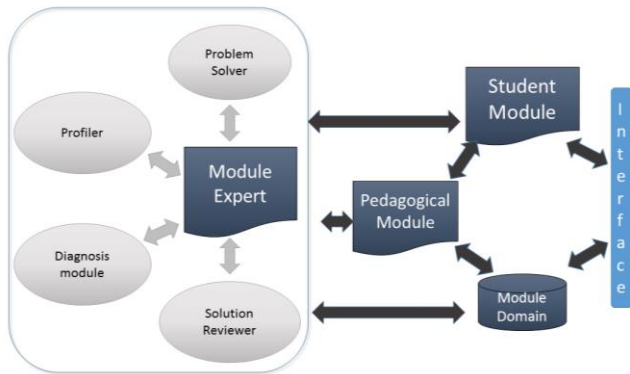

Fig. 5. Architecture of the Learning Environment

Student Model: is an open student model, where for each pedagogical unit there is a concept associated. In the model of the problems submitted by the student are stored one evaluation and one diagnostic for each solution, the support used by the student, for example, tips, didactic materials or others problems representation (for example: to resolve a deduction natural problem, the student could have some doubt about any rule application and request to the system a truth table about the current problem).

Expert Module: The expert module contains the expertise of the system in digital logic, composed of three sub modules (Problem solver, Evaluator (evaluates solutions proposed by students) and Diagnoser (diagnosis mistakes of the students)). Each sub-module works as a traditional expert system that contains a knowledge base, an inference engine and an explanation module. To implement this module, we have used the Inabit shell [8].

Pedagogical model: responsible for the management of the student-tutor interaction, playing different pedagogical roles in that aspect, including task sequencing over the curriculum structure and a knowledge-based assistant that requires services from the Expert Module. This assistant poses problems to students waiting for detailed solutions, and then the system evaluates the provided solution, eventually providing suitable feedback.

IV. SCENARIOS AND EVALUATION

The purpose of this section is to evaluate the proposed approach through some example scenarios for which different examples were performed. Despite being hypothetical, it shows the value of the proposed approach in terms of the adequate behavior demonstrated by the assistant, by connecting one resource to another.

A. Dynamic Interactions

The proposed system is designed to help students learn to solve problems on digital logic involving the manipulation of Boolean or logical expressions, making the links between the representations adopted. Here, the student starts a session, getting a problem to be solved. Each problem is presented as an expression to be turned into a target expression, for example, its simplified form. In this case, the student is required to declare explanations of their steps troubleshooting, showing each step and the corresponding justification. If the student answers incorrectly or tip application, step-by-step guidance is provided for him.

As shown in Figure 2, the system can interact with the student based on a troubleshooting scenario, such that: (1) the system selects and puts problem for the student, considering their current cognitive profile, or (2) alternatively, the student poses problems to be answered by the wizard, showing step by step solution with their justifications. From (1), when the wizard proposes a problem for the student, it can ask for a hint, or present a solution to the problem posed. In this case, the system provides the student with a suggestion or an evaluation.

Fig. 6. Learner-assistant Interaction

To summarize, a functional view of the tutor system proposed by interacting with the student, can be summarized in four steps, as follows:

- (I) the system, via sequencer, selects and presents the student with a problem of a given scenario;
- (Ii) The student chooses which representation you want to start to solve the problem from the available options, then the student provides a comprehensive solution, displaying every step;
- (Iii) The student operates the logic circuit by repeated application of the rules or laws of Boolean algebra and propositional logic, according to the choice made to operate
- (Iv) For each step, the system creates a vision of the logic gates language: a corresponding digital circuit for the current expression, the same being done for another symbolic representation, if that is the one. In addition, the system (evaluator) evaluates the step-by-step solution, what if there is an error, the troubleshooter tries to detect errors and their causes in the solution presented by the student, using a incorrect rule base. The evaluator or diagnostician, sends information to be processed by the student modeler, updating the student model. Where appropriate, the system, via

educational module, provides assistance with tips or other educational resource, as the situation of difficulty presented by the student.

Alternatively, step (i) may be changed to a situation in which the student would be responsible for choosing the problem and then request the system (via resolver) that resolves the problem through an approach, showing each step of the solution, and also explain the use of each step, but mapping each step in the other forms of representation.

As can be seen, the Figure 3 system screens comprises:

- 1- System Options: Problem solver, Evaluator (Evaluator) and Rule (Rules);
- 2 Problem descriptions: Problems are described in natural language or directly in a symbolic language;
- 3 Desktop: Where the student can observe each step of solving a problem. In this part of the system are shown to simplify the form of the expression or logical path algebra, each step of simplification with the corresponding rule and system feedback;
- 4- Issue expression: area reserved for the choice of the rule, editing sending the partial solution;
- 5 A. area made up of the complete solution submit button or the button "did not understand" where the student can tell the system that did not understand the problem;
- 6 Help: In this area, the student can seek help system asking for a tip or watching a video.

V. CONCLUSIONS AND FUTURE WORK

In this paper we presented the proposal and implementation of an interactive learning environment with a knowledge-based assistant designed for helping students to learn digital logic using multiple representations, taking into account a problem-based learning approach, especially focusing on logic expressions problem solving. The preliminary results using this assistant are positive, mainly with regard to its feasibility. Another conclusion is that our work is, to the best of our knowledge, the first in the literature to present a large in scope and concrete solution for problem solving with multiple representation in Boolean algebra and classical logic. Therefore, this work set out to answer the following question:

”How to provide multiple representations for digital logic domain”, having an assistant to accomplish this domain knowledge. For immediate future work, we will invest in interface aspects as well as performing more experiments, this time, as part of a regular digital logic course.

Abstract—In this paper, we present Adaptive Vision Studio (AVS)—a novel tool for creating image processing and analysis algorithms. AVS has been applied in post-graduate computer vision course for students of Automatic Control and Biotechnology at Silesian University of Technology. This software is a powerful environment with ready-for-use image analysis filters for computer vision experts as well as for engineers, who are beginners in this field. AVS has been published as a freeware version for non-commercial and educational purposes recommended for students and engineers, who want to learn how to develop complex image processing algorithms. Lite version of AVS is freely available at <https://adaptive-vision.com>.

I. INTRODUCTION

The use of cameras and automated image processing methods is widespread in industry and applications, in which we would like to enable computers to understand and interpret visual information from static images and video sequences [1]. The applications are of a wide range and significance, including robot vision, face recognition, image denoising, medical imaging, object recognition and many others. However, a large variability in data (varying lighting condition, pose, orientation, scale, color calibration) causes that it is not possible to prepare an universal algorithm for various engineering applications. Therefore, all vision problems have to be solved individually. To limit the time that is needed to prepare a full vision system, an advanced flow-based software called Adaptive Vision Studio (AVS) has been developed. This software has been created by Future Processing company in cooperation with the scientists from Silesian University of Technology.

This software uses visual programming language and is designed for rapid prototyping and building advanced vision systems. AVS software is the most powerful graphical environment for machine vision engineers. It is based on dataflow and comes with a comprehensive set of powerful, ready-for-use image analysis filters. It is also successfully used in post-graduate courses in Automatic Control and Biotechnology at Silesian University of Technology.

Understanding vision algorithms requires using a variety of images and test the effect of applying various parameters. Transfer of personal experience to students during laboratory classes with only a few test images is a challenge. It could be even more difficult to explain how video processing algorithms

work. In an ideal situation, students should be able to understand the described algorithms and their parameters influence on the final result. Due to time constraints during laboratory classes, students are able to implement only some vision algorithms. It seems therefore reasonable to use interactive tools to help them understand the nature of other machine vision algorithms, often too complex to implement in the classroom laboratory.

According to the literature, there are several environments applied in image processing courses. The review and comparison of several tools for learning computer vision can be found in [1], [2]. In this group there are several commercial software packages. The most popular commercial tool seems to be Matlab with Image Processing Toolbox, which is widely used in the scientific community for fast prototyping and in educational process [3], [4]. Image processing courses have also been conducted with other commercial software such as Mathematica [5], LabView [6]. There are also many non-commercial solutions based on C [3], [7], [8], Java language [4] or Python [9].

In this paper, we present a novel tool useful for image processing learning that allows resolving a real life computer vision problems without specific programming skills and experience in image processing. We present also the exercises prepared for students of Automatic Control (focused on aspects of quality control in manufacturing) and Biotechnology (focused on aspects of medical image processing). The presented exercises can be used at other universities in image processing course.

The exercises are based on improving the quality of the analyzed image, image segmentation and features finding of the objects such as: location, size, shape, average color or intensity etc. Based on these features, we performed counting identified objects, classification of objects etc. AVS allows to work on images acquired before starting the program and on images acquired in real-time for example from GigE vision cameras. Lite version of AVS is available free of charge at <https://adaptive-vision.com/>. The next Section provides a brief description of AVS and concept of programming in this environment. In Section 3 we present exemplary real-world problems and finally we conclude the paper in Section 4.

II. INTRODUCTION TO ADAPTIVE VISION STUDIO

AVS is a dataflow-based software designed for machine vision engineers. AVS does not require the user to have any experience in low-level programming. Nevertheless, it is a highly specialized tool for professional engineers and a fully-fledged visual programming language. It could be an ideal tool supporting education of future engineers. AVS facilitates the understanding of the basic computer vision algorithms, and allows them to quickly create complex projects.

Adaptive Vision visual programming is based on its 4 core concepts: Data, Filters, Connections and Macrofilters.

Data—AVS supports different data types starting from simple ones like integers, reals, by image-related types (Image, pixel etc.) to geometric ones. AVS also supports arrays, i.e. variable-sized collection of data items that can be processed together. For each data type, there is a corresponding array type. For example, just as 4 is a value of the Integer type, the collection 1, 5, 4 is a value of the IntegerArray type. Nested arrays are also possible. Filters—the basic data processing elements in the data flow driven programming. Figure 1 depicts a typical Adaptive Vision filter which usually has several inputs and one or more outputs. Each of the ports has a specific type (e.g. Image, Point2D etc.) and only connections between ports with compatible types can be created. Values of unconnected inputs can be set in the Properties window, which also provides graphical editors for convenient defining of geometrical data. When a filter is invoked its output data can be displayed and analyzed in the Data Preview panels (see Figure 2). It should be also pointed that some data types can be automatically converted at filter inputs (e.g., real and integer numbers to strings).

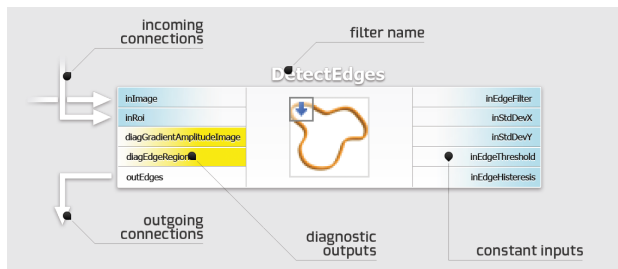

Fig. 1. Example of AVS Filter

Connections - transmit data between filters, but they also play an important role in encapsulating much of the complexity typical for low-level programming constructs like loops and conditions. Below are the types of supported connections and their symbols:

-  basic flow of data,
-  automatic data type conversions,
-  for-each processing—successive array elements are processed,
-  conditional processing.

Macrofilters—reusable subprograms with their own inputs and outputs. Once a macrofilter is created it appears in the

Project Explorer window and since then can be used in exactly the same drag-and-drop way as any regular filter. Most macro-filters (we call them Steps) are just substitutions of several filters that help to keep the program clean and organized. Some other, however, can create nested data processing loops (Tasks) or direct the program execution into one of several clearly defined conditional paths (Variant Steps).

AVS environment enables not only the graphic design of complex machine vision algorithms, but it is also a powerful tool for testing of developed solutions—all intermediate results can be viewed and analyzed, and parameters can be adjusted in real time as presented in Fig. 2.

Final solutions created in AVS can be exported to C++. The generated code uses Adaptive Vision Library and compiles to a native EXE file. Another option to use created program outside the studio application is export to run-time executable file which can be used with the special run-time module.

Although image analysis algorithms are usually the most crucial, a Human-Machine Interface (HMI, end-user's graphical interface) is most often also a very important part of a machine vision application, especially in the industrial setting. AVS comes with an integrated graphical designer, which allows for creating nice looking user interfaces in a quick and easy way. Its capabilities encompass composing highly customized "front panels", where the end-user will be able to set selected parameters and see or verify the inspection results.

AVS comes with a comprehensive set of powerful, ready-for-use image analysis filters. The library of image analysis filters that come with Adaptive Vision Studio can be described as composed of two sets:

- a set of well-known general image processing and computer vision algorithms,
- a set of ready-for-use tools specialized for industrial inspection systems.

There is a special type of filter in AVS commonly used in our examples, namely the **Formula** filter. A formula block makes it possible to write down operations on basic arithmetic and logic types in a concise textual form. Its main advantage is the ability to simplify programs, in which calculations may require use of a big number of separate filters with simple mathematical functions. Formula notations consist of a sequence of operators, arguments and functions and are founded on basic rules of mathematical algebra. Their objective in Adaptive Vision Studio is similar to formulas in spreadsheet programs or expressions in popular scripting languages. Below are two examples of the formulas used in the 'Vehicle Speed' application:

```
outToDraw = ( inSpeed > inMinSpeed )
             and ( inSpeed < inMaxSpeed )
             and ( inVehicleCenter.X > inMinX )
             and ( inVehicleCenter.X < inMaxX )
outSpeed =
    inDistance * ( 1 / inReversePixelSize )
    * inFPS / ( inFrames - 1 ) * 3.6
```

AVS includes a variety of powerful filters, but it is possible to integrate your own C++ code using so-called user filters if

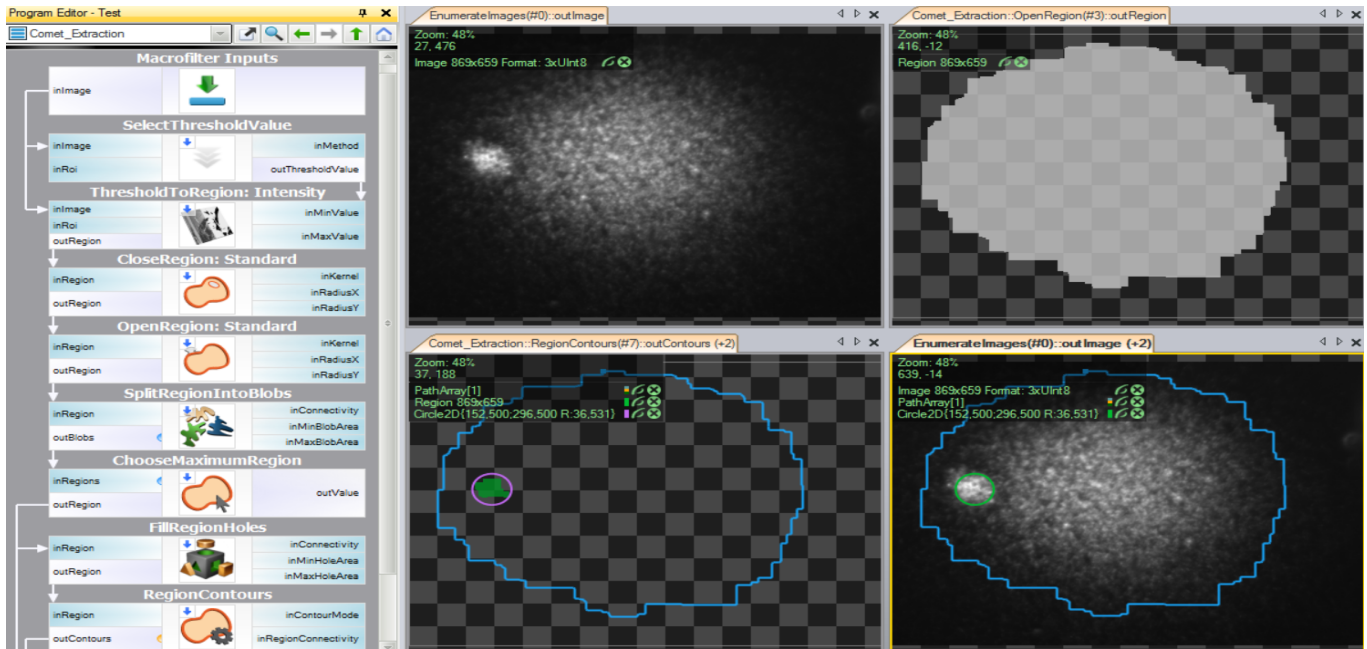

Fig. 2. A part of automatic comet extraction algorithm developed in AVS.

necessary.

III. PRACTICAL EXAMPLES OF LABORATORIES REALIZED IN ADAPTIVE VISION STUDIO

At our university, we realize some image processing courses for students in Automatic Control and Biotechnology with specialization in Bioinformatics. The introduction to image processing during an undergraduate course is realized in Matlab, but on master study, we propose the students to solve the real-life problems in their preferred image processing environment. For last five years, we have proposed the students to realize this laboratories in the AVS environment.

Below, we present three problems and our exemplary solution in AVS that are solved by students during the computer vision laboratories at master level curriculum.

A. Biomedical image analysis

The comet assay is a useful method for assessing DNA damages caused by different genotoxic agents described in [10]. The main aim in this problem is to properly localize the comet and segment its head, and measure some characteristics. The damage is quantified by measuring the amount of the genetic material, which migrates from the nucleus to form the comet tail. One of the most widely used comet's parameter is the percentage of DNA in the tail. It is calculated as the ratio between the total intensity of the tail and the total intensity of the comet (head and tail together). The foremost advantage of the comet assay is that it analyses individual cells, thus allowing the measurement of the heterogeneity of response within a cell population. The images used in this exercise were observed using a fluorescence microscope and gathered from Molecular Biology Laboratory at Silesian University of Technology.

Recently, several automatic methods of comets extraction have been proposed [11]–[14]. However, biomedical images are quite interesting for analysis due to their complexity and the students will become aware of difficulties connected with medical image analysis. To simplify the analysis, the images prepared for the laboratory exercise contain only single comet.

In this approach, we presented a two step solution, in which the comet regions are detected based on the simple thresholding methods. In the first step the comet is segmented using Otsu method and post processed using morphological operations. Then, the regions in obtained binary image are labeled and the biggest blob is chosen for later analysis. Finally, the possible holes are filled and the contour of the comet extracted. In the second step, the head is extracted in similar manner, but instead of Otsu method entropy based thresholding was applied only for pixels that belong to the previously selected comet ROI. A part of automatic comet assay analysis with temporary results in AVS was presented in Fig. 2. Exemplary results of properly detected comets and their head are depicted in Fig. 3.

B. Object detection and recognition

Object detection and recognition is one of the main tasks in computer vision systems. The objects may vary with regards to many features such as color, size, shape, texture, orientation, number of holes etc. [15]–[17]. The main goal of this exercise is: in static color images find standard six-sided red dice and recognize the number of white dots on a visible side using AVS software.

The images containing dice were acquired by a mobile phone camera in the resolution 2016x3584 pixels. Figure 4 shows two examples of these images and below enlarged

Fig. 3. Results of comet tail and head extraction.

details showing the dice. The background is simple gray, but the scene contains many objects that are not a dice, which makes the task more difficult. Some objects have similar color, area and shape. Also, the objects cast shadows and cause reflections which additionally complicates the task.

Fig. 4. Two samples of acquired images and dice in detail view.

The most characteristic features of the dice are color, shape and area. The dots located on a dice also can be characterized by color, shape and area. Students who solved the task proposed many different solutions. One of the best is based on several stages of image processing and based on knowledge about the seeking object. First, the area which may be a dice is found, and then in this area the dots are sought. The main application built in AVS is divided into four parts as shown in Fig. 5:

- **EnumerateImages**—scans a disk directory for image files and then returns the images one by one in consecutive iterations,
- **Dice_Segmentation** (macrofilter)—applies a threshold to the input image in *HSV* color space, performs morphological postprocessing, region labeling and classifies them by area,
- **Dots_Segmentation** (macrofilter)—operates in the region of interest (ROI) obtained from **Dice_Segmentation**, applies a threshold to extract almost white objects that can be the dots, performs morphological postprocessing, region labeling, classifies the regions by area and circularity features,
- **Results_Drawing** (macrofilter)—computes the number of dots, displays a string on the top of images presenting the number of calculated dots and draws a cross in the dice center.

The parameters and detailed view of each operation of used main macrofilters are shown in Fig. 6-7. For example, the dice region thresholding in *HSV* may be performed for $H = (200, 255)$, $S \geq 140$, $V \geq 40$ as shown in Fig 6, the dots regions must have circularity [18] higher than 0.42 and area belongs to the interval (34, 150) in pixels as shown in Fig. 7.

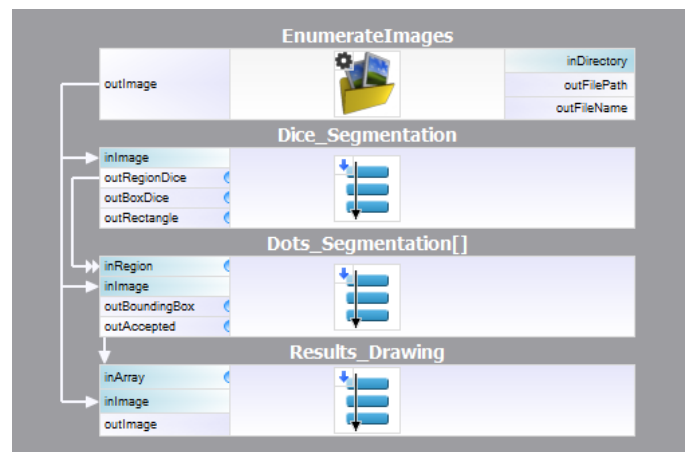

Fig. 5. Dice and dots detection main application.

The results for the four test images are shown in Fig. 8-9. In any case, the number of dots (5, 3, 6, 4) was correctly identified, also for different orientation of a dice in relation to the surface (Fig. 9—5 dots). The proposed solution is not sensitive to shadows and light reflection. Sometimes, the

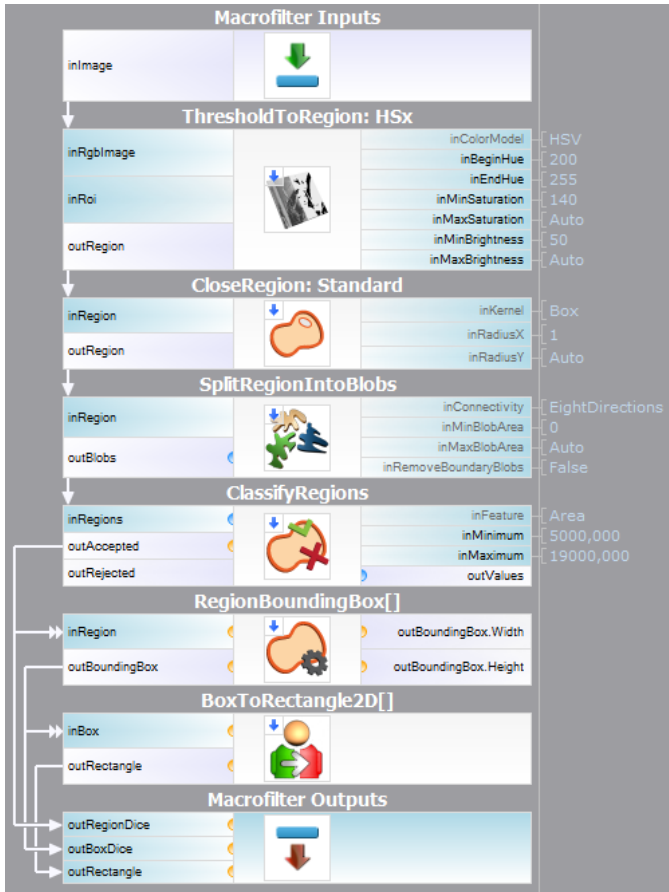

Fig. 6. **Dice_Segmentation** macrofilter—detail view with parameters.

initially segmented area of the dice is too large (Fig. 9—4 dots), but the second Dots_Segmentation macrofilter locates the dots in the right place and the center of the dice is correctly set. The test images in this task are quite difficult. In practice, in computer vision systems, the background is usually much simpler and lighting is better.

C. Video sequences processing

In practical applications, instead of performing operations on individual images, more often it is necessary to process video sequences, taking into account the relationship between successive frames. For this reason, modern automatic control engineer should have basic knowledge and skills for such operations.

During the computer vision courses conducted at our university, the students solve the problem of measuring the speeds of vehicles based on the sequence of surveillance cameras using the AVS environment.

The main issue to be solved in this task is the correct segmentation of moving objects. In this work, a hybrid version of background subtraction and thresholding of temporal frame differences was used. In this solution, the attempt was made to make the system insensitive to scene selection and environmental changes, so the running average background adaptation

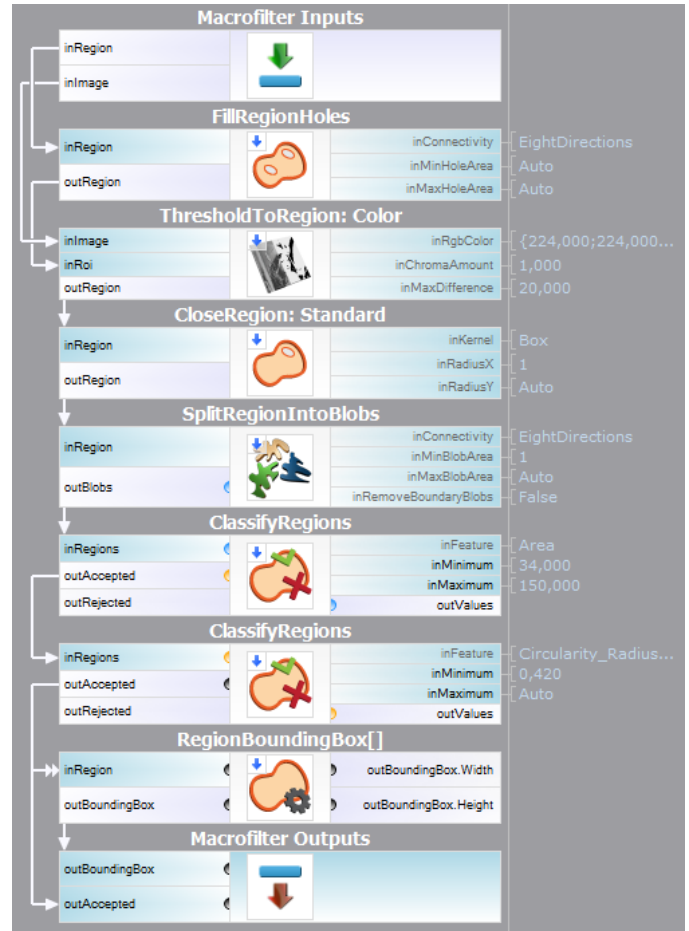

Fig. 7. **Dots_Segmentation** macrofilter—detail view with parameters.

model was used [19]:

$$B_{i+1} = \begin{cases} \alpha F_i(x, y) + (1 - \alpha) B_i(x, y) & \text{if } F_i(x, y) \in \text{Background} \\ B_i(x, y) & \text{if } F_i(x, y) \in \text{Foreground} \end{cases} \quad (1)$$

where F_i and B_i denote the current video frame and the background image, respectively, α is the learning factor, typically $0.05 \dots 0.1$.

The analyzed problem can be divided into several tasks that are reflected in the logical structure of the program which is shown in Figure 10.

- **Read_Video**—reads a frame sequence from a video file and generates main program loop (could be replaced with camera acquisition block).
- **Preprocessing** (macrofilter)—performs filtering and color to gray-scale conversion.
- **Background_adaptation** (macrofilter)—one of the two main tasks for this application, performs background detection and adaptations based on equation 1, detailed macrofilter diagram with parameter used is presented in Figure 1. It should be noted that *Background* variable is passed between consecutive iterations by special AVS structure called *register*.

Fig. 8. Results of dice detection and number of dots calculation.

Fig. 9. Results of dice detection and number of dots calculation.

- **Vehicle_detection** (macrofilter)—segmentation of moving vehicles based on background subtraction combined with thresholding of temporal differences and region morphological processing (Fig. 12).
- **Speed_calculation** (macrofilter)—computes vehicles speeds based on their displacement between consecutive frames, scaled based on real length of observed area (Fig. 13). This macrofilter uses a typical filter for video processing **LastObjects** which aggregates objects between consecutive program iterations. The main

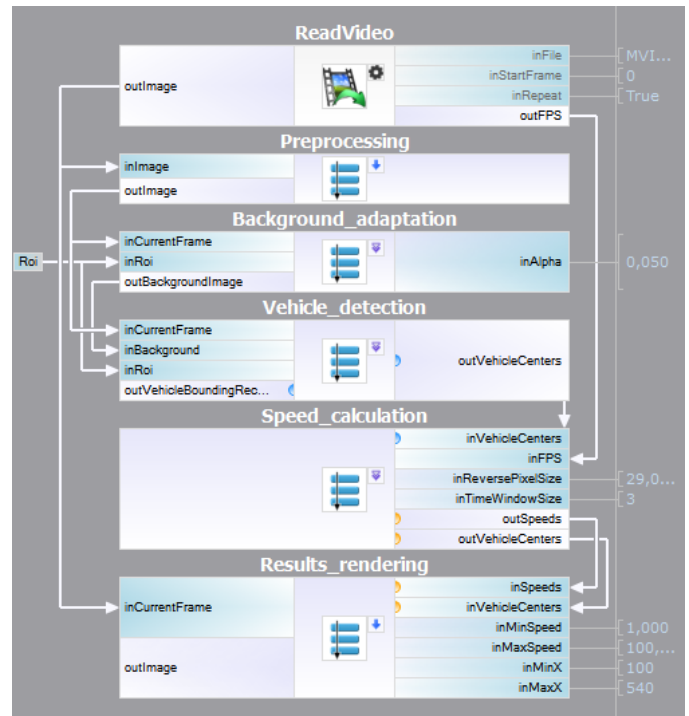

Fig. 10. Vehicle Speed—main application.

problem encountered in this task was to match the corresponding points in successive frames belonging to the same vehicle. The proposed solution is based on the special data structure of paths, available in AVS environment which allows grouping adjacent paths and direct path length calculation.

- **Results_rendering** (macrofilter)—renders speeds of tracked vehicles on the input frames with some restrictions (only valid speed values near the frame center are displayed).

In order to improve the efficiency and robustness of the proposed solution, image analysis is limited to the preselected region of interest (ROI). Adaptive studio supports any-shape ROIs in majority of image processing filters, so we can fit ROI to cover only the road area. The ROI mask used in our solution is shown in Figure 14(a). Examples of velocity measurements are shown in Figure 14(c) and the visualization of detected vehicles in Figure 14(b). Detected objects are visualized using the built-in AVS features, which allow presenting graphical objects such as blobs, rectangles, paths, etc. in the form of overlays in the output image. Verification of the accuracy of speed measurement is not fully possible, however, on the basis of comparative tests, we can assume that the results are reliable. Tests carried out on several video sequences show that apart from a few exceptions, the detection of moving vehicles is running flawlessly. In addition, it is possible to fine-tune the parameters of the algorithm so that the results were even better.

However, the presented solution is still not complete, e.g., there is no analysis of occlusions and due to the small area

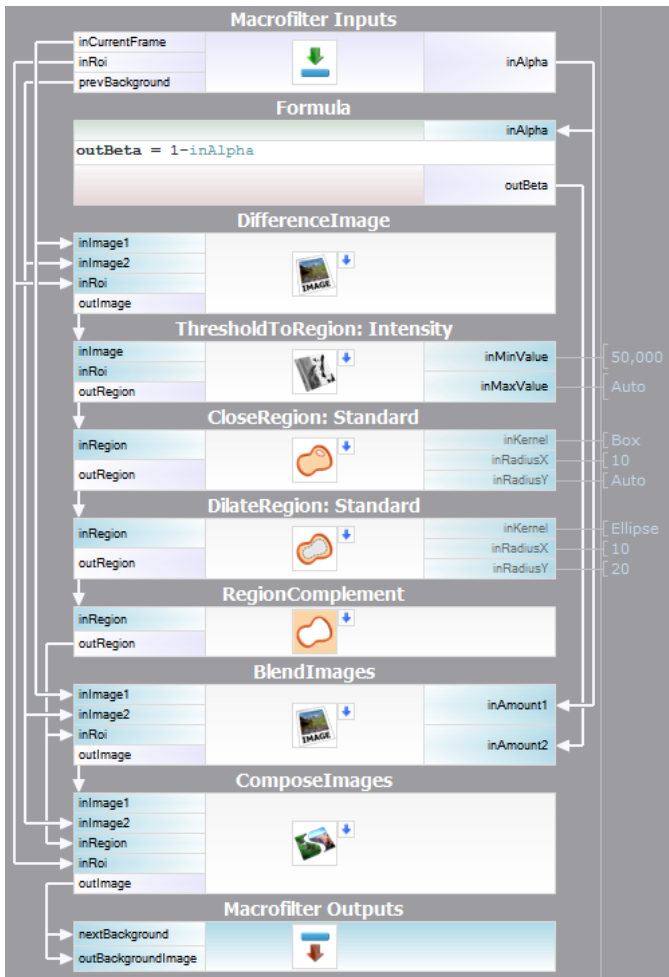

Fig. 11. **Background_adaptation** macrofilter.

covered by the camera, it is not possible to measure the speed of large trucks.

IV. CONCLUSIONS

Most students enjoy the visual nature of the project and were surprised that they could write a program to accomplish so much after just one programming course. A few students wrote very creative programs within the time limit of a single laboratory (1.5 hours) without any previous knowledge of AVS.

The effectiveness of using this software in teaching image processing was evaluated in several steps. First, a student at introduction laboratory has to work in a new environment, but on later laboratory exercises the students have the possibility to use other programming software that they have used in the previous courses, such as Matlab or OpenCV in C++. All students choose the AVS as they environment to work. We also ask about their experience in using this software and they outline its simplicity and easiness in viewing the temporary results of image processing steps in their application. The students were also confident that the exercises have more practical form and will be more useful for them in their future

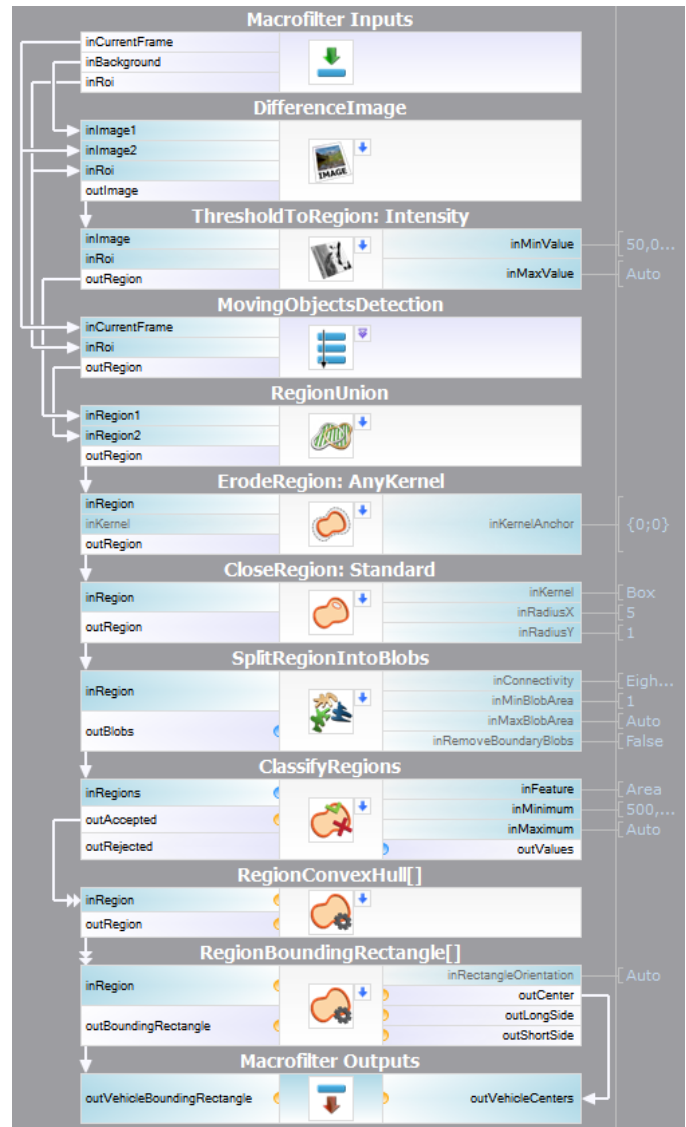

Fig. 12. **Vehicle_detection** macrofilter.

work. These facts prove that the proposed AVS studio can be effectively used in image processing learning process.

Another advantage observed by the teachers was the fact that students were able to realize more exercises during the laboratory time. When these exercises were realized in Matlab environment, the students very often have to finish their work at home and present their work in the form of a laboratory report. It sometimes causes some plagiarism in their work, but now their work is evaluated during the laboratory and this issue is not observed any more. The students were also more engaged in their work and the solutions of the proposed problems are more creative than those created in Matlab.

The main assumption is that the students have a basic knowledge about digital image processing and are familiar with the idea of algorithms and their possible applications. However, in our opinion it can be an ideal software for demonstrating the practical aspects of computer vision algo-

ritms even for students not familiarized with programming, such as those who study biotechnology, chemistry or biology. Using AVS, the students also can quickly and thoroughly understand the operation of advanced algorithms without the need of implementing them. The students focus on proposing a ready solution to the problem, which increases their creativity. Last, but not least, the AVS software is a powerful complete environment which can also be successfully used for learning machine vision engineers.

Abstract - Recently, a brand new instructional system named the electronic dual-board (EDB) was created and put into practice in China. To find out the opportunities and challenges of the system in the instruction, the research was conducted in a primary school and a university from March to June in 2013. The results indicated that most of the participants' attitude towards the EDB was positive. Especially, the primary school students preferred to attend the class with the EDB. However, there were some technical problems in the EDB. Moreover, using the EDB, the teacher should face up to some challenges, such as how to create the new resource, how to adjust the teaching plan and how to carry out teaching design. In order to make full use of the EDB, the suggestion of using the system was collected from both the students and teachers in the end.

Index Terms –evaluation of CAL systems; interactive learning environments; country-specific developments; elementary education; adult learning

INTRODUCTION

During the rapid progress in the application of information technology in education, new instructional systems were introduced into the classroom constantly to improve the effect of instruction. Recently, a brand new instructional system which was based on dual coding theory was invented. The system was called the Electronic Dual-Board (EDB) which consisted of a control center, two electronic whiteboards and a suite of software for editing and presentation. Its main functions included presentation, writing, drawing graph, highlighting, annotating, drag-and-drop activities, screen shade, zooming and the introduction of digital resources made the teaching colorful. It looked like the interactive whiteboard (IWB), but it was different from the IWB in many aspects. For instance, with two whiteboards the area of presentation was enlarged, which could support presentation of different contents at the same time. The content of text and video corresponding to the same topic, or the current page and the former page in PowerPoint (PPT) could be rendered simultaneously. Moreover, the specific software and hardware of the EDB were developed to enhance the functions of edit, presentation and interaction.

Since April in 2011, the EDB has been put into practice in a primary school named No.1 Chang-Qing primary school. This system was also introduced into other primary schools and high schools such as the affiliated middle school of Central China Normal University and Tibet high school. Besides, the system was practiced in some universities in

China, including the Central China Normal University, Hubei Normal University etc. Because the EDB was a brand new instructional system, the teachers and students might have encountered many opportunities and challenges when they used the system. But to our best knowledge, the most research focused on the using pattern of the EDB. However, the challenges and opportunities of using the system had been an open issue left.

Facing the music, the research was proposed to analyze the opportunities and challenges of the EDB by employing the interview method. Throughout half a year more than twenty-four students and ten teachers were monitored and investigated in a primary school and a university. Actually there were really many challenges and opportunities that the teachers and students faced when they used the EDB in their classes.

The rest of the paper is organized as follows: the related works on the EDB and The IWB are presented in section 2. The scheme of the research is rendered in section 3. The findings and discussions are described in section 4 in details. Section 5 concludes with a summary and future research plans.

RELATED WORKS

Basically, the literature related to the EDB could be divided into two categories. One was to discuss the design and realization of the EDB from the perspective of technology. The other was to find the effective pattern of teaching and learning from perspectives of teachers and students.

With the development of two-track teaching mode, the dual-split screen device started to apply in classrooms because it can support various display modes easily. Yang (2012) launched the dual-split screen device design research. It was proposed that the overall design of the framework as well as specific implementations from the actual application needs.

Wang (2011) discussed how to conduct “Dominant-the Main” in the EDB environment. With combining theoretical and empirical research, “Dominant-the Main” teaching mode was integrated into the EDB environment. Zhang (2012) focused on how to design, implement and analyze Clicker, an interactive tool of the EDB, assessment project. Based on case studies of electronic boards and Clicker, the paper pointed out an overall strategy about designing Clicker classroom assessment in the EDB environment.

The research of the subject-related teaching and learning with the EDB had been conducted by other scholars. For instance, Wu (2012) presented functions and characteristics of the EDB. Then a Chinese lesson was designed by utilizing this platform and discussed the applications of the EDB in the Chinese subject. Similarly, Du and Lu (2012) investigated the EDB application in the subject of history

and put forward to three pieces of advice about using this platform. That was to define the teachers' position, manage properly the process of instruction and "act according to actual circumstances" in instructional design.

Due to the lack of literatures related to the EDB until now, the works on the IWB were reviewed in this part as well. Over the last decade, the IWB had been applied in many countries such as Australia, Italy, Mexico, the Netherlands, New Zealand, Turkey, the UK, and the USA. Specifically in the UK, the government invested a huge amount of money in the IWB in 2004 because the government was in the belief that their use in the educative process would raise attainment among British school children (Hall & Higgins, 2005). In order to support the use of the IWB, they even set up the national whiteboard website and gave teachers more assistance in the resources and technologies.

Numerous studies mostly focused on investigating the use of the IWB in classroom environments. These studies addressed the issues from a variety of perspectives. For example some focused on the use of the IWB in particular subject areas (Glover, Miller, Ave-ris, & Door, 2007; Merrett & Edwards, 2005); some paid more attention to teachers' perspectives (Loveless, 2003; John, 2005); and others minded learners' perspectives (Hall & Higgins, 2005; Wall, Higgins, & Smith, 2005).

Bruce and Rose (2010) conducted a treatment/control research. The main aim of this research was to determine the extent to which the use of interactive whiteboard technology was associated with upper elementary students' self-reported level of motivation in mathematics. A similar research was carried on in Turkey for determining the attitudes and evaluating the views of 10th grade students towards the IWB in mathematics classes, which was a part of a quasi-experimental research (Tataroglu & Erduran, 2010). In this research, qualitative and quantitative data were collected. The research revealed that students were positive toward using the IWB in classroom.

Moloney (2011) discussed instruction of Chinese subject under the environment of the IWB. The research verified the IWB could provide help for all aspects of Chinese learning through organizing and implementing instruction in the high schools in Sydney, Australia (Moloney, 2011).

Sad and Ozhanb(2012) designed an empirical approach to investigate the views of primary students about the use of the IWB in their classes from attitudinal and pedagogical perspectives (Sad & Ozhanb, 2012). The research conducted group interviews to fifty primary students who had about two years of experience regarding the use of the IWB in their lessons. Results showed that the students like instruction with the IWB. Aydinli and Elaziz (2010) investigated the use of the IWB in the field of foreign language learning in Turkey. The conclusion indicated the vast majority of students had positive attitudes and perceptions towards using the IWB in their courses (Aydinli & Elaziz, 2010).

Bakadama et al. (2012) designed a questionnaire including ten items to identify the teachers' perceptions about the benefits of using the IWB in instruction. The research combined qualitative and quantitative approaches. The questionnaire was distributed to fifty teachers, and three teachers were interviewed. The result of the research revealed that the majority of teachers use the IWB as an

overhead projector and for internet research but they did not make use of the many other advanced s features of the IWB (Bakadama & Asiri, 2012).

SCHEME DESIGN

In order to find the opportunities and challenges that the students and teachers faced up to when they used the EDB, an empirical approach was conducted which involved interviewing the students who took part in the class with the EDB and the teachers whose duration of regular teaching experience with the EDB was no less than one year. By analyzing, summarizing and sorting the results of the interviews, this paper aimed to give a comprehensive description of authentic experiences in terms of the opportunities, problems, challenges, and suggestions.

✧ Interview outline design

A series of semi structured interviews was designed in the research. The interviews focused on the teachers' and students' overall attitudes and views towards the usage of the EDB in their classes during the past and current semesters. Four open-ended questions were prepared for the interviews to guide the interviewees and to probe into the participants' views deeply. Due to the different role of the teachers and students, some questions were divided into different pieces according to the role. Reference to the subjective evaluation of the image, the scale for some answers was defined to make the numerical analysis. The specific questions were as follows:

- 1) What were your attitude towards the instruction with Electronic Dual-Board. (One a scale of 1-5, rate the attitude towards the EDB. 1 being rejection, 2 being indifference, 3 being acceptance partial, 4 being acceptance full and 5 being preference) (for both teachers and students)
- 2) What were the advantages of Electronic Dual-Board compared to the traditional blackboard or interactive whiteboard when you were teaching or learning? (for both)
 - 2.1) What was the convenience that the EDB brought to you? (for teachers)
 - 2.2) Could the EDB have some impact on motivating your interest in learning? (One a scale of 1-4, rate the degree of interest motivation. 1 being negative, 2 being no impact, 3 being a little, 4 being remarkable) (for students)
- 3) What were the disadvantages of Electronic Dual-Board in the actual instructional process? (for both)
 - 3.1) What were the barriers when you organized a class with the EDB? (for teachers)
 - 3.2) Did the EDB have some side-effects on you when you attended the class with the EDB? (One a scale of 1-4, rate the number of side-effect of the EDB. 1 being zero, 2 being less than 2, 3 being less than 4, 4 being more than 6, 5 being lots of) (for students)
- 4) What suggestions would you propose to improve course instruction and enhance students' engagement in classes with Electronic Dual-Board? (for both)
 - 4.1) Provided your suggestion had been accepted and realized, would you like to keep on teaching with the EDB? (for teachers)
 - 4.2) what would be your attitude towards the EDB if your suggestion had been accepted and realized? (One a scale of 1-5, rate the new attitude towards the EDB after suggestion accepted. 1 being rejection, 2 being indifference, 3 being

acceptance partial, 4 being acceptance full and 5 being preference) (for students)

To smoothly carry out this interview and collect effective data, it was necessary to design interview outline. According to each question, some guided words were provided. For example, to the second question, Screen Lock, N-Function, Dual-track teaching, Serialization of the teaching process design, and supporting multiple teaching methods were offered to inspire the interviewees to think of the question completely.

✧ Participants

Sampling for this research was divided into two steps. First, according to a purposive sampling approach, two schools, the No.1 Primary School of Chang-Qing and Central China Normal University, were selected. The participants included the students and teachers who had more than one year of experiences in learning and teaching with the EDB. Next, based on random sampling, the final interviewees were selected from the candidates of teachers and students in step 1. Ten teachers and twenty-four students from the two schools participated in this research finally. In the teacher group, three of them were primary teachers (teachers in the No.1 Primary School of Chang-Qing) and the rest teachers were from the Central China Normal University. In the student group, half of the students were from the No.1 Primary School of Chang-Qing. They were divided into two groups. One was from year 4 and the others were from year 5. There were 12 students from the Central China Normal University. Similarly, they were divided into two groups randomly with equal members.

✧ Data collection and analysis procedures

In order to collect rich data, focus group interviews were utilized instead of individual interviews. Focus groups can be used “to gain unique insight into existing beliefs, behaviors, and attitudes” (Byers & Wilcox, 1991, p. 71). The interaction focus groups provide high quality data in a social context where people can consider their own views by hearing the views of others (Fraenkel et al. 2012; Patton, 2002). Thus one can “promote talk on a topic that informants might not be able to talk so thoughtfully in individual interviews” (Bogdan & Biklen, 2007).

At the beginning of the interview, we introduced the purpose of the interview and told the interviewees what they should talk about. We played the role of a moderator and interviewer. We not only needed to open ears to the words what the interviewees said but also guided the interviewees to clarify their answers. It took at least 50 minutes for every interview.

Besides, the details of these interviews were recorded by using a recorder pen to identify and analyze commonalities throughout the interviews. After the interviews, we transcribed and sorted the results into four themes. In order to summarize the contents of the recording, we listened to the recording again and again, constructed and named categories to capture some recurring contents. Based on the inductive approach, the categories mentioned would be grouped in the four themes. Then, the numbers about each category were counted. The categories would be ordered by the statistic numbers from the most frequency to the least.

FINDINGS AND DISCUSSIONS

From March to June in 2013, six interviews were held and ten times of the class with the EDB were participated in to observe the usage of the EDB. The example of a class employing the EDB was shown in Figure 1. Figure 2 indicated the presentation interface using software of the EDB.

Figure 1 A Class Using The EDB

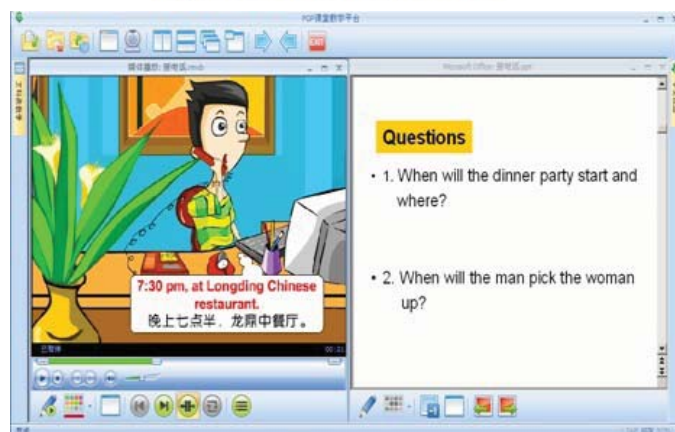

Figure 2 Presentation Interface of The EDB

Six audio files of the interviews and three video files about the classes with the EDB were collected. After distilling and analyzing the data, we generated the following results.

✧ Attitudes towards the instruction with the EDB

The students' attitude to the EDB was shown in figure 3.

Figure 3 Attitude towards The EDB

Most of the participants' attitude towards the instruction with the EDB were very positive. Especially, the primary students stated that they wanted to have classes with the EDB extremely compared to the traditional classroom with blackboard. They thought the classes with the EDB were interesting and efficient. For the university students, they remarked that they were able to accept the EDB completely.

For the teachers, one of the primary teachers said that he could accept the EDB. However, when he was asked whether he would like to continue to teach with the EDB, he stated that the difference between the EDB and the IWB was little ["If I can use the IWB properly, the IWB can also enhance our teaching efficiency. Why should I change to the EDB"]. The other teachers expressed that they would like to proceed to organize the classes with the EDB.

✧ *Advantages of the EDB compared to the traditional blackboard or the IWB*

The analysis revealed the basic categories of the advantages of the EDB. The categories were listed in Table 1.

Table 1 Advantages of The EDB

Categories	Numbers of references				
	University Teachers	Primary Teachers	Under-graduates	Primary Students	Total
Double-screen display	4	2	5	6	17
Facilitate learning	2	2	6	2	12
Better visual presentation	0	1	3	4	8
Total	6	5	14	12	37

The most mentioned advantage about the EDB was the double-screen display including N-1 Function, Lock screen and Dual-track teaching. The N-1 Function was referred to as that current page of courseware (such as courseware of PPT) was shown on one of the two boards. The previous page was shown on the other board at the same time. The contents of the two boards were relevant. Four university teachers stated that they often used this function. Some undergraduate students also praised this function. Additionally, in the process of teaching, when you (who is 'you'?) needed to show the details of the structure or content about some knowledge, you could use the "Lock screen". When you locked the screen of content, the courseware could proceed on the other board. ["I like to use this function of the EDB in the process of teaching structures of plant."(a primary school teacher)]. In the opinion of students, in this way they could have an entire understanding of knowledge and promote the construction of knowledge. ["Dual-track teaching is not only beneficial to our research, but also saves time and improves teaching efficiency. So, we can learn more knowledge." (the primary school students)]. The Dual-track teaching mode based on the dual coding theory means that teaching contents are presented in the form of double-picture, which can promote the learner's brain language system and non-verbal reinforcement for the reception of information. According to the theory, the left and right sides of the EDB could exactly present relevant contents at the same time.

The second most outstanding advantage mentioned was to facilitate learning. Some of undergraduates highlighted that on the one hand, it was convenient for them to take notes. On the other hand, by comparing the relevant knowledge, it was helpful for them to understand and remember what they were learning. Moreover, the function of the geometry sketchpad could draw the regular graphics, avoided the limitations of traditional teachers' freehand graphics such as inaccuracy. In addition, a few students said that the teachers' writing on the EDB could be saved as it was required, which were good for them to review after classes.

Additionally, a few students referred to as that the form of the EDB to present resources was no longer a monotonic projection screen. Two boards enlarged the space of presentation and allowed a variety of related teaching resources to be accessed at the same time. Several college students mentioned that using the EDB to watch courses with videos was better than using the projection. Moreover, the one side of the EDB could play the video, and the other side could present the corresponding text, which mobilized their left and right brains fully. In this way they not only understood what they were learning but obtained more knowledge to expand their horizons.

Besides the advantages of the EDB in instruction, the degree of interest motivation was investigated. The results were depicted in figure 4.

Figure 4 Degree of Interest Motivation

Based on the results, it was concluded that most of the primary students thought the EDB had impact on the studying interest significantly. And most of the university students thought the impact was a little. Therefore the EDB could have influence on studying interest to some extent.

✧ *Disadvantages of the EDB in the actual instructional processes*

The analysis of the data revealed basic categories about the disadvantages of the EDB in the actual instructional processes. Specific categories were listed in Table 2.

Table 2 Disadvantages of The EDB

Categories	Numbers of references				
	University Teachers	Primary Teachers	Under-graduates	Primary Students	Total
Writing questions	7	3	5	3	18
Technical problems	4	1	2	2	9
Resource constructions	1	3	0	0	4
Health problems	0	2	0	0	2
Total	12	9	7	5	33

The disadvantage mentioned most about the EDB was writing problem. If the pen was not in the precise position, the writing was delayed and not fluent. The interviewees, almost all, believed that the writing function of the EDB was a barrier for the classes owing to its insensibility because the board writing was the necessary for a class. Therefore, the writing problem degraded the effect of the EDB in classes remarkably. ["In the math or similar courses, the formula and calculation occupies a large proportion. So the writing is an essential part. Once the writing problem appeared, the class would not be able to continue" (a university teacher)].

The second most mentioned disadvantage was the technical problems category. The teachers were annoyed with the

interruption and inefficiency caused by technical problems. In general, the technical problems consisted of software and hardware problems. For example, the software was lack of minimum function ["The software has no function of minimum, so the teacher cannot run other programs on the computer simultaneously. It isn't comfortable." (a university teacher)], the system shut down inexplicably ["When the system collapses, the teacher must restart the computer. To do so, it is not only to waste the time, but also to distract the students' attention. It is not good for teaching" (a undergraduate student)], the arrangement of wire for the EDB was outside, which might cause many evitable troubles ["The outside wiring are harmful to students. Moreover, it is easy to appear problem" (a primary school teacher)].

Resource constructions were mentioned many times in the interviews. It was referred to as that there were few matched resources for the EDB. Though the dual board was very convenient for making courseware and supported many types of resources, many teachers still felt difficult to create resources by themselves. Some teachers believed resource constructions had to be considered ["Not all teachers master the skills of creating resources. For them it is a waste of time to make resources oriented to a specific platform." (a university teacher)].

The health problems to use the EDB was another minor but very important category. Some teachers felt that it was not good to look at screen for a long time ["When the students watch the screen for a long time, it is likely to have side effect" (a primary school teacher)]. Previous research also reported primary school students' concerns about the similar health problems caused by the IWB including "headaches, sore eyes, and epileptic fit" (Wall et al, 2005).

Besides the disadvantages investigation, the degree of inconvenience of the EDB was investigated. The results were shown in figure 5.

Figure 5 Number of Side-effect

Based on the investigation, it could be concluded that most of the primary students thought the number of side-effect of the EDB was less than 2, and most of the university students thought the number of side-effect was more than 3. It could be found out that there were certainly a few side-effect brought to the students by the EDB.

✧ suggestions for improving instruction with the EDB

At the end of every interview, the interviewees were asked for some suggestions for improving course instruction with the EDB. Resulting categories were listed in Table 3 from the most frequency to the least across the different interviewees.

The top suggestion given by the interviewees was to splice the two boards seamlessly or reduced the gap between them. On the one hand, the technique of seamless splice had been

achieved in other fields. On the other hand, the seamless splice was convenient and helpful. Some teachers believed it would help to teach ["Only in this way, it is the perfect combination of single and double board. Teachers have the right to choose the use form of dual board based on the teaching design."(a university teacher)]. Some students agreed with this idea and highlighted the change would offer the better visual effect ["If we are in a big classroom, the characters on the each board are too small to see when we are at the back of the classroom. So, decreasing the gap between the two boards will enlarge the space of presentation, and sometimes we can use them as a single big board" (a undergraduate student)].

Table 3 Suggestions towards The EDB

Categories	Numbers of references				
	University teachers	Primary teachers	Under-graduates	Primary students	Total
seamless splice	5	1	5	2	13
Auxiliary blackboard	4	2	2	0	8
Matched resource	2	3	0	0	5
Training teachers and students	0	2	1	1	4
Total	11	8	8	3	30

The second most proposed suggestion was to add an auxiliary blackboard. Many interviewees, especially the science teachers, thought the dual board could not be the substitute to the blackboard completely. A dual board was not suitable for all the situations in a class ["Like science course, formulas appear more frequently. Many formulas need to write during teaching, but not to just show by the PPT. Though blackboards are regarded as the traditional medium, we have got used to them. Why should we change?" (a university teacher)]. In addition, some courses of arts also needed to combine the dual board with the blackboard ["I have learned paleography course, the teacher writes ancient words on the dual board. These words look very weird. If he can write on the blackboard, the result will be much better. And those words are marvelous on the blackboard"(Undergraduate)]. Because the EDB was still at the initial stage and it was not suitable for all the circumstances as well, combining two boards could be helpful.

Providing more resources was another important suggestion. Many teachers felt difficult to design lessons using the EDB ["When teaching with the dual board, we need the resources supported. However, the dual-board provides limited resources. So, we must create them by ourselves. But doing it all by ourselves is difficult and unrealistic"]. With the matched resources, teachers could concentrate on the teaching design.

At last, several students believed training on how to use the EDB should include both teachers and students. In a class, interaction was very important. If students did not know how to use the EDB, troubles would appear in interaction. ["If we ask a few students to show their ideas on the dual board, we will have to teach them the correct way of using it.

Otherwise, incorrect operations are a waste of time or cause the crash of the system” (a primary teacher)]. The students accepted new things faster than some of teachers and they might help teachers to use the EDB in classes. Therefore, it was necessary to provide EDB training for students as well. Besides the collection of the suggestion for using the EDB, the attitude towards the EDB had been investigated again if the suggestion should be accepted. The results were shown in figure 6.

Figure 6 New Attitude towards The EDB

Based on the investigation, it could be found out that the attitude of the university students was changed obviously. Most of them thought they would accept the EDB fully, even prefer to using the system if the suggestion had been taken. And most of the primary students prefer to taking the class using the EDB. Therefore, It could be foreseen that the EDB would have a bright future in instruction if some improvements should be made.

CONCLUSIONS

The purpose of this research was to analyze the opportunities and challenges of the EDB. The results indicated that the students' and teachers' attitudes towards the EDB were positive because the system was convenient for teaching and learning, because of the features of double-screen display, learning facilitation, and better visual presentation. However, many challenges of the EDB should have to be overcome, such as the writing problem, the technical problem, and lack of the resource, if the EDB should spread over China even more widely. In addition, the suggestion had been collected to improve the course instruction with the EDB. In the next step, some researches will be conducted to find out the solution to the other challenges, such as what on earth shall be prepared for, how to adjust the teaching plan, how to carry out teaching design and how to intervene in the teaching process.

Abstract— Flow Visualization is both the practice of making fluid physics visible and a course that focuses on the practice of making those images, as short video and stills. Since 2003, this course has been cross-listed as a mechanical engineering elective and a fine arts studio course, and brings together mixed teams of engineering and fine arts photography or film students. With its focus on the production of aesthetically pleasing and scientifically useful images of fluid flows, it is one of the few course offerings that explicitly calls upon engineering students to use an aesthetic sense in their studies. In prior work, this course was associated with a positive shift in affect toward fluid flows, which we measured through the Fluids Perception Survey (FluPerS) [1]. In the same survey, students expressed a greater awareness of fluids. This outcome was in contrast to the survey results from Fluid Mechanics, a traditional engineering core course, with a highly analytic, mathematical approach. Exit surveys of students in Fluid Mechanics reveal a negative shift in affect, which is typical of other technical courses, with no comments about awareness of fluids. The increased awareness of fluids can be termed an expansion of perception – when learners see everyday objects, events, or issues through the lens of the content [2]. Expansion of perception is often associated with deeper conceptual understanding and the ability to transfer learning to new settings. Building on the prior survey work, we conducted interviews with students from Flow Vis, both engineering students (n=4) and art/film students (n=5), in addition to Fluid Mechanics students (n=3), at the beginning and end of a semester. Their comments, along with open responses in the survey (n=86), are being analyzed using an iterative process to develop an emergent coding scheme. We want to discover what about Flow Vis helps students, both from engineering and art, internalize and apply their understanding of fluids. What role does the emphasis on aesthetics, so familiar to the art students, so uncommon in coursework for the engineers, play? Finally, how can we adapt the teaching practices from Flow Vis for other courses, other content areas? Analysis of data and future course suggestions are discussed.

Keywords—aesthetics; flow visualization; fluid mechanics; pedagogy; perception; student engagement; transformative experience

I. BACKGROUND AND SIGNIFICANCE

Student engagement has been found to be a complex problem, relating to multiple constructs such as motivation, goals, self-efficacy, and emotion or affect [3]. As a result of this complexity, engagement is often assessed broadly, using data such as persistence in a major or degree attainment as proxies. Yet, we know that constructs like engagement are

impacted at the course level. In particular, technical courses in math and science tend to cause a negative shift in affect [4]–[8]; students emerge from a course less interested in the content than when they began, and they report believing the content less useful and less important. This effect is largely immune to varying pedagogy. To investigate the content-related shifts in affect, we use a lens called the transformative experience.

The transformative experience is a learning experience with three hallmarks. Students: 1) apply course content in everyday life without being required to (also called *motivated use*); 2) see everyday objects or situations differently, through the lens of the new content (*expanded perception*); and 3) value the content in a new way because it enriches everyday affective experience (*affective value*) [2]. The transformative experience stems from John Dewey’s seminal theory of experiential learning, and is influenced by his work on the value of aesthetic experiences [9], [10]. In brief, we want students to be able to perceive concepts they have learned in the larger world, put those concepts to work, and derive meaning or satisfaction from that experience.

While prior studies have cataloged a wide range of influential student characteristics both extrinsic and intrinsic [11], aesthetics and perception have not been considered. Our broad investigation of the impact of aesthetics and perception on student learning was prompted in part by unsolicited student comments such as “I’ll never ignore the sky again” or “I see examples of flow vis all the time now.” The present investigation centers on the course that elicited those student remarks, Flow Visualization (Flow Vis), and demonstrates the utility of the Deweyan transformative experience as a framework for capturing aesthetics and perception.

II. COURSE DESCRIPTION

Flow Vis brings together engineering and fine arts photography or film students to produce aesthetically pleasing and scientifically useful images of fluid flows. This includes both undergraduates (mostly juniors or seniors) and graduate students. Engineering majors use the course as a technical elective, and the art/film majors count it as part of a studio requirement. There are typically 40-50 students in the class, which has been offered annually since 2003. Figures 1 and 2 show sample images from the course.

Some sessions are lecture-oriented, especially early in the semester, when topics include imaging basics, light-matter

This material is based upon work supported by the National Science Foundation under Grant No. EC-1240294.

interaction, and fluid mechanics. Later class sessions focus on students presenting their work. There are six projects over the course of the semester that can be still photographs or short videos. For the first assignment, students work independently,

Fig. 1. Image by student Trevor Beatty; Food dye exhibits the Rayleigh Taylor instability, forming toroidal vortex rings in a mirrored image, 2013.

partly to demonstrate the challenge of controlling a flow while documenting it visually. Students also independently photograph cloud formations throughout the semester for two assignments. Aside from the cloud images, the only specification for image content is that it must document fluid mechanics. Students are assigned to teams using CATME [12] to share resources and expertise for the last three assignments. For each team assignment, students have individual creative control of their images, while supporting teammates.

The images are presented during class. The professor and other students comment on the image. To foster honest, encouraging critique and ensure all students participate, students may bring their laptops and can log in anonymously to offer comments. Discussion spans fluid physics and aesthetics. The professor often supplies keywords that can be used to research the phenomena present in the image.

The written explanation of the image is due one week later. In one to four pages, students provide the context for their images such that someone else could attempt to re-create them. The paper includes apparatus, materials, and photographic techniques used, and an explanation of the phenomenon demonstrated. Art students write generally about the physics involved, while engineering students should estimate the appropriate non-dimensional properties (such as the Reynolds number) and provide time and spatial resolution based on flow speed and field of view. All students are expected to cite references. Graduate engineering students cite technical, refereed literature and write at a professionally publishable level.

The course culminates in a show in the Engineering Center lobby. Students are encouraged to submit their work to various competitions, and their work is displayed on the course website (www.flowvis.org). The grading standards emphasize taking

each assignment seriously (including the written explanation), collaborating in groups, and providing thoughtful feedback.

III. PRIOR WORK

In order to gauge student affect in the Flow Vis course, the Fluids Perception Survey (FluPerS) was developed in Fall 2008. The survey design uses an item response modeling approach [13], often used in the education research community. The survey defines “appreciation of fluid flow”, as well as a continuum on which an individual’s responses are mapped. The survey was administered and refined over several semesters. Validation results were published in 2012 [1]. The survey offers statements such as “Visualizations of fluid flow are very beautiful” and “the study of fluids is useful to me as an engineer.” Students respond on a five-point scale of agreement.

As a control during this work, students from the Fluid Mechanics course, as well as another thermofluids elective, Sustainable Energy, were also surveyed. Fluid Mechanics students demonstrated a negative shift in affect; Flow Vis students showed a positive shift; and those in Sustainable Energy were neutral. To investigate the aspects of these courses influencing shifts in affect, our current study was initiated.

IV. METHODS

Three courses were included in the current research: Flow Vis, the technical elective described above, Fluid Mechanics, the required, more traditional course, and Sustainable Energy, another thermofluids elective. Students were invited to participate in the research during class and via email. All students were asked to complete both pre- and post-course surveys. Interviewees replied to an email invitation that went directly to the research interviewer, not through the professors. Thirteen students were each interviewed twice, once early in the course, and once after the course had completed. See Table 1 for a summary of data collected.

These were individual, semi-structured interviews intended to cover both known research interests and to allow students to convey other ideas they felt were important about their experiences. Early course interviews were conducted after the first assignment had been turned in. The researcher guided the early course interviews to deliberately address: engineering (or artistic) identity, past work in visualization, past collaboration experiences (especially outside of their disciplines), and preconceived notions about the course. Post-course interviews addressed identity, collaboration within the course, specific logistics of the course, as well as overall impressions. For the most part, subjects did not have to be asked about visualization as it was central to the course. These interview data are undergoing an open-coding analysis, where new themes emerge along with evidence for the a priori claims of the researcher [14], a multi-step, iterative process [15].

The most recent survey data included 31 pairs of responses from Flow Vis students (that is, the same student completed both the pre-course and post-course survey). Fluid Mechanics provided 55 pairs of responses, and Sustainable Energy

provided 13. The survey contained both numerically scored items (on a Likert scale), and open response items. Numerical items will be evaluated statistically. Open response items will be coded with an emergent coding scheme similar to that of the interviews.

Surveys	55	31	13

V. PRELIMINARY FINDINGS

In the interviews, students conveyed their attitudes about the Flow Vis course, revealing traces of what impact the course has, and why. Preliminary coding of the interviews has focused on identifying the hallmarks of the transformative experience: *motivated use*, *expanded perception*, and *affective value*, as related to the fluid physics content.

Engineering interviewees described using their fluids knowledge in new ways, even in early course interviews (labeled int 1). We might call this scaffolded *motivated use* of the content. Scaffolded, because the use of content is assigned not spontaneous, yet still in a new context:

- Every single time we talk about photographic technique, or develop a flow product or a combustion project, those are all backed up with examples from the real world.... It's not just this is a problem from the book or 'ignore friction here'. All these things are real applications, all factors are considered. –Eng. student (Sub 03, int 1)
- [Flow Vis] is like Fluids 2. Now that you know the basics, you can apply them to making cool artistic pictures. – Eng. student (Sub 01, int 1)

Later in the same interview:

- I feel like [art students] are going into the dark trying to find art, and I am going in dark trying to take pictures of my ideas. –Eng. student (Sub 01, int 1)

This last excerpt points to the openness of the assignments, which was associated with a sense of exploration, instead of finding existing answers. Often *motivated use* takes the form of tinkering with ideas. Students commented on this mostly in their second interviews (labeled int 2):

- You can modify your pathway [in Flow Vis]. In math there's only one way, but in [Flow Vis] it was more along the lines of this experiment is how you choose to direct it. –Eng. student (Sub 03, int 2)
- In Flow Vis, the end is so variable, that it was very dependent on the person. –Eng. student (Sub 01, int 2)
- [in other courses] you create such a rigid thought process rather than a really flexible, dynamic space. – Eng. student (Sub 09, int 1)

- [experimental film] is such a lofty term and it's used a lot, [but] here we were truly experimenting, which is the most beautiful part about it. You are producing something through experiment. –Art student (Sub 16, int 1)
- I love the open-endedness of pretty much everything in that class. –Art student (Sub 16, int 2)

Among the art students, some identified as experimental film makers, and commented that capturing images such as the ones in Flow Vis are important for adding texture and evoking emotions in their work. One film student commented that he had learned as much about using his camera in the first two weeks of Flow Vis as he had in a whole semester of a photography course. This highlights the concentrated nature of the early sessions of the course, which enable students to begin finding and capturing flow images quickly. Getting to hands-on assignments swiftly may be worth replicating, as it supported the scaffolded motivated use of content.

While engineering students commented on the way Flow Vis showed them fluids content in a new context, the art students commented on *expanded perception*:

- In terms of appreciating flows and keeping a keen eye out for it, that's totally improved drastically... I don't want to make another film without including one flow vis. –Art student (Sub 07, int 2)
- I learned to investigate texturally ... It's right under your nose, bubbles in the dishwasher, water under your feet by the creek... it opened up a more microscopic kind of beauty. –Art student (Sub 16, int 2)

This motivated use and expanded perception of the content was also connected to *affective value*. Students felt excited, were engrossed, and took pride in their work:

- I feel like I'm out of my element, which is fun and exciting. –Eng. student (Sub 01, int 1)
- I just had a blast. I was really proud of what I did.... I'm excited to see [the final exhibit]. My family is going to come. –Art student (Sub 07, int 2)
- One of my projects, I noticed I can do this and it will look much more interesting. I spent three times as long. I didn't even know it. –Eng. student (Sub 03, int 2)
- I took more pride in [my Flow Vis work]. Just because I didn't feel that any of it was, pardon my language, absolute bulls***. I feel at times [professors] assign work because they have to, we need it for grades or something. [In Flow Vis] you were actually doing something. – Eng. student (Sub 09, int 2).

Some trends in the interview data surfaced unexpected similarities between the two groups and the benefits of collaboration between them. This included acknowledgement of the other group's expertise:

- [The engineer's explanation] went whoosh, right over my head. I didn't understand the physics and

mathematics, but I understood why that reaction occurred in simple terms. –Art student (Sub 02, int 2)

- There were a lot of things that [the film maker] pointed out that I wouldn't have thought of when taking photographs, certain angles, certain lighting... all this art technical stuff. I had no idea what he was talking about. – Eng. student (Sub 03, int 2)
- The engineers were looking deeper into what we were seeing. I wouldn't have done that before. I think it's cool. I do value it. –Art student (Sub 07, int 2).

This mutual respect contributed to the collaborative work by the teams:

- We played off of each other perfectly because they were just interested in making the experiment and I was interested in capturing it. –Art Student (Sub 16, int 2)

Another point in common: both groups expressed a dislike for the papers with a begrudging appreciation for what they learned through the process:

- There's times I'm really interested in something and I don't know why... But to have it thought out and put down on paper really helps me think about it creatively. – Art Student (Sub 16, int 2)
- [the paper] backs the image up, gives a secondary way to understand what is going on, maybe more in depth. Maybe the video brings you and makes you want to understand it, and then you can read that and figure out what you just watched. – Art Student (Sub 05, int 2)
- The only thing that I didn't like was writing the papers. The engineering part, I wrote like I normally write any experimental paper. But for the artistic side I felt like I was telling more of a story. I didn't expect that. I liked the storytelling part of it. –Eng. Student (Sub 03, int 2)
- I think I have a better understanding about what the Reynolds number actually means from [writing the papers]. After my fluids class, you think it's just this number. It can actually tell you a lot. –Eng. Student (Sub 09, int 2)

However, the requirement of the paper did discourage at least one art student from taking more risks with the work:

- If I could omit the scientific part [of the paper], I would have liked that. It made me reluctant to try things more complex, because I'm like, oh s*** after I do this, I'm going to have to explain this scientifically. –Art student (Sub 16 int 2)

Among the engineering majors, some chose Flow Vis precisely because they are or were photography hobbyists. This could be viewed as a source of bias in the investigation of positive affect; however, others cited past fascination with ocean waves or other natural fluids phenomena as guiding their choice to take the course. We view both types of past experiences as a potential indicators of the latent desire among engineering students for an aesthetic experience relating to their work.

Fig. 2. Image by students Emily Howard, Preston Wheeler; Colliding water jets result in a 'fishbone' instability, 2012.

VI. RELATED AND FUTURE WORK

In ongoing analysis, we hope to discover the most relevant features of Flow Vis for developing a positive shift in affect, and the role of aesthetics in that process. Our initial work has focused on comparing engineering and art students within Flow Vis. Future analysis will 1) compare Flow Vis engineering student responses to those from Fluid Mechanics and Sustainable Energy courses, and 2) identify possible shifts in attitude between early-course and post-course responses.

As part of our study of how certain pedagogical methods influence positive affect, we have adapted features of Flow Vis, including an emphasis on aesthetics, and applied them to a new course, Aesthetics of Design. In it, students designed and built projects as they developed a *design aesthetic*. While the course did not feature the mix of students present in Flow Vis, three instructors with varying expertise offered insights from fields such as mechanical and electrical engineering, computer science, photography, and music. Similar to our findings with Flow Vis, most students relished the opportunity to design with fewer constraints and were able to articulate their aesthetic in a final paper accompanying the project [16].

Ultimately, using courses such as Flow Visualization as a guide, we would like to develop a pedagogical model that enables instructors to incorporate aesthetic dimensions into their courses. Aesthetics, with its potential to initiate and sustain student engagement, represents an untapped resource for improving engineering education experiences.

Abstract—The development, expansion, and assessment of a step-based computer-aided tutoring system to teach linear circuit analysis is described. Circuit problems and fully worked, error-free solutions to same are created automatically and randomly with any desired characteristics, varying both the layout and numerical values. Students therefore have access to an unlimited source of both examples and practice problems of variable difficulty. A unique feature is that students input each stage of their work in a variety of forms including redrawn circuit diagrams, equations, matrix equations, numerical answers, multiple choice answers, and sketches of time-dependent waveforms. Students receive immediate feedback on the correctness of each step of their work. The solutions use analytical methods, rather than the numerical methods used in a tool like PSPICE. A total of 15 tutorials are now available, including DC and AC circuits and two on Laplace transforms. The system has been used by over 1950 students to date. A randomized, controlled laboratory-based study finds a statistically significant learning gain of 1.21 standard deviations compared to working conventional textbook problems. Another randomized, controlled classroom study found a strong preference of students for this system over a widely-used commercial publisher-based homework system, as well as higher scores.

Keywords— *linear circuit analysis; computer-aided instruction; step-based tutoring*

I. INTRODUCTION

Linear circuit analysis is a key topic in electrical engineering curricula, and is also studied by many other engineering majors. At Arizona State University (ASU) for example, we currently teach about 19 large sections (~70-80 students) each year using a large number of faculty. Student retention and graduation rates can be significantly impacted by their experience in this course. To improve that experience and help teach the course more efficiently, we are developing computer-assisted instruction as a substitute for conventional homework [1-4]. By providing immediate feedback on every step of a student's work, we expect to enhance learning, promote complete mastery of the topics, and reduce the time required to grade student homework manually. Student frustration should be reduced by avoiding their spending many

hours to solve equations that are incorrectly written in the first place, or that are based on an incorrectly re-drawn circuit diagram in a multi-step solution process.

II. DESIGN PRINCIPLES AND NOVEL APPROACHES

A wide variety of computer-aided instruction or intelligent tutoring strategies have been employed previously to help teach linear circuit analysis topics [5-21]. However, the only systems that are currently widely deployed are those that accompany circuits textbooks on publisher web sites such as McGraw-Hill's Connect®, Pearson's MasteringEngineering®, Wiley's WileyPLUS, and others, which provide mainly algorithmic problems where a few element values are randomly varied and the student is asked to input numerical answers. A meta-analysis of different types of tutors by VanLehn found that the typical effect size for such answer-based tutoring systems is a Cohen d -value of 0.31 standard deviations (σ). However, step-based tutors, such as the one we are developing, average d -values of 0.76, nearly as good as the average effect of expert human tutors ($d = 0.79$) [22]. This difference is considered to be a major reason that the controlled, randomized laboratory-based study discussed below, which compared use of our tutorial exercises to working conventional textbook problems, found a large and statistically significant effect size of $d = 1.21 \sigma$.

Our system differs from previously described and publisher-based systems in the following ways:

1. An unlimited number of topologically different circuit diagrams can be generated on demand, where both the circuit layout and element values vary randomly. The complexity of these circuits can be varied at will. Existing publisher-based systems and other web-based systems [18, 19, 23-25] only vary a few element values randomly, and a given problem is essentially the same regardless of specific numerical values. If a fully worked solution is provided to students for a given set of values, it is essentially trivial to modify that solution using a different set of values. Also, when such systems allow multiple attempts and supply the correct answer after a failed attempt (without providing the full solution), students have been reported to fail their first attempt deliberately to get an answer

This work was supported by the National Science Foundation through the Transforming Undergraduate Education in Science, Technology, Engineering and Mathematics Program under Grant Nos. DUE-1044497 and DUE-1323773.

they can use to check their method [23]. Our system avoids these problems by creating a completely new circuit diagram after showing students correct answers and fully-worked solutions. Further, virtually all prior systems have used a finite bank of pre-created problems and circuit diagrams (even if some element values are varied) [6, 10, 12, 16-20, 23-27]. In such a case, the answers must be pre-computed by the tutorial authors, which is a very laborious and time-consuming process [25] (which one of the authors can himself attest, having done so for the publisher site of a popular circuits textbook!), and is also prone to human error. Moreover, if a student completes all of the available pre-generated exercises, and still does not understand a concept or procedure, they are left with nothing that is fundamentally new on which to practice. Further, a finite bank of problems means that there may not be problems available over a wide range of difficulties or complexities, which some students may need to be able to progress at a pace that is comfortable or appropriate for their individual needs.

Very few systems have attempted to generate circuit problems randomly. Yoshikawa *et al.* did so, but only for series/parallel combinations of resistors, inductors, and capacitors, and not in more general cases [8]. Cristea *et al.* described a more general algorithm to create AC circuit problems whose solutions are integer values, but it is not clear if the resulting circuit graphs and element values were translated into actual circuit diagrams, as none are illustrated [9, 28]. It is also not clear if worked solutions (as opposed to numerical answers) were generated.

2. Fully worked solutions and answers to the randomly generated problems are produced automatically, using the same methods used in textbooks, such as node and mesh analysis, superposition, source transformations, and Thévenin and Norton equivalents. Most prior systems require manual solution generation by developers or instructors as noted above, which can be subject to error. Existing tools such as PSPICE, etc. typically used modified nodal analysis for solutions, which is not a method normally taught in introductory circuit analysis courses.

3. Very importantly, our system is step-based, and accepts a large variety of student input types. Equations are accepted and evaluated using a special template-based system, and simplified forms of the equations and matrix equations can also be entered (with both real and complex values). Numerical answers and multiple choice answers are also accepted. Important unique features are the interactive waveform sketcher (which is currently being adapted to sketch asymptotic Bode plots also) and circuit drawing and editing modules described below. We do not currently use any natural language dialogs, provide for virtual laboratory experiments or simulations [6, 11, 12, 29], or accept algebraic expressions as final answers [17-19, 25], though a generalization to the latter is possible.

Most existing systems accept only multiple choice or short answers [5, 6, 11-13, 16, 27], numerical answers [6, 18, 19, 23-25, 30], or equations [10-12, 17-19, 25, 26, 31]. Solution of complex circuit analysis problems may however involve re-drawing the circuit diagram (as in superposition, source transformations, Thévenin and Norton equivalents, etc.). A

complete step-based tutor therefore requires that students have the ability to do that interactively, as we provide. Further, certain problem types involve sketching expected waveforms or Bode plots, so the ability to accept those inputs is also important.

4. Another unique feature of our system is the use of certain pedagogical devices, such as color coding of nodes to facilitate identification of elements in parallel, and color coding of equation terms and placement of correspondingly colored arrows or voltage drops on a circuit diagram to help show the origins of KCL or KVL equations. The integration of equations into circuit diagrams [32] and the use of color-coding for different quantities such as currents and voltages [33] has been studied, but we know of no other software that uses these devices.

5. A special feature of our system is that we offer both fully worked examples (with detailed explanations) as well as interactive problems of the same type, where the student must supply all steps. Both examples and problems are typically available at several progressively increasing levels of difficulty. This feature avoids the typical student complaint for textbook examples that the “problems are nothing like the examples!” The student is typically allowed to select an appropriate starting level (within certain limits), so that strong students are not required to solve problems that are trivial for them, and weaker students can progress at a gentler pace. The system advises (but does not force) students to view examples or descend to an easier level if they make too many mistakes. Further, any problem can be converted to a fully worked example by “giving up” at any point, after which a new problem of the same type and difficulty will be offered to the student. Most existing systems seem to offer only problems, without examples. It is well established that inclusion of both examples and corresponding isomorphic practice problems improves learning [34-36]. In particular, learning from examples is important in the early stages of learning, specifically in the first stage and early part of the second of four stages in the schema of Anderson *et al.* [37]. In later stages, problem solving practice becomes more important [37]. While it is not currently implemented, we could incorporate a fading strategy into our program, where worked examples gradually become less and less complete and require students to fill in the missing portions [38].

6. Our system aims to cover essentially the complete content of a typical introductory linear circuits course, though a number of areas are not yet included. Many other systems have been limited prototypes, sometimes covering only a narrow range of topics [16, 26], though some systems have been more comprehensive [6, 18, 19, 25].

7. A number of prior studies have developed intelligent tutoring systems in this area, which generally feature both an expert system and a student model (ideally including typical “bugs” or mal-rules) [5, 6, 8-10, 27, 28, 31]. Such a system typically adjusts the problems and content according to the student model, to adapt to individual students. Our system currently uses a limited amount of adaptation, but it logs and stores all student actions in the system to a central server, and it can automatically generate problems of any desired difficulty

Each colored +/- symbol pair corresponds to a term in KVL equation #1 of 1.

Current constraint equations:

$$I_1 - I_2 = 3\angle 0^\circ \text{ A}$$

KVL equations for each mesh or supermesh:

$$I_1(9\ \Omega) + I_2(3\ \Omega) + (3\ \Omega)I_x + I_2(-j5\ \Omega) + 2\angle 0^\circ \text{ V} + I_1(j2\ \Omega) = 0$$

Equations for control variables of dependent sources:

$$I_x = -I_1$$

Simplified mesh equations:

$$\begin{array}{rcl} 1\ I_1 & -1\ I_2 & +0\ I_x = 3\angle 0^\circ \\ (9+j2)\ I_1 + (3-j5)\ I_2 & +3\ I_x & = 2\angle 180^\circ \\ 1\ I_1 & +0\ I_2 & +1\ I_x = 0 \end{array}$$

Matrix form of mesh equations:

$$\begin{bmatrix} 1 & -1 & 0 \\ 9+j2 & 3-j5 & 3 \\ 1 & 0 & 1 \end{bmatrix} \begin{bmatrix} I_1 \\ I_2 \\ I_x \end{bmatrix} = \begin{bmatrix} 3\angle 0^\circ \\ 2\angle 180^\circ \\ 0 \end{bmatrix}$$

Sought variable equations:

Finding the voltage V_o across the I_1 current source is tricky, because the voltage across a current source is whatever it needs to be. Therefore, we need to sum all voltage drops from one end of this source to the other using a path that does NOT go through the current source, and use KVL.

The drops are considered positive if they have the same polarity as the desired voltage, or negative if they are reversed. We choose to do this on the side where the resulting expression will be the simplest, using mesh #1.

$$V_o = I_1(9\ \Omega) + 2\angle 0^\circ \text{ V} + I_1(j2\ \Omega)$$

Solution:

$$V_o = 17.78\angle -30.41^\circ \text{ V}$$

$$I_1 = 1.745\angle -46.55^\circ \text{ A}; \quad I_2 = 2.201\angle -144.9^\circ \text{ A}; \quad I_x = 1.745\angle 133.5^\circ \text{ A}$$

Compute the following quantity for this circuit:

V_o

$$V_1(j\omega) = 2\angle 0^\circ \text{ V}$$

$$I_1(j\omega) = 3\angle 0^\circ \text{ A}$$

Fig. 1. Automatically generated steady-state AC circuit problem, showing the computer-generated equations and solution and the interface where the student can request detailed explanations. The dashed red line illustrates a supermesh, and the voltage drops around it are currently labeled and color-coded to match the terms in the corresponding KVL equation.

and complexity. Thus, a more intelligent system could later be built on top of our problem generation and user input engines. Such a system would then feature a wide “bandwidth,” in the language of intelligent tutoring systems, because of the highly detailed inputs it is able to accept at each stage of a student’s work.

8. A key distinguishing feature of our study is the use of controlled experiments using random assignment of students to different conditions and rigorous tests for statistical significance of our results. No formal evaluation has been described for many existing systems [5, 8, 9, 16, 23, 27, 28, 30], and in some cases they do not appear to have been tested with students. Weyten *et al.* found no statistically significant effect on performance [17]. Oakley performed a quasi-experimental study of his system that found improved course grades and lower drop rates, but did not report statistical significance or any measure to ensure that the experimental and control sections of the class were equivalent in terms of average GPA or test scores [19]. Butz did report detailed statistical analysis in a quasi-experimental study on several cohorts, and found significant improvements on several output measures [6, 7]. It is unfortunate that Oakley’s and Butz’s systems are no longer apparently in use. However, no prior study of a practical computer-aided instruction system in this

area has reported a controlled, randomized trial of their system, which is the most reliable way to validate effectiveness.

In comparison to prior work, our system therefore has some significant distinguishing features such as random generation of an unlimited supply of problems of any desired difficulty, automatic solution generation, a user interface that accepts a fully variety of student inputs for step-based tutoring, special pedagogical features, wide planned scope, and evaluation using controlled, randomized experiments.

III. PROBLEM AND SOLUTION GENERATION

For randomly generated problems to be useful, they should have characteristics similar to those usually found in textbooks. Those characteristics have been described in detail elsewhere [1], but involve ensuring that the problems are soluble (not inconsistent), do not typically contain elements that are shorted or “dangling” (except when desired for specific pedagogical purposes), and do not contain elements that are “redundant” (i.e., whose presence has no effect on the rest of the circuit). Elements in series with ideal current sources or in parallel with ideal voltage sources are in the latter category. More generally, we do not normally want a circuit to be “hinged,” meaning that we should not be able to draw it in a way that two or more

portions are connected only by a single wire. In that case, the separate portions are essentially independent circuit problems (unless connected by dependent sources whose control variables are in the other portion, or by magnetic coupling). The “sought quantity(ies)” or unknown variables for which the student is asked to solve should further usually be chosen in a way that they are not trivial to determine. For the sake of graphical convenience, we allow only planar circuits, and require that they be laid out on a square grid.

For even moderately complex circuits, random placement of elements on such a grid will produce a valid circuit only an extremely small fraction of the time, which is not a practical method. The algorithm of Cristea *et al.* can generate valid netlists [9, 28], but a suitable layout must then be devised, and there does not appear to be any guarantee that the circuit will be planar as required for mesh analysis. We have instead opted to generate the layout directly rather than the netlist, which is a

The goal is to find the inverse Laplace transform of the function,

$$\mathbf{F}(s) = \frac{5(s+40)}{(s+10)(s^2+10s+29)}.$$

The first step is to factor the quadratic terms in $\mathbf{F}(s)$. For the general quadratic equation $as^2 + bs + c = 0$, the roots are given by:

$$s_{1,2} = \frac{-b}{2a} \pm \sqrt{\left(\frac{b}{2a}\right)^2 - \frac{c}{a}},$$

which implies

$$(s - s_1)(s - s_2) = 0.$$

For $s^2 + 10s + 29 = 0$, we have

$$\begin{aligned} s_{1,2} &= \frac{-(10)}{2} \pm \sqrt{\left(\frac{10}{2}\right)^2 - 29} \\ &= -5 \pm j2. \end{aligned}$$

So,

$$s^2 + 10s + 29 = (s + 5 - j2)(s + 5 + j2).$$

Therefore, $\mathbf{F}(s)$ can be written in factored form as

$$\mathbf{F}(s) = \frac{5(s+40)}{(s+10)(s+5-j2)(s+5+j2)}.$$

The inverse Laplace transform is obtained by expressing $\mathbf{F}(s)$ in a partial fraction expansion:

$$\mathbf{F}(s) = \frac{k_0}{s+p_0} + \frac{\mathbf{k}_1}{s+\mathbf{p}_1} + \frac{\mathbf{k}_1^*}{s+\mathbf{p}_1^*},$$

where $p_0 = 10$, $\mathbf{p}_1 = 5 - j2$, and $\mathbf{p}_1^* = 5 + j2$.

Note: * denotes the complex conjugate of a complex number and $-p_0, -p_1$, etc. are the poles of $\mathbf{F}(s)$.

The values of \mathbf{k}_i 's are obtained as follows:

$$\mathbf{k}_i = (s + p_i)\mathbf{F}(s) \Big|_{s=-p_i}.$$

Therefore,

$$\begin{aligned} k_0 &= \cancel{(s+10)} \frac{5(s+40)}{\cancel{(s+10)}(s+5-j2)(s+5+j2)} \Big|_{s=-10} \\ &= \frac{5(-10+40)}{(-10+5-j2)(-10+5+j2)} \\ &= \frac{5(30)}{(-5-j2)(-5+j2)} \\ &= 5.1723 \end{aligned}$$

Fig. 2. Portion of an automatically, randomly generated and worked example of an inverse Laplace transform (web-based).

bit more complex but avoids the layout step. The layout generation is performed in three separate steps as described elsewhere [1]. **Step 1:** We start with a “topology” composed only of open and short circuits, where some of the shorts later become circuit elements but the opens remain open. The topology may not be hinged or have dangling segments, and determines the number of meshes. **Step 2:** Generic circuit elements are then substituted for the required number of short circuits, taking care to place at least two elements on each mesh, including the “outer mesh,” so that nothing is shorted. A second check for hinging is made. **Step 3:** A tree of the resulting layout is chosen at random, and voltage sources and inductors substitute for generic elements on the twigs of that tree, while current sources and capacitors are placed on its links. Resistors (or all passive elements, in the AC case) can be placed anywhere. Sought quantities and dependent source control variables are then selected randomly in accordance with desired specifications and certain rules. This procedure is a sufficient but not necessary method to avoid situations that might violate Kirchoff’s laws and create inconsistencies (other than those due to dependent sources). Since dependent sources can still cause problems, the circuit is checked for solvability and rejected if necessary, but few iterations are usually needed.

Node and mesh equations are then generated automatically, using supernodes and supermeshes as needed, and can be re-written for any user specified choice of ground in the nodal case. Equations for the sought branch currents, branch voltages, branch powers, and/or non-branch voltages are also generated. Doing so can require the use of KCL or KVL in the case of current sources in node analysis or voltage sources in mesh analysis, respectively, for which a complete textual explanation is generated. Users can select any particular KCL or KVL equation to highlight, in which case individual current arrows leaving a node or supernode or individual voltage drops around a mesh or supermesh are placed on the diagram and color-coded to match specific terms in the equation, as illustrated in Fig. 1 for an AC circuit. Note that AC circuits can be generated directly in the phasor domain, or starting in the time domain. In the latter case, the student is first required to convert element values to impedances at the specified frequency before

proceeding with the analysis. We are currently extending the analysis routines to handle reactive elements appropriately for DC circuits, as a pre-requisite to solving transient problems in the $t < 0$ or $t = \infty$ steady-state cases.

IV. NEW WEB-BASED MODULES

A. Laplace Transforms and Inverse Transforms

A recently added module in our system addresses the mathematical aspects of performing direct and inverse Laplace transforms. This module is entirely web-based, using PHP for the server portion with HTML5 and JavaScript for the client side and no plug-ins of any kind. The entire module can be accessed from mobile devices as well as PCs. The first portion involves an interactive tutorial (with multiple choice questions at each step), illustrating the definition and application of the transform integral, along with an explanation of the transform concept as that of an “avatar” that represents the time-based function in a parallel universe, the s -domain. The student is led through a typical derivation of a transform, and supplied with a detailed transform table, where clicking on any entry in the table leads to a detailed derivation of a given transform pair. A second table summarizing the properties of the transform is provided, and the two tables can be invoked in a separate browser tab for reference at any time. The student is then led to an example generator, which creates fully worked examples for all of the common transform types. We have provided a high level of detail so that students can readily understand the procedure.

For the inverse transform case, the system again generates fully worked examples showing partial fraction decompositions in great detail, as partially illustrated in Fig. 2. Both simple and complex conjugate poles are handled automatically (multiple poles to be added soon). The process is spelled out in a higher level of detail than in most textbooks.

The next step is interactive exercises, where students are asked to work similar problems themselves. The equation entry interface will be template based,

similar to what we use in the VB6 portion of our system, and is currently under development. The student will then be required to complete a certain number of exercises of gradually increasing complexity of each type, leading to mastery-level comprehension.

B. Waveform Sketching

In studying reactive elements such as capacitors and inductors, students are often asked to relate the current or voltage as a function of time to the opposite quantity. This process involves graphical integration or differentiation, which often poses significant problems for students. To help them overcome this difficulty, we provide examples of such

Capacitors and Inductors

Question 2.7.1 (ID 225)

Section 2 of 3

The voltage across a $20\ \mu\text{F}$ capacitor is shown below. Find the current through the capacitor from 0 to 70 ms.

Solution:

First write the expression for the above graph:

► Expression Details

- The voltage is a ramp from 0 to 30 ms with a slope

$$m = \frac{\Delta v}{\Delta t} = \frac{10\text{ mV} - 5\text{ mV}}{30\text{ ms} - 0} = 0.167\text{ mV/ms} = 0.167 \times 10^{-3}\text{ V}/10^{-3}\text{ s} = 0.167\text{ V/s} = 0.167\text{ V/s}.$$

The voltage intercept is 5mV. Thus,

$$v(t) = (0.167\text{ V/s})t + 5\text{ mV} \quad 0 \leq t \leq 30\text{ ms}.$$

- The voltage is constant from 30 ms to 40 ms, so

$$v(t) = 10\text{ mV} \quad 30\text{ ms} \leq t \leq 40\text{ ms}.$$

► Detailed Solution

For $0 \leq t \leq 30\text{ ms}$,

$$\begin{aligned} i(t) &= C \frac{dv(t)}{dt} \\ &= (20\ \mu\text{F}) \frac{d}{dt} [(0.167\text{ V/s})t + 5\text{ mV}] = (20\ \mu\text{F}) (0.167\text{ V/s}) \\ &= (20 \times 10^{-6}\text{ F}) (0.167\text{ V/s}) = 3.34 \times 10^{-6}\text{ C/s} \\ &= 3.33\ \mu\text{A}, \end{aligned}$$

because $C = \text{F V}$ and $\text{A} = \text{C/s}$.

For $30\text{ ms} \leq t \leq 40\text{ ms}$,

Fig. 3. Portions of a web-based example in the waveform sketcher module. (Several portions have been omitted for brevity. The actual solution describes every portion of the waveform.)

randomly-generated problems of various types, worked in great detail as illustrated in Fig. 3. The problem was created and solved automatically by the system, including the final sketch of the current waveform (not shown). Once students have viewed examples, they will be asked to work very similar problems using the interactive waveform sketcher module we described previously [2-4]. At any point, they will be able to give up if necessary and view the computer generated solution, but then be given a different problem of the same type to solve. More generally, the student can be asked to sketch a waveform for various quantities like charge, current, voltage, power, or stored energy.

V. CONTROLLED, RANDOMIZED EVALUATIONS

To date, two separate evaluations of software effectiveness have been performed. In the first, we used 33 student volunteers in a laboratory setting, all of whom were currently enrolled in our EEE 202 class at ASU or who had completed it within the last year. One qualitative and one quantitative topic were selected for study, namely identifying elements in series and parallel, and writing DC node equations, respectively. All subjects were administered a pre-test and post-test covering these areas, randomly assigning them to one of two similar test forms for either the pre-test or post-test. They were then randomly assigned to work problems from the textbook we normally use, selected to correspond as closely as possible to the subject areas, or to use our series-parallel identification or node equation tutorials for the same periods of time (25 minutes and 35 minutes, respectively). This test is an authentic one as assigning textbook problems is the method most often used now in our course. The pre- and post-test data is shown in Table I for the both experimental and control groups. The learning gain was about 10 \times higher for the group using the software. The difference was significant, $t(19.7) = 3.303$, $p < 0.05$ without assuming equal variances, and the Cohen d -value (effect size) was 1.21 pooled standard deviations (σ), a large effect. A motivational survey administered in this experiment also yielded better results for the software condition, with an effect size of 0.91 σ ($p < 0.05$).

To further compare our software with existing algorithmic homework systems, we randomly assigned students in one section of EEE 202 at ASU in Fall 2014 to either a) use the step-based Circuit Tutor system for node analysis problems (using both the node equation writing tutorial and a second tutorial in which they must perform a complete numerical solution of the node equations as well), and use a commercial answer-based homework system to work mesh analysis problems; or b) use Circuit Tutor for mesh analysis problems (using both the mesh equation tutorial and a complete equation solution tutorial), and the commercial system for node analysis problems. The problems in the publisher-based commercial system were algorithmic versions of end-of-chapter problems in the corresponding textbook, and were selected to be very similar to the problems assigned in the Circuit Tutor tutorials. The above required assignments counted towards their homework grade (20% in total of the course grade). There were five required problems on each topic in the commercial system, and six or more required problems in Circuit Tutor (depending on the level at which students start, and how many

Table I. Controlled, Randomized Laboratory-Based Study of Learning Gains.

	Exptl. Group	Pre-Test Score	Post-Test Score	Gain
Average	Textbook	58.6	61.6	2.9
Median	Textbook	60.5	67.0	1.5
Std. Dev.	Textbook	25.3	28.0	14.1
Average	Software	57.8	86.4	28.6
Median	Software	57.0	85.0	30.0
Std. Dev.	Software	22.1	11.5	14.9
Std. Dev.	Pooled	23.0	20.5	14.1

problems they give up on), though they had to work out complete numerical solutions in all of the commercial system problems but only in two or more of the Circuit Tutor problems. In the commercial system, students were allowed up to four attempts to enter the correct numerical answer (with the same element values each time), and received full credit for any correct answer. Circuit Tutor gives feedback after every step (an equation has been entered, simplified equations have been entered, the matrix equation has been entered, or the final numerical answers have been entered), and allows multiple attempts on numerical entries. It provides a fully worked solution to any problem if a student gives up, with no penalty (but requires working a new problem of the same type). It further allows students to view any number of worked examples at any level of difficulty.

The average assignment scores, taken as a measure of successful completion, were 40.2/50 on Circuit Tutor and 33.6/50 in the commercial system, with standard deviations of 16.2 and 15.9, respectively. (These figures combine the node and mesh assignment scores.) The difference is significant with $p < 0.008$, and the effect size is $d = 0.41 \sigma$. Further, a full 64% of the Circuit Tutor users obtained 100% of the credit on their assignment, whereas only 26% of the commercial system users did. Moreover, after the due date of the required assignment, both groups (each of whom had used Circuit Tutor for one of the two topics, and the commercial system for the other) were given access to the system they were not originally assigned to use for each topic, to permit additional voluntary work (for no additional credit). Of the group assigned to use the commercial system for a given topic, fully 32% or 34% of them voluntarily completed at least one tutorial level in Circuit Tutor, and of those doing so, the average number of levels completed was 6.5 of an available 10. Further, 16% or 17% of the students completed all available levels in Circuit Tutor voluntarily. On the other hand, no students at all completed any voluntary work at all in the commercial system. This difference indicates a clear preference of students for the Circuit Tutor system over the commercial one. Students were not specifically surveyed about their relative opinions of Circuit Tutor and the commercial system, but in open-ended comments, seven of them volunteered such a comparison, and all strongly favored Circuit Tutor over the commercial system. A sample comment was that "I like this much better than [commercial system name]!!! I feel like I learn more going through the circuits than being told I'm wrong for one flat answer." However, we consider a preference expressed by

Table II. Sample Verbatim Student Comments on Software from Spring 2014.

Series-Parallel Tutorial

- Wish Unit Games were available. Also wish that there were versions of circuit tutor for superposition, and other concepts. This Program taught me these concepts quickly and well.
- I understand the difference between series and parallel so much better now! Thanks!
- This game was brilliant and really helped me in understanding how to spot parallel and series circuit elements. I think there needs to be more resources like this.
- I really liked this game and the tutorial before the game. I think the tutorial explained things really well and I was able to get through the game quite easily. I learned a lot of series and parallel circuits that I didn't fully understand before doing this exercise. Very helpful! We should do more of these!
- If there were video tutorials, that'd be great instead of reading through textual information.
- Coloring the nodes was EXTREMELY helpful. I honestly would have never thought about doing that. Thanks for the help

Nodal Analysis

- More chances to write out an equation, as sometimes just making a simple sign error was the issue and could have been resolved on the following guess.
- I thought I had a good understanding of Nodal Analysis but this exercise really helped
- Could have used this to study before exam.
- A tutorial at the beginning, like with the first module, would have been helpful.
- I liked how there was an option to view new circuits without penalty.

Mesh Analysis

- Cleared my confusion on Mesh Analysis. Thanks again! I hope you do other exercises on other circuit's topics (Thevenin .. etc)
- I like these games! They help drill the concepts in too :)
- More enjoyable than a standard HW.
- These are awesome!
- This was also very helpful in understanding this topic. Lots of great practice.

doing extra work to be much more significant than any survey response.

VI. CLASSROOM USAGE AND SURVEY STATISTICS

Our current system includes 15 tutorials that are available to students, covering identification of elements in series and parallel, writing both AC (phasor) and DC node equations

(including voltage constraint equations, supernodes, and dependent sources), and writing AC and DC mesh equations (including current constraint equations, supermeshes, and dependent sources). Another covers the effects of different types of terminals on series relationships (such as those used to measure voltage, "view" input impedance, or connect an arbitrary subcircuit). Others then teach students to combine resistors, inductors, capacitors, and general impedances in series and parallel, including complicated multi-step simplifications. Two new web-based tutorials focus on the mathematics of Laplace transforms, teaching students to perform direct and inverse transforms, including partial fraction decomposition with simple or complex conjugate poles. As of Spring 2015, our tutorials have been used (usually as required homework exercises) by over 1950 students in 42 class sections at Arizona State University, University of Notre Dame, University of the Pacific, Morgan State University, Messiah College, South Mountain Community College, and Chandler-Gilbert Community College. Testing has therefore involved a diverse set of institutions.

Each time a student completes a tutorial, we administer a simple two-question survey about their experience. First, we ask them how useful the software was in learning the assigned topic, with possible responses of "very useful," "somewhat useful," "not very useful, or "a waste of time." The percentage of each response has remained roughly constant at 70%, 25%, 2%, and 2%, respectively, for data from Spring 2013 through Fall 2014. The percentage of students rating them as very or somewhat useful is therefore about 96%. We also collect open-ended comments, which have mostly been very favorable (Table II). Students particularly like the coloring of the nodes and the way in which that helps them visualize the circuit nodes. The main request has been to expand the topical coverage, which we are in the process of doing. Students often comment that the system helps build their confidence, that they like the gradual increase in exercise difficulty, that they appreciate not being penalized for wrong answers, and that they appreciate the detailed explanations that are available.

We also administered a more detailed, 12 question survey to those who used the software in Fall 2013 through Fall 2014. The survey used a four-point Likert scale to gauge whether the software was useful and well-designed, whether the difficulty and coverage are appropriate, and whether it is preferred over conventional homework assignments. The average favorable ratings in these categories were 87%, 85%, and 78%, respectively. Ratings by students at Notre Dame were uniformly higher than those at ASU, suggesting that the software can be employed usefully at institutions of different types. Favorable results were also found for Morgan State University students, though they tended more to feel that the difficulty and length of the exercises was too high.

VII. CONCLUSIONS

Our computer-based interactive tutorial system now includes 15 tutorials and features an improved, highly capable graphical circuit editor, the ability to generate and solve AC circuits using phasor analysis in addition to DC circuits, and a fully developed web-based waveform sketching tool that can assess the correctness of student drawings. At the same time,

usage of the system has been expanded to many more class sections both at ASU and several other universities and community colleges. High levels of student satisfaction have been achieved. A large quantity of log file data is being analyzed and used to iteratively refine the existing tutorials, with the eventual objective of achieving “perfect learning” of the covered topics by all students. New tutorials are also under development.

ACKNOWLEDGMENTS

We thank Drs. J. Aberle, M. Ardakani, R. Ferzli, S. Goodnick, R. Gorur, G. Karady, H. Mao, B. Matar, L. Sankar, D. Shin, Meng Tao, C. Tepedelenioglu, T. Thornton, D. Vasileska, Chao Wang, Hongbin Yu, and Hongyu Yu for using our software in their sections of EEE 202 at ASU. We also thank Y. Astatke for using it in EEGR 202 at Morgan State University, H. Underwood for using it in ENGR 236 at Messiah College, J. Ross for using it in ECPE 41 at the University of the Pacific, T. Frank for using it in EEE 202 at South Mountain Community College, B. Matar for using it in EEE 202 at Chandler-Gilbert Community College, and A. Holmes for using it in ECE 2630 at the University of Virginia. We thank Daniel Sayre of John Wiley & Sons, Inc. for providing the textbook copies used in our laboratory experiment and for his support of the project.

Abstract—The paper presents the implementation of an Intelligent Tutoring System. The paper consists of two sections. The first section describes the framework of the Intelligent Tutoring System. In this framework, the elements of course design are identified as competencies, instructional activities and assessments. These elements are aligned using a tool called the Taxonomy Table. The second section describes the implementation. The system has been implemented on top of the Learning Management System Moodle. Prior to implementation, a study of the parameters required in a Learning Management System to build an Intelligent Tutoring System on top of, was carried out; and an evaluation of two open source Learning Management Systems was performed, which led to the decision to build the tutoring system using Moodle. Subsequently, the implementation of the expert, tutoring and student modules using Moodle are presented.

Keywords—Intelligent Tutoring Systems, Learning Management Systems, Moodle

I. INTRODUCTION

Intelligent Tutoring Systems (ITS) are computer applications that provide one-on-one instruction to students and aim to identify their shortcomings.

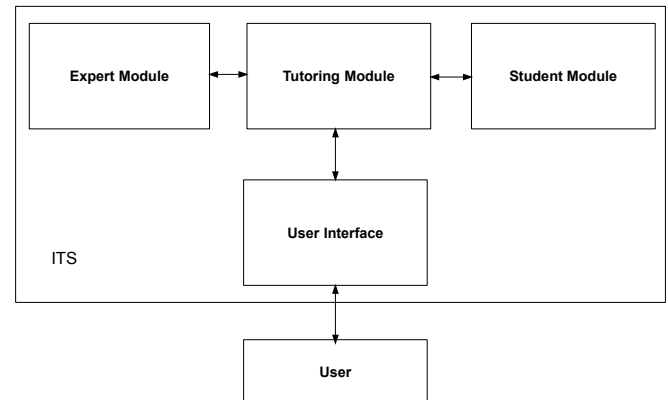

Fig. 1: Structure of an ITS

ITS typically consist of four modules as shown in Figure 1: [3] the Expert Module, which comprises of facts and rules of the particular domain to be conveyed to the student; the Tutoring Module, which designs and regulates instructional interactions with the students; the Student Module, which is a dynamic representation of the students current state of knowledge; and the User Interface, which controls interaction between the student and the system. Implementation of ITSs have been carried out in numerous ways, using technologies such as LISP, CGI and others. In this paper, we present the implementation of an ITS built upon the Learning Management System Moodle. Learning Management Systems take care of creation, delivery and management of content and assessments. They help to manage grades more consistently and efficiently. They also help in ensuring compliance of the e-learning content to standards such as SCORM, AICC and IMS. While the initial learning curve in using an LMS can be high, instructors soon realize that this is a one-time effort. Effective usage of an LMS can reduce the effort spent on administrative activities, thereby enabling the instructor to put increased focus in teaching and associated core activities. For example, with the right LMS content creation (both

instructional content and assessments) for a course can be a one-time activity, with incremental updates to content during subsequent offerings of the course. Because of these advantages, the use of such systems has become nearly ubiquitous, and institutions and corporates support them for both their pedagogical and administrative benefits [2].

Some of the popular LMSs are Blackboard, Desire2Learn, Moodle, ATutor and Sakai among others. The decision as to which LMS to use can be a challenging one and is based on many factors. Different organizations have different needs from an LMS. These needs dictate the factors that govern the choice of a LMS and the relative priorities of these factors. For example, corporates use LMSs typically to conduct training programmes that last between a day and a month, whereas educational institutions typically have courses which last for longer duration (e.g., a semester). Even within educational institutions, different kinds of institutions have different needs. For example, a medical institution would need to store specialized content such as videos of surgery and radiology images [4], where an engineering college would require content which would include presentations, documents and so on.

The paper has been divided into two parts, an overview of the framework of the ITS and the implementation based on the stated framework.

II. FRAMEWORK OF ITS

In this work, framework for an ITS has been defined. The framework is based on the premise that good course design consists of three elements: competencies, instructional activities and assessments [8]. A competency, also referred to as learning outcome, learning objective, instructional objective etc., is defined as an effective ability, including attributes, skills and knowledge, to successfully carry out some activity which is totally identified [8]. Instructional activities are activities used to facilitate students to acquire the competencies. Assessment Items are used to collect information about the students acquisition of the competencies. It utilizes a tool called the Taxonomy Table [7], which checks alignment of the elements based on Cognitive Level and Knowledge Category [8]. Tutoring rules have been designed based on the alignment of the elements. Tutoring rules are course-specific. The course on which the student is tutored is developed based on this framework.

The tutoring system consists of an instructional activity, presenting a formative assessment instrument of the lesson, evaluating the response of the student, and guiding (tutoring decision) the student to the next stage based on her performance. Taxonomy table is a table of six cognitive levels and eight categories of knowledge. The competencies of a course are located in the cells of its taxonomy table. Instructional activities and assessments aligned with competencies are located in the same cells or cells associated with lower cognitive levels and the same category of knowledge.

As discussed, the course is defined in terms of competencies. Each competency has associated with it a single Unit-of-Learning. Therefore, Competency C_i has associated with it UOL_i , where 'i' indicates the index of the competency. For example, consider competency C_1 . C_1 will have a Unit-of-Learning UOL_1 . This is as depicted in Figure. UOL_i consists of 'k' Units-of-Study ('k' varying from two to six) that

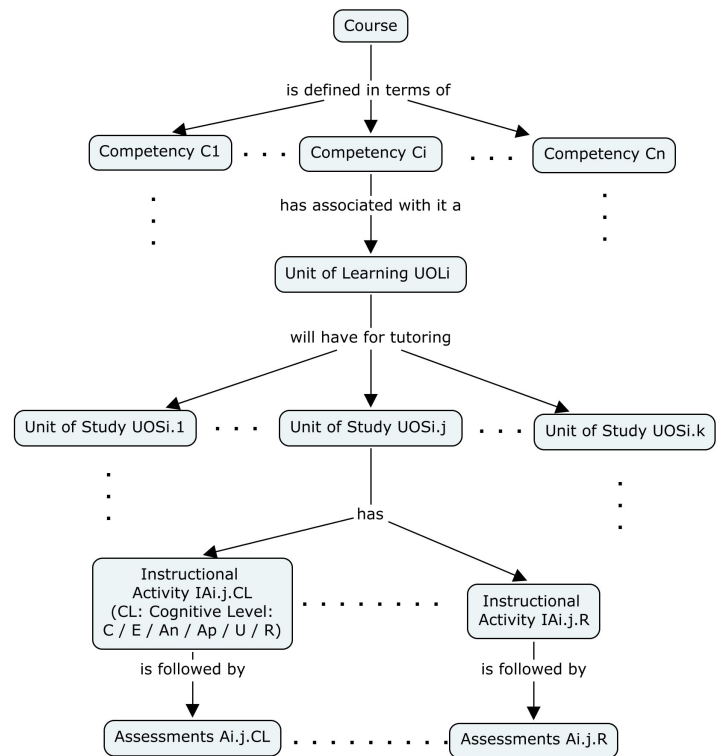

Fig. 1. Expert Module of ITS

are denoted as $UOSi,j$, where 'j' indicates the index of the Unit-of-Study. The Units-of-Study may belong to different cognitive levels than that of the Unit-of-Learning. $UOSi,j$ consists of several Instructional Activities for all cognitive levels pertaining to $UOSi,j$. These Instructional Activities are denoted as IAi,j,CL where i,j is the index of the Unit-of-Study and CL is the cognitive level that the Instructional Activity addresses. For example, assume UOL_i has associated with it Units-of-Study $UOSi.1$ belonging to Understand / Procedural, $UOSi.j$ belonging to Apply / Procedural, $UOSi.k$ belonging to Apply / Procedural. Each of these have associated with them Instructional Activities as follows:

- 1) $UOSi.1$ has Instructional Activities $IAi.1.U$ belonging to Understand and Instructional Activity $IAi.1.R$ belonging to Remember.
- 2) $UOSi.j$ has Instructional Activities $IAi.j.Ap$ belonging to Apply, Instructional Activities $IAi.j.U$ belonging to Understand and Instructional Activity $IAi.j.R$ belonging to Remember.
- 3) $UOSi.k$ has Instructional Activities $IAi.k.Ap$ belonging to Apply, Instructional Activities $IAi.k.U$ belonging to Understand and Instructional Activity $IAi.k.R$ belonging to Remember.

Figure 1 describes the framework of the Expert Module of the ITS.

We have taken into consideration the course Data Structures designed for an undergraduate course in engineering.

III. DETAILS OF IMPLEMENTATION

Moodle is a Free and Open Source LMS. Moodle is designed to provide educators, administrators and learners

with a single robust, secure and integrated system to create personalized learning environments and is guided by social constructionist pedagogy. As it is an Open Source System, Moodle allows a high level of extensibility at all levels. Moodle is implemented using the LAMP stack with the front end using PHP, back end using MySQL and the web server Apache. The following sections explain the implementation of the Expert, Tutoring and Student Modules using Moodle.

A. Expert Module

In this framework of the Intelligent Tutoring System, the Expert Module consists of representation of the competencies, instructional activities and assessments and their alignment. Each of these elements are represented in Moodle as follows.

1) *Competencies*: Moodle incorporates a module called the "Outcomes" Module. Outcomes are specific descriptions of what a student has demonstrated and understood at the completion of an activity or course. They may also be termed as Competencies or Goals. Outcomes can be enabled using the Site Administration > Advanced Features. Specific Outcomes can be added under Course Administration > Grade Administration > Outcomes as shown in Figure 2. Figure 3 is the list of complete outcomes uploaded to the course.

2) *Instructional Activities*: The Expert Module consists of Instructional Activities which are named and tagged appropriately. Instructional Activities may be of several different types, including Webpages, Files, Books, IMS content packages, Labels, Pages and URLs. Not all aspects of instructional activities may be accessed by the student at all times. In fact, some aspects of instructional activities may never be accessible to students. Therefore, instructional activities which are not to be accessed at a particular time are restricted from access by the student. Internal information such as cognitive level, knowledge category are added to the description section. This information is not revealed to the student so as to avoid confusing the student with too much information.

3) *Assessments*: The Expert Module consists of Sets of Assessment Items, pertaining to every cognitive level of each Unit of Study. Assessments are represented using the question types amenable to automatic assessment available in the Question Bank (available in Course Administration > Question Bank). The Sets of Assessment Items are represented using the Categories feature of the Question Bank Module, available in Course Administration > Question Bank > Categories. For the sample course on Data Structures, at the highest level namely the competency level a category is created for each Competency / Unit of Learning as shown in Figure 4.

Further, each Unit of Learning consists of several Units of Study. A category is created for each Unit of Study as shown in Figure 5.

Subsequently, each Unit of Study consists of several sets of items. Each set at the first level in the UOS consists of several sets of items pertaining to a particular cognitive level. Let us consider UOS1.1, UOS1.2 and UOS1.3, which belongs to the cognitive levels Understand, Apply and Apply respectively. Therefore, UOS1.1 has categories [A1.1U] and [A1.1R]; UOS1.2 has categories [A1.2Ap], [A1.2U] and [A1.2R], and UOS1.3 has categories [A1.3Ap], [A1.3U] and [A1.3R] as follows in Figure 6.

Subsequently, each set of assessment items consists of several sets that consist of items of a similar type. For example, let us consider the sets of problems in [A1.2Ap].

[A1.2Ap] consists of 9 sets of items, namely {A1.2Ap1}..{A1.2Ap9}. These are stored as separate categories as shown in Figure 7.

Each category at the lowest level consists of questions (items) which belong to a similar type.

B. Tutoring Module

The tutoring rules are implemented primarily by restricting access to different instructional activities and assessments based on the current performance of the student. In order to do that, the "Restriction" settings must be enabled under Site Administration > Advanced features > Enable conditional access and Site Administration > Advanced features > Enable.

1) *Sets of Assessment Items*: Subsequently, each Unit of Study consists of several sets of sets of items. Each set at the first level in the UOS consists of several sets of items pertaining to a particular cognitive level. Let us consider UOS1.1, UOS1.2 and UOS1.3, which belongs to the cognitive levels Understand, Apply and Apply respectively. Therefore, UOS1.1 has categories [A1.1U] and [A1.1R]; UOS1.2 has categories [A1.2Ap], [A1.2U] and [A1.2R], and UOS1.3 has categories [A1.3Ap], [A1.3U] and [A1.3R] as in Figure 8.

Subsequently, each set of assessment items consists of several sets that consist of items of a similar type. For example, let us consider the sets of problems in [A1.2Ap]. [A1.2Ap] consists of 9 sets of items, namely {A1.2Ap1}..{A1.2Ap9}. These are stored as separate categories.

Each category at the lowest level consists of questions (items) which belong to a similar type.

2) *Tutoring Rules*: Assessments are delivered using the "Quiz" module. Using these settings, quizzes may be restricted based on the level upto which the student has completed a task. Each set of assessment items at the lowest level of hierarchy has a quiz associated with it. Let us consider the set of items {A1.2Ap1}, which belongs to the superset [A1.2Ap], which is a set of sets of items belonging to cognitive level Apply associated with UOS1.2. An assessment instrument is created to deliver a representative problem $a \in \{A1.2Ap1\}$ by creating a Quiz from the activity menu.

Upon creating the quiz, prior to adding items to the quiz, the following settings are set appropriately.

- *Adaptive settings*: The adaptive settings ensure that the students' previous items of a quiz are taken into account while delivering representative items of a set. For example, if a student attempts a representative problem $a \in \{A1.2Ap.1\}$, and does not perform satisfactorily, he is redirected to attempt a representative problem from the pre-decided set {A1.2U.1}. Upon performing satisfactorily in the representative item $a \in \{A1.2U.1\}$, he is redirected back to {A1.2Ap.1} but this time, must attempt a different representative item from the item attempted earlier. Enabling these settings (in combination with the random question selection explained subsequently) ensures that the student

Fig. 8. Sets of Sets of Assessments for UOS1.1, UOS1.2, UOS1.3

is delivered a different item each time he attempts the quiz.

- **Outcomes:** The outcome (competency) to which the quiz (representative problem, in this case $a \in \{A1.2.Ap.1\}$) is associated with is selected in the Outcomes section of the quiz. This ensures the proper tracking to deliver the snapshot of the students' performance required in the Student module. As $\{A1.2Ap1\}$ is associated with C1, the outcome is appropriately selected.
- **Common Module Settings:** So as to keep the details of the assessment opaque from the student, the details pertaining to the Set ID are stored in the common module settings.
- **Completion Settings:** These settings indicate whether a student has completed a quiz or not. They are set so that a student may not manually mark an activity to be complete, and must receive a grade in order to indicate whether the activity is complete or not.
- **Restriction Settings:** These settings are critical for proper execution of the tutoring rules. Once again, let us consider the same example set $\{A1.2.Ap.1\}$. If a student performs unsatisfactorily on representative

problem $a \in \{A1.2.Ap.1\}$, he is redirected to a quiz that delivers representative problem $a \in \{A1.2.U.1\}$. This quiz remains hidden unless the student has performed unsatisfactorily on representative problem $a \in \{A1.2.Ap.1\}$. Therefore, the settings for a quiz delivering representative problem $a \in \{A1.2.U.1\}$ are defined as shown in the Figure 12.

- **Random question settings:** Subsequent to defining the appropriate settings listed above, the representative item from the appropriate category needs to be added to the quiz. In order to ensure that the student is delivered different representative items for each attempt of the quiz, a random question from the appropriate category is added as follows. On the empty quiz, of the two options of "Add a question" and "Add a random question", the option "Add a random question" is selected.

Subsequently, the appropriate category from which the random question is to be generated is chosen. In this case, that category is $C1 > UOS1.2 > A1.2.Ap > A1.2.Ap.1$.

C. Student Module

The student module consists of a snapshot of the students' progress at any given point in time. In this framework, the

Fig. 9. Adaptive Settings

Fig. 10. Outcomes Settings

Fig. 11. Common Module Settings

Fig. 12. Completion Settings

Student Module would consist of the instructional activities / assessments completed by the student, which would thereby indicate which competencies have been attained by the student. Progress is measured according to the Competencies and Units-of-Study completed by the student, which are uploaded in the form of Outcomes. Therefore, first "Completion tracking" is enabled for the course under Course Administration > Edit course settings.

Further, a snapshot of the student's progress at any point in time is available in the gradebook, under Course Administration > Grades.

IV. CONCLUSION

A framework for an Intelligent Tutoring System has been described. The framework consists of the three elements of course design competencies, instructional activities and assessments. The framework for the Intelligent Tutoring System is implemented using the Learning Management System Moodle. The representation of the Expert Module (broadly, the competencies, instructional activities and assessment items), the Tutoring Rules in the Tutoring Module and the snapshot of the

student's progress in the Student Module were implemented for a course on Data Structures in an undergraduate engineering programme.

Abstract—Open Educational Resources include a diverse range of materials making it the most representative icon arisen within the Open Content movement. Users who access and use OERs could be classified into one of these three groups: instructor, student and self-learner. To provide personalized lists of OERs according to the user profile and personal preferences, the user should be characterized by an open and scalable model. In this paper, an open linked vocabulary is proposed to describe user profiles of the open educational resources, which take into account the challenges and opportunities that an open and extensible platform as the Web can provide to learn about the OER users, and from this knowledge, offer the most appropriate resources.

I. INTRODUCTION

Different projects arising under the philosophy of Open Access (OA) have helped to facilitate and to make accessible to all users the online learning. The OA initiatives framed in the educative context have "significant implications, and allows distance educators to play an important role in the fulfillment of the promise of the right to universal education" [1]. Open Educational Resources (OER) include a diverse range of materials making it the most representative icon arisen within this movement.

Considering the personal interests of people that access to the open educational resources, OERs are not only useful for students of educational institution, but also they are used by self-learners or who are part of a kind of informal learning.

The most used tools to find the resources in the Web are the search engines. However, due to the huge amount of available resources, and because the traditional research systems does not consumption the users knowledge, thousand or millions of results are returned. The failure to find relevant material to support a teaching and learning process can be an inhibiting factor in the process of formal or informal learning.

Unlike the search engines, the recommender systems filter the resources taking into account the users interests, and they are able to give a better user support when the users are trying to find the resources they need. The issue is that these systems to be effective require big amounts of data; in closed or specific e-learning environments there is the possibility of modeling a wide range of users variables such as; preferences, styles, goals, learning aims between others. Considering that one of

the OER users profiles is the self-learner or people who do not belong to a formal education system, thus, the collection of interaction information that helps to build a user profile is limited.

In this paper, an open linked vocabulary is proposed to describe user profiles of the open educational resources. As is known, the platform on which OER users are identified, participate and contribute is the Web; in this regard, there are challenges and opportunities that an open and extensible platform can provide to learn about the OER users, and from this knowledge, offer the most appropriate resources.

The user's representation is based on computable schemes, and it fed on Web data structured and organized through systems of open knowledge. The usage of vocabularies and formal languages of the Semantic Web enables to reuse and interoperability of user's data between several applications. Moreover, the modeling of user interests through knowledge organization systems will allow to implement query and support services so that they can understand the topics and relations around the domain and finally, people will know how to better conduct the search of material.

Continuing with this paper, the main proposal to describe Web users, and their main constraints when modeling heterogeneous users in a open learning environment are put forward in the section II. The design and preliminar validation of the User Profile for OER recommendation tasks are put forward in the section III, and the section IV. Finally, in the section V, the conclusions and future work are appeared.

II. THEORETICAL BACKGROUND

A. Standards and data models to represent users

In order to represent a learner, a widely know specification is PAPI Learner Standard (Public And Private Information) proposed by the IEEE Learner Model Working Group. PAPI was launched in 2001 and has served as a reference to some proposals as [2], [3].

PAPI defines different elements to record descriptive information about students' knowledge and preferences, as well as personal contact information, security settings and general privacy, among others. The draft 8 from the specification lets

us to specify different views of learners' information, this way, those using this model can choose the parts that are appropriate for their application.

Moreover, the consortium IMS GLC (IMS Global Learning Consortium) created the specification, IMS LIP (IMS Learner Information Package)[4]. An initial draft specification appeared in 2001 and, in 2005 the final specification was formalized.

The IMS LIP standard has been used in the construction of student models and some applications like: Elena¹, L4All², EPET³, Europass CV Application⁴, among others. The specification divides the learners information into eleven categories or data structures, these categories include: biographical and demographical students data, objectives and competencies, accessibility, degrees, activities and relationships.

One of the cons of these two specifications is that they are not extensible, in other words, they have not evolved to consider features and user preferences that arise in an open online learning environment. Another problem identified in [5] is that IEEE PAPI and IMS LIP do not facilitate the sharing and reuse of profiles stored on different servers.

Nowadays, in order to improve interoperability and scalability of user profiles between different systems, most proposals are based on representations based on ontological models. There are implementations of models using OWL or RDF(S) languages. Among the related works about semantic models proposed to represent the user profile, we can highlight the following:

Among the high-level specifications to describe Web users, there are: i)FOAF (Friend Of A Friend)⁵, and ii) vCard⁶ standard proposed by the IETF and currently published in RDF/OWL format by the Semantic web Interest Group. Both FOAF and vCard propose identification metadata and contact as: names, age, nickname and email. FOAF also allows the description of some professional information and user interests. Finally, we can name the collection Person⁷ of the Schema.org specification, driven by major Web search engines.

Another proposal that defines the profile of a Web user shows up in [6], although in this case, the profile is projected in order to incorporate it in recommender systems based on content, for it models the profile based on words of the pages visited by the user.

For purposes of personalization of content and specifically for adapting Web content, the ontology GUMO (General User Model Ontology) [7] defines individual characteristics of a person, as: physical and emotional states, characteristics and personality; in addition, in [7] the Markup Language (UserML) is proposed to manage the communication between different applications to share the user model. Another proposal to facilitate the development of e-learning systems is presented in

[3] custom, where a model student profile based on the IEEE PAPI specification is proposed.

To provide personalized access to documents, [8] defines a domain ontology that organizes the Web documents so that each document is classified as a particular concept in the domain of ontology, then, according to the history of user navigation is the interests of users are collected and recorded in the user model.[9]

Another group of user profiles, focus on ensuring portability and reuse of profiles between systems that adopt the same metadata schema: [2], [5], the LLO ontology (Learner Ontology for Planning of Lifelong Learning), the ontology U2MIO [10].

Although, the proposals mentioned try to model the users profile in a wide spectrum of dimensions, in a Web context, by the dynamics of users data, it seems to be useful to focus in such aspects that in a mid-term will capture the nature of the users interest. To sum up, in order to model the users interest and preferences, the authors have found the following proposals.

- A model to describe the users preferences (local and global) expressed in terms of resources and domain of interests; the learning of users interest, getting trough data mining methods is based on the characteristics or attributes of an object which is graded by a user. [11]
- The experimental vocabulary WI (Weighted Interest Vocabulary) which was developed in 2009 in order to cover the requirements of the Project NoTube; WI models the users preferences inside an environment o determined context; the relevance of significance for the user can be established through weight which value can change depending of the context.
- The STOUN ontology (Spatio-Temporal Ontology of User Preference) defines three types of preferences (positives or negatives) and the dimensions that can affect them such as activities, devices, localization, time, and event.
- CC/PP (Composite Capability/Preference Profiles) allows describing a devices capacities and the users preferences; this information can be used to guide the content adaptation that is presented in a determined device.
- The FRAP ontology (Framework for Ratings and Preferences)⁸ allows the open interchange of the users preferences. The framework is independent from the domain. [12]
- The same organization that developed FRAP, which is called CTIC, proposes the ontology RECO⁹ that differs in the objective and in the proposal of the ontology FRAP. RECO represents a ordered list of elements given by a recommendation system, whereas FRAP captures the users preferences. The RECO ontology defines a vocabulary to represent preferences and ratings as restrictions through a RDF graph.

TABLE I. REQUIRED CHARACTERISTICS OF THE USER PROFILE

Feature of the OER User	Current proposals	Requirements of the User Profile
The user can have different levels of knowledge. On the other hand, one of the forms that a user uses to express their learning information needs is through interest expressed as concepts.	Works such as [12], [10] define a model of web user independent from the domain, i.e. they are re-usable in any field; but, they are too general to determine the knowledge of the user in a determined subject; this can affect the performance of the personalization task.	The model must capture the current state of knowledge of a user in a specific field and it must be able to be used to interpret with open knowledge repositories; so that, it can enrich the user profile from these sources. Therefore, recommender systems can take advantage of the potential of the semantic relations, which are expressed, in open systems of organization of knowledge.
An OER user does not center his or her participation in a specific learning system or in a unique material repository; actually, he or she will not be register in any platform.	A considerable number of approaches for users modeling as [14], [11] have focused on the identification of profiles of teachers and students based on their preferences and needs as users of a determined system or a controlled environments.	The model must be flexible to characterize users who little is known, i.e., the profile should model the user preferences depending on the educational material distributed in different repositories, in order to take advantage of the OERs metadata.
OER user can participate in learning communities that emerged spontaneously. Since it has become massive the use of social networks, people use these services to share material, data and preferences.	Approaches as [15] y [16] are experimenting with public data from social sources since they provide an acceptable way to identify user interests. To infer user behavior, techniques based in learning machine are applied; they can be intensive in data processing.	The model should distinguish user profiles from heterogeneous systems (including social services); therefore, it must capture the user data dynamics and model the shared communitys interests of users using techniques applicable to the Web. [9]

Another dimension in which some founded Jobs are centered is the characterization of the user as a part of a network. In [13] is proposed an approach for a multi-layer building of communities of interest (COI), which is based on the analysis of the users individual preferences that are described in the profiles. The method builds users profile interests based in specific concepts with the purpose of find similarities between users; the profiles are divided in groups of interest, based on this, some layers of COI are found. Another work that deserves to be named is one presented in [9] in which a model based interest ontology is proposed, it can be used to determine the close neighbors by calculating the semantic similarity of interest models of two users.

B. Characterization of the User of the Open Educational Resources

In this section are analyzed the main conclusions of the present state of users profile modeling against the nature and characteristics of an open learning environment user, supported by oERs; as well as how this relation affects the recommender systems which should provide customized listings according to the users interests and preferences.

From the information in Table I, the authors can conclude that a OER users profile should be flexible; so, it should allow represent users under contrary scenarios: anonymous users or reserve ones with little known information vs. active users in

the web, generally with presence in networks or communities. Also, the model should be extensible and interoperable, so that, it can connect with other representations in order to take advantage of the large amount of open data that are published in different knowledge systems and in OERs open repositories of metadata.

III. DESIGN OF THE OER USER PROFILE

A. User profile requirements

In order to ensure the successful our proposal and according the findings that were found in the literature review, the model of user of OER should keep the following design principles:

- 1) Based on semantic structures, i.e., the model must be able to be combined with controlled vocabularies and open systems of knowledge organization. This feature enables the enrichment and inference of new user profile data and above all enables the organization and classification of users according to common interests. Taking advantage the potential of different knowledge domains they are encoded on the web as linked data. The knowledge about the domain of interest to the user, allow to do better recommendations according to the level of knowledge the user has on an issue.
- 2) Support distributed information: the model should facilitate the representation of user profiles from heterogeneous and distributed systems, which are enabled to share information about learner or teacher.
- 3) Privacy and data protection: In order to ensure the integrity and privacy of user data, the attributes that the user has decided to share in your public profile have to be considered. You must also take into account other information, both personal and critical, which should not be shared with others external agents.
- 4) Personalization. The data model of OER's user must be flexible to support adjustments in two ways: i) extension through the addition of new user features and its environment, and ii) personalization according to specific purposes or environments.

B. User Profile Dimensions

The organization of user characteristics and the environment in which he/she interacts, encapsulating the attributes in different dimensions allows to build a interoperable model of the user, so different applications can share the model with different purposes. The Figure 1, shows the different categories of data that could characterize an OER's user.

In addition, as shown in Figure 1, different categories of user data may influence others: i) due to the exercise of academic and professional activity, the user can acquire different skills and abilities; ii) the previous experience and the current user activity can determine their learning objectives and motivations; iii) finally, i) and ii) more the context information can influence the interests and current decisions of the user.

Although the user profile can be used for different purposes, on this paper, the user preferences constitute the fundamental dimension of our design. The following reasons justify this decision: i)) the users background both academic as

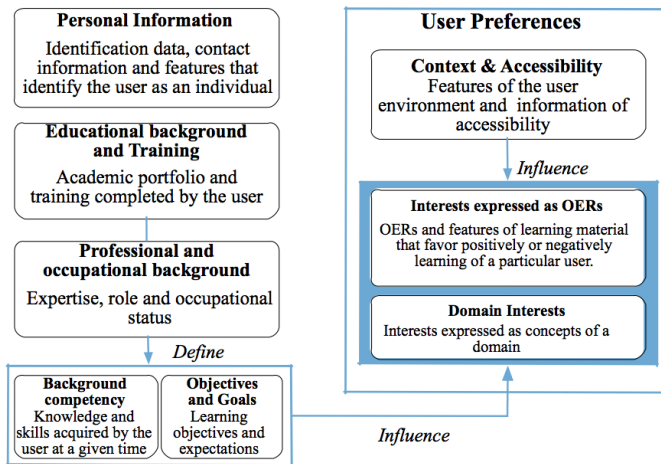

Fig. 1. Dimensions of the User Profile

professional have an important role in customization tasks oriented to content adaptation [17], this differs from our primary purpose, the recommendation of OERs. ii) The collection of information about the objectives and expectations of learning, in an open learning environment can be complex or limited.

C. User's Preferences

A preference is a mental state of an individual respecting from a subset of items from a universe of alternatives.

To provide lists of relevant OERs according to the interests of a particular user, it is proposed to specify a grade or rating for each user preference through a quantitative or qualitative scale; the value that is assigned to represent the importance of this element to the user.

In order to support different methods of filtering information, the user model has been designed to withstand at least three types of user preferences:

1) *User Interests expressed as concepts of a domain of knowledge*: The interest model of the user, being based on thesaurus or other knowledge organization systems, it can be used to exploit hierarchies of concepts and provide the necessary support the user can define in more precise interests. [9]

Example 1: Topic recommendation. An user (:User1) has expressed interest by the subject of Software Engineering (:SoftwareEngineering). Open Sources of Knowledge as DBPedia¹⁰ enable the automatic extraction of the subtopics of this discipline, which can be recommended to the user to refine their interests, if it is required.

```

IF
[ type (:Software_Engineering . :Concept) AND
  interest (:User1 . :Software_Engineering) AND
  narrower (:Software_Engineering . :Software_design) AND
  narrower (:Software_Engineering . :Software_requirements) AND
  narrower (:Software_Engineering . :Software_architecture)
]
THEN
[ recommends (:User1 . :Software_design) OR
  recommends (:User1 . :Software_requirements) OR
  recommends (:User1 . :Software_architecture)
]

```

¹⁰<http://dbpedia.org/About>

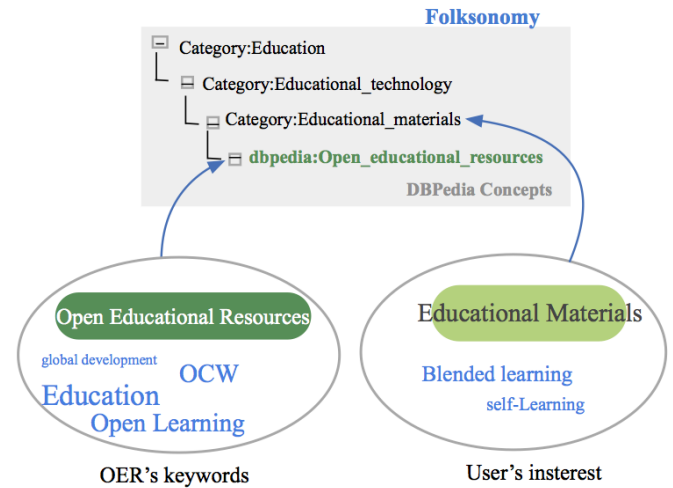

Fig. 2. Mapping between OER concepts and User interests

Another application of interest expressed as linked concepts by semantic relations is the location of the resources related to given subject and their variations or derivations.

Example 2: OER recommendation. In Figure 2, it can see that it is possible to map user interests expressed as concepts and keywords of OERs, thus, systems can provide recommendations for resources without them having the same words of the user. The same approach can be used to find similar users and provide recommendations based on collaboration.

2) *Documents and/or preferred attributes of OERs*: The user's preferences for a particular group of OERs, or their features that describe it, they can be used to apply approaches based on content filtering, in order to take advantage of the large amount of metadata exposed by open repositories of learning material.

3) *Demographic information and accessibility*: This information is useful to filter the most appropriate items of information according to user context. This dimension includes: location, language, age, and information accessibility and user device used to access the educational content. The PAPI [18] specification also adds metadata such as learning style and physical limitations.

By including this information in the user profile, systems sensitive to the context could be created according to the particular tastes of each user; for example, for a student who manages one language, it may result a priority to find the resources that are in her/his mother tongue.

D. Conceptual Model of the User Profile

The design of the OER user profile begins with the construction of the conceptual model. Therefore, at this point, our goal is to identify and describe the terms of the user model to improve the discovery and recommendation of open educational resources

One of the fundamental tasks of the conceptualization of the model is building the terms of the glossary, which specifies the metadata and user variables and concepts related. Table II

TABLE II. EXCERPT OF THE TERMS GLOSSARY

User Concept		
Metadata	Description	Range of values
names	User names	Text
description/summary	Resume or information descriptive of the user	Text
e-mail	Email preferred for the user	email
Localization	User location, i.e. a city, region or country	URL
Language	Source language of the user	URL
Web page	URL of the user's home page	URL
Profile Concept		
Metadata	Description	Range of values
Identifier	User profile ID	URL/string
User	Social account user	URL
Source	Source address of the user profile information	URL
Creation date	Date of the profile creation	Date
Published date	Date of the profile published	Date

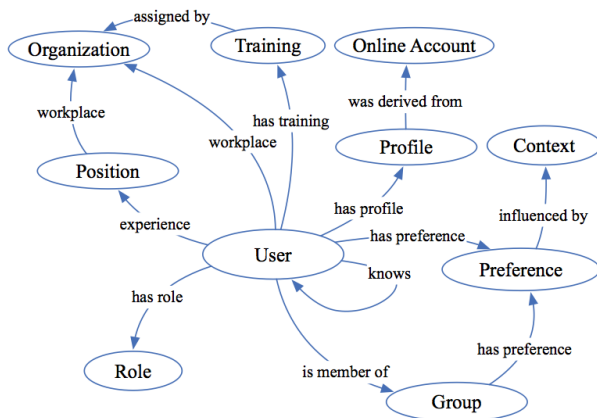

Fig. 3. Conceptual Model. A top level view

shows an extract of the terms identified for concepts User and Profile shown

As shown in Table II, to build the glossary terms may appear new terms, such as Concept Profile. This concept includes the information necessary to identify the web profile of an user, and it is used to identify the source and provenance of the user's information.

From the glossary of terms, the next step was to build the diagram of binary relations between concepts. In the Figure 3 it is presented the high level conceptual model resulting from this process.

E. Reuse of ontological and non-ontological resources

The reuse of ontological and non-ontological resources reduces the time for creating an ontology and associated costs; also it contributes to the quality of ontology. citeVillazon2011

From the analysis of the proposals referred to in paragraph 2.1, it was selected those models that offer greater coverage of the terms identified in the Glossary of Terms and ensured a high probability of interoperability and semantic consistency with the conceptual definition of the model chosen. Main vocabularies that are selected are listed:

- Simple Knowledge Organization System (SKOS)¹¹ vocabulary used to organize the users interest defined by concepts.
- FOAF¹² y vCard¹³ are used to describe the basic information of people and organizations.
- Dublin Core (DC)¹⁴ y Dublin Core Metadata Initiative (DCMI) Metadata Terms¹⁵ provide needed metadata to describe the users preferences depending on of OERs.
- VIVO¹⁶, ontology for describing different concepts in academic and scientific domain.
- Open Provenance Model Vocabulary¹⁷ to describe the origin of the data from Web users.
- Schema.org¹⁸, set of metadata schemes that improve the discoverability of an appeal by Web agents.

Attributes, properties and entities that are not considered in these vocabularies, were designed and created as part of our proposal.

IV. REPRESENTATION AND VALIDATION OF THE USER PROFILE

Once built the ontological model, various user profiles were defined in order to determine the capacity of representation of the model designed. Namely, three user profiles are considered: i) a person who regularly uses digital educational resources to support their work and acquire the skills required in their occupational tasks; ii) a student of an educational program, who want to supplement the study material provided in class; and iii) an instructor who want to find the material related to a particular subject.

The first type of user could well correspond to a self-learner profile. In e-learning, self-learner is an active user on the web that is not necessarily enrolled in an educational institution and supports their learning processes using resources found on the Web.

Then, certain characteristics that could distinguish to a self-learner when interacting and search online material are described: i) is professional and entrepreneur, ii) generally set their own learning objectives; iii) it subscribed to some social networks such as Facebook, twitter and LinkedIn; iv) regularly, publish and share relevant material that he/she has been used in his/her training process; v) his/her interests are related to different knowledge areas and topics; vi) dominates

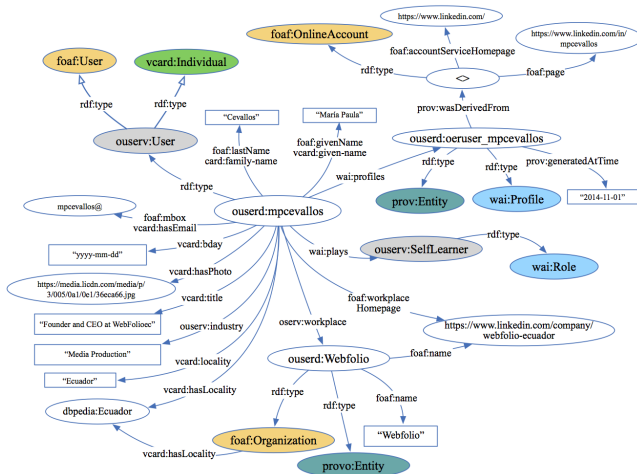

Fig. 4. User Data Representation. Personal Information

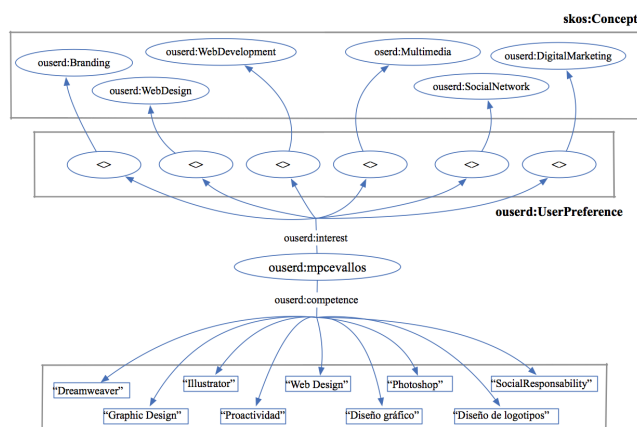

Fig. 5. User Data Representation. Preferences based-on concepts

certain subjects but can also be beginner in emerging issues; and vii) user is enrolling in courses and other free online learning resources. Figure 4 shows the semantic representation of the personal data of a user corresponding to the profile described, and Figure 5, the user preferences and their skills are presented.

As shown in Figure 5, the ratings or weights of each topic of interest are unknown. To complete the profile, the system can explicitly request this information to the user via a Web form or implicitly the interests can be updated when the user interacts with the system.

V. CONCLUSION

In this paper, authors have proposed a User Profile for the OER recommendation, which take into account i), the constraints and opportunities that an open learning environment could offer in real time to obtain users information; and ii), the general characteristics that identify a OER user; and iii) the particular characteristics that can make it possible to differentiate one group of users from other.

The creation of the model has been addressed by a set of requirements that the online learning and open demand and the current proposals do not cover. Part of the proposal

validation was made considering a set of scenarios; concretely, in this work was exposed the representation of an self-learner because in this group is more likely to find the widest range of OERs users; they can be beginners or highly qualified in a topic, they can have the ability to handle bibliographical resources or they can ignore the research mechanisms and tools. Therefore, the user profile has been designed to support these features and to provide sufficient knowledge to recommender systems because they have to differentiate the types of users and satisfy the needs of both beginners and advanced users.

Currently, the authors continue evaluating and validating the created model, before publishing it according to the Best Practice Recipes for Publishing RDF Vocabularies ¹⁹. The usage of the profile in recommendation tasks will be key to the feedback this work. In this moment a knowledge-based recommender system is being implemented considering the present approach.

Abstract—Digital Image Processing (DIP) consists of a set of techniques to acquire, represent and transform digital images. Through these techniques, it is possible to extract and identify information of images and improve the visual quality by facilitating human perception and interpretation by computer systems. However, the Digital Image Processing teaching is hindered by the complexity of implementation of many techniques, on several occasions is not possible that student visualize the results of DIP techniques when are discussed during the course. This paper presents an experiment over a web platform to support the teaching of digital image processing. The goal of this platform is not replace coding techniques, but allow rapid visualization and experimentation of studied methods, without be necessary to install software or previous knowledge of a specific programming language.

keywords: Digital image processing, teaching/learning platform, web platform

I. INTRODUCTION

The increase of computing devices performance and the advances in image acquisition methods have made the Digital Image Processing (DIP) an important way for solving problems of different areas [1].

The Digital Image Processing has become an important tool to several organizations from different areas, which uses solutions based on DIP; in academy is a research subject; and in daily life with the popularization of multimedia applications [1] [2].

DIP applications use several algorithms, highlighting: image acquisition, enhancement, filters, transforms, segmentation, border detection and classification. Thereby, the discipline of Digital Image Processing became subject of teaching in many higher education courses, such as computer science and engineering, mapping science and engineering, geology, agronomy, electrical engineering, electronics engineering and agronomic engineering [1].

However, the strong mathematical background necessary to understand DIP algorithms and the time for development of those algorithms hamper the development of classes and homeworks. In that way, it is infeasible on several occasions to visualize the results of DIP techniques as they are discussed during the course. These issues might make the teaching and learning of DIP discipline demotivating for the students [1].

Thus, it is important to use tools to assist in teaching and learning DIP techniques and methodologies, through execution of algorithms and display results dynamically. Nevertheless, the most popular tools available have drawbacks as the high-value of commercial license, operating system dependence or necessity of to learn a specific programming language.

In this paper it is presented a web platform to support teaching of Digital Image Processing. Through this platform the user can create image processing streams and view the result without writing code. In addition, the web platform offers facilities, such as independence of operating system and hardware.

In order to evaluate the web platform, it was conducted an experiment with a group of students. Initially, the students developed the same activities using the web platform and MATLAB (commonly used tool in introductory courses of DIP). Next, the students filled a form to evaluate and discuss both approaches.

This paper is organized as following. Section II presents basic concepts of Digital Image Processing, in particular the steps that make up a digital image processing system; Section III presents related works to this; Section IV presents the web platform, and brief comments about implementation aspects; Section V describes the experiment and presents results obtained; in addition, in Section VI the conclusions and future work are presented.

II. DIGITAL IMAGE PROCESSING

The Digital Image Processing consists of a set of techniques to capture, represent and transform digital images with computer assistance. Those techniques seek identify and extract information from images and improve visual quality, facilitating human perception and automatic interpretation by computer systems.

The schema of Digital Image Processing system is depicted in Figure 1. There are four stages: *acquisition*, *processing*, *storage* and *output* [2].

A. Acquisition Stage

The first step consists in image acquisition using a device to capture signals from different source (i.e. light and X-ray).

Fig. 1. Digital image processing system stages: acquisition, processing, storage and output – Adapted from [2]

Also, it is stored into files according to formats defined to image for later processing. Among the acquisition instruments are video cameras, scanners and embedded sensors on satellites.

It is important to note that the resulting image has imperfections, which demands specific treatment before applying the processing technique.

B. Storage Stage

The storage stage is one of difficulties in the design of a Digital Image Processing system. This stage can be divided into three models: short period storage, which occurs when the image is being used for processing; mass storage, responsible for operations that require relatively quick recoveries; and storage for future recovery [2].

C. Processing Stage

The **processing** stage refers to algorithms to handle images. This stage can be partitioned into two steps: pre-processing and segmentation. The pre-processing is useful when the images obtained from the acquisition stage have imperfections due to poor lighting conditions or capture device characteristics. In turn, *segmentation* seeks to partition a set of input data in structures with relevant semantic content for the activity in question.

1) *Pre-processing*: This step aims to improve the image quality and prepare it for the subsequent processes. Depending on the image in question, can be applied different techniques, because efficient methods for a given problem are not satisfactory in others [2].

The pre-processing can be performed both in space domain and frequency domain. This step is, also, divided into approaches to enhancement and image restoration.

The approach of enhancement is responsible for improving the image quality or emphasize any image particularity through any heuristic – such as changes in contrast or histogram. In the other hand, the restoration aims to recover or rebuild lost details during the acquisition stage with methods of smoothing noise and blurring.

2) *Segmentation*: The **segmentation** aims to partition a set of input data in structures with relevant semantic content for the activity in question. The structures refer to objects or parts of objects that help in the image interpretation. As result, for example, it is possible to extract objects that are merged with the image background, providing the basis for further processing.

The complexity of segmentation step depends on the interested image: it is low when the image of interest has few and well defined objects, especially when combined with a background with a good contrast; it is complex when one wants separate many noisy regions and low contrast.

There are different ways to perform the segmentation of an image, highlighting the methods based on threshold and active contour.

Threshold based methods can be classified into automatic global and adaptive processes. The global process utilizes histogram properties to perform the segmentation, while the adaptive performs a subdivision in the image and applies a threshold on each subdivision, resulting in multiples shades of cut that are interpolated to give the new pixels of the image. Threshold based methods have advantage of less sensitivity to background irregularities and local variations.

On the other hand, active contour based methods use techniques based on border detection, known as snakes. These methods are characterized by to try to adjust a curve on the border of an object of image and have a lower sensitivity to noise. In this way, such methods can be applied efficiently on images with a high noise level while maintaining a better continuity of the contour [3].

D. Output Stage

The last stage of a digital image processing system is the output, which aims to display the result presentation (show the obtained result to the user). Also, the obtained result can be used as input to another processing. The output can be through monitors, printers or even communication protocols.

III. RELATED WORKS

The teaching and learning of digital image processing is research and development target both in academia and business. Several appropriate tools for teaching and learning of digital imaging processing can be found, whether free or licensed commercially [1].

A software that we can highlight is MATLAB, a desktop tool widely spread in engineering courses and has a set of toolboxes for several areas, including differential equations, statistics, signal processing and image processing. It uses a proper programming language for the development of technical applications, C-like syntax. However, its main disadvantage is the high cost to obtain a license.

The GNU/OCTAVE is an alternative to MATLAB, a free tool originally created for design of chemical reactors. Just as the MATLAB, has a faster programming language than more conventional programming languages. Nevertheless, in

both tools is required previous knowledge of their particular languages for develop algorithms.

In contrast to MATLAB and OCTAVE, which require a previous knowledge of its programming language, we can cite Khoros. Among its features, there is a complete environment image processing consisting of an attractive visual programming interface, which makes it more practical the application of computational methods for image visual processing.

At first, Khoros was a free tool, open source and offered a system that allowed the extension of new functions within its toolbox. But, over time, did not follow the technological advances of software and ceased to be a free tool [4].

One environment of the Khoros platform is the Cantata (see Figure 2), and is intended for DIPs that have a high degree of abstraction. Whereas the output image of a processing can be used as input to another processing, this environment allows to create a process stream. This stream is described as a directed graph.

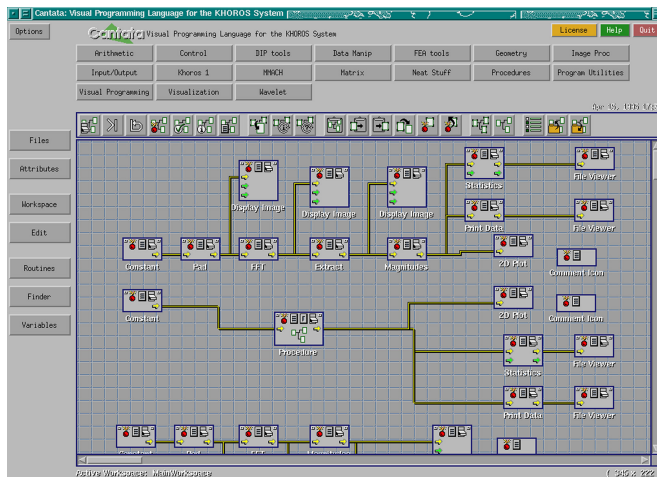

Fig. 2. Cantata environment of the Khoros platform - Source [4]

Based on Khoros, Cyclops has been developed. Cyclops is a platform that allows the modelling of stream image filters through a graphical environment. By the tool, the user can create filters streams, adjust parameters and view results. Furthermore, this tool allows streams to be saved for future use. The Figure 3 illustrates the Cyclops user interface with a created stream [5].

Adesso was developed in the 2000s, and is an authoring system of scientific programs based on the component/solution paradigm that uses a database and XML technology. For this platform, different toolboxes for image processing were created, including educational tools in Digital Image Processing [6].

Among these toolboxes, we can cite the "Toolbox of image processing using the python language". Through this toolbox teaching materials are available to DIP learning using the Python programming language [7].

PhotoPix is a tool developed in C++ and designed for Windows environment. It aims to separate the processing

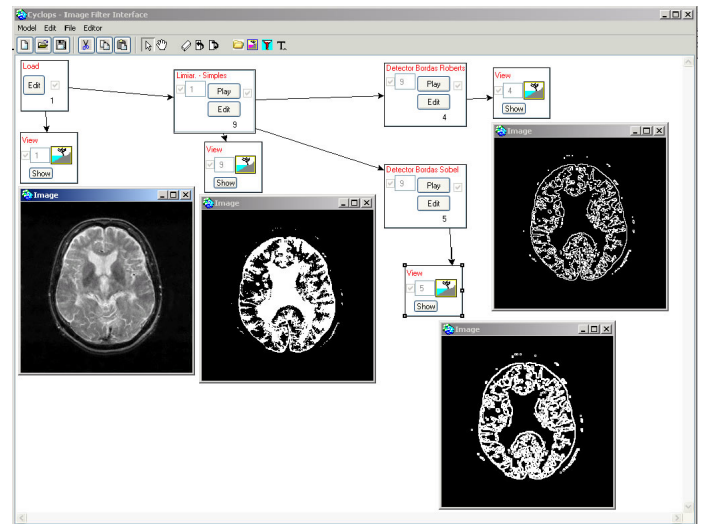

Fig. 3. Cyclops environment with a processing stream - Source [5]

algorithms of code in order to benefit portability across different hardware platforms and APIs. However, it is necessary previous knowledge of the language to add new algorithms [8].

Based on PhotoPix was developed PhotoPixJ, a tool that has a high degree of abstraction and facilitates addition of new algorithms. For being developed in Java, is independent of operating system, requiring only the installation of the Java virtual machine [8].

Another study found in the literature is the Image Analyser, which possess focus on statistical analysis of images in the frequency domain. The purpose of Image Analyzer is unite theory and practice of image processing using the DFT (Discrete Fourier Transform) [9].

Concerning the thermal images is highlighted the TermUV, a tool that allows acquisition, pre-processing and processing of thermal images. This process is performed by a graphical user interface, as illustrated by Figure 4. Through the tool can be created reports and the results are stored in a database [10].

Lastly, SimPle is an educational project developed in Java. In this tool, through the menu, is possible to apply filters and DIP techniques that are displayed in a new window. As the results of methods application are displayed in a different window, links are not displayed with the previous image, making hard the viewing of processing stream [1].

IV. THE SUPPORTIVE ENVIRONMENT FOR TEACHING AND LEARNING DIGITAL IMAGE PROCESSING

In a previous work entitled "Plataforma web para auxílio ao ensino de processamento digital de imagens" [11] was presented a platform to aid in DIP teaching. Similarly to Cyclops and Cantata, this platform represents the processing stream through a directed graph (digraph).

On this platform, three vertices represent acquisition, pre-processing and segmentation. However, there is no freedom for the user creates its own stream, since there is a limitation

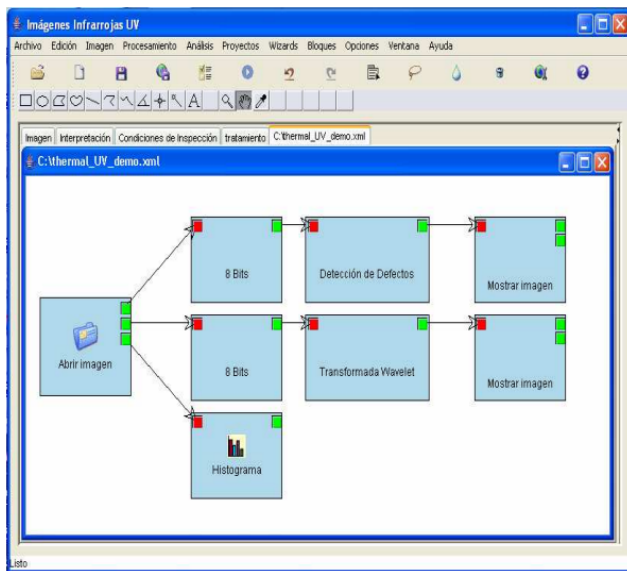

Fig. 4. TermUV's graphical interface - Source [10]

to apply only one filter in each process step (pre-processing and segmentation).

The Figure 5 illustrates a processing stream by this platform. The acquisition process consists of an upload of a digital image that will be processed (labeled by *a*). The pre-processing aims to prepare the image for segmentation and for this several techniques are available (such as grayscale, sepia, smoothing and so on). We can observe in Figure 5 the application of pre-processing methods: grayscale (labeled by *b*) and negative (labeled by *c*). From the resulting image of pre-processing, the segmentation is applied. From Figure 5 is possible see the application of segmentation in the resulting image of grayscale process, with border detection method (labeled by *d*) and mean removal method (labeled by *e*).

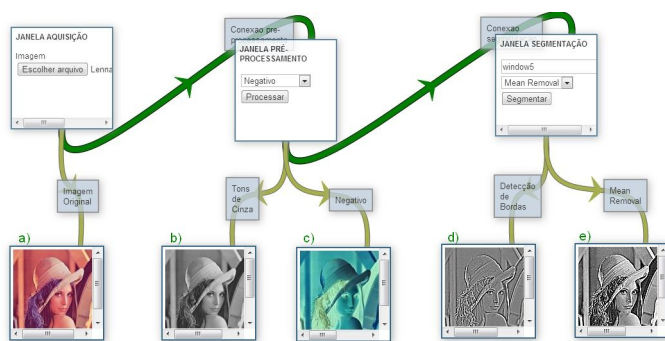

Fig. 5. Example of a processing stream by the Plataforma web para auxílio ao ensino de processamento digital de imagens

Starting with this platform, the goal is to develop a new platform based on web technologies to support teaching of Digital Image Processing. The features of this platform include:

- *Run in web environment:* The use of web technologies ensures operating system independence. To access the

platform only is need a browser that supports HTML5 with internet access;

- *Be visual:* The development of code is unnecessary, quickly showing result of applying the techniques offered;
- *Create Projects:* Possibility of the user to create and store projects, and starting from them create your own processing streams;
- *Be free:* To use the platform is only needed a previous registration for project management. Commercial license is not required.

A. Aspects of platform implementation

The user interface for image processing was built using HTML5 features, a modern mark-up language that allows graphical representation of information on the internet. This language has new tags compared to previous versions, which facilitate work with scripting languages such as JavaScript, and the canvas element that allows graphics manipulation. In order to produce dynamic and attractive content to the user is used the javascript language.

A MySQL database is used for persistence of project data, users, and resulting images from the application of processing methods available on the platform. The choice of MySQL is justified because it is a free and cross-platform tool.

The PHP is used as back-end language and is responsible for project and users management, image processing, organization of the processing stream, and communicate with database. The PHP scripts run through AJAX (Asynchronous Javascript and XML) calls performed via javascript by the user interface. The use of AJAX makes unnecessary the page refresh to view new processing results.

B. Digital Image Processing Methods

The processing functions of digital images present on this platform have been developed using the PHP language together with the *imagemagick* library. The *imagemagick* allows, among other features, to create, delete and resize images, draw geometric figures and text manipulation.

Imagemagick procedures are performed through terminal commands. The syntax for manipulate an image is similar to follow: `convert lenna.bmp -bias 50% -morphology Convolve LoG:0x2 lapgauss.bmp`. In this procedure on an input image (*lenna.bmp*) is applied the method to obtain the Laplacian of Gaussian, resulting the output image (*lapgauss.bmp*).

To create the histogram is used the tag canvas together javascript language. This choice was made because the *imagemagick* had unsatisfactory results in performed tests.

We can highlight among the methods in platform the RGB conversion filters for grayscale, image blurring, border detection, histogram generation, thresholding, and morphological segmentation filters. For latter, for each mathematical morphology operation, a structuring element is required or an element whose shape and size are previously known [12].

C. Platform Operation

The platform is available through identification. The identification is used because it allows that projects can be organized by the user and that the processing to be reused.

After identification, it is possible to load and manipulate digital images by the user interface; the processing methods of the images are presented in a unified way. Among these features are: create a new project; open or delete an existing project; load an image; apply a filter; enlarge an image; apply zoom in an image; delete a stream; display the histogram of an image and display the processing stream.

In order to allow a better view of the processing stream, the results of the applications of the techniques are displayed in a digraph. In this way, whenever is applied a processing on the image, a new node appears in the digraph with an edge linking the node that contains the original image and the node that contains the resulting image. Thus, different streams can be observed simultaneously, which allows that the users compare the results obtained in the same view.

After loading an image by platform, this image will be represented as the first node of digraph and all other nodes will be connected to it by some path. A dialog box opens for the user configures the processing parameters before to apply a filter to an image. To apply a filter to image, a dialog box opens for user configure processing parameters.

Figure 6 illustrates the platform interface after an image has been loaded. The digraph has only one node and on image contained on this node can be performed any available processing by platform.

Fig. 6. An initial image loaded by the platform

In Figure 7 is illustrated the same digraph of Figure 6 after several processing. For each processing has added a new node containing the resulting image. In this Figure we can observe two processing sub-streams. The operation performed between the label 1 and 2 is common to both streams and displays the grayscale operation. In sub-stream composed by labels 2, 3 and 4 are performed the operations of thresholding with

isovalue 20% and aperture using a disk as structuring element, respectively. In sub-stream composed by labels 2, 5 and 6 are performed the operations of thresholding with isovalue 50% and aperture using a disk as structuring element, respectively. It is noted that on resulting images of processing may be applied new processing, creating a combination of processing.

Fig. 7. Digraph created by the platform after several processing

In addition, nodes of digraph can be moved and deleted, and over the images can be performed zoom operation, facilitating the visualization of the results. Thus, the objective is that the user experience becomes more attractive and facilitates the learning process of DIP techniques.

V. EXPERIMENT

A. Experimental context

A good way to evaluate a teaching tool is through an experiment [13]. The experiment allows collecting feedback from a group of participants about a new tool or approach. Through this feedback it is possible to have evidence about efficiency of a tool/approach or identify their weaknesses.

An experiment was conducted to evaluate the advantage of using platform in teaching and learning DIP. The experiment was executed at São Paulo State University (Universidade Estadual Paulista – UNESP), campus at Presidente Prudente, with undergraduate students in Computer Science ($n = 33$) from different academic years.

Commonly in introductory courses of DIP, the main tool used in teaching is MATLAB. The purpose of this experiment was to introduce to participants the platform as a visual tool that complements the educational concepts of DIP. Importantly, the tool is not intended to replace the MATLAB but offer a dynamic approach for rapid results visualization of methods covered in class.

Most of the participants had no contact with MATLAB ($\sim 76\%$) and also did not have DIP knowledge ($\sim 67\%$).

Furthermore, none of participants had previous contact with the proposed web platform.

B. Hypotheses

The main goal is to analyze whether the visual approach has benefits in understanding DIP concepts when compared to traditional approach. Thus, the hypothesis is: the proposed web based approach is more efficient than the commonly used.

C. Experimental design

The experiment was divided into four stages. In the first stage we presented basics of Digital Image Processing.

The second stage consisted in the presentation of MATLAB syntax, with emphasis on its toolbox dedicated to Digital Image Processing. At same stage, participants were asked to convert a color image to gray-scale using MATLAB. Still using MATLAB, participants applied the threshold on the image obtained from the previous process.

In third stage the platform was briefly presented and asked to the participants to reproduce the stream of operations performed in the second stage.

Finally, in the last stage we ask to the participants to fill a form with a set of assessing questions the platform and about the practicality of use as an auxiliary tool in DIP learning. Through this form it has also enabled participants to provide suggestions and critics to platform.

D. Experiment Data Analysis

The first aspect considered in the form filled out by the participants was the ease of viewing of the techniques presented to be used MATLAB and be used the platform. The participants had an answer with five alternatives (very easy, easy, medium, hard and very hard) for the assertion that the approach facilitated the results visualization obtained by the processing stream.

The Figure 8 shows the distribution of responses obtained by experiment for the first aspect considered. From the chart represented by Figure 8, we note that none of participants considered hard to visualize the processing stream through the platform, while 36.36% considered hard to visualize when used only MATLAB.

Still on the same chart, we can note that 72.72% of the students consider the visualization of the processing stream by the platform easy or very easy, while 15.15% consider the visualization easy or very easy with only MATLAB. Thus, we can say that the use of platform makes it easier to see the processing stream when compared with the only use of MATLAB.

The second aspect considered was the approval of use of MATLAB and platform to help in DIP learning. In this aspect the participants had alternatively five responses: strongly disagree, disagree, indifferent, agree and strongly agree.

The Figure 9 shows the distribution of responses to the approval of use of the tools to aid in DIP learning. Through the Figure 9, we can see that the vast majority of participants believed that the use of these tools assist in learning DIP

Fig. 8. Distribution of answers for easy viewing from the process stream

(75.75% agree to use the platform, while 84.84% agree to use of MATLAB). Thus, according to participants of the experiment is beneficial to use of MATLAB and platform to DIP teaching.

Fig. 9. Distribution of answers to the assertion that tools assist in teaching DIP

In a last aspect we asked to the participants to opt for a tool that they believe offer a better view of the processing stream. The Figure 10 illustrates the distribution of responses in choosing between the tools. The chart represented by Figure 10 shows that 46% participants prefer to use the platform. Note that 24% of respondents believe that the combination of tools is the best alternative for visualizing the stream, coming against the initial hypothesis.

Finally, the Figure 11(a) shows the distribution of preference for participants with previous knowledge of DIP, while the Figure 11(b) shows the distribution of preference for participants without previous knowledge in DIP. Note that for students with prior knowledge the use of the platform is well accepted.

VI. CONCLUSIONS AND FUTURE WORK

In this paper we presented a platform based on web technologies to aid teaching and learning DIP course. By using the web platform has been a gain in ease of access, since it can be accessed from any operating system through a browser that supports HTML5.

Fig. 10. Preferred distribution tool for visualizing the processing stream

(a) Participants with knowledge in DIP

(b) Participants without any knowledge in DIP

Fig. 11. Preferred tool to visualize processing streams for participants with or without knowledge of DIP

As the processing performed are displayed in a single view and the results are structured through a digraph, it is easy for students to view and understand processing streams. It is worth noting that the platform has not intended to replace the coding algorithms, but provide a dynamic experience of the covered techniques.

An experiment was conducted with a group of students in order to verify the acceptance of the platform. Through

the experiment was possible to see a good acceptance of the participants regarding the platform. Furthermore, a promising approach is to use the platform coupled with traditional tools (such as MATLAB).

With the feedback obtained from experiment, some possible refinements were identified and motivate other experiments in future. Among those refinements are the implementation of more processing techniques discussed in higher education courses and the availability of the processing pseudocode. Finally, it can be interesting to perform the processing on client-side (via browser), to reduce traffic on the internet, benefiting low speed connections.

Abstract—Distance Education is a modality widely used in the teaching-learning processes. To support the distance education or blended courses there are educational environments called Virtual Learning Environments (VLEs). These environments support the process of communication between students, teachers, tutors, and the community, allowing everyone to participate in an interactive mode and with availability of teaching materials, both in academia and in the corporate environment. Also, there are several techniques for adaptation resources for students in VLEs found in literature like context-awareness, collaborative learning, and adaptation by Artificial Intelligence (AI) technologies, such as agents and ontologies. Thus, this paper aims to summarize the information obtained in the literature about educational adaptation to students in VLEs supported by a pedagogical theory. For pedagogical theory, Piaget Constructivism was chosen. To obtain this information in literature, a Systematic Review was performed in order to answer three research questions. The results and analyses of the review are also discussed. This study intends to contribute with designers and developers of educational applications, giving a broad view of the area of adaptation resources supported by Constructivism and making some recommendations.

Keywords—*Adaptation; Virtual Learning Environments; Constructivism*

I. INTRODUCTION

Distance Education is a modality widely used in the teaching-learning processes. To support the distance education or blended courses there are educational environments called Virtual Learning Environments (VLEs). These environments support the process of communication between students, teachers, tutors, and the community, allowing everyone to participate in an interactive mode and with availability of teaching materials, both in academia and in the corporate environment. So, many VLEs such as Blackboard [1], Brightspace [2], and Moodle [3] are in continuous process of development and testing in distance courses.

However, despite this huge use of educational environments, they usually offer learning resources in the same way for all students, resulting that the learning may not become effective for all because of several particular characteristics that each student has [4]. This therefore may create difficulties

of knowledge acquisition for some students or even lack of interest by the students in the use of learning environment. So, aiming to solve this problem, there are several techniques for adaptation resources for students in literature e.g., context-awareness [5], [6], collaborative learning [7], and adaptation by Artificial Intelligence (AI) technologies, such as agents and ontologies [8], [4]. In this paper, we considered the term “adaptation resources in VLEs” as the action of changing content (e. g., activities passed, learning objects delivered, and interface changing) in VLEs to adapt according to the students’ characteristics using some technology.

Thus, this paper aims to conduct a systematic review with the information obtained in the literature about educational adaptation to students in VLEs supported by a pedagogical theory. This study is considered relevant because of the importance of identifying, classifying and disseminating research in computer science and education areas, which aims to address the resource adaptation methods presented to the student in the teaching and learning processes. The scope of this research was restricted to Piaget Constructivism pedagogical theory [9]. This theory is applied in several works in the literature testifying the increasing of students’ effective learning [10], [11], [12], [13], [14], [15], [16].

To obtain this information in literature, a Systematic Review was performed. A Systematic Review “is a means of identifying, evaluating and interpreting all available research and relevant information on a research question, a topic or phenomenon of interest, and aims to present a fair assessment of a research topic, using a reliable methodology, rigorous and auditable” [17]. In addition, our Systematic Review was characterized by three research questions that will be answered in Section III:

- **Q1:** Which adaptation techniques shown to students in VLEs are most often currently used?
- **Q2:** From Q1 answer, which adaptation techniques shown to students in VLEs use a Constructivist approach?
- **Q3:** Which suggestions could be given for developers of educational systems aiming to use adaptation in VLEs in a Constructivist manner?

In the first question, the idea was to create a comprehensive study with the adaptation techniques most commonly used nowadays. In turn, the second question defines which adaptation techniques of educational resources in VLEs are within a constructivist perspective. With the results of these questions, the third question tries to make recommendations for developers of educational applications based on future trends evidenced from conclusions about the adaptation techniques found in the constructivist perspective.

This study intends to contribute with designers and developers of educational applications, giving a broad view of the area of adaptation resources supported by Constructivism. The text is divided into four sections. Section II presents related works and concepts. Section III describes the Systematic Review process and presents the results from this research, showing the adaptation techniques most used in VLEs under a Constructivist approach. Finally, Section IV presents final considerations.

II. ADAPTATION IN VLEs USING CONSTRUCTIVISM: THEORETICAL BACKGROUND

The definition of Constructivism is a conception of knowledge and learning, which derives from the genetic epistemology of Jean Piaget [9], that starts from the idea that the knowledge is constituted by the interaction of the individual with the social and physical environment, by virtue of its action and not by any prior endowment, nor the information that the student receives at classroom by the teacher. In Education area, this theory has a dissatisfaction with an educational process that consists of only repeat, recite, teaching what is already done, rather than making act, operate, exchange ideas, create, build from the reality experienced by students and teachers.

In the Systematic Review process conducted, several forms of implementation of Constructivist features in VLEs were observed. The Intelligent Open Challenges System (IOCS) [12] is a proposal for a multi-agent system to adapt some patterns of Piaget's Clinical Method. It has a strategist agent, performing mediation between the IOCS and the user. The proposed system aims to work learning through the application of challenges consisting by logical-mathematical proofs of open conception, worrying to acknowledge and document the reasons for the user compared to the solution, as well giving visibility to ongoing cognitive processes.

In turn, the work presented in [13] proposes "a general framework of multi-strategic learning environment" and analyzes in details each strategy in the VLE. This improves the interest of learning by students and promotes students to carry out personalized learning, improving the quality of teaching-learning processes. The Oscar Conversational Intelligent Tutoring System (CITS) presented in [14] is a system using natural language interface in order to allow learners constructing their own knowledge through discussions. Oscar CITS mimics a human tutor by detecting and adapting to student's learning styles whilst directing the conversational process.

In [15] a Constructivist approach to Adaptive Hypermedia Educational Tool is presented. The learning platform assesses user's knowledge and presents contents adapted according to

the characteristics of the student. This platform allows permanent automatic feedback and support, through teaching methodologies and educational activities. On the other hand, in [16] the study objective was built an e-learning system for a course of Programming Project using Constructivism. Based on this system, the authors conducted experimental teaching and presented how the Programming Course influenced the performance of university students. And in [18] an approach of case-based reasoning for Educational Adaptive Web-Based Systems using fuzzy logic to adapt e-learning contents according to the students learning styles and their individual needs is presented.

In the Systematic Review done, were found some research works dealing with Constructivism and collaborative learning described below. According to Dillenbourg [19], a wide used "collaborative learning" definition is "a situation in which two or more people learn or attempt to learn something together". And in some works dealing with collaborative learning we found the term "Computer-Supported Collaborative Learning" (CSCL). CSCL is a research field focusing on collaborative activities between students supported by computers. With the support of computer networks, students may do cooperative learning activities as "accompanied mutual education, group discussion, exercises and team projects, without the limitation of time and space" [20].

In [10] is presented Omega Network, a proposal to the social and adaptive e-learning areas. In particular, the authors want to distinguish the candidates that act as a point of help in an academic course of e-learning. This way, it was possible to use all the activities and features offered by VLE with technologies such as: adaptive presentation, collaborative filtering, and peer tutoring.

As way to overcome the feeling of isolation and consequent students' dropout in VLEs, the work presented by [11] presents an experiment with the model called i-Collaboration promoting collaboration between students in a VLE. This model is based on the use of Virtual Learning Companions (VLCs) agents as collaboration monitors based on Constructivist theory. These agents are integrated into collaborative tools to know each student profile and his behavior in the learning environment.

As examples of studies that use explicitly the term CSCL, we can mention [21], that is proposed an architecture that provides support for adaptive techniques of collaborative learning into a CSCL environment. The proposal combines adaptation rules and dynamic support through recommendations via a system of accessible and adaptive guidance. Another related work is [22], in which the authors used a multi-agent system in order to develop a CSCL application to form student groups improving collaborative learning. In [23] CSCL and Constructivism are used. Such research has a proposal of a theoretical framework that leverages attention guidance in a social approach to facilitating the process of central domain concepts, principles, and interrelations between them based on social interactions. In [24] is presented an architecture that facilitates the integration of features in a scenario of collaborative learning using the Moodle VLE. The proposal of [25] presents a pedagogical approach supported by a virtual environment to improve and

facilitate cooperative authoring in programming for Computer Science.

Also, in the work presented by [26] is proposed the integration of a set of CSCL tools in a VLE, as a complete sequence of learning activities based on a Constructivist approach. In [27], the authors want to explore the behavior patterns of collaborative learning of students in several simulation systems. Two CSCL learning environments (simulation of Augmented Reality and Traditional simulation) using mobile devices were designed in order to help college students in Physics.

In the conducted Systematic Review, some works that use mobile learning (m-learning) with Constructivist theory were found. The popularization of VLEs and the growth of mobile applications in education has emerged m-learning with a high degree of mobility anywhere and anytime. M-learning is frequently associated with context-awareness feature. This term means "the computer ability to sense and act upon the information provided by its environment, such as location, time, temperature, and user identity" [28].

The educational paradigm considered in COMTEXT project [5] is Interactionist-Constructivist. The tools within the learning environment COMTEXT aims to support the development of competencies in order to promote interaction among a community of students, focused on knowledge sharing and skills development. The authors consider four elements in the work: the knowledge about learner profile and his needs; the physical, temporal and social context that is moving around the learners; the educational paradigm; and the possibilities of wireless and mobile technologies.

In [29] is proposed an m-learning environment that can be used to provide customized learning, which uses the interaction of intelligent agents, which can improve the automated information gathering, planning lessons, customizing learning materials and collaboration between instructors and learners in a Constructivist perspective. Furthermore, the work in [30] describes an environment of personalized m-learning to the University College Dublin aiming provide content delivery to promote an efficient Constructivist learning anywhere/anytime for students. The VLE offers access both via desktop computers and mobile devices, an interactive tool, customized interfaces, reuse of learning objects, recommendation of educational resources, and similar peers.

The proposal presented in [31] consists in a proposal of collaborative learning objects under mobile devices technology allowing creation of teaching units for activities in a collaborative mode between students. The work uses three main approaches: learning objects, CSCL, and m-learning.

Regarding another works found in this Systematic Review using AI technologies, in [32] is presented an educational game for mobile devices based on multi-agent systems. In [33] the authors show courses adaptation according to the student's learning styles. In turn, in [34], an intelligent Java-based framework to provide mobile services (m-Services) in an Info-Station environment is presented. The environment is supported by an HTTP container. A multi-agent system

behaves as a bridge between m-Services applications and users using mobile devices.

We can thus see that there are several studies in literature that deal with educational adaptation technologies using Constructivist features applied to VLEs. The following section describes how the Systematic Review of literature was performed and its results.

III. EXECUTION OF THE SYSTEMATIC REVIEW

In the Systematic Review process, we seek to find answers to the research questions already presented in Section I. We used a search string with the following terms: "profile", "profiling", "profilng", "personalization", "personalisation", "adaptation", "adaptive", "adaptivity", "context-awareness", "VLE", "virtual learning environments", "constructivism", "constructivist", "CSCL", "computer-suported-collaborative-learning", "collaborative learning".

The retrieved publications by the search engines (IEEEExplore, ACM Digital Library, Scopus, Elsevier, Compendex) were organized by the manager references software Mendeley (<http://www.mendeley.com/download-mendeley-desktop/>). This software allowed indexing of items, i. e., a list with the names and other information for instant searches.

The criteria for publications be selected and analyzed in details are described below.

1. Exclusion Criteria:

- Publications whose full text is not available;
- Publications those are only available as an abstract;
- Publications those are a letter from the editor;
- Publications in which the context is not related to adaptation techniques in VLEs or not related to constructivist approach.

2. Inclusion Criteria:

- Publications presented as full papers; short papers and works in progress are counted if they are within the research scope;
- Publications addressing topics that are related to adaptation resources and Constructivist practices in VLEs.

A. Analysis and Discussion of Results

In the digital libraries searched, 951 publications were found in total. Of these, were finally selected 108, corresponding to 11.35% of publications found. To achieve this final number of publications, we used the inclusion criteria established above.

Table I summarizes all adaptation techniques found in the selected publications, ordered by the number of occurrences of adaptation techniques found. Thus, context-awareness was the technique with highest number of matches found (51),

followed by adaptation by agents (35), collaborative learning (33), and so forth. In Table I it is also possible to see further description of the adaptation techniques found. Importantly, in a publication may have occurred more than an adaptation technique. Therefore, the sum of all occurrences of adaptation techniques (218) is greater than the number of all selected publications (108).

TABLE I. ADAPTATION TECHNIQUES FOUND IN ALL SELECTED PUBLICATIONS.

Position	Adaptation Technique	Number of Occurrences	Definition
1	Context-awareness	51	Defined in Section II.
2	Adaptation by agents	35	Using software agents from AI. Agents are computational systems capable of autonomous action in some environment in order to achieve their project goals [35].
3	Collaborative learning	33	Defined in Section II.
4	Learning styles	19	A learner style is the distinctive and habitual way the learner acquires knowledge [36].
5	Fuzzy logic	12	Is a form of many-valued logic that deals with approximate, rather than fixed and exact reasoning [37].
6	Students' interests	10	Interests that students may have in the course.
7	Planning	8	Planning in AI is "the task of coming up with a sequence of actions that will achieve a goal" [38].
8	Competency-based adaptation	8	Related to the students' competencies.
9	Learner model	7	The learner model is made up of learner information considered most important for the adaptation and customization processes in VLEs in order to achieve a more effective learning by students, such as personal information, preferences, and academic information [39].
10	Ontologies	7	Is a formal naming and definition of the types, properties, and interrelationships of the entities that really or fundamentally exist for a particular domain of discourse [40].
11	Content recommendation	7	Recommendations according to students' characteristics.
12	Standards	7	Standards were used allowing content adaptation. The most cited were IMS LIP [41] for students' characteristics and CC/PP [42] for mobile devices.

13	Programmed instruction	3	It consists of self-teaching that presents material structured in a logical and empirically developed sequence [43].
14	Swarm intelligence technology	2	It consists on "the collective behavior of decentralized, self-organized systems, natural or artificial" [44].
15	Meaningful learning	2	Refers to "a learning way where the new knowledge to acquire is related with previous knowledge" [45].
16	Learning objectives	1	Learning objectives "should describe what students should know or be able to do at the end of the course that they couldn't do before" [46].
17	Adaptation by templates	1	Using predefined templates for adaptation in order to create a course.
18	Markov chains	1	A Markov chain is a stochastic process with the Markov property. The term "Markov chain" refers to the sequence of random variables such a process moves through, with the Markov property defining serial dependence only between adjacent periods (as in a "chain"). It can thus be used for describing systems that follow a chain of linked events, where what happens next depends only on the current state of the system [47].
19	Formative assessment	1	This process is "a range of formal and informal assessment procedures employed by teachers during the learning process in order to modify teaching and learning activities to improve student attainment" [48].
20	Genetic algorithms	1	Is a search heuristic that mimics the process of natural selection. This heuristic is routinely used to generate useful solutions to optimization and search problems [49].
21	Knowledge transfer	1	Knowledge transfer is "the process through which one unit (e.g., group, department, or division) is affected by the experience of another" [50].
22	Feedback messages	1	Feedback messages given to students on a Constructive manner, stimulating the students to achieve the correct answer.

A fact that has observed in this study was to find 58 studies (53.7% of total) which use m-learning approach from 108 selected publications. Moreover, for adaptation technique that

uses standards, which got 7 occurrences in Table I, the standards most cited were Instructional Management Systems Learner Information Package (IMS LIP) [41] for students' characteristics and the Composite Capabilities/Preference Profile (CC/PP) [42] characterizing the mobile device that the student uses. Importantly, regarding to the adaptation technique by learning styles (19 occurrences in Table I), the style that appeared more frequently was the Felder-Silverman [51]. Using Artificial Intelligence techniques for adaptation by agents, the most widely used framework was Java Agent Development Framework (JADE) (<http://jade.tilab.com>).

Another interesting information obtained from this systematic review was that of all selected papers, approximately 57% of them had their adaptation techniques tested. Meanwhile, the remaining 43% not tested their approaches or were papers of literature reviews or surveys. Regarding the VLE used, the most cited was Moodle [3] (approximately 14% of selected papers), although in most studies there was no VLE explicitly cited or even used (approximately 38% of selected papers).

The number of works that do not use Constructivist approach from the 108 selected publications was 59 (55% of total), but the 49 (45%) remaining use. Table II shows only the adaptation techniques in which a Constructive approach was used from all selected publications ordered by number of occurrences. In this situation, "collaborative learning" was the technique with the highest number of occurrences found (25), followed by adaptation by agents (17), fuzzy logic (10), context-awareness and learning styles (9 occurrences each), and so on.

TABLE II. ADAPTATION TECHNIQUES FOUND IN ALL SELECTED PUBLICATIONS USING A CONSTRUCTIVIST APPROACH.

Position	Adaptation Technique	Number of Occurrences
1	Collaborative learning	25
2	Adaptation by agents	17
3	Fuzzy logic	10
4	Context-awareness	9
5	Learning styles	9
6	Students' interests	8
7	Ontologies	4
8	Learner model	3
9	Content recommendation	2
10	Planning	2
11	Competency-based adaptation	2
12	Learning objectives	1
13	Markov chains	1
14	Formative assessment	1
15	Feedback messages	1

Returning to the research questions, based on information obtained from results of the Systematic Review, the answers found are described below.

- **Q1:** Which adaptation techniques shown to students in VLEs are most often currently used?
- **A1:** Table I shows all adaptation techniques in VLEs found in this research and the number of their occurrences. According to Table I, the three adaptation techniques found with the highest number of occurrences were: context-awareness, adaptation by agents, and collaborative learning, respectively with 51, 35, and 33 occurrences each. Thus, we can notice that context-awareness is the adaptation technique currently most common in the surveyed literature. In the research works read, context-awareness could be achieved through features in the students' equipment (e.g. GPS, RFID, wireless sensor networks) and student characteristics (preferences navigation, answered activities, frequency of students in VLEs and his learner model). Importantly, in some studies the context-awareness technique was used in combination with other techniques seen in Table I, as adaptation by agents, learner model, and standards.
- **Q2:** From Q1 answer, which adaptation techniques shown to students in VLEs use a Constructivist approach?
- **A2:** From all adaptation techniques found in Table I, Table II shows only adaptation techniques in VLEs using a Constructivist approach and the number of their occurrences. And from all the 22 adaptation techniques described in Table I, 15 of them have been used on Constructivist approaches. And all of 218 occurrences, 95 (43.5%) used adaptation techniques in VLEs with a Constructivist approach. In this case, collaborative learning had the highest number of occurrences (25), followed by adaptation by agents (17), and fuzzy logic (10). Importantly, although collaborative learning is often present in Constructivist approaches, not all studies that use Constructivism deal with collaborative learning and vice versa. This can be seen in Tables I and II. For example, although 33 occurrences have been found collaborative learning, 8 of them did not use Constructivist practices.
- **Q3:** Which suggestions could be given for developers of educational systems aiming to use adaptation in VLEs in a Constructivist manner?
- **A3:** Based on some studies with a greater emphasis on technology rather than the pedagogical aspects, the first suggestion is validate the pedagogical aspect, not only the technologies used. A good work within Informatics and Education area must have a good pedagogical foundation and not only technological innovations, without being supported by an educational theory. Another suggestion for

developers of educational systems is consider using the 7 adaptation techniques found in this study that does not use Constructivist practices (standards; swarm intelligence technology; meaningful learning; adaptation by templates; genetic algorithms; knowledge transfer; and programmed instruction). However, especially when dealing with programmed instruction, as this technique is opposed to the Constructivist practices, developers should check which can be availed from the Skinner theory [43]. Alternatively, developers can use some adaptation techniques based on Constructivism and also the same techniques based on programmed instruction, to compare which of the two approaches would bring better satisfactory results. Another suggestion is to integrate several techniques already using Constructivist practices, allowing VLEs more adaptable to the students' needs. For example, the VLE can provide activities that promote student reasoning and constructive feedbacks to students according to learning styles, skill levels of students, answers of activities and interests. Thus, through feedback that allows the dialogue with the student, he is not just a receiver of information. This dialogue can also mediated by software agents. Another suggestion is to develop applications and Constructivist strategies for m-learning environments, since many works (53.7% of 108 selected publications) using m-learning have been detected in this Systematic Review. For example, content adaptation techniques could stimulate collaborative learning between students and adapt the content shown to the students depending on mobile device features, such as screen size, processing power, memory, location, among others, but in a Constructivist manner. As another idea, according to the learner profile, some personalized activities could be passed to student execute in groups of recommended colleagues to discuss about a specific theme, constructing knowledge through interaction between students. The AI technologies such as agents, ontologies, fuzzy logic, and swarm intelligence could form the groups depending of the students' profile and the constructivist pedagogical theory would be applied to promote interaction between students through collaborative learning in activities passed by teacher.

IV. FINAL CONSIDERATIONS

In the distance education and blended courses, the common practice has been the use of VLEs. In the reviewed literature were found a summary of several techniques for adaptation resources applied in VLEs, in which they have the purpose of a higher degree of student satisfaction and a better effective learning by him, supported or not by a Constructivist theory. Thus, this paper aimed to characterize the state of the art on the adaptation resources in VLEs under a Constructivist

perspective, obtaining information such as which are the most commonly used techniques in the literature and which techniques are used in a Constructivist manner. Based on the research results, some suggestions were given to developers of educational systems who want to make their VLEs more adaptable to the students' needs.

With this study, we provide reflections on the research found that involve the concern with adaptation techniques in VLEs for students. In addition, with this systematic review, researchers can have easy access to research initiatives data in Informatics and Education dealing with this area.

Increasingly, with popularization of the use of mobile devices, the development and use of these devices adapted to educational systems will be more frequent. Furthermore, another fact observed is the adaptation technique of collaborative learning was often observed and thus the developers of educational systems may enhance this practice, also checking the effective learning of the student. In the Artificial Intelligence area, it was observed that there is a wide use of software agents and fuzzy logic. In this case, they may be responsible for an intelligence layer in VLEs, easing the process of content adaptation in courses. Therefore, all these facts found in this study contribute to give suggestions to the developers of educational systems that are interested in working with adaptation resources using a Constructivist approach, by concluding and perceiving that there is a promising future in this research field.

ACKNOWLEDGMENT

The research was supported by Coordination for the Improvement of Higher Level – or Education – Personnel (CAPES) and the The National Council for Scientific and Technological Development (CNPq), Brazil.

Bridging the Divide: Strategies for College to Career Readiness in Computer Science

Wendy A. Lawrence-Fowler, Laura M. Grabowski, Christine F. Reilly
Department of Computer Science
The University of Texas-Pan American
Edinburg, TX, USA
wfowler@utpa.edu

Abstract— The conversations and debates concerning how a student's time on campus translates to better results upon graduation are not going away. Every day institutions of higher education are challenged to explicitly demonstrate and provide a clear articulation of the value of education as measured by post-graduation employment. We discuss strategies implemented in a computer science program to address the issue of student preparation for the workplace of the 21st century. We discuss the extension of more traditional experiential learning methods including project based courses, capstone courses, cooperative experiences and internships to assist students in developing the necessary skills required to transition from college to the workplace.

Keywords—*experiential learning, career readiness, computer science*

I. INTRODUCTION AND MOTIVATION

In 1976, the headline of Newsweek magazine was "Who Needs College?" [1]. The article's commentary is almost identical to that of today's politicians, pundits and the general public who question how a student's time on campus translates to better results upon graduation and debate the value of a college education. There is a shift in the perception of what the role of a university education is. As described in the Washington Post [2], "students and their parents increasingly view college as training for that first job out of college rather than a broad education for life that provides them with the ability to learn and move through multiple jobs and a career." Adding to the confusion, academia, government, industry, and the media make conflicting claims about the adequacy of the workforce: Is the supply and demand for workers in balance? Is there a particularly severe need to increase the supply and quality within the STEM workforce? Are there simply skills mismatches between employer needs and employee skills? Are students ready to transition to the workforce? No matter the answers, institutions of higher education are challenged every day to explicitly demonstrate and provide a clear articulation of the value of education as measured by post-graduation employment, and stakeholders must make decisions with contradictory, confusing or incomplete data [3].

Lumina Foundation's CEO Jamie Merisotis points out that the shift to a knowledge-based workforce has led to a general confusion about postsecondary education and what postsecondary credentialing means. Merisotis suggests that the confusion leads to an employer's lack of confidence in a graduate's readiness for the workforce. He proposes a

transformation of what he refers to as "today's fragmented postsecondary landscape" into one that is student-centered and learning based so that the meaning of the credential is clearer to employers and students [4][5].

In contrast to a traditional higher education model of transferring knowledge, there must be a shift in focus to learning and a shift in the responsibility for the management and direction of learning to the student [6][7]. The move towards making graduates career ready essentially amounts to finding ways to learn basic knowledge, and transforming these capabilities into deeper learning in order to create a flexible and adaptable individual with the appropriate skills to survive in the 21st century [8]. To survive, individuals must adapt and learn in ways that are unprecedented in the formal educational arena.

As university faculty, we have a vested interest in ensuring that our students are employable when they graduate, and we want to help the community understand the value of a college education. We also value a liberal arts education, and work to balance the principle of an education where students learn to become thinkers with the current trend towards an education that prepares students for a job. In this paper, we discuss the approaches we take in our curriculum to help students become well-rounded individuals, as well as prepared for the computing workforce.

We begin by discussing current marketplace factors faced by science and engineering majors. Next, we present the approach we take through our curriculum to help students develop marketable skills while learning to become lifelong learners. We end with a series of narratives based on capstone project experiences and discuss how the capstone project can be used as an opportunity for students to choose specific skills to refine.

II. MARKETPLACE FACTORS

Historically, the developed world benefited from an industrial economy that offered employment opportunities for all skill levels. However, the combination of globalization, pervasive technical advancements, and shifting demography has changed the employment equation. The knowledge economy, with flexible technology and high performance work systems, demands more skilled and autonomous workers [9]. Job requirements are extended beyond specific discipline based skills and knowledge to more general skill sets including learning, reasoning, communicating, and problem-solving with knowledge that cuts across domains [2][9][10][11]. As Kolb

and Yeganeh point out, "Expertise at learning has become a key capability necessary for survival, success and fulfillment" [7].

Though it is often thought that graduates should enter the workforce as a finished product, technical and scientific knowledge evolves so quickly that it is possible that a person's body of knowledge may become obsolete within a few years. In domains undergoing rapid development such as computer science, it is not whether a graduate is ready for the labor market that is most important, rather, upon completion of a degree, students must have not only useful and marketable knowledge and skills, but also the ability to adapt to a continually evolving workplace.

There are a variety of marketplace factors that have influenced our design of a university-level curriculum in computer science. We particularly consider the changing demands of the 21st century workforce. We look at employment rates and the perceived skills gap, the qualities that employers desire in recent college graduates, and we look at the transition from college to career. These issues guide our discussion of the strategies we implement to prepare students to become successful in their transition into the workforce.

A. 21st Century Competencies

The 21st century skills are defined as competencies required for present and future jobs and include knowledge, skills, abilities, work values, work contexts, and work interests, as well as key tasks and activities required by distinct occupations [9][12]. The U.S. Department of Labor's Occupational Information Network (O*NET) program has developed a database with detailed information on the competencies of workers by occupations [12]. Using the O*NET data, Carnevale and colleagues at the Georgetown University Center on Education and the Workforce identified competencies highly associated with occupations requiring computer science training [13]. These include cognitive competencies, such as knowledge of math, physics, and other scientific and engineering fields, as well as complex problem solving skills, technology design, and programming. Non-cognitive competencies include preferences for investigation and independent work [13].

In *Revisiting the STEM Workforce*, a companion report to *Science and Engineering Indicators 2014*, the National Science Board describes multiple pathways to these competencies. They identified a need to assess, enable and strengthen workforce pathways and suggested a heavy reliance on higher education in preparing students [3].

B. Employment Supply and Demand

Given the challenge of ever changing job requirements, Carnevale suggests that a 21st century worker's prospects "are increasingly grim" without a postsecondary education [3].

In 2012 6.2 million scientists and engineers were employed in the United States, representing 4.8% of the total United States workforce [14]. From 2008 to 2012, employment in these areas increased by an annual growth rate of 1.5%, while overall U.S. employment contracted by 0.9%. Although science and engineering employment was concentrated in two occupational groups, computer

occupations (56%) and engineers (25%), when viewed as an aggregate, the increase in employment hides the differential degrees of growth and decline in specialized occupations in these areas [14], an important element in fully understanding employment.

Because labor markets in science and engineering differ greatly across fields, industries and time, it is easy to identify a specialization that is in short supply. For example, employment in social media may be expanding, while other occupations shrink or are moved off shore. And though it is true that highly skilled professional occupations almost always have lower unemployment rates than the rest of the US workforce, there are surprisingly high unemployment rates for recent graduates such as engineering (7.0%), computer science (7.8%) and information systems (11.7%) during the first year [15].

This leads us to focus on how we can better prepare our students for the workplace. We looked at additional marketplace issues in an effort to determine what we can do to increase their competitiveness in the marketplace. Do they lack general 21st century skills, STEM competencies, or computer skills? What do employers want? Are there issues related to transitioning from college to the workplace?

C. A Skills Gap?

In a recent survey commissioned by the Chronicle of Higher Education and Marketplace, over half of the employers said they had trouble finding recent graduates to fill positions at their company or organization. Nearly one third gave colleges fair to poor marks for producing successful employees, criticizing degree holders for lacking basic workplace proficiencies [16]. A recent Bentley University study revealed that there are significant disconnects between students' perceptions of their preparation and employers' expectations of students' preparation, and a disagreement over who is responsible [17]. In a survey of 126 CEOs of major U.S. companies conducted by Business Roundtable and Change the Equation, 97% cited the "skills gap" as a problem [18].

Jeffrey Selinger in The Washington Post asserts, "As the price tag of college skyrockets and the job market for recent college graduates tightens, students and their parents increasingly view college as training for that first job out of college rather than a broad education for life that provides them with the ability to learn and move through multiple jobs and careers" [2]. He goes on to suggest that most college seniors are not ready for professional jobs. They either don't have the hard skills in computer coding and data analysis, or, more important, the soft skills employers are seeking such as problem solving and the ability to communicate and collaborate with co-workers and customers.

Conversely, Paul Krugman in the New York Times reports that multiple studies have found no support for claims that inadequate worker skills explain high unemployment [19]. Other discussions in the news media have suggested that the change in the relationship between job openings and unemployment denotes merely a mismatch due to geography and demography [20], or that it is not a skills gap that

employers are referring to, but rather an experience gap that is holding recent graduates back from the best jobs [6]. Following from this, it has been suggested that colleges should be closing this gap by ensuring that students get meaningful experiences preparing them for work long before they finish school [6].

D. *What Do Employers Want?*

The majority of employers say that possessing both field-specific knowledge and a broad range of knowledge and skills are important for recent college graduate to achieve long-term career success [21]. In broadest terms, demonstrated proficiency in cross-cutting skills related to communication, teamwork, ethical decision-making, critical thinking, and applying knowledge in real-world settings rank as employer's top priorities when hiring [9][22]. The ability to listen, interpret, follow instructions, and communicate with other people both orally and through writing are also listed [23], as are skills that demonstrate aptitude in a social setting and an ability to work in a team [24][25].

An Association of American Colleges and Universities survey found that employers place the greatest value on demonstrated proficiencies in skills and knowledge that cut across all majors; 88% of surveyed employers thought that it was important for colleges and universities to ensure that students are prepared to complete an applied learning project, and 60% thought that all students should complete a significant applied learning project before graduating [21]. The majority of employers stated that they were more likely to consider a job candidate who had participated in an internship, senior project, collaborative research project, or a field or community based project than a candidate who had not.

E. *Challenges for Transition from College to Career*

Currently, most students have opportunities to learn large amounts of domain knowledge and skills, but with few learning opportunities embedded in real work. Yet, when they graduate they are expected to be capable of applying knowledge and skills with flexibility. They must know what to use when, and they are expected to adapt their knowledge and skills to a variety of situations. We have found that even with project-based and capstone courses students may not be well prepared in domains outside of computer science. More importantly, they lack the skills to understand and remedy this situation. Though they should be ready for continued professional development, they may not be. Boshuizen's example of a software engineer who graduated and within five years had to not only stay up to date by learning a new language, but also adapt to completely new concepts and technologies with the introduction of the next disruptive technology [8] provides an example of the most sought after career skills – those skills related to job retention [26].

Smith and Gast [27] proposed, "There is a great myth that all seniors are ready for graduation and their impending transition into careers or graduate education." This is supported by research reported by Goleman, LaPlante, and Shivpuri and Kim suggesting that many students finish college or enter the workforce only to find that they are ill prepared for dealing with many aspects of both their personal and working lives [28] [29] [30]. Even though job-related domain

knowledge is critical for workplace success, there are other necessary skills needed for success in the workplace.

The transition to a career is often difficult because it requires the reorganization of self and the development of a new set of beliefs about life and career. Building on Erikson's theories of ego identity development in which he argues that establishing an ego identity (an understanding of who we are within the context of who we have been and our place in the social order) is the primary task of adolescence [31], Macia contends that college students are at the point of developing identity as a result of exploration and commitment [32]. Hansen talks about this as an identified point in an individual's life when they face anxiety and a sense of being adrift, lost [33]. After years of learning the system of how to succeed in school, the twenty something college graduates are thrown into the world of work with no real understanding of how to succeed in it [33]. They are forced to learn a new set of skills and attitudes that align with the workplace [34][35]. He identified critical issues that graduates face when making the transition from college to work [33]. Those that can be addressed in curriculum include:

- Time related issues - shifting from planning one's own schedule to working five days a week, eight hours a day,
- Learning everything you didn't learn in college and dealing with people of different personality types,
- Professionalism in the workplace based on who you are and what you want to do, and
- Developing a reputation as a valuable employee.

Another approach to address this transition is through internships. To develop mastery, students must acquire component skills, practice integrating them, and know when to apply them. Providing an opportunity to reflect on and integrate their academic experience into the workplace as a professional, quality internships focus on critical skills that employers value highly new employees will need to be successful: risk-taking, leadership, teamwork and collaboration, critical thinking and problem solving [6][36]. The National Association of Colleges and Employers reported that 63% of paid interns received at least one job offer post-graduation [21]. Lander reports that in 2012 69% of companies with 100 employees or more offered fulltime jobs to their interns and that interns had a seven in ten chance of being hired by the company they interned with [37].

III. ENHANCING DEVELOPMENT OF WORKPLACE READINESS

Degree programs in computer science are designed to prepare students with marketable expertise to enter the computing and information fields, as well as the skills and education required to adapt to the rapidly changing characteristics of the fields [38]. Anticipating shifts in skills and abilities, CAC (Computing Accreditation commission) within ABET (Accreditation Board for Engineering and Technology) provides guidelines that challenge faculty to prepare computer science graduates for careers and continuous learning in the ever changing knowledge-intensive workplace [39][40]. Thus, computer science education must cultivate a

wide range of capabilities that extend from current engineering and professional practice to those skills and knowledge sets that will result in the next generation of computer scientists with the abilities to lead and solve challenges well into the 21st century [41]. In this section, we describe the bachelor's and master's degrees that are offered by our department and discuss how various learning approaches are incorporated into our curriculum. We then discuss ideas for personalizing the curriculum based on the experiences and desired learning outcomes of individual students. The final section presents narratives as examples of how the capstone project has been personalized for our students.

A. Computer Science Curricula

The University of Texas-Pan American (UTPA) offers ABET accredited degrees in computer science and computer engineering, and master's degrees in computer science and in information technology. In Fall 2014, approximately 300 students were enrolled in the computer science bachelor's degree, 250 students in the computer engineering bachelor's degree, and 150 in the graduate programs. In addition to providing a core body of knowledge in the domain, the educational objectives for the degree programs include providing graduates with an understanding of social, professional and ethical considerations related to their disciplines. This paper discusses our use of deliberate practice, experiential learning, and the undergraduate capstone course and the graduate level master's project course to provide personalized opportunities for students to better prepare themselves for their careers.

The undergraduate curriculum for both the computer science and computer engineering degrees begins with a course to introduce the discipline. The course sets context for the remainder of the program, providing a foundation for the fundamental concepts of problem solving, algorithms and programming. Concrete exercises with limited solution spaces keep students focused on one or two issues at a time. For the last quarter of the course, robots are used to provide opportunities for students to integrate all of the course concepts with immediate and concrete visual feedback. Over the next two years, the curriculum focuses on skill development by introducing progressively more abstract concepts. It incorporates deliberate practice in both lectures and labs in which student performance is compared against an ideal model of performance to help students develop programming skills, as well as introduce problem solving and languages. The curriculum moves from concrete examples with demonstrations of concepts and constructs to more abstract levels of problem solving. This deliberate practice facilitates a "spiral of knowledge development" [36].

A junior level course in systems programming provides an opportunity to complete an individual semester long project in four well defined stages. This creates a space within the curriculum that allows students to transition from iterative practice to more experiential learning. This shift allows them to develop a knowledge framework that organizes both factual and domain knowledge. Students are able to increase their learning effectiveness through four modes of learning:

experiencing, reflecting, thinking, and acting, all of which are skills and abilities found in the 21st century competencies [36].

During the final year of the undergraduate curriculum, students typically take courses that have more open-ended projects, and students complete a capstone project.

The master's curriculum focuses on providing students with an opportunity to develop a deeper understanding of fundamental concepts of computer science, as well as broaden exposure to specialized topics. Through elective courses and a capstone project, students can choose to focus on a particular area of interest. Computer science master's students have two choices for the capstone project: a one-semester project or a two-semester thesis. The information technology master's curriculum is designed for students who earned a bachelor's degree in a field that is not computing based. The first semester courses provide a leveling experience for these students. At the end of the information technology degree program, students complete a one-semester project.

B. Project Based Courses

The deliberate incorporation of experiential learning in engineering and computer science education is common [36][42][43]. We suggest that a key is to give students project-based work or field studies earlier in their academic career. This provides students with more activities that integrate the lessons of the classroom with the real world [42]. These experiences can be used to address either false beliefs or potential gaps in knowledge and skills that might prevent graduates from successfully advancing their education, finding a job, and succeeding in their career.

We require a project based course in software engineering in each of the undergraduate degrees which may be taken after students have completed courses in advanced algorithms and data structures and in systems programming. The course provides a formal approach to the state-of-the-art techniques in software design and development with focused discussion on project planning, requirements, specification, system design, testing and implementation, and integration of the knowledge that students have learned in their other classes. Team projects are used to provide some experience in real world problem solving. The nature of the projects requires that students learn to not only apply software engineering principles, but, more importantly, develop collaborative and project management skills and expand their written and oral communication proficiency. Teams work on identified problems or challenges, most often involving concepts outside of the students' domains of expertise. This forces students to expand their existing knowledge base beyond the principles of their discipline and software engineering. Addressing a real problem adds value and motivation to the learning experience: the project becomes a challenge with multiple options for a solution, not just an exercise. Students take ownership, and the process to a solution results in identifiable learning outcomes [4][23][44]. At the graduate level, a similar course is offered for both of the degrees. The graduate software engineering course places more emphasis on issues of project management and resource management.

All of the software engineering courses provide an opportunity for students to experience a number of Hansen's critical transition issues. To successfully work within a team students must learn to shift their planning from self to that of the team, often resulting in concessions to schedules developed by the team. They must learn to deal with individuals with different skill sets and different personalities. On a team they must represent their skills and knowledge with honesty. If successful, they learn how to be a valuable team member.

Aside from a required theory course and a capstone senior project, the undergraduate curriculum provides the freedom for students to choose multiple paths through their upper division courses. Through discussion with faculty, students choose pathways that help them reach short term and long term career goals.

Both the undergraduate and graduate database courses include a semester-long project in which students work in groups to design and demonstrate the use of a relational database schema. Students select their own project topic and are encouraged to work with a real client or real problem. The project is divided into phases that are spread throughout the semester. Student teams receive feedback from the instructor on the deliverables for each phase and are encouraged to modify their design based on this feedback prior to progressing to the next phase. The structured phases of the database project help students to understand the software design process, while the open topic of the project provides students with the opportunity to customize the project based on their own interests and learning goals.

These example courses provide a formative learning environment where students can reflect on their experiences, assess their performance, apply feedback to improve their work, and identify their strengths and their weaknesses. Multiple presentations that address content and process allow students to refine communication skills. One of the critical skills desired by employers, and as Jarrett of KORU explains, communication is one of the easiest skill areas to improve in a short amount of time [2][29].

C. Internships

Though we encourage students to participate in internships, we are faced with two significant challenges. The first is that there are 21 million college students and only 2 million internships. The "simple" solution is to create 19 million more paid internships, but it seems highly improbable that this will happen. The second challenge is more closely aligned with our specific student populations. Many of the students have commitments that do not allow them to leave the region until after graduation. To address this challenge, we work with our local community to create opportunities for service learning and in this way create opportunities similar to those available through internships. For example, a student's volunteer work with a local nonprofit on social media can evolve into a paid position with the organization. Similarly, an unpaid internship at a local school district can lead to a permanent position. Recently, a project started in a software engineering course with a potential client turned into an opportunity for a team hire for the summer to complete the work.

D. Capstone and Master's Project Courses

The undergraduate curriculum includes a capstone senior project in which students construct a software product, following it through the stages from initial specification to the final completed project. The master's in computer science requires a thesis or final project, and the master's in information technology requires a final project. Those students who intend to extend their education beyond the master's level are directed towards the thesis option, while those students who intend to use the master's as their terminal degree are directed towards the final project.

The role of the capstone course is for students to integrate and synthesize learning from within the academic major to help students see the coherence across the discipline's body of knowledge. In the senior design and senior project courses in computer science, typically the goal is to promote coherence and relevance of general education and to foster conceptual connections between a student's general education and that in computer science. Design projects foster integration and synthesis within computer science and often require students to delve into other knowledge domains. The courses provide students many opportunities to explicitly develop skills, competencies, and perspectives that were either only tacitly or parenthetically introduced in other areas of the curricula (or missed altogether), improve their career preparation and facilitate their transition from an academic environment to the workplace.

E. Thinking about Career Readiness

We contend that it is important for student success to recognize the role that universities can play in helping students work on personal competence skills, social skills, and career and employment skills concurrently. Career development processes can be embedded in the curriculum and assist students in understanding, evaluating, and developing their personal competencies as they prepare to transition to the workplace. We can add focus on the time of transition from school to work, so that we might better prepare graduates to make this transition - to change their mindset from one geared toward freedom and autonomy to one of structure and teamwork [17]. Getting a job should not be something done after college, rather it should be a multistep process within the curriculum.

IV. EXAMPLE EXPERIENCES

Knowing that "context and continual integration across time" promotes the transfer of knowledge in new contexts, we have opted to go beyond traditional experiential learning methods including project based courses, capstone courses, cooperative experiences and internships to provide further opportunities to assist students in developing the necessary skills required to transition from college to the workplace. We began by developing a simulated corporate environment distributed over time and space to better assist students in transitioning from college to career [42]. Small group contexts provided opportunities for students to learn to communicate clearly in multiple media formats, deal with managing and applying large quantities of data, and making decisions with incomplete information. Students learn to transfer existing knowledge in changing contexts while simultaneously

implementing changes in the areas of personal growth and career development.

In an effort to more closely address the college to career transition, we then extended the simulated environment to support students in meeting academic goals and expectations, facilitating college and career planning and transition to the workplace. By scaffolding the learning experience, students had opportunities to master common skills while still allowing them to tailor individualized learning based on their post-secondary goals. Even though specific student goals and pathways varied, all students were expected to meet similarly rigorous standards. The specific student experiences were shaped by the students' goals, not their prior performance, and were also flexible, allowing students to alter programs to align with their changing post-secondary plans.

The following personal stories provide examples. The goals and expectations for students covered a wide range of knowledge and skills that extended beyond computer science and information technology domains. Their pathways reflect individual career interests and aspirations that were driven by state and national economic needs in conjunction with personal circumstances.

A. Lilia's Story

Though hesitant to accept an internship 864 miles from her family, Lilia was able to coordinate care for her two young daughters with her parents. So, after her junior year as a computer science major, she accepted a summer internship in the technology division of an international food processing company. With her daughters in trusted hands, she was able to focus on the experience and fully participate in a well-structured corporate internship program.

As with numerous other internships, at her internship exit interview, Lilia was offered a job upon completion of her degree. She had a corporate job waiting for her, with the potential for a long and successful career. It would have seemed that she would return to school, breeze through her classes, graduate, and move her daughters half way across the country to begin a career. Though she did return to school, and her classes went well, she returned from her internship, not doubting her computational skills, but rather concerned about her writing. Rather than completing a traditional capstone senior project, she worked with her faculty advisor to craft an experience that met the definition of the senior project, but more importantly focused her attention on honing her writing skills.

Lilia decided to complete a service learning project involving the creation of detailed and complete requirements and specific analysis documents for a software project supporting all organization of a local non-profit. By combining service learning, basic writing and software engineering, Lilia was able to practice professional writing in a situation that required her extant knowledge of the software development process. An unintended outcome of the experience was the opportunity for her to improve her evaluative and intentional listening skills as she elicited requirements from the non-profit's staff.

B. Salmon's Story

Salmon participated in a museum reservation system project as part of the graduate software engineering course. He also took the required database course, but worked on a different project. For the capstone project for the master's degree, Salmon decided to focus on the database component for the museum reservation system. His project expanded the project from the software engineering course by considering a database design for a more general-purpose system that could be used by organizations that handle reservations for a variety of types of events, including tours, room reservations, and reservations of resources. Additionally, the database provided for the storage and retrieval of membership information and staff assignment for events.

This project helped Salmon develop a variety of skills that he will use in the future. When planning the database design, he combined the requirements of the museum with those of another potential client. This required him to abstract the specific needs of each client and focus on how these specific needs could be met by a flexible and general database design. Additionally, he considered how the schema could adapt to new customers in the future. The ability to design a product that is flexible enough to meet the requirements of currently unknown customers is an important skill that is required in the corporate world. Additionally, Salmon wrote documentation for the database design that explained the design and provides a sample application with examples of how the database can be used for creating reservations and generating reports.

C. Victor's Story

Victor's master's project also evolved from the graduate software engineering class project, but with a quite different direction. His role focused on development of the prototype, and it was demonstrated for the class and the client at the end of the semester. The goal of Victor's master's project was to deliver a completed software application to the museum and assist the staff with setting up and rolling out the product.

Over the summer, Victor took control and responsibility for his own learning and engagement with the project. Victor worked on fleshing out the aspects of the system that the team had not included in the prototype. To enhance the functionality and usability of the software, Victor reviewed the requirements document, and incorporated several features that his class team had not included in their requirements.

By early fall semester, Victor thought that the product was nearly completed and looked forward to taking the application to the museum for testing. But the situation at the museum had changed over the summer. Personnel at the museum had changed, so the software would be delivered to a new client representative. As a result, Victor had to handle a number of changed and added requirements. Victor was able to deliver nearly all of the changes and make several adjustments to enhance usability. Near the end of the semester, Victor helped the museum's information technology specialist set up the software to run on the museum's server. Victor also created an extensive help/training video to support the software and offered to provide a rollout period for the software in case the client encountered problems.

In addition to his project, Victor served as a teaching assistant in the computer science department. Working closely with an experienced faculty member over two years, Victor took on more and more responsibility for the delivery of a freshman level computer science course. During his first semester, he assisted the faculty member with a structured lab component. During the second semester he volunteered to both lead lab and occasionally provide a lecture. Reflecting on his experience and the student outcomes, Victor experimented with novel methods for content delivery during his third semester. Finally, during his fourth and last semester, roles were reversed, and the faculty member served as his assistant.

Although Victor had considered a career in software development, upon graduation, Victor accepted an offer to teach at a local community college.

V. CONCLUSION

It is our hope that insights and stories we share will help others experiment with strategies leading to changes in the curriculum that accommodate the boarder landscape of learning required in computer science to maintain a strong, capable workforce, as the workforce needs of the country change. We suggest that these extensions to traditional experiential learning serve as strategies for deliberate and intentional cultivation of skill sets beyond those of the discipline. As a result, students are equipped to better articulate career goals, skills and abilities, and their relationship to the major. They are able to explain the connection between what they are learning in their discipline and the world of work. We propose that these experiences help students move beyond becoming lifelong learners; the experiences assist students to position themselves for lifetime employability. The experiences equip students to strategically and successfully navigate transitions. They serve to support their successful navigation of the path from college to the workplace with clarity, confidence and competence.

Finally, we suggest that although the strategies discussed have been successfully implemented at the faculty level, it is appropriate to intentionally embed career development skills that support the evolving economy into the fabric of the curriculum across the institution. The jobs are there; so is the perception of a "skills gap." There is also an experience gap - one that universities can help bridge.

Abstract—Active military and student veterans navigate engineering education in ways both similar to and different from their civilian counterparts. This Work in Progress describes variation in institutional environments through interviews with campus administrators and inspection of university websites at four institutions. Three emerging themes are identified: 1) the presence/absence of key student policies, 2) variation in student support services, and 3) gaps in provision of such services. Interviews provide data on the challenges faced and assets brought by veterans, from the point of view of administrators. We find that serving veterans is an area of recent and increasing importance to these institutions and that the level of services offered is evolving to include veterans resource centers, training for students and faculty on veterans' issues, and web portals to access veteran-specific information.

Keywords—student veterans; institutional context; university policies

I. INTRODUCTION

As of 2011, nearly a million veterans had used the benefits offered through the Post-9/11 GI bill, and many campuses are seeing significant increases in the numbers of veterans [1], [2]. Military veterans hold tremendous promise for expanding and diversifying the engineering workforce. Yet, little is known regarding the educational pathways and experiences of student veterans in engineering including the institutional factors that shape their experiences.

To better serve student veterans, educational institutions across the country have been charged to “provide meaningful information” to service members, veterans, and their family members to “ensure that educational institutions provide high-quality academic and support services” to active-duty members of the military and student veterans [3]. Institutions have responded to this Executive Order by offering student veteran programs of varying levels of depth and breadth. For example, one report indicates that 62 percent of universities provide programs and services specifically for student

veterans; 71 percent indicated that such programs and services were an integral part of their institution's strategic plan [4].

Through a collective case study across four institutions, University of San Diego (USD), North Carolina State, Purdue, and Clemson, we aim to address gaps in the literature on the experiences and outcomes of student veterans in engineering with a particular focus on the complexities of institutional contexts as they relate to this group. Our overall study seeks to discover why veterans choose to pursue a Bachelor's degree in engineering, how student veterans' military experiences shape their academic experiences, and what are the experiences of student veterans in engineering. This Work in Progress aims to address our fourth key research question, namely how do institutions support veterans in general and in undergraduate engineering education in particular? Later work will include interviews and focus groups with student veterans themselves in engineering to understand how university policies and practices and their military experiences affect their academic experience and success. In its entirety, our study aims to provide actionable information to engineering colleges as they seek to diversify and to service members as they are transitioning to college life.

II. METHODS

A. Data Sources

To better understand the environment and educational context of each institution, we reviewed institutional websites and other materials for information targeted specifically to veterans and conducted semi-structured interviews with key informants who were knowledgeable about policies and services related to veterans. We used a snowball sampling methodology [5, p. 237] and asked each informant for names of others who could provide additional insights. In all cases, we interviewed the VA Certifying Official, a position required by the Veterans Administration for students at an institution to receive benefits. Other interviewees included: administrators

responsible for diversity, engineering advisors, Student Veterans Association (SVA) officers and advisors, admissions officials, counseling center personnel, and veteran services coordinators. In all, we interviewed 23 people – 5 at NC State, 9 at Purdue, 6 at Clemson and 3 at USD. Our interview guide included common information objectives but probes and follow-up questions were tailored to the respondent's position. All interviews, except the first three were recorded and transcribed by a professional transcriptionist; detailed notes were taken at these first interviews. As many of these informants are eager to improve their understanding of the needs of student veterans on their campuses, the research team maintains contact with some of them to remain abreast of relevant changes to the institutional environments and to share best practices from other institutions. Themes were identified by the lead author, with concurrence from her co-authors, from transcript data and informally gathered information using constant comparative analysis [6]. Through member checking, we asked several informants to review and validate our findings.

B. Study Institutions

The four institutions were selected to represent variation in geographic location, proximity to military installations, availability of support services for veterans, enrollment size, school history and mission, and other characteristics. Each of these campuses was identified as a 2014 Military Friendly Campus. A brief description of the institutions is provided below. More detailed information can be found in [7].

Clemson, NC State, and Purdue are land grant institutions, founded in the mid- to late-1800's with agricultural and engineering roots. All three are in the top 25 in undergraduate engineering enrollment and in the top 30 in undergraduate engineering degrees conferred [8] and offer a broad range of fields of study in engineering. Both NC State and Clemson are within two hours' drive of major military installations. Purdue is not but is home to the Military Family Research Institute, described below. In contrast to the much larger land-grant institutions, the University of San Diego (USD) is a Roman Catholic liberal arts institution, founded in 1949. The Shiley-Marcos School of Engineering offers undergraduate degrees in electrical, mechanical, and industrial and systems engineering. Unique to USD is the dual BS/BA degree for all engineering students. San Diego is the home to several major Navy and Marine installations.

In 2014-2015, the total number of veterans using GI Bill benefits at the four institutions was 175 at Clemson, 296 at NC State, 346 at USD, and 379 at Purdue. In Spring 2015, NC State had the most student veterans using the GI Bill in engineering with 56. Each of the other three institutions had fewer than 30. Of note is that veterans make up approximately 5% of the undergraduate engineering students at USD and 1% or less at NC State, Purdue, and Clemson.

III. EMERGENT THEMES

In this early stage of our research, we have identified three themes that shape student veteran experiences on our respective campuses: the presence/absence of key student policies; the availability of student support services; and gaps

in the provision of such services. At each institution, there has been a heightened emphasis placed on improving services for veterans and the policies that provide the framework for these services. We have also identified a few challenges faced and assets brought to campus by student veterans from the perspective of our key informants.

A. Theme 1: Presence/absence of key veteran student policies

1) *Trajectory for change:* All four universities currently participate in the Yellow Ribbon Program, which covers costs of attending the institution beyond what is provided by the GI Bill for post-9/11 veterans and dependents. This program helps veterans afford private colleges such as USD and offsets out-of-state tuition costs at Clemson, NC State, and Purdue. The latter three institutions each provide funding for up to 50 undergraduate veterans per year on a first-come, first-served basis, although more eligible students apply than there is money available; USD does not limit the number of veterans who can receive the benefit as long as they are qualified. Once accepted to the Yellow Ribbon program, students may continue to receive the additional support until either they graduate, their benefits are exhausted, or they are no longer in good academic standing. The amount of support is set by the institution, ranging from \$3,500/year at Clemson to \$8,466/year at USD, with half paid by the VA. Since 2012, GI Bill beneficiaries at NC State have been offered special payment plans, not available to other financial aid recipients, to coincide with their receipt of benefits.

The Veterans Access, Choice, and Accountability Act of 2014 (PL 113-146) requires that as of July 1, 2015, all states provide in-state tuition at public colleges to all veterans using Post-9/11 GI Bill benefits within three years of leaving the service, regardless of their state of residence. The governors of North Carolina and South Carolina signed compliant bills into law in June 2015. Indiana has provided in-state tuition to qualified veteran students at public universities since 2013. While this would appear to effectively eliminate the need for the Yellow Ribbon program at state institutions, there are exceptions in the law that make the program's continuation likely.

Lokken and colleagues have described a military-friendly campus as an institution that strives to identify and remove barriers to the educational goals of veterans and to create smooth transitions between military life and college life [9]. Such campuses also enhance campus awareness of the student veteran population and develop proactive support programs to meet student veterans' needs [10]. USD, NC State, and Purdue are identified as among 1,700 "military friendly" schools in 2015 by Victory Media (<http://www.gijobs.com/schools/>) [11]. USD uses the trademarked "Military Friendly School" seal on their Military and Veteran Students web page to highlight their commitment to their student veterans. Clemson is currently investigating how to regain the military friendly designation that they received in 2014, although informants there emphasized that they are most focused on serving student veterans and that obtaining the military-friendly recognition is a secondary goal.

At the institutional level, each of our land grant institutions is focusing more on student veterans than they have since the

original GI Bill in the 1940's and 1950's. At that time, USD was just beginning so it never had the focus on veterans that it does now. Clemson and Purdue have implemented "Green Zone" training for faculty, staff, and students to help them better understand the challenges faced by veterans and the campus resources available to support them. Clemson has a history as a military institution but a new president has given renewed focus to veterans' issues by elevating the ad hoc Student Veteran Committee to formal advisory committee status. The current president of USD is a military veteran. North Carolina has positioned itself as the "Nation's Most Military Friendly State" [12] and the University of North Carolina System is undertaking system-wide initiatives to be more welcoming of student veterans; these initiatives will then be adopted at NC State. Purdue is the home of the Military Family Research Institute, created in 2000 with funding from the Department of Defense, with a mission to improve the lives of service members and their families through research and outreach [13].

2) *Engineering policies and practices:* Clemson, NC State and USD generally admit veterans to engineering as transfer students. When they seek advice from engineering or the Certifying Official at these institutions, they are advised to take prerequisite math and science courses at a local community college at their own expense, rather than use GI Bill benefits, which are both time and dollar limited. Advisors indicate that taking the courses at a community college, in addition to the cost savings, allows veterans to transition to college and academic expectations more easily.

The land grant institutions require first-time-in-college students in engineering to wait a year before declaring a major to meet prerequisites and explore, through introduction to engineering courses, which engineering discipline, if any, is the best fit. Those entering as transfers, however, like most veterans, are allowed to declare a major immediately upon entry to the school except at Purdue. There, all engineering students are admitted to the First-Year Engineering program and are required to take a series of prerequisites, including a two-semester introductory course on engineering. Typically, students declare a major at the end of the first year. USD engineering students have a common curriculum for the first two years, no matter what major they declare, so they maintain the benefit of exploration and can change majors easily without impacting time to graduation.

B. Theme 2: Availability of Student Support Services

1) *Veterans' resource centers:* During the 2014-15 academic year, Clemson, Purdue, and USD all opened veterans' resource centers. Each aims to provide a centralized place for veterans' needs. At Purdue and USD, this center is a suite located in the student union and is a gathering place for veterans with a lounge, TV, conference room, and other amenities. Their resource centers also host the VA Certifying official(s), Veterans' Student Services Coordinator, and space for the SVA chapter. Clemson University's Student Veteran Resource Center is located in a small room that serves as a lounge and study area in one of the main buildings on campus. The Military Affairs Committee at NC State and the Division of Academic and Student Affairs Strategic Planning Taskforce

both have subcommittees charged with finding a similar space on that campus as it is a recognized need.

2) *SVA chapter:* All four campuses have a local chapter of the Student Veterans' Association, a national association with a mission to "provide military veterans with the resources, support, and advocacy needed to succeed in higher education and following graduation" [14]. Each chapter holds monthly meetings and occasional special events. At NC State, the SVA chapter holds meetings on the engineering campus, in addition to the main campus, to be more inclusive of veteran engineers.

3) *Web pages specific to veterans:* All four institutions have web portals where links to resources of interest to both veterans and prospective students are aggregated. Such a portal, when comprehensive, can give separating service members, and others, one-stop information about campus services targeted to veterans. Students are pointed to information about admissions; the GI Bill and financial aid; campus resources such as the counseling center and disability student services; campus organizations such as the SVA; and external resources such as the nearby VA hospital or local veterans' organizations. Unfortunately, at all four campuses, some information relevant to veterans requires a targeted search to locate. In other words, someone would need to know where the information might be located in order to find it. In addition to a portal for veterans, some departments and services on each campus have added a specific link for veterans to their departments' web pages. Table 1 shows university departments and services where veteran specific information is available either by a link or a web search.

TABLE I. WEBSITE RESOURCES FOR VETERANS (AS OF 4/22/15)

Veterans Specific Links From	Clemson	NC State	Purdue	USD
Admissions	X	X	X	X
Career Services			X	X
Cashier		X		
Counseling Center		X		X
Dean of Students	X			
Engineering				X
Financial Aid			X	X
Housing		X		X
Registrar	X	X	X	X

C. Theme 3: Gaps in Support Services

1) *Data collection:* Since only students who receive GI Bill benefits are required to provide their veteran status, identifying the true number of students and applicants who are veterans is a challenge across institutions. Further, many of those receiving benefits are actually not veterans but are spouses and dependents of veterans or service members. Clemson and NC State have recently added a question about veteran status to their admissions applications; USD and Purdue use The Common Application (www.commonapp.org) which asks about "Armed Services Status" with a drop down list containing: "Currently Serving," "Previously Served," and "Current Dependent."

One issue known to administrators is the reluctance of some veterans to self-identify, particularly veterans who are female, were non-combat, or did not retire [15]. Fernandez [16]

offers several potential explanations: they do not want to be stigmatized by faculty and staff as possibly suffering from PTSD, they want to disengage entirely from the military, and they are resistant to giving out personal information, among other reasons. Students using veterans success centers likewise must self-identify. Because of the lack of centralized collection of veteran status at the university level, information gathered is ad hoc, residing with the certifying official, the SVA chapter, veterans' success centers, and advisors. This makes it more difficult to provide information about services to those veterans who do not self-identify.

2) *Credit for military training.* Admissions officials and engineering departments often do not give credit for training completed while in the military. At USD, department chairs have the authority to extend academic credit for military training as a result of discussions with the Provost's office during a previous NSF grant [17]. Technical training from a Sailor/Marine American Council on Education Registry Transcript (SMART) can be used to satisfy the requirement of up to two introduction to engineering classes. At NC State, the policy is to give credit only for physical education, although the UNC System is studying the transfer of credits issue and developing a system-wide policy to provide additional credit for military training.

3) *Points of contact.* The veterans' resource centers seek to provide a single point of contact for student veterans and their families. However, offices with which veterans interact, such as admissions, registrar, cashier, housing, and others, would also benefit from having individuals within the offices who are knowledgeable about the unique needs of veterans. Where those positions are available, they are highly regarded by the other parts of the campus communities that serve veterans. Although not an official part of the job requirements or duties, several of these offices have had staff who are veterans or advocates who have provided ad hoc support for veterans. Through our interviews, we have found that many of the people who have stepped up to be a point of contact in a particular department or volunteer to serve on military and veterans affairs committee have a personal interest in veterans' issue, often because they are veterans themselves or have a family member who has served.

IV. OBSERVED CHALLENGES FACED BY STUDENT VETERANS

Veterans share many challenges with other non-traditional students due to their age, transfer status, and work-life balance issues related to marriage and children. Through their interactions with the veterans, our informants identified a number of challenges that appear to be unique to them. They observe that it is challenging for students to transition from a highly structured environment in the military to one with far less structure, as found in higher education. Advisors and counselors note the disinclination of student veterans to seek help for academic or personal issues. A percentage of veterans have service-related disabilities, which may or may not be obvious to the casual observer, and may require accommodations such as a particular seat assignment or receiving extra time on tests. Our informants observe that some veterans, however, may be uncomfortable asking for or receiving accommodations despite their need.

V. OBSERVED ASSETS BROUGHT BY STUDENT VETERANS

Informants described strengths that student veterans bring to the university in general, and to their studies in particular. Generally, student veterans have "grit," are adaptable to change, and possess high levels of motivation and maturity enabling success. In addition, veterans are perceived as grateful for the opportunity to be earning their degrees. The diversity and depth of their military experiences enriches classroom experiences and their work ethic and dependability are useful for classroom-based projects that rely on teamwork. Their inclination to support one another is viewed as both positive (student veterans have a built in support network) and negative (relying on one another may preclude them from seeking assistance from non-veterans). Our future work will explore how these and other assets shape student experiences in engineering in particular.

VI. CONCLUSION AND FURTHER RESEARCH

The initial results of our analysis reveal that the four campuses are at different stages in the development of services for student veterans. For example, our study institutions offer varying levels of training to the campus community about veterans issues. Clemson and has offered Green Zone training every semester since Fall 2013 and Purdue offers it to departments on demand and individuals when enough have requested it while NC State is in the process of training the trainers to offer it in the future; USD is investigating the suitability of offering it, in part due to our inquiries. USD offers a legal clinic specifically for veterans while the other institutions do not offer such specifically targeted services. Although there are coordinated efforts at each campus, many student veteran services are offered on an ad hoc basis due to a particular individual's personal motivation as a result of his or her own service or that of family members. These champions are among the advocates for more effective student veteran policies and programs.

In the last few years, there has been an acceleration of efforts to serve student veterans. There is more administrative support for these issues on all four campuses and student veteran centers opened on three of these campuses in 2014-15. This makes our study especially timely as we will be able to investigate how such efforts evolve. This increased interest makes sense given the expected drawdown of the military and the predicted increase in the number of student veterans seeking an education and employment in the private sector.

This study has provided a foundation for our future work that will be from the perspective of veterans themselves. With this groundwork, we will be able both to speak knowledgeably with veterans regarding services on campus as well as determine how well the administrators' perceptions of veteran's service aligns with the experiences of the veterans themselves. Future studies will examine the pace, depth, and breadth of these services and information resources more fully as well as investigate the lived experiences of student veterans. Our goal will be to identify those resources which best meet the needs of student veterans in engineering and create smoother pathways to enrollment and graduation.

ACKNOWLEDGEMENT

We would like to thank our key informants for their assistance with this research and our advisory board for their support of this work.

Abstract—Lab kits allow students to take home laboratory equipment to complete experiments on their own time. Kits like these can expand access to hands-on experiences for online courses and to budget-strapped campuses. Although students like these kits, no previous studies compared student learning outcomes on assignments using these new kits with previous laboratory equipment. During the 2014-2015 academic year, we conducted a quasi-experiment to compare students' achievement of learning outcomes. Half of the laboratory sections in each semester used the existing equipment, while the other sections used the new kit. The objectives of the laboratory assignments were the same and the instructions were kept as close as possible between the two groups.

I. INTRODUCTION

Laboratory experiences help link theory to practice for undergraduate students [1]. More specifically, [2]–[4] each describe the importance of laboratory experiences in control systems courses, despite challenges such as budget constraints, space limitations, class size, and limited teaching resources [3], [5]–[7]. Providing laboratory experiences to off-campus students is a new consideration with the rising popularity of online courses [2], [8], [9].

A. Background

In a control systems laboratory, students typically learn the following skills: building the system, modeling and analyzing the system, developing a controller to meet performance requirements, simulating the controller and system, observing the physical system, collecting the data, and using the data to improve the system model or control tuning [2], [3], [7]. Although [10] believes the controls laboratory experience should prepare students for a career in control systems, these skills can also benefit students who choose not to pursue such careers. Experiments based on DC motors have been identified to meet these skills for controls laboratory experiences [4], [11]. Not only is it straightforward to control the position a DC motor with a proportional-integral-derivative (PID) control [11], a DC motor setup can be expanded to create more complex setups like the inverted pendulum [4].

Lab kits have become popular as the cost of the required hardware has decreased [12]. The contents of each kit vary based on the learning objectives of the course and can be

assembled by the instructor [5], [12], adapted from an existing kit [13] or purchased as a complete kit such as Lego Mindstorms NXT [14], [15]. With a lab kit, students can take home laboratory equipment and complete experiments on their own time [12], [13].

The literature includes examples of lab kits that are similar in cost but not used in control systems courses. The Arduino prototyping kit described in [12] costs about \$95 and was designed for a multidisciplinary course on perception, light, and semiconductors. The Mobile Studio IOBoard described in [16] has multiple versions ranging in price from \$80–\$130; it is primarily used in undergraduate circuits courses.

Additionally, kits have been designed for control systems courses. Students use the Science and Engineering Active Learning (SEAL) System to develop a cart with an inverted pendulum attachment [5]. The SEAL System kit costs about \$100 plus \$179 for a myDAQ from National Instruments [5], [17]. The MESABox uses an Arduino and costs approximately \$180 [13]. The MESABox kit includes multiple motors and sensors and is based on an off-the-shelf kit from Sparkfun that contains more components than required for the targeted course. The laboratory experiments designed for the MESABox cover a variety of controls topics including using the Arduino programming language and wiring all of the circuits. The DC motor control equipment detailed in [4] includes a motor, gearbox, encoder, and \$80 of hardware components to build a non-portable kit for approximate total of \$400 [4], [18].

End-of-semester satisfaction surveys show these kits have been well received by students [5], [7], [12]. However, these studies do not present data to show whether students achieve the intended learning outcomes with these kits. [4], [13] presented student ratings of their own proficiency on learning outcomes before and after taking the class, but there were no direct measures.

B. Purpose

In this study, we aim to replace the basic functionality of an introductory control systems laboratory with an affordable kit. The target budget for the kit is \$100 because this approximates the cost of other affordable kits and engineering textbooks [12], [16]. Once the kit was built, we sought to

answer the question: Can an affordable kit achieve the same learning outcomes as traditional equipment? To evaluate the effectiveness of the new kit, we conducted a quasi-experiment during the 2014-2015 academic year. This paper presents the initial analysis of the quantitative data collected to compare student learning outcomes between the two groups.

II. METHODS

A. Context of the Study

Control Systems (GE 320) is the first of two required control systems courses for all General Engineering majors at the University of Illinois at Urbana-Champaign. The course topics include Laplace transforms, linear mechanical and electrical system modeling, transfer functions, system stability, and feedback control design to specifications. The prerequisite courses for GE 320 are Introductory Dynamics and Intro Differential Equations. Additionally, GE 320 students must have completed or be concurrently enrolled in Analog Circuits and Systems. Most students take GE 320 course during their junior year or fall semester of their senior year. In the fall of 2014, 59 students enrolled in the lecture and one of six concurrent laboratory sections. In the spring of 2015, 33 students enrolled in the lecture and one of four concurrent laboratory sections. Half of the laboratory sections used the existing equipment (comparison group) and the other sections used the new kit (treatment group). The authors were not involved in teaching the course during the study.

During the 16-week semester, each student participated in six two-hour laboratory sessions, each with a different experiment to complete. The first two experiments introduced the equipment, the next two experiments developed models of the DC motor, and the fifth experiment implemented three different position control algorithms [19]. The last experiment repeats system identification and control design on a new system. Students worked in groups of two (or three if necessary) to complete the experiments. However, they submitted individual answers to pre-lab and post-lab questions as well as two-page laboratory reports.

B. Equipment

The new kit designed for GE 320 consisted of a Raspberry Pi (a single board computer), DC motor, a 3D printed stand, and the associated sensors. It costs about \$130. A photo of the kit appears in Fig. 1. The existing equipment included an analog computer, DC motor, sensors, oscilloscope, function generator, and multimeter, together costing about \$15,000 per station [20]. A photo of the existing equipment appears in Fig. 2.

Even though the kit was designed to be portable, the department purchased six kits for students to use in the laboratory under the same conditions as the existing non-portable equipment used in the course. The objectives of the laboratory experiments were the same and the instructions were kept as close as possible between the two types of equipment.

Fig. 1. New Kit

Fig. 2. Existing Equipment

C. Procedure

Quantitative and qualitative data were collected each semester to compare student learning outcomes. The quantitative data included exam scores, laboratory report scores, concept inventory scores, and answers to Likert scale questions on the end-of-semester satisfaction survey. The concept-inventory test is a multiple-choice test constructed by drawing questions from a test that was previously developed to assess students' knowledge about control systems by [21] for mechanical and mechatronics students. Consequently, the original test included questions only about mechanical systems. Students in GE 320 study both mechanical and electrical systems during lecture, but emphasis is placed on electrical systems. We replaced the last question with an equivalent electrical circuit question to ensure a balance between mechanical and electrical systems. A faculty member who has taught GE 320 reviewed the test to ensure the questions were suitable. Student volunteers completed the concept-inventory test and survey on the last day of lecture.

The qualitative data include laboratory observation, student reflections from their individual laboratory reports, and open-ended questions on the satisfaction survey. The analysis of qualitative data is still on going.

TABLE I
FALL 2014 GROUP DEMOGRAPHICS

		Treatment	Comparison
Gender	Male	16	19
	Female	10	8
Class Standing	Junior	13	13
	Senior	12	11
	Other	1	3
Exchange student	No	95%	82%
	Yes	5%	18%
GPA	Average	3.4	3.3

III. PRELIMINARY RESULTS

Table I presents the demographic characteristics of the students in the fall of 2014. Exchange student status and GPA, on a four-point scale, were self-reported. Gender and class standing were calculated from the course roster. Each group has similar demographics and is representative of the overall General Engineering program.

We investigated whether students would achieve the same learning objectives with both types of equipment. In particular, we tested whether the two groups differed in their exam and concept inventory scores.

We started the quantitative analysis of fall semester data by calculating descriptive statistics and plotting the data in histograms. These statistics are presented in Table II. The histograms for each exam are shown in Fig. 3-5 and for the concept inventory in Fig. 6. Then we checked the data for outliers using Grubb's test and normality using the Jarque-Bera test. Exam 1 and the final exam each had one low scoring outlier in the comparison group. Once the outliers were removed, the data from each group and exam were approximately normal.

Finally, we ran a two-sample, two-tailed, t-test for each exam. An $\alpha = 0.05$ was used in each test. Based on this test we do not reject the hypothesis. The Cohen's d effect size and power were also calculated with each test; see Table II. Since the power is very low, additional data will be collected in the spring semester. However, only the concept inventory test will be the same for both semesters.

Even though low scores are expected on concept inventory tests, we checked for other factors that could have influenced the outcome. However, there was no correlation between the time spent taking the concept inventory and the score and very low correlation between the self-reported GPA and the concept inventory score.

IV. CONCLUSIONS AND FUTURE WORK

The initial quantitative analysis of the fall semester data indicates that achievement of the learning outcomes with both types of equipment are the same. However, the power of the tests is low, so more data was collected in the spring semester. Complete analysis of all of the quantitative and qualitative data is still ongoing.

TABLE II
FALL 2014 EXAM AND CONCEPT INVENTORY DESCRIPTIVE STATISTICS

	Treatment			Comparison			Cohen's	
	<i>n</i>	<i>M</i>	<i>SD</i>	<i>n</i>	<i>M</i>	<i>SD</i>	<i>d</i>	Power
Exam 1	24	79.4	14.2	26	82.0	11.6	0.2	0.1
Exam 2	26	83.0	9.4	27	84.3	7.7	0.1	0.1
Final Exam	26	86.1	7.1	25	83.2	7.7	0.4	0.3
CI	16	32.6	11.6	19	35.4	12.0	0.2	0.1

Fig. 3. Exam 1 Results

Fig. 4. Exam 2 Results

Future quantitative analysis includes the survey responses and laboratory reports. Select pre-lab and post-lab questions will also be analyzed using a paired t-test. Qualitative data sources will be coded for themes related to the equipment and overall laboratory experience.

Hands on Project experience in a core class focused on sustainability

Anoop Desai
Associate Professor
Mechanical Engineering
Georgia Southern University
Statesboro, GA 30458

Abstract--This paper seeks to present the findings of an effort to teach sustainability through involving students in hands on projects. The findings have been spread out over three semesters. The course under consideration is part of the core curriculum and is open to students from any major across the university. It is offered by the department of mechanical engineering at a university in the southeast United States. It emphasizes aspects related to global sustainability.

The course focuses on shedding light on sustainability related issues such as environmental pollution, resource utilization, and economics of sustainability. It resorts to innovative design practices as well as novel product ideas as a tool to enhance sustainability. To this end, the course emphasizes hands on learning through design, development and analysis of products from the point of view of sustainability.

Students from all majors across the university typically take this class. They are encouraged to think about a problem critically and approach it from the design perspective in order to try and solve the underlying environmental problem. A physical product prototype is required as part of the final project. In view of the fact that sustainability is comprised of three main pillars namely: environmental, social and economic, students are also required to examine the profitability of their project on a rudimentary level. Students are free to work either individually or as part of a group. Class presentations are due at the end of each semester and are comprised of a design prototype, economic analysis and the environmental relevance of their design solutions. An evaluation rubric is used to grade the final projects in terms of innovativeness, environmental impact and economic justification. To this end, the paper presents examples of a range of student projects.

Keywords-- Sustainability; project; core curriculum; three pillars of sustainability

I. INTRODUCTION

Sustainability related topics are being increasingly taught at many universities across the United States[1], [2], [3]. Phenomena such as global climate change, ever decreasing resources, rocketing oil prices, and food and water shortages are beginning to take on crisis proportions. As a result the topic of sustainability is becoming more commonplace within the public conscience as they realize the gravity of the problem. This is especially true of the younger generation that is arguably more environmentally conscious than their forefathers. Students from all majors are typically interested at least to some degree in sustainable living and enroll

accordingly in classes focused on sustainability. This paper presents the course structure and examples of some hands on projects in a core class focused on this topic.

Sustainability is defined as the ability to meet the needs of the present without compromising the ability of future generations to meet their own needs. It deals with improving the quality of human life while living within the carrying constraints of the supporting ecosystems. Said constraints are often biophysical in nature. Any change in an ecosystem can be classified as elastic or plastic. Elastic strain implies the ability of an ecosystem to regain its original properties once the stress has been removed. On the other hand, ecosystems that are subjected to so called plastic strain are often unable to retain their original characteristics and undergo a severe deterioration over time if left unchecked. In principle, there three main pillars of sustainability namely: environmental, social and economic. In order to qualify as a sustainable practice or a sustainable solution to a problem, all three issues need to be addressed simultaneously. For example, a product cannot be termed as being sustainable if it encourages environmental conservation, but ignores the economics and social cost of that conservation. In other words, the question can be asked: conservation, but at what cost (economic and social cost)?

The course being taught at Georgia Southern University addresses this issue by incorporating a final project to be presented at the end of the semester. This practice also ensures that students get involved in the concept of sustainability and focus on actively solving problems through designing products instead of indulging in passive learning (reading material from a textbook and take exams) [4], [5]. It is not sufficient to consume less and to reduce, reuse and recycle. The solution could lie in a different approach to sustainability namely design. Could humankind live sustainably by designing products and processes that are at once greener (environmental pillar), profitable (economic pillar) and socially conscious (social pillar)? Such products and processes will typically tend to use fewer resources and will have the support of the community not because it is the right thing to do, but because it is also the profitable thing to do. To this end, students examine the cost benefit of their product design as well as its profitability.

The following section presents an overview of the course and presents some examples of students' projects from past semesters.

II. COURSE STRUCTURE

TCGT 1530: Global sustainability and Innovation is a core class offered at Georgia Southern University. It is offered

throughout the year and is open to students from all majors across the university. The class usually has about 125-150 students in one section. Students from a variety of majors such as political science, music management, humanities, foreign languages, business and marketing etc. are enrolled in the course. Course content focuses on topics such as definitions of sustainability, environmental conservation, and energy sources (including conventional and non-conventional sources), Water, water pollution and desalination as well as sustainable water management, manufacturing methods, the concept of reverse supply chain, closing the loop through green manufacturing and the economics of sustainability. Students are evaluated on their performance on four exams (including a final exam), an in class group debate (debating the pros and cons of a specific technology for instance) and a final project. Students are free to work in groups or individually on the final project. In terms of topical coverage, the basic information is imparted in addition to quantifiable parameters in terms of pros and cons of different technologies. For instance, the principle of solar power is explained in detail (scientific basis), different types of solar power are explained (such as Concentrated Solar power, photovoltaics and solar paint), as is the deficiency associated with the technology (efficiency of most PV panels is about 20-25% only). Students are then encouraged to apply principles learned in class to real world projects whereby they can seek to further the cause of sustainability. The focus of the class is to solve problems through proactive product design whereby resources can be used repeatedly as long as such use is done on a sustainable basis.

III. FINAL PROJECT

The final project accounts for about 15 % of the final grade. Participation in the final project is mandatory and it encourages students to think creatively about environmental issues. Some students choose to work in groups (no more than 4 students per group), while others prefer to work by themselves. It has been observed that students that work by themselves are often the more creatively inclined and arrive at a more comprehensive solution than students working in groups. One of the main requirements of the final project is that students create a physical working prototype of a product or process that they are trying to improve (even infinitesimal improvements count for credit). Alternatively, said product or process could be a brand new invention that could replace an existing product/process. This prototype is brought to class and presented during the final week of the semester. Accompanying the physical prototype is a presentation of how the product/process contributes to enhanced sustainability: Does it simultaneously achieve conservation, profitability and social following? To this end, an economic analysis of the product is conducted. The cost for building the prototype is computed. The selling price is ascertained. This is generally a function of the maximum price that the market will bear (if there is a market for that product, a survey of a minimum of about 30 customers will reveal the mean selling price along with the standard deviation) and not based on a standard 'mark up' above total cost. Given this background, the profitability of the product can be computed by calculating the profit

margin per unit. The thinking is that if the product and business as a whole is profitable, more people might want to get in on it, thus building a social following. Thus, the practice of sustainability would not necessarily have to depend upon public subsidies, rather it would be self-sustaining.

TCGT 1530 has had the final project component built into it only very recently. The course has been offered in this specific format for the last four semesters. The following paragraphs will present some of the types of students' projects that have been presented in the past.

IV. EXAMPLES OF STUDENT PROJECTS

Final projects span the entire spectrum of creativity and uniqueness. Some projects are inspired whereas a significant number of projects are either 'me too' types of products (products incorporating repetition of existing ideas) or are downright low on the creativity scale. It has been observed that students with a scientific background don't necessarily give rise to creative ideas and vice versa. Knowledge of material learnt in class such as fermentation process, neutralization reaction, functioning of a solar panel etc. is often used in an actual functional design project. It is always stressed that students observe all safety precautions as appropriate in designing and fabricating their products (including use of personal protective equipment as necessary). Students work on their ideas and projects out of class (This is not an in class activity).

Solar powered cell phone charger: An example in this context was a student project from Spring 2014 when a couple of students who were music management majors proposed the idea for a solar powered cell phone charger. The set up consisted of a mini solar panel that was connected to wire and was designed to charge a cell phone purely based on solar power. The process of charging the cell phone was demonstrated in class using a light bulb as a source of light. The fact that a couple of music majors formulated and fabricated a product of this nature is especially noteworthy. In this case, harnessing solar power to generate electricity (used to charge the phone) constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability analysis combined with demonstration of public benefit constitutes the social pillar of sustainability.

Moss based Foot Mat: Another noteworthy project was presented by a Biology student who created a moss based foot mat in Spring 2014. The foot mat was brought to class and presented. Some of the issues in the manufacturing process were discussed. For example, the student's first attempt at trying to make the moss grow successfully was met with failure. She had to make sure that strict guidelines in terms of sunlight, moisture, nutrients etc were followed in order to make a viable product. In this case, using an organic 'green' moss with an intent towards conservation and environment friendly disposal at end of life constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability

analysis combined with demonstration of public benefit constitutes the social pillar of sustainability.

Organic Soap: This is an oft repeated example that is presented in varying forms almost every semester. Students working in groups make soap organically using glycerin and other organic components. This soap is then either cut into bars or poured into molds (such a turtle or a rabbit etc) before solidification. It is claimed that because such a product is free of harmful chemicals, it is helpful to the skin and the overall health of the individual. Fragrance may or may not be added to the soap depending on the inclination of group participants. In this case, using organic ingredients to make the soap and environment friendly manufacturing processes constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability analysis combined with demonstration of public benefit as well as raising public awareness of the benefits of organic soap (to their skin and overall health as opposed to chemicals used in off the shelf soap products) constitutes the social pillar of sustainability.

Organic Cleaner: A student presented this product during Fall 2014. The cleaner was based on vinegar as its main constituent. It was demonstrated that it was able to successfully clean stains from utensils, window panes etc. It was also argued that given the lack of harmful chemicals in the cleaner, it was safe to use and would not lead to the causation of harmful skin infections. In this case, using organic ingredients to make the cleaner (vinegar based) and environment friendly manufacturing processes constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability analysis combined with demonstration of public benefit as well as raising public awareness of the benefits of organic cleaner (to their skin and overall health as opposed to chemicals used in off the shelf cleaning products that could contain potentially harmful carcinogenic compounds) constitutes the social pillar of sustainability.

Paper mache basket: This project was presented by a student working on her own in Fall 2014. This project was more reminiscent of an arts and crafts project, but promoted use of recycled paper. Strips of paper from old magazines were rolled up into circular patterns and glued together into a cohesive basket pattern that was very tough and almost impossible to break. Such a basket could primarily be used for ornamental and decorative purposes. This student was successful in selling the product online. In this case, reusing old paper to make the baskets and environment friendly manufacturing processes constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability analysis combined with demonstration of public benefit and demonstrated practice of recycling constitutes the social pillar of sustainability.

Organic detergent: This project was presented by a group of students in Fall 2014. Using their knowledge of chemistry and chemical formulation, they formulated a detergent that was devoid of harmful chemicals and was thus conducive to

good health from the users' perspective. It was demonstrated that this product was able to remove stains from clothes and yet remain harmless because of its benign composition. In this case, using organic ingredients to make the detergent and environment friendly manufacturing processes constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability analysis combined with demonstration of public benefit as well as raising public awareness of the benefits of organic detergent (to their skin and overall health as opposed to chemicals used in off the shelf detergent products) constitutes the social pillar of sustainability. It is to be noted that the benefits are achieved without compromising functionality

Ethanol: An Information Technology major presented this project during Summer 2014. She used her knowledge of the process of fermentation using yeast to make ethanol from sugar. She also designed an interactive website to help promote and market her product to the community. In this case, using organic ingredients to make the ethanol and environment friendly manufacturing processes constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability analysis combined with demonstration of public benefit constitutes the social pillar of sustainability. This is a special case that demonstrates the fact that learning can be achieved by truly stepping outside of one's comfort zone. As an IT major, this student apparently had no educational background in terms of ethanol production processes. Thus, the fact that she was able to successfully create the product despite this obvious shortcoming is even more commendable. In terms of actually using her IT background, she used it to facilitate outreach and marketing the product by creating her own website.

Coasters made from recycled jeans: This project was presented by a student during Fall 2014. She used the seam from a pair of old jeans to make a coaster for a coffee table (drawing upon the theme of recycling). She was able to advertise this product online and was successfully able to sell it in that forum. In this case, reusing old jeans to make the coasters and environment friendly manufacturing processes constitutes the environmental pillar, costing and profitability analysis on a batch scale production constitutes the economic pillar and profitability analysis combined with demonstration of public benefit and demonstrated practice of recycling constitutes the social pillar of sustainability.

Additionally, there have been numerous other projects worth mentioning such as a portable trash collector made out of recycled materials, displays made out of bottle caps, glasses made out of used bottles etc, which cannot be elaborated in this paper due to space restrictions. It will be realized that the nature of projects is very diverse. The only constraint on the creative thinking process is that the final product should contribute to enhanced sustainability. A rubric is used to assess the quality of the final product and its presentation. It can be argued that the process of innovation and creativity itself is impossible to assess as is the future success of the product under consideration. The author acknowledges both

arguments. The projects are being assessed not with intent to critique the creativity of the participants, but their contribution and level of participation.

Since the hands on project is evolving on an ongoing basis, future emphasis will be an introduction to methods of mass manufacturing, packaging, and a focus on reducing amount of packaging materials used during transportation.

V. ASSESSING THE FINAL PROJECT

Each project is assessed on a scale of 1-5 (1: Poor and 5: Excellent). Each of the sustainability pillars is addressed. A variety of questions is asked and rated on the aforementioned scale. For example, does the product ameliorate an existing situation related to sustainability? If so, how successfully does it accomplish this? Is the product an improvement on an existing product? Does the product minimize use of raw materials on a net basis? Is there a market for the product? How large is said market? How profitable is the product? What is the level of complexity of the process that resulted in manifestation of the product? What was the level of professionalism of the students in terms of their presentation skills? How involved were the students in creating their projects? It was observed that about 60% of the students scored between 3 and 4 on the economic analysis. 20% of the students scored between 4 and 5 on the same analysis. Most students (85%) were professional in terms of final presentation. Very few if any projects were truly unique, but given the fact that this is an introductory course in sustainability being offered to ALL students (irrespective of their major), a very high level of uniqueness is not really expected in terms of final projects.

It has to be borne in mind that the final project is still in its experimental phase in terms of assessment and constraints. This is still a work in process and will continue to evolve over time. The author hopes to be able to present a more comprehensive paper at some point in the future that will offer a more substantial overview of this activity.

VI. CONCLUSION

An overview of course content focused on sustainability and innovation was presented in this paper. A few examples of successful student projects from the past were also presented. The set of constraints imposed upon the projects was discussed as well as the process of assessing the final project. It is hoped that the hands on activity that is designed to get students actively involved in sustainability topics (which is the primary intent of the final project) will achieve its intended goal over time. The author intends to collect sufficient data over at least eight semesters after in order for any discernible trend to merge in terms of student learning. At this stage, the intent is to share the findings in the form of a full paper at this forum.

Bioinformatics Curriculum Development and Skill Sets for Bioinformaticians

Huanmei Wu, Amrith Palani
Bioinformatics Program
School of Informatics and Computing
Indianapolis, IN, USA
{hw9, apalani}@iupui.edu

Abstract— The rapid advancement in biological data acquisition technologies has led to massive biological datasets, which requires the development and application of computational methods to analyze and interpret the information. Bioinformatics is the confluence of biology, computer science, and information technology. The Bioinformatics programs are offered by more than 100 universities in the United States, and much more worldwide. Different degree (including BS, MS, and PhD), and certificate programs in Bioinformatics have been performed. The current bioinformatics programs in the US have been studied, regarding their curriculum, program competencies, sizes of the faculty, and student enrollments. The job market is also explored for bioinformatics professional training and career planning. The bioinformatics skill requirements are analyzed. Systematical analysis is carried out by integrating the core competences and curriculum improvements in bioinformatics. The potential employers for bioinformatics professionals are analyzed according to the properties of the companies, such as the sizes, the focus areas, the locations, the skill requirements, and other information. The results provide guidance for bioinformatics curriculum development, such as the minimized courses to cover the basic required skill sets for a bioinformatics student to be a successful bioinformatician. In addition, the analytical results are applied to the redesign of the curriculum in our bioinformatics program which offers MS, PhD, and PhD Minor. In summary, the systematic study of the existing bioinformatics programs in the US and the current market needs for professionals in bioinformatics provide great insight for education in bioinformatics. It helps the curriculum development and reexamination. It also provides the students with the required knowledge for their future career.

Keywords—*Bioinformatics; Competencies; Skills; Job Markets*

I. INTRODUCTION

The massive biological data, such as data generated from the human genome project and electronic health records, has led to the great need of computational techniques and machine learning over the big data. The field of bioinformatics emerges when computing meets information. Simply speaking, bioinformatics is an interdisciplinary field among biology, computer science, and information technology. Bioinformatics has significantly contributed to the cures for human diseases, improvements of crop quality and production, creation of new technologies, and novel applications to medicine and industries. With the high throughput data generation in

biological science, the necessities for bioinformaticians are on the rise. Hence, it is necessary to train the next generation of bioinformatics professionals with the required skills to prepare them as future successful bioinformaticians.

Bioinformatics programs have been offered at different levels in the US, from BS to MS and to PhD programs. Due to its multidisciplinary nature, it is important that the bioinformatics curriculum will benefit both the computer scientists and the biologists. Different approaches and strategies for bioinformatics education have been proposed [1-3]. Especially, there are great advocate for conveying the computational and information technology skills for biologists to meet the challenges for the big data sciences. The biomedical data analytics, especially for the -omics era, is another challenging area [1, 2]. In addition, the program competencies have been discussed among researchers and educators. For example, some previous work concluded that biology, computer science, statistics, ethics, and core bioinformatics are the five main broad areas of competencies required for bioinformaticians [3].

In this manuscript, the US bioinformatics programs have been investigated and the current job markets for bioinformaticians have been explored. The results provide great help for educational professionals to improve the existing bioinformatics programs based on the specific program requirements and competencies. In addition, the results provide great support for the students to equip themselves with the necessary bioinformatics skills for the bioinformatician job market openings, and help the biology and informatics students to get prepared if they are interested future careers in bioinformatics.

II. US BIOINFORMATICS PROGRAM OVERVIEWS

The various bioinformatics programs have been studied regarding their hosting departments and schools in the United States from two sources. One source is the US bioinformatics education provided by the *Bioinformatics Organization* [4], which lists the bioinformatics programs, arranged for each state and each university. There are total 95 Bioinformatics Programs listed from this web site, including degree programs of BS, MS, and PhD, as well as certificate programs. The other source is Startclass.com [5], which provides detailed comparisons of different bioinformatics degree programs, such

Figure 1. The school names where the Bioinformatics reside.

as the smart rating, acceptance rate, average SAT range, the total number of enrolled students, the number of incoming students, the in-state and out-of-state tuition, and other informatics. For example, the smart rating will combine the information of five attributes: the financial affordability, the career readiness, the admission selectivity, the expert opinion, and the academic excellence. These five attributes again are based on some statistics on ranking from several other sources, such as Forbes, U.S. News, etc.

The following sections introduce the current state of the bioinformatics programs, by combining the information obtained from these two sources, and the program information from the specific program websites.

A. Academic Structures of Bioinformatics Programs

To be noted that the *bioinformatics* programs are also called as *Computational Biology* or *Biomedical Informatics* by some universities.

First, the host departments and schools of the bioinformatics programs are studied. It has been observed that a bioinformatics program can reside in different academic units. Most popularly, the bioinformatics programs are offered by the College of Arts and Sciences (25%), the College of Engineering (17%), the School of Medicine (13%), the School of Sciences (13%), and the School of Sciences and Mathematics (11%). Figure 1 displayed the names of randomly selected 52 schools, based on *Wordle* image [13], where the sizes of the letters in the image are corresponding to the percentages of the school names. For example, College of Art and Sciences is the largest in the figure as it is the most frequent schools who offers bioinformatics programs.

Usually, the bioinformatics program is a program inside a department, commonly inside the Department of Biology, Department of Computer Science, or Department of Engineering. Sometime, bioinformatics may be a direct program under the umbrella of a school, such as the School of Medicine, or School of Informatics. Table 1 lists the popular department names where the bioinformatics program resides.

In addition, bioinformatics can also be an interdisciplinary program through collaborations of several departments. One example is the Computational Biology and Bioinformatics (CBB) program at Yale University. The CBB is an inter-departmental PhD program, with collaboration from departments of biological science, statistics, applied math, etc. In addition, a few bioinformatics programs are joint efforts among multiple universities. For instance, the University of Pittsburgh and Carnegie Mellon University jointly offer a PhD

Table 1. The popular department names offering Bioinformatics programs.

Department Names	Percentage
Biology	10.5%
Biomedical Informatics	10.5%
Computer Science and Engineering	10.5%
Biological Sciences	7.9%
Bioinformatics	5.3%
Bioinformatics and Computational Biology	5.3%
Computer Science	5.3%
BioHealth	2.6%
Bioinformatics and Medical Informatics	2.6%
Biological and Biomedical Sciences	2.6%
Cellular and Molecular Biology	2.6%
Computational Medicine and Bioinformatics	2.6%
Computational Biology	2.6%
Medical Informatics and Clinical Epidemiology	2.6%
System Biology	2.6%

Figure 2. Bioinformatics degree programs distributions.

program in Computational Biology. Some universities don't have a formal bioinformatics program. Instead, Bioinformatics is offered as minor or certificate programs.

Second, the formal degree programs in Bioinformatics include undergraduate and graduate degrees, ranging from BS to MS to PhD. A detailed review of 69 bioinformatics programs, which have the detailed degree information, showed the degree distributions as illustrated in Figure 2. Basically, Graduate degrees are offered by 80% of all the bioinformatics programs. Master programs (MS) in Bioinformatics is the most popular degrees, which is offered by 65% of all the Bioinformatics programs. Of all the bioinformatics programs, 35% and 39% of them offer the BS and PhD programs, respectively. In addition, there is no programs which only offer BS and PhD (without MS) degrees. In fact, most programs offering a PhD degree in Bioinformatics do not offer the BS degree. There are only three Bioinformatics programs offered all the three degrees from the 69 programs.

Figure 3. The Bioinformatics program faculty sizes.

Third, the ***bioinformatics program sizes***, such as the numbers of faculty members and the numbers of students, are also studied. Some of the universities do not have the specific faculty information on their program web sites. For the 69 programs with the faculty information listed, the number of faculty in the bioinformatics programs are demonstrated in Figure 2. Most of the programs list all the faculty members together, including the core bioinformatics faculty and the adjunct faculty. Basically, 21 programs (42%) have 20 or less faculty members, with an average of 10 faculty members per programs. There are 13 universities have faculty members between 21 and 40, with an average of 30 faculty members per program.

Most bioinformatics programs do not list their student information on the web site. Only a limited number of programs have their current graduate students listed. Based on the limited information of 20 bioinformatics programs, the average number of MS and PhD students for the bioinformatics programs are 36 students per programs.

B. Curriculum and program competencies

The emerging trend of large scale of biological data has restrained the traditional biologists from utilizing the information and has led to the needs of programming and computer software for data analytics, which led to the 'data-driven science'. At the same time, the Bioinformatics programs have to adapt to meet these new needs. In addition, as an emerging interdisciplinary field, a Bioinformatics program is facing new challenges for curriculum design, course organizations, and training delivery approaches.

The program challenges also affect the trainees ultimately. For example, it is natural for some trainees to wonder if they have been provided or will receive the best and practical training in bioinformatics so that they are career-ready upon completion of their degree programs [6]. The bioinformatics programs are expected to have trainees from different life science and computer science backgrounds, as the bioinformatics is the bridge between life science and computer science [7]. The programs are expected to deliver intensive training in both biology and computing skills, in order to provide the workforce with individuals with an

interdisciplinary set of skills necessary for bioinformatics projects.

Students with strong computer science background are expected to have the capability in creating or modifying bioinformatics software systems and/or applications to address questions in bioinformatics research. Students with life science background are expected to have applied knowledge on how to operate on existing bioinformatics tools and to apply the tools for specific bioinformatics projects. Their strong life science background will facilitate them in the interpretation of the results [8].

In addition, it is necessary to include hands-on training on bioinformatics tools, online data repositories, such as UniProt [9] and GenBank [8], as well as the use of Basic Local Alignment Sequence Tool (BLAST) [7] for identifying sequence similarities in both DNA and protein sequences. It would be better for a single application to integrate multiple bioinformatics applications for training the students in bioinformatics. Such examples include BioManager, which is used in Australia to tutor undergraduate students [7], and the Bioinformatics Training Network [10-12]. Using the BioManager web application teaching tool, the undergraduate students are trained to be familiar with sequence alignment, microarray analysis, protein structure and function prediction, proteomics, motif searching, and many other basic technologies in bioinformatics.

It is a general perspective that the three main areas of bioinformatics are genomics, proteomics, and systems biology [9]. Genomics includes sequencing, assembly, and analysis of DNA. Proteomics specifically deals with the protein structures and functions. Systems biology involves computational data modelling of biological systems which can be molecule, tissues, organs or whole organism.

Existing program courses and curriculum designs are based on these three major areas of bioinformatics. The ***major competencies*** of bioinformatics programs are listed in Figure 4 based on keywords extracted from some bioinformatics web sites. The standing out competencies includes biological database management, genomics, molecular biology, proteomics, statistical methods in bioinformatics, algorithms, bioinformatics programming, systems biology, structural biology, next generation sequencing, data mining, big data analysis, computer modelling, machine learning, and other major skills.

The expected ***program outcomes*** are based on the major competencies and major bioinformatics areas. To be more specific, combining the different bioinformatics programs, upon completion of the graduate degree programs, a student is expected to possess the following bioinformatics capabilities:

- Have a sound knowledge of statistics, computer science, biology, proteomics, and genetics; be able to apply them in their bioinformatics projects;
- be able to search and apply bioinformatics tools from a variety of sources, such as books, journal articles, and online encyclopedias;
- have hands-on experiences and have worked on projects related to different areas of bioinformatics.

Figure 4. The major competencies of Bioinformatics programs.

- design and conduct biological data management and computational experiments;
- be able to analyze and interpret data based on their biological knowledge;
- apply their knowledge and skills to address some problems in biology oriented research and be able to program to achieve the objectives;
- possess soft skills, such as efficient communication among team members, good presentation skills, excellent written summary, and fluent verbal discussion;
- apply the best practice and follow the ethical guideline in decision making, information sharing, and privacy protections, in a global, economic, environmental, and societal context.

As mentioned before, the major bioinformatics competencies are illustrated in Figure 4, using the *Wordle* images. It can be seen that the Biological Database Systems, Genomics, Molecular Biology, statistical methods in Bioinformatics and others are all part of the expected competencies for the Bioinformatics programs.

III. CAREER FOR BIOINFORMATICS STUDENTS

Detailed examinations on the job market for bioinformaticians in the US have been performed. The summary information below are from two major job postings portal sites: indeed.com and monster.com.

A. Job opportunities and requirements

The job market for bioinformatics students is promising. The bioinformatics graduates can work on various related fields with varying titles. Sample industrial job titles include data scientist, research associate, computational biologist, bioinformatics scientist, bioinformatics scientist, bioinformatics analyst, software engineer, senior software engineer, and others. There are also openings in academia as postdoctoral fellows, research scientist, research professor, and

Figure 5. The job postings for different job titles (based on a search of keyword of “Bioinformatics” in April 2015 from Indeed.com).

faculty positions (such as assistant professors for PhD students in Bioinformatics). The top ranked job titles for bioinformatics job openings from Indeed.com are illustrated in Figure 5.

The salary package for bioinformaticians starts from \$40,000+ and goes up to more than \$120,000. With more experience in the field, one can go higher over the salary ladder. Based on more than 4000 job postings in bioinformatics only from Indeed.com, the distributions of job opportunities and the salary ranges are illustrated in Figure 6. Bioinformatics job positions for the salary range between \$40,000 and \$60,000 have the most openings by itself (>1600), which is the entry level jobs for bioinformaticians. The combined job postings for intermediate level in bioinformatics, salary range between \$60,000 and \$80,000, have about 1200 job postings. The more

Figure 7. The required skills for entry level jobs in Bioinformatics.

Figure 6. The salary ranges and number of job postings for Bioinformatics professionals.

advanced level jobs for bioinformaticians, with salary range between \$80,000 and \$100,000, have many opening (>700).

The more advanced jobs, such as directors and managers, requires extensive experience in the fields, with salary more than \$100,000. However, the job postings are getting less, with 280 postings in the \$100,000+ category and 120 postings in the \$120,000+ category. Thus, the majority of careers for bioinformatics graduates are in the entry, intermediate, and advanced levels, which are 83% of all the job postings.

Many job postings specifically state that a *graduate degree* in Bioinformatics or related fields are required, although there are opportunities for Bachelor's degree holders. In addition, job seekers with PhD degrees have more openings. A lot of job postings explicitly indicate that PhD degree is preferred over MS and BS degrees.

Regarding the working experiences, a minimum of 3 years working experience on average was required, even for most of the entry level jobs. The required years of experience vary according to the levels of jobs. Usually, a higher paid job required more experience.

B. Skill requirements

Detailed analysis of the skill requirements for different job openings has also been performed. Since the focus on this work is to guide the education program, the skills requirements for the entry level jobs have been summarized below, which are interested in by most bioinformatics degree students. Similar analytical results can be performed on intermediate and advanced jobs.

The required skills for randomly selected 100 entry levels jobs are illustrated in Figure 7 as *Wordle* image [13]. The Figure showed that the most required skills for bioinformatics jobs are programming skills, bioinformatics algorithms, data mining, statistical analysis, database managements, genomics, next generation sequencing, big data analytics, bioinformatics software tools, and others.

More information of the required skills in bioinformatics is summarized below:

- Bioinformatics tools: Samples tools are sequence alignment tools, such as Blast [13-14] or Bowtie [15], the Genome Analysis Toolkit (GATK) [16-17], the Integrative Genomics Viewer (IGV) [18-19], the software system for Next Generation Sequencing, Microarray & qPCR and Data Analysis (Partek), and tools for Ensembl-Havana GENCODE gene set (Ensemble).

Some tools are for database search systems, such as the life science research tool (Entrez), scalable machine learning tools (Mllib), an open source machine learning library for the Python programming language (Scikit-Learn), and a suite of programs for interacting with high-throughput sequencing data (Samtools).

- Statistical software systems: such as SPSS and SAS. In addition, statistical analysis using R or Python is highly demanded.
- Programming skills: It was required for most bioinformatics jobs to be familiar with programming languages. Other than general programing, for

bioinformatics, the most popular programming languages or script languages are R, Perl, Python, Java, and Matlab. At least one of these programming languages will be listed in the job requirements.

- Biology knowledge: Knowledge from molecular biology, cancer biology, and/or modern biology is needed. This is the domain knowledge needed to understand and analyze the data, and interpret the analytical results.
- Genomics and genetics: Genomics and genetics are the core bioinformatics skill sets and are required for almost every bioinformatics job. For example, skills for high throughput sequencing technologies, next generation sequencing, and computational genomics are in high demands.
- Database management: Databases, including traditional relational database systems (e.g., SQL Server or Oracle), NoSQL databases (e.g., MongoDB), big data analytics (e.g., Vertica), and other big data databases (e.g., TCGA) are common required knowledge for potential bioinformatics job seekers. Especially, for big data management or analysis, it is a widely open field and is in great demands.
- Data mining and machine learning: for example, hierarchical clustering and decision trees are common required techniques.

Some additional skills required for the jobs are good communication skills, managerial skills, good team player, ability to multi task, and work independently. These additional skills are the small words in Figure 7.

It can also be observed that there are some overlaps between Figure 4 and Figure 7 (the competencies and the skill requirements). In fact, the more overlap, the better, as it will show that our program competencies meet the job market for bioinformatics.

C. Employers for Bioinformaticians

Based on the job postings, the top 15 companies who have the most job postings in bioinformatics are summarized in Table 2. It can be observed that the leading employer is Leidos, which is a biomedical research Incorporate. It develops and applies advanced technologies for translational research in cancer and AIDS treatments. The second largest company is Illumina, which is a leading developer and manufacturer for next generation life science tools and integrated systems for large-scale biological data analysis. Other tops companies all on biomedical related research and development.

Another way to investigate the bioinformatics job market is the locations of the job postings, which is summarized in Figure 8, for the top 15 locations who have the most job postings. The blue colored areas are on the west coast, mainly in California, which is about 40% for the top 15 locations. The green colored areas are on the east coast in Boston Metropolitan areas, NIH campuses, and New York. The east coast is more than 44% of the top locations. The red colored locations are in the middle areas of the US, which is only 16%, just a little more than Cambridge, MA along. Thus, most of these bioinformatics employers are in the west or east coasts.

Table 2. The top 15 companies who have the most job postings in Bioinformatics. The jobs column lists the number of columns in a random day in April 2015..

Company	Jobs
Leidos	99
Illumina, Inc.	43
Mount Sinai Medical Center	31
The Jackson Laboratory	21
Thermo Fisher Scientific	21
Broad Institute	21
Human Longevity, Inc.	19
Genentech	19
MedImmune	18
Ingenuity Systems	18
Cold Spring Harbor Laboratory	15
QIAGEN	15
New York Genome Center	15
University of Chicago	14
Mayo Clinic	14

Figure 8. The geographical distribution of the job market in bioinformatics for the top 15 locations.

In addition, if there is a big city with a large medical center, the employment opportunities in bioinformatics will rise, such as in Chicago or Houston. For relative small cities, the job market for bioinformatics is limited. For example, in the city and the metropolitan areas of Indianapolis, IN, there is only 6 openings in bioinformatics, although there is the largest

medical school in the US and a lot of biotechnology companies, besides the giant pharmaceutical company, Lilly, is right next to the city.

IV. APPLICATIONS OF THE INFORMATION OBTAINED

The information learned from this study provides great guidance for the redesign of the curriculum, help for the students to self-evaluated their potential bioinformatics skills, and promotion of hands-on experience for bioinformatics professors, educators, and students.

The bioinformatics program at IUPUI offers both MS and PhD degrees [20-21]. Based on the survey results, the curriculums have been revisited and the competencies have been examined. The information from this project help the bioinformatics programs in the following matters:

- *Eliminate redundant contents:* By examining the program competencies and the individual course outcomes, the redundant contents across courses have been identified and resolved.
- *Develop new course modules:* to cover all the required skills, modular courses of 1 or 2- credits have been designed to cover specifically of one or two required skills. This will guarantee that our students are career ready upon graduation. For example, for the biology oriented students with limited background, the programming courses (R, Python, Matlab, Java) are taught in their first semester entering the programs. This will make sure they are ready to work on bioinformatics projects from the beginning.
- *Reorganize the course offering schedule:* The course offering schedule has been revisited to make sure that the students meet all the prerequisites when they are ready to learn a new skill.

In addition, all the students in our bioinformatics program are provided the opportunities to have hands-on experiences, starting from the beginning of their MS programs. All full-time MS students are provided with partial scholarships and hourly research assistantship. Of course, all the PhD students are fully supported. With acceptance of the scholarships, the students are expected to work on bioinformatics projects upon entering the programs. The student records showed that this is a great way to increase the students' experiences and to improve the portfolios of the students when they are ready for jobs. The employment record shows that our students are more than 95% employed after two months of their graduation.

V. CONCLUSIONS

The bioinformatics education in the United States has been studied and the potential employments of the bioinformatics students has been investigated. The current state of the arts of the bioinformatics programs nationwide has been summarized. The bioinformatics program competencies and the career skill

requirements are described in details. Overall, the bioinformatics is a promising field with high demands, better payments, and interesting projects.

Abstract—For textbooks on technical topics, the typical amount of text used is more than what many college students will read. Some teachers observe, and students report, that students commonly skim such text. As such, a writing style that aggressively minimizes text while still teaching the core technical topic may improve student learning; if text is short enough, students may then read and study the text more carefully.

The objective of this study was to compare the effect of text quantity on amount learned.

We created and compared content styles using a lesson that taught Google search techniques. The two main content styles were normal text and minimal text. The normal text style included 6-12 sentences followed by 1-3 examples. The minimal text style included 1-2 sentences followed by 1-3 examples.

We conducted a randomized control study with 168 participants enrolled in a college-level Introduction to Computing course for non-computing majors. Each participant was randomly assigned one lesson style. We provided a pre-lesson and post-lesson quiz, each with ten questions. Additionally, the participants completed background and follow-up surveys. The study was part of a course homework assignment, so self-selection bias was limited. The course is primarily taken by non-majors and covers the basics of Word, Excel, and HTML.

An improvement score is a participant's post-lesson minus pre-lesson quiz scores. The average improvement score for minimal text was 2.4 (6.5 – 4.1), which is higher (p -value < 0.01) than the average improvement score for normal text of 1.1 (5.1 – 4.0).

Thus, teaching the same topic using less text led to more learning. The conclusion is not that materials should be watered down, but rather that great attention should be paid to using minimal text while teaching the same core topics.

Keywords—digital learning; digital education; digital content; lesson assessment; text length, minimal text, college education, college textbooks, STEM.

I. INTRODUCTION

Completing textbook reading assignments improves student learning [4][10], and students are encouraged to complete the readings [3][9][13]; however, 94% of students spend less than two hours per reading assignment [1]. Text length may be a cause. Normal text lengths may use 6 – 12 sentences and 1 – 3

examples to cover a core concept, as shown in Fig. 2(a); whereas, minimal text lengths may use just 1 – 2 sentences and 1 – 3 examples, as shown in Fig. 2(b).

The objective of this study was to compare the effect of normal text and minimal text on the amount learned by students.

II. BACKGROUND

Cognitive load is the amount of mental effort a learner uses during a learning task. Cognitive load theory [8] defines three types of load: intrinsic, extraneous, and germane. Intrinsic load is the load added by the difficulty of the material. For example, adding two small integers has less intrinsic load than dividing two large integers. Extraneous load is the load added by the style of presentation. For example, a description of a square using a drawing has less extraneous load than with verbal descriptions. Germane load is the load added by developing an organized pattern of thought.

Research in instructional design has sought to reduce the learner's extraneous load and increase the germane load [11][12]. This paper focuses on the reduction of extraneous load by reducing the amount of text used to teach a subject.

Text length has been identified as an impactor of reader understanding [5]. Concise text was found to improve usability by 58% [7], where usability is defined by: time to complete a task, errors made during the task, amount remember by user after task, time to recall site's structure, and subjective satisfaction of the user. Longer text has been shown to negatively impact student understanding for secondary language learners [6]. Also, converting written text to spoken text has been shown to reduce extraneous load [2]. However, previous work has not simply measured how much text length impacts the amount a student learns. The problem is especially critical for STEM (science, technology, engineering, math) topics where a solid conceptual understanding of concepts is crucial for a student's continued success in an academic program. We have developed materials using an aggressively minimized-text approach, with anecdotal evidence that the minimal-text approach was well-liked by students and led to improved learning; this paper seeks to provided concrete evidence via a controlled study.

III. PARTICIPANTS

The participants were undergraduate students at the University of California at Riverside enrolled in a basic computing course during the 2013 Fall quarter. The course (CS 8 Introduction to Computing) introduces basic computing applications such as Microsoft Office and web applications, intended for non-computing and non-engineering majors and having no prerequisites. Traditionally, 98% percent of the students are non-computing and non-engineering majors.

307 students participated in the study, of which 164 were randomly assigned to a normal text group and 143 were randomly assigned to a minimal text group. Participants had one week to complete the assignment. Participants from the last three days spent an average of 2 minutes on the lesson, whereas students from the first four days spent an average of 7.5 minutes on the lesson. Thus, students from the last three days were excluded for clearly rushing through without trying and thus improperly skewing results. So, 85 participants from normal text and 83 from minimal text were included in the analysis.

The participants were blind to the conditions and specific purpose of the experiments. The participants were participating as part of their computing applications coursework. The experiments were approved by University of California at Riverside's IRB (Institutional Review Board).

IV. DESIGN

Participants were given one week to complete the assignment by the instructor. Participants who completed the assignment in the last three days were excluded due to apparently rushing the assignment.

The two lesson styles were evaluated for quantity of learning and student engagement. A first measure was the

number of correct answers on the pre-lesson assessment. A second measure was the number of correct answers on the post-lesson assessment. A third measure was the improvement score, which is the second measure minus the first measure. A fourth measure was the length of time spent on the lesson. Fifth through eleventh measures were the follow-up survey questions on how the lesson was used and how useful the lesson was perceived to be.

For each of the third through eleventh measures, we used a Student's T-test to determine whether the lesson styles were significantly different. The T-tests were computed with 2-tails and unequal variances parameters. We applied a Bonferroni correction to account for the multiple tests, so a p-value of $(0.05 / 9) = 0.006$ was needed for statistical significance.

V. MATERIALS

The study was located on a single webpage and included 6 tabs. Only one tab could be viewed at a time, and participants could only progress forward between tabs. At the bottom of each tab was a button to proceed to the next tab. If the button was pressed for the first time but at least one of the input fields was not completed, then the page would generate a pop-up informing the participant that a field was incomplete. Otherwise, the current tab would disappear, and the next tab would appear.

The study page was titled: Digital Education Study. The page included that: "the purpose of this study is to evaluate different ways of presenting educational content." Also, the page included: "Your responses are completely anonymous." The participants were asked to "please refrain from leaving this webpage, using other devices, or asking others for assistance on the content."

In Tab 1, the participant was randomly assigned a unique

Fig. 1. The pre- and post-lesson assessments given to all participants included 10 multiple choice questions.

1 Google search tips

Searching the Internet for particular web pages, songs, movies, images, etc., is one of the most common tasks that a person performs on a computer today. Most people just use the basic standard search technique of typing in key words or even a full question, like: What low-cost foods are also healthy? While that technique often works, sometimes people get frustrated that when they just can't find what they are looking for, especially when what they are looking for is very specific. This frustration occurs not only during Internet searches, but also searching for a particular email too, which is very common these. However, there is good news: What many people don't realize is that there are a few search techniques that can really help narrow down those search results, hopefully leading to finding exactly what one is looking for.

Sometimes during a search, you are looking for a very specific combination of words. For example, you might be looking for a specific person who has a name like "Parviz Spaghetti". Consider the following search: Parviz Spaghetti. That search will turn up tens of thousands of pages, mostly about spaghetti, and people named Parviz, and much more. But really you are only interested in seeing pages about the specific person with the name "Parviz Spaghetti", and don't want to have to wade through thousands of pages.

Fortunately there is a solution. One of the simplest and most effective ways of finding something very specific during an Internet search is to use quotes. In a search, **quotes** around words causes the search to search for those words within the quotes, in the exact order that they appear within the quotes, without any other words in the middle. For example, "circle of knowledge" would only find sites with those three words in that order; a site with just "circle of your knowledge" would not match. Quotes are especially useful when searching for a specific phrase, like the famous statement from Albert Einstein about one's "circle of knowledge". Quotes are also very useful when searching for a person's name, using their first and last name.

For example, sites with *knowledge circle*, or *circle of your knowledge*, would NOT match with Einstein "circle of knowledge".

Quotes are useful to find a specific combination of words. But sometimes the problem with search results is that search is returning pages that have nothing to do with the subject one is interested in, but instead just happens to use the same words as the search. For example, suppose you were searching for adventurous things to do in California, like perhaps mountain biking, whitewater rafting, cave exploring, etc. You might type the following keywords in your search: California adventures. But, the results would be entirely dominated by pages relating to the amusement park named: California Adventure, run by the Disney corporation What's needed is a way to *exclude* results that involve Disney, so the pages that really interest you appear.

identifier that was associated with each activity and submitted answer by the participant. The unique identifier was stored in temporary browser cache. Tab 2 was a brief background survey asking in which school or college the student's current or intended major was, in what year in college the student was, and an agreeability statement: "I am very good at performing searches on Google." The agreeability statement had the following choices: Strongly agree, agree, slightly agree, slightly disagree, disagree, and strongly disagree.

Tab 3 was a pre-lesson assessment with 10 multiple choice questions, ordered the same for each participant, and shown in Fig. 1. Each question covered one or two concepts that were also covered in the lesson. At the top of the assessment, the participant was informed that these questions are to assess prior knowledge, so the participant was informed to "give each question your best and move on."

Tab 4 was a lesson on web searching with Google. The lesson was randomly assigned with equal chances to be either the minimal text or normal text style, shown in Fig. 2. Both styles covered the same concepts, including the same 1 – 3 examples per concept. Minimal text had 211 words; normal text had 1,255 words. A timestamp was recorded when the lesson appeared.

Tab 5 was a post-lesson assessment with the same questions as the pre-lesson assessment. A timestamp was submitted when the post-lesson assessment appeared. Tab 6 was a follow-up survey with five agreeability statements about the lesson, two multiple choice questions assessing how the student interacted with the lesson, and an open-ended short answer question about the lesson style. The agreeability

(a) 1 Google search tips

Using **quotes**, as in "circle of knowledge", searches for exactly those words in that order. Quotes are especially useful for a specific phrase or a person's name.

Einstein "circle of knowledge"	Sites with <i>knowledge circle</i> , or <i>circle of your knowledge</i> , would NOT match.
--------------------------------	--

Using a **minus** before a word, as in -Disney, excludes sites that have that word.

California adventures	Results dominated by Disney's amusement park by that name.
California adventures -Disney	Results now mostly outdoor activity sites; no Disney info.

Including **site:** in a search, as in site:.edu, restricts searches to domains with that ending.

does soda cause obesity	Yields news articles, opinion sites, university articles, etc.
does soda cause obesity site:.edu	Yields only pages from from Harvard, Stanford, Princeton, etc.
does soda cause obesity site:harvard.edu	Yields only pages from Harvard.

Including **filetype:** in a search, as in filetype:pdf, limits results to files of that type.

What is dry ice filetype:ppt	Finds PowerPoint files discussing dry ice.
------------------------------	--

statements were: "the lesson was sufficient to do well on the post-lesson quiz," "I was engaged with the lesson," "the lesson was the right length," "I liked the writing style," and "I am very good at performing searches on Google." The agreeability statements had the following choices: Strongly agree, agree, slightly agree, slightly disagree, disagree, and strongly disagree.

VI. PROCEDURE

The course instructor assigned the study webpage as homework, in which the participants were given one week to complete the study webpage. The participants chose where and when to complete the study webpage. To maintain anonymity, after completing the study webpage, the participant filled a form to submit his/her student ID number—the student ID number was not associated with the randomly-assigned unique identifier. The instructor accessed the student ID number to award course points.

VII. RESULTS AND DISCUSSION

An improvement score is a participant's post-lesson minus pre-lesson quiz scores. The average improvement score for minimal text was 2.4, which is significantly higher (p-value < 0.001) than the normal text improvement score of 1.1, as shown in TABLE I.

TABLE I. STUDENTS ASSIGNED MINIMAL TEXT IMPROVED SIGNIFICANTLY MORE THAN STUDENTS ASSIGNED NORMAL TEXT.

	Pre-lesson quiz	Post-lesson quiz	Improvement score
Minimal text	4.1	6.5	2.4
Normal text	4.0	5.1	1.1
		p-value	< 0.001

Additionally, participants rated agreeableness of statements on a scale of 0 (strongly disagree) to 6 (strongly agree). Participants rated "The lesson was the right length" for minimal text as 4.8, which is higher (p-value < 0.001) than the normal text score of 3.8, as shown in TABLE II. Also, participants rated "I liked the writing style" for minimal text as 4.3, which is higher (p-value = 0.03) than the normal text as 3.0.

TABLE II. STUDENTS ASSIGNED MINIMAL TEXT WERE SIGNIFICANTLY MORE SATISFIED WITH THE LESSON THAN STUDENTS ASSIGNED NORMAL TEXT.

	Normal text	Minimal text	p-value
Lesson was right length	3.8	4.8	< 0.001
Liked writing style	3.0	4.3	0.03

For the agreeability statement "The lesson was sufficient to do well on the post-lesson quiz", participants assigned minimal text rated 4.6 of 6 and normal text rated 4.5 of 6, which were not significantly different (p-value = 0.67). This suggests that both lessons covered the core topics sufficiently.

For the agreeability statement "I was engaged in the lesson", participants assigned minimal text rated 3.8 of 6 and normal text rated 3.3 of 6, which were almost significantly different (p-value = 0.09). The minimal text was more engaging, but not significantly so.

For the agreeability statement "I am very good at performing searches on Google" in the background survey, participants assigned minimal text rated 2.1 of 6 and normal text rated 2.1 of 6. However, in the follow-up survey with the same question, participants assigned minimal text rated 3.9 of 6 and normal text rated 4.4 of 6, which were almost significantly different (p-value = 0.01). The participant's belief in how much was learned was inverse to the amount actually learned. Perhaps the participants assigned the normal text believed they learned more because more text was presented; however, students actually learned more with the minimal text.

The question "How did you interact with the lesson?" had 5 options ranging from "I read every word in the paragraph text and examples" (rated as 5 of 5) to "I didn't really read the lesson" (rated of 1 of 5). Participants assigned minimal text rated 3.5 on average, which is almost significantly (p-value = 0.008) higher than normal text that rated 3.0.

The question "For reading assignments in your classes, how much of the assigned reading do you typically complete?" had 5 options from "100% of the reading" (rated as 5 of 5) to "0% of the reading" (rated as 0 of 5). Participants assigned minimal text rated 4.0 on average and normal text rated 3.9 (we would not expect a difference among the groups). So, the participants overall say they read about 75% of the assigned reading in their classes.

Participants spent more time with the minimal text (8.4 minutes) than the normal text (7.3 minutes); the difference was not significant (p-value = 0.83). Reading the normal text should have taken *longer* than reading the minimal text, so this indicates that participants may have skimmed over the normal text.

Minimal text naturally leads to a more structured presentation using items like tables or lists. To determine the impact of the tables used in the minimal text, we actually had a third group of students use a hybrid lesson using the normal text but with the examples in table form rather than text. Those students' improvement scores were about midway between the normal text and minimal text groups. We note however that the normal text in typical textbooks usually do not use tables in such an extensive manner due to resulting in unusual-looking content.

VIII. TECHNIQUES TO REDUCE TEXT

Creating minimal-text material requires careful attention to reduce text as much as possible while ensuring coverage of core topics, or as Antoine de Saint-Exupery wrote: "perfection is attained not when there is nothing more to add, but when there is nothing more to remove." Several general techniques were used for the minimal-text used in this study, including 1) concise and clear writing using simple declarative sentences, 2) avoiding or removing text that distracts readers from the core topic, and 3) matching the presentation format to the material presented. We highlight some examples of these techniques to illustrate.

One technique to write clear and concise text is to use simple declarative sentences, consisting of subject, verb, and object, as in "Quotes are especially useful for a specific phrase." This style specifically avoids using superfluous prepositional phrases, such as "when searching" in "Quotes are especially useful when searching for a specific phrase." Such prepositional phrases are only needed when the context is unclear; searching is clearly the context, and the prepositional phrase can be removed here without losing meaning. Additionally, a sentence should start with the real subject to clearly indicate the sentence's main point. Avoid starting sentence with pronouns, as in "It is", as the subject can be ambiguous, which may require some text elsewhere to clarify.

Another technique is to remove text that distracts readers from the core concepts, and focus on presenting core concepts first. While text motivating the need for a topic is important, such text should be kept to a minimum. One common method used to motivate topics is storytelling, often entailing setting up a scenario, defining actors, describing what the actors want to do, and finally introducing a problem they face, all before finally defining the core topic or concepts. Such motivational

examples may require 1-2 paragraphs and half a dozen sentences, as in the first two paragraphs of the normal-text style, shown in Fig. 2. The minimal-text approach instead presents the core topic first, then uses examples to provide the same motivation. With carefully chosen examples, the same motivation can often be conveyed without lengthy text that only serves to motivate. In some case, motivational examples may be needed. Motivational text should focus on providing the minimal text needed before introducing the core concept.

A third technique is identifying presentation formats that are best suited for the topics being presented. The minimal-text style used in Fig. 2(b) uses tables to present example searches with the left column presenting the search and the right column explaining. This presentation format avoids sentence text required to describe or present the example, as in starting a sentence with “For example” or “Consider the following search.” Additionally, as the relation between the left-column example and right-column explanation is clear, the explanations start with “Yields” rather than “This example search yields”; further reducing text.

IX. FUTURE WORK AND LIMITATIONS

This study focused on one particular subject. An intrinsically more challenging subject may benefit more from minimal text, whereas an intrinsically less challenging topic may benefit less. Additionally, this study focused on how text quantity impacted learning. A list of writing rules and guidelines would be helpful for helping authors write clear and minimal text that help students learn more.

A future study might include each participant being shown multiple lessons, such that each lesson has a different lesson style. This may help better understand the students predisposition toward each lesson style.

Future work also includes assessing impacts of text length on multiple other topics, identifying and measuring rules for writing minimal text, and measuring additional learning formats for optimizing learning, such as clear writing, images, animations, learning questions, assessment questions, and interactive tools. Learning questions are another way of reading, wherein the student learns a concept by working through incrementally harder questions that start from a known concept. Assessment questions are designed to test a student’s understanding.

One limitation of this work was that students were awarded course points for simply participating in the lesson and not awarded points for working through the lesson. Also, other than the participation of the lesson, the information in the

lesson was not otherwise a part of the course. So, the incentive for a student to work through a lesson was missing.

X. CONCLUSION

The minimal text lesson had more than double the effectiveness than the normal text. The conclusion is not that materials should be watered down, but rather that great attention should be paid to using minimal text while teaching the same core topics.

ACKNOWLEDGMENT

Changsha, China
{lly1990,vlab, shengyu}@csu.edu.cn

Abstract—Experimenting in computer science course is challenging due to the limitation of site, equipment and special experiment tools. In this paper, based on the analysis of the experiments features of computer science curricula, such as, Principle of Computer Organization, Digital Image Process, Digital Signal Process etc., we design two kinds of virtual lab platforms and develop corresponding virtual lab systems for the courses in computer science curricula. In the first virtual lab, every experiment instrument in real lab is visualized as a Java component. In the other kind of virtual lab, the algorithm students learn in the course is packed as a Web Service component by C, C++ or Java. In both platforms, those components are listed in the system. Students are able to select Java components or Web Service components as the experiment they want to do need and integrate them by building connections between them. Then, the students can set input for the experiment in the input component. After click the button of run, the result will be display for the students in the platform. In the two kinds of virtual lab, students can also write the code in the platform. After it is submitted, those codes will be transferred as a component by the platform and be added in the component list. Then they can use them as the components provide by the platform. So, they can test if the algorithm they write is correct. Both platforms are developed by Java Applet and can be run by a browser. By using our system, students can experiment at any time and any place via the Internet. Teacher is also able to do experiment in the classroom. Based on the platforms, 6 virtual lab systems have been developed and used by more than 5 universities in China. Those virtual lab systems have been received favorably by teachers and students.

Keywords—*Virtual laboratory Platform, computer science curricula, JavaBean component, web services*

I. INTRODUCTION

Experimentation is an important part of the study in computer science curricula, which can give students a way to improve what they learned in the classroom and textbook and improve their ability for coding and understanding of theoretical knowledge. Experimentation is also important for students to get an active, engaging learning experience [1–6].

With the rapid development of Internet, Virtual Lab (VL) has become a new solution for experiment. By using VL, the traditional approach to teaching and experimentation has greatly changed at any educational level. The user can

access virtual lab and perform experiments at anytime and in any places [8].

The paper analysis the feature of experiment of the Computer Science Curricula and divided part of them into two types: complex process and heterogeneous resources, and introduces the design of the virtual lab platform which makes the experiment more convenient and more creative, and introduces the implementation of the key technology of those two type of virtual lab systems according their experiment type. The easy-to-use virtual lab system has been received favorably by students and teachers.

Our contributions in this paper are as follows: we design and develop a virtual lab platform for computer science curricula based on the analysis of the experiment of part of the courses. The platform is easy-to-use for students at any time and in any place. Based on the platform, we design and develop 6 virtual lab systems for courses of computer science curricula according to the type of its experiment.

II. RELATIVE WORK

Virtual lab is a hardware and software operating environment which is used for replacing part of or all of the operating steps for traditional experiment. At present, many scholars have done a lot of research on virtual laboratory. In April 2010, Science introduce an introductory chemistry virtual laboratory, Yaron et al have established a online general chemistry virtual laboratory[9], students can freely choose chemical instruments and reagents chemical experiment in the this laboratory. Bal et al have established a virtual laboratory of a switched reluctance motor which use of LabView as a user interface and invoke Matlab through the Matlab&Simulink[10]. Li et al. have developed a distributed intrusion detection system based on the virtual machine, and analyzed the experimental results of different virtual machine environment[11]. Li et al. have established a physical virtual experiment, which private virtual experiments of electron, optics and pulley [12].

Virtual lab system of computer hardware courses has been improved a lot. Brigham Young University describes a computer organization course on the Web [13]. Students can write and execute assembly language programs on a virtual machine with LogicWorks 3 (Interactive Circuit Design Software), which provides graphical means for user input and

simulation output. They can also design and implement the CPU of the virtual machine via a CAD package. The University of Edinburgh develops HASE system [14]. It is a hierarchical computer architecture design and simulation Environment, encompassing both hardware and software. The virtual laboratory of the University of Calgary [15] comprises two locations: a remotely controlled instrumentation laboratory and a digital design experiments collection where the operation of the basic digital circuits is simulated with html applets. Huang proposed a java-based distance learning environment [16], which is a computer-aided instruction (CAI) system for electronic instruments. Students can learn how to use oscilloscopes, function generators, and logic analyzers.

III. ANALYSIS OF EXPERIMENT OF COMPUTER SCIENCE CURRICULA

The experiment of each curriculum in computer science has its own characteristics. In this paper we analyzed the requirement of experiment of most curriculums and classify them in to two main types: complex process and heterogeneous resources. Its course classification by experiment is shown in Table. 1.

TABLE I. THE COURSE CLASSIFICATION BY EXPERIMENT

Type	Curriculum	Requirements of the Experiment
Complex Process	Theory of Circuit, Analog Circuit, Digital Circuit, Principle of Computer Organization, Computer System Architecture, etc.	Students need to master the principle and performance of experimental devices, and to know the function and the application of experiment components
Heterogeneous Resources	Digital Image Process, Data Structure, Computer Algorithm, Principle of Digital Signal Process, Cryptography	Students need to master the basics theoretical knowledge of the course, deepen understanding of the classical algorithm through practice, and be able to design new algorithms.

Complex Processes: This type is generally present in the experimental of the hardware-related courses. The purpose of these courses is to enable students to master the principles and related hardware performance. The purpose of experiment of these courses is to combine theory and practice, to deepen the understanding of the basis theoretical knowledge through practice, and improve students' ability of design and innovation. In this kind of experiment, students first need to master the principles of hardware components and corresponding performance, then choose the appropriate hardware components to build the structure and set the parameter of the components, and execute the processes and get results. There are many experiment components in the experiment process in this type of experiment. Connection relationship between the experimental components is very complex. There is a complex relationship and a lot of control data path in the experiment. Moreover, the experimental devices in such courses generally are electronic chips which can truly concurrent execute. So, the virtual lab platform should solve the parallel problem of the virtual chips.

Heterogeneous Resources: This type is generally present in the experimental of the algorithm design courses. The purpose of these courses is to enable students to master the basics of relevant theoretical knowledge and apply it. The purpose of experiment of these courses is to practice the theoretical knowledge into practice, to deepen the understanding of the basis theoretical knowledge through practice, and improve the abilities of students. In this kind of experiment, students first need to design or implement an algorithm, then test it and analysis the correctness and performance of the result. The experimental process of this type of courses is generally simple. The sequence of experiment components performed is generally linear. Meanwhile, the experiment component is an implementation of some algorithm. There may be different kind of programming language used for program by the student, such as, Java, C++, even Matlab. So, the virtual lab platform should solve the integration of those heterogeneous components.

The above is the characteristics of two types of courses and it is also the requirement of their experiment. At the same time, the other goal of the platform is to provide a convenient, flexible and easy to use experiment environment for students' experiment. As a new solution for experiments in Computer Science Curricula, the platform must solve those problems in traditional experimentation model. To achieve this goal, we have defined a list of criteria for the platform.

Open and convenient: First, the platform should be able to access by students in 7*24 model, so, when a student has a new idea, he can design and test their idea at any time. Second, the platform should be convenient for the students, thus they don't need to install any software for the experiment.

Innovative: The platform should not just provide a replication experiment model for the students. Students should be able to choose the experiment element and set up the experiment flow according to the needs of their experiment. They also should be able to design their own algorithm and submit the algorithm the platform for testing and analyzing.

Visualized: The platform should provide visual experiment result for students, therefore they can determine the correctness of the experiment flow designed by them.

IV. THE DESIGN OF THE VIRTUAL LAB PLATFORM

A. Architecture of the Platform

The Architecture of the virtual lab platform is shown in Fig.1. The virtual lab platform includes two parts, the server and the client. The client is developed by Java Applet technology, which make the user can use the virtual lab system in any browser with the Java VM through Internet or intranet. Therefore it provides an experiment platform to the user in anytime, at anywhere. It meets the need of open lab which is difficult in real experiment model.

The server includes a database, JavaBean library, Web service component library, collaborative experimental support and user management. The user information, group information and experiment configuration information are stored in the database. The virtual components in the complex process

model experiment are stored in the JavaBean library. The algorithm components developed by Web-service are stored in the web-service library. Collaborative experiment server is used for remote collaborative experiment, for group collaboration experiment management and message forwarding. The user management is used for user rights management, experimental operation and process management.

The client includes design panel of experiment process, analysis and execute of experiment process, and the collaborative experiment client. The user can choose the virtual experiment components and build the experiment process in the design panel. After the experiment process is built, the client will execute the experiment process in the local Java VM.

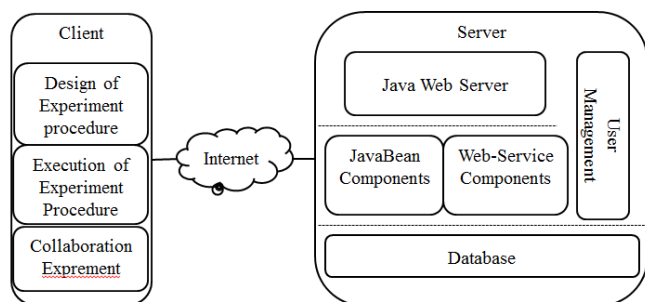

Fig. 1. The architecture of the virtual lab platform

There are some interactions between client and server sides. Firstly, the client tries to connect with web server through browser. After entering the virtual lab, browser will download the Applet pages automatically from the server to the client. Through the Applet, users can choose the experiment component, configure parameters of components, and start to run experiment. Then the client will submit the configuration parameters to the server and request for the Java class files of corresponding components. The server will send these Java class files to the client when it receives the request. Then the codes will be executed on Java Virtual Machine (JVM) at local. At last, the simulation result will be returned to the client.

B. Design Panel of Experiment Flow

The interface of client is shown in Fig.2. It contains three areas: design panel of experiment process, menu and toolbar, virtual experiment component. The menu an toolbar provides the basic operation for users, such as, open, save the file, the start or stop the experiment, rollback and redo of the experiment process, help.

The virtual experiment component contains the list of virtual experiment components in each virtual lab system. All those components are added to the list according to the XML files in the system. When user click one of the components, its information will be displayed blow the list.

The design panel is used for users to build the experiment process. The user clicks the component in the left list and places it in any area of the design panel by clicking the location in the design panel. At the same time, the user can connect the ports of two components to build the experiment process. The virtual experiment components in the design panel can be

moved in the panel by the user. Several connected components can be combined as a new virtual experiment component by the user. The panel is able to be zoomed out and moved by the user. All the operation in building experiment process can be redo or rollback.

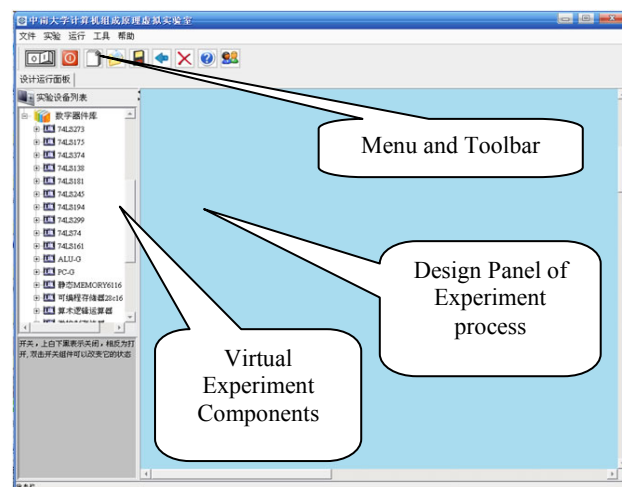

Fig. 2. The interface of client

C. The Virtualization of Hardware Experiment Component

In the complex process type experiment, the hardware experiment component especially the electronic chip is the main resource of the experiment. The variety of those components is huge, and the function of them is complex. At the same time, the connection between them is also very complex. So reusability and extensibility is very important in the virtualization of those components.

The JavaBeans component is a combination of Java technology and component technology, is an integrated assembly model. The JavaBeans is used in this paper to virtualize the hardware experiment component. Each experiment component is packaged as a JavaBeans component, the pin or port of them are packaged as a port. According to the input data, the JavaBean component to perform the appropriate method to simulate the real experiment equipment function to complete the transformation of input data to output data.

The virtualization of hardware experiment component is shown in Fig.3.

Fig. 3. Virtualization of hardware experiment component

In the platform, the user can also define the virtual experiment component as they need and integrate it into their

experiment process. It is only need the user to program the component in Java language in accordance with the JavaBean standard and the system of rules, not need them to get the source code of the platform.

D. The Virtualization of Algorithm Design Component

In the heterogeneous resources type experiment, the algorithm design experiment component is the main resource of the experiment. In this type of experiment, one algorithm may be implemented by multi programming languages, such as Java, C++, and the third-part software may also be used sometimes. For example, Many algorithms are implemented by C++ and Matlab in the Digital Image Process. Meanwhile, the client of the virtual lab platform is implemented by Java. A method to connect JavaBean component(mainly provide data input and result display) with the component implemented by another programming languages is necessary for this type of virtual lab system.

Web (Web services) is a distributed architecture based on XML and Internet technology. Web services technology provides an integrated and interactive mechanism for distributed applications in heterogeneous, autonomous and loosely coupled. In the paper, all the algorithm components are packaged as a Web Service. Different from JavaBean, all the Web Service component is executed in the server, the client just call the Web service and transfer the result to the next component.

The user-defined Web service can also be integrated in the virtual lab system. There are three ways for user to submit their web service component in the system: 1) the user submits the source code of Java or C++ to the server, the client provide an area for source code submitting. After get the source code, the server will compile it and do the security test. If it is all passed, this web service will be added into the components list in the left side of client interface. 2) The user submit the source code which call the third part software in the server(Matlab is now available), the server do the same work as the previous. 3)The user register a exit web-service into the system.

E. Scheduling of Virtual Experiment Component

A trigger scheduling mechanism based on data-driven to control the executive sequence of components is used in the platform. It improves efficiency and real-time responses of the system. This trigger scheduling mechanism based on data-driven can be described as follows:

Each component is initialized as a thread, and all components communicate with each other by wait-notify mechanism and lock technology. Only if a component receives new data from one of its preceding components and notified by it, it will be driven to execute its function. Otherwise, it is always in waiting state, and will have no chance to run.

The concrete process is as follows: At first, the initial values of all components' pins are null, and the value of "dataflag" is set to 0. When a user starts experiment, dispatch-control module analyzes the experimental flow, then constructs each component as a thread and puts it into a thread group. Except data source components, most components call method

wait() to be in waiting state. When data source component has been allocated by the CPU scheduler, it will call method nextDevice() to obtain the information of relevant succeeding components. If the values of "dataflag" in the succeeding components' input pins are 0, the data source component will get and invoke its functional methods with Java Reflection technology. Then it generates new outputs and sends them to the input pins of the succeeding components. Finally, the data source component notifies its succeeding components and waits for being triggered by user again.

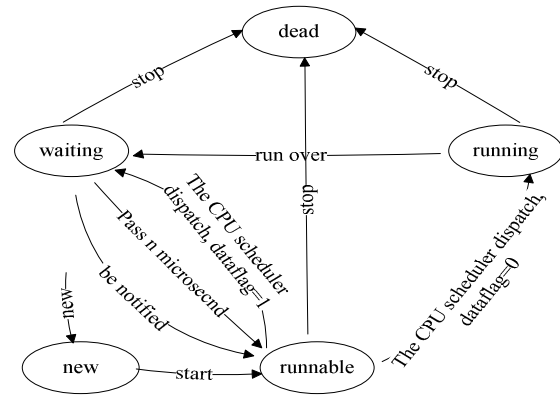

Fig. 4. The state transition diagram

If there is any succeeding component in which the "dataflag" is 1, the data source component randomly waits for a period of time and then check the "dataflag" values again. If all succeeding components are notified, the data source component can adjust itself to a state waiting for running. When it is allocated by the CPU scheduler, it will do the similar operation as the data source component. The difference is that it will be in waiting state again after it notifies its succeeding components. When users click "stop" button in the experiment, the thread group will be stopped, and the experiment will be finished. The state transition diagram is shown in Fig.4.

In order to guarantee successful execution of component, all components must do an atomic operation which can not be interrupted. The atomic operation includes the following operations:

- (1) Execute functional method and send new outputs to the succeeding components.
- (2) Set values of "dataflag" in input pins of the succeeding components and notify them.
- (3) Change the values of its own "dataflag" of input pins.

The virtual lab platform adopts class-lock mechanism to guarantee the execution of atomic operation. The class-lock mechanism represented by synchronized (Class) means that: all threads share only one lock, the component which owns the lock will execute preferentially, and the rest threads should stay in the waiting queue. Only when the atomic operation is over and the lock is released, waiting threads can contend for the lock to execute their function. The process of components scheduling is shown in Fig. 5.

For the special component with bidirectional pins, its pins can be changeable while running. The system defines an attribute variable named “Direction” to represent its running direction. When a component is running, we can get and set “Direction” dynamically by calling methods `getDirection()` and `setDirection()` with Java reflection technology. Then, the component does the corresponding operation according to the current value of the attribute Direction.

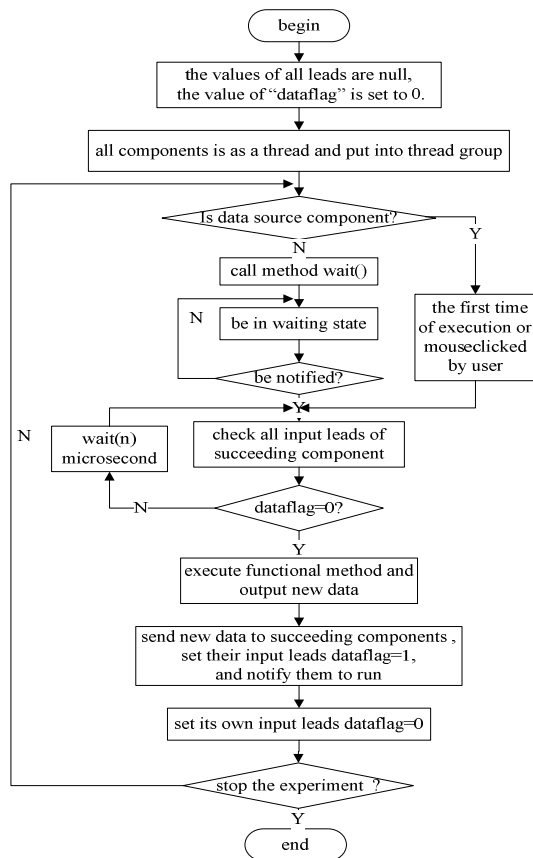

Fig. 5. The flow sheet of components dispatch

V. EXAMPLES OF THE VIRTUAL LAB SYSTEM OF TWO TYPES OF EXPERIMENT

A. The virtual lab of Principle of Computer Organization

The experiment of PCO(Principle of Computer Organization) is a typical complex process type experiment. All the experiment components are electronic chips. The connection of those components is very complex in some experiment of PCO. There is also a loop in the experiment process.

The model computer experiment is the most complex experiment in the PCO. A model computer is a simple but complete CPU mode. It is the best way for students to understand the principle of compute and how chips work collaboratively under the control of the instructions.

A model computer contains micro control chip, timing system, arithmetic logic unit, memory, etc. Some of them are composed by many tiny chips. The connection diagram of a

model computer is shown in Fig.6. The user can select virtual experiment components from the components tree in the left side and place it in the design panel, then connect their ports by connections. The system provides a preset experiment process of model computer. The user can open it from the menu. This procedure contain micro control chip(designed in this system), memory(6116 chip), arithmetic logic unit(2 74LS181 chips) and other chips.

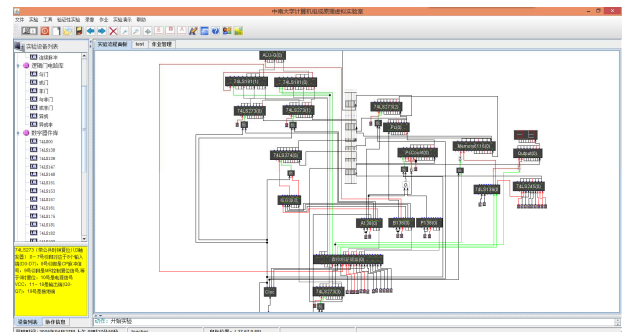

Fig. 6. The experiment flow of model computer

After the experiment is built and the power is turned on, the model computer is ready to run. Then the user can open the model computer debugging windows by the menu, which is shown in Fig.6. In this window, the right side is used for display the sketch map of the model computer, the left side is use for user to input machine code and control the code running.

In this experiment, we use the preset code in the system, which get two input data and plus them. After the preset code is inputted into the system, the user can execute the code one by one on machine code or micro instruction, even on clock. The port and its connection will become red when an available signal is set on it. The state of sketch map and experiment process will change together. The Fig.6 and Fig.7 is the state after a micro instruction of machine code of ‘add’ is executed.

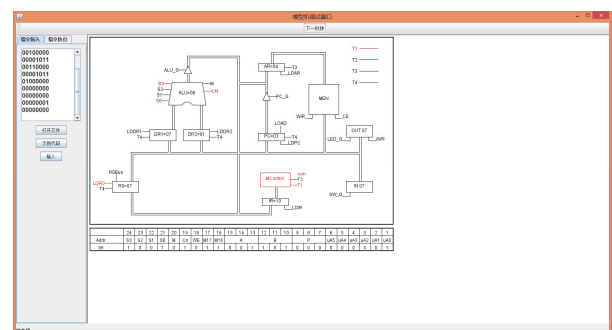

Fig. 7. he interface of model computer debugging

B. The virtual lab of Digital Image Process

The experiment of Digital Image Process is a typical heterogeneous resources type experiment. In this course, the student designs the algorithm of image processing. How to check the validity of the algorithm is difficult in traditional experiment model, because the student need to program the input and output code for the test.

Digital image processing experiments contains many complex and abstract algorithms. MATLAB has a powerful image processing capabilities, and its toolset contains a large number of sophisticated digital image processing functions. OpenCV is also an efficient image processing tool, which implements the general algorithm of digital image processing. In the system, all these heterogeneous components can be packaged as a Web service and integrated into the platform. The platform also supports researchers used their own familiar programming language to develop components and these components are integrated into the platform and compared with the original proven components of the platform.

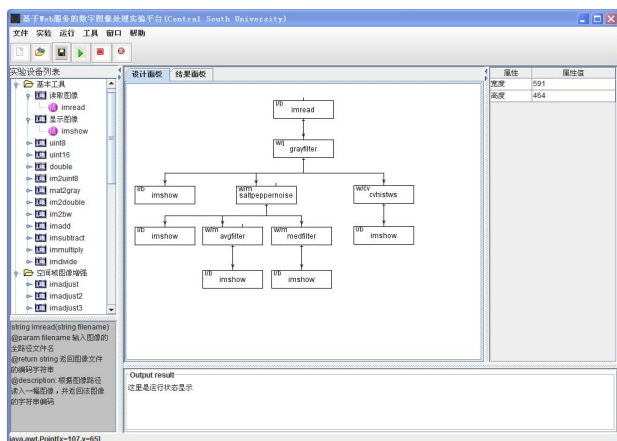

Fig. 8. The expriement flow of image enhancement

There is an experiment of image enhancement point in the design panel shown in Figure 8. In this experiment, the imread component, imshow component are JavaBean components, saltpeppernoise component, avgfilter component and medfilter components are the MATLAB service components, grayfilter component is a Java service components; cvhistws is a OpenCV service component. The result of this experiment is show in Figure 9.

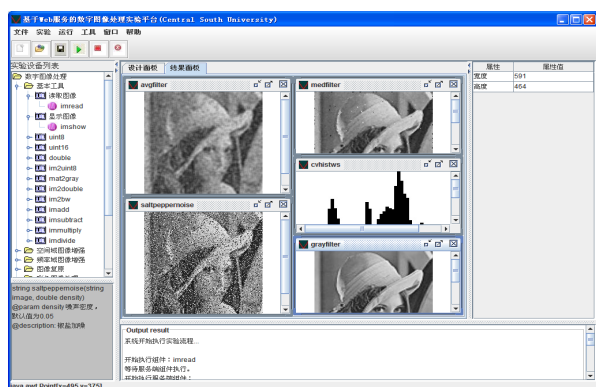

Fig. 9. The result of the virtual experiment

C. Other virtual lab systems

Based on the virtual experiment platform, we have developed Digital Circuit virtual lab system in the complex process type and Operation System, Digital Signal Process and

Cryptography virtual lab systems in the heterogeneous resources type.

VI. THE APPLICATION OF THE VIRTUAL LAB SYSTEMS

All the virtual lab systems of the computer science curricula are used in our university for the students in computer science, information security. And, the virtual lab system of PCO is used in the Beijing Institute of Technology, Guangdong University of Finance and Economics and Hunan Open University. The virtual lab system of Digital Image Process and Operation System are used in the Guangdong University of Finance and Economics.

According to the feedback of those universities, students have responded to the virtual lab platform enthusiastically and favorably, and some of their teachers are also interested in using them in the classroom.

VII. CONCLUSIONS

In summary, we designed and developed a powerful and flexible virtual lab platform and virtual lab systems based on the platform. This virtual lab system has its own virtualization and scheduling mechanism of the virtual experiment components according to whether it belong to a complex process type or a heterogeneous resources type.

Base on the research, we try to design the virtual lab system in HTML5 and cloud computing and other virtual lab system for other specialties.

Cloud-based Teaching in an Engineering-Physics Course

John M. Long

School of Engineering

Deakin University

Geelong, Victoria, Australia

jlong@deakin.edu.au

Abstract— This paper presents a transition from passive, traditional delivery of teaching to an active, “cloud-based” method, in a freshman engineering-physics course. The course is delivered to a traditional on-campus cohort, and also to an off-campus cohort by means of distance education and online learning. Cloud teaching refers to delivering education by means of websites and mobile-technology applications, where constant student attendance at the host campus is not always necessary. This is contrasted with traditional on-campus teaching, which occurs in a classroom. The use of lectures has been reduced while the use of tutorial and lab classes has increased. The new course structure was delivered for the first time in 2014, has run for two semesters, and will continue in 2015. It was found that student performance in the new structure was no worse than that in the older structure. Off-campus students in general welcomed the changes, while on-campus satisfaction did not change from before to after the transition.

Keywords— *Educational technology; Physics education; Cloud learning; Flipping the classroom*

I. INTRODUCTION

Most undergraduate engineering degree programs begin with one or two freshman courses in physics. This sets the educational foundation for studies in specific engineering disciplines. In recent years, research and practical experience have been driving education in engineering from a teacher-centered, passive approach to a student-centered, active approach. In this new model, responsibility for learning, content delivery, and even assessment has increasingly been placed on the student, rather than on the instructor. Thus new innovations in teaching have appeared in the forms of studio classrooms, fewer lectures, more tutorials, workshops and practical activities, the use of videos to deliver content that traditionally was given in lectures, and “flipping the classroom,” where classroom activities focus on problem-solving and applications, and homework involves reading the text and viewing video presentations to absorb concepts and primary course content.

Physics education has come a very long way from the techniques found in the likes of the classic *Feynman Lectures* [1]. It was from an age where teaching occurred in a classroom, often containing several hundred students. Even by the late 1980’s whiteboards were a recent innovation, and not all

classrooms had them. Desktop computers were just becoming common and were still hideously expensive. The best computers found in undergraduate physics laboratories of the day were often nothing more than a Commodore-64, or at best an IBM XT. Programs were written either in BASIC or in FORTRAN. PC’s became widely used in teaching by the mid-1990’s, the same time the use of the Internet was accelerating. About this time calls for “active-learning” in physics appeared [2, 3]. In the late 1990’s and early in the new century the use of computers in education (both physics and engineering) and the Internet to assist communication among students and teachers finally became commonplace, and textbooks that emphasized active learning were published [4]. The same trend happened in Australia [5]. However, at least in America, physics teaching was still largely held in the classroom, and teaching guides, such as that by A.B. Arons [6], assumed that students would still attend class. Experiments in classroom innovations also began about this time, where classes were designed to be collaborative and full of the latest technology. For instance, North Carolina State University reorganized its physics classrooms away from lecture theaters [7], and its experiments in teaching led to the SCALE-UP model of teaching students in studios [8]. In this model, students study the course content at home, generally by reading, and in class they perform group experiments, solve problems, and other activities. The model has been widely adopted in the United States [9] and also in Australia [10]. One criticism of the studio-teaching model is that students are expected to learn the primary concepts on their own by reading the textbook. In this author’s experience, this expectation works in some universities and not in others. Some students need to be taught the basic concepts by a means other than reading, especially students who are more visual learners.

Students themselves are increasingly looking to the Internet for learning resources neither assigned nor provided by their professors. Indeed, on being confronted by a problem, many students now look to Google and YouTube before consulting their textbooks, lecture notes, or other “official” course material. Students are especially looking to videos to learn physics, engineering, and other sciences. Due to growing up with television, movies, videos, and especially now that these are so easily available, younger generations learn visually much more than by reading and careful study. This has led to new education models again. A combination of active learning,

technology advances, Internet communication, and how modern students think has led academics to radically change how they teach. In modern times, this is expressed as “flipping the classroom” [11].

II. FROM FLIPPING THE CLASSROOM TO CLOUD-BASED TEACHING

One may characterize the “traditional” course in physics as containing large class lectures which present concepts and introduce problem solving; smaller tutorials which reinforce problem solving and concepts that are difficult to understand; and lab classes where students confirm key concepts experimentally and gain experience in measurement. Outside of class, on their own or in small study groups, students read and study textbook material and work out problems.

In the “flipped-classroom” model, traditional classroom activities and homework are swapped around [12]. Students learn concepts and the basics of problem solving outside of class. This is accomplished either by studying the text material or by watching videos, or both. Class time is partly spent doing what was formally homework: problem solving and reinforcing concepts. This model also frees up time for lecturers to perform more demonstrations and small interactive experiments, which hopefully makes the learning process more interesting and practical for the students. One of the educational goals is to make classroom learning less passive and more active. Many education researchers have been advocates for active learning in physics for many years. Modern technology, the Internet, and very rapid communication to mobile devices has pushed along a very increased use of video presentations in course material, studio teaching, and other examples of flipping the classroom.

The use of videos in teaching physics has become particularly widespread in recent years, and has come a long way from the classic 1980’s physics video series, *The Mechanical Universe* [13]. The sheer number of video presentations in physics has increased by massive amounts, as has their demand from students. Many universities now routinely video-record their lectures and make the recordings available to students. In Australia, two prominent video-teaching programs are the *PHYSclip* series at the University of New South Wales [14, 15], and *Work-it-Out* at Murdoch University in Western Australia [16]. A simple Google search reveals numerous videos for teaching physics, both on *YouTube* and elsewhere.

Deakin University has extensive experience and expertise in distance education [17], and delivers several undergraduate and postgraduate programs to students who do not attend on-campus classes [18, 19]. This includes a fully accredited major in engineering. Deakin is taking the concept of flipping the classroom one step further by trialing a new teaching model it calls “Cloud teaching” [20]. The name originates from the application of cloud computing to education [21, 22], and refers to delivering educational materials by means of multiple websites and mobile-technology applications, where constant student attendance at the host campus is not necessary. The motivation for this very significant shift in educational pedagogy lies in the fact that students today learn in a different

ways than their parents did, and universities must keep up with social changes in a cost-effective way. In addition to swapping conventional lectures with in-house videos of lectures, Deakin is moving the delivery of educational multi-media onto mobile devices, such as tablets and smart phones, giving students access to educational materials 24 hours a day, anywhere within Australia and overseas. Content itself comes from both the lecturer and also from outside sources, since much is available either freely or under license from other universities and educators. The multi-media material itself is stored “in the Cloud”, rather than only on the university’s web-servers. This is contrasted with traditional on-campus teaching, which occurs face-to-face in a classroom. If they wish, students studying “in the Cloud” can communicate with their lecturers and teachers by means of websites, email, *Skype* and web-conferencing applications such as *Blackboard-Collaborate*. In the context of a freshman-physics course, this paper presents one such transition from passive, traditional delivery of teaching to an active, Cloud-based method.

III. FRESHMAN ENGINEERING PHYSICS AT DEAKIN UNIVERSITY

All first-year engineering students enroll in SEP101, Engineering Physics. For many years the course has been taught in both on-campus and off-campus modes [23]. Currently (2015) the starting enrollment numbers are approximately 120 on-campus and 130 off-campus. The course has five key learning outcomes. On completing the course, students can demonstrate their ability to:

1. Explain basic principles in physical mechanics, fluids, and engineering moments;
2. Apply these principles to natural phenomena;
3. Solve technical problems in basic mechanics;
4. Perform and report on basic physical measurements;
5. Employ experimental methodology.

Running 12 weeks, the course covers kinematics, Newton’s laws, conservation of energy and momentum, rotation, fluid mechanics, oscillations, waves, engineering moments, and moment of inertia. The students also perform six three-hour lab experiments during semester, and write up their experiments in a lab notebook. The reading material is Halliday’s classic book supplemented by readings from a popular statics text. The assessment is 60% final examination, 20% problem-based assignments, and 20% lab reports. Possible final grades are from the Australian system: 80-100% High Distinction (HD), 70-79% Distinction (D), 60-69% Credit (C), 50-59% Pass (P), and below 50% Fail.

Prior to 2014, the course was run in the traditional way for on-campus students and via distance education for the off-campus students [23]. On-campus students attended four hours of lecture and one hour of tutorial each week (five hours class time), and a three-hour lab class every two weeks. Assignments were textbook problems solved on paper and graded by teaching assistants. Lab experiments were written up by hand in class and graded by the lab instructor. Students were expected to study the text material prior to class, and work on solving problems at home.

Off-campus students each received a study pack containing printed study guides written by the lecturer, an overview of the course, and lab manual. Material from the library (books, videos, etc.) was mailed to the students on request. Students mailed their assignment and lab work into the university. Student work was graded by the teaching staff, then mailed back to the student with written comments and corrections. Communication between students and the lecturer was by email, telephone, and fax. Lab classes for off-campus students were conducted on weekends [24]. These students performed all six experiments in a single eight-hour session. Sometimes special arrangements were made for a small number of students who could not attend weekend lab classes. These students were usually given alternative experiments that could be performed at home, including one that students could perform by remote control [25]. For a few semesters, lab classes were “web-cast” to off-campus students by means of video conferencing [26]. Details on how Deakin University School of Engineering has delivered distance education can be found in references [27] and [28]. In more recent years SEP101 has employed university web-sites and learning-management systems to deliver material to the whole cohort, not just off-campus [29]. On-line tutorials based on web-conferencing began in 2009 [30]. Responding to demand from off-campus students, the lecturers began video-recording the lectures in 2012, and providing these recordings to all students.

IV. TRANSITION TO CLOUD-BASED TEACHING

The aim of this work was to shift the on-campus teaching pedagogy from a passive approach to an active approach, essentially “flipping the classroom”, while at the same time maintaining or improving learning outcomes and student satisfaction. The changes were also intended to improve the educational resources available to off-campus students.

Prior to 2013, technological advances in teaching this course proceeded one by one, as new techniques and software applications became available. Most of the advances were applied with off-campus students in mind. On-campus students shared the benefits of these developments because they were made available to everyone. In 2013 the course material was completely redeveloped to follow not only a flipped-classroom model but also a cloud-learning model.

The redevelopments began by dividing up pre-recorded lectures into 10-20 minute segments and arranging them by topics (fig. 1). Each recording shows alternating Power-Point slides and projections from a document camera. Topics, concepts, and key equations are illustrated by Power-Point, and hand-written problems or other illustrations are recorded by the camera. The lecturer’s voice is also recorded throughout. Each video was made available to the students as an .mp3 downloadable audio file, an .mp4 video file, or streamed directly to the students PC, tablet, or mobile device.

Next, a series of detailed video presentations were produced to introduce each of the six lab experiments [31]. All the videos and existing study guides were imbedded into a redesigned course website (fig. 2), driven by the *Desire2Learn* software platform [32]. In this website, for each topic, additional resources were provided such as lecture notes,

video-recorded tutorials (produced in class by means of a tablet-PC [33] and *Camtasia* software) where specific problems were solved, and recordings of the current semester’s lecture classes. The website also had an on-line discussion area where students and lecturers could post messages and replies. On-line tutorials continued, with one evening set aside each week for off-campus students to talk to the teaching staff, ask questions, and work on problems together. The course also employed the *Wiley-Plus* [34] website for the textbook, where students checked their answers to homework problems, obtained formative feedback on their work, and also submitted their two sets of summative assignment problems. Students submitted their lab reports on-line via the course website.

The assessment methodology did not change from 2012 to 2014. All students completed the final exam. Off-campus students attended designated exam centers set up throughout Australia by the university. This new format for the course ran in semester one 2014 (on- and off-campus), summer semester 2014-2015 (off-campus only), and is currently running in semester one 2015 (on- and off-campus).

The on-campus class format was also modified. Lectures were reduced from four to two hours per week. Tutorial classes were increased from one to two hours per week. One tutorial hour was in a classroom, dedicated to answering questions and solving problems. The second was held in the physics teaching laboratory for the students to view demonstrations; perform

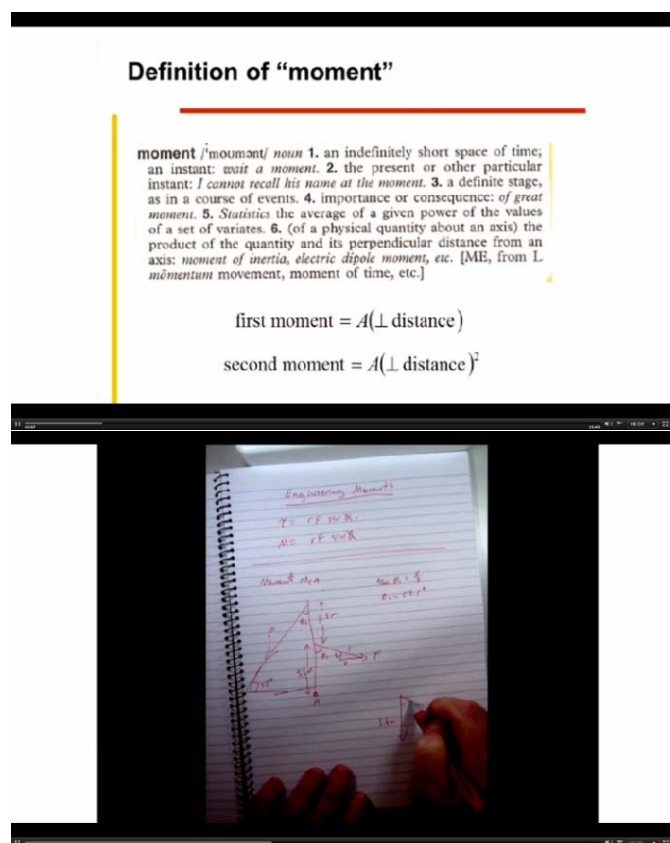

Fig. 1. Example of a lecture recording on engineering moments (top: Power-Point; bottom: document camera)

Fig. 2. Sample section from an on-line study guide

short experiments to illustrate concepts and give the students more experience in handling experimental gear. Each week the lecturer presented an experimental problem for the students to investigate during the hour. Such problems included verifying key physics equations in kinematics, free-fall, Newton's laws, buoyancy, and conservation of mechanical energy. When only one or two sets of apparatus were available, the lecturer and students volunteers performed the experiment in front of everyone.

On-campus lab classes remained unchanged. Off-campus students were required to perform one experiment at home early in semester. The at-home experiments were a choice between a Microsoft-Excel and a basic measurement activity; and oscillations of springs and pendulums. All these activities are easily done on a kitchen table with materials and tools available from a local hardware store. Then they performed the remaining five in the weekend lab session. All students were instructed to view the lecture and lab videos prior to attending the corresponding lecture or lab class.

Average overall grades for on-campus and off-campus were compared over the years 2012-2014. At the end of every semester, students were invited to fill out and submit evaluations of how they perceived the course progressed and helped them to attain the learning outcomes. The University employed a single evaluation system across all courses, posing a series of 10 standard statements concerning quality of course materials, teaching quality, perceived difficulty of the course, and effectiveness of the university library. The results of these surveys are publicly available on the University website [36]. This evaluation system has been successfully tested for statistical validity [37]. Students indicated their agreement with a number of statements by a number on a five-point Lickert scale (1 = strongly disagree, 5 = strongly agree) [38]. Students also had the opportunity to make specific comments. This work focuses on three quality statements:

1. "The course materials in this unit were of high quality."
2. "The on-line teaching and resources in this unit enhanced my learning experience."
3. "This unit was well taught."

V. RESULTS

Table 1 shows the average student grades for the cohorts in years 2012-2014. Summer semester grades are included in the off-campus results. The reported uncertainty on each figure represents half a standard deviation. Interestingly, while on introducing the cloud-learning structure in 2014, the average off-campus grades show no significant change, the on-campus average and median increased by nearly 10%. While the statistical validity of this result is yet to be tested, it suggests that the cloud-learning model was beneficial to on-campus learning.

What did the students think of the changes? Table 2 shows representative student suggestions prior to 2014, before the changes were implemented. Students asked for more interesting lectures, improved organization of the course website, additional instruction on using laboratory data-loggers (PASCO Explorer GLX), and fewer experiments to perform on the one-day weekend sessions.

Figs. 3–5 show the average student responses to the three evaluation statements. Error bars represent the standard deviation of the mean for each datum. While the students expressed general satisfaction with the way the course was delivered each semester (90% of scores are above 3.0), the results are mixed. On-campus satisfaction with the course materials and on-line resources remained steady. Their satisfaction with the teaching quality decreased slightly. The overall trend for off-campus was an increased satisfaction in all three areas. On the quality of the course materials, on-campus students expressed greater satisfaction than off-campus students, and apart from summer offerings, the overall level of satisfaction did not vary much. As for the on-line teaching resources enhancing learning, there are no obvious trends. The overall course satisfaction hovers around 3.5 for 2013-2014. The jump in scores for summer 2014 is encouraging, although only 10 students filled out that survey.

TABLE I. AVERAGE AND MEDIAN GRADES 2012-2014

Year	Number on-campus	Number off-campus	Avg. on-campus grade %	median on-campus	Avg. off-campus grade %	Median off-campus	Avg. grade overall %	Median overall
2012	134	44	61 ± 6	61	62 ± 11	52	61 ± 9	60
2013	138	64	62 ± 7	61	61 ± 11	60	62 ± 8	61
2014	133	65	68 ± 8	68	59 ± 12	61	64 ± 9	67

TABLE II. PRE-2014 STUDENT COMMENTS – WHAT NEEDED IMPROVING

Enrolment	Comment
On-campus	Lectures need to be re-designed.
On-campus	Lecture content. I found them un-engaging.
On-campus	Using the GLX in tutorial/practical. Maybe we should have a lesson in the first week, solely dedicated to the GLX.
Off-campus	Online study materials very messy hard to organize and learn from them.
Off-campus	Practicals for off campus students could be arranged bit differently. Time-wise it was too hard to complete in one day.
Off-campus	There wasn't enough time in the one Saturday practical day to complete all 6 experiments.

Fig. 3. Student responses to the statement “The course materials in this unit were of high quality.”

Fig. 4. Student responses to the statement “The on-line teaching and resources in this unit enhanced my learning experience.”

Fig. 5. Student responses to the statement “This unit was well taught.”

Table 3 lists some student commendations on the course changes. On-campus students welcomed the tutorial classes in the lab, where they could engage with real-world physics at a leisurely pace and perform their own investigations. Many students liked the layout of the new course website and the imbedded lecture videos. Suggestions on improvements are given in table 4. Some students found all the information overwhelming, especially when they saw apparent inconsistencies between various elements or changes in English accent or expression. A few students wondered if the videos recorded in the previous year were outdated.

TABLE III. WHAT STUDENTS LIKED ABOUT THE COURSE CHANGES

Enrolment	Comment
On-campus	I enjoyed the one hour labs with Dr Long, they were relaxed and informative.
On-campus	Being able to play with the equipment in the labs during the labs, all the while actually proving the theory.
Off-campus	Each set of week's work is on the cloud.
Off-campus	Firstly, being an (external) student and doing this subject as cross-institutional study, I've been very impressed by the learning resources Deakin provides on the Cloud website. It is very easy to navigate and it is made very clear what to do and how to study the content. Being an online subject, it is not the easiest to learn when there is little interaction with students or teachers, but the videos (lectures etc.) on the website provide good insight to the learning objectives required. The discussion forums are another great idea for student and teacher interaction.
Off-campus	The recorded lectures were for the most part brilliant.
Off-campus	The (online) tutorials are great and there are a lot of online resources available if you apply yourself.

TABLE IV. STUDENTS' SUGGESTED IMPROVEMENTS

Enrolment	Comment
On-campus	(Agreement) between laboratory instructions from videos, lab manuals, instructors' interpretations of the lab requirements was very poor.
On-campus	The online tutorial system's online format was difficult to operate. It has very hard to understand sentences, especially if English is not your first language. Overly mathematical keeps on using very hard to follow English that even Australian students struggle to understand.
Off-campus	Work through the content on the whiteboard (not the document camera).
Off-campus	Organization of the lectures - many lectures had 3 different filenames, or were repeated across different videos, or were recorded a long time ago.
Off-campus	Perhaps the lecture videos could be updated since I've noticed some of them are from 2012 and 2013.

VI. DISCUSSION

The changes experienced by the two student cohorts was more significant for on-campus than off-campus. On-campus students experienced large changes in how classes were run and how they were expected to prepare for those classes. The expected study habits for off-campus students did not change as much, although the use of video was seen as an enhancement of course materials. The differences between on-campus and off-campus results are not surprising. The two cohorts are quite different [39]. On-campus students are largely 17-19 years old, fresh out of high school, and this course is one of the first they experience at university.

Off-campus students tend to be older and professionally more experienced. They have jobs, families, and the pressures that go with them. They study part-time, often work full-time, and in the author's experience, find balancing family, work, and study quite difficult. Some live in very remote parts of Australia [27]. In terms of "customer-service" and value for tuition, they tend to be more demanding than the younger on-campus students. The summer offering of this course adds an additional complexity to the data. Semester three runs over the Christmas and summer holidays. Experience in summer teaching shows that students can easily fall behind in their studies due to the distraction of the holidays. If one considers the evaluation results of semester three in isolation from semester one, an increase in off-campus-student satisfaction from 2012 to 2014 can be seen.

This is only a preliminary study. As further data is obtained from future years, time will tell whether the changes really enhance learning and student satisfaction. In a private discussion with a physics professor from a small mid-western American university, it was noted that when the classroom is flipped, student satisfaction tends to drop sharply, then slowly increase again over some years as the students get used to the new format.

The decision to shift towards flipping the classroom and ultimately cloud learning was made in 2012. After a period of planning and consultation, work on revising the course began

in 2013, and was completed to the present stage in early 2014. It is now in the evaluation and reporting stage. During the planning stage, a "wish-list" of possible video clips to include was drawn up, and the number exceeded 50. With limited time and resources, it was decided to focus on improving how the lab experiments were introduced and a series of high-quality videos introducing each of the lab experiments was the result. Existing video lectures were used in the new on-line study guides.

Offering this course for several years by distance education made this process considerable easier. Most of the educational "infrastructure" was already in place, and the course's delivery to a non-classroom cohort was already established. Thus many elements of the new structure did not have to be produced from scratch.

The next step in this process is four-fold, and will take a few years to complete. First, publicly available physics resources produced elsewhere will be incorporated into the course materials. This will include links to other universities and YouTube, which has a large number of accurate, interesting, and freely-available videos describing all aspects of physics. Conversely, similar videos produced at Deakin will also be made available via YouTube. Secondly, the teaching team will produce its own physics video clips to help keep the course material in a local context. Thirdly, the lecture recordings that found their way into the on-line study guides will be redone to a higher quality. In the meantime the students will be consulted to obtain advice on what resources are the most useful to them. Finally, the data on student outcomes will be more carefully analyzed for statistical significance and student demographics.

VII. CONCLUSION

A freshman engineering physics course was redeveloped to shift the on-campus content from a structure of passive lectures, tutorials, and homework towards a flipped model of more active on-campus teaching, and ultimately to a cloud-teaching model. It was hoped that the changes would enhance learning in the off-campus cohort as well. The use of lectures has been reduced while the use of tutorials and practical lab sessions has increased. The new course structure was delivered for the first time in 2014, has run for two semesters, and will continue in 2015. It was found that student academic performance in the new structure was no worse than that in the older structure. In the case of on-campus students, there was an increase in overall average and median grades. Off-campus grades remained steady. On-campus students showed no significant change in satisfaction from before the changes to after the changes. Off-campus students welcomed the changes. Similar transitions to "cloud teaching" are being implemented in other courses in the university's engineering-degree program.

Abstract—This work in progress describes a technique of course design in the form of learning objects (LO) sequences. We defined the distance between LOs (metric of learning objects space based on revised Blooms Taxonomy) and used it to design an objective function. This function is a sum of distances between LOs in the given sequence learning prerequisites of a course and its learning outcomes. In addition, the function contains penalties for the violations of the learning sequence, when, for example, one or more learning prerequisites for the given LO are absent in learning outcomes of previous LOs and course's prerequisites. A genetic algorithm was used to find LOs sequences complied with the given requirements of the course. To provide the series of experiments, this algorithm was realized as a computer-aided application in the development environment Microsoft Visual Studio 12. These series showed that the suggested technique is suitable for automated course design based on big amount LOs. Several suggestions to develop the technique are given at the end of this paper.

Keywords— *Course design; learning prerequisites; learning outcomes; learning object; learning sequence; genetic algorithm*

I. INTRODUCTION AND RELATED WORKS

Contemporary educational society has access to various learning resources and technologies to design and build a course according to given requirements. At the present time, interdisciplinary courses have become very popular because contemporary science and technologies are based on the mixing of two or more fields of knowledge. Thus, teachers are exposed to a wide variety of learning resources and learning objects (LOs) [1] and they have a difficult task in choosing a convenient sequence for the given course design. In addition, students have relevant tasks to choose in order to achieve desired skills [2]. According to this review, there are a number of approaches, including methods using evolutionary algorithms. Paper [3] describes the merging of two ontologies: learning outcomes and Bloom's taxonomy. It shows rules and reasoning mechanisms for identifying the position of learning outcomes relative to each other. Bloom's taxonomy, along with other parameters of an LO's (exercise's) difficulty, is used also in [4] where individual learning paths in programming learning are under consideration. The technique of the construction learning path (or composed curriculum) on the graph of learning objects is presented in [5]–[7]. Their main idea is that there are two phases: first, when we select potential objects to

build the possible learning paths, and second, when we find the best path. The authors of [7] also note that some LOs have learning outcomes not required for the given course.

In this work in progress, we tried to unite some features and advances presented in the abovementioned works to design and create the implementation of the technique to design LO sequences with the use of levels of skills given in the revised Bloom's taxonomy (RBT). The required learning prerequisites (LPs) and learning outcomes (LOCs) should be defined for the LO sequence. In this paper, we consider the following questions:

Q1. How can the distance between one LO, relative to another, in levels of RBT (LO-space metric) be defined?

Q2. How can the objective function to receive the optimal LO sequence for the given LP and LOC be built?

II. THE DISTANCE BETWEEN LEARNING OBJECTS

To evaluate the distance between LOs, we are using levels of the RBT: the "Remembering" relates to the first level, the "Understanding" relates to the second levels, and the "Creating" relates to the sixth level. Suppose we are given a skill, e.g. complex systems simulation, that is one of the learning outcomes of LO #1 and one of the learning prerequisites of LO #2 (LO #2 is the next LO about LO #1). The distance between these LOs in respect to this skill equals zero if the level of the skill in both LOs is the same. If the level of the skill in LO #2 is higher than the level of this skill in LO #1, the distance is defined as follows:

$$Dist_{1,2}^{skill} = \sum_j d_j^{skill}, \quad (1)$$

where:

- the index j is related to intermediate levels between levels of the skill in LO #1 and LO #2, respectively, and the level of LO #2;
- d_j^{skill} is the distance between the skill's level $j - 1$ and j (it can be evaluated by experts).

If the level of the skill in LO #2 is lower than the level of this skill in LO #1, the distance is the negative value received by the formula (1). The negative value of the distance means that LO #1 defines one or more levels of the skill in the LOC which are not required to start learning LO #2.

Suppose we are given several skills with numbers 1, 2, ..., $m_{1,2}$, in both LOs. Let us introduce a weighting factor p_k for the k -th skill (the sum of these factors for $m_{1,2}$ skills is 1). Then we can write the formula for the evaluation of the distance:

$$Dist_{1,2} = \sum_k p_k Dist_{1,2}^k, \quad (2)$$

where k is the index of skill.

Formula (2) assumes that all $Dist_{1,2}^k$ are positive. If one or more $Dist_{1,2}^k$ are negative, we replace them by zero and we can note singly the related indexes k . If the existent skill in the LOC of LO #1 is absent in the LP of LO #2, it means that this skill is not required to start learning LO #2 and the related distance equals zero.¹ If the existent skill in the LP of LO #2 is absent in the LOC of LO #1, it means that LO #1 does not provide a related required skill for LO #2. The distance between these LOs in respect to this skill may be defined by a value, which significantly exceeds the maximum possible distance in a case where these skills exist in both LOs (it is a penalty for a lack of skill in the LOC).

Distances between the given LPs of the course (course under construction) and the LPs of LOs, LOCs of LOs and LOCs of the course may be calculated in a similar way.

Therefore, we defined the LO-space metric (Q1).

Let us show the LO's metric using the following example. Suppose that we have the two following objects:

- LO_1 "Introduction in Gravity Model" with the following learning outcomes: "Gravity model" of "Understanding" level and "Calibration of gravity model" of "Remembering" level;
- LO_2 "Calibration of Double Constrained Gravity Model" with the following learning prerequisites: "Gravity model" of "Analyzing" level and "Calibration of gravity model" of "Analyzing" level.

Let the distance between levels "Understanding" and "Applying" for "Gravity model" be 4 and the distance between levels "Applying" and "Analyzing" be 3. Let the distance between levels "Remembering" and "Understanding" for "Calibration of Gravity Model" be 2, the distance between levels "Understanding" and "Applying" be 3 and the distance between levels "Applying" and "Analyzing" be 5. Define the weight for "Gravity model" as 0,6 and the weight for "Calibration of gravity model" as 0,4. Then, according to the formulas (1) and (2), we have the following distance:

$$Dist_{1,2} = 0,6(4+3) + 0,4(2+3+5) = 4,2 + 4 = 8,2.$$

III. THE OBJECTIVE FUNCTION AND USAGE OF THE GENETIC ALGORITHM

A. The Objective Function

For the evaluation of the objection function, we should have the following data: (1) the list of the skills and their levels of LPs of the course, (2) the lists of skills and their levels in LPs and LOCs of LOs in the sequence, (3) the list of skills and their levels in LOCs of the course. The meaning of the objective function is the sum of the smallest distances between LOs in the sequence, the course's LPs and the course's LOCs. In addition, the objective function may be subjected to the following types of penalties:

- a) penalty for the absence of the required skill before the LO or the course's LOC;
- b) penalty for the negative distance between LOs (or LO) and the course's LPs or LOCs and LO in respect to the given skill, when, for example, the required level of the given skill in the LPs of some LOs is lower than the related skill's level of the course's LP;
- c) penalty for an unnecessary skill, when one or more skills of LOs in the sequence are never used in related LOs and course LOCs.

Thus, we may write the following objective function (Q2):

$$W(LS) = \sum_{j>i} Dist_{i,j} + F_a(LS) + F_b(LS) + F_c(LS) \rightarrow \min \quad (3)$$

where:

- LS is the sequence of learning objects (the controlled factor);
- i and j are indexes of LOs;
- F_a , F_b , and F_c are the penalties of the abovementioned types.

The boundaries are defined from the initial set of learning objects and as an option – the maximum number of LOs in the learning sequence.

Suppose that we have a course's LPs and LOCs, the learning sequence is as shown in Fig. 1. S_k^l is the l -th level of the k -th skill. We can then note that the distance between the first LO and the course's LP in respect to the first skill equals zero. The distance between the third LO and second LO in respect to the fourth skill is a positive value. Since the fifth skill, required for the second LO, is absent in the LOC of the first LO and absent in the course's LP, we have the penalty of type "a." The penalty of type "b" is between the second and the third LOs in respect to the fifth skill. Lastly, the penalty of type "c" can be added for the second skill, which is in the LOC of the second LO.

¹ We may define a penalty instead as zero, if we have an interest in finding the LO that does not provide unnecessary skill(s).

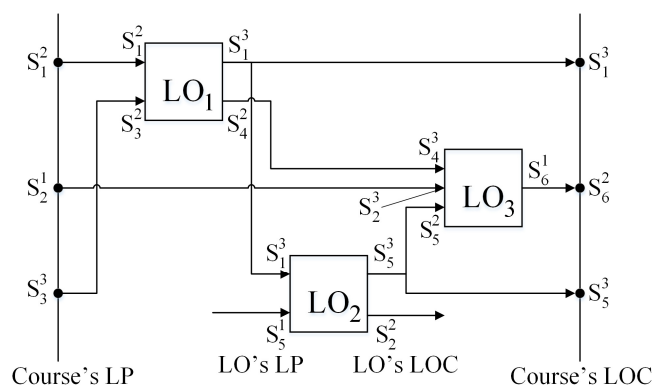

Fig. 1. Example of a course's LP and LOC, and learning sequence with levels of the skills.

B. Genetic Algorithm

To compose the course (learning sequence) with a certain LP and LOC we use a genetic algorithm (GA). We used the initial step of *population initializing* (random generating of sequences, which can contain two or more similar LOs) and standard genetic operators in the iteration loop: *crossover*, *mutation* and *selection*. A *learning sequence* is defined as an *individual* with single chromosome and *LO* – as a *gene*. Formula (3) is used as a fitness function.

Crossover. Each individual is crossed with another random individual by a one-point crossover. The point of crossing is a random point in a shorter individual in a crossing pair. During crossing over, we strive to reduce repeats of LOs in children. In particular, if the LO in the part before the crossing point of the second individual occurs in the part after the crossing point of the first individual, the exchange of related LOs is not proceeded. For example, suppose we defined the following learning sequences: ABC_DEFH and ZEA_JCO (the symbol “_” is the crossing point). We receive the following pair after the crossing over: ZBA_DEFH and ABE_JCO. The received individuals are added to the population. Thereby, we expand our population.

Mutation. In this procedure, we change the order of education elements in a course with a certain probability that is given as a parameter. We do not touch the elite part of the population.

Selection. We use the elitism method for the individuals' selection.

The abovementioned genetic algorithm with fitness function (3) was implemented with the use of language C# in the environment of Microsoft Visual Studio 12. The developed computer-aided program allows us to manage the LOs database and add to an LO's record the description of virtual learning labs (VLL). If a VLL was realized as a cloud service in the CLAVIRE platform [8], the program offers an option to choose a learning model of a VLL's usage for an educational purpose. These models were described in [9].

IV. THE IMPLEMENTATION OF THE TECHNIQUE FOR THE “URBAN TRANSPORTATION SYSTEMS PLANNING” COURSE DESIGN

To check the abovementioned approach we used the learning resources available in the site “Sakshat Virtual Labs.”² On the basis of these resources, we designed the possible scheme of the considered course (Fig. 2). This course considers the following LOs:

1. Volume, Speed and Delay Study at Intersection
2. Regression Analysis
3. Category Analysis
4. Growth Factor Distribution Model
5. Singly Constrained Gravity Model
6. Doubly Constrained Gravity Model
7. Calibration of Singly Constrained Gravity Model
8. Calibration of Doubly Constrained Gravity Model
9. Model Split

The LOs are inserted in six topics: (T1) urban transport simulation, (T2) trip generation, (T3) trip distribution, (T4) model split, (T5) constrained gravity model, and (T6) model calibration. To save space for this paper and make Fig. 2 more vivid, we have hidden the intermediate skills. The following skills are presented in Fig. 2: (S1) apply, create regression, (S2) apply distribution laws, (S3) multinomial logic model, (S4) understand process of mode split, (S5) apply and understand the calibration of Singly Constrained Gravity Model, and (S6) apply and understand the calibration of Doubly Constrained Gravity Model.

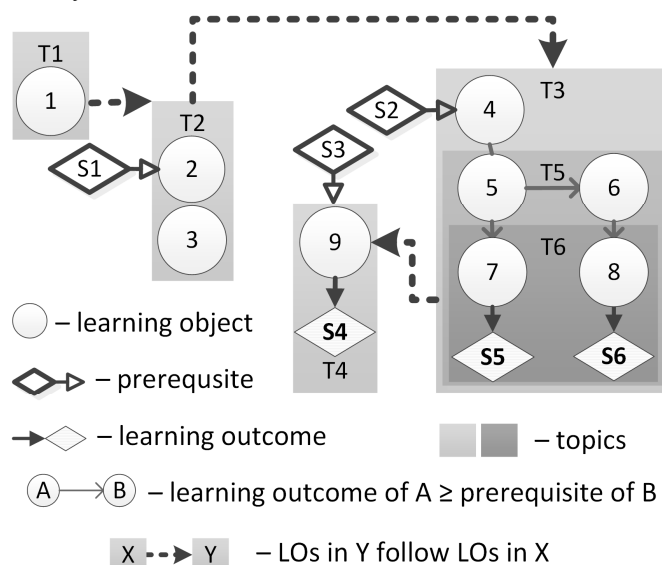

Fig. 2. The possible scheme of the course "Urban Transportation Systems Planning"

² <http://deploy.virtual-labs.ac.in/labs/civil13/>

We held two series experiments with the course's LPs S1–S3. Skill S4, as a course's LOC, was given for the first series, and S6 was given for the second series. The first series showed that to acquire the S4 skill, a student should complete LOs 1, 2 (or/and 3), 4, and 9. The second series gave the sequence: 1, 2 (or/and 3), 5, 6, and 8. The results obtained fit into the designed scheme. Therefore, this experiment confirmed the possibility of a course's design with the use of the offered technique.

V. CONCLUSION AND FUTURE WORKS

In this work in progress, we suggested the technique and related computer-aided software for the course's design in terms of the learning objects' sequence matter with the use of the revised Bloom's taxonomy and a genetic algorithm. The objective function was defined in this work and was used in the genetic algorithm. The experiments showed that the presented technique is suitable for finding a learning path among a few convenient LOs. Its main feature is arranging LOs in accordance with Bloom's taxonomy, thus providing more freedom in constructing a learning path and allowing the connection of objects without direct dependency.

This technique serves as a starting point in our research and will be upgraded through the experience that has been gained by other authors [2]. However, the current weakness is that two problems are solved by one algorithm: selection of relevant objects and their ordering. Also, it does not yet include different criteria of path construction (for example, multidimensional difficulty as in work [3], or type of students' perception) so it can become universal and can be upgraded to the social sequencing method or to the individual sequencing method, or contain both approaches. To analyze the real needs of finding a learning path we designed a full-fledged example in the area of programming and computer graphics using resources such as [10]. In addition, we intend to use the updated technique for design and update courses of our double degree master's programs [11].

Abstract— Service learning is a hands-on pedagogical approach where students participate in activities that are beneficial to society. In engineering, Project-Based Service Learning involves the development of a product for the benefit of an individual or an organization. Being engaged in PBSL provides students with opportunities to design and develop innovative solutions for real clients. Research on the impact of service-learning programs reveals a positive effect on students' understanding of social issues, and improves their communication, teamwork, and cognitive skills. Yet, only a small amount of research has assessed the long-term impact on engineering graduates after several years of integration in industry. This study follows a flagship project that includes several programs involving populations with special needs. The study uses the Grounded Theory Methodology that allows revealing ideas that could not be foreseen. The study's first phase focuses on the perceptions of graduates who participated in a Rehabilitation Biomechanics course that includes development of assistive devices for a disabled people. Analysis of interview protocols reveals their growing awareness of the roles of engineering solutions in assisting people with special needs, the effects on their interests, and the new skills and understandings they take to the workplace.

Keywords— Engineering education, Service Learning, People with disabilities, Assistive devices, Grounded theory

I. INTRODUCTION

Service learning (SL) is a hands-on pedagogical approach where students participate in activities that are beneficial to people and communities, while providing broad learning experiences. SL has been integrated in many academic institutions worldwide in a variety of disciplines including engineering in undergraduate and graduate programs, in both curricular and extra-curricular frameworks.

Project-based service learning (PBSL) in engineering programs includes development of a product for the benefit of an individual or an organization. Being engaged in PBSL provides students with opportunities to design and develop real

and innovative solutions for real clients. PBSL may be part of capstone design courses that involve the construction and testing of prototypes or courses that may be limited to paper design [12][7][13]. Courses are elective or mandatory and deal with various engineering areas [6]. A few examples are EPICS - Engineering Projects in the Community Service in Purdue University [5], the MIT IDEAS Global Challenge [10], SLICE - Service Learning Integrated at a College of Engineering in the University of Massachusetts Lowell [6], and EWB - Engineers Without Borders [<http://www.ewb-international.org/>].

Some of the engineering projects are intended for people with disabilities, and incorporate the design and development of assistive devices for the disabled.

Evaluation research has been conducted to measure the effectiveness of the various programs with regard to their learning outcomes. A meta-analysis of forty courses in the social sciences that include service learning reveals a positive effect on students' understanding of social issues (e.g., attitudes associated with cultural awareness, tolerance of diversity and ethical reasoning skills), personal insights (e.g., perception of leadership ability, determination and persistence), and cognitive development (e.g., problem-solving and critical thinking skills) [14]. Bielefeldt et al. group the potential impacts of PBSL on students into five main categories: student knowledge; student skills; attitudes and identity; recruiting, retention and diversity; and professional performance. The impact on faculty implementing PBSL in their courses has been less researched, but they report it is motivating for them and for the students while requiring requires more time than other pedagogies [1]. Recent research on student perceptions of design projects that involve developing assistive devices for children with disabilities reveals students' satisfaction with regard to the preview of industry, development of teamwork skills, and increased empathy for people with disabilities [13].

Only a small amount of research has been carried out so far in assessing the long-term impact of projects connecting academia and community on engineering graduates. This study follows a flagship project at OBC—a medium-size college of engineering located at the country's periphery—that encompasses several different programs all dealing with

activities of students and faculty for populations with special needs. The study aims to evaluate the impact of the project on graduates' personal and professional life after several years of integration in industry, as well as its influence on other parties involved and the overall effect on the institution.

II. FLAGSHIP PROJECT

The Israeli Council for Higher Education (CHE) seeks to promote proactive involvement of academia in social activities, looking at it as academia's third role beyond research and education. The flagship project at OBC is part of the CHE's initiative to direct the expertise of the academic institution on behalf of the community in which it is located. Those expected to gain are the community, as well as faculty, students, and relevant research areas.

The flagship project's goals are: a. to establish an interdisciplinary academic knowledge center of applied research for the development of engineering solutions for disabled people that is open and accessible to the public, and b. to create an infrastructure of OBC's collaborations with institutions that deal with rehabilitation and employment of people with disabilities.

The main ingredient of this flagship project is the development of unique engineering solutions for people with disabilities. Some are customized solutions for private purposes in accordance with a specific disability, and others are solutions for the workplace (e.g., an electronic waste recycling plant that employs individuals with disabilities) or for public spaces (e.g., playgrounds adapted for children with disabilities). The activities are conducted as part of academic courses, capstone projects, or internships, and at the college's entrepreneurship center. The flagship project also includes volunteer activities of students in social organizations and general studies, research related to people with disabilities and involving faculty and students, and a web site that aims to share the public's accumulated knowledge in these areas.

III. METHODOLOGY

The study is qualitative and follows a constructivist-interpretive Grounded Theory (GT) methodology of a systematic generation of theory from data [8][12][4]. Data comprise interviews, texts, observations, videos, and other sources. The main characteristics of the GT methodology are initial coding of meaningful units and categorization of data—identifying main themes that emerge and labeling them; concurrent collection and analysis of data; writing memos—recording researchers' thoughts during the study; constant comparative analysis and use of inductive logic and abstraction so theory is gradually constructed from data; theoretical sensitivity—researchers' awareness of their own perspectives and professional knowledge; and selecting a core category that encapsulates all the others and integrating relevant existing theories until finally accomplishing a comprehensive explanation of the phenomena, which is the generated theory [3][11].

The study was planned as longitudinal research and incorporates an assessment of several programs within the

flagship project, separately for each program. It concludes with integration and meta-analysis of the accumulated findings.

Research tools include questionnaires and interviews with students, lecturers, and stakeholders from outside the institution. Other information is collected from students' reflection reports, clients' satisfaction regarding the products developed by the students, therapists in the rehabilitation institutions regarding their interaction with the students, documentation of activities such as videos, and academic and other publications of researchers involved in the flagship project.

The study's first phase focuses on the perceptions of graduates who participated in a Rehabilitation Biomechanics course three or four years ago. This elective course has been taught for several years. It is a semester-long course (13-14 weeks) where students develop small-scale projects intended for the disabled community involving real clients (students in school or people from a rehabilitation center). There is direct interaction of the students with disabled people who are involved to some extent in the design process of the device. They define their needs, take part in choosing a solution from amongst several options/concepts, receive the product directly from the developers, and submit a client evaluation of the designed product after a period of four to five weeks of use. Students may also connect with the clients' families if needed. Prior to this course the students must complete a mandatory conceptual design course, and it precedes the capstone project course.

IV. INTERVIEWS WITH GRADUATES

Graduates of the Rehabilitation Biomechanics course have been interviewed. The participants are asked to tell their stories about their experiences regarding the devices they developed for disabled people, without interruption or guidance to focus on certain aspects. This approach allows revealing ideas that could not be foreseen. Later during the interview the list of questions is examined so aspects of interest that were not mentioned by the participant are raised by the researchers.

Each interview starts with collecting details of the year of graduation, field of expertise, current employment, previous jobs, and current role in the workplace. The opening question is: Tell us about the projects you have carried out during your studies at OBC that involved people with disabilities. What did you derive from this course? Other questions asked—if not answered spontaneously by the participants—are: What did you learn from the project about the needs of people with disabilities in the engineering context and in general? Did the project have an impact on your professional or personal life in any way? Describe the interaction between the disabled customer and yourself, and to what extent was s/he involved in the design process? To what extents do engineering professionals have an obligation towards people with disabilities? To what extent are you interested in engineering development for the population of people with disabilities? Following are profiles of the graduates and their projects.

[ET] Project: Designed and fabricated 1) a folding sunshade for an electrical wheelchair, 2) a workstation for the cognitive

impaired in an electronic waste recycling factory. **Employed** as a department director on the production-line in a company that manufactures and markets an extensive range of stainless steel fittings and flow products.

[EG] Project: Designed and fabricated a sliding device enabling the client to bridge a 20 cm gap between the chair and the floor. The device assists the client during transition to and from the chair, obviating the need to lift the client during transition. **Employed previously** as a development engineer for design of medical fittings at medical company. Currently employed at OBC as a project advisor for rehabilitation projects at a local hospital, while trying to fulfil the requirements for medical school.

[VO] Project: Designed a device for carrying a backpack on a posterior posture walker. **Employed** as a development engineer at a company that engages in the design, development, and manufacture of degreasers and washing machines.

[KA] Project: Designed and fabricated a foldable wheelchair insert for a CP client that fits into the luggage compartment of a cab, allowing the client to travel using a manual wheelchair with an orthopedic insert, which can be dismantled or reassembled within two minutes. **Employed** as a project manager at a water systems company.

[MA] Project: Designed and fabricated a device enabling a pelagic client to insert his sleeping bag into its sack. **Employed** as a project manager at an international hi-tech company engaged in a wide range of defense projects.

VI. ANALYSIS AND PRELIMINARY RESULTS

Five of the interviews' recordings have been transcribed and coded according to the GT guidelines so far. The following section describes several themes that emerged.

A. Attitudes toward Developing Engineering Solutions for People with Disabilities

The participants described the conflict between the sense of duty and responsibility they feel for the disabled, and the lack of economic viability of products tailored to a specific client. Although there are off-the-shelf products for people with disabilities, the types of disabilities are very varied, and often require adjustments and individually customized solutions. **[ET]** *"This entire population has not received enough real answers, and no one has delved into its needs. These people have only the basics and they have to make do with them. It is sad to see. There is much to do in this area."* **[KA]** *"There is a huge hole regarding the issue of aids for the disabled."*

There is a growing sense of missed opportunity. The engineers recognize that developing a customized product is often not difficult: **[ET]** *"A job that may take me two to three weeks can mean the world for such children."* **[VO]** *"If, as a mechanical engineer, I could provide this type of help I would be very happy."*

One student, who has more entrepreneurial experience than the others, offered to solve the conflict in a way that has commercial potential. Problems of customers with different

disabilities could be solved with a generic solution according to principles of universal/inclusive design [9]. **[MA]** *"I can create something that requires very expensive production technology. There is no chance of implementing it for this niche market. Instead, I can adjust something that exists, solve such problems in many different ways, and turn the total of all these solutions into something more generic, and on that basis make the necessary adjustments for a particular client."*

Students also referred to the importance of exposure and experience when developing accessories for the benefit of the disabled as part of the academic framework. **[ET]** *"At what stage in life do we have an opportunity to do this? Not when you're married with kids, you start work... whereas when you are a student you have time available to do it ... it seems to me to be the right time, and the college is the incubator."*

Beyond feelings of personal commitment, the respondents expressed a sense of collective commitment, of corporate responsibility. **[ET]** *"I think that the company or organization that employs such people has to take it upon itself."*

Their experiences stimulated business and entrepreneurial thinking: **[ET]** *"There is currently no such thing in the market. We wanted to develop it into something that is more entrepreneurial, I think it can also be successful."* **[EG]** *"This is something that goes through my head every day since this course. I've already done countless checks to address these sectors... Everyone will benefit from this, both emotionally and materially ... there is no such thing today."* **[VO]** *"I can see the business potential of companies who address the areas of biomechanical rehabilitation."*

B. Interaction with Disabled People and Changes in Attitude

Interacting directly and personally with a disabled person, whether adult or child, led to an overwhelming change in perceptions of this population, especially in terms of interpersonal communication. The first meetings were accompanied by fear and embarrassment, but they were quickly replaced by rapport and cooperation, thereby removing communication and "otherness" barriers. **[EG]** *"At first I tried to talk at his level ... I realized very quickly that I need to talk to him normally and directly. Maybe he won't give you feedback, but he understands everything. And that's something that made me completely alter my communication with people like that. Since then, every time we meet, I speak perfectly normally."* **[VO]** *"At first I did not know how to behave, but after a very short time I understood that I should ignore the differences between us. Ultimately these children are very happy and active... You can't even call them disabled ... They're just different. I really liked working with them."* **[MA]** *"...It can also be very painful in terms of appearance. It requires understanding and acceptance. I come from wanting to really help, not simply to finish my project."*

The interaction included home visits, the involvement of the clients in defining their needs, the selection of a solution from a number of concepts, and finally, the delivery of the final product to the clients and the use of the product. This all led to feelings of joy and satisfaction on both sides. **[ET]** *"It was heartwarming to see that she really wanted us to help her. She would hug us when we came and went, the father too. What*

chance is there that someone who is almost an engineer would think about them and give them an answer to something like that ...?"

C. Effects on Personal and Career Development

Exposing students to the needs of people with disabilities echoes their current employment and their thoughts concerning future development, whether regarding further studies in the field, contributing to the community, developing aids for the disabled, or going into business in the field.

AG specialized in biomechanics and the internship included planning and development of medical devices. *"Within a very short time I knew I was going to make a change in my life ... and I'm trying to be accepted to medical studies... One day I came to the hospital independently, as a volunteer. I went into a daycare center for cerebral palsy children and asked if I can maybe start a project. ...one of the things I do [at OBC] is to mentor students in the development of projects for the hospital ..."* [VO] *"Today I am considering a master's degree in biomechanics rehabilitation."* [ET] *"This exposure opened my mind to more directions ... it helped me understand the need to focus more on these populations."* [KA] *"It contributes to you as a future engineer, in dealing with a real problem that requires an answer when you have limited time, and at the same time create interactions with suppliers and customers."*

It is apparent that the points that were chosen and perceptions reflected in their statements relate to the current occupation of each person. For example, AT has started a new role as head of department for the production of stainless steel parts. He tries to instill changes in the work environment of the employees in his department to positively affect output. *"Someone who has gone through this experience as a student and then works, will surely want to promote it. They took me in as the engineer in a management role... The first thing I looked at in the department was how the employee feels. So I ordered floor mats for them, adding marks of where to put everything on the table ... It opened my eyes and now I look at things differently. It is difficult to implement but when the worker produces another fifty or sixty parts because he has these mats, others will see it and eventually there will be change."*

MA is in the role of a project manager and responsible for receiving and absorbing new engineers. He refers to the impact of his experiences in college on his perspectives. He assumes that product design is a platform for training students to deal with a real customer. The student is required to understand the problem presented by the client and formulate a strategy for the development of a solution, thus gaining engineering experience during studies. He talks at length about his interviews of candidates, some of whom are still students, and what he looks for: *"Today in job interviews you ask what project you are working on, and what you have done. A person who comes in with a project, which at the end of the process results in a product, has something to talk about in a job interview. At first you have to know the requirements of the customer or how the customer will use the product, to understand that you have to match the customer's requirements to the engineering capabilities, we need not only a product solution, but a solution designed properly that is fun and comfortable to use ..."*

VII. DISCUSSION AND FURTHER RESEARCH PLANS

A main mission of engineering is to design and develop solutions to problems for the wellness of human beings. This study seeks a deeper insight into the impact of students' involvement in projects for people with disabilities in their personal and professional lives, and on the way they perceive the role of engineering in society several years after graduation; accordingly, a qualitative research approach was chosen. The flagship project involves a major investment, as do other learning service programs around the world, and knowing more about their outcomes is highly important. Research findings may help promote the project at OBC as well as in other institutions and communities.

An outcome from the interviews is that PBSL experience in rehabilitation biomechanics has contributed to the development of students' personal and professional skills: (a) One of the most important skills for an engineer dealing with design is the interpersonal communication with the client. Precise collaboration over the nature of the needs of the disabled is challenging because of the difficulties in communication, so the ability to remove the barriers is of utmost importance to get to the root of the problems to be solved. This skill may contribute positively also to working with clients from different disciplines and cultures. (b) Students have encountered other fields of expertise and development circles that hands-on projects in a real setting allow. Protocols analysis shows that this awareness of specific needs can transfer to the "normal setting" of a workplace, exemplified by one of the graduates, a department manager at present, who implemented changes in the working conditions of his department workers to improve the efficiency of their work, having in mind a similar experience he had in his learning service. (c) The direct interaction with disabled customers in their natural surroundings has had an immense effect on the students. The interrelation changed the way they view people with disabilities today.

Experience in the full process of product development may assist students in succeeding in job interviews; it also has an effect on their interests and future study aspirations. One participant has applied to medical school and another plans a second degree in rehabilitation biomechanics. The achievement of designing and manufacturing an assistive device according to specific needs, coupled with helping disabled people gain more independence, yielded strong emotions of satisfaction and meaningfulness.

Those interviewed so far were the first to respond to our invitation to join the study and may have special characteristics (such as more enthusiasm towards these projects). Therefore we will continue interviewing other graduates. In addition, we plan to interview students who participated in other SL courses, lecturers involved in the project, and other stakeholders.

The themes raised by the participants illustrate the potential of PBSL programs involving interaction with disabled people to achieve learning outcomes such as understanding of professional responsibility and understanding the impact of engineering solutions in a global and societal context (ABET). Consequently, the experience seems to contribute to the development of their professional identity as engineers.

Abstract—Software engineering is largely a communication-driven, team-oriented discipline. There are numerous hurdles for ensuring proper communication and interaction between all project stakeholders, including physical, technological, and cultural barriers. These obstructions not only affect software engineering in industry, but in academia as well. One possible issue that is often overlooked in software engineering education is how to best educate Deaf and hard-of-hearing (Deaf/HoH) students, and how to fully engage them in the classroom.

In this paper, we present our experiences in teaching software engineering to Deaf/HoH students. In the classroom, these students work very closely in activities and on project teams with their hearing peers. We also present recommendations for creating a more robust software engineering educational experience for not only Deaf/HoH students, but for hearing students as well.

We encourage instructors not only in software engineering programs, but in other computing disciplines to consider our recommendations and observations in order to enhance the educational experience for all students in the classroom, whether Deaf/HoH or hearing.

I. INTRODUCTION

Efficient and effective communication is an integral part of most software projects. This includes proper communication between all stakeholders of the project — customers, management, users, and developers. Communication is also very important in the educational process, between instructors and students, and between student peers. This is often made more difficult with the different communication abilities of students and instructors.

A recent study by Gallaudet University reported that between 9 and 22 people out of every 1,000 in the United States have a severe hearing impairment [3]. Even with the availability and effectiveness of sign language interpreters to assist student and faculty communication, the educational experience is typically significantly hindered for both Deaf/HoH students and their hearing classmates. Studies have found that Deaf/HoH students were only comprehending 50-80% of interpreted or assisted lectures, in comparison to 84-95% from their hearing peers [14], [15]. Universities across the United States face considerable challenges in educating students with disabilities in computing fields [8]. Students with disabilities are much less likely to pursue careers in computer science and engineering, and the dropout rate for these students is high [6], [16], [4].

The Software Engineering Department at the Rochester Institute of Technology (RIT) is the first and largest undergraduate program of its kind in the United States [13]. RIT is also home to the National Technical Institute for the Deaf (NTID), with a goal of providing technical and professional education to Deaf/HoH students, with over 1,500 Deaf/HoH student enrollees [17]. Even though NTID is a separate college from the rest of the university, its students often attend classes with hearing students. Interpreters and other necessary resources are made available to all students on an on-demand basis. They are available for classroom lectures and activities, team project time outside of class, or whenever else they are requested by the student. NTID is a two-year college, so many of its students will transition to one of the many other colleges at RIT (including Software Engineering). Additionally, not all Deaf/HoH students at RIT begin their college career in NTID.

Software engineering is a team and communication-driven discipline [18]. At the Software Engineering department at RIT, our courses typically include a team project component. These teams may be comprised of both hearing and Deaf/HoH students. Other than the additional resources such as interpreters provided by the university, Deaf/HoH students are treated just like any other students in the program. While we have achieved a considerable amount of success educating students with hearing loss in our software engineering program, we have also faced significant hurdles. Despite the best efforts of the interpreters, Deaf/HoH students are prone to losing a large amount of both verbal and nonverbal communication through an interpreter. Group discussions and multiple conversations are largely impossible for interpreters to fully communicate to the Deaf/HoH students [2].

This work is not only aimed at helping Deaf/HoH students and faculty, but their hearing counterparts as well. In both academia and in industry, students are very likely to work with differently abled coworkers, bosses, and customers, which may include visual or other physical impairments, including hearing. Students need to learn to effectively and efficiently work with a diverse set of people. Not doing so will not only limit their effectiveness in the workplace, but also limit the people they are able to work with.

In the following paper, we discuss some of our experiences and future work in creating the most robust educational experience as possible for our Deaf/HoH students in the software engineering educational process along with observations and recommendations from a Speech Language Pathologist (SLP). We propose the following work in the hope that it may assist

instructors and students at other institutions. The specific goals of this work are to:

- Share our experiences in instructing Deaf/HoH students in the field of software engineering.
- Create a *Best Practices* guide for instructors.
- Discuss common mistakes in educating Deaf/HoH students.
- Discuss improvements to be made, both at our institution and others.
- Lay the groundwork for future work in this area.

The remainder of this paper is organized as follows: Section II describes our experiences and lessons learning with instructing Deaf/HoH students. Section III provides recommendations for students and instructors when interacting with Deaf/HoH students. Section IV provides a list of related works. Section V addresses limitations and future research to be conducted, and Section VI summarizes the findings of this work.

II. OUR EXPERIENCES

In order to understand the perspectives of faculty and hearing and Deaf/HoH students, we asked each group to fill out an anonymous survey based upon their experiences. For both the hearing and Deaf/HoH student participants, we sought a wide and diverse range of students. The students ranged from freshmen to seniors, and some had profound hearing loss while others were able to hear through the use of hearing aids or cochlear implants [23].

In the following section, we will discuss some of the student and instructor feedback we received.

A. Student Deaf/HoH Feedback

We first asked Deaf/HoH about some of their biggest communication challenges in their courses. Some responses were:

“It’s hard for all of us as a whole including hearing [people]. We may have an increase in difficulty in communicating with our professors because some of them speak at the speed of light, while others have heavy accents.”

“The biggest challenge I had during class was trying to figure out the instructions given to me from the professor.”

The Deaf/HoH students provided very mixed reviews regarding their software engineering experiences. While several students provided very positive experiences, others expressed concerns and displeasure over their experiences. Very early in the team-based project component of many courses, many Deaf/HoH students felt unwelcome by their hearing teammates. They immediately felt like others in their team largely viewed them and their disability as a burden and many hearing students wished to avoid being on teams with them. Deaf/HoH students felt that their teammates did not know how to deal with them, and were largely ignorant of how to communicate, interact, or even act around them.

While even a small level of ignorance is not desired, it is expected. What is the significant amount of reported ignorance at an institute such as RIT, where a significant portion of the student body is Deaf/HoH. This problem is likely much more profound at other institutes without so many Deaf/HoH people in the student body.

One of the recommendations that Deaf/HoH students had for helping to limit this ignorance by having the two groups of students perform team-building exercises, getting to know one another before the start of the group activity. One student stated:

“Generally, we [Deaf/HoH students] just need exposure. Both sides need to be willing to communicate. And sometimes, a student just isn’t a good student, which reflects badly on one side. Feeling a connection (for example, becoming friends) is really helpful. Get to know the other person. Do team-building exercises.”

Deaf/HoH students also stated that they have had good experiences when they’ve advocated for themselves, and been proactive in the work being done with their team. Some of the student quotes include:

“I would recommend that they advocate for themselves as much as possible so as to ensure that they are included as much as possible in the team’s work.”

“I would say participate and communicate a lot. Take a leadership role! This is actually no different than a non-deaf person, but when there’s a mixture of hearing and deaf students, communication is even more important. A mixture multiplies communication problems, so it’s super-important to communicate well. Taking a leadership role means not just sitting there and expecting others to do the work. This is very hard in a classroom environment, unfortunately, but it needs to be done.”

Many students also said that they preferred to use the note-taking service, as it helped them very much with reviewing the course material after lecture or lab hours. (Note-taking is a service provided by NTID in which a hearing student takes detailed notes, combining slides and spoken content.)

“Notetaking helped a large amount! It was very nice and convenient to be able to go back and look at the material on my own time.”

“I use the notes from the note-taker to review for quizzes and tests. Since I started doing that, I feel like I’m more able to contribute to the class or group.”

While RIT has a large and excellent group of interpreters which is readily and freely available to students upon request, there were still some issues. Many students described difficulties with attaining an interpreter for team meetings since they had to request one in advance. This posed a problem for shorter, ad-hoc team meetings, or ones scheduled with little notice. Some students also described issues with the lack of technical background most of the interpreters had.

They were often unable to understand computing acronyms and terminology, leading to a large amount of communication loss in translation. While this is an issue which can certainly be examined, we sympathize with the interpreters because it is not reasonable to expect them to be an expert in such a wide-range of difficult, technical areas. Many Deaf/HoH students also stated that they did not utilize interpreting services made available by the University since they did not feel like they needed this assistance. Much of this feedback is surprising, especially considering RIT has one of the largest, if not the largest, set of interpreters available at any institution in North America. This leads us to believe that similar problems not only exist at other institutions, but may be even more profound.

TABLE I: Example Questions: Deaf/HoH Students

Question	Responses
How was your overall experience with the other members of group projects?	Poor: 13%, Neutral: 34%, Good: 53%
During class time, do you feel that you are "in the loop" regarding the coursework?	Yes: 80%, Sometimes: 13%, No: 7%
During class time, do you feel that you are at the same level as your peers?	Yes: 60%, Sometimes: 13%, No: 27%
When working in a group, do you feel confident communicating with hearing team members?	Always: 40%, Sometimes: 53%, Rarely: 7%

Most Deaf/HoH students indicated that they wanted to interact more with their team, but were unable to do so. Their team would often relegate the Deaf/HoH students to non-leadership roles so they would not have to interact with the team as much. In other situations, the communication lost through the use of an interpreter hindered their ability to interact more in team meetings. One reasonably simple recommendation is to have only one person on the team speaking at a given time, which would allow the single interpreter to not be overwhelmed with the virtually unachievable task of trying to relate several conversations at once. One student stated:

"Communication was the main issue for me because everyone was talking at once and I was completely lost."

Communication in the classroom and in smaller groups is paramount to the success of all students, especially those who are Deaf/HoH. Good communication comes from focus. Many of the Deaf/HoH students said that the learning material was rushed and unclear, which led to issues understanding the material and subsequently diminished their credibility during smaller ad-hoc group meetings. Students reported that the instructors would typically speak and perform an in-class demo at the same time. When the Deaf/HoH students tried to follow along with the demo, they cannot see the interpreter and the monitor, whiteboard, or projection screen at the same time.

Another issue that many Deaf/HoH students discussed was lag time: the time that it takes for the interpreter to hear what another student, group, or the professor is saying and interpret it into sign language for the Deaf/HoH student to see. Even though the interpreters do their best, there is usually around a 2-3 second delay between what is said and what is signed. Regardless of this, Deaf/HoH students still were able to understand the information that was signed to them. Many of the Deaf/HoH students said that they thought the interpreters did a great job overall:

"Yes, an interpreter was there to interpret in the classroom and made the communication go smoothly."

B. Hearing Student Feedback

Creating a cohesive learning environment is important for both hearing and Deaf/HoH students. We created an anonymous survey asking hearing students about their experiences with working on a team comprised of both hearing and deaf/hard of hearing students and asked them to rate their experience as *below average*, *average*, or *above average*. Table II illustrates that an overwhelmingly large portion (75%) of hearing students rated their experiences as being below average. Based on the feedback attached to the survey, a large portion of negative feelings are due to extra time required to complete tasks due to the communication barrier. Most hearing students felt that properly run team meetings and better overall communication practices could have alleviated most of the issues.

TABLE II: Example Questions: Hearing Students

Question	Responses
How would you rate your experience with teams comprised of both hearing and Deaf/HoH students?	Below Average: 75%, Average: 13%, Above Average: 13%
Have you found that the services offered, such as an interpreter or notetaker, has been adequate to address your team needs?	Yes: 33%, Somewhat: 67%, No: 0%
Did you typically have an interpreter at your meetings?	Yes: 25%, No: 75%

Many hearing students feel that the Deaf/HoH student does not advocate for themselves in the group and therefore the other members of the group are lost on how to interact with the them. One student said:

"My teammates and I ended up picking up the work the hard-of-hearing teammate would have completed because we did not want to fall behind on the project."

Many hearing students also expressed issues in bringing the Deaf/HoH students up to speed whenever they met in a group. Most of these meetings were ad-hoc and therefore had to rely on other means to communicate since interpreters were not always available. When interpreters were requested for these meetings, many of the hearing students felt that they did very well in conveying the information to the Deaf/HoH students. Additionally, many of them felt like they did not do enough to accommodate the Deaf/HoH student and welcome them in their group. It was also mentioned that the flow of communication was significantly easier to facilitate if one of the members in the group knew sign language.

"It's nice to have an interpreter, but it's not always possible. I am not an interpreting major but I have been forced to do some amateur interpreting out of necessity."

When group members communicated electronically with Google Docs or another form, documentation for their projects went much more smoothly.

"Documentation [went much better] because almost all conversations were recorded electronically."

Due to the risk of miscommunication and the effort required to include the Deaf/HoH person, it was easier to simply exclude them from the project by assigning them a less strenuous workload.

“This [text-based communication] made it very difficult to explain assignments and the work we needed done - the [Deaf/HoH] student ended up doing almost no work on the project.”

Hearing students had their own struggles with incorporating the Deaf/HoH student in their work and their group. Having interpreters was a great help, but unfortunately the option was not always available. While none of the survey respondents questioned the quality of the interpreters, many felt that the lack of interpreters hurt their interactions. In many cases, the Deaf/HoH student felt that they did not need one and could communicate well enough without them, and thus did not request an interpreter for either their in class work, or their project work outside of class. Several hearing students stated that the lack of an interpreter really hurt their team communication. Other hearing students echoed the thoughts of the Deaf/HoH students in that communication was made more difficult since the interpreters did not understand, and therefore were not able to effectively interpret, a wide range of technical terms. One student stated:

“Even though they tried their best, interpreters were unable to understand (and therefore) communicate many of the technical terms and ideas. Interpreters were not present for many of the meetings due to a variety of reasons. Maybe the deaf student did not request them or were not available due to ad-hoc meetings.”

Some hearing students acknowledged problems with how they treated a Deaf/HoH teammate. From the beginning of a team-based project, many hearing students felt that they did not do enough to welcome or gain understanding with the Deaf/HoH student who was working on their team. Even though this meant more actual assigned work for the hearing teammates, many felt that it was easier to simply ignore the Deaf/HoH students in their group and not make them as much of a part of the team as their hearing counterparts. Even though they could see that many of the Deaf/HoH students were trying to become more involved with team activities, many hearing students stated that they did not have the patience to work with or understand Deaf/HoH students and would not properly involve them with their team.

“The increased difficulty in communication made it difficult to explain and assign work — almost to the point where it was easier to just assign to someone else and not include the deaf student.”

“There is a language barrier which prevents smooth in-person communication between team members. Deaf tend to be left out of conversations and ad-hoc decision making. The technology for smooth communication and interpreters are available ad-hoc and require extra planning. Typing is inefficient.”

Many hearing students also felt that Deaf/HoH students have learned to work autonomously from the rest of their team. Software engineering is largely a team-based exercise, which relies upon strong team cohesion to deliver a high quality product on time and on budget. Software engineers working away from the rest of their team goes against much of how we actually want to teach the students to create software using the proper engineering mindset.

Regardless of whether Deaf/HoH members are part of the team itself, team-related issues that need to be addressed during the course of a project still arise, ranging from the technical to personal and interpersonal issues. Learning how to properly address these situations is an important part of the learning process. Far too often, however, students would fail to address various issues with their Deaf/HoH teammates largely due to the communication barriers. As an example, many did not wish to involve a 3rd-party interpreter in possibly confrontational issues.

Even with a significant amount of communication and cultural differences to overcome, hearing students generally had a very positive experience when working with Deaf/HoH students. Many took the time to understand Deaf culture and learn American Sign Language (ASL) to varying degrees. Most hearing students acknowledged that Deaf/HoH students thought just like everyone else and, just like hearing teammates, some were good teammates and worked hard, while others did not try to contribute much to the team. Many students enjoyed the experience of working with a more diverse set of teammates.

“I enjoyed it because it brought in a new perspective for the team to work with. As a result, we were able to deliver high end products that met a larger scope of users.”

“...it [working on a team with Deaf/HoH students] was a good experience that opens your eyes to how different people can be.”

This diversity had other positive effects for the team as well. One student stated that the extra documentation and extra focus on communication had a positive effect on their final product:

“What went well is that they[Deaf/HoH] are just as capable as anyone else, and the fact that we are going at a slower pace allows for an actual full thought process to occur instead of trying to blaze through half-thought-out options.”

C. Faculty Feedback

We surveyed 7 Software Engineering faculty members about their experiences with having Deaf/HoH students in their class projects. A wide range of instructors responded to our questionnaire — from brand new faculty to 30-year tenured faculty. In general, most instructors did not notice many significant abnormalities or problems with Deaf/HoH students in comparison to ones who were hearing. One common observation was that documenting classroom materials was a significant help in keeping everyone up to date.

TABLE III: Example Questions: Faculty

Question	Responses
Do you feel like you were adequately prepared to have a deaf/hard of hearing student in your class?	Yes: 33%, Somewhat: 50%, No: 17%
Do you feel like there were provided sufficient resources to address the needs of the student, both in and outside of the classroom?	Yes: 83%, Sometimes: 17%, No: 0%
As an instructor, have you used any resources offered for the support of deaf/hard of hearing students?	Yes: 17%, No: 83%

Most of the feedback regarding the interpreters was very positive, with some instructors feeling that they were doing an excellent job with terminology, while others saying there were understandable difficulties. A common theme was that it was important to get the Deaf/HoH students involved in team-based projects and help to motivate their participation in groups. One example statement:

“Be sure to include the students in group activities, etc. Sometimes it can be hard to distinguish between barriers or issues caused by the disability and individual personality traits of the student.”

Many faculty said that having a Deaf/HoH student in their classroom really made them rethink their method of communicating their curriculum to the class. Many of them took the feedback they received from the Deaf students to heart and improved their own methods of teaching:

“Have the same expectations of Deaf/HoH students as you would anyone else. If extra time is needed on tests, follow that procedure (or any other accommodations listed). CC [closed caption] any video used. Don’t speak to the board while lecturing, your other students will appreciate that too.”

Additionally, many of the RIT/NTID interpreters faced struggles within their own field. Three interpreters that were interviewed claimed that many of the instructors here at RIT do not fully understand how to teach Deaf/HoH students. This may stem from lack of experience or training, but this is something they say the majority of interpreters have noticed. It was suggested that a workshop for instructors and faculty would help immensely. They were informed that RIT did, in fact, provide workshops, but that workshops were not mandatory.

One other issue that was brought up was that in New York state, there is no certificate requirement for interpreting education. RIT does have RID (Registry of Interpreters for the Deaf) certified interpreters, but not all interpreters have this certification. There are different levels of certification: community interpreting is the most basic; medical and educational interpreting require a much higher level of certification. Some suggested that RIT could pay for the newer interpreter’s certification tracks, which would lead to an increase in the quality of interpreters overall. RIT currently does not pay for certification fees, and this led to a lack of motivation to take the certification exams. This, combined with the fact that certification is not a job requirement has made certification a lower priority to many interpreters. Recently at RIT, the Promotion Career Ladder Committee (PCLC) was established, chartered with helping interpreters to pursue higher levels in their career and driving participation in their career. An

Fig. 1: Primary Challenges for Each Group (%)

increase in number of certified interpreters could improve the clarity of technical information interpreted for the Deaf/HoH student.

D. Analysis

Most faculty felt that the resources available to them for communicating their material to Deaf/HoH students was adequate enough for the Deaf/HoH students to succeed in and pass the course. Interestingly, most Deaf/HoH students reported that they felt the teacher’s materials were unclear and very vague, some feeling that the information itself was vague and therefore was interpreted as vague. This can amount to a large roadblock in the success of these students in the academic learning environment.

III. RECOMMENDATIONS

With an eye on the primary challenges shared by each party, shown in Figure 1, this section includes recommendations for each person or interaction: Instructors, Deaf/HoH Interaction, Classroom Lectures, Group Work, Deaf/HoH Students, and for all students based on our research. Many of these recommendations were derived from our own observations, best practices from previous publications, and recommendations from a Speech Language Pathologist.

A. For Instructors

Working with a Deaf/HoH student is a new experience for many instructors. Teachers in the elementary and secondary levels have training on how to differentiate lessons and teach to a more diverse group of young people yet most still require support from specialized teachers or Teachers of the Deaf (TOD) to understand how to best educate Deaf/HoH students. At the university level, instructors are not typically versed in teaching philosophies and differentiation strategies, and do not have the strict support services from a TOD received by their elementary and secondary counterparts. Due to this,

instructors entering a university where they may have students who are Deaf/HoH and are of mixed backgrounds, learning styles, and/or abilities may feel unprepared for differentiating their instruction style. They may also be unaware that small accommodations in the classroom can make for a much different communication and learning environment.

In this section we will discuss some measures instructors can take to communicate and teach more effectively to any class, but specifically classes of both hearing and Deaf/HoH students. A goal of this work is to assist instructors in the computing field in becoming more knowledgeable and understanding in ways they can help enhance the educational experience for students who are Deaf/HoH in their courses. Some general recommendations for interactions with Deaf/HoH individuals are:

General Interactions with Deaf/HoH individuals

- When speaking with a Deaf/HoH individual, look at and speak to the individual not toward the interpreter. Speak clearly and naturally.
- Keep sightlines open and clear from obstruction — seeing the speaker's face is important for speechreading (lipreading) and nonverbal communication such as facial expressions.
- Clarify/repeat messages and/or give examples. Allow for repetition of information, do not say “never mind” if the information was missed.
- Deaf/HoH students may use different modes of communication: American Sign Language (ASL), Signed Exact English (SEE), Pidgin Signed English (PSE), Cued Speech, speechreading, and spoken/written English or other languages.
- Deaf/HoH students may have access to auditory information via a hearing aid, cochlear implant and/or FM system. Each student will be different in their ability to utilize the auditory and spoken avenue for communication.
- Familiarize yourself with Student Access & Support Services and Disability Services available on campus (C-print, interpreting, note-taking, tutoring).
- Students who are Deaf/HoH and also have an additional disability or blindness are known as “Deaf Plus” or “Deafblind” respectively. Numerous supporting resources may be found on the web.^{1 2 3}

Classroom Lectures

Dual or multi-directional attention is a huge barrier in a classroom for Deaf/HoH students. Dual attention refers to the consideration needed to attend to two stimuli simultaneously. Hearing people often do this with little effort (you may listen to a teacher while taking notes or looking at a handout). “In contrast to hearing students who use dual channels — auditory and visual — for the input of classroom information, Deaf/HoH students tend to rely primarily on a single channel

— the visual channel.” [22]. A classroom is full of auditory and visual channels that a Deaf/HoH learner must process through a mostly visual sense. (i.e. watch an interpreter, see information on the board, take notes, and look at handouts or a computer screen). For those with auditory access, they must also try to process the spoken message from the professor and filter out extraneous conversations and noises. All of this can be overwhelming when trying to focus on multiple channels simultaneously. This often results in the Deaf/HoH student missing information in one of these areas. The following are recommendations for ensuring quality classroom lectures:

- Talk with the Deaf/HoH student(s) about their communication preferences and needs.
- Determine which services (if any) they will be using throughout the course (C-print, note-taking, interpreting, etc).
- Allow them preferential seating.
- Allow for all information to be accessed visually, (put everything up on the board, access slides on course website, etc.)
- Face the class when speaking. Speak first, then write on the board, try not to speak while facing away from the class or writing information that the student will need to see at the same time.
- Account for interpreter lag time. Although most skilled interpreters are extremely fast and efficient at relaying information, there will always be a bit of a lag time when interpreting. Time delay can affect turn taking and make it difficult to stay current in the conversation [21]. Consider the situation where an instructor may call on a hearing student to answer a posed question before the interpreter has even finished signing the original question [12].
- Ask students to raise their hand and say who they are before speaking — this is helpful for the student and/or interpreter to be able to indicate who is speaking and where the speaker is.
- Provide notes and new vocabulary in advance. Pre-teach technical vocabulary if possible. Discuss vocabulary terms with interpreter (or student) prior to the lecture to ensure that the terms will be explained clearly.
- Document the goings-on of the class and publish on a class website.
- Design lesson plans in an organized, sequential manner.
- Using a chat program or message board for discussions outside of class can help with communication process. Examples include Google Docs, Gchat, question forums, or online resources provided by your school.
- If a student uses an amplification device:
 - Cut down on extraneous noise (limit side conversations, limit shuffling of chairs, close doors/windows, etc.).

¹<http://www.rit.edu/ntid/deafplus/about-website>

²<http://www.rit.edu/ntid/support-services>

³<http://www.rit.edu/studentaffairs/disabilityservices/info.php>

- Consider students seating arrangements and allow for preferential seating.
- Consider the acoustics of the classroom (tile flooring, humming computers, outdoor noises, sound reverberation, etc.) [1].

Groups

Group work can be one of the biggest challenges in a software engineering courses. Working in a mixed hearing and Deaf/HoH group makes communication more challenging. Faculty need to take the lead by setting up clear guidelines and make comments on interaction with clear reinforcement. One option is to create a point system for group involvement where bonus points are assigned based on collaborative accomplishments. If using this option, when group work is occurring in the classroom, wander around and assign extra points to those teams that are working collaboratively. Establish roles, responsibilities, and expectations in group interactions. Encourage interaction amongst all group members.

Research shows that although giving communication strategies (turn taking, eye contact, facing toward communication partner, etc.) is important and useful for group work, it doesn't seem to be as powerful as using an overriding open/transparent way of communicating through technology. (i.e. g-chat, white board, Google Docs, question forums, etc.) [12]. The use of a chat program can help with communication by allowing each student the time to process the information and clearly communicate responses while working collaboratively. The level of complexity of communication goes up when everyone is involved and able to fully participate [12].

Based upon some of the responses from our surveys, some recommendations are:

- Encourage Deaf/HoH students to take leadership roles within the group.
- Get to know your group mates — lead team-building exercises to encourage communication.
- Maintain the same group for the semester — once students set up working relationships with their group and develop communication strategies that work for them, encourage them to use the developed relationships to their advantage.
- Deaf/HoH students should advocate for themselves as much as possible.

B. For Deaf or Hard of Hearing Students

We next provide recommendations for Deaf/HoH students to ensure that they receive the best possible learning experience. To advocate for themselves, Deaf/HoH students may:

- Determine which access and support services will be most useful for you to utilize. Use them to support your work in lecture and group work.
- Notify the professor of any and all services you are using and how they can support these services to the best of their abilities.
- Inform the interpreter if you do not understand their signing, a term presented, or parts of the material.

- Go to office hours, email, or communicate electronically with your instructors to discuss any questions or concerns you may have.
- Explore other avenues of support for your communication needs within a group when an interpreter is unavailable to you. Consider researching which technological supports will work best for you, such as web-based chat programs or document programs (g-chat, Google Docs), text-to-voice/voice-to-text mobile or computer app options (C-Print, Dragon), and Video Remote Interpreting (VRI).
- Develop communication rules or “Communication Courtesy” within a group. Examples could be:
 - Acknowledging the speaker
 - One person speaks at a time
 - Raise hand to take a turn
 - Limit interjections and distractions
 - Utilize a note-taker in the group and share all notes
 - Consider the environment, lines of sight, lighting, and acoustics

C. For All Students

It is important for all students in a group to feel that each group member is equally contributing. Each group member wants to feel valued and should be equally relied upon for work. Regardless of hearing status, if a member of a group is viewed as apart from the rest, excluded, not “pulling their weight”, or not willing to collaborate or compromise, it will change the dynamics of the group and could result in a lower quality end product. All students need to learn how to work effectively in groups and develop strategies to ensure all group members fully participate and the work is completed to the standard of all group members. Learning how to properly address group situations and to work collaboratively is an integral part of the university learning experience.

D. General Recommendations

Based on the information collected from our surveys and research, we believe that further research and information is needed to determine the extent to which the following recommendations can be achieved:

- Instructors at universities with high concentrations of Deaf/HoH students should be required to take a workshop or course designed to introduce them to teaching Deaf/HoH students, give overview of support services available to students, and how to adjust the classroom environment to best support these students.
- Technology-based departments should work more closely with the interpreters and the interpreting department to support terminology development for courses that contain jargon central to the subject.
- Find better more user-friendly strategies for students in mixed hearing status groups, with the goal of allowing them to communicate freely and effectively.

IV. RELATED WORK

This paper represents the first known work on students with hearing loss and software engineering education. However, there are numerous previous papers that discuss Deaf/HoH education in computing. Ross [19] described several methods of teaching programming to deaf students, one of which was through the use of a dynamic library of programming language examples. Other problematic areas for deaf students have also been conveyed, including difficulties with professional note-takers and interpreters due to their lack of a computer science background, resulting in a significant loss of information.

Cavender *et al.* [8] described a 9-week summer program for students with hearing loss. This program is designed to provide a catalyst for the academic careers for Deaf/HoH students. This is largely accomplished through the use of tutors and mentors for these students, some of the lessons included the need to inform instructors on how to more properly educate Deaf/HoH students and the need to recruit tutors and mentors who are themselves differently abled so they may better relate to the students. One surprising finding is the communication variations which exist in the Deaf/HoH community along with the diversity of accommodation needs. Not all Deaf/HoH students possess the same sign language communication skills, nor do they necessarily have the same preference in sign languages. Students may communicate using American Sign Language (ASL), Signed Exact English (SEE), or “Simultaneous Communication” (Simcomm).

Burgstahler *et al.* [6] discussed several ways of increasing the participation of students with various disabilities in computing fields. Included in these was the collaboration and knowledge sharing of disability service programs across the United States where strategies for recruiting and retaining disabled students in computing fields is discussed. This work also stated that disabled students were underrepresented in computing and that increasing the participation of disabled students would require a collaborative effort from students, educators, and employers.

In order to assist educating Deaf/HoH students in computing disciplines, several papers have been written. Kheir and Way [10] discussed using real-time speech transcription in order to assist the inclusion of Deaf/HoH students in computer science courses. An affordable solution was described which greatly assisted HoH students in these computer science courses. Li and Xu [11] studied an inquiry-based teaching model for Deaf/HoH students. Inquiry-based teaching models are very student-oriented and allow students to investigate real-world computing problems under the direction of the course instructor. This research found that such a model would be beneficial for Deaf/HoH students.

Bueno *et al.* [4] described several methods of assisting instructors in adapting e-learning content. The primary contribution of this work was a tool which processes lecture text for Deaf/HoH students. This tool highlights words or expressions which are difficult to understand for Deaf/HoH students and links them to external visual resources. A visual resource is used because numerous studies have found that Deaf/HoH students who predominately communicate via sign language process images more efficiently than words [20]. This paper also discussed some of the manners in which Deaf/HoH

students learned differently compared to hearing students. One example is the observation that Deaf/HoH students learn at their own pace which is very distinct from the pace of their hearing classmates [5].

V. LIMITATIONS & FUTURE WORK

While we have addressed a significant amount of issues for Deaf/HoH education, there is still a substantial amount of research to be done. While software engineering programs are rapidly growing from their beginnings in 1996 [13], they still represent a minority of computing education fields worldwide. We believe, however, that a substantial portion of our lessons learned and recommendations will be applicable to not only other computing fields, but to a vast array of other programs as well. We surveyed a relatively large number of hearing and Deaf/HoH students and faculty, but this obviously represents only a very minor subset of these respective groups at only a single institution.

The use of technology and computing to support communication for Deaf/HoH individuals is an expanding field with innumerable other areas of research ranging from allowing hearing and Deaf/HoH to communicate using a Kinect [9], all the way to creating mobile devices which can assist Deaf/HoH individuals with medical responders [7]. We understand that the use and development of new technologies and communication techniques will not replace the need for skilled interpreters who relay information clearly and effectively or improved methodologies and understanding by instructors and students. Deaf/HoH individuals are not members of a homogeneous group and each will have their own preferred method of communication. In the case of our students, some prefer to use interpreters over technologically-based communication, but education for all students is a case-by-case basis, regardless of hearing status, and there is no “one size fits all” approach.

VI. CONCLUSION

Deaf/HoH students are typically underrepresented and encounter significant hurdles in computing curriculums in higher education. In the Software Engineering department at RIT, we have a higher number of Deaf/HoH students than the typical university due to the presence of NTID on campus. While there are numerous challenges yet to be overcome, we hope that instructors and students will benefit from our work at other institutions. Additionally, we encourage further research and knowledge sharing in improvements to Deaf/HoH education, not only in software engineering, but in computing as a whole.

Getting the Attention of Underrepresented Minority Community College Students to Consider Engineering as a Career

Mary R. Anderson-Rowland, Armando A. Rodriguez, Anita E. Grierson

Arizona State University

Mary.Anderson@asu.edu, aar@asu.edu, Anita.Grierson@asu.edu

Abstract – In order to have more students in engineering and computer science, we need more students interested in these fields. Many community college (CC) students believe that engineering is boring and has little to do with their lives, but also admit that they know very little about engineering. Our research question is: How can we best get the attention of CC students in order for them to get engineering and computer science on their radar screen to consider as a career? In particular, we are asking if a different approach is needed for underrepresented minority students than majority students. A survey was given to 72 students (21 minority) students at one non-metropolitan CC and 159 (112 minority) students at another. In this paper, we will compare the beliefs about engineering and computer science by ethnicity within each college and across the two CCs. Results show that a higher percentage of non-minority students at the first school are interested in engineering and computer science as a career (63%) than minority students (52%) and at the second school, a higher percentage of minority students (45%) than non-minority students (35%) are interested in engineering or computer science, even if about 20% of each group admit that they really don't understand what engineering is all about. The minority students appear to be more interested in working with robotics and are more likely to believe that engineering and computer science have nothing to do with their life than do non-minority students.

Index Terms – Undergraduate engineering and computer science students, Underrepresented Minorities, Recruitment

I. INTRODUCTION

Community college (CC) students are a prime source for increasing the number of engineers and computer scientists in the United States. Forty-six percent of all U.S. undergraduates are enrolled in a CC, as well as 41% of first-time freshmen, 61% of Native Americans, 57% of Hispanics, and 52% of Blacks. In addition, 57% of all CC students are women. [1] The majority of CC students do not earn a certificate, an Associate Degree, or go on to a four year school. However, “72% of community college students who transfer with an associate degree complete a bachelor’s degree within six

years. (Only) 56% of CC students who transfer without an associate degree complete a bachelor’s degree within six years.” [2] The success rate of transfer students depends on the type of institution to which they transfer. “Only students who transferred to a four-year public institution had a higher eight-year completion rate than their peers who began at a four-year public institution (74 percent and 63 percent, respectively).” [2] Based on our experience, there are many more CC students who, with the proper encouragement and support, would go on to earn a Bachelor’s degree, even in engineering and computer science. Henceforth in this paper the term “ENGR” shall include engineering and computer science.

For over ten years we have been talking to CC students about ENGR. This work was partly funded by NSF grants, most recently an S-STEM (#1060226) and STEP (#0856834). A crucial, first step to having more students interested in these fields. Students in non-metropolitan CCs may have very little knowledge of ENGR and have seen very few, if any, role models in ENGR. For seven years we have been talking ENGR with mathematics and science students in rural CCs. In each case we were the first engineering professors to visit their campus to talk about these majors. For these students it was not a matter of “changing the conversation,” it was a matter of starting a conversation. [3]

Many CC students believe that ENGR is boring and has little to do with their lives, but also admit that they know very little about ENGR. These students may also hold several myths about ENGR which they use to conclude that ENGR is not for them. Our research question is: How can we best get the attention of CC students, especially underrepresented minority students, in order for them to get ENGR on their career radar screen?

II. BACKGROUND

We have worked with upper division ENGR students for 13 years. During these years we have had many conversations with these students about their reasons for choosing and staying in ENGR. In addition, we have researched and surveyed ENGR students over these years. In Fall 2012, we administered a survey we designed for CC students in classes

at our five partner CCs in order to answer the question: “What about ENGR attracts or does not attract you?” [3] After asking for demographic data, and verbally telling the students that we considered computer science to be a part of engineering, we asked the question: “Is engineering your career choice?” If the answer to this question was “Yes,” the student was directed to check all of the factors that were true for them as to why engineering was their choice. If the student answered, “No,” they were directed to a separate list of items where they were asked to check all the factors that were true for them as to why engineering was not their choice. For either list, the student was asked to rank their top three as 1= most important, 2=2nd most important, and 3=3rd most important. [4]

The survey was given to students in math and science classes with the permission of the instructor. We administered the survey before we began our dialogue so as not to influence the answers. The survey was taken by 338 students, 118 females and 220 males. Of these respondents, 189 said YES to engineering and 149 said NO to engineering. For students who said YES to engineering and based on their top 3 reasons, the top six reasons were: money, like math/science, exciting, many job opportunities, challenging, and want to make a difference. Money was clearly the main reason that students said there were interested in engineering. The 50 females who said YES to engineering had a similar top six (with a different order of ranking) as the 139 males who said YES with the following exception that “Want to help people” was ranked 6th and “Many job opportunities” was ranked 7th. The males who said YES to engineering included “Like to solve problems” in their top 6, and not “Want to make a difference,” which was ranked 8th. [4]

In analyzing the top 3 reasons that students were not interested in engineering, we found that the top reasons were: does not sound interesting to me, not good enough at math, think engineering is simply too hard, do not like math, not aware of many engineering job opportunities, and I want to work outside, not in an office. “Do not like physics” was the 7th highest rank reason. This information informs topics that are good to discuss with students who do not know much about engineering. [4]

The three most significant differences ($p < .025$) between females and males in their reasons for saying YES to engineering is that men valued many job opportunities, rewarding, and like to solve problems more highly than did females. Males were more concerned about job security than females and females were more likely to give challenging as a reason to say YES to engineering ($p < .10$). Trends ($p < .16$) were seen in that females were more likely to like math/science, to want to help people, and to consider job flexibility a factor. [4]

For the students who said NO to engineering, the largest difference ($p < .025$) between females and males was that females were less aware of many engineering job

opportunities. At the $p < .10$ level, females were more likely to say that engineering did not sound interesting to them and were less likely to say that they did not like to study. At the trend level, females were more likely than males to say that they were not good enough at math, engineering is simply too hard, that engineering would be boring, and that they did not like computers. [4]

The items from aforementioned survey were used to develop a new survey. A major difference in this survey is the students were asked for their degree of belief of a statement and not just if they believed it or not. The 22 items were listed in random order, but basically came from four categories: interest, lack of information, misperceptions, and inadequate information. This survey was given to students at two non-metropolitan CCs, which included a few high school students co-enrolled at the CCs. The total number of students was 64. [5] The mathematics level of the students was from pre-calculus to differential equations.

From the combined responses, the statements with the most positive responses were: I want to use my career to make a difference, ENGR jobs have a lot of flexibility and variety, I want to use my career to help people, ENGRs work outside as well as in offices, ENGR has many job opportunities, I could use ENGR to help my community, and the US needs more ENGRs to stay competitive. [5]

Only 25 of 63 students (student totals vary by how many answered each question) agreed or strongly agreed with the statement “I understand what an ENGR does.” Items showing the most lack of understanding were: An ENGR must be a “brain,” An ENGR major must love math, ENGRs have low unemployment rates, and ENGRs have the highest starting salaries with a Bachelor’s degree. These items are commonly misunderstood and need to be clarified for students. [5]

Of the 63 students who responded to the statement, “I’m interested in Engineering or Computer Science as a degree,” 26 (41.3%) strongly agreed or agreed with the statement, 12 (19.0%) were neutral, and 25 (39.7%) either disagreed or strongly disagreed with the statement. Additional analysis showed that students who are interested in ENGR generally understand what an ENGR does and students, who do not understand what an ENGR does, are not that interested in ENGR. [5]

III. LITERATURE REVIEW

In spite of the need for ENGRs in the U.S. and the many attractive attributes of the profession, few students are choosing ENGR as a career. Only 11% of freshmen students are studying engineering and only 3% are studying computer science. [6]. We have already mentioned that CCs are a great source for more ENGRs, and since CCs have a higher percentage of underrepresented students than universities, there is the potential for more diversity in ENGR through

recruitment at the CCs. We also know that many of the students at CCs have not yet decided on their major. Through our own research, we have discovered that 30% of the ENGR students in our program only decided on ENGR while they were at the CC. [7] This fact gave us the incentive to spend time travelling to CCs to talk to students about ENGR to make sure that ENGR was one of the careers that they considered.

The U.S. Education Department reports that only 60% of students entering four year institutions earn a Bachelor's degree in six years, and only 31 percent of public community college students go on to complete either an associate or a bachelor's degree in six years. [8] We believe that if we can help students find an interest in ENGR that students will be more likely to enter and to be retained in these fields.

Although there has been increased attention paid to CCs by the National Science Foundation and other funding agencies, the CC is still a largely untapped resource for interesting more students to major in ENGR. For several years there has been an emphasis on changing the message about engineering. A Committee on Public Understanding of Engineering Messages, "Changing the Conversation" was published in 2008. [3] The primary idea to come out of this study was that engineering needed to be presented in more positive ways, in ways that emphasized the areas that females, minority students, and males wanted to have in a career. As we shall see in this paper, many students still have little or no idea of what engineers or computer scientists do. With this lack of knowledge about the careers, it is very difficult for students to decide they want to pursue this career.

Other research has focused on what community colleges can do to better prepare their students for transfer to a four-year, comprehensive research university. [9] Zhang and Ozuna adopted Rendon's [10] validation theory to explore the students' experience in the CC and concluded that CC faculty were the most important support for participants' interpersonal validation experiences. In order for this to work for recruitment into ENGR, this means that the CC students need to be exposed to ENGR either through their CC faculty, guest speakers, or ENGR student role models, as well as informed advisors.

IV. THE SURVEY/METHODOLOGY

Grounded theory has been used for the development of a survey with CC students about their thoughts on engineering and computer science as their career. Our grounded theory is very closely connected to Social Cognitive Career Theory [11] with career choice factors as follows:

- Environmental variables as financial resources and access to role models and social supports;
- Cognitive person variables such as outcome expectations, self-efficacy, and goals;

- Other person factors such as gender and ethnicity.

Students were first asked if they were interested in ENGR and why. From these answers a survey with 22 items was constructed. Sixty-four students at two non-metropolitan CCs were asked to rank their belief in each statement on a Likert scale.

In Fall 14, a similar survey was given to 71 and 159 students at two non-metropolitan CCs and their beliefs about ENGR were analyzed by gender. In this paper, we will analyze their beliefs about ENGR by ethnicity and compare the results. See Table I for the statements by category.

<i>Interest:</i>
1. I am interested in Engineering or CS as a career
2. Engineering and CS do not interest me
3. Working with robotics would be interesting
<i>Lack of Information</i>
4. I do not really understand what engineering and CS are about
5. I understand what an engineer or computer scientist does in their career
<i>Misperception</i>
6. An engineer or CS major must be a "brain"
7. Engineering and CS are too difficult for me
8. Engineering and CS majors require too much work for me
9. An engineer or CS major must love math
10. I don't like Physics and therefore do not want to be an engineer or CS major
11. Engineering and CS majors are not well suited for women
12. Engineering and CS have nothing to do with my life
13. Engineers work outside as well as in offices
14. I want to use my career to help people
15. I think I could use engineering and CS to help people
16. I want to use my career to make a difference
<i>Inadequate Information</i>
17. Engineering and CS have many job opportunities
18. The US needs more engineers and CS majors to stay competitive internationally
19. Engineering and CS have the highest starting salaries after a Bachelor's degree
20. Engineering and CS have low unemployment rates
21. Engineering and CS jobs have a lot of flexibility and variety

Table I. The 21 Statements in the Engineering Interest Survey.

The survey used in this study is similar to the survey described in the Background section. The previous survey results were based on 64 students and we wanted a larger sample. Also, we

changed this new survey to only have 21 statements instead of 22 by eliminating the statement “Engineering and CS sound interesting.” We believe that the statement “I’m interested in Engineering or Computer Science as a career” is a more accurate statement, as well as being more inclusive. We still include the statement “Engineering and CS do not interest me” as a check for validity.

The statements were listed at random in the surveys. The students were asked to judge each statement according to a Likert scale from 5 to 1: Agree Strongly, Agree, Neutral, Disagree, Disagree Strongly. The number of participants in this study are shown in Table II. The totals vary since not all students identified their gender, ethnicity, and ENGR interest.

CC	Female	Male	Under represented Minority	Non Minor ity	Total
A	40	31	21 (29.2%)	51	72
B	70	89	112 (70.4%)	40	159
Tot.	110	120	129	91	231
%	47.8%	52.2%	56.8%	41.4%	

Table II. Gender and Ethnicity Breakdown of Students Taking Survey in CC A and CC B.

From Table II we note that the underrepresented minorities (African American, Hispanic/Latino, and Native American) are 29.2% at CC A and 70.4% at CC B. We can also see a good representation of females in the survey.

V. ANALYSIS OF SURVEY

In order to better understand the students who took this survey let us consider Tables III and IV.

In Table III we see the breakdown for the percentage of students at CC A, who declared they were interested in engineer or not, further broken down by minority and gender status. At CC A we see that 40% of the students who took the survey were interested in ENGR. Of the 20 underrepresented minority students who declared their ethnicity, 7 (33.3%) were interested in ENGR. The percentage of females interested in ENGR at CC A is 23.1% (9/39) and the percentage of males interested is 61.3% (19/31). These are encouraging percentages.

In Table IV, we see that 34.6% of the students at CC B who took the survey are interested in ENGR (a somewhat lower percentage than CC A). Of the 109 underrepresented students, 36 (33.0%) were interested in ENGR. This percentage is the same as that at CC A. The percentage of females interested in ENGR at CC B is 12.9% (9/70) and the percentage of males interested in ENGR is 51.7% (46/89). The percentage of females is quite a bit lower than for CC A (although their numbers are small) and the percentage of males interested in

ENGR at CC B is somewhat lower than at CC A. This percentage of males is still very encouraging (61.3% and 51.7%).

CC A: Count of Engineering/Non-Engineering			
	Female	Male	Total
Engineering	9 (23.1%)	19 (61.3%)	28 (40%)
African American	1	0	1
Asian	1	4	5
Caucasian	5	11	16
Hispanic	2	4	6
Non-Engineering	30 (76.9%)	12 (38.7%)	42 (60%)
African American	0	1	1
Asian	4	0	4
Caucasian	17	6	23
Hispanic	8	2	10
Native American	1	1	2
No Response	0	2	2
Grand Total	39 (55.7%)	31 (44.3%)	70 (100%)

Table III. Distribution of Students by Gender, Ethnicity, and If They Are Interested in ENGR Career or Not at CC A.

CC B: Count of Engineering/Non-Engineering			
	Female	Male	Total
Engineering	9 (12.9%)	46 (51.7%)	55 (34.6%)
Asian	1	1	2
African American	0	1	1
Caucasian	3	10	13
Hispanic/Caucasian	0	1	1
Hispanic/Latino	5	27	32
Native American	0	2	2
No Response	0	4	4
Non-Engineering	61 (87.1%)	43 (48.3%)	104 (65.4%)
Asian	5	0	5
African American	1	4	5
Caucasian	14	6	20
Hispanic/Latino	36	27	63
Native American	3	2	5
Other	1	2	3

Table IV. Distribution of Students by Gender, Ethnicity, and If They Are Interested in ENGR or Not at CC B.

In a previous presentation, we explored the survey results from a gender point of view. [12] At CC A, we discovered that although the females agreed with males on some issues,

they disagreed with them on many others. The females and males agreed (no statistical difference) that they wanted to use their career to make a difference and wanted to use their career to help people, indicating that these are good messages for both females and males. Not enough females or males understood what ENGRs do (50% and 65%, respectively). Less than half believed that ENGRs command the highest salary with a Bachelor's degree (42.5% for females and 48% for males). There was a statistical difference between the beliefs of females and males (with females having a lower percentage) on: ENGRs have many job opportunities, ENGRs have a low unemployment rate, the U.S. needs more ENGRs, and working with robotics is interesting. Females were also less likely to believe that an ENGR could help their community. The females and males agreed that an ENGR must be a "brain," must love math, and ENGR requires too much work. Ten percent of the females said that ENGR had nothing to do with their life. The females and males disagreed with the statements, "I am interested in ENGR as a career" and "ENGR jobs have flexibility and variety," with the females having a lower percentage of belief. On two categories the females had a higher percentage than the males: "I don't like physics, therefore I don't want to be an ENGR" and "ENGR is too difficult for me."

When we looked at CC B, contrary to CC A, the females and males only disagreed statistically in their beliefs on ONE item: "I am interested in an ENGR career," (females: 21.4% and males: 61.8%). At the same time there were many differences among the females at CC B if we compared them by whether they were interested in an ENGR career or not. Also, there were many differences in beliefs by ethnicity at the second CC. A conclusion from these studies is that it is not enough to look at one CC, even a non-metropolitan one, and assume that all non-metropolitan CCs are alike. In addition, these CCs are both classified as HSIs.

In this paper we wish to explore the results from an underrepresented minority view. First we will compare the responses of the minority students with those of the non-minority students. In Table V we have ranked the questions in order of the percentage of students in the minority category who strongly agreed or agreed with the statement.

In this survey, the biggest difference between the minority and the non-minority group of students was that 100% of the minority students agreed that there were many job opportunities in engineering and CS, while only 84.3% of the non-minority students thought so ($p=.002$). The next highest statistically significant difference was that 71.4% of the minority students and only 37.3% of the non-minority students thought that the highest salaries for baccalaureate graduates was in ENGR ($p=.004$). Falling close behind in significance ($p=.005$) is that 90.5% of minority students believed that ENGRs work outside as well as inside. Another very significant difference ($p=.020$) between the groups is that 76.2% of the minority students agreed that an engineer or CS

major must love math, while only 49% of the non-minority students did. This last result seems contrary to common logic.

CC A: Statement about (Engineering and CS) =ENGR	% Agree Min	% Agree Non Min	p-value
Have many job opportunities	100	84.3	.002 ***
Want career make difference	95.2	90.2	.419
Want career to help people	95.2	86.3	.181 *
Work outside/inside	90.5	64.7	.005 ***
US needs more ENGR	90.5	74.5	.071 **
Must love math	76.2	49.0	.020 ***
Highest starting salary at BS	71.4	37.3	.004 ***
Must be a "brain"	66.7	58.8	.526
Jobs have flexibility/variety	61.9	51.0	.390
Work with robots interesting	61.9	70.6	.483
Help people in community	61.9	62.7	.947
Interested in ENGR career	52.4	62.7	.419
Understand their career	47.6	58.8	.385
Low unemployment rates	47.6	39.2	.514
Don't like physics	28.6	17.6	.330
Do not understand ENGR	25.0	23.5	.980
Too difficult for me	25.0	19.6	.629
Do not interest me	23.8	25.5	.880
Require too much work	14.3	15.7	.87.9
Not well suited for women	00.0	2.00	.313
Nothing to do with my life	00.0	7.80	.037 **

Table V. Comparison of Percentages of Students at CC A Who Agreed with Each Statement by Minority Status
***= $p<.025$, **= $p<.10$, *= $p<.182$

Two items were judged somewhat differently statistically by the two groups. "Engineering and CS have nothing to do with my life" was believed by 7.8% of the non-minority students, while none of the minority students believed it ($p=.037$). While 90.5% of the minority students believe that the U.S. needs more ENGRs to maintain an international competitive edge, only 74.5 % of the non-minority students did ($p=.071$). The fact that there is a base near the school may help to account for the fact that over 75% of each group believed the statement.

For the statement, "I want to use my career to help people," although not statistically significant ($p=.181$), this p-value is low enough to note this as a trend. It may be that minority students are more likely to believe this (95.2%) than non-minority students (86.3%). The fact that both groups had a quite high percentage, shows that it is a good to point out to

students that there are many areas of ENGR that directly help people. Obvious examples of this are biomedical, civil, chemical, and industrial engineering.

Now let us consider the same survey results for CC B. In Table VI we see these results.

CC B: Statements about (Engineering and CS) =ENGR	% Agree Min	% Agree Non Min	p- value
Use career to make a difference	88.9	82.5	.342
Use my career to help people	82.1	80.0	.777
Many job opportunities	72.2	75.0	.731
ENGR work outside/inside	68.2	62.5	.519
US needs more ENGR	66.4	57.5	.328
Work with robots interesting	64.8	45.0	.030 ***
Must love math	63.6	45.0	.042 **
Must be a "brain"	56.5	35.9	.023 ***
Help people in community	54.2	52.5	.854
Jobs have flexibility/variety	51.4	42.5	.333
Interested in ENGR career	45.9	35.0	.223
Understand their career	45.8	35.0	.228
Highest salary after Bachelor's	39.3	25.0	.087 **
Lowest unemployment rates	29.0	35.9	.434
ENGR do not interest me	27.4	32.5	.549
Don't understand ENGR	23.4	22.5	.911
Require too much work for me	22.4	07.5	.010 ***
Too difficult for me	18.9	10.3	.163 *
Do not like physics	16.7	22.5	.438
Nothing to do with my life	09.3	17.5	.213
Not well suited for women	06.5	00.0	.006 ***

Table VI. Comparison of Percentages of Students at CC B Who Agreed With Each Statement by Minority Status

***= $p < .025$, **= $p < .10$, *= $p < .182$

The biggest discrepancies between the beliefs of the minority and non-minority students at school B were, in order, on the statements that ENGR is not well suited for women ($p=.006$), ENGR requires too much work ($p=.010$), and an ENGR must be a "brain" ($p=.023$). Interestingly, no non-minority students agreed with the statement about women not fitting well in ENGR, but 7 of 107 minority student thought so. This is a topic that needs to be discussed, especially with minority students. There was a statistical difference of $p=.010$ between minority (22.4%) and non-minority (07.5%) students that being an ENGR takes too much work. Again, more minority students (56.5%) than non-minority students (35.9%) percentage-wise believed that a person needed to be a "brain"

in order to be an ENGR. All three of these statements are beliefs that could hold some minority students from choosing engineering. These results support the general research that shows that females and underrepresented minority students tend to have a lower self-confidence.

Two other differences between the minority and non-minority students show up in this survey that could tend to make minority students overlook ENGR. A high percentage (63.6%) of the minority students agreed that an ENGR major must love math, while only 45% of the non-minority students believed so ($p=.042$). Although not statistically significant, a trend was evident with the statement "Engineering and CS are too difficult for me." Among minority students, 18.9% agreed with this statement, while only 10.3% of the non-minority students did so ($p=.163$).

Two additional differences between the minority and non-minority groups were in the favor of minority students considering ENGR. More minority students (39.3%) than non-minority students (25%) believed in the statement on high starting salaries for engineers ($p=.087$). More minority students (64.8%) than non-minority students (45%) agreed that it would be interesting to work with robotics ($p=.03$).

We need to point out that we do not get the same results from the two schools regarding minority and non-minority beliefs. It is important to understand that the populations of CC students at a particular school may have its own personality and that the same message about ENGR may not be apropos for all schools.

Regarding the high starting salaries that ENGRs earn, for school A, 71.4% of the minority students and only 37.3% of the non-minority students ($p=.004$) believed the statement. For school B, again the minority students believed the statement (39.3%) more than the non-minority students (25.0%) at $p=.087$. It is interesting to note, the higher percentage of minority students at school A, who believed the statement than at school B. Since more of the minority students believed that ENGRs make very good salaries, this should be a positive factor for more underrepresented minorities entering ENGR.

The other common statement that "ENGRs need to love math," was believed by 76.2% of the minority students at school A and by only 49% of the non-minority students ($p=.02$). At school B, 63.6% of the minority students agreed with the statement, while only 45% of the non-minority students did ($p=.042$). The percentages were higher at both schools for minority students. The results of the agreement with this statement could account in part why there are not more underrepresented minority students in ENGR.

We were also interested in the strength of the interest in ENGR as a career by percentage of students, minority or non-

minority, and female or male. In Table VI we summarize these statistics.

"I am interested in Engineering or CS as a career"				
	Minority	Non-Minority	Female	Male
CC A				
Agree	11 (52.4%)	32 (62.7%)	17 (42.5%)	26 (83.9%)
Neutral	4 (19.0%)	6 (11.8%)	6 (15%)	3 (9.7%)
CC B				
Agree	50 (44.6%)	14 (35%)	14 (20%)	55 (61.8%)
Neutral	20 (17.6%)	7 (17.5%)	12 (17.1%)	16 (18.0%)

Table VI. Number of Students Who Agreed or Were Neutral on the Statement: "I Am Interested in ENGR as a Career" by Ethnicity, Gender, and Community College

In Table VI, we also included the numbers of students who believed that they were neutral on the statement. The neutral beliefs may have been because the students are still undecided on their major or do not know much yet about ENGR. As long as the student did not disagree with this statement, there is a possibility that they may still become interested in ENGR.

We see from Table VI that at College A, a higher percentage of non-minority students are interested in ENGR, while at College B, the percentage is higher with minority students. At both schools there is a much higher percentage of males interested than females, although the ratio is about 1/3 as many females at one school and about 1/2 at the other school. The percentage of neutral students is surprisingly quite consistent across all categories. It is unknown why the percentage of students interested in ENGR is so much higher in school A. It could be a bias of the type of classes that we visited at each school since the selection of classes is somewhat random, depending on which classes are available at the time of the visit and which instructors give us permission to speak with their classes.

VI. CONCLUSIONS AND FUTURE WORK

A primary conclusion of this study is that the beliefs of students about ENGR vary by school and ethnicity, as well as gender. Practitioners who speak with CC students would do well to try to understand the students at any particular school in order to better focus their message in trying to get students to put ENGR on their radar as a possible career.

It is clear from this survey again, that certain myths are still alive and well and that several attractive aspects of ENGR careers are not well known by CC students.

These surveys give us a good picture of many beliefs that students have about ENGR, but we do not know (for lack of longitudinal studies

) how effective our presentations are, even though we try to address the myths, misperceptions, and lack of information to the students with whom we dialogue. Future work should include securing evaluations from the students after our presentation to see if we are eliminating any of these myths and misunderstandings and to determine which parts of our message are the most effective.

Future work includes comparing the CC student views with high school students to see if our message needs to be different for high school students. We also want to do additional analysis with respect to gender and ethnicity, as well as to analyze the difference in beliefs between students who are interested, neutral, or not interested in ENGR. We encourage others who are speaking in CCs and high schools to better understand the population of students to whom they are speaker in order to make their presentations have more impact by speaking to students about areas in which they little information or have misinformation, as well as those areas in which they are most interested.

ACKNOWLEDGMENT

Special thanks go to Ms. Maria Sanchez Tellez, graduate assistant, who put the survey into EXCEL and made histograms of the data for analysis.

Abstract—Many engineering courses are transitioning from traditional paper textbooks to online and multimedia instructional modules to present content to students outside of class time. As the use of these online resources expands, research about the effective use and production of these resources should grow in tandem. We study the effect of three different educational interventions: expandable worked examples, assertion headings, and hand-drawn figures on students' learning and affective responses in online instructional texts for an introductory electrical engineering course. Although measures of students' performance on technical content showed few significant changes, affective measures of student course satisfaction with the materials had improved.

I. INTRODUCTION

Textbooks form the backbone of nearly every college course [1]. They are considered an “indispensable resource” by many professors [2]. Novice teachers and those teaching outside their expertise depend on textbooks to an even greater extent [3]. Teachers use textbooks to supplement material covered in class or to provide more information on topics that could not be covered fully in class. Today teachers are pushing basic knowledge acquisition toward out-of-class activities (“flipping the classroom”) in order to open up more class time for high-impact instruction [4]. As students are expected to learn more outside of class, the role of textbooks in explaining material has risen in importance. In this context more than ever, teachers need high-quality textbooks that have been proven to be effective learning aids [4].

Current evidence suggests that textbooks are failing their goal of supporting student learning. Most students do not read their textbooks to understand the topic, but rather to reduce anxiety about upcoming exams [2], [5]. Fewer than half of students use their textbooks even once a week [4], [5], [6], [7], [8], [9]. This low usage is partially explained by student perceptions of textbooks. Students must *perceive* a textbook as useful for the textbook to be an effective learning tool [10], [11]. Students do not believe reading the textbook produces a tangible improvement in exam performance [6], [8].

Student perceptions are not entirely to blame for low textbook usage, however. The structure of textbooks also plays a role. College seniors can locate relevant textbook content independently [8], but younger students must be told *exactly* what to study [7], [5]. Since students do not know what material in the textbook is relevant to their exams [9], they favor their instructors' lecture notes over textbooks. Textbooks

must clearly signal the boundaries between essential and non-essential information; otherwise students will waste precious study time focusing on unnecessary information, or they may give up on the textbook as a study resource altogether [5]. If educators want students to read textbooks, they must maximize students' ability to learn while engaged with the texts [12].

Increased demand for effective textbooks requires greater knowledge of what makes textbooks a useful tool for promoting student learning [4], [2]. Both private corporations [13], [14] and universities [15] are expanding their exploration of electronic textbooks to reduce costs and increase availability for students. This expanding development of electronic textbooks provides an exciting chance to change students' perception and use of textbooks for the better. Students who encounter new electronic formats with animations, interactive elements, and dynamic content might find that textbooks are still ineffective at helping them study, or they might find that textbooks are evolving into more effective learning tools and will begin to use textbooks more often. Increased textbook usage by students will liberate teachers from spending class time on basic material and allow them to deepen student learning in the classroom.

To explore how to create effective online engineering textbooks, we studied how different textbook authoring styles affected student performance and satisfaction in a first-year engineering course: Introduction to Electronics (ECE 110). Specifically, we studied the effect of assertion headings [16] and expandable worked examples [17] on student performance and satisfaction. We present some background on these interventions before describing the research study, its results, and its implications for instructional practice.

II. BACKGROUND

Research on the use of textbooks has uncovered some features that students report as being useful for learning [1]. Students consistently rate worked examples [1], [7], [2] as the most useful elements in college science, technology, engineering, or mathematics (STEM) textbooks. A **worked example** shows all the solution steps needed to reach the final answer to a problem and sometimes includes the reasoning behind taking those solution steps. See Table I for a typical worked example. Worked examples are a common instructional tool to teach problem solving skills in structured domains such as engineering and physics [18]. More so than their

classmates, struggling students depend on worked examples to help them learn [19], [18]. Additionally, most students rely almost completely on worked examples and chapter reviews without reading the chapter text at all [2].

TABLE I. WORKED EXAMPLE FROM ALGEBRA.

$5 = 3x - 1$	Solve for x .
$5 + 1 = 3x - 1 + 1$	Add 1 to both sides to eliminate the -1. Attack the object furthest from x .
$6 = 3x$	Add numbers and cancel.
$6/3 = 3x/3$	Since x is multiplied by 3, we divide both sides by 3 to isolate x .
$2 = x$	Do the arithmetic, x is isolated!

Unfortunately for the instructors and authors designing worked examples, the effectiveness of worked examples depends on their specific structural features [20]. Text and images must be properly integrated [21], [18], [22] for worked examples to be most effective. Many worked examples in textbooks lack detail [19], [10] or strategic information [23], [24], [25], [26]. The presence of additional problem-solving explanations can sometimes even hamper learning [27]. Some researchers believe there is no possible algorithm to consistently design effective worked examples [10]. Though much research has been done on worked examples [18], little is focused specifically on college-level STEM textbooks.

Development of worked examples is further complicated by the **expertise reversal effect** [28], [21], [29], [30]. Expertise reversal occurs when an educational intervention is effective for low-skill learners, but is less effective for high-skill learners (or vice versa) [31], [32], [33], [34]. To understand expertise reversal, consider the analogy of adding training wheels to a bicycle. Adding training wheels onto the bicycle of a child first learning to ride would greatly assist the child in becoming a proficient rider, but adding training wheels to the bicycle of a Tour de France cyclist would be a debilitating burden on their performance. Likewise, pedagogical techniques that help some students can be ineffective or even detrimental for experienced students. Skilled readers can waste precious cognitive resources on information they already understand [24], [22]. This expenditure of cognitive energy reduces the potential for learning new material.

The expertise reversal effect presents educators with a problem: how can teachers design worked examples to help both novice and experienced students? One potential solution to this problem is the use of **interactive worked examples** [17] with *optional* extra detail. An interactive worked example allows the reader to display or hide extra explanations, allowing experienced readers to bypass redundant material (a contributing factor to expertise reversal). Expandable examples are a promising way to mitigate the expertise reversal effect, but there is little research on developing interactive worked examples for electronic STEM textbooks.

Chapter reviews and summaries are the second-most used textbook element by students [1]. Students frequently fail to understand how the text material fits together. Students frequently cannot discern the overall takeaway message of the text. This failure in comprehension is exacerbated when the text fails to provide **global coherence**. A passage of text has

global coherence when a reader can relate each statement in the text back to the main topic of the passage and comprehend the overarching message of the chapter or section. A lack of global coherence often reduces reader comprehension and understanding of the reading material [32], [35].

One way to increase global coherence in textbooks is to improve an important part of textbooks that students already use: section headings [1]. Headings, end-of-chapter summaries and in-chapter reviews can moderate learning and comprehension through global coherence [32], [35]. Possible methods to improve the global coherence of section headings in textbooks can be found in research on effective science presentations and proofs. Rather than using a short topic-subtopic slide title during PowerPoint presentations like “Diode Current Flow,” a presenter can use a complete sentence assertion title such as “Diodes allow current to flow in only one direction” to improve coherence and learning during presentations [16]. The assertion title provides global coherence by summarizing the content presented on the slide. Similarly, comprehension of mathematical proofs can be improved when the principle of the proof is asserted before the proof itself [36]. Assertion headings appear in some successful STEM textbooks [37], [38], but there is no research on their effectiveness.

This study examined whether two features of an online engineering textbook would improve or impede a student’s ability to understand and learn material from the textbook. We conducted a concurrent mixed-methods study to investigate two research questions regarding assertion headings and interactive worked examples.

Research Question 1: Do expandable worked examples improve academic performance and course satisfaction compared to static examples and mitigate the expertise reversal effect observed in static worked examples?

Research Question 2: Do assertion section headings improve academic performance and course satisfaction in an online engineering text compared to topic-subtopic headings?

While we explored the first two questions, feedback from student volunteers about hand-drawn figures raised a third research question. We used a sequential mixed-methods study to explore the third research question:

Research Question 3: Can hand-drawn diagrams increase student satisfaction more than computer-generated diagrams?

III. METHODS

This study examined a first-year course, Introduction to Electronics (ECE 110). ECE 110 is a required course for Electrical Engineering and Computer Engineering majors at a large, public research university in the American Midwest. ECE 110 was selected for our study because the course instruction team was already dissatisfied with the available textbook options for the ECE 110 curriculum. The ECE 110 instructors planned to write their own instructional text before researchers of this study became involved. These procedures were approved by our university’s Institutional Review Board (Protocol #14927) overseeing human subjects research.

During the semester our study took place, 445 students enrolled in ECE 110. In this class, 74% of students were freshmen, 19% were sophomores, and 7% were upperclassmen. For

gender demographics, 85% of students were male and 15% of students were female. For race and ethnicity demographics, 37% of domestic students were Asian, 58% were white, 7% were Latino, and 3% were any other race (students could select more than one race, some are double counted). Additionally, 31% of students were international students.

To explore the effect of assertion headings and expandable worked examples in an engineering instructional text, the researchers and ECE 110 instruction team collaboratively created online text resources for ECE 110. The ECE 110 course website included course notes and worked examples, which together played the role of a textbook for ECE 110.

Each chapter of course notes covered two 50-minute lectures of material and contained text, figures, headings, a table of contents, and an end of chapter summary, much like a typical textbook. Unlike a typical textbook, the course notes included assertion headings (see Figure 1). The text was formal but friendly in tone. Each chapter contained numerous internal links to other parts of the text and external links to other websites. The figures were hand-drawn in full color.

Each chapter of the course notes was accompanied by interactive expandable worked examples. Similar to the examples in a standard textbook, the expandable worked examples included a problem statement, full-color computer-generated figures, equations, and explanations of the steps to solve the problem. However, unlike a standard textbook, the expandable worked examples could expand to show small sub-steps and manipulations that would consume too much space in a traditional paper textbook or would be superfluous for more experienced learners. Only problem steps that a student would be expected to show on an exam (expert-level work) were visible by default. Additional explanatory problem steps were hidden by default to avoid distracting the students who did not need more information, but these details could be displayed by clicking a button. All the expandable worked examples were written in an informal tone and explained both the steps taken to solve the problem and the rationale for taking each step. See Figure 2 for a sample of expandable worked example content.

QUANTIZATION Quantizing samples to levels and then to sequences of bits leads to quantization error.

A sequence of samples like $v[n]$ in Fig. 5 is not a digital signal because the sample values can potentially take on a continuous range of values. In order to complete analog to digital conversion, each sample value is mapped to a discrete level (represented by a sequence of bits) in a process called quantization. In a B -bit quantizer, each quantization level is represented with B bits, so that the number of levels equals 2^B .

Fig. 1. Sample of the course notes. The topic-subtopic heading is “Quantization.” The assertion heading is “Quantizing samples to levels and then to a sequence of bits leads to quantization error.”

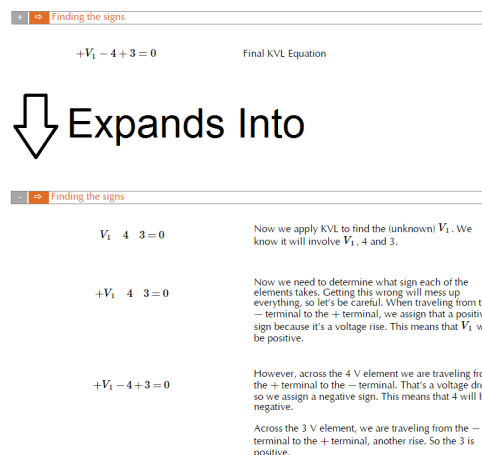

Fig. 2. Before-and-after picture of part of expandable worked example. Clicking the ‘+’ button expands the sub-steps in a particular problem step. Simple operations like sign conventions in the right column can impede a first-time learner.

Worked examples were displayed in a two-column format because the ECE 110 instruction team preferred that format and it was easy to produce examples that way. However, displaying information in two columns can impede learning because the reader must integrate multiple sources of information that are spatially separated into a single mental construct. This phenomenon is referred to as the split-attention effect [22]. To minimize potential problems from the split-attention effect, the left column (which contained figures and equations) was designed so that it could be followed independently of the right column (which contained explanations).

During the summer before the main study, we conducted a small pilot study to test the course notes and expandable worked examples with undergraduate volunteers. The initial pilot study produced an unexpected finding. Students spontaneously voiced strong opinions about the hand-drawn diagrams in the course notes. Students claimed that the hand-drawn figures were more believable and more attractive than the computer-generated figures in the worked examples. To explore this unexpected finding, we added our third research question: “Can hand-drawn diagrams increase student course satisfaction compared to computer-generated diagrams?” See Figure 3 for an example of the difference between hand-drawn and computer-generated figures in our study.

Fig. 3. Comparison of the same diagram drawn by hand (left) and typeset by computer (right).

We selected two chapters of course content for examination during the study: *Diodes* and *Sampling*. We selected these chapters because of their timing in the course. Each topic was covered in lecture just after an exam. The ECE 110 instruction team felt that holding our study shortly before an upcoming exam would be unfair to the students and would reduce response rate because students would prepare for exams rather than participate in the study.

We constructed two versions of each worked example from the *Diodes* and *Sampling* chapters. The experimental version included the expansion feature, whereas the control version did not. The control version worked examples had the same level of detail as a typical textbook worked example.

We constructed two versions of both the *Diodes* and *Sampling* chapters of the course notes. The control version of the course notes contained only ordinary topic-subtopic (noun phrase) headings, whereas the experimental text also included assertion (complete sentence) headings (see Figure 1). The control version of the course notes contained topic-subtopic phrases in the table of contents, whereas the experimental course notes contained assertions in the table of contents. In both versions of the text, the assertion statements were listed at the end of each chapter as a chapter summary. Chapter summaries are considered good practice for textbook authoring [1], so we included them to avoid bias against the control text. Both versions of the course notes contained identical text and figures; only the table of contents and section headings varied.

We partitioned students into three stratified random groups with equal numbers of freshmen and females. In each chapter, the control group (group TS) received course notes with topic-subtopic headings and low detail, non-expandable worked examples. The first treatment group (group AH) received course notes with assertion headings and expandable worked examples. The second treatment group (Group EO) received no course notes and only expandable worked examples to see if text passages would be ignored [39], [2]. Each group received one variant of the content in the *Diodes* activity, and a different variant during the *Sampling* activity (see Table II). This alternating treatment reduces the risk of bias against one text variant because of non-identical groups of students.

TABLE II. THE COURSE MATERIALS AVAILABLE TO EACH GROUP OF STUDENTS ON EACH TOPIC.

	Group 1	Group 2	Group 3	Response rate
<i>Diodes</i>	- Topic-subtopic headings in course notes - 2 Low-detail examples (N=57)	- Assertion headings in course notes - 2 Expandable examples (N=73)	- No course notes - 2 Expandable examples (N=74)	204/444 (46%)
<i>Sampling</i>	- Assertion headings - 5 Expandable examples (N=46)	- No course notes - 5 Expandable examples (N=51)	- Topic-subtopic headings - 5 Low detail examples (N=46)	143/444 (32%)

One week before *Diodes* was covered in lecture, we released the experimental versions of the *Diodes* course notes and worked examples to all ECE 110 students via email. Each student was linked to one variant of the course notes and worked examples (Table II). All students were also linked

to the same online technical content quiz over the material covered in the *Diodes* chapter and an attitudinal survey about the electronic course materials (See Table III). The students had until the day before *Diodes* was covered in lecture to complete the quiz and survey outside of class time. This timing eliminated the effect of the lecture itself on students' quiz performance. One month after the *Diodes* activity, a second activity was released covering the *Sampling* content, which followed the same format.

Students could take as much time as they wanted to complete the activity (course notes, worked examples, quiz, and survey). Due to the experiment design we could not measure the time it took students to complete each activity, but students in the pilot study took under an hour to complete similar activities. Unlike other studies of reading comprehension [32], students could read each activity's course notes and examples while completing the activity's quiz, much like natural studying. For fairness, all versions of the instruction materials were released after that activity's quiz was due. Participation in the study was optional but participation could be credited toward a portion of students' class participation grade in ECE 110, worth 1% of their final course grade. In the *Diodes* activity, 45% of ECE 110 students chose to participate, and in the *Sampling* activity only 32% of students participated.

To explore the satisfaction dimensions of our research question about expandable examples, we included two Likert scale items in both activities and asked a free response question during the *Sampling* activity. To explore the satisfaction dimensions of our research question about assertion headings, we asked one Likert scale question both activities and asked a free response question in the *Sampling* activity. To explore our research question about hand-drawn figures, we asked one free response question in the *Diodes* activity (see Table III). The responses to this free response question (see Table IV) informed the construction of quantitative Likert scale questions included in the *Sampling* activity (see Table XII).

TABLE III. SUMMARY OF ACTIVITIES FOR EACH CHAPTER.

<i>Diodes</i> Activity	<i>Sampling</i> Activity
- 6 conceptual questions - 2 quantitative questions	- 2 conceptual questions - 5 quantitative questions
- What do you think of the complete sentence headings? - Rate the usefulness of the expandable worked examples. - Did you find the expandable features of the examples useful? - Do you prefer hand-drawn or computer-generated diagrams?	- What did you think of the complete sentence section headings in the Sampling chapter? - Rate the usefulness of the expandable worked examples for the Sampling topic. Did they help you learn? - Did you find the expandable features of the examples useful? - 9 questions on aspects of hand-drawn figures, influenced by the free response questions in the <i>Diodes</i> activity
Why do you prefer hand-drawn or computer-generated diagrams? (160 responses)	- Why did you find the complete sentence titles helpful or unhelpful? (48 responses) - Why did you find the expandable feature helpful or unhelpful? (48 responses)

Three coders analyzed the responses to the free response questions in the *Sampling* activity. Given the small dataset, the author established an initial codebook independently. A second coder applied the codebook to the data. Disagreements were used to refine and finalize the codes and their definitions. To test the trustworthiness of the coding scheme, a third coder coded each response independently before comparing notes

with the author. These final comparisons were used to calculate an inter-rater agreement of 75%.

Responses to the free response question “Why do you prefer hand-drawn or computer-generated figures?” from the *Diodes* activity were coded by two researchers. Because we could find no prior research documenting students’ preferences, we began coding without an a priori coding scheme. A codebook was developed through an iterative process before codes were finalized. In the first phase of analysis, two researchers cooperatively established an initial codebook for 30 of the 160 responses. Using the preliminary codebook in the second phase, both researchers independently coded 50 of the remaining responses, and used disagreements to refine the codebook. In the third phase, each researcher coded the remaining 80 responses independently and any disagreement was counted against the validity of the coding scheme. Disagreements were resolved through discussion. We obtained an inter-rater reliability of 95% for the final 80 codes. These codes inspired a group of Likert scale questions in the survey in the *Sampling* activity (see Table III).

We analyzed the nine code-inspired Likert scale survey items from the *Sampling* activity by grouping them into three categories: one for items about neatness and readability, one for items about affective responses, and one for items about credibility. For each pair of survey items, we computed a linear correlation coefficient. For groups of survey items that had at least moderate correlation coefficients ($r > 0.5$) for each pairing, those survey items were combined into a composite score. No survey items fit into more than one group. We did not conduct an exploratory factor analysis of the data. These composite scores were reduced to a four-point scale of 0-3 (see Tables X and XI). Survey items that did not correlate well with any other survey items were discarded, since we could not establish validity for those items.

Since the first exam preceded the study, we used students’ scores on the first exam of the semester to estimate baseline ability and preparedness for each treatment group. We used scores on the *Diodes* and *Sampling* quizzes to measure differences in performance between treatment groups.

According to the Shapiro-Wilk test, quiz and exam scores were not normally distributed. We used the Kruskal-Wallis test rather than Analysis of Variance (ANOVA) to analyze quiz scores and exam scores because ANOVA is sensitive to deviations from normality at small sample sizes. We chose a α value of $\alpha = 0.01$ for the quantitative analysis of quiz scores and exam scores because we were equally concerned with false positive and false negative errors. We measured effect size with Cohen’s d since we did not observe large differences in variance of quiz scores or exam scores between groups.

IV. RESULTS

We used students’ scores on Exam 1 to measure differences in ability between treatment groups. We found no statistically significant differences in students’ preparation during the *Diodes* and *Sampling* activities (Table V).

We used students’ scores on the quizzes to measure treatment effects between groups. Only one statistically significant difference was found: The students given topic-subtopic course

TABLE IV. CODES FOR RESPONSES TO “WHY DO YOU PREFER HAND-DRAWN OR COMPUTER-GENERATED FIGURES?”

Hand - Inviting	Students have a positive affective response
Hand - Relatable	Hand-drawn figures are more similar to what students produce
Hand - Clean and Clear	Hand-drawn is easier to read
Don't Care - Clean and Clear	No preference as long as it is clean and clear to read
Don't Care - Equally effective	No preference as long as both can be understood
Don't Care - Indifferent	No preference
Computer - Relatable	Computer-drawn figures are similar to what the students must produce
Computer - Clean and Clear	Computer-drawn is easier to read

notes and traditional examples scored higher than the students given the assertion headings notes and expandable examples on the *Sampling* quiz.

TABLE V. PAIRWISE COMPARISONS OF QUIZ AND EXAM SCORES FOR EACH GROUP DURING THE *Diodes* AND *Sampling* ACTIVITIES. THE LETTERS INDICATE THE GROUP THAT PERFORMED BETTER. STATISTICALLY SIGNIFICANT RESULTS ARE BOLDED. T

Group Comparison	Exam Effect Size d	Quiz Effect Size d
<i>Diodes</i>		
TS vs AH	0.38 AH	0.12 TS
AH vs EO	0.11 AH	0.29 EO
EO vs TS	0.27 TS	0.17 EO
<i>Sampling</i>		
AH vs EO	0.19 EO	0.27 EO
EO vs TS	0.13 TS	0.45 TS
TS vs AH	0.32 TS	0.72 TS

Students responded positively to the expandable worked examples with more than 80% of students responding favorably (see Table VI). The response to the expansion feature itself was even more positive, with 40% of students choosing the most positive response.

TABLE VI. STUDENT RESPONSES TO LIKERT SCALE QUESTIONS REGARDING THE EXPANDABLE WORKED EXAMPLES.

Question	Bad	Poor	Good	Great	Mean (0-3 scale)	Response Rate
Rate the overall usefulness of the worked examples (<i>Diodes</i>)	4 (2%)	32 (16%)	119 (60%)	46 (22%)	2.03	45%
Rate the overall usefulness of the worked examples (<i>Sampling</i>)	3 (2%)	17 (14%)	78 (66%)	21 (18%)	1.98	27%
Did you find the expandable feature of the examples useful? (<i>Diodes</i>)	3 (2%)	17 (9%)	89 (50%)	71 (40%)	2.27	40%
Did you find the expandable feature of the examples useful? (<i>Sampling</i>)	3 (3%)	3 (3%)	53 (50%)	46 (44%)	2.35	24%

Analyzing student responses to the free response question

“Why did you find the expandable feature helpful or unhelpful?” yielded a codebook of seven codes. A list of those codes and their definitions is shown in Table VII.

TABLE VII. BRIEF CODEBOOK FOR “WHY DID YOU FIND THE EXPANDABLE FEATURE HELPFUL OR UNHELPFUL?”

Code	N	Code Description	Exemplar
Organized	7	Student finds the expandable examples cleaner	<i>“Doesn’t take too much space if you don’t need to see the work. Explanations are helpful.”</i>
Work By Myself	10	Encourages student to try the problem before looking at solution	<i>“The expandable feature allowed me to either work out the problem on my own or click for help if I needed it.”</i>
Detail	13	Likes the level of detail they can get with the expansion feature	<i>“Sometimes I’m confused with some very basic stuff, and when it happens, these things help me.”</i>
Skip What I Know	4	Student doesn’t have to look at information they already know	<i>“Yes it is helpful because we can open the parts we want to read and close the parts we already know.”</i>
Disorganized	3	Hard to follow, disorganized	<i>“It was unhelpful because it disturbed the flow of ideas from section to section.”</i>
Autoshow	8	Wishes the problem was fully expanded	<i>“This is just an extra step. I find it much better if the author just left the equation on the page instead of hiding it first.”</i>
Helpful	10	Misc. positive responses	<i>“They are great! allow for good interaction”</i>

The “Detail” code was applied to statements that revealed students’ appreciation for the level of detail they could get with the expansion feature. The presence of the “Detail” code indicated that some students benefited from the large number of sub-steps shown in the expandable examples. Many students struggle with only a single sub-step [19], and can be without recourse if that sub-step is not shown in a worked example.

The “Skip what I Know” code was applied to statements where the student mentioned the ability to skip or ignore the collapsed portions of the example easily. The presence of this code indicated that some students liked being able to easily ignore superfluous information. The presence of this code was expected from the worked examples literature [18].

Together the “Skip what I Know” and “Detail” codes capture the potential mitigation of expertise reversal, supporting our hypothesis for Research Question 1. Two exemplar quotations reveal the differences in how students reacted to the expandable examples based on their level of expertise. When asked why they found the expandable examples helpful, one student responded, *“Yes, it is helpful because we can open the parts we want to read and close the parts we already know.”* This more advanced student did not want to be distracted by superfluous information and uses the expansion feature to avoid superfluous information. In contrast, a less advanced student responded to the same question with, *“Sometimes I’m confused with some very basic stuff, and when it happens, these things help me.”* Without the ability to view sub-steps, students might end up missing a basic concept or forgetting a trivial manipulation [19], and they may be unable to find this information in other places.

The “Work by Myself” responses indicate that breaking up the example into phases (and hiding the details) may promote healthier study habits. These responses were unexpected because we had not found prior evidence from the literature suggesting this result. Some students slowed down and attempted problems on their own rather than copying the solution steps. When asked why he or she found the expandable examples helpful, one student responded, *“You are given a hint in the right direction of how to solve the problem, but are not just given the answer straight away. This discourages me from just looking at the answer without really giving the problem a shot.”* With the inclusion of multiple sub-steps, students can open them individually, and try to solve the next part of the problem before viewing the solution.

The affective response to the assertion headings was both strong and positive (see Table VIII). Most students (more than 85%) rated the assertion headings as more useful than ordinary topic-subtopic headings.

TABLE VIII. RESULTS FOR THE FREE RESPONSE QUESTION “WHAT DO YOU THINK OF THE COMPLETE SENTENCE HEADINGS?”

Question	Bad	Poor	Good	Great	Mean (0-3 scale)	Response Rate
What do you think of the complete sentence headings? (Diodes)	2 (1%)	12 (7%)	73 (40%)	94 (52%)	2.4	40%
What do you think of the complete sentence headings? (Sampling)	4 (4%)	11 (10%)	41 (38%)	51 (48%)	2.3	24%

TABLE IX. CODES FOR FREE RESPONSE QUESTION “WHY DID YOU FIND THE COMPLETE SENTENCE TITLES HELPFUL OR UNHELPFUL?”

Code	N	Code Description	Exemplar
Summary	15	Headings provide takeaway main points after reading	<i>“Rather than simply mentioning the general ideas covered in the section, the complete sentence titles also gave insight into what exactly we should take away from each section.”</i>
Prepare	10	Headings help the student know what to pay attention to.	<i>“It was a good indication of the main idea that I needed to get out of the notes.”</i>
Navigation	2	Heading help student find the information	<i>“If I want to know how to compute a certain thing or want to understand a certain topic, I can scan the titles.”</i>
Problem Solving	2	Heading help the student solve problems	<i>“They are applicable and can help me solve problems!”</i>
Content	6	Headings provide extra information	<i>“The complete sentence titles give more information about the subject at hand.”</i>
Unhelpful Length	5	Sentence headings are too long	<i>“It was too much to read.”</i>

The “Summary” and “Prepare” responses to the free response question “Why did you find the complete sentence titles helpful or unhelpful?” indicated that the assertion headings gave students a take-away main point. Students (especially novices) are not yet skilled at discerning what information is vital and what information is tangential, and the assertion headings helped students identify key information. Students

expressed two subtly different views on this aspect. Some students used the headings as a way to verify they had read correctly *after* reading (Summary), others used the headings as guideposts to inform them what they should look for in the text *before* reading (Prepare). These data support our hypothesis for Research Question 2: The assertion headings successfully increased global coherence in the course notes. The “Summary” and “Prepare” responses to the free response question “Why did you find the complete sentence titles helpful or unhelpful?” indicated that the assertion headings gave students a take-away main point. Students (especially novices) are not yet skilled at discerning what information is vital and what information is tangential, and the assertion headings helped students identify key information. Students expressed two subtly different views on this aspect. Some students used the headings as a way to verify they had read correctly *after* reading (Summary), others used the headings as guideposts to inform them what they should look for in the text *before* reading (Prepare). These data support our hypothesis for Research Question 2: The assertion headings successfully increased global coherence in the course notes.

Based on the free response question “Why do you prefer hand-drawn or computer-generated figures?” we created three hypotheses and survey items in the *Sampling* activity to address each one. First, we hypothesized that students prefer hand-drawn figures for affective reasons, such as a perception of caring from the instructor (items 16, 17, 22). Secondly, we hypothesized that students prefer computer-generated figures for reasons of legibility (items 19, 21, 23 and 24). Last, we hypothesized that hand-drawn figures may raise trust concerns for students (items 18 and 20).

The code-inspired Likert scale items from the *Sampling* activity yielded more precise information about some of the themes discovered during the free response question “Why do you prefer hand-drawn or computer-generated figures?” We combined items involving legibility (see Table X) into a composite index of 3 items, and also combined items about emotional response (see Table XI) into a composite index of 4 items. The items are shown with the student response that inspired the creation of that survey item in Table XII.

TABLE X. THE LEGIBILITY COMPOSITE INDEX OF THE SURVEY ITEMS 19, 20 AND 24 FROM THE *Sampling* ACTIVITY.

Strongly Prefers computer-generated	Slightly Prefers computer-generated	Slightly Prefers Hand-drawn	Strongly Prefers Hand-drawn	Overall (0-3 scale)
14 (15%)	44 (47%)	32 (35%)	3 (3%)	1.25

TABLE XI. THE EMOTIONAL COMPOSITE INDEX OF SURVEY ITEMS 16, 17, 20 AND 22 FROM THE *Sampling* ACTIVITY

Strongly Prefers computer-generated	Slightly Prefers computer-generated	Slightly Prefers Hand-drawn	Strongly Prefers Hand-drawn	Overall (0-3 scale)
8 (9%)	15 (16%)	58 (62%)	12 (13%)	2.2

The emotional composite index was composed of four survey items and examined the emotional response to hand-drawn figures (see Table XI). Responses indicate that students feel more confident with, more cared for by, and more invited

TABLE XII. THE LIKERT SCALE ITEMS FROM THE *Sampling* ACTIVITY.

#	Survey Item	Inspiring Response	Code
17	Hand-drawn figures help me learn how to draw those figures better for myself	<i>“Easy to compare to my diagram”</i>	Hand-Relatable
16	Hand-drawn figures make me feel like the instructors care more about my learning	<i>“Feels as if the person cared for the education.[sic]”</i>	Hand-Inviting
22	Hand-drawn figures are more inviting and less intimidating	<i>“The hand drawn ones just seem friendlier and more welcoming”</i>	Hand-Inviting
20	Hand-drawn figures are more credible	<i>“Hand-drawn perceived as more accurate”</i>	Pilot Study
24	I am more likely to pay attention to a computer-generated figure than a neat, legible hand-drawn figure	<i>“I don’t really know, I find that I’m less likely to glaze over them though”</i>	Hand-Inviting
21	Computer-generated figures are easier to interpret	<i>“Easier to read”</i> (occurred verbatim 4 times in the sample)	Computer-Clean and Clear
19	Computer-generated figures are easier to read	<i>“Easier to read”</i>	Computer-Clean and Clear
18	Computer-generated figures are less likely to have errors	<i>“Hand-drawn perceived as more accurate”</i>	Pilot Study
23	Neat, legible hand-drawn figures are less cluttered than computer-generated diagrams	<i>“The symbols on computer are more spaced out and clutter up the diagram”</i>	Hand-Clean and Clear

by hand-drawn figures. The index favored hand-drawn figures by about 3:1. From these results alone, we cannot determine whether the positive emotional responses will lead to increased textbook use or increased performance on exams. Research shows a relationship between a student’s perception that their professor cares about them personally and higher motivation to engage in the course [11]. We were particularly encouraged by one response from a student who responded that the hand-drawn figures made them feel that the professor cared about their education (see Table XII).

The legibility composite index was composed of three survey items and examined the value of neatness and readability in figures (see Table X). Responses favor computer-generated figures over hand-drawn figures by about 2:1. Some students may have been comparing computer-generated figures in ECE 110 to all the hand-drawn figures they had seen in previous classes, and some may have been comparing them to only the hand-drawn figures from the ECE 110 course notes. Negative experiences with sloppily drawn figures in previous classes may have amplified the response to these survey items.

V. DISCUSSION

The quantitative results do not show much statistical significance, but the free response answers are over 90% in favor of expandable examples. Based on the coding results, students value the expandable examples for the reasons we hypothesized they would, choosing to use or ignore the expansion sections depending on their own preparedness for the particular problem at hand. Responses to “Why did you find

the expandable feature helpful or unhelpful?” like this one “*Yes it is helpful because we can open the parts we want to read and close the parts we already know*” support our hypothesis for Research Question 2. Novice students could access the detail they needed to solve the problem, but advanced students could skip the details they already knew. With no prompting, students recognized this purpose of the expandable examples.

Surprisingly, the expansion steps acted as a speed bump for students; they attempted the problem, instead of copying the solution. Students know they need to solve problems independently in order to succeed, but often succumb to the temptation of copying solutions [40]. With expandable examples students can more easily resist the urge to use the entire solution, but if they get stuck, they have the option to view the key part of the solution. Expandable worked solutions could bring extra value to online solution manuals, encouraging students to work through the solutions rather than look for quick answers.

Since students prefer to read summaries of chapters over the whole body of the text [1], [2], it is important that educators developing textbooks consider the amount of time it takes students to study when creating and evaluating the usefulness of pedagogical materials [12]. Students are concerned with whether a particular passage helps them solve the problem at hand and do not want to waste time reading unnecessary information in the text. By scanning the headings for relevance to their current task rather than reading the whole section, students can spend less time looking through irrelevant materials. In this small study, the assertion headings did not have any significant effect on quiz performance, but the free-response questions indicate that the assertion headings helped students focus on the important parts of the material while they were reading the text. Given the small amount of extra writing involved, assertion headings may be a quick and easy way to add value to textbooks and increase their use.

Unfortunately, the possible effect that assertion headings have on the author of the textbook while writing could not be studied. Because the author of the course notes wrote them with the assertion format in mind, we suspect having assertions in mind influenced his style of writing. We suspect that conforming to the assertion form constrains the writing of the text, forcing the author to maintain global coherence for each passage. Many textbook chapters have crowded sections with too many ideas jockeying for prominence and meandering passages with no main thesis. The author of the course notes casually reported that writing with the assertion format in mind caused him to focus his writing. Additional research is needed to investigate this idea.

The majority of students agreed that hand-drawn figures allow them to be more confident in their own ability to draw similar figures from the material. This theme came as a surprise to us. It appears that a sort of vicarious self-efficacy [11] effect may be generated by the hand-drawn figures. Though a computer-generated figure and a hand-drawn diagram represent the same circuit, students feel a hand-drawn figure is easier to replicate and compare to their own work. Since students do most, if not all, drawings of circuits on paper in introductory courses like ECE 110, hand-drawn diagrams in the course notes or textbook may affect the quality of student drawings or the ability of students to turn computer-generated images into their own drawings without having seen someone else do it

first. A future study could investigate the effect of hand-drawn figures on the quality of circuit sketches produced by students.

Students’ responses to “Hand-drawn figures make me feel like the instructors care more about my learning” were encouraging. To succeed, students need to feel that their instructors care about them [11]. Perhaps students inferred their instructors cared more because students know that neatly drawn figures take time to make and believe that only a caring instructor would spend the time to make a nice figure. Another possible explanation is that simply knowing someone personally created the figure may affect students emotionally. Drawing figures *neatly* entails an extra time cost to authors compared to computer generation, and also imposes consistency problems on larger works with multiple authors. Our results do not suggest changing all textbook figures to hand-drawn ones. However, figures students are expected to replicate might be more effective if they are hand-drawn in the textbook.

A. Limitations

We had no control for time-on-task in any of the experiments, given the natural studying design of the study. Furthermore, the short (1 hour) time of exposure to the content was not long enough for students to deeply learn the material. The demographic makeup of students participating in the two activities may have shifted. Some students may have ignored the assertion headings, or members of the control group may have found the end of chapter assertions equally helpful. Prior experience with the technical content topics was not controlled for, nor did we perform any rigorous pretest/posttest comparison. The implicit difference in difficulty of the content between the *Diodes* and *Sampling* topics may also muddy results. Similar to McNamara’s study [32], it is possible that some students actually performed better when exposed to less coherent materials. It is possible than even a small difference in initial preparation by the Assertion Headings group could have had a large impact on performance in the much more difficult *Sampling* activity. The affective responses may be skewed positive due to the Hawthorne effect [41], person-positivity bias [42], and acquiescence response bias [43]; the highly positive ratings of the new course materials must be interpreted with caution.

VI. CONCLUSIONS

The textbook innovations explored in this study had a marked affective impact on students. The effect on students’ feelings toward the instructor, self efficacy, and self-regulation indicate these techniques are worthy of further investigation (given the low additional cost of implementation over traditional textbook writing). Due to several confounding factors and the exploratory nature of the experiments, no firm conclusions can be drawn on the influence of these textbook writing styles on student performance or willingness to read their textbook more. However, the survey responses are encouraging.

The changing nature of textbooks with technological innovations provides an unprecedented opportunity to change the perception of textbooks and increase their use. To help textbooks evolve from costly and unhelpful materials to exciting and valuable resources, additional research on textbook construction is warranted.

A. Acknowledgment

The authors would like to thank the ASEE NDSEG and UIUC GATE programs for funding support.

Abstract— Postsecondary matriculation is important for a young person's future financial and social positioning. Matriculation can be attendance at a four-year institution, two-year program, or a trade school of some kind. Scores on standardized tests such as the SAT are often components of a student's application to attend a postsecondary education institution. This is a follow up study to one in which students ($n=35$) from the same school attended a STEM summer camp. The STEM camp lasted 13 days and engaged students in project based learning activities 8 hours per day. Students attended classes on robotics, bridge building, solar power, and other challenging, informal learning activities. The results of that study found statistically significant gains for both reading and writing, although not for math. This study followed up with 27 of those students by obtaining their SAT scores and matriculation to postsecondary education data. Correlations between SAT and matriculation, confidence intervals for SAT results, and effect sizes are given. Further research recommendations are discussed.

Keywords—STEM, SAT, matriculation, informal learning, project based learning

I. INTRODUCTION

The Aggie STEM summer camp combined two key elements to bring about student success: an informal learning environment and project-based learning. Students can learn in many different ways and the traditional school setting gave only one platform for teaching and learning. Informal learning environments offered students experiences outside of the typical classroom walls and enabled them to engage with content in a new and exciting way. These informal settings could take place in many forms, such as after school programs, museum trips, and summer camps. Project-based learning, a method of instruction that was hands on and practical, enabled students to put their knowledge to work. Collaborating to achieve a common goal, students could strengthen their understanding by applying their content knowledge to real world problems. The Aggie STEM summer camp offered opportunities for students to engage in project-based learning activities and to enhance their knowledge of the STEM disciplines. A national emphasis on science, technology, engineering, and mathematics (STEM) and increasing college attendance have made endeavors such as the Aggie STEM summer camp a growing interest to researchers, politicians, and parents. Therefore, researchers followed the academic progress of students who had attended the Aggie STEM summer camp and investigated how they performed on national standardized tests and their eventual matriculation to postsecondary study.

A. STEM

In recent years, interest has grown concerning the learning and teaching of STEM disciplines in the United States. This growth resulted from the performance of students in the United States compared to that of their international peers on math and science exams and the lack of students graduating with STEM degrees to fill the growing number of STEM jobs in the United States. These two areas were critical in insuring that the United States maintains a position of leadership on the international stage.

The Programme for International Student Assessment (PISA) was an international study in which a test evaluating student proficiency in mathematics, science, and reading was administered. These students were 15-year olds, and the sample was representative of each nation's student population. The PISA test was first administered in 2000 and has been repeated every three years since that time. Results of the 2012 administration listed the United States as 27th in mathematics and 20th in science when compared to other Organisation for Economic Co-operation and Development (OECD) member countries [1]. While the actual scores of students from the United States have not statistically significantly changed from the 2009 test, the United States' ranking has changed. This indicated that students from other nations were outperforming students from the United States. Such a downward trend in the rankings was startling, especially for a nation that was seen as the technology and innovation leader of the world [2; 3; 4]. These students who were performing below their international peers were the future workforce and leaders of tomorrow.

The workforce being produced in the United States was also an area of growing concern. The number of researchers in science and engineering fields was increasing at a higher rate outside of the United States in countries such as South Korea and China [5]. This increased number of researchers dedicated to the creation and growth of new knowledge in STEM fields could be perceived as a challenge to the United States' leadership in these areas. On the other end of the job market spectrum, positions that may not be seen as STEM jobs still require proficiency in problem-solving, basic STEM knowledge, and technical expertise [6; 5]. Having a population of workers that lacks proficiency in STEM disciplines and the associated problem solving skills in an ever increasingly interconnected and technological economy could threaten the productivity of the United States. In response, President Obama launched the Educate to Innovate campaign with the purpose of raising student understanding, interest, and attainment in STEM areas [7]. This project and others were crafted in an attempt to bring the United States to the forefront in mathematics and science achievement and to meet the domestic labor force needs of an innovative economy.

This need for more students to be proficient in the STEM disciplines and a more STEM competent general public catalyzed the development of the Aggie STEM summer camp, an informal learning environment in which students engaged in STEM related tasks through project-based learning (PBL). Informal learning settings and PBL were cornerstones in the creation of the Aggie STEM summer camp because they have

been shown to engage, motivate, and inspire students in a multitude of ways.

B. Informal Learning

Informal learning has been defined in many different ways. The definition applied in this paper emphasized learning that occurred outside the school setting, was voluntary in nature, and was developed separately from the school curriculum [8]. Informal learning programs originally developed out of concerns for improving school achievement, youth safety, and exposure to enrichment opportunities in the arts and sciences [9]. Activities that were classified as occurring in an informal setting could range from watching television or shopping in a mall to playing on a sports team or going to museums [10; 11]. The home was an important informal learning environment where parents could play an impactful role in the development of a child's numeracy and literacy skills [12]. More structured informal learning environments consisted of museums, zoos, afterschool youth programs, clubs, and science media designed for learning [13]. Reports have shown that these structured informal learning environments play an important role in students learning science [14; 11; 15; 16]. Increasing the content knowledge of students by utilizing informal learning environments could be critical in addressing the issues of innovation and a STEM proficient workforce. Beyond learning content in informal learning environments there were affective benefits as well.

The benefits of structured informal learning environments were more than cognitive. Field trips to science centers could generate in students enthusiasm and wonder that would not normally develop in the traditional classroom setting [17; 18]. Research has shown that motivation, attitude, and academic engagement play key roles in mathematics and science achievement [19; 20]. These experiences may also create an interest in the STEM disciplines, which had an impact on students deciding to pursue STEM as a career later in life [21]. Real world applications that were meaningful to students raised their interest in STEM [22], and these additional programs encouraged students to consider college majors in a STEM field [23]. The STEM subjects were traditionally male dominated, but these informal learning environments gave girls an opportunity to learn in these fields in a non-competitive setting [18]. Increasing student interest in and motivation to pursue STEM through informal learning opportunities could help address the issues of international competition and an under skilled domestic workforce.

The combination of informal learning and STEM has been the focus of research and financial investment. The National Science Foundation, through its Science Learning + program, will provide up to \$14.4 million in grant funding for researchers to investigate best practices in informal learning with a specific focus on STEM learning for students of all backgrounds [24]. Reference [25], in its report of recommendations to the president, suggested that students be involved in out-of-school STEM learning activities including after school programs, STEM contests, and summer programs. The Aggie STEM summer camp fit these recommendations and sought to motivate young people to pursue STEM fields.

C. Project Based Learning

The method of instruction prevalent at the Aggie STEM summer camp was project-based learning (PBL). PBL was described as students working to solve real world, difficult problems through an inquiry process that required gathering information, collaborating with peers, developing a plan, and presenting a unique solution [26; 27; 28]. This active learning engaged students in problem solving that was substantially different from the traditional classroom and emphasized the use of knowledge in a context. Therefore, while rote knowledge may not be enhanced by PBL, evidence has shown that PBL enhanced the application knowledge of students [29]. This application of knowledge translated into students being able to use their formally taught knowledge in meaningful ways, thus helping them make the connection between the classroom and real life.

Benefits to using PBL, much like the benefits of engaging in informal learning, were both cognitive and affective. PBL was found to be beneficial in increasing young children's knowledge and made learning enjoyable and meaningful [30]. Middle school students who learned in a classroom that effectively implemented PBL learning strategies appeared to be more engaged and more motivated in the classroom than students in a classroom that used traditional lecture methods [31; 32]. At High Tech Middle, where students were admitted based on a lottery system and where PBL was an integral part of the learning experience, students performed at a high level on standardized tests, and 99% of graduates went to college after high school [33]. In the high school science classroom, the use of PBL was shown to prepare students to be more successful than similar non-PBL instructed peers [34]. Implementation of PBL over a three-year period in one high school resulted in higher student motivation, greater self-image, and an increase in the total number of students meeting college entrance requirements [35]. Real world applications that required students to combine knowledge that they acquired from the classroom in order to address problems could help students to see themselves as the problem solvers of the future. PBL was used widely in engineering courses on the college level because of its similarity to actual engineering work that involved the application of an interdisciplinary set of knowledge to complete a project that could possibly take a long period of time to finish [36]. While PBL and informal learning may improve students' readiness for college, some young people may be asking the question: Is it still worth going to college?

D. College Enrollment

As the cost of college attendance has increased in recent years, many were left asking if it was profitable to go to college. Research has shown that earning a college degree compared to only a high school diploma or less still has great economic benefits and even more so now than at any other time in the modern era [37]. Even with debt and missing out on potential earnings during college, average students could recover the cost of attending college by the age of 40, meaning that all earnings after that point were returns on their investment in a college degree [38]. Students who earned a college degree had a median income 50% higher than the

median income of their peers who only had a high school diploma [39]. During times of recession, those without a college degree were more likely to lose their jobs than those with a college degree [40]. Earning a college degree increases earning power and could help with job security, even in an unstable economy. Having the opportunity to go to college could be a challenge, with many admissions committees looking at a long list of criteria for admittance. However, one trait of many that universities had in common was an interest in performance on the Scholastic Achievement Test (SAT).

One item used by many colleges in admissions decisions was scores on the SAT. This test, taken by many high school juniors and seniors, was comprised of critical reading, writing, and mathematics sections and was accepted as a component of admissions decisions by almost every college and university [41]. Each section of the SAT had a maximum point value of 800 points. SAT test scores and high school grades have been shown to be predictors of college success, making achievement on this exam even more critical [42; 43]. Recognizing the importance of doing well on these exams, students have turned to many informal learning sources to improve their performance. Millions of dollars have been spent sending students to learning centers, taking test preparation courses, and purchasing test prep manuals to reinforce knowledge assessed on the exam and gain test taking skills that may give students an advantage on test day [44]. Informal learning opportunities have been shown to be a means of increasing student success; however, this investment at its extreme has been criticized as overly pressuring students to attain an unrealistic expectation [45]. The investment and importance placed on the SAT put achievement on the exam in the national spotlight. Due to the SAT being so widely used and accepted as a metric of student ability, results on the exam by graduating seniors could be used to identify achievement gaps that exist in the United States. These gaps limit the potential of some groups of students to attain college admissions and the associated benefits of a college degree.

Differences in performance on the SAT existed based on gender and ethnicity [46]. Since 1972 a performance gap has existed between males and females on the SAT. The average scores for college bound seniors in both the critical reading and mathematics sections have been in favor of males. This gap was smallest for critical reading, with gender differences each year ranging from 2 to 13 points. For mathematics, the gap was consistently larger, ranging from 31 to 46 points. The combined scores of both test sections yielded an average gap of 44 points in favor of males from the years 1972 to 2014. When investigated by ethnicity for graduating high school seniors in the year 2014, the average SAT combined critical reading and mathematics scores for Asians was 1121, Blacks was 850, Hispanics was 910, and Whites was 1053. Average scores by ethnicity and gender indicate gaps in achievement and may contribute to the explanation as to why there exists an underrepresentation of minority groups and women in STEM fields. Gender gaps within these ethnic groups were evident and were generally consistent with the overall gender gap. These differences in achievement beckon researchers and educational innovators to come up with new solutions to address inequities.

The Aggie STEM summer camp was developed to increase students' content knowledge and to instill in them a desire to pursue a STEM field and college in general. The informal learning environment complemented the students' school learning by enabling them to engage in the same subjects but in a different context. Through the implementation of PBL and by being located on a college campus, the Aggie STEM summer camp sought to increase student interest and motivation to pursue STEM fields and to create an environment in which students could see themselves as future undergraduates.

II. METHODOLOGY

During the summer of 2010, The Aggie STEM Center provided a two-week long STEM residential summer camp for underrepresented secondary students from one urban inner city academy in Texas. These students ($n = 35$) participated in an intensive STEM focused curriculum for 13 days. Sessions included real world science and mathematics applications through project-based learning (PBL) activities, robotics, university engineering and science lab tours, radio and television communication, museum tours, and SAT preparation. For example, one of the STEM projects students were given was to design and build a popsicle stick bridge that could hold as much weight as possible. Students engaged in the engineering design process and were required to plan and develop designs for their bridges prior to construction. On the final day, these bridges were tested and the one with the highest load capacity won. The SAT preparation sessions were held daily focusing on mathematics, reading, and writing for a minimum of one hour. Emphasis was placed on these three content areas plus general test taking strategies. These sessions supplemented advanced mathematics, science, and engineering instruction that students received during the remaining 7 hours of the camp day. The content of the PBL activities was not directly aligned with specific SAT type questions, although students did have to utilize some knowledge that can be tested on the PSAT and SAT to complete the projects. Students took PSAT tests at the beginning and at the end of the camp.

After the camp was over, Aggie STEM maintained contact with the students informally through its website and social media. School visits and supplemental instruction were conducted three times during the school year until all students had graduated in 2014. This study demonstrated the learning successes that can be achieved through STEM project based learning during a summer camp and with periodic follow-up and interaction via social media at a major Texas university with underrepresented high school students.

The final SAT scale score used for college admittance was available. Due to the longitudinal nature of this study, eight students relocated and were lost to the study leaving a reasonable study sample that still reflected the original group ($N=27$). The final sample consisted of 10 females and 17 males. There were two Asian, 11 Black, 11 Hispanic, and three White students in the final sample. Data analyses consisted of recommended methods [47; 48; 49; 50]. The recommendation for data analysis was to report findings in a way that promotes meta-analytic thinking so that conclusions can be drawn across studies [51; 52]. Therefore, in addition to disaggregated means, standard deviations, and correlational analyses, non-sample

size dependent estimates of importance were used. Data were analyzed using 95% confidence intervals and Cohen's d effect size estimates. Data confirmation follow-up was scheduled for the semester following post secondary matriculation.

III. RESULTS

When examining overall longitudinal performance, students matriculated at a much higher rate than that of the school overall: 52% as compared to 28%. Pearson r correlations were calculated between PSAT and SAT scores. The PSAT scores were derived from the post test scores taken during the summer camp. Results showed that PSAT scores were nearly perfectly correlated with SAT scores (Reading PSAT with Reading SAT, $r = 0.999$, Math PSAT with Math SAT, $r = 0.999$, Writing PSAT with Writing SAT, $r = 1.000$). The correlations were not unexpected because the PSAT and SAT tests were shown to be strongly correlated [53; 54; 55]. The overall matriculation rate of 52% included four students for whom matriculation information was not available but who remained in the total. This method ensures a conservative estimate. Matriculation data came directly from students, whereas the school provided SAT scores. The most common issue in failing to obtain matriculation information was wrong or changed telephone numbers and/or closed or incorrect e-mail addresses. Of the sample, 48% had not committed to a post secondary institution with 62% having decided to pursue or having a full-time job, of which 15% chose to enlist in the U.S. armed forces. Point-biserial correlation coefficients were calculated between SAT results and matriculation. The point-biserial correlation coefficient was algebraically equivalent to Pearson r , however point-biserial characterized the relationship between an intervally scaled variable, in this case score results on the SAT, and a dichotomous variable, in this case matriculation [56]. The correlations between scores and matriculation were: 0.408 with Reading SAT, 0.542 with Math SAT, and 0.338 with Writing SAT scores. The correlations between matriculation and Reading SAT scores and matriculation and Math SAT scores were statistically significant at the 0.05 level. It was possible that while Writing was perfectly correlated between PSAT and SAT it was not as important to matriculation. Perhaps post secondary institutions place a greater emphasis on Mathematics and Reading scores in admission decisions. Students would benefit from knowing that added emphasis on reading and mathematics could result in more favorable college admission results.

A planned follow-up during the summer resulted in fewer than 30% successful contacts so no further data were gathered to determine first semester success or changes in matriculation. There was both a practical and statistically significant difference in scores when comparing students who had matriculated ($M=1070$, $SD=104.73$) and who had not matriculated ($M=932$, $SD=82.78$) (see Figure 1). The Cohen's d was 1.45 favoring those who had matriculated. While one would expect the group who matriculated to have scored higher, the effect size was impressively large being nearly 1.5 standard deviations different. To examine the potential for matriculation more closely, the mean scores for males, 1028.82 ($SD= 96.43$), and females, 961 ($SD= 96.43$), indicated that there was no statistically significant difference (See Figure 2),

but the Cohen’s d (0.596) indicated the results were practically significant.

Figure 1. Post secondary matriculation by SAT scores.

Figure 2. Gender by SAT scores.

When considering male and female performance for students who matriculated into a post secondary program, the scores were not statistically significantly different ($M_f=1001.67$, $SD=105.60$; $M_m=1121.25$, $SD=71.40$) (See Figure 3). However, the mean difference was 119.58 points, which accounted for a Cohen’s d effect of 1.37 that was large. Males exhibited a practically important gain over female scores.

The sample was ethnically diverse but the sub-groups were small. When considering the group as a whole there were

neither statistically nor practically significant differences by ethnicity on obtained SAT scores (see Figure 4).

When considering only those who matriculated into a post secondary program, the means were slightly higher than for the whole group but only marginally. Only one Asian student matriculated so a point on the graph represents that estimate. While that number was larger than for the group it was hard to draw conclusions about a single case. There were no practically or statistically significant differences (see Figure 5).

Figure 3. Gender by SAT scores for post secondary matriculation.

Figure 4. Ethnicity by SAT score.

Figure 5. Ethnicity by SAT score for post secondary matriculation.

IV. DISCUSSION

The United States has been the technology and innovation leader of the world. That mantle, however, is in danger of leaving the United States as other countries are taking steps to improve the mathematics and science knowledge of their students. The Aggie STEM camp was designed to help meet the challenge of growing a generation of young people interested in and motivated to pursue a postsecondary education with a STEM major specifically in mind.

The informal learning environment that a camp such as the Aggie STEM camp provides is an ideal setting for engaging students in new and exciting ways. This opportunity to learn outside of the traditional classroom creates an environment for mutual attainment regardless of gender and apart from the pressures of standardized testing. PBL compliments this environment well by giving students hands on learning opportunities. This strengthens their ability to apply classroom knowledge in real life situations or with tasks that resemble what they will be doing in future careers.

Another emphasis of the camp was to give students a college like experience. With students residing on campus for the duration of the camp and experiencing some aspects of the college life, they were able to see how it will differ from their high school experience. Such exposure to a college campus would hopefully motivate students to take steps that will help them matriculate later in life. SAT preparation can make a difference in student performance on the SAT and thus make an impact on whether or not they are accepted to a university. This study followed students who experienced the Aggie STEM summer camp into postsecondary matriculation.

The students who came to the Aggie STEM summer camp were successful in several ways. They matriculated to postsecondary schooling at a higher rate than the average of students at their school. This informal learning experience on a

college campus may have contributed to students seeing themselves as future college students and may have instilled in them a sense of belonging on a college campus. Students were also successful in their performance on the SAT. Gender gaps did exist for the data collected from these students; however, the gaps that traditionally exist for ethnicities were not prevalent. These results show that while the Aggie STEM camp experience, and possibly other informal learning environments, may not be able to completely eradicate performance inequities, the camp experience could be a means of minimizing these gaps.

SAT score results were correlated with matriculation to a postsecondary institution. These results showed that a relationship between performance on the SAT and decisions to matriculate existed, especially for mathematics and reading. The SAT is often used in college admissions decisions, so a higher performance on these tests would make a student more appealing to a university or other institution's admissions board.

The Aggie STEM summer camp has been further developed since the time of the initial data collection. New projects have been created to increasingly engage students in activities that are interesting and that utilize classroom knowledge in new, applicable ways. The camp itself has grown in attendance so that now multiple camps are necessary to accommodate all of the students that are interested in attending. As the camp continues to grow and impact the lives of students, further research can be conducted.

Further research needs to be conducted on informal learning environments, project-based learning, and STEM education. One limitation of this study was the small sample size. Future research on informal learning, PBL, and STEM education could benefit from using a larger sample size. Research investigating the potential of informal learning environments to reduce achievement inequities found by ethnicity and gender could indicate how best to support and encourage the involvement of underrepresented groups in colleges and careers. Informal learning environments that encourage collaboration in a non-competitive environment may help to address these issues. Research can be done with longitudinal tracking of students through postsecondary matriculation. The current study attempted to longitudinally track students through their first year of matriculation but was unsuccessful in doing so. Such a long-term study would yield greater insight into the possible far reaching implications informal learning and PBL have on students. More research on the use of PBL and the teaching method's impact on student motivation and interest may help to clarify PBL's strengths. Studies that use a pre/post test evaluation of student interest and motivation with a PBL teaching intervention may yield such results. Finally, STEM education is a national issue that many are attempting to address. In order to insure the continued prosperity of the United States, developments in understanding how students best learn STEM and what can be done to interest more students in the STEM disciplines are critical.

Abstract— In this work, we report the outcomes from the IUPUI STEM outreach program “STEMCorp” that inspires high school students to pursue STEM majors. The STEMCorp program was modeled after the Multidisciplinary Undergraduate Research Initiative (MURI) at IUPUI. MURI research program introduces undergraduate students from at least two different departments with mentors from different disciplines to address research issues that may compose both engineering and sciences. The STEMCorp program brings undergraduate students to work with faculty and high school teachers to create a positive impact in enriching the high school students by introducing them to engineering and science with emphasis on nanotechnology for future careers. The program describes the collaborative activities between faculty, undergraduate students and high school STEM teachers in the creation of project-based, student-centered learning modules in the field of nanotechnology. The paper details the activities of the STEMCorp participants including their experiences in developing working partnerships and creating and implementing learning modules in the designated high school courses. The success of the program is assessed by the measurable outcomes of high school students’ research projects. Specifically, two different learning modules are presented, including the processes used in the development of these modules and their outcomes. The collaborative research

discussions between the faculty, undergraduate students, and high school teachers are detailed, covering research methodologies, hypothesis, and expected outcomes.

Index Terms—STEM, nanotechnology, research experience for teachers, high school students, projects, collaboration

I. INTRODUCTION

MURI is a research program that was established at IUPUI more than 10 years ago. It was created to encourage multidisciplinary projects from across schools [1, 2]. Projects offered by mentors from different disciplines have led to unique research experiences for undergraduate students. More than 40 students are funded every semester from this program. The projects are analogous to industrial models where different engineers and scientists work together on a multidisciplinary project. One example of such a collaborative project is a battery system, where electrical engineers contribute to the electrical and mathematical models while mechanical engineers contribute to the thermal science issues within the system. Chemical engineers, however, are also experts in the electrochemical process of the system. Control engineering and computer engineering may add to the optimization and safety of the devices. Likewise, in many medical research projects, students from biology, bioengineering, computer engineering, image processing, among many others, may contribute to such multidisciplinary research. These programs operate with the same ideology; using information and skillsets from various disciplines to achieve a common goal. This approach can provide more rounded and comprehensive solutions to modern day problems.

It has been widely acknowledged that there is a need to improve students’ STEM skills and increase diversity in STEM fields at all levels of education [3-6]. A necessary step in addressing this need is drawing students to STEM disciplines at an early age thereby assuring that they have developed necessary skill sets for college degrees in STEM fields. For this, based on the MURI model, a pilot project,

Submitted on April 27th, 2015. The authors are with the Schools of Engineering & Technology and Science at Indiana University-Purdue University Indianapolis.

Dr. Mangilal Agarwal is a Associate Director for Research Development and Director of Integrated Nanosystems Development Institute (INDI) at IUPUI, 755 W Michigan St. Indianapolis, IN 46202 USA (*Corresponding Author: agarwal@iupui.edu)

Ms. Qurat-ul-Ann Mirza and Mr. Joseph Bondi are undergraduate students in the School of Science at IUPUI.

Dr. Brandon Sorge is a Research Associate at the STEM Education Research Institute at IUPUI.

Dr. Maher Rizkalla is a Professor & Associate Chair of Department of Electrical and Computer Engineering and Member of Integrated Nanosystems Development Institute (INDI) at IUPUI.

Dr. Richard Ward is a Professor of Anthropology and Dentistry Faculty of University College

Mr. Feldhaus is a High School Teacher at Irvington Public School, Teaches Biology and Human Genetics.

Ms. Amy Hinshaw is a High School Teacher at the Health and Biomedical Sciences, Metropolitan School District of Lawrence Township.

Dr. Kody Varahramyan is a Professor of Electrical and Computer Engineering at IUPUI.

“STEMCorp,” was designed to form collaboration among high school teachers from urban schools, IUPUI students who have been successful in STEM fields, and IUPUI faculty who have demonstrated interest in improving STEM education. The project also builds on IUPUI’s existing strengths in nanotechnology outreach and education through the Integrated Nanosystems Development Institute (INDI) [7]. INDI provides a good infrastructure for student-mentor interactions, which was utilized because nanotechnology has proven to be a STEM subject attractive to high school students. More specifically, the project builds on the success of the already established INDI nanotechnology camps for high school teachers and students that were established four years ago [8]. The need for a better means of transferring the content and the skills from these camps into classrooms has been identified by high school teachers who have taken part in assessments at the end of the camp sessions. The STEMCorp collaborative research team addresses these concerns as research questions and provides solutions that relate to this gap in transference.

The STEMCorp program is developed and administered in collaboration between the following three IUPUI campus units:

The Center for Research and Learning (CRL) [9]

This center is associated with the Office of the Vice Chancellor for Research. CRL is dedicated to serving students through a series of undergraduate research programs overseen by CRL program leaders. These programs offer students the opportunity to carry out innovative research, scholarship, and creative activity with faculty mentors through internally and externally funded programs. CRL programs expose and engage students in research experiences, providing effective pathways for lifelong active learning, scholarship, and professional development. The vision of CRL is to create and sustain world class programs in inquiry-based student learning through innovative multidisciplinary collaboration and effective mentoring, and promote lifelong active learning and professional development.

A. The STEM Education Research Institute (SERI) [10]

SERI is dedicated to education research in STEM fields, combining knowledge of teaching and learning with deep knowledge of discipline-specific science content. Based on this, the institute is dedicated to the development and dissemination of STEM education programs in collaboration with external partners. The vision of SERI is to be a nationally and internationally recognized center of excellence for STEM education research, contributing to the advancement of STEM education in Indiana and the nation.

B. The Integrated Nanosystems Development Institute (INDI)

INDI is a research center comprised of faculty from the Schools of Science, Engineering and Technology, and Medicine. The given faculty have expertise in a wide range of

fields, including chemistry, physics, biology, material science, electrical and computer engineering, mechanical engineering, orthopedics, pathology and laboratory medicine. The vision of INDI is to be a resource for the realization of nanotechnology-based miniaturized systems that contribute to the economic growth and social advancement of Indiana and the nation and benefit humanity as a whole.

II. STEMCORP

For STEMCorp, the project was divided into four distinct phases.

A. Phase I

Three high school science teachers from the Indianapolis area were recruited, three IUPUI faculty in STEM disciplines were identified (one from science, one from engineering, and one from education), and six undergraduate students (STEMCorp scholars) in STEM fields were recruited who served as the research scholars in the summer and as high school teaching assistants and peer mentors in the academic year.

B. Phase II

The STEMCorp scholars participated in three weeks of INDI’s nanotechnology camp activities, including the sessions for high school students and high school teachers. In addition, the scholars participated in the CRL’s summer undergraduate research program and attended a series of research and professional development workshops designed to enhance their research skills. The STEMCorp Scholars also obtained documentation required to engage in human subject research and to work with minors. At the end of Phase II, the team delivered the following:

- 1) *Initial needs assessment data*
- 2) *A set of activities that can be used in high school classrooms to further nanotechnology-related skills*
- 3) *Guidelines for the facilitation of these activities*
- 4) *A prototype for a mobile kit that contains the materials needed to implement these activities*
- 5) *A set of online resources (web quests, videos, interactive games, etc. that can be used to further enhance students’ skills)*
- 6) *A schedule for piloting the activities in the classrooms during the following academic year.*

C. Phase III

The research team implemented the activities with the high school students. The high school teachers took the lead and IUPUI STEMCorp scholars assisted the teachers. The Program Coordinator, IUPUI faculty, and the high school teachers all served as mentors for the IUPUI STEMCorp scholars.

D. Phase IV

Finally, in Phase IV, the STEMCorp team will reassemble to assess outcomes and write a final report on the results. Deliverables for this phase of the project will be

- 1) research abstracts, posters, and papers from the STEMCorp student scholars
- 2) final reports from the IUPUI faculty mentors, high school teachers, and the program coordinator
- 3) needs assessment data and program evaluation outcomes gathered by the two SPEA students
- 4) presentation of results at one conference at a minimum
- 5) development of options for sustaining the STEMCorp program

Both formative and summative assessment methods are being employed including surveys, interviews, focus groups, and analysis of research products (teaching modules). The inputs from these assessment methods will be used to reflect and to enhance the program. In continuation of Phase IV, participants will review and evaluate their individual experiences of their first summer and academic year participation in the program, as part of their work. Reporting of the student experiences will take place through participation in the CRL's summer poster symposium, the IUPUI Research Day symposium, and/or the Indiana University Undergraduate Research Conference. Phase IV will also include collaborative work by the "community of practice" with the product of a summary "white paper" reviewing outcomes of the assessments and evaluations. In addition, the white paper will identify the elements associated with successful completion of STEM coursework and make recommendations for sustaining the program.

III. OUTCOMES

A. Short-term Outcomes

- 1) Indicators identified for competence in nanotechnology-related knowledge and skills mapped to high school standards.
- 2) Collaboration among faculty from IUPUI Schools of Science, Engineering & Technology, and Education; high school science teachers interested in integrating nanotechnology-related content and skills into their high school curricula; and IUPUI STEM majors interested in research and nanotechnology.
- 3) Increased knowledge and skills related to nanotechnology among IUPUI faculty, high school teachers, IUPUI STEM majors, and the approximately 200 high school students from schools represented by teachers in the program.
- 4) Increased research, mentoring, and professional development skills for IUPUI STEM majors.
- 5) Materials and resources related to nanotechnology skills identified and links placed on INDA and SERI websites for use by other community schools.
- 6) Hands-on mobile nanotechnology teaching kits developed for use by CRL scholars and high school teachers in the field.

B. Long-term Outcomes

- 1) Changes to high school curricula to integrate nanotechnology knowledge and skills.

- 2) Increased number of participating high school students selecting STEM majors in college (especially those related to nanotechnology).
- 3) Increased number of participating high school students selecting IUPUI as their college of choice.
- 1) Increased number of CRL scholars going on to graduate school in STEM-related fields (especially those related to nanotechnology).

IV. RESULTS AND DISCUSSIONS

Two teaching modules have been developed under STEMCorp so far.

A. Example Project 1

Project 1 was conducted by high school students at local career and technical center. The students involved were high school juniors or seniors in their third-year of the Project Lead the Way Biomedical Science curriculum. In the first semester, students designed a lab to compare the antimicrobial effects of silver nanoparticles, silver ions, and traditional antibiotics on the growth of multi-drug resistant bacteria. Most students compared the zone of inhibition created by the different potential antibiotics. Students wrote lab reports describing their findings.

In the second semester, student groups researched ways to use nanotechnology for the early detection of cancer and presented their findings. Students created 3-D models demonstrating how the device works, image 1.

Image 1: 3-D models of lab on a chip and nose sensor constructed by students at McKenzie Career Center using simple school supplies.

Students were given a pre-test and post-test (N=76). To measure the change in their knowledge of nanotechnology, nanotechnology devices and their usage in cancer detections. The questions include:

1. Which of the following is/ are nanoscale objects?
 - a) An antibody.
 - b) A hydrogen atom
 - c) A strand of DNA.
 - d) A cancer cell
2. Elaborate on the nanotechnology processes for detecting cancer?
3. Much research is devoted to developing better methods for diagnosing cancer. Describe TWO of the problems or limitations of the current cancer diagnostic methods/ tools.

4. List TWO types of nanotechnologies or nanomaterials used in the detection of cancer.

5. Explain how ONE developing nanotechnology for cancer detection works.

- Include as many details of the process as you are able.
- Be sure to discuss why this is a NANO-technology.
- What is NANO about it?

6. Describe ONE advantage that nanotechnology devices/materials have over our traditional methods of diagnosing cancer.

These questions were assigned point values. The first two questions were worth one point each, questions three through six required detailed description and thus were assigned multiple points.

For the pre-test, the majority of students from the class responded “I don’t know” to the above set of questions. After the activity, they were given a post-test which was identical to the pre-test. The questions were designed to test their knowledge of nanotechnology processes, current research in cancer diagnosis using nanotechnology and advantages in nanotechnology devices that may have over traditional methods of cancer diagnosis.

Figure-3: Shows the percentage of students that answered correctly. 68-out-of-76 students, 89.5%, provided two nanotechnologies or nano-materials that are used in cancer detection.

Scores from all 76 students were averaged to 86%. Students scored high on questions relating to cancer detection (Figure-3) However, students struggled with identifying the three nano-scale objects, and only 48 students answered it correctly.

Overall, student response was highly positive and their feedback with the module was encouraging.

B. Example Project 2

This project is a two week long Project Based Learning Unit (PBLU) that focuses on creating a model of a renewable energy source that is best suited to produce energy at the local Charlestown state park. Students picked their own groups based on group roles, collaborated in their group, fulfilled their specific group roles, and presented to a professional audience as a cohesive group.

The four group roles were Project Coordinator, Scientist, Engineer, and Nanotechnology Specialist. The Project Coordinator updated the teacher, twice a week, on how the group was doing, helped other students with their tasks, and was responsible for any work of absent students. The Scientist collected data for a renewable energy source assessment, created arguments for the best type of renewable energy source based on data, and did research on renewable energy sources to pick the best possible one. The Engineer used a 3D printer to create a working model of a renewable energy source and did research on renewable energy source structures. Finally, the Nanotechnology specialist explained how nanotechnology is used in this field, turned in a presentation on how nanotechnology can affect renewable energy technology, and researched renewable energy sources.

Each member also presented their group’s final product. Some interesting points of the project are: 1) students collected real world data on light intensity, water speed, wind speed, and biomass at Charlestown State Park. From this, the students decided on the best renewable energy source (solar, hydroelectric, wind energy, or biomass) based on the collected data; 2) students created a dye-sensitized solar cell; 3) students created a 3D working model of energy technology using a 3D printer. All of the groups operated by using one or more of the following: 1) identification of specific relevant group roles decided on by group members, 2) creation of a group contract to make group norms and ways to deal with in-group problems; 3) presentation to professionals in the field during a gallery walk, and 4) reflections on project outcomes and group and individual performances. This last piece is especially important because it builds metacognitive skills the students will need to self-evaluate.

This project was developed to help students realize the importance of renewable energy sources, introduce them to nanotechnology, demonstrate how nanotechnology is used in many renewable energy sources, express how nanotechnology is becoming more relevant in modern science, technology, and medicine, and expose them to how collaborative projects are conceived, implemented, and given exposure in the real world. The goal was to build the necessary skills among students to teach self-reflection, constructive feedback norms, presentation skills, constructive problem solving skills, and to give the students a better grasp on how scientific inquiry is implemented in the real world.

Participating students (N=39) were given a pre- and post-assessment that consisted of multiple choice questions to gauge the student’s basic understanding of general

nanotechnology and renewable energy concepts; fill in the blank questions to test a student's understanding of the integration of nanoscale processes in renewable energy sources; and open ended questions to gauge a student's understanding of what nanotechnology actually is. Between taking the pre-assessment and post-assessment, students created dye-sensitized solar cells and were taught on how nanotechnology plays a role in solar cells. The students were also given a basic introduction to what nanotechnology is and other applications of how nanotechnology is used in modern technology.

The students showed a 49.7% increase in individual score on the post-assessment when compared to the pre-assessment. Students showed a 28.4% increase in their general nanotechnology and renewable energy understanding and a 73.2% increase in their understanding of lab-specific questions. Open ended questions from the pre-assessment showed that the students did not have a good understanding of nanotechnology. The post-assessment indicated that the students gained a basic understanding of nanotechnology and would still like to learn more about nanotechnology and how it can be integrated into modern technology. From the assessment, the students showed a base understanding of the integration of nanotechnology in solar cells, however many students were interested in learning other applications. From this, it can be inferred that by providing an introduction of nanotechnology to high school students their interest will increase and they will possibly do further research. To help facilitate this, students can be provided with other examples of nanotechnology integration and given sources for independent research.

V. CONCLUSION

The two projects conducted at high schools covering healthcare and renewable energy projects indicate the success of the STEMCorp activities. These two projects served as a pilot study where the STEMCorp, faculty, high school teachers, and undergraduate students have all participated in the initiation of these projects. These projects showed success, however, some aspects of each project would have helped them develop much quicker. Early coordination between the advisors, students, and teachers would have led to quicker success of this program. Nonetheless, once there was proper coordination, there was a great impact among the students. By sending a student from STEMCorp to the high schools, students showed more interest in learning about nanotechnology and other STEM related subjects. The collaborative work between the various units from INDI, STEMCorp, SERI, CRL, and University faculty have led to the success of this program. The outcomes of these activities have enhanced the students' understanding of nanotechnology. By introducing students to the research in nanotechnology, they are aware of modern applications of nanotechnology in energy and medicine and hence, understand possible careers in nanoscience.

VI. ACKNOWLEDGEMENT

The authors would like to acknowledge the Venture Fund

from the Solution Center at IUPUI and the Indiana Space Grant Consortium (INSGC) award through Purdue University. The experiences from STEMCorp and IUPUI Nanotechnology Discovery Academy (INDA) also led to a Research Experience for Teachers award (#1406995) from the National Science Foundation. The authors also appreciate the efforts of Mr. Vinay Kumar Suryadevara for his assistance with the formatting of this manuscript.

Abstract—As the world’s energy usage continues to rise while the natural energy sources continue to dwindle, it is becoming more important that the general public’s awareness of energy is increased. The National Academy of Engineering, NAE, has deemed this issue so important that five out of the fourteen Engineering Grand Challenges deal with energy. Raising awareness with children about energy consumption and generation issues will help create a sense of familiarity and potentially, a desire to follow career paths that deal with solving these future energy challenges. Introductory energy modules are being taught in K-12 classrooms in California, New Jersey, and Pennsylvania with support from the National Science Foundation, NSF, GK-12 Ph.D. Candidate Fellows of Drexel University and the Dragon’s Teach Program, which stems from the UTeach Program in the country.

A Localized Energy Awareness Program, LEAP, has been formed through a K-University STEM collaborative project. Curriculum is being taken from the university level and broken down to each K-12 level to give insight into the topic of energy. In the new Next Generation Science Standards, NGSS, for science and engineering practices there are eight practices that should be taught at each level of K-12. Through these practices and the NAE Grand Challenges, energy awareness modules have been developed to bring into K-12 and Drexel University freshman engineering classrooms. The modules focus on the current energy usage situation, current active methods of energy harvesting including renewable and non-renewable energy sources, and modeling (drawing, building and computing depending on age group) new solutions and awareness for the energy crisis.

Surveys are being used to gauge the effectiveness of our activities with the students, teachers, and participating undergraduate and graduate students. This is a work in progress and results of the surveys and work are still being processed.

Index Terms—K-12 STEM Education, Energy Awareness, NGSS, Energy Education.

I. INTRODUCTION

The world’s energy usage continues to rise while the natural energy sources continue to dwindle. It is becoming more important to increase the general public’s awareness of energy consumption and usage, especially with children. The National Academy of Engineering, NAE, has deemed this issue so important that five out of the fourteen Engineering Grand Challenges deal with energy[1]. The most important age group to raise awareness with is the one that is accessible through school and is going to take over the world and all of the problems it faces. Raising awareness with children

about challenges involving energy will help create a sense of familiarity and potentially, a desire to follow career paths that deal with solving these future energy challenges. This is seen in many studies of energy awareness that have been conducted over the years [2], [3], [4], [5].

This module focuses on STEM (Science, Technology, Engineering and Mathematics) education in K-12 and first year university. A Localized Energy Awareness Program, LEAP, has been formed through a collaborative STEM project. University-level material and has been broken down to each grade level to provide insight into the topic of energy. This has been done previously in the authors work [6], [7]. In each grade level, discussions ranging from “What is energy?” to “How can renewable energy be used more?” are brought into the classroom as students learn new material and model their inputs, ideas and solutions through drawing, building physical models, and using virtual reality software. Overtime, students will work off of each previous grade level’s work to further build on and improve upon already thought-out plans.

In the new Next Generation Science Standards, NGSS, for science and engineering practices, Appendix F, there are eight practices that should be taught at each level of K-12 [8]. The main NGSS practices shown in these modules are the following: (1) Asking questions and defining problems, (2) Developing and using models, (3) Planning and carrying out investigations, (5) Using mathematics and computational thinking, (6) Instructing explanations and designing solutions, and (8) Obtaining, evaluating and communication information. Through these standards and the NAE Grand Challenges, energy awareness modules have been developed. The modules focus on the current energy usage situation, current active methods of energy harvesting including renewable and non-renewable energy sources, and modeling (drawing, building and computing depending on age group) new solutions and awareness for the energy crisis. This project has been grouped in the age levels that the NGSS provides their standards: K-2, 3-5, 6-8, and 9-12.

II. METHOD

This project is broken down into many areas of study and age levels. The common goal is to raise awareness around en-

ergy and the energy crisis that is occurring in the world. With awareness comes the need to solve the problem at hand. The first and most known method of accomplishing this is through alternative energy sources or renewable energy sources. This is the focus matter of this module from kindergarten all the way through first year university students. They are learning about what energy is, why it is so important to our day to day lives and how it effects their local environments, i.e. classroom and homes.

This brings the problem at hand into their focus and center and makes it easier to grasp because it is relatable. From here the students then start to develop methods on how to make their local environments more efficient through the alternative energy solutions they have learned about through assorted activities depending upon grade level. This has also been seen to work in a Taiwanese project where the students in primary and secondary schools have implemented alternative energy methods directly to engage with the students [9].

This project starts before the material reaches the students. It begins with the teachers. The perspectives of the educators is the starting point because their views are what will be passed down to the students and carried on throughout the classroom long after the module has been ran. The teachers that are and have agreed to run the modules within their classrooms took an energy awareness survey. This survey was based on the DeWaters' Energy Literacy Survey that focuses on knowledge, attitude, and behavior [5], [10]. This provided a great comparison of energy values across the United States. The survey included states of New York, New Jersey, Pennsylvania, Washington D.C., Florida, and California with a nice split of 54% and 46% east coast and west coast, respectively, comparison.

A. Pedagogy

This project is has formed a collaboration group of Drexel University's National Science Foundation, NSF, GK-12, Department of Education, DOE, Graduate Assistance in Areas of National Need, GAANN, and UTeach programs [11], [12]. These groups were selected due to their involvement with the local inner city Philadelphia schools. This collaboration has now outreached to high schools, middle schools and elementary schools all over the United States and in many different subject matters including mathematics, core sciences, language arts, social studies, and art. Outreach is still looking to incorporate Texas and South Dakota in addition to the states listed above.

All modules are set up to use two or three days of 40 - 60 minute class periods depending on grade level. Each grade level section is broken down with curriculum content appropriate for that learning and age level. The teachers involved with the project work with the collaboration to adapt each module content to the appropriate level of the classroom with the common goals of the project intact. The Dragon's Teach program is one way these modules will be implemented into the different classrooms from 3 - 8 grade levels along with the NSF GK-12 program within the 9-12 grade levels.

The modules are primarily taught by the teachers with the assistance of an engineering Ph.D. Candidate. This is to assure that the teachers are learning the material and are able to run the module by themselves as the project moves forward in coming years.

B. Content of Grade Levels K-2

At the beginning, the focus is on learning about energy and evaluating where the students are by creating a large K-W-L chart. The class holds a discussion about what they know about energy, what it is and where it comes from. Their answers go in the "K"now column of the KWL chart. Then ask them what they would like to learn about energy. These questions go into the "W"ant column of the chart [13]. Following these discussions, interactive activities allow the students to visually see energy in a physical way are completed. One example is the jumping jacks exercise where the students do jumping jacks until they become tired and an explanation of "running out of energy" is done. Afterwards the KWL chart becomes completed with filling in the last column, "L"earned. The students then make sun mobiles to show how much energy the sun provides us and how much the sun is used in and effects our local surrounds.

The main focus of the second day is now to get the students to creatively start thinking about the how they can use the sun as alternative energy to improve their current surroundings, their classroom. At this level, the students will create models via drawings of their classrooms. They need to come up with one thing they would change in their classroom to use alternative energy. Before this can begin, a class discussion on what uses energy in the classroom is done. This allows the students to recognize what around them uses energy and how much energy each item uses. In groups of two or three the students can then create their own ideas. The groups allow them to bounce ideas off of each other and learn how to work in groups to solve problems. After drawing their ideas, the students will present their invention or adaptation that uses alternative energy. This is part the eight NGSS for science and engineering practice: (8) obtaining, evaluating, and communicating information [8].

C. Content of Grade Levels 3-5

For the first day again, the focus is on learning about energy and evaluating where the students are at by creating a KWL chart for the discussion. Renewable energy coloring books have been created based on the California Energy Commissions Energy Quest [14]. These teach the students about six different types of renewable energy: solar, wind, hydro/ocean wave, geothermal, biomass, and biofuel. At the end of each coloring book the students are given a page to create their own invention using the type of renewable energy that is in the booklet. There are four coloring books in total. This can be done in groups, pairs or individually based on the teachers desecration of their students.

For the second day, the focus moves to their current environment, their classroom. In groups of 2 or 3 the students

discuss and create a list about what in their classroom uses energy. From this they draw their most energy-efficient classroom within the poster paper provided to them. They should draw ideas from what they've learned about energy and the renewable alternatives available, as well as their lists of items that use energy in their classroom. To conclude the project, each group presents their energy-efficient classroom with an explanation of their design.

D. Content of Grade Levels 6-8

The first day of this level is still dedicated to understanding what the students already know and what they want to learn about energy. This will be done through classroom games such as Family Feud, The Price is Right, and Jeopardy, which have all been adopted and placed in classroom settings previously [15], [16]. The energy material here have been adapted to these formats and provided to the teachers with making sure that the highest priority is raising awareness about the energy crisis and renewable energy sources. The students are then shown the K-5 energy efficient ideas and solutions.

This will leads to the students choosing an idea they want improve upon. Next, the students will start modeling their ideal through sketching. Once their ideas are presented and discussed with their teachers, another step in the NGSS (6), they are given building materials (paper, cardboard, markers, crayons, glue, tape, poster board, etc.) to actually develop and build a prototype of their energy-efficient classroom [8]. Finalizing their prototype, the students present their models to the classroom with a small write up of their understanding of how their improved invention will make their classroom more energy efficient.

E. Content of Grade Levels 9-12

The high school level will stay in common practice of dedicating the first day in the classroom to an introduction of energy awareness. This is done through an interactive lecture with the students that has been provided to the teachers. The high school students will now improve upon the 6-8th grade level's ideas and models. The students will be choosing which model they would like to improve upon. This time the students will not only be expanding upon their classrooms, but the school as a whole. They have the option of their high school or the elementary/middle school that the idea originated from. From here, the students have the choice to develop a working-physical model or a virtual-reality model. The virtual reality require computers and software. Therefore this can only be done where the appropriate funding is available. The working physical models use electronic and mechanical structures. Students may use solar cells, build windmills, build generators, hydro dams, etc. This is researched and developed entirely by the student.

With the curriculum and length of this project, the classrooms should be high school science and/or engineering classes. Currently, more than 10 high school science classrooms are in collaboration with the project through the NSF GK-12 Program. Finally, the students present their work to the

class and principal of the school of choice as a way to make it more energy efficient and create an actual impact in the local environment.

F. Content of University

The university level is almost identical to the 9th-12th grade curriculum. The important thing here is that it is for a freshman design engineering class. The students have the engineering physical and virtual reality model requirements to fulfill. At the end the students have to present their work to either the school district that they have done the work for or a company that may be willing to invest or donate to create their project.

As seen in this section, the grade levels each differ, but the goal is to have each grade level build off of the previous grade level's work and ideas. This is important within the NGSS. This is a long term project that will be implemented with many school systems across the U.S. It doesn't take a large amount of class time, but brings excitement and knowledge around the topic of energy. This is important with the energy crisis in the world. As seen in American Association for the Advancement of Science, AAAS, Project 2061 Atlas of Science Literacy, students need and education on energy and the influence it holds in their daily life styles [5].

III. PRELIMINARY RESULTS

Preliminary results have been taken from the teachers working with the project in the states of C.A., N.J., N.Y., D.C., and F.L. through an energy awareness survey based on Dewaters' Energy Literacy Survey using the survey tool Qualtrics. [10]. Although all participants remained anonymous to obtain unbiased and truthful data some profile statistics was taken. The age group was between 20 to 61 years with 71% under 30 years of age. The participant pool consists of 29% male and 71% female and teach a wide range of topics and grade levels. This is a comparison study between the teachers and their knowledge of energy awareness across the country. Cross tabulations were ran between west coast and east coast K-12 and university teachers. They were surveyed based on the three areas of energy awareness: knowledge, attitude, and behavior. The results varied in each category, especially in comparison of location within the United States.

TABLE I
ENERGY AWARENESS

	East	West
Knowledge	56.8%	60.1%
Attitude	72.1%	83.4%
Behavior	48.2%	65.0%

The results seen in Table 1 show positive attitudes for the east and west cost. However, the level of knowledge and behavior drop. When determining the level of knowledge the teachers themselves had, they were surveyed on basic questions of renewable energy and energy usage/waste. None of the teachers could name six main renewable energy sources. However, 69% could name solar and wind. One teacher

actually named natural gas as a renewable energy and 23% couldn't name even one renewable energy source.

When it came to energy awareness education 92% of the teachers stated that they either "strongly agree" or "agree" that energy education should be a part of every school's curriculum. However, only 31% have taught energy awareness in any manner in their classrooms. None of the teachers have used the NGSS in their classrooms nor are they familiar with the NGSS. Only 50% have even heard of the NGSS with 79% being mathematic or science educators.

Overall, California was more motivated and aware of the conservation of energy and ways to save energy. They put their motivation into action and try to save energy at most times. However, in understanding where energy is mostly wasted in an average American home: heating and cooling of a home, less than 50% of Californians were aware that heating and cooling the house is the most wasteful. The eastern states actually were more aware of this. This is most likely due to the fact that all four seasons are witnessed on the east coast, where as California barely uses the heating and cooling tools of a home.

IV. DISCUSSION AND FUTURE WORK

The results of this work allude to the conclusion that energy awareness is necessary in K-12 and university education. Therefore an innovative practice and collaboration has been developed and put into action to accomplish this. Through the development of modules for each grade level in energy awareness the students learn what energy is, how it is used, what is renewable vs. nonrenewable, and what they can do to improve energy efficiency in their local environments. These modules are formed through energy awareness curriculum, the NAE Grand Challenges and the NGSS for engineering and science.

The preliminary results show that the education of energy needs to start with the teachers. By educating the teachers on the subject matter they will be better equip to teach the generation of students that will need to solve the energy crisis. When asked if just taking the survey has made them more aware of their energy usage, the teachers replied with a positive 86%. Therefore, just introducing the topic to teachers had an impact and continuing with the project will create a larger impact with them and by extension, their students.

The STEM energy awareness project is already in motion in California, Pennsylvania, and New Jersey and is expected to run full circle within the next school year. Florida, Washington D.C. and New York are expected to start running the modules in the fall. Contact has also been made with South Dakota and Texas school systems as well. Feedback and data will come through surveys and project results as the modules continue to run in the different classroom levels. The future goal is to see change within the schools associated with the project on becoming more energy efficient and the students seeing the STEM fields applied in a positive way.

ACKNOWLEDGMENT

Abstract— It is important to bring engineering to young people, and it is better to do so at an early age. In this case, the goal is to show children aged 10-15 years how electromagnetism works, and how we can find it in common tools that surround us. To do so, we are developing a remote laboratory that will be used in the sessions of science and technology in a school. Concept of electromagnetic crane has been chosen because a crane is a common tool. It is an object used in construction and in factories. Using electromagnet power to move metal objects is also a common concept that children can understand. Using these tools as an example, we seek to bring science to everyday life and promote the interests of children and young people in engineering and technology. The aim is to encourage them to seek education in engineering programs in the future, and teach them to understand and appreciate how important technology is.

Initially, the laboratory will move left and right in a circumference of 350 degrees and permit up and down different preselected masses. Also, students can increase or decrease the voltage of the electromagnet to raise masses. The entire system will be accessible remotely by the student who will be able to move the crane, activate or deactivate the electromagnet, and lift or take down the masses.

At the same time, the user interface displays the image of the laboratory and a graph showing the relationship between the power and its capacity to lift the mass every time the student applies voltage to the solenoid. All of this will allow us to see the effect that the applied voltage has over lifting the mass.

This work in progress is associated with different learning environments to adjust the experience at different ages which range between 10 and 15 years.

The students will interact with the remote laboratory from their homes, but also, the laboratory can be used in the classroom taking advantage of the data displayed through the user interface. Another objective is to show how engineering and science allow us to control remote objects and measure their effects through technology. Planting in students the seed of curiosity may be a good way to arouse the interest of future engineers.

Keywords—remote laboratories; technology; children; schools; crane; electromagnetism

I. INTRODUCTION

A good way to bring technology to children is through practice. After the line started within the Go-Lab project, UNED in collaboration with Karbo School developed a remote laboratory whose purpose is to be explaining how electromagnetism works.

As it explained in this work, we consulted teachers who teach children between the ages of 10 and 15 years old and with their suggestions we developed an ILS (Inquiry Learning Space) named "The power of electromagnetism", [1]. This ILS, combined with the laboratory, could help explain concepts such as magnet, electricity, electromagnetism, mass, weight, etc., in classroom.

An ILS is a web content framework that uses text, multimedia, links, etc. to create a learning environment using a website. The ILS contents a learning path that uses different phases to bring the content of a subject easily to the student. This path contents an Orientation, Conceptualization, Investigation, Conclusion and Discussion phases. The remote laboratory is content into the Investigation phase.

On the same way it was developed a simple, graphical user interface for the cited laboratory. The user interface shows what is happening all time on the laboratory, and it helps to explain on a visual way the above concepts.

As a result, it has developed the "Electromagnetic Crane Laboratory", [2]. This whole process, objectives and outcomes are explained in this paper.

II. A PRACTICAL, USEFUL AND REMOTE TOOL

When we develop a remote lab, we consider different factors that would help to deliver a session in classroom, but it also help the students to learn by themselves in practice the subject learned in theory. Definitely, we look for that this tool will be:

- Practice: it is essential that the student and the teacher have a real (not virtual) tool that allows them to demonstrate how the laws of physics work (in this case the electronics and magnetism) in a simple way, but reflecting all the potential and importance these laws have.

- Useful: it must be possible that this tool can be use in classroom by the teacher, but also directly accessible by students from home. This facilitates the students' ability to review the classroom session at any time the student wishes, and even facilitates further learning from home.
- Remote: this feature transforms the laboratory to a teaching tool that goes beyond the physical barrier of the classroom itself and the school building. Furthermore, the laboratory being available on Internet giving students and teachers access from home, which improves accessibility for students with physical barriers (disabled) or who, because of time, cannot access to the classroom in person.

Another interesting aspect of having a remote laboratory is being able to transfer the lessons to other environments. A teacher can travel to a remote village, a garden, or a museum with a laptop and there, conduct sessions using the remote laboratory. To do this, he/she only need an Internet access.

Classroom is no longer limited by the physical building where sessions are taught. With this tool, we can expand the environments, opportunities, and options for session learning.

Likewise, the teacher can prepare their sessions at home, using the remote laboratory without having to travel to the location of the laboratory. This allows him/her to save time and reduce travel costs as sessions can be prepared in advance and find and correct session errors. Also, teacher can test the practical exercises of the session previously presents them to the classroom. Since the remote laboratory is a tool, a teacher can use it to prepare and integrate their sessions, [3], [4]. The use of robotic or mechanical laboratories is a good method to bring closer the students to science and engineering, [5], [6].

III. USING FAMILIAR ELEMENTS BY THE STUDENT

It is needed to provide an easy user interface of the laboratory (Figure 1), but is also essential that the student is comfortable with that laboratory. To do this, there is nothing better than using everyday items that students can understand quickly.

In this case, we chose different elements that anyone can see daily in a city:

- Crane: in any city it is common to find cranes for construction. The element itself has been in use in one form or another for centuries and is an easily recognizable icon for any child. Also its use and operation is simple and straightforward: a rotational movement from right to left 360°, which in this case has been limited by certain physical bumpers (in this case 180°), and a limited upward and downward movement along the floor and the top of the crane.
- Polystyrene balls with tacks: play the role of a subject of study since the aim of the experiment is to deduct; using the tools and information given to it; the mass of each one. Each of these balls has a different amount of metal tacks whose work is twofold: firstly, be used to fix with security to the electromagnet, and secondly, to make these balls vary in grams (mass).
- Electromagnet: the key of this laboratory, which can be operated with different intensity by the student or teacher to raise a polystyrene ball and to deduce its mass.

Common and understandable elements for students of cited ages, but as well they are low in cost. If for any reason, parts need to be replaced, this can be done economically. So it is possible to increase the life of the laboratory and thus its profitability.

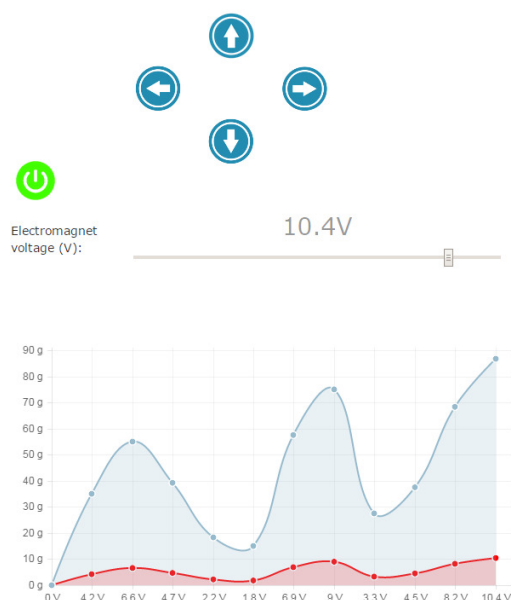

Figure 1. User interface of Electromagnetic Crane Laboratory.

As a result, the presentation of laboratory to the students is simplified, and the learning time to use it, is reduced. That, accompanied by a visual user interface with graphic elements indicating the degrees of movement or the voltage value, and a graph that can dynamically calculate the relationship between the applied voltage and the maximum lift mass, allows students to take the laboratory control almost from the start.

The development of theoretical formulation that confirms the usefulness of this laboratory is explained below.

The magnetic field energy per unit volume is:

$$w = \frac{1}{2} \mathbf{B} \cdot \mathbf{H} = \frac{1}{2} \mathbf{B} \cdot \mathbf{B} / \mu_0 = B^2 / 2\mu_0$$

$$[w] = \text{Joules/m}^3 = \text{Pascales}$$

Energy per unit volume of magnetic field is a pressure and can be interpreted as a magnetic pressure.

The magnetic force on a ferromagnetic material can then be calculated by multiplying by the area:

$$F = (B^2 \cdot A) / (2 \cdot \mu_0)$$

* B is the magnetic field (measured in Teslas)

* F is the magnetic field strength (in Newtons)

* A is the area of the pole faces (in m²)

* μ_0 is the permeability of free space ($4\pi \cdot 10^{-7} \cdot \mu_0 = \text{H/m}$)

As the magnetic field B will be produced by an electrical current I through a coil with N turns, we can write the field B as:

$$B = \mu \cdot N \cdot I / L$$

* N is the number of turns of the conductor

* I is the current in Amperes == V / R (electromagnet circuit)

* L is the length of the magnetic circuit

Substituting the force is:

$$F = (\mu \cdot N^2 \cdot I^2 \cdot A) / (2 \cdot L^2)$$

$$F = (\mu \cdot N^2 \cdot (V/R)^2 \cdot A) / (2 \cdot L^2)$$

Since each μ , N, R, A and L are constant then

$$F = K \cdot V^2, \text{ where } K = (\mu \cdot N^2 \cdot A) / (2 \cdot R^2 \cdot L^2)$$

$$[K] = N/V^2$$

Since $F = m \cdot g$, then

$$m = K \cdot V^2 / g = K' \cdot V^2$$

Thus we can calculate K' in a practical way by taking a series of samples and adjusting by a quadratic regression to a parabolic function

The chart reflects the above relationship and allows modifying the voltage dynamically inferring the mass of the ball by simply reading their approximate value in grams before they fall off the electromagnet.

Furthermore, intuitive elements have been searched for the user interface with the aim of increasing the ease of use by the student or teacher and looking for to simplify its usefulness. The elements used are:

- Buttons with their respective arrows, indicating the direction of movement. Clicking on them you can move the crane from right to left or up and down the electromagnet.
- Button to activate or deactivate the electromagnet. On that way user can turn on or turn off the voltage applied to the electromagnet immediately and directly.
- Slider to increase or decrease the power of the voltage applied to the electromagnet.
- Graph that indicates dynamically the relationship between the voltages applied to the electromagnet and mass to rise it at a given moment.
- Indicators that represent the final position of the crane and the voltage being applied to the electromagnet and to help user to see the motion and voltage limitations in each case.
- A webcam that allows students follow in real time the evolution of the whole laboratory all time. Both the crane itself and the process to follow to catch and release the test balls. It allows students deduce the mass of the ball by increasing or decreasing the voltage applied to the electromagnet.

All these elements facilitate interaction, reduce learning time to use laboratory and allow practical use of it without tutoring or monitoring.

At the same time, the development of the laboratory ensures the security and integrity of the internal software and hardware mechanisms that prevent the crane for a exceeding of a 180 degrees rotation, or a maximum application of more than 12 volts.

IV. USING REUSABLE ELEMENTS BY THE TEACHER

Another important element to consider is the use of reusable elements for sessions taught by the teacher.

For this, the laboratory should be configured as a tool in the teaching process. Laboratory was configured as an independent element but can be integrated into an existing learning environment.

In this case, within the theory explained in classroom sessions, the teacher can use the lab as a "test bench", where, without risk to himself/herself or his/her students, he/she can prove the theory previously taught.

In order to a remote lab will be a tool and not a problem for the teacher, it must meet certain characteristics:

- Easy learning: laboratory should be as easy to use as possible. The teacher should not have to spend much time learning to use it, because otherwise, he/she will not use it as a tool because the loss of time will not make it a practical tool.
- Neutral: laboratory must be neutral. That means that its design must be easily adaptable to different learning sessions or different ages. Thus, the laboratory can be integrated much better in any educational itinerary.
- Operative: laboratory should be used to check items already seen in theory. The interface, through the use of graphics, images, or mere observation, should address particular theoretical problems in an easy and reliable manner.

All these factors should help the teacher consider the laboratory as a useful tool, and feel free to use it when the occasion demands.

There is an important difference between a virtual laboratory and a remote laboratory. A remote laboratory lets use a real hardware, software and architecture. The user can manage and control robotic equipment (crane in this case) on your own in real time, and can see and test real behavior using a webcam.

The sessions were designed, by the teachers, fitting the age of the students. As an example can be cited that in early stages the theoretical content was focused on the physical concepts as mass or weight, but in older stages the crane was used to explain more difficult issues as parabolic movement among others.

Crane acts as an important factor to keep the attention and motivation of the students in sessions, but it is a useful tool for the teacher because can use it in real time any moment during the session to explain or complement theoretical concepts.

Both in early and older stages of age the crane has been a focus for several questions out of the mere subject, for example the students want to know how is possible to control the crane remotely and how works Internet of Things devices and architectures to let use the crane through Internet a browser and smartphones or PCs. All of this increases the learning experience of the students and teachers, and shows new

possibilities to get the attention of the student during the sessions.

V. CONCLUSIONS

Simplicity of use of this laboratory allows students and teachers to start using it from the beginning, both in person and remotely. Currently, the laboratory and ILS associated with it are hosted in the Go-Lab project repository allowing direct access from several schools in different parts of the world in real time.

This research decides to use the power of Internet of Things devices and architectures to bring new educational tools. Usually the Internet of Things point of view is more focused on the domestic, wearables, automotive or ludic uses, but as we have demonstrated on this research it is possible to move it to education and learning tools.

This flexibility of use and the ability to use the lab remotely are providing an educational value outside the classroom that makes it attractive for both teachers and students.

From a teacher's perspective, with the ability to integrate it into their sessions and adapt it to their specific needs, it becomes a tool to prepare his/her classes.

From the point of view of the students, the possibility of use it in the classroom and remotely allows them to review the sessions in the comfort of home if needed and as often as desired.

At the same time, the daily nature of the materials used for the development of the laboratory allows the teacher to justify new topics for discussion at his/her sessions, e.g. construction, physics, gravity, parabolic motion, etc.

From the beginning, teachers' suggestions and recommendations have been taken into account in order to enhance the usefulness of the laboratory.

The good reception of this laboratory has led to further discussions with Karbo School to continue developing new remote laboratories within the educational environment of primary and secondary levels.

UNED has been developing several projects in this direction and intend to continue on that line to strengthen engineering and technology among young people, and provide teachers with new tools to increasingly bring the experience to their students.

Abstract—Open Educational Resources (OERs) have provided new perspectives for the construction, access and sharing of knowledge. While OERs can bring benefits to, and impact on education, there are still challenges to their widespread production and use. One of the challenges faced by developers (including educators and practitioners) of OERs has been how to produce quality and relevant learning materials, capable of being reused and adapted in different learning situations. In our work we propose and define an agile learning design method to support the design and creation of OERs. It is based on agile practices from software engineering and on practices of learning design from the OULDI project at the UK Open University. We illustrate our ideas with an experiment that validates the proposed method through its application in the design and creation of an OER in the software testing domain. The results obtained so far have shown that the method is feasible and effective for the design and creation of OERs.

Keywords—open educational resources; learning design; agile practices

I. INTRODUCTION

Open Educational Resources (OERs) have provided effective mechanisms for open and flexible education, expanding access to knowledge with reduced costs and enhancing cooperation and collaboration. They promote and support innovative practices in teaching and learning. OERs can be characterized as teaching, learning and research materials in the public domain or released under an intellectual property license allowing their free use or re-purposing by others¹. They include full courses, course materials, lecture notes, modules, textbooks, streaming videos, images, software and any other tools, materials or techniques used to support the construction and access to knowledge.

Although the creation and adoption of OERs have been gaining support and incentives from institutions and researchers across the globe, the full potential of OERs has not yet been reached [14]. One of the difficulties faced by educators and practitioners is to understand the implicit design behind OERs to know how to reuse them in their own teaching contexts [17]. Making the design more explicit helps to capture its key aspects, as well as the learning objectives, the activities

and outcomes associated with the learning materials, supporting both teachers and learners [20].

Instructional Design (ID) is an approach for designing learning instructions. It is defined as a systematic application of scientific principles about “how people learn” to develop instruction [13,21]. The term “instructional” means anything that is done purposely to help and facilitate learning [22].

With the advent of Web 2.0, new approaches for designing learning materials have been proposed. Learning Design (LD) has emerged within this context, bringing a broader perspective to teaching and learning and helping with the definition, creation, and sharing of effective pedagogical designs of learning materials [12,17]. LD consists of a set of activities supporting the understanding, description and sharing of pedagogical design practices. Research on LD has increased in the last few years primarily due to a gap between the potential and actual use of technology to support teaching and learning [12]. However, initiatives to foster the design and creation of quality OERs with reduced time and costs are still incipient.

The need for systematic and flexible approaches to the design and creation of OERs is highlighted by several authors [2,24,25]. This paper offers a contribution to address this need, by proposing a method for the development of OERs that learns from practices in other disciplines, namely the practice of agile methods in software development.

Agile methods gained prominence in software development, to address problems of long delivery times, and of software that has not fulfilled its promises or solved what was required. They promote simplicity and flexibility to deliver products and services that are relevant and add value to the market in due time. One of the characteristics of agile methods is that they are “people-centered”, encouraging and prioritizing effective collaboration and involvement of users in the development to deliver software more quickly and efficiently [4].

The concerns and characteristics of agile methods resonate with the needs identified in the development of OERs, as previously mentioned. The collaboration and involvement of users (educators, learners) is also appealing in the context of the development of OERs [8,10].

In our work we propose and define an agile LD method to support the design and creation of OERs based on agile

¹ hewlett.org [last accessed on 03-2015]

practices from software engineering [1,7,26] and on practices of LD that originate in the Open University Learning Design Initiative (OULDI) project proposed by the UK Open University [12]. The OULDI was funded by JISC, a public body that supports and champions the use of digital technologies in education and research across the UK. Our proposal builds on a preliminary version firstly introduced by Arimoto and Barbosa [3]. We validate our method with an experiment involving the design and creation of OERs to teach software testing, a topic within software engineering education.

This paper is organized as follows. In section II we discuss related work; in section III we describe the main characteristics of the agile LD method for OERs; section IV reports on an experiment to validate the method by designing and creating an OER within a software testing domain; concluding remarks and further work are presented in section V.

II. RELATED WORK

Instructional Design (ID) has a long trajectory as an approach for designing learning instructions in a systematic way. "It is the process of deciding what methods of instruction are best for bringing about desired changes in student knowledge and skills for a specific course content and specific student population" [13,23]. Learning Design (LD) has emerged more recently over the last decade, primarily in Europe and Australia. "It has developed as a means of helping teachers make informed choices in terms of creating pedagogically effective learning interventions that make effective use of technologies" [18,12].

LD and ID are closely aligned but have distinct focuses. As argued by Conole [13], ID focuses on designing the instructions to meet learning needs for a specific audience and setting, while LD takes a much broader perspective and regards design as a dynamic process, which is ongoing and inclusive, considering all stakeholders involved in the teaching and learning.

The OULDI was initiated in 2007 to derive a more "practice-focused approach for LD" [11]. It defined a method, tools and a notation to represent LD including: (1) different types of design representations to help guide design decision-making process; (2) digital tools to help visualize and represent designs; and (3) mechanisms to encourage the sharing and discussion of learning teaching ideas, including face-to-face events [12].

Design representations in the OULDI include [11]:

1. *Macro-level* (the course map view): an overview of main components of the course to enable educators and practitioners to think about the design of a course using 4 dimensions: content and experience, guide and support, communication and collaboration, and reflection and demonstration.
2. *Meso-level* (the learning outcomes view): a notational vision showing how learning activities and assessment tasks are linked with learning outcomes of the course.
3. *Micro-level* (the task swimlane view): a map of tasks that the learners undertake to the learning materials and tools they use during the activities in the course.

4. *Pedagogy Profile*: types of activities in which learners participate during the course or sequence of learning events. These are categorized as assimilative, information handling, communication, productive, experimental, adaptive and evaluation.
5. *Course Dimensions*: details on the nature of the course, a refinement of the course map view.

As highlighted by Avraamidou and Economou [5], levels 1 up to 5 of the OULDI cannot be seen as separate parts. LD often requires refinement and improvement. This implies that the design process should allow moving back and forwards through the levels according to the needs. Although the OULDI approach intends to make the design more explicit, it does not specify the steps and guidelines for a LD process.

There are other initiatives using LD. Learning Activities Management Systems (LAMS) [15] is a platform that offers automated support for LD. This platform is used to design learning activity sequences, describing the whole teaching process including learning contents, learning activities, and assessment. The Learning Design Support Environment (LDSE) [19] is another initiative in this direction. Both LAMS and LDSE have in common more self-contained and complex environments than the OULDI, which difficult their use. The demand for the creation of learning materials as OERs within the expected cost and schedule, together with the lack of time [27] to produce these materials, also highlight the need for more agility in the LD process.

In the context of LD, there is a lack of initiatives that explore the use of agile methods; this is not the case with ID. Bahl [6] proposed an approach for ID based on ADDIE [28], and Scrum [26]. ADDIE is a generic model for ID used for the development of instructional materials and training; whilst Scrum is a well-known agile method used for the management and planning of software (and non-software) projects. The approach proposed by Bahl defines a linear and iterative cycle:

1. *Initiation and planning* of the overall project, including project definition, pedagogical needs, objectives, stakeholder's identification and high level budget and timelines.
2. *High level analysis* of functionalities needs to prepare a high level project plan.
3. *Iterative design & development* of functionalities reviewed by experts at the end of each iteration.
4. *Feature integration* of functionalities implemented throughout the cycles.
5. *Solution roll out* culminating with the closure of the project.

Willeke [29] discusses the use of Scrum in ID in an online educational course at Ohio Christian University with the following quantitative improvements:

- *Satisfaction*: positive feedback on the Scrum process, contributing to a better quality course.
- *Time saving*: the time invested reduced over 30%, and the time for total development dropped 40%.
- *Internal communication*: the interaction and communication within the team involved in the process increased, allowing problems to be solved quicker.

Despite this success, Willeke [29] mentions the need of a cultural change for the adoption of an agile approach in the educational environment. These initiatives also fall short of the application of some agile practices such as the active participation of users (e.g., potential learners), throughout the development. Our proposed method combines a wider range of agile practices with LD; in particular, it gives emphasis to the collaboration and active participation of users to ensure the quality and relevance of the produced learning material.

III. AN AGILE LEARNING DESIGN METHOD FOR OPEN EDUCATIONAL RESOURCES

We propose an agile LD method for OERs based on a combination of agile software design practices and OULDI practices. This method allows designs to be modified, repurposed and evolved according to the needs of users emerging during development. Pedagogical design practices are embedded in the development of OERs improving quality and facilitating reuse and adaptation. It also accommodates change and improvement, minimizing cost and impact.

The agile practices, in Table I, are combined with LD, assisting and guiding the design and creation of OERs:

- Users (educators² and potential learners) actively participate throughout the development, either in person or via collaborative technologies (wikis, microblogging, social networking and messaging systems). They assist in the identification and establishment of learning objectives, activities and pathways, content and assessment.
- Collaborative development is promoted by the constant interaction and communication amongst all involved. Several activities are carried out in group brainstorming and workshop sessions, either face-to-face or by synchronous communications tools (text mode or videoconference). This helps to reduce time and effort and enables effective design of OERs.
- Architecture/Design envisioning is used early in LD activities to sketch a design (initial architecture and resources) to obtain an overview of the OER, and help educators and potential learners to think about the key elements.
- Iterative modelling/design produces sketches of OER's modules that are revised in each iteration; they represent the learning activities, and connections to learning outcomes, content, the tools and assessment.
- Design storming is used for the flow of activities and the strategies for the development of the OER. It triggers refining and decomposition of activities into individual activities and tasks, helping educators and potential learners to reflect upon an aspect of design.
- Refactoring improves the learning structure and content without changing the learning outcomes. It is performed whenever an opportunity for change and/or improvement is identified.
- Evaluation is carried out early and continuously throughout the development, especially at the end of

each iteration. With the design of small modules of the OER, educators have the opportunity to check whether the modules designed are in agreement with those planned. It is possible to identify new designs, modifications or inclusion of new activities and content, and improvements in relatively short periods of time, minimizing the cost of change.

TABLE I. AGILE DESIGN PRACTICES

Practices	Description
Active users participation	Users are involved in the development process, helping to identify and solve problems and mistakes and providing rapid feedback to the team
Collaborative development	All team members constantly interact and communicate throughout the development process, promoting a collaborative and productive environment
Architecture/Design envisioning	Initial software architecture and requirements are designed at the beginning of a project to identify and think through critical issues
Iterative modeling/design	Software functionalities are designed at the beginning of an iteration to identify team's strategy for that iteration
Model/Design storming	Software functionalities are designed on a just-in-time (JIT) basis to reflect on specific aspects of team's solution
Refactoring	Small changes are performed to improve part of a solution without changing its semantic meaning
Early and continuous Evaluation	Testing and validation activities are conducted at the beginning of the project and extend throughout the development process

Our agile LD method is structured in four steps or macro-activities (Establish the initial architecture, Plan and create the structure, Refine the structure/create the content and Evaluate), as shown in Fig. 1.

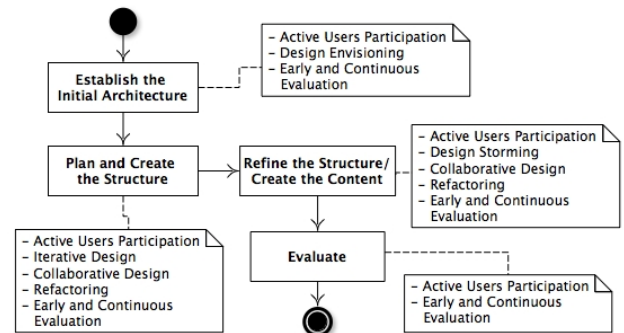

Fig. 1. Agile LD method for OERs: an overview

A. Establish the initial architecture

This step defines an initial architecture for the OER (Design envisioning) based on the Course Map View from OULDI. At the beginning of development, all users including educators and potential learners come together by a brainstorming session (face-to-face or by synchronous communications tools – videoconference) to identify and think about critical issues and the main elements of the intended learning. The initial architecture of the OER is sketched without too much detail (“just barely good enough”), as the design should be constantly evolving throughout the iterations.

Educators start by drafting the learning objectives and the context or domain of the OER. Irwin DeVries [16] highlights that many OERs do not have basic elements of LD such as learning objectives. This makes it hard to assess the OER in terms of its overall purpose, and the pedagogical alignment of learning materials, activities and assessment. He also argues that learning objectives are essential elements for reuse; they

² By using the term “educators” we also include practitioners, teachers, lectures and tutors.

help identify if an OER has the level of coverage and depth appropriate to be used in a different context.

Educators specify the context or domain in which the OER will be applied. For instance, whether the OER will be a key part of a course in the curriculum, a complementary part of a course, or a short specialization course. They also need to include cultural and languages issues in the OER's context.

Pre-requirements and specific knowledge needed to use the OER are defined. The estimated time (duration) for the application/use of OER in a particular course or training is also specified. For instance, a short course or class may require only a few hours while a full course (such as a complete software engineering course) may require weeks or months.

Educators identify the primary content of the OER. There is no need to identify all content a priori; further content can be added or changed throughout development. In order to identify content, the following issues should be considered:

- the way in which the OER will be delivered to learners, i.e., face-to-face, online or both;
- the way in which learners will be supported, i.e., face-to-face, online or both; and,
- the kind of activities learners will need to perform.

Typical examples of content include: lessons, lab activities, study guides, examples, readings, support materials, case studies, pilot projects, surveys, systematic reviews, and experiments/controlled experiments.

Educators need also to define learning assessment activities to help teachers gather evidence from learners to adjust and improve their teaching strategies. In the same way, learners can improve their learning strategies according to these activities. Learning assessment activities are defined considering:

- whether the assessment activities will be online, paper based or both; and,
- whether the assessment strategies will be diagnostic, formative, summative or all of them.

Typical examples of learning assessment activities include: in-text questions, self-assessment questions, brief in-class assessments, oral presentations, team projects, papers, essays, and exams (written or oral).

Educators also need to think about the way in which learners will interact and collaborate with educators and colleagues when using the OER within a course, and consider:

- whether learners will communicate and collaborate with their colleagues online, face-to-face or both;
- whether learners will communicate and collaborate with educators online, face-to-face or both; and,
- whether learners will perform their activities individually, peer-work or work in a group.

Typical examples of means of communication and collaboration include: synchronous and asynchronous tools (such as instant messaging system, forum and email), and face-to-face tools (such as workshops, brainstorming sessions, work in groups, peer-to peer works and seminar).

At the end of this step, all those involved in the design and creation of the OER (including educators, designers, media

creators³ and potential learners) need to agree on the initial architecture of OER and approve it.

B. Plan and create the structure

This step plans and creates a learning structure for the OER in the current iteration, representing the connections between the main elements for learning to achieve an effective learning pathway. The design is created "just enough for now, since we can always come back later" (Iterative Design)[1]. It prioritizes the most relevant aspects to be addressed by the OER. Other aspects considered less important are discussed later.

Initially, educators together with the designers, media creators and potential learners plan and agree the releases to be delivered in a short period of time, usually ranging from a week to month (depending on the complexity and size of OERs). In terms of OERs, a release corresponds to modules or small sets of modules (or components, topics) considered "ready" to be used by potential learners. A release is composed by learning activities, contents, assessments, roles and tools needed to meet the learning objectives of the OER.

The modules of the OER are designed in a few short iterations, each lasting hours, days or a few weeks. Short iterations promote visibility for the OER; an opportunity for users to perceive how the design and creation of the OER is progressing during the development.

Educators prioritize small modules or parts of the OER to be designed and created in the current iteration based on the initial architecture of the OER established in step A. They introduce these modules to designers and media creators, indicating what should be done with each one.

Educators along with designers and media creators come together in a brainstorming session to discuss the design of the OER to obtain a structured process for the learning. Based on the initial architecture of the OER, they establish the activities that learners will perform (learning activities) to achieve the desired learning results. This helps them reflect on the flow of the activities of the OER and the strategies for its development.

The learning activities are linked with the intended learning outcomes, content, tools and assessment activities. A sketch of this mapping is created based on the meso-level (learning outcomes view) from OULDI. The structure of the OER is reviewed and approved by educators and potential learners, serving as input for the next step.

C. Refine the structure /create the content

In this step the learning structure of the OER is refined and related content is created. Designers and media creators come together to discuss how to design effective learning materials with embedded pedagogical design practices. The active participation of all users (mainly the educators and potential learners) is essential.

Designers together with educators refine and decompose the OER activities in simpler activities and atomic tasks, helping them to reflect upon one aspect of the design solution

³ We refer to media creators the responsible for editing and updating all contents and media associated to the OER.

and how they can transform it for a more effective OER. This refinement is based on the micro-level (task swimlane view) from OULDI.

Learning content and the required media are developed: text documents, html pages, wikis, multimedia files (such as podcast, streaming videos and animations), images, open textbooks, and lecture notes. These materials can be developed from “scratch” or reusing third-part material. Educators and media creators should search for suitable materials that could be reused and adapted to meet the learning objectives.

When third-part material is used to compose a new OER there is a need to check and assess whether: (1) the file format is modifiable and suitable to the desired needs, (2) the licensing policies are explicitly defined, allowing reuse and modification, (3) the contents are from reliable sources (institutions engaged with education, renowned authors, etc.), (4) the content fit the didactic and pedagogical objectives, among others.

Licensing policies to share the OER must be established. An OER must be shared through an open license with little or no restriction on its (re)use and adaptation. The licensing policies for an OER need to consider: (1) the authorship and intellectual property rights of third-part materials (when used), (2) how the OER will be available (non-commercial allowed or not), and (3) the appropriate license according to items 1 and 2.

Primary metadata for the OER are identified and gathered. Metadata describe relevant characteristics of the OER, facilitating its reuse and recovery by search engines. When an OER has integrated metadata, any user can easily find it.

Media creators and users (educators/potential learners) work in constant collaboration. New solutions and improvements could be highlighted through feedback provided by interactions and cooperation with users. Media creators constantly refactor their solution aiming to simplify and enhance it.

The structure of the OER, activities and content are regularly reviewed throughout the development to detect mistakes and other problems which may affect the quality of OER. Media creators must update the work to reflect the necessary corrections and changes.

D. Evaluate

This step evaluates and approves the work and artifacts delivered in each iteration which compose a release. Educators and potential learners are involved in verifying whether the learning pathways associated with the content contribute to the learning. They also analyze whether the type of content and activities, learning assessment, and tools are appropriate to the purpose of the OER, e.g., aligned with the learning outcomes.

Peer review should evaluate the design quality, and academic staff and domain experts should also evaluate it.

Also, designers and media creators need to think about the strategy adopted during iteration, focusing on how they can improve their work. They should identify “what worked well” and “what did not work well” during the iteration. They also discuss “what needs to change and improve” in the next iteration. Lessons learned and feedback from the evaluation are

gathered and will be used for improving the following iterations, contributing to the continuous improvement process.

Early and continuous evaluation of the design process helps clarify the problems and solutions and identify the needs for corrections and improvements. The OER modules, or part of them, can be reviewed by educators and potential learners throughout the process, and any change can be made at any stage of the development. This is one way to ensure the design quality and therefore the OER as a whole.

Once the OER module (release) has been approved by the educators, it can be used in a teaching environment. Its use by a group of learners is critical to identify weaknesses and propose improvements. Educators should provide the support needed by learners in their activities and monitor their progress. Data about the learners experience should also be collected and analyzed to improve the quality of the OER.

Effective access to the OER release should be through platforms or repositories and institutional or stand-alone websites. Media creators need to check whether the OER is made available together with associated metadata, according to packaging standards, and appropriate license.

IV. APPLYING THE AGILE LEARNING DESIGN METHOD

An experiment was conducted within the software testing domain in order to evaluate the applicability and effectiveness of the Agile LD method by comparing it with an AD-HOC approach. With an AD-HOC approach the development is informal with no defined process to guide the development.

We chose to perform an experiment to allow a more rigid control on the environment, and a more rigorous manipulation of the phenomenon we study. An experiment can generate more concise results based on quantitative analysis, providing evidence of the validity of our proposal to create OERs. It can also allow the generalization of the results within a population, and the replication of the experiment.

In the experiment we refer to our proposal as AM-OER (Agile Method for the Development of Open Educational Resources). The research questions for the experiment were:

- How effective is the AM-OER in the creation of OERs compared to AD-HOC approach?
- How efficient is the AM-OER in the creation of OERs compared to AD-HOC approach?
- How much better are the results obtained by AM-OER compared to AD-HOC approach?

The subjects of the experiment were 8 participants including graduate students (MSc and PhD), educators and researchers in Computer Science from the Institute of Mathematics and Computer Sciences (ICMC) at University of São Paulo (USP).

The participants were divided into two balanced groups with the same number of participants. We also tried to create homogeneous groups according to the level of knowledge of each participant, especially in relation to the development of learning materials and software testing.

Both groups created the same module of an OER, representing a full class (3 hours of duration) within the

software testing domain, focusing on Functional (Black-box) Testing and its criteria, including Equivalence Partitioning Testing and Boundary Values Analysis. Each group had 4 hours and 30 minutes to finish the work.

Before the developmental activities of the experiment, the participants took part in a training, lasting 2 hours and 30 minutes. The training covered topics related to OERs and software testing, especially regarding to the specification of the OER module to be created within this domain. Furthermore, the group of participants that used the AM-OER was also trained into the main aspects of the method. The materials used in the training were also made available to the participants. During the experiment, the groups could not communicate each other.

We consider some factors that may affect and impact the analysis and interpretation of the results from the experiment. The main threats to validity of the experiment:

- *Internal validity*: the AM-OER method cannot provide well-defined steps to guide the development of OERs, requiring appropriate training.
- *Extern validity*: the number of subjects is relatively small and may not adequately reveal the applicability and effectiveness of the AM-OER in the development of OERs. The level of experience of subjects can also influence in the validation. Furthermore, the experiment must be performed in laboratories adequately furnished with computer and internet access.
- *Construct validity*: the responsible for the experiment must be careful with the treatment of variables in order to meet the objectives predefined.

A. General Overview of the OER Module

The group using the AM-OER created the module following the agile design practices for OERs discussed in Section III.

The learning objectives established for the module were:

- Students will summarize the fundamentals of Functional Testing.
- Students will argue and defend the two major Functional Testing Criteria: Partitioning Functional Testing and Boundary Values Analysis.
- Students will be able to apply the Partitioning Functional Testing and Boundary Values Analysis.

The module is in the context of a software testing course. The target audience includes undergraduate students in Computer Science and other related areas. It can also include students interested in learning about Functional Testing. As prerequisites and experience, the students must have basic skills on fundamentals of programming and software testing.

The content required for the module include guidelines, lessons, examples, supporting materials and specification and the implementation of a selected program (Calendar program named Cal). Assessment activities include essays, self-assessment questions and reports. The means of communication and collaboration include chat, forum, peer-to-peer work and discussion in group.

A sketch of the learning structure of the module is shown in Fig. 2. According to the figure, a student enrolled in a software testing course can take as *activity Design and execute test cases using Functional Testing Criteria*. A learning outcome could be that the learner has acquired practical knowledge on the subject (*Demonstrate ability to apply Functional Testing Criteria*) according to evaluations conducted throughout the course (*Report on Design and Execution of Test Cases*).

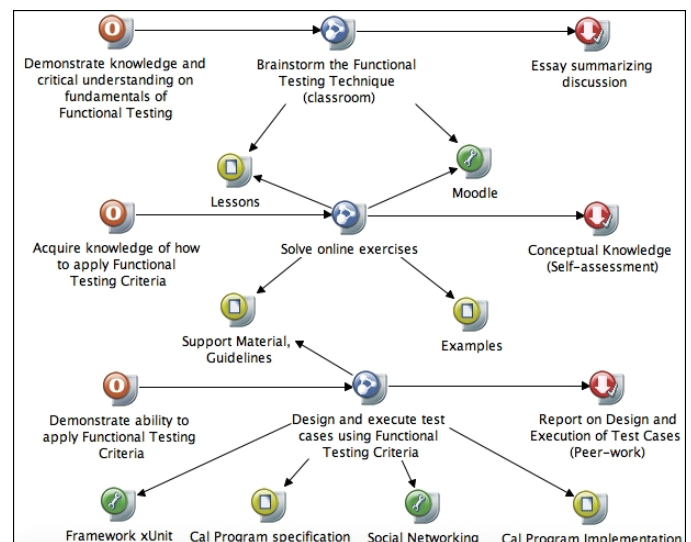

Fig. 2. Learning structure of the module

Figure 3 shows a sketch of a refinement of the structure of the module above for the activity *Design and execute test cases using Functional Testing Criteria*. It contains atomic tasks associated with their content and respective assessment activity.

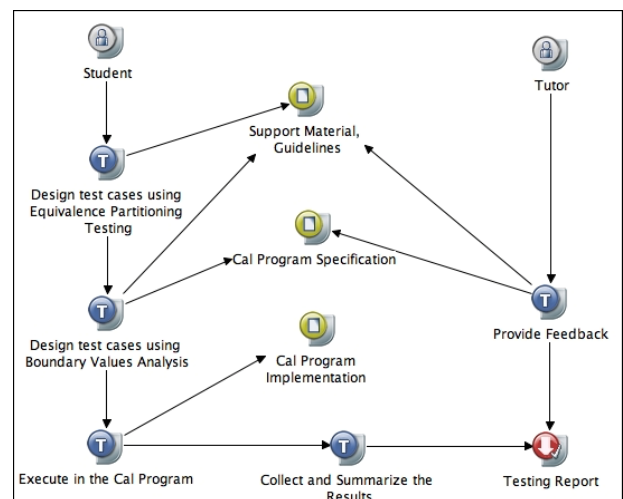

Fig. 3. Refinement of the learning structure

The Functional Testing module is composed by html pages, text documents, lecture notes, images and video. Fig. 4 shows one of the proposed activities to assess students.

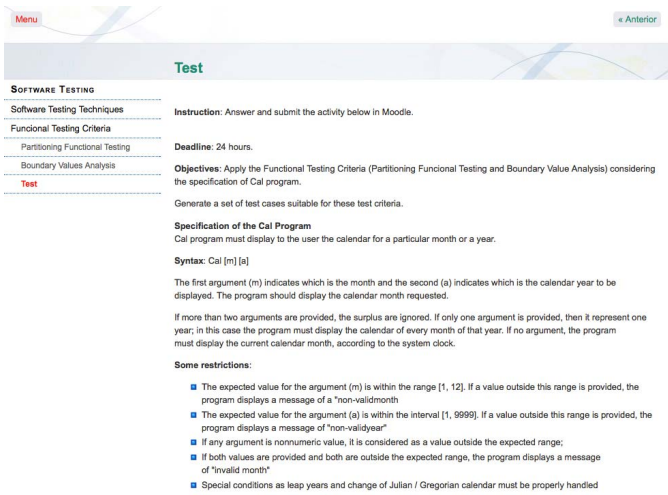

Fig. 4. OER on software testing

B. Comparing Effectiveness

Effectiveness measures the capacity of each approach in the development of the planned OER. It is related to the OER module “planned” to be developed and to the OER module “developed”.

Figure 5 shows the results obtained by each approach, displayed by box-plots representing the sample data in three quartiles. The first quartile or lower quartile (Q1) corresponds to the value related to a quarter of data. The second quartile (Q2) corresponds to the value representing the median of the sample data, whilst the third quartile or upper quartile (Q3) corresponds to the value representing three quarters of the sample data. The box-plots also show the minimum and maximum values of the sample. As can be observed, the minimum and maximum values of box-plots range from 50 to 100%. In the sample of AM-OER, most of the percentage of results achieved is between 80 and 100%.

Fig. 5. Results obtained by each approach

The metric to calculate effectiveness was: $\sum(x_i / y_i) * 100$, $i = 1..n$, where x_i is the average percentage of requirements fulfilled by each approach whilst y is the requirement planned to be fulfilled.

According to the results it seems AM-OER presents better level of effectiveness, achieving 86,2% against 65% of AD-HOC approach.

In order to statistically infer that the effectiveness of AM-OER is greater than the effectiveness of AD-HOC approach we test the hypotheses established for it. Both samples associated to effectiveness are presented as percentage. In this case, test for proportion is indicated.

The hypotheses related to effectiveness are:

- *Null hypothesis* (hypothesis we want to reject): the effectiveness of AM-OER is similar to the effectiveness of AD-HOC approach, $H_0: \mu_{AM-OER1} = \mu_{AD-HOC1}$.
- *Alternative hypothesis*: the effectiveness of the AM-OER is higher than the effectiveness of AD-HOC, $H_1: \mu_{AM-OER1} > \mu_{AD-HOC1}$.

In the experiment we adopt the usual practice of admitting a low value or level of significance for both errors: $\alpha = 0,5$.

To test both samples for equality proportions we use the function `prop.test()` from R software, a free software environment supporting statistical computing and graphics. The obtained result was $p\text{-value} = 0.004$. There is a statistical significance when the p -value is lower than the level of significance used in the experiment. Therefore we reject the null hypothesis $H_0: \mu_{AM-OER1} = \mu_{AD-HOC1}$ and accept the alternative hypothesis $H_1: \mu_{AM-OER1} > \mu_{AD-HOC1}$.

C. Comparing Efficiency

Efficiency measures the effort required by each group of participants to develop the planned OER. It is related to the OER module developed by each group of participants and the time (in hours) spent to develop it. The metric to obtain the efficiency was: $\sum(x_i / y_i)$, $i = 1..n$, where x_i is the average percentage of requirements fulfilled by groups on each approach whilst y is the time (in hours) spent by them.

Table II shows the results of efficiency obtained for each approach. It is noteworthy that the higher value obtained, the greater the efficiency. It seems that AM-OER presents better level of efficiency, 0.86 against 0.73 of AD-HOC approach.

TABLE II. EFFICIENCY OF EACH APPROACH

Approach	Time (in Hours)	Requirements Fulfilled	Efficiency
AM-OER	4.5 / 4.5 (100%)	86.2%	0.86
AD-HOC	4 / 4.5 (89%)	65%	0.73

In order to statistically infer that the efficiency of AM-OER is greater than the efficiency of AD-HOC there is a need to test the hypotheses established for efficiency:

- *Null hypothesis* (hypothesis we want to reject): the efficiency of AM-OER is similar to the efficiency of AD-HOC approach, $H_0: \mu_{AM-OER2} = \mu_{AD-HOC2}$.
- *Alternative hypothesis*: the efficiency of AM-OER is higher than the efficiency of AD-HOC, $H_1: \mu_{AM-OER2} > \mu_{AD-HOC2}$.

The result was $p\text{-value} = 6.174e-11$. Thus, we reject the null hypothesis $H_0: \mu_{AM-OER2} = \mu_{AD-HOC2}$ and accept the alternative hypothesis $H_1: \mu_{AM-OER2} > \mu_{AD-HOC2}$.

D. Comparing Quality Results

The quality of the results is measured by a specialist according to the percentage of compliance to quality attributes / desirable characteristics of an OER derived from the definition and main characteristics of an OER.

In Fig. 6, box-plots were created to show the percentage obtained by each approach regarding the quality of the results. The box-plot of AM-OER shows the results are closer to 80% and 100%, ranging from 50% (minimum value) to 100%. On the other hand, the box-plot of AD-HOC shows a higher variation, ranging from 0% to 100%. Discrepant values within of set of values are considered outliers (0%).

Fig. 6. Quality of the results of each approach

In order to statistically infer that the quality of the results of AM-OER is greater than the quality of the results of AD-HOC there is a need to test the following hypotheses:

- *Null hypothesis* (hypothesis we want to reject): the quality of the results of AM-OER is similar to the quality of the results of AD-HOC approach, $H_0: \mu_{AM-OER3} = \mu_{AD-HOC3}$.
- *Alternative hypothesis*: the quality of the results of AM-OER is higher than the quality of the results of AD-HOC approach, $H_1: \mu_{AM-OER3} > \mu_{AD-HOC3}$.

The result was $p\text{-value} = 3.419e-05$. In this case, there is an evidence to reject the null hypothesis $H_0: \mu_{AM-OER3} = \mu_{AD-HOC3}$ and accept the alternative hypothesis $H_1: \mu_{AM-OER3} > \mu_{AD-HOC3}$.

E. Qualitative Analysis

To explore the applicability of the AM-OER in the development of OERs we also investigate a set of research questions covering three perspectives: appropriateness/usefulness, ease of use and satisfaction. The answers for the research questions were provided according to the following scale: (a) 1 – Strongly disagree, (b) 2 – Partially disagree, (c) 3 – Indifferent, (d) 4 – Partially agree and (e) 5 – Strongly agree.

Figure 7 summarizes the results of all questions covering appropriateness / usefulness, ease of use and satisfaction by box-plots. According to the results, the majority of answers ranging between “4 - Partially agree” and “5 - Strongly agree”. The results show a tendency of the acceptance of the AM-OER in the development of OERs. However, other assessments must be conducted in order to provide more consistent results.

Fig. 7. Qualitative analysis

Participants also provided suggestions for changes and improvements to the AM-OER. The data collected during this analysis will be used later to refine the AM-OER.

This study shows that agile design practices together with LD practices are feasible to design and create OERs.

II. CONCLUSIONS AND FURTHER WORK

In this paper we proposed and applied an agile LD method to support the design and creation of OERs. Our main goal is to provide an explicit and flexible agile LD method that considers not only LD as a dynamic process but also allows for the design to evolve incrementally, and be modified, repurposed and enhanced as needed. We defined the agile LD method to facilitate the reuse and adaptation of OERs and to contribute to their quality by embedding pedagogical design practices. The method provides a more collaborative approach to the development of OERs, prioritizing the participation of users throughout the process to meet their real needs. This can reduce the development time and effort, promoting an effective production process for a sustainable supply of OERs.

The method has been initially evaluated through an experiment. Considering the quantitative analysis, the results obtained so far have shown that the method is effective and efficient to the development of OERs. In terms of its applicability, the preliminary results indicate that the method is useful and easy to use, especially for non-experts in the development of OERs.

Regarding the limitations of the experiment conducted, we highlight: the number of participants was small, what may affect the representativeness of the sample of population, and the time allocated to the experiment was not sufficient, but we were constrained by the unavailability of participants.

We intend to refine and evolve our proposal based on the results of the experiment and on the feedback from participants. For further validation, we plan to replicate the experiment on a larger number of subjects. Also, other experiments will be planned and developed within different knowledge domains. The OERs created by using our proposal should also be evaluated in terms of their effectiveness in student's learning.

ACKNOWLEDGMENT

We are grateful to the Brazilian funding agencies FAPESP, CNPq and CAPES for their financial support. We also thank the Open University (UK) by the opportunities and support given during internship (November/2013 to April/2014) related to this work.

Student-Perceived Effectiveness of Online Content Delivery Modes

Julia S. Mullen and John M. Sullivan, Jr

Department of Mechanical Engineering

Worcester Polytechnic Institute

Worcester, MA 01609

Email: jsm@wpi.edu, sullivan@wpi.edu

Abstract—This Work In Progress focuses on student perceptions of the effectiveness of three content delivery modes; a) traditional, residential in-class b) class capture for asynchronous online delivery, and c) modularized targeted content videos for online and blended or flipped classroom mode.

Despite the growth of MOOCs and the concomitant shift from long lecture videos to learning modules, many online courses still rely on a class capture method. A recent study on video use by students in online courses recommends the use of short videos, six to nine minutes in length, based on student viewing habits. [1] The student behavior was inferred from click-stream data captured within the LMS but there was no direct interaction with students to gauge impressions of the content delivery or impact on learning. To improve both the residential and online experience requires a deeper understanding of those features which promote learning in each approach. Some of this understanding can be gleaned from traditional academic course evaluations, but student perceptions yield an additional level of understanding.

For this study we analyzed data from multiple offerings of a 7-week graduate level numerical analysis course; Application of Finite Element Analysis. Over three years this course was offered residentially and online using multiple delivery modes. We categorize the delivery modes as Traditional, Class-Capture, and Modularized/Blended. Each student studied the material using one delivery mode and was then asked to review the material using another delivery mode. The students were asked to evaluate the perceived learning attained based on their original content delivery mode and the alternate mode. The feedback from this analysis, combined with traditional course evaluations will be used to develop a more comprehensive and objective survey to be used in the next round of courses.

I. INTRODUCTION

Increased focus on Massively Open Online Courses (MOOC)s has raised awareness of online learning and sparked significant debates about the value of online learning and its place in the academic landscape. Despite the debates, it is clear that graduate engineering programs must support both full and part time students. While full time students have the flexibility to attend lecture courses on a university schedule, most part time students are full time practicing engineers who need to take courses at a time and place that fits into an industrial work week. Traditionally this meant online courses where the in class lectures of a residential course were recorded and posted for remote students to watch offline. These courses are generally asynchronous with support via email, discussion boards and occasional video conferencing.

Concurrently, the use of technology to build online courses has lead to an increase in flipped or blended learning modalities at the university level. Here we define a Flipped or Blended modality as a learning modality that requires the student to independently work through content and course material prior to a face-to-face class meeting. Using this definition we see that "Flipped Classrooms" are not novel, as any liberal arts seminar course requiring reading prior to a discussion section or engineering course requiring laboratory preparation prior to a laboratory can be considered blended or flipped. We choose this definition for the simple reason that engineering education must be a combination of theory and practice and we aim to increase the amount of time devoted to building solutions such as devices, systems or software. Furthermore, as content has moved online in the form of documents, ebooks, websites and YouTube videos, what the engineering professor offers a student is the example of an expert's approach to design, analysis and trouble-shooting. For students, a blended learning environment offers the opportunity for the novice to observe the way an expert approaches application of the theory to the design, development, testing and modification cycle to create a solution.

Despite increased use of video and screen capture presentations in both online and blended course instruction, there is little research regarding the relative effectiveness of these delivery mechanisms. Several studies aimed at capturing student perceptions of the flipped classroom pedagogy [2], [3] focused on student acceptance of the new pedagogy. While the outcomes were positive and qualitative evidence suggests that students create deeper understanding using the flipped classroom this does not address the effectiveness of the delivery mechanisms. Older studies, such as [4] compared fully online to blended learning, asking students to connect the format to their level of learning, while [5] considered the components and interface design required for effective e-learning. These studies parallel the comparison of traditional classrooms to the flipped pedagogy, providing important insights into student preferences but don't directly address the effectiveness of the delivery. The aim of this study is to uncover a set of questions and metrics that can be used to capture the benefits and limitations of various delivery modes.

II. METHODOLOGY

The course used for the study was a graduate level Mechanical Engineering course in the application of the Finite Element Method. The students ranged from upper level undergraduates pursuing a BS/MS program to second year graduate students. The course included the theoretical and practical development of numerical simulations of physical phenomena using the Finite Element Analysis. As with any numerical technique, the practical aspect of Finite Element Analysis required developing software solutions for each assignment. While some engineering disciplines have extensive undergraduate experience with software development, in general this is not true of mechanical engineers. On average the students were familiar with using third party software but had little programming experience and no software development background.

Over the past three years the course has been offered for residential and remote students using multiple delivery formats. The residential section was offered once using traditional lecture and twice using a blended format. During the same time, the online section was offered four times, twice using class capture and twice using modular videos targeted for each topic covered in the course. The modularized videos are part of a course redesign using the edX pedagogy. [6] In this design, each section of a traditional lecture course is broken into individual concepts that must be mastered by the student. The decomposition yields a concept map where each concept is equivalent to a unit within the edX course pedagogy. When using the edX approach to building a course, concepts are delivered using video, written text and simulations. Interspersed between the concept units are assessment units; questions, problems and discussion topics meant to review and consolidate the learner's understanding of the concept. At the time of the last Finite Element Analysis offering we did not have an open edX instance running for students, so we incorporated the philosophy into each of the targeted videos, notes and questions and supplied them through our Blackboard platform.

For this study, the Class-Capture mode relied on lecture capture, wherein each two-hour, in-class lecture was captured and posted for asynchronous viewing. Our second method for content delivery examined the modularized, targeted topic videos described above. The modularized presentations spanned the same course content as presented in the in-class and lecture-capture sections. A third content delivery mode flipped an in-class course offering by delivering the modularized content online prior to class meetings, using the same targeted topic videos. Within the formal class time, students worked on homework and group endeavors, but did not receive formal lectures. We categorize the delivery modes as Class-Capture, Modularized, and Blended, respectively.

Our initial appraisal of delivery styles is based on standard course evaluations used at our institution. The questions closely resemble those in [4]. The Institute's standard course evaluation includes twenty-six questions primarily focused on evaluating the instructor's teaching ability. All questions are to

be answered relative to other courses taken at the institution and are scored on a five point scale where 1 is "much less" and 5 is "much more". We selected the four survey questions that emphasized student perceptions of learning and effort, namely

- The amount I learned from the course (relative to other courses) was
- The intellectual challenge presented by the course (relative to other courses) was
- The amount of reading, homework and other assigned work (relative to other courses) was
- The amount of effort I put into this course (relative to other courses) was

The responses to the course evaluation questions provide some insight into the student perceptions of the overall course relative to other courses at the same institution. To develop a better understanding of the relative merit of class capture and modular, single concept videos, we asked the summer 2015 online section the following questions:

- does the shorter single concept video v the class capture video help you learn?
- what is the added benefit of the single concept video?
- what are the drawbacks of the single concept video?
- some videos are still 20 mins long, would it be better to break these up?

This unscientific survey produced anecdotal information that helped us frame our most recent experiment.

Based on the answers to the evaluations and the anecdotes from the summer online section, we selected a topic common to the course that had been taught in multiple modes. To capture student perceptions of the content presentation modes, we asked students to review the material using a delivery option different from that used in the course they had completed. We selected a specific topic, Numerical Quadrature, for the content delivery comparisons. The Class-Capture mode covered this topic in a two-hour lecture. The Modularized delivery mode used three 10-minute objective-specific videos. Each video included two self-check assessment sections to verify student understanding of the concepts presented in the video. The Blended delivery used the same three objective-specific videos, but replaced the self-check assessments with an in-class group project with Instructor support as needed.

The study participants are students who successfully completed the course within one of three delivery modes. The students were asked to evaluate the perceived learning attained based on their original content delivery mode and the alternate mode by answering the following questions.

- What was your level of understanding the theory?
 - based on your original class delivery mode
 - based on the alternate delivery mode
- How confident are you to be able to use this material in a future application?
 - based on your original class delivery mode
 - based on the alternate delivery mode
- How do you rate the ease of information retrieval at some later point in time?

- based on your original class delivery mode
- based on the alternate delivery mode
- What modifications would aid your learning having experienced at least two class delivery modes?

We acknowledge the inherent bias that will exist when a student is asked to review previously presented material via a new delivery mode. However that bias exists in all situations. Those students that initially received a modularized delivery mode will receive the lecture-capture style and vice versa. The bias associated with going from mode A to mode B will be consistent with (and hence negate) that of going from mode B to mode A.

These responses, in combination with the evaluations and summer student survey will be used to gauge the effectiveness of different online delivery modes. The last question is an open-ended question which will guide future studies delineating the differences between class delivery modes in terms of student learning and effectiveness.

III. PRELIMINARY RESULTS AND DISCUSSION

A. Course Evaluations

Table I presents the results from the current course evaluations as gathered for all courses at our institution. The table is presented for three course delivery modes: a) Traditional, residential in-class delivery; b) Lecture capture purely online; and c) Blended/Modularized Online.

TABLE I
INSTITUTION COURSE EVALUATIONS

Question	Traditional In Class $N = 33$ \bar{x}, σ	Lecture Capture Online $N = 17$ \bar{x}, σ	Blended/ Modularized $N = 16$ \bar{x}, σ	Significant Difference at 95% Level
1	4.73, 0.45	3.59, 1.3	4.5, 0.76	Yes
2	4.72, 0.46	4.41, 1.1	4.64, 0.63	No
3	4.33, 0.78	3.82, 0.88	4.07, 0.83	No
4	4.67, 0.54	4.41, 0.80	4.38, 0.77	No

The blended/modularized online mode had two subgroups - those that did the blended or flipped classroom and those that did the modularized online course redesign following the edX pedagogy. However, there was no statistical difference between these two delivery modes and their results were merged in column 4. There was no statistical difference between the Blended/Modularized delivery mode vs the Traditional In-Class mode, columns 2 and 4. However, there was a statistical difference at the 95% confidence level between the Traditional In-Class Mode and the Lecture-Capture Mode (columns 2 vs 3) for question 1 as delineated in the last column (column 5).

Question 1 asked the student how much they had learned relative to other courses. The student responses strongly indicate that they learned the least when the class delivery mode was lecture capture. The intellectual challenge, amount of reading and amount of effort between the delivery modes was not significantly different, questions 2 thru 4, respectively.

B. Summer Student Survey

In the summer of 2014, a 7 week online section was taught using the edX style modular approach. During the third week of the term, at roughly the half way mark, an informal survey was sent to the students, using the questions previously itemized in the Methodology Section. The number of responses was small and are included here as anecdotal information that helped inform the next phase of our study. The overwhelming response was that the shorter modular videos lead to greater understanding because

- it was easier to focus on the single topic and be confident that they understood the concepts
- the topic and concepts weren't lost in a lot of other information
- it was easier to rewind and review the shorter video.

While all of these comments suggest more effective learning using shorter videos, the last comment is particularly significant. Students stated that they were more likely to review a short one or two concept video when they got stuck or confused particularly while attempting to apply the concepts to the development of scientific software.

C. Ongoing experiment

The evaluation questions described in the Methodology were sent to previous students coupled with a link to the material presented through an alternate delivery mode. These responses will be tabulated and added to our existing results by the end of this summer.

IV. CONCLUSION AND FUTURE WORK

We delivered three variants of a graduate level Finite Element Analysis course to residential and online students. The variants included traditional lecture and lecture capture, targeted concept videos for online sections, and a blended (or flipped) section using targeted concept videos for the content delivery and pre-class preparation. Based on course evaluations and a brief survey of online students, we created a set of questions to ascertain student perceptions of delivery mode effectiveness. Using these questions, we surveyed students to gain insight into the effectiveness of delivery strategies. To accomplish this, students who has successfully completed the course in one of these modes were asked to review the Numerical Quadrature module delivered in a mode different from their initial introduction.

This Work In Progress analysis provides another step toward understanding how to create and deliver online content effectively, whether for online or blended courses. To improve the quality of both online and blended learning, we need to determine what questions, learning management system analytics and assessments best highlight the adjustments needed to strengthen learning and understanding.

Topic Based Segmentation of Classroom Videos

Tayfun Tuna, Mahima Joshi, Varun Varghese, Rucha Deshpande, Jaspal Subhlok, Rakesh Verma

Department of Computer Science

University of Houston

Abstract—Video of classroom lectures is a valuable and increasingly popular learning resource. A major weakness of the video format is the inability to quickly access the content of interest. The goal of this work is to automatically partition a lecture video into topical segments which are then presented to the user in a customized video player. The approach taken in this work is to identify topics based on text similarities across the video. The paper investigates the use of *screen text* extracted by Optical Character Recognition tools, as well as the *speech text* extracted by Automatic Speech Recognition tools. An automatic text-based segmentation algorithm is developed to identify topic changes and evaluated on a set of twenty-five lecture videos. The key conclusions are as follows. Screen text is a better guide to discovering topic changes than speech text, the effectiveness of speech text can be improved significantly with the correction of speech text, and combining screen text and accurate speech text can improve accuracy. Results are presented from surveys showing a high level of satisfaction among student users of automatically segmented videos. The paper also discusses the limits of automatic segmentation and the reasons why it is far from perfect.

I. INTRODUCTION

Video is gaining popularity as a learning resource. Video recordings of classroom lectures are often made available as additional material for a conventional course, as the core of a distance/hybrid learning course, or posted publicly for community learning. Lecture videos are posted on a large scale on portals such as MIT OpenCourseware and Apple's iTunes University. In recent years MOOCs (Massive Open Online Courses) driven by video and other features have emerged as a potential disruptive technology for the delivery of education. There is a substantial body of research that has established that video is a versatile learning resource that is considered valuable by students and instructors [1], [4], [15], [17], [18]. The lecture videos that capture the overall classroom interaction provide an experience that mirrors the actual class to the students who are not able to attend. However, video is also commonly employed by students to access specific information, not just to replace missed lectures. In particular, review of the class content, e.g., for quizzes and exams, is an important use of video. Efficient retrieval of the appropriate information in a long lecture video is a major challenge with the video format. Therefore, dividing videos into topical segments is important for the advancement of video as a learning tool.

The research presented in this paper is in the context of the ICS (Indexed, Captioned, Searchable) Videos project at the University of Houston[18], [22]. The goal of the project is

to ease navigation of lecture videos, making them a companion resource for learning, similar to a textbook. A video lecture is automatically partitioned into segments based on image and text analysis. We refer to this process as *indexing* or *segmentation*.¹ Video is searchable for keywords and concepts. Captions are developed for videos with speech recognition and crowdsourcing by students. All videos for an entire course (or department) are treated as a single “videobook” stream with global indexing and search capability. Several thousand students were surveyed and hundreds of students participated in focus groups during the project. Conclusions from this project relevant to the research presented in this paper are i) videos are a very valuable learning resource and ii) indexing enhances the value of videos significantly [3], [22].

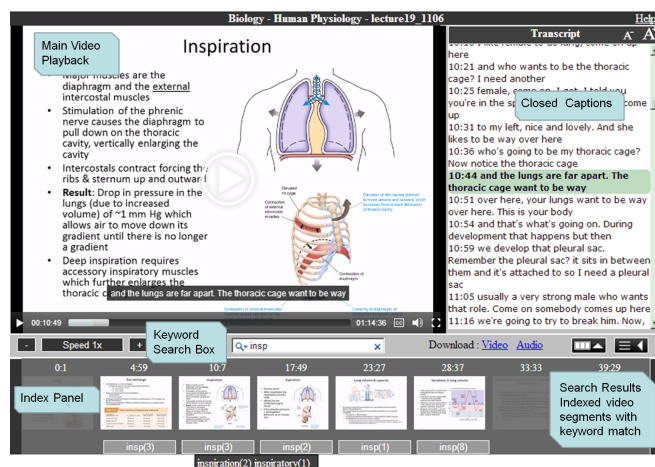

Fig. 1. ICS Video player with index points, search box, captions and transcript

The ICS Video player that encapsulates indexing, search, and captioning is illustrated in Figure 1. An index panel is situated on the bottom of the player; each index point represents a new topic in the form of a screen-shot of the video at that point of time. Users can navigate different topical segments of the video by clicking these index points. A search box is located below the main video playback for searching inside the video. Keyword search across videos is also supported. Captions are displayed as an overlay at the bottom of the main video playback window, in addition to a separate transcript window on the right side.

The goal of the research presented in this paper is to automatically partition a lecture video into topical segments, which can then be presented to the users as visual index points. However, automatically segmenting a video lecture by topic or

Contact email: jaspal@uh.edu

¹In this work, the terms *indexing* and *segmentation* are used interchangeably.

subtopic is a very challenging problem as the precise meaning of a topic is subjective. The approach taken in this work to identify topics is based on text similarities across the video. A segmentation algorithm based on *cosine similarity*, a common metric to measure the similarity between two blocks of text, was employed. For topic-based segmentation, two approaches were investigated based on *screen text* or *speech text*. Screen text is the text that appears on the video frames, which typically corresponds to the viewgraphs used in teaching a class, but can also be from other sources such as web pages. Screen text is extracted with the help of optical character recognition (OCR) technology [20]. Speech text is the text corresponding to the audio in a lecture video, which includes everything spoken by the instructor as well as the interaction with students. Speech text is gathered by using an Automatic Speech Recognition (ASR) system. For selected videos, automatically generated speech text was corrected manually to remove errors in speech recognition.

Evaluation was done on a set of twenty-five lecture videos from courses in Computer Science and Biology and Biochemistry. The ground truth was established by asking the lecture instructor or another topic expert to manually identify topic transitions in the video. The segmentation obtained with screen text, speech text, corrected speech text, and combinations of these were evaluated for accuracy against the instructor generated ground truth. The inherent inaccuracy of human segmentation was also measured by asking multiple subject experts to segment the same videos by topic. The results show the accuracy of different approaches to segmentation as well as the limitations of the text based automatic segmentation process. The main reasons for errors in automatic segmentation are also presented based on a manual analysis of some of the videos employed for evaluation.

This paper is organized as follows. Section II discusses prior work related to segmentation of lecture videos. Section III discusses the extraction of screen text and speech text. Section IV presents the text based automatic indexing algorithm. Section V discusses the evaluation methodology and presents the results of indexing algorithm employing screen text and speech text. Section VI presents the results of evaluation of indexing by student users based on survey results. Section VII discusses the reasons for indexing errors with slide text and speech text. Section VIII contains conclusions.

II. RELATED WORK

In general, video segmentation or indexing requires the detection of key frames or labels that indicate a change of content in a video [6], [8], [11], [14]. A multitude of methods have been developed that use low-level image properties, such as color and texture, to group contiguous video frames and provide reasonable automation while lacking the ability to provide topical segmentation [2], [7], [12], [16]. The work presented in this paper focuses on classroom lecture videos or screencasts. We employ similar techniques as a preprocessing step for detecting the slides in lecture videos.

Topic based segmentation of lecture videos requires processing the screen text extracted by OCR, and/or speech text extracted by ASR. Various methods have been developed that use both OCR and ASR data for content-based video retrieval,

semantic multimedia retrieval, and meta-data generation [10], [13], [25]. Extraction of segments and keywords from both OCR and ASR methods and ranking the keywords is discussed in [25]. Comparing the speech text segments for similarity to determine the topic boundaries is studied in [10] employing a dictionary-based approach that compares selected features among segments. However, human supervision is required for customizing the dictionary for a particular subject area. The indexing in our work is different as the video indexing method is unsupervised and fully automated.

In summary, the main directions of related research are indexing of movie videos, segmentation based on visual properties, and extraction and analysis of OCR and ASR keywords. These are complementary to the work presented in this paper. The main subject of this paper is how speech and text compare as the input for segmentation of videos, if they can be used together, and the reasons why these approaches often fail.

III. EXTRACTING TEXT FROM VIDEOS

The main research objective of this paper is segmentation of video lectures based on textual content of the lectures. Here we discuss how different types of text are extracted from a video.

A. Screen Text

Screen text is obtained by applying Optical Character Recognition (OCR) tools to video frames. Typically this text corresponds to viewgraphs employed during the lecture but can also include other content such as web sites or files displayed during a lecture. One of the premises of this research is that an analysis of screen text can provide guidance on topic transitions in a video lecture.

After a comprehensive analysis of available OCR tools, we opted to use the MODI (Microsoft Office Document Imaging) tool set. We found that OCR tools generally have limited effectiveness at recognizing text in the presence of 1) certain text and background color and shade combinations, 2) text mingled with colorful shapes, and 3) small and exotic fonts. To increase the detection efficiency of text on video frames, we used simple image processing techniques for image enhancement (IE) prior to the application of OCR tools. IE operations employed include segmentation of text, enlargement with interpolation, and color inversion. The process of obtaining screen text from videos employed in this research is detailed in [23]. Typically an accuracy of well over 90% is obtained with this enhanced OCR extraction framework. Hence this work does not consider manual correction of OCR errors.

B. Speech Text

Spoken text is simply the text corresponding to the audio in a recorded lecture. It primarily consists of the lecture from the instructor but may also include student interaction. Speech text can provide important information that determines topic changes in a video.

Various ASR(Automatic Speech Recognition) tools are commercially available and we experimented with *Dragon Naturally Speaking*, *Windows Speech Recognition*, and *YouTube*. In the end, YouTube was employed based on an

analysis discussed in [5]. The accuracy of speech recognition varies widely based on the instructor and lecture content. The average accuracy in our experiments was only around 68%.

C. Hybrid Text

Hybrid text is simply the union of screen text and speech text. In order to utilize the strengths and topic-related keywords from both speech and screen text, we employed a hybrid text type for video indexing purposes. It should be noticed that the volume of speech text typically far exceeds the volume of screen text.

D. Corrected Speech Text

All ASR tools generate significant errors when employed on the speech component of classroom videos. There are various reasons for errors, such as a heavy accent, technical vocabulary, poor recording, and the colloquial nature of a classroom lecture. The speech text was corrected manually using a crowdsourced caption editor [5] in order to evaluate the impact of ASR errors on topic based video segmentation. The average speech text accuracy on selected videos was improved from 68% to 99% with this correction process.²

IV. TEXT-BASED INDEXING

Indexing is the task of dividing a lecture video into segments that contain different topics. A video is composed of a sequence of thousands of images (or frames). In order to process video data efficiently, a video segmentation technique should detect scene changes and find the unique images. Therefore, video segmentation task involves two steps as depicted in Figure 2. First step is preprocessing to identify all transition points, i.e., places where the image on the video changes significantly. Subsequently, a subset of these transition points are selected as index points representing topic change based on text analysis. The assumption is that topic transitions happen at transition points which typically represent slide changes in a lecture.

A. Preprocessing: Identifying Transition Points

Identification of transition points is based on a comparison of successive frames in the video. Frames are commonly recorded in 24-bit RGB representation; color value for each pixel is encoded in 24 bits where three 8-bit unsigned integers (0 through 255) represent the intensities of red, green, and blue. Corresponding pixels in successive frames are considered different if they differ by a minimum RGB threshold when the RGB values of the pixels are compared. The threshold value is chosen empirically after evaluation of a large number of diverse lectures. Details of the process of identification of transition points is discussed in [23].

²About 1% of the words were not correctly identified by students making the corrections manually. The ground truth is the instructor's version of the transcript.

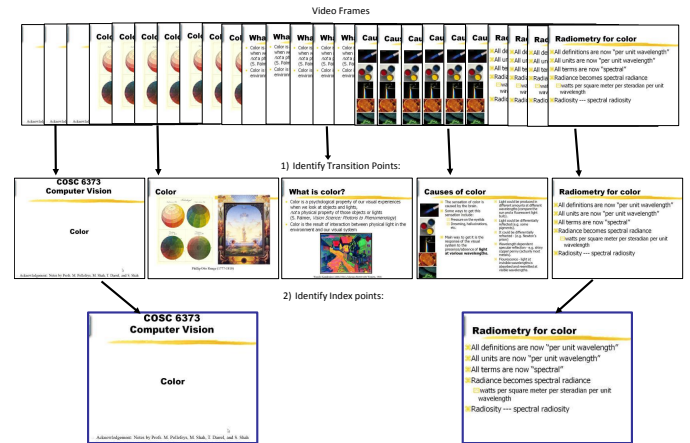

Fig. 2. Indexing framework steps: 1) Transition points (unique video frames) detected by RGB Color difference. 2) Index points representing different topics are selected among the transition points.

B. Text Similarity Metric: Cosine Similarity

The core idea of text based segmentation is that different topics are represented by different groups of words. Comparing the frequencies of different words in blocks of text establishes how similar they are in content and topic. Intuitively, a video splits into different topical segments at the point where the mix of words being used in video frames changes significantly. And this change can be detected by a comparison of the similarity of two text blocks. While many different text similarity metrics have been discussed in literature, we used *cosine similarity*, a well known and proven metric in information retrieval and text mining [9], [19]. It is a measure of similarity between two vectors, calculated by the dot product of the vectors divided by the product of their norms as shown by the formula below. The vectors A and B correspond to the frequency of words in the context of text based segmentation.

$$\cos(\theta) = \frac{A \cdot B}{\|A\| \cdot \|B\|} = \frac{\sum_{i=1}^n A_i \cdot B_i}{\sqrt{\sum_{i=1}^n A_i^2} \cdot \sqrt{\sum_{i=1}^n B_i^2}}$$

An example of text similarity calculation is depicted in Figure 3. Three frames and their word frequency vectors are listed. The cosine similarity between the vectors representing adjacent frames is computed as follows.

$$\begin{aligned} \text{cosine_similarity}(Frame_1, Frame_2) &= 0.57 \\ \text{cosine_similarity}(Frame_2, Frame_3) &= 0.19 \end{aligned}$$

This matches the intuitive judgment that $Frame_1$ and $Frame_2$ are more similar to each other than $Frame_2$ and $Frame_3$. The implication is that any topic change inside this sequence should start with $Frame_3$. Cosine similarity measure is normalized with respect to document length as it compares the relative frequency of common words.

C. Text-based Indexing Algorithm

The main purpose of the indexing algorithms is to partition a lecture video so that each segment represents a topic. Before the indexing phase, the lecture video is divided into transition segments. [21], [24]. The segmentation algorithm repeatedly

	Frame1	Frame2	Frame3
			
	Birds fly. Birds chase fish.	Cats chase birds. Cats eat fish.	Trees are green. Birds visit trees.
	Frame1	Frame2	Frame3
birds	2	1	1
cats	0	2	0
chase	1	1	0
fish	1	1	0
fly	1	0	0
green	0	0	1
trees	0	0	1
visit	0	0	1

Fig. 3. A sequence of frames and their frequency of word vectors is computed to determine similarity text similarity

merges the smallest segment in the video to the segment on the right or left, based on cosine similarity with a group of segments on the left, and a group of segments on the right, respectively, as illustrated in Figure 4. An empirically selected value of *Grouping Duration (480 seconds)* determines the number segments on the left and right that are included for text comparison. The algorithm is explained as follows.

Data: A list of transition points ;
Required number of index points (N);
Grouping duration in seconds;
Result: N index points that are a subset of given transition points;
repeat
 Select transition segment with smallest duration;
 if the similarity is more towards right group **then**
 merge right;
 else
 merge left
 end
until Number of transition points == Required number of index points;
Algorithm 1: Text-based indexing algorithm

A pictorial example of the algorithm is provided in Figure 4. In this example, the similarity of the smallest segment K is compared with the left as well as the right group and merged with the most suitable neighbor depending on the similarity value.

We have employed a simple indexing algorithm that assumes a fixed number of index points. A detailed comparison of different algorithms is included in [21]. However, the goal of this paper is to compare speech text and screen text as the input for indexing, and we believe this algorithm is adequate for this purpose.

Fig. 4. Text based indexing algorithm: Shortest segment compared to left and right group of neighbor segments and merged based on similarity

V. EVALUATION

The objective of evaluation is to measure the accuracy of segmentation based on screen text and speech text.

A. Evaluation Framework

A suite of 25 video lectures listed in Table I was selected for evaluation. The subject areas were Computer Science and Biology and Biochemistry. The sources of the video were lectures recorded at the University of Houston and the Coursera website. The textual content of the videos was obtained by using OCR methods and YouTube as discussed in Section III. For a subset of the videos, the text obtained from YouTube was manually corrected for ASR errors for evaluation.

TABLE I. LIST OF SOURCE OF COURSES USED FOR EVALUATION

Source	Major	Course Name	Lecture Count
UH	Computer Science	Introduction to Computing	4

UH	Computer Science	Digital Image Processing	2
UH	Computer Science	Computer Architecture	2
UH	Biology	Human Physiology	3
Coursera	Computer Science	Compilers	3
Coursera	Computer Science	Cryptography	2
Coursera	Computer Science	Machine Learning	2
Coursera	Computer Science	Probabilistic Graphical Models	2
Total			25

A major difficulty in evaluating an automatic segmentation algorithm is that the ground truth, i.e., the optimal set of index points, is often not obvious even to the instructor of a course. It is very challenging to decide if a transition point is the start of a subtopic or not. The creator of each lecture video (normally the instructor teaching the course) was asked to rate every transition point on its appropriateness to be an index point based on the extent to which it represented a change in the topic. The following scale was used for ranking:

- Definitely Index Point (+2)
- Probably Index Point (+1)
- Probably Not Index Point (-1)
- Definitely Not Index Point (-2)

However, the output of the segmentation algorithms is binary, i.e., each transition point is determined to be an index point (1) or not an index point (-1). The quality of the set of index points identified by an automatic indexing algorithm is determined as follows. Suppose the ground truth for a transition point is “Definitely Index Point”. Then if the algorithm correctly identifies it as an index point, +2 is scored, while if it is incorrectly identified as not an index point, then -2 is scored. Now suppose the ground truth for a transition point is “Probably Index Point”. Then if the algorithm correctly identifies it as an index point, +1 is scored, while if it is incorrectly identified as not an index point, then -1 is scored. Similarly, +2 or -2 is scored for segments rated as “Definitely Not Index Point” and +1 or -1 for segments rated as “Probably Not Index Point”. The scoring mechanism is illustrated in Figure 5. The sum of all individual scores is added to determine the raw indexing score for a video that we label as the Video Indexing Score (VIS).

Suppose the video lecture contains n transition points. Each transition points will have a ground truth score and an algorithm score. If G_i and A_i are the ground truth score and the algorithm score, respectively, of transition point i then the overall Video Indexing Score is represented as:

$$VIS = \sum_{i=1}^n (G_i * A_i)$$

		Ground Truth			
		Definitely Not IP	Probably Not IP	Probably IP	Definitely IP
		-2	-1	+1	+2
Algorithm Output	-1 (Not IP)	(+2)	(+1)	(-1)	(-2)
	+1 (IP)	(-2)	(-1)	(+1)	(+2)

Fig. 5. Video indexing scoring for different ground truth values and algorithm results

Finally the accuracy score of an algorithm for a video is computed as a percentage of the theoretical maximum VIS score for the video corresponding to theoretically optimal indexing. It should be noted that this metric is designed for comparing algorithms but not necessarily an indicator of absolute accuracy; the accuracy score drops in a non-linear fashion with errors in indexing, and can theoretically be negative.

B. Human Accuracy

The ground truth employed for evaluating indexing algorithms is the information on index points provided by the instructor. However, it is important to note that experts familiar with the subject matter are likely to come up with different ground truths. In order to validate this, an experiment was conducted where two subject matter experts were asked to index a set of videos and the results were compared against the ground truth provided by the instructor. The results are tabulated in Figure 6. Figure 6 (a) shows that the two experts

have different accuracy on different videos, although their average accuracies are very close; 0.750 vs 0.762. Figure 6 (b) shows that the the difference in accuracy between the two experts varies between 4% (video 2) and 42% (video 8) with an absolute average difference of 13%. The implication is that further enhancements could improve the performance of video indexing algorithms, but it may be impossible to achieve perfect accuracy because of the uncertain nature of the ground truth. In the results of this paper, we also plot *human relative indexing accuracy* which is the accuracy achieved by an algorithm as compared to the average accuracy of our human experts.

(a) Indexing accuracy of human experts

(b) Absolute difference in accuracy of human experts

Fig. 6. Evaluation of indexing by human experts

C. Results

The text based indexing algorithm was employed to segment a suite of twenty five videos with screen text, speech text, and hybrid text; the latter simply being the union of screen text and speech text. The accuracy was measured in relation to the ground truth. Additionally, the relative accuracy as compared to human indexing was also computed based on the discussion earlier in this section, and is represented as *Human Relative Indexing Accuracy*. The premise is that an algorithm can at best achieve human accuracy. The results are presented in Figure 7.

We observe that the accuracy of segmentation with screen text is somewhat higher than that with speech text, while the accuracy of segmentation with hybrid text is in between the two. The accuracy varies in the range between 82.8% and 86.3% as compared to human accuracy. However, screen text is not the best choice for every video; 19 videos showed better segmentation with screen text while 6 videos showed better segmentation with speech text. We speculate that the reason for overall higher accuracy of screen text is that speech text has errors and screen text is sparse but is still likely to contain the keywords that define topic transition. The hybrid approach did not improve over the screen text, possibly because it is

Fig. 7. Automatic indexing accuracy for screen text, speech text and hybrid text

dominated by speech text as the sheer volume of speech text far exceeds screen text. Perhaps better ways of combining speech text and screen text can lead to results superior than what can be achieved individually.

Speech text is automatically generated from lecture audio by YouTube. It typically had many errors because of the weakness of automatic speech recognition. Further, the quality of speech text varied significantly among videos. Figure 8 plots the accuracy of automatic indexing for different ASR error rates. It is clear that the accuracy of speech recognition is an important factor in automatic indexing.

Fig. 8. Average indexing accuracy in relation to accuracy of automatic speech recognition

Additional experiments were conducted to determine any relationship between the human judged quality of speech text and the corresponding accuracy of automatic indexing. A scale from zero to five was developed to rate the quality of speech text:

- 5- Excellent
- 4- Very Good
- 3- Good
- 2- Average
- 1- Poor
- 0- No Text

Each video lecture was heard for 10-15 minutes by one of the authors in order to assign a quality rating to the speech text. No videos were rated 0 or 5 in this process. Subsequently the segmentation accuracy was measured for each group separately for analysis. The results are presented in Figure 9. The figure again shows a positive correlation between the quality of speech text and the quality of indexing.

Fig. 9. Average indexing accuracy in relation to human judged quality of automatic speech recognition

To further explore the relationship between the speech recognition quality and indexing effectiveness, we performed an evaluation using manually corrected speech text. Speech text from 11 of the videos was manually corrected with the help of the ICS captioning tool. The accuracy of segmentation with speech text, corrected speech text, and screen text for these 11 videos is displayed individually in Figure 10 and summarized in Figure 11. Corrected speech text leads to significantly better segmentation accuracy as compared to (uncorrected) speech text and performs better than screen text.

Fig. 10. Indexing accuracy with corrected speech text for selected lecture videos

In summary, the screen text received from OCR tools was better for segmenting lecture videos than speech text generated by ASR tools. However, the quality of speech text is important for accuracy and corrected (and hence virtually error free) speech text is better than screen text for segmentation. Simple hybrid text obtained by combining speech text and screen text did not perform any better than screen text alone. Experiments were not performed for corrected screen text because the automatically derived screen text was fairly accurate; usually over 90%. However, this will be a subject for future work.

Fig. 11. Average indexing accuracy with screen text, speech text and corrected speech text for selected videos

VI. SURVEY RESULTS

Indexed Captioned Searchable (ICS) Video usage is assessed to develop an understanding of the overall perceived value of the video lectures as well as the value of video indexing. Surveys were administered over 5 years in more than 10 semesters [3]. Figures 12 and 13 show the response of approximately 120 students from Spring 2013 and Fall 2013 semester to a forced-answer question about the usefulness and value of the indexing. Figure 12 shows that well over 90% of respondents agreed, that the video indexing was helpful, that the placement of index points in the video timeline was appropriate for the lectures, that the layouts of the index images made the index feature easy to use, and that the index points separated a lecture into logical segments. In this figure “Disagree strongly”, “Disagree” and “Disagree slightly” is merged to “Disagree***” due to the low number of responses.

Fig. 12. Quality of video indexing

Responses to additional questions on the value of indexing are presented in Figure 13. Students are strongly supportive of the statements that the index feature functioned well, that the index points provided enough information to identify video segments of interest, and that the index made it easy to navigate the video. The statement that index points represented the start of a new subtopic had somewhat weaker support than the other assertions. It is important to note that even imperfect indexing is perceived as very valuable by the students.

In open-ended comments, students reported several benefits from using the index including (a) saving time, for example one student wrote, “I did not have to wade through the rest of the lecture just to answer one question”; (b) skipping through material the student was familiar with to get to the

Fig. 13. Value of video indexing

challenging sections; and (c) returning to a section of the lecture if an interruption occurred. For example, one student wrote, “Sometimes I would have to pause the lecture to take care of other responsibilities that I had to attend to, and when I was ready to come back to the lecture I’d pick up exactly where I was at. It was great!”. Another student said, “The indexing feature, in my opinion, is one of the best parts regarding this video player. It separated the lecture into reasonably sized sections and made it easy to know where to pick a lecture back up if I had to stop watching for a while.”

VII. DISCUSSION

Several videos were manually analyzed to understand why the screen text and speech text based algorithms sometimes provided incorrect index points in lecture videos. We illustrate some of the reasons with examples.

A. Speech Text Limitations

Figure 14 summarizes the reasons for the errors in segmentation with speech text.

Fig. 14. Causes of segmentation errors with speech text

The most common reason for erroneous results in most of the lecture videos for speech text segmentation is the *poor quality of caption text* that leads to unrecognized text, incomplete sentences, incorrect technical words representing topic information, etc. Reduced audio quality predictably degrades the caption quality and segmentation accuracy as well. One possible solution is to manually correct the speech text but the process is labor intensive. *Different speech text content* such as instructor talking about weather, exams, or assignments, that are irrelevant to the topic flow is another leading cause of poor segmentation. This can potentially be minimized in the future by only using a glossary of subject terms for indexing. Other causes include switching to a topic away from the main flow of the lecture, such as citing examples and review of a topic discussed earlier.

B. Screen Text Limitations

Figure 15 summarizes the reasons for the errors in segmentation with screen text.

Fig. 15. Causes of segmentation errors with screen text

The largest source of errors in segmentation is *OCR errors* that lead to incorrect text data as a result of failure to recognize the text characters accurately, even though the OCR based text retrieval is overall fairly accurate. There could be various reasons for this, such as the size of the characters, presence of mathematical formula, or handwritten texts in a slide; an example of which is shown in Figure 16. Accuracy with manual correction of OCR errors is worth investigating but not a practical solution.

Fig. 16. Hand writing leads to OCR detection errors

Another problem with screen text is the scenario where the *screen text contains low topic information*. An important underlying reason is visual content with little textual information, such as the example shown in Figure 17. A hybrid approach of combining the text, image, and audio data could be a possible solution to solve this problem.

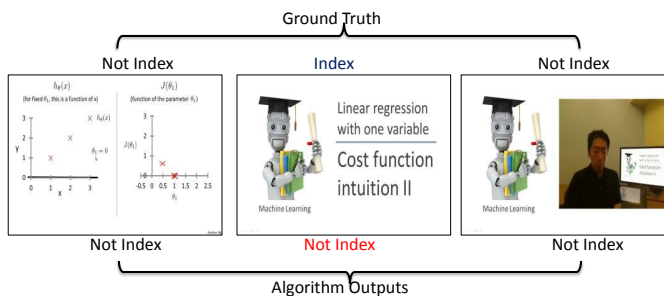

Fig. 17. Video frames with low volume of text lead to inaccurate indexing

Other reasons for errors that were discovered include visiting websites that leads to irrelevant text recognized by OCR, outline/subtopic slides in lectures, poor lecture organization such as browsing in a word file or switching windows, which again lead to irrelevant text recognition by OCR for the segmentation algorithm.

VIII. CONCLUDING REMARKS

The ability to automatically segment videos based on topics can significantly enhance the value of classroom lecture video as a learning resource. This paper investigates the use of screen text obtained with the help of Optical Character Recognition (OCR) tools and speech text obtained with Automatic Speech Recognition (ASR) tools to drive a text based segmentation process. The results show that screen text led to more accurate segmentation of videos in comparison with speech text from ASR tools, in large part because the errors in speech recognition far exceeded the errors in text recognition. Manually corrected speech text provided better data for indexing than screen text. Manual correction of screen text is not analyzed in this work. However, it should be noted that manual correction of screen or speech text are not practical options.

Screen text is typically based on instructor's viewgraphs and hence is well prepared and focused. Speech text, on the other hand, is improvised and not as focused, but the amount of text is plentiful. The conclusion is that screen text and speech text both contain useful information for lecture indexing. We believe that it should be possible to jointly use speech text and screen text for improved segmentation, but that is a subject for future research; our simple experiments did not show benefits of using them together over the better individual method.

More research is needed to achieve consistently good topic based segmentation. In this paper we have used a simple text based algorithm for video segmentation. Other algorithms, particularly those based on machine learning, hold significant promise towards achieving accurate topic based segmentation, perhaps close to what can be achieved by humans. Future improvements in OCR and ASR will have a great beneficial impact on the accuracy of topic based segmentation. Even for the topics addressed in this work, a set of twenty-five video lectures is not enough to derive firm conclusions and can only be considered preliminary work.

Finally student surveys in this project have shown clearly that classroom videos are an important learning resource and that segmentation by topics is very valuable. We hope future research will address the challenges involved, and lecture videos will be made widely available to students.

ACKNOWLEDGMENTS

We would like to acknowledge the contributions of several members of the ICS Videos group that developed the infrastructure for the project. We thank Olin Johnson, Nouhad Rizk, Shishir Shah, and Chad Wayne; the instructors who participated in the evaluation, along with the students in their classes. We thank Lecia Barker, who developed the evaluation mechanisms employed in this work. We would also like to thank the anonymous reviewers who helped improve the paper significantly.

Partial support for this work was provided by the National Science Foundation's Division of Undergraduate Education under Course, Curriculum, and Laboratory Improvement (CCLI) program with Award No. DUE-0817558. NSF support was also provided under grants DGE-1241772 and CNS-1319212. Abstract—The advent of massive open online courses (MOOC) poses challenges for teaching and learning programming. This paper has analyzed these challenges and thereby proposed a self-motivating learning platform for students in the introductory programming course. Novel mechanisms of online assignments and examination have been introduced. Our platform provides functions for self-motivating learning and practicing in MOOC, which makes it distinguish from the others. For example, self-paced timetable with supervision, self-motivated exercise contents, exercise market, and relative ranking. The automatic grading approach is also a highlight. Programs even with syntactic or semantic errors can be automatically graded. Our platform gains popularity among both students and teachers. The platform has been used together with a programming MOOC. This course is ranked as the third most popular courses among over 500 courses. The platform has also been used by more than 100 other universities. The application of the platform in both MOOC and the traditional classroom courses has shown that students' self-motivation in learning programming has been greatly promoted, and their practical skills have also been significantly improved.

Keywords—MOOC; programming; learning platform; online assignments; online examination

I. INTRODUCTION

Massive Open Online Course (MOOC) is a recent development in the area of e-learning and distant education. In addition to creating an easy access to a standard curriculum, MOOC allow students to learn at their own speed and learn from each other using online social networking tools. As a result, some prominent MOOC, such as various classes from Stanford University, edX, Coursera, and Udacity, have attracted tens of thousands of participants. For instance, as of November 2012 more than 1,900,241 students from 196 countries have enrolled in at least one course by Coursera [1].

The huge popularity shows that the time is ripe for MOOC[2]. However, challenges exist and there is still plenty of room for improvement.

One challenge of MOOC is that the student retention rates are very low[3]. Adamopoulos et al. developed a hedonic-like

approach to identify important concepts that affect online course retention and estimate their relative importance based on textual reviews submitted by students on special online communities[1]. According to their research, the sentiment of students for assignments and course material has positive effects on the successful completeness of a course. Therefore, "how to design a course which will provide participants with positive experiences so as to motivate the students?" becomes an important issue.

The massive scale also poses significant technical challenges. One of these challenges focuses on homework exercises and exam problems: creating a large and diverse set of problems of varying difficulty, automatically grading them, and preventing plagiarism[4].

This paper describes our work towards addressing these challenges for the introductory programming course. The main contributions are as follows.

- The challenges brought by MOOC for programming have been analyzed in detail.
- A self-motivating learning platform has been proposed and developed by us. This platform is suitable for both MOOC and the traditional classroom courses.
- New mechanisms of online assignments and examination are proposed and implemented.

II. MOTIVATION

As programming courses are practice-based, the improvement and assessment of students' practical skills should become a priority[5]. At the same time, as the first computer professional foundation course, programming course also bears a heavy responsibility of cultivating students' interests in studying computation knowledge. Therefore, cultivating the students' self-motivated habit from the beginning of the course is very important for interdisciplinary talents for the future.

However, in traditional approach many teachers still prioritize lecturing theory instead giving the priority to practical work. Besides, many courses are dull and uninteresting with non-motivational exercises. Such courses result in high dropout rate.

Different approaches of teaching programming to overcome these problems emerged: game programming[6-10],

pair programming[11-13], visual programming [14], individual work, collaborative work, simulation tools, role games, test-first approach, test-driven approach etc..

Most of these methods focus on learning within the classroom, however, nowadays in the context of MOOC, new mechanisms are need. MOOC has changed the way of teaching and learning. Traditional teaching practice was always "dominated by teachers" whereas MOOC is "student motivated". Students can decide what, when and where to learn.

Besides, in our teaching practice of programming, we found that the following factors obstruct students' learning experience.

- The setup of assignments can not distinguish the students significantly. This sometimes leads to "lazy students".
- Lack of environment for supporting self-motivated practice.
- Lack of supervision and guidance for the students' self learning process.
- Lack of objective, fair assessment of students' performance.

As a result, the following issues need further study. This is the motivation of our research.

- How to provide a learning supporting environment to switch the programming teaching from a "narrow" to a "broad" class?
- How to provide a mechanism to motivate each student to take part in the programming practice?

- How to effectively supervise and guide student's self-learning process?
- How to avoid plagiarism that commonly appears in students' assignments?
- How to assess students' practical skills objectively and fairly?

III. SELF-MOTIVATING LEARNING ENVIRONMENT FOR STUDENTS

To solve the problems proposed in Section 2, we have done some research work on automatic grading [15,16], course management[17], and plagiarism detection of programming assignments [18], and transformed our research results into practice, to build a self-motivating leaning platform for students as shown in Fig. 1. It consists of the following supporting systems.

- **A self-motivated online assignments system** (<http://sse.hit.edu.cn/train> ID:12345 PSW:123123) supporting self-motivated online assignments submission, evaluation, and management.
- **An automatic grading system based program semantic analysis** (<http://sse.hit.edu.cn/exam/login.aspx> ID:demo PSW: demo) providing online examination and assessing students' practical skills.
- **An interactive network teaching platform based on Moodle** (<https://cms.hit.edu.cn/>) supporting course management, forums, lab submission and grading, etc.
- **A paper and exam management system** assisting the above systems.

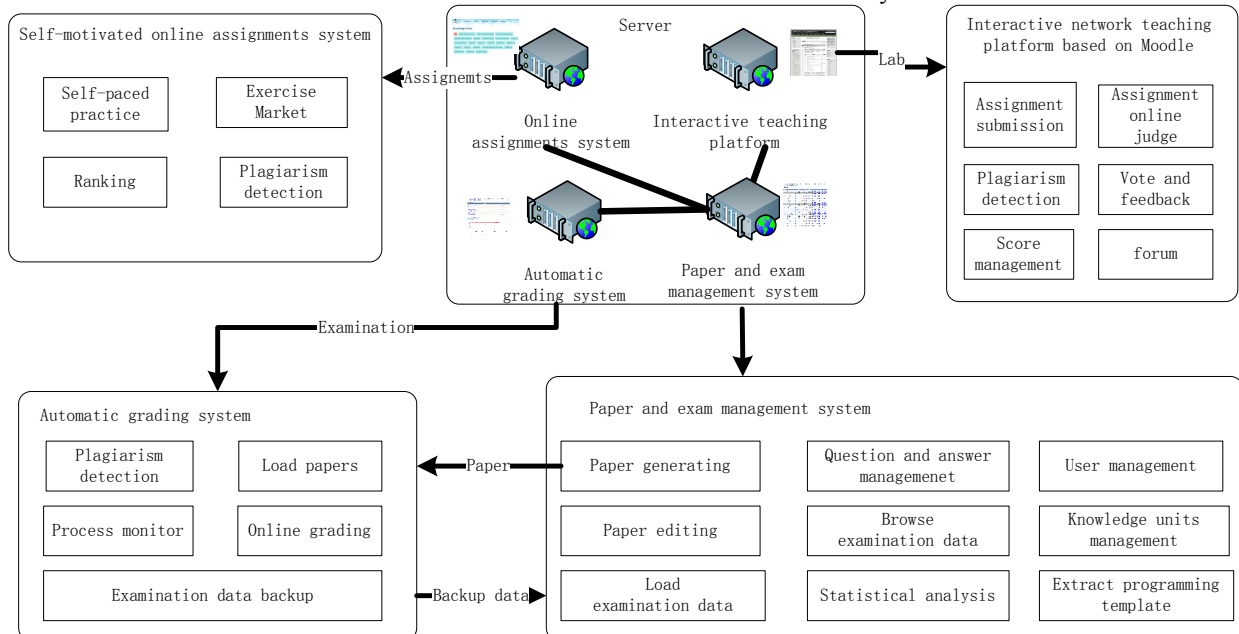

Fig. 1. The self-motivating leaning platform

All these systems have been widely used. Besides the traditional functions provided by a network platform, such as forums, online assignments submission, our network platform also provides some advanced functions. These advanced functions make our platform distinguish from the other network teaching platforms. Especially, the online assignments

system integrates many novel mechanisms for motivating students' self-learning and practicing in MOOC, such as self-motivated exercise contents, self-paced timetable with supervision, plagiarism preventing, iterative submission and automatic feedback, exercise market, and relative ranking. The automatic grading system is also a highlight of our work. It

adopts a new grading approach combining program semantic analysis and testing. Programs even with syntactic or semantic errors can be automatically graded based on the degree of implementing the specification. The initial version of the system adopted the client-server architecture. We extended it to the browser-server architecture to make it suitable for MOOC. In the following sections, we will focus on the mechanisms of the online assignments system and the automatic grading system.

IV. MECHANISMS OF MOTIVATING STUDENTS WITH ONLINE ASSIGNMENTS

The teacher manual evaluating student's programs is low efficiency and causes heavy workload. For a class with hundreds or thousands students this is mission impossible. In MOOC, peer grading serves as a critical tool for scaling the grading of complex, open-ended assignments. Despite promising initial trials, it does not always deliver accurate results compared to human experts [19,20].

In addition, the traditional assignments setup usually limits the students to do the same assignments during the same period. This is not suitable for MOOC, as students are allowed to learn at their own speed.

Moreover, how to motivate the students participating in not only programming practice but also assignments setting is not sufficiently considered.

In response to these issues, we have developed a self-motivated assignment online evaluation system. The system runs on a network server, teachers and students can use a standard web browser to access the system anywhere.

A. Self-paced timetable with supervision

Students can use a supervised self-paced timetable for the assignments. Different from completely self-paced timetable, which allows students to do the assignments anytime (e.g. completing all the assignments in one day, even if this is not good for the students), our online assignments system gives some supervision to the learning process, while giving the students some degree of freedom.

Exercise Settings	
Exercise Time	40 Minutes
Repeat Times	1
Daily Exercises Limit	5

Fig. 2. Teachers can set the number of daily exercise and time limit for each exercise

As shown in Fig. 2, the teacher sets the minimum number of assignments to be finished before final examination, the maximum number of daily exercises, the maximum repeat times for an exercise, and the time limit to finish each exercise.

A student can choose the days to do the assignments when he is available, but he can not do all the assignments in only a few days as limited by the daily maximum exercise number. Besides, the time for finishing an assignment is strictly setup. If a student does not correctly finish the assignment in time, he will fail the assignment and need to practice more. This mechanism gives students some degree of freedom to schedule their assignments, meanwhile, promotes the students to develop a good habit of practicing and correctly finish the work as soon as possible.

B. Self-motivated exercise contents

As shown in Fig. 3, daily homework is no longer arranged by teachers, instead, students choose which type of exercise to do in accordance with their studying progress (by chapter number or knowledge units).

More important, the contents of daily exercises and practice subjects are no longer all identical for all the students. They are randomly extracted from the subject pool by chapter or knowledge unit chosen by the students.

C. Iterative submission and automatic feedback

00:20:00

Submit

Q1308. (Prime number) A natural number 1, 2, 3, 4, 5, 6, ... is called a prime number if it is greater than 1 and has exactly two divisors, 1 and the number itself. According to the definition 0, 1, and negative integers are excluded as a prime number. For example, 5 is prime, since no number except 1 and 5 divides it. On the other hand, 6 is not a prime (it is composite), since 6 = 2 x 3. 1) Write a function that determines if a number is prime. the prime number is no more than 10¹²; 2) Use this function in a program that determines whether the input number from keyboard is a prime number.

Fig. 4. Students can resubmit their programs within the specified time

The process to complete exercises is self-motivated. The students' programs are automatically evaluated by the online test-driven automatic grading system (ACM Online Judge). A student can immediately see the score, after submitting his program. As shown in Fig. 4, within the specified time, he can modify, resubmit, and retest the program again and again, until

a satisfying score is got. The iterative mechanism helps students to cultivate the habit of independently thinking and self-motivated learning.

D. Introducing marketing mechanism into exercises

Experience has shown that example code can not only help students become familiar with programming language syntax, but also can help students to understand the essence of programming language. In fact, programming starts from reading and studying other people's code.

The market mechanism of exercises is introduced as shown in Fig. 5. The mechanism is to support and encourage students to publish their own designed subject for the other students. The student published a high quality subject can earn some “golden points” as a bonus. This mechanism has three advantages.

Firstly, it can motivate students’ learning experience. In order to provide high quality subject, the students must master the corresponding knowledge. This promotes the students to study harder.

Secondly, students can use the “golden points” earned in the exercise market and choose whether to view the topic sample code. This can promotes their understanding of the essence of the knowledge they are not familiar with.

Thirdly, it helps in creating a large and diverse set of problems of varying difficulty.

For a seller:

- It will take 1 golden coin when you apply to put a self designed exercise on sale.
- The application will be verified by the administrator.
- Besides the golden coin paid by the buyers, extra reward will be given by the administrator if you publish a high quality exercise.

For a buyer:

- You need to pay the designer 1 golden coin when you buy a exercise.
- If you passed the exercise, you can get the bonus.
- Besides the bonus set by the seller, extra reward will be given by the administrator if you give a high quality answer.

Fig. 5. The marketing mechanism to encourage students to publish subjects

E. Various ranking mechanisms

In order to promote students’ enthusiasm in participating in the programming practice, a variety of ranking mechanism is introduced as shown in Fig. 6. The teachers can motivate students to practice more and difficult exercises by setting scores for assignments, number of self designed excises, degree of attention got by the self designed excises and so on. A relative ranking mechanism is adopted. A student with the best performance can get the highest score. By contrast, the students with the poorest performance get the lowest score. The competition element increases the motivation of the students to complete the task to the best of their ability. Students feel like “they are playing an online upgrading game”,

so that they become positive, especially top-notch students come to the fore.

G. From anti-plagiarism to plagiarism prevention

The plagiarism detection function of our platform can automatically detect similar source code. However, we found that this post hoc anti-plagiarism did not agreeable in practice. We hope to prevent plagiarism before it happens.

As demonstrated earlier, assignments are randomly extracted from the subject pool, and the time for finishing each assignment is strictly setup. By doing this, the chance of plagiarism is greatly reduced, because the students who want to copy programs from others can seldom wait in front of the computer everyday. Besides, they may not have enough time to modify and submit the copied programs within the time limit. This forces students to think independently.

V. MECHANISMS OF MOTIVATING STUDENTS WITH ONLINE EXAMINATION

A. Fair and impartial assessment of students’ practical ability

The traditional automatic grading systems usually only test the running results of programs, rather than evaluating the

2015 IEEE Frontiers in Education Conference
1922

syntactic structure and semantics of programs. To overcome these drawbacks, we have developed an automatic grading system as shown in Fig. 8. It not only evaluates the running result but also evaluates whether a program meets the programming specification by analyzing and understanding the program structure and semantics. In the examination, students programming and debugging on a computer, and then submit their programs to the automatic grading system, scores are shown to them immediately. With our system, the students can get fair scores, which evaluates their practical ability more objectively.

At the same time, our automatic grading system can strengthen the monitoring of the entire process of the examination. It performs real-time monitoring of the IP of the student machine, to check out whether it has a portable hard disk, and disables the portable hard disk, so as to prevent cheating.

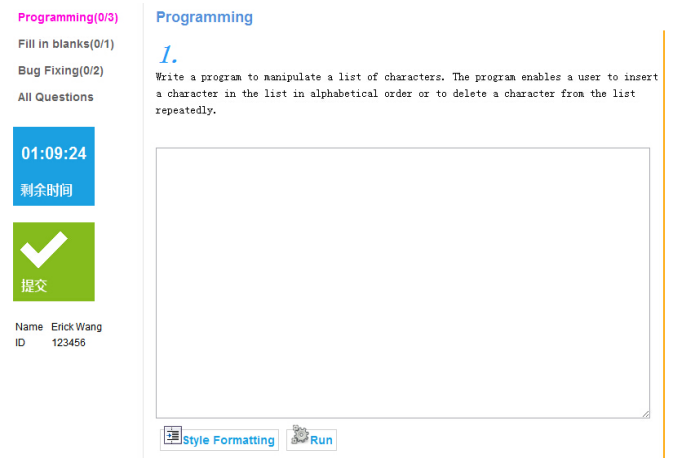

Fig. 8. Automatic grading of student programs

B. Double examinations

We provide two online examinations during the term, i.e. the midterm and the final exam. The objective of the midterm examination is to provide students with the opportunity of “finding themselves inadequate, and then making progress through hard work in the next examination”, so as to achieve the purpose of enhancing students’ programming practical ability.

VI. APPLICATION AND BENEFITS OF THE PLATFORM

The self-motivating learning platform has been used together with our C language programming course on the MOOC platform established by the Chinese Ministry of Education. As shown in Fig. 9, this course is ranked as the third most popular courses among over 500 courses.

Our platform has also been used in the traditional programming courses. In particular, the automatic grading system has been used in the final examination in the C programming courses and the graduate enrolment examination in our university. It has also been used by more than 100 universities, such as Beijing University of Posts and Telecommunications, and Northeastern University.

Fig. 9. The C programming language course is ranked as the third most popular courses on the Chinese MOOC platform

In order to evaluate whether our platform can enhance the students’ self-motivation in learning programming, we did some statistical analysis on one class with 138 students. These students were trained with the platform. And the corresponding mechanisms of on-line assignments and examination were carried out. In this class, the students had to finish 6 lab experiments. The assignments were optional, and a relative marking mechanism was carried out. The programs for the experiments and the assignments were automated graded.

Fig.10 shows the number of programming assignments correctly solved by the students in ten weeks’ class. 41 percent of the students correctly solved over 20 assignments per week. The new mechanisms has effectively promoted the programming practice of students.

Number of correctly finished programming assignments

Fig. 10 Statistics on the number of correctly finished programming assignments

Table I . STATISTICS ON THE GRADES OF LABS

above 90	80-90	60-80	below 60
124	7	4	3

Table I shows the grades for the labs. As the students had done much programming practice, most of them they got high lab scores. 127 of the 138 students got marks of above 90 (The full score is 100). Their programming skills have been greatly improved.

We also collected online questionnaire based on the students’ experiences. Totally 102 questionnaires were returned. More than 80% of the students had fun in learning programming using our platform. 71.6% of the students said

that using the platform improved their programming skills. 82% of the students agreed that the self-paced timetable with supervision mechanism helps them in arranging study time more reasonable. 98% of the students like the automatic grading mechanism. 78.4% of the students worked harder stimulated by the relative ranking mechanism. In general, the results were positive, showing that using the platform enhanced both the learning experience and motivation.

VII. CONCLUSION

In this paper, we discussed the MOOC challenges for programming and the importance of motivating students to practice programming. A self-motivating learning environment for students has been developed. The novel mechanisms of the online assignments and examination have been demonstrated in detail. The platform gains popularity in both MOOC and the traditional classroom courses.

In the future, we will collect more data to evaluate and improve our platform as well as the mechanisms.

Abstract—The Open Educational Resource concept was proposed several years ago as a way to develop the Open Movement principles in the educational domain. Despite the open and participative view underlying this proposal, there has not been a significant adoption of this concept by users. Many problems and barriers have been considered and analyzed. Nevertheless, we consider that a main issue is the contradiction among the definitions proposed and the real support provided by platforms. In addition, there exist also different approaches to the concept by users and organizations. In this paper we call for a real open approach to the Open Educational Resource concept and introduce a platform where specific functionalities have been introduced to support its development.

Keywords—Open Educational Resources, Open Movement, Creative Common Licenses

I. INTRODUCTION

The term Open Educational Resources (OER) was coined at UNESCO's 2002 Forum on Open Courseware [1] to designate "*teaching, learning and research materials in any medium, digital or otherwise, that reside in the public domain or have been released under an open license that permits no-cost access, use, adaptation and redistribution by others with no or limited restrictions*". More than a decade after the issue of this definition, current implementations of the OER concept are not fully compliant with all the ideas embodied in it. There are a contradiction between the principles of the Open Movement, the real understanding by users and the functionalities provided by supporting platforms. These contradictions can be more clearly observed in contrast to the development of the Open Movement in other fields, specially in Open Software.

From a practical point of view, this contradiction can be observed in web platforms supporting users to store and share OER. Some relevant examples are: OpenStax, MERLOT or OER Commons. These sites do neither allow users to adapt the resources hosted nor to access the source files. For a resource just a printable or preview version (e.g., a document in PDF) is usually provided. Nevertheless, the provision of source files is a key principle in the open culture. In the open

software domain, the availability of the source code is recognized as a key factor for the successful development of the openness spirit. Similarly, the use of Creative Commons (CC) licenses has been spread, but their management is not easy when we consider combinations or adaptations.

A possible consequence of this situation is the low success of the OER movement. Several inquiries have been published about this [2, 3, 4]. Similar, the European Commission has funded several projects that also identify this issue: Ariadne, OrganicEdunet, Open Science Resources, Concede, KPP, OERTest, OpenDOAR, OPAL, ROLE and Open Discovery Space. The questions that we are bringing here are about the OER adoption by teachers and the poor support in existing platforms. We ask for the development of new systems providing a better OER support more aligned to the real open principles. In concrete we propose a Edu-AREA, an OER platform that embodies some key points: sharing of source files, online editing, resource linking, license management and referencing management.

The paper is organised as follows. Next section introduces the Open Movement, taking into account its development in different fields. Next, OERs are reviewed, taking into account platforms and user views. In section IV Edu-AREA functionalities are described focusing on the support of OER. The paper finishes with some conclusions.

II. THE OPEN MOVEMENT

A. The Open Concept

Nowadays there is an Open Movement in several domains. that share a set of common values [5], namely:

- Open exchange. People can learn more from each other when information is open. A free exchange of ideas is critical to creating an environment where people are allowed to learn.
- Collaborative participation. When we are free to collaborate, we create. People together can solve problems that a single person may not be able to solve on their own.

- **Rapid prototyping.** Rapid prototypes can lead to rapid failures, but that leads to better solutions being found faster. People learn by doing.
- **Meritocracy.** In a meritocracy, the best ideas win. Everyone has access to the same information. Successful work determines which projects rise and gather effort from the community.
- **Community development.** Communities are built around a common purpose. They bring together diverse ideas and facilitate the sharing of work. Together, a global community can create beyond the capabilities of any one individual. Together, we can do more.

Adopting these values, the Open Movement has been quite meritorious in the following domains:

- **The Open Movement** was initiated in the software community. The term Open Source was proposed as a way to provide open access to software source code. In this way, others can view the code, copy it, learn from it, alter it and share it. This means an opportunity to modify and evolve software in accordance to cooperative and collaborative models. Many people prefer open source software not just because the development process. In addition, they can have more control over the code as they are allowed to examine it to ensure it is not doing anything they do not want it to do. Some people also find open source software more secure and stable than proprietary software, because a large community is involved in the continuous detection and correction of errors. Some relevant projects are GitHub [6], Git repository supporting collaboration in software development; OpenStack [7], an open community of questions and answers.
- **Open Hardware.** In the same way as open software grants access to source code enabling its modification and redistribution, open hardware makes available all information required to replicate a hardware device or to design a new device as a variation of the original one (e.g., mechanical and electrical schematics, bills of material, programmable logic's source code, etc.). Most frequently, the software that drives the hardware, is also released according to a free/open license. In many cases, free and open-source hardware projects rely on existing open-software licenses [8] instead of creating new ones. Note that these licenses may clash with patent-based protection laws. Some relevant open hardware projects related to education are Arduino [9], NetFPGA [10] or Raspberry Pi [11].
- **Open Science.** The academic peer review process involves research authors evaluating one another's work, often anonymously. The open approach applied to this area demands to perform this process in a more transparent way, so readers can better understand how and why a piece of research have been considered valuable and suitable for publication. In other way, open principles also call for publishing through "Open Access" formulas. Often, researchers are asked to transfer the copyrights on their work when they agree

to let the journals to publish it. Then, researchers are charged by publishers when they get access to research materials on journals and libraries. Sometimes these fees are very high and research is only available to people that can pay for it. To tackle this situation, some institutions have promoted and adopted open access policies to grant public access to research publications. Some relevant projects are Open Journal Systems[12], journal management and publishing system based on Open access principles; OpenBEL [13], a language that represents scientific findings from the life sciences in a computable form.

- **Open Health.** Open initiatives related to the health sector are focused on two directions. First, on supporting the use and development of open software. Second, on providing open access and sharing of medical information. This is a main challenge as medical records usually involve sensible data and hard constraints. Some relevant projects are GNUHealth [14], a free Health and Hospital Information System with several functionality; Openhealth [15], about eHealth/mHealth solutions based on the management of wireless biomedical devices in Body Area Networks under the IEEE standards and Open Mobile Terminal Platform.
- **Open Government.** The Open Movement applied to the government calls for more transparency. As technology allows people to communicate in much better, faster and free ways (i.e., not just from a publisher to a large number of readers), governments have an opportunity not only to be transparent, but also to go a step further and become more participative.
- **Open Data.** Data should be freely available to everyone to use and publish. It is usually focused on non-textual material, such as maps, genomes, chemical compounds, etc. This can be related to open initiatives in Science, Government, etc. Linking Data is about using the Web to connect related data that wasn't previously linked or to lower the barriers that limit other linking methods. Some relevant projects are LinkedOpenData [16]; open-data.europa.eu, the European Commission open data initiative.

B. The Open Movement in Education

The Openness Movement is also very active in education [17]. This has promoted a philosophy about how people should produce, share and build value education. Barriers such as financial costs, proprietary technologies and legal mechanisms that prevent collaboration among scholars and educators should be removed.

The following initiatives related to the Openness Movement in Education are considered as the most relevant:

- **Open Educational Resources (OERs).** They are educational materials that are provided following the principles of the open movement. A key point from our point of view is that resources should not just be easily accessible to be used by others, but also in a form that

facilitates their modification, adaption and evolution to support their localisation to new contexts and needs. Next sections provide an extended discussion about this initiative.

- OpenCourseWare (OCW). It is a “free and open digital publication of university-level educational materials. These materials are organized as courses, and often include course planning materials and evaluation tools as well as thematic content”. The reference institution insofar OCW is concerned is MIT. It initiated this program in 2002 offering online its course contents for free. Since then, dozens of universities worldwide also offered their contents online and joined around the The Open Education Consortium.
- Massive Open Online Courses (MOOCs). MOOCs are free online courses without formal entry requirements nor participation restrictions. They include interaction, feedback and assessment (via automated quizzes or peers), but do not necessarily lead to official credentials. In some cases educational materials are not free and modification by others is not allowed. Most of the MOOC movement is based in the US, although many universities around the world also joined these initiative.

There are some key differences among the three initiatives above:

- MOOCs and OCWs are basically oriented to online learning, while OERs are also applicable to blended and face to face education.
- MOOCs involve the provision of services and functionalities to support the development of the courses (e.g. registration, assessment, collaboration, feedback), while OERs and OCWs are mainly about educational materials.
- The OER movement is focused on supporting collaboration and sharing of resources among teachers. The goal is to promote innovation, creativity and the development of a participatory community where all the people can contribute. The idea of the openness movement is more clear, not just openness of the materials or services.

III. OPEN EDUCATIONAL RESOURCES

The OER concept has been proposed from the openness movement trying to adopt its principles, but it is a multifaceted idea that different users and initiatives consider in different ways. In addition to the UNESCO, other international organisations have already proposed their own views (e.g., William and Flora Hewlett Foundation, OECD, Commonwealth of Learning, European Commission, etc). A main discussion topic is about the level of openness and the availability of the source files. Licensing is another common issue, but Creative Commons (CC) is being adopted as the reference to define usage conditions and also to provide attribution based on commercial, share-alike and no-derivation terms. These terms are not fully aligned to the open movement principles, but at least

they require users to reflect and be aware of them. It is important to notice that if a material is provided with no copyright nor licensing information, by law it cannot be used, modified or distributed by others. An option to solve this limitation in the U.S. could be the Fair Use doctrine, that allows others selected uses of copyrighted material without copyright holders' consent, but it is open to interpretation.

There are other topics relevant to OER. This section analyses a variety of views considering types of OER, supporting tools and end-users.

A. Types of Open Educational Resources

Different type of OER can be considered [18]:

- Resources created for educational purposes. This includes multimedia documents, simulations, educational games, podcasts, webcasts but also simple HTML resources. Currently, a main research field is how to make learning objects (i.e., specific digital objects created for learning purposes) available and reusable, transforming them into real OERs.
- Articles, textbooks and digital equivalents. This type of resources contains typical objects provided by libraries, such as articles, papers, books or journals. When becoming freely available, this class of objects is connect to the concept of Open Access (cf. Sect. II.A).
- Software tools and web applications are used for different purposes, such as producing or authoring learning resources, such as simulations, but also for communication and collaboration. Objects of this class are usually referenced as Open Source (see section II.A).
- Instructional/educational designs and experiences. Educators are highly dependent on successfully planning and designing their learning experiences. This type of resources includes access to instructional designs, didactical plans such as lesson plans, case studies or curricula. It also includes one of the most valuable resources: sharing experiences about materials and lessons between colleagues.
- Web assets. This class of objects refers to simple resources (i.e., assets) like pictures, hyperlinks, videoclips or short texts that are not usable on their own in a learning context but can be used to clarify or illustrate a certain topic. For example, these are the typical objects found by using a Web search engine (e.g., Google).

B. OER Platforms

According to the rapid pace of technology evolution, we can consider that the OER concept was proposed many years ago. In addition, it is something not completely new, but more or less an evolution or adaptation of similar concepts in other fields, including e-learning. For example, at the beginning of the century it was very popular the learning object concept. This can be a reason why there exist a quite large number of

platforms that are related to the OER movement. Some of them, as MERLOT, are even previous to the UNESCO definition. Table I provides a view of some of the most relevant platforms. They are featured in columns as follows:

- URL: web address of the platform.
- Source. If the platform enables users to include the source files of the resources. In many cases NS is included to indicate (that the authors are) “Not Sure”. Notice that only Openstax clearly enables to include source files.
- Tools. If the platform provides tools to create and edit resources online or offline. These functionalities are instrumental to support the openness principles.
- Repository. If the platform can be used to store, search and retrieve resources. Most of the platforms provide this functionality. In some cases they also act as Referatories, including just references to resources in other locations.
- Courses. If the platform manage not just assets, but also resources that are combinations of other resources in higher aggregation units.
- Community. If the platform includes functionalities and services to promote the communication and collaboration among users.

We can extract some conclusions from this table. First, the variety of views reflected in the different options, and second the lack of a winner platform that provides the best support in all categories. From our review, the best platforms are OER Commons, Openstax and MERLOT.

C. User Views: Survey Results

Similar to the existence of many OER platfoms, several surveys have been carried out during the relative long live of the OER concept. In October 2014 a large survey was published referred to the U.S. collecting answers from 2 144 higher education teachers [19]. Between two-thirds and three-quarters of college faculty members say they are unaware of OER.

As part of our research, we conducted a survey among primary, secondary and high school teachers in Galicia (Spain) and Northern Portugal. The survey is available in Galician, Portuguese and Spanish (check it at the bottom of the following page <http://www.edu-area.com>). We collected answers from 565 teachers about questions related to lesson planning and monitoring. In addition, some questions about OER were included. Results obtained show teachers’ awareness about OER, but also their understanding of the implications of the OER idea.

A first question asked was “Do you know what are Open Educational Resources (OER)?”. Options include “No” and three types of “Yes” to capture the level of experience: “I have already heard about them, but I have not used them yet”; “I have already used OER created by other teachers”; and “I have already created and used OER, and shared it with other teachers”. Fig.I shows the results obtained. More than a third of the teachers answered “No”. If we add to this number the number of teachers that heard about OER but never used them, we get a figure between two-thirds and three-quarters, as in the U.S. survey. The number of teachers that already have created and shared some OER is around 10%. This result shows the low awareness about OER.

TABLE I. OER PLATFORMS AND KEY FEATURES CONSIDERED IN THIS PAPER

Platform	URL	Source	Tools	Repository	Courses	Community
OER Commons	https://www.oercommons.org/	NS	Yes	Yes	Yes	Yes

FIGURE I. . NUMBER OF ANSWERS TO THE QUESTION “DO YOU KNOW WHAT ARE OPEN EDUCATIONAL RESOURCES (OER)?” IN A SURVEY AMONG 565 TEACHERS

We included in the survey a set of questions to try to check teachers’ understanding about the OER concept. These questions have a common starter: “If you had to describe the OER concept, how would you do it ...?”. Then, several issues were included. “OER are available for free”; “OER can be edited and modified”; “It is possible to use parts of an OER to create other resources”; “OER should include some license”; “It is important to provide attribution”. Possible answers are: “Not necessarily”; “It could be”; “It should be”. From our view of the OER concept all issues should be answered as “It should be”. Fig. II shows the results to these questions. Almost all the issues have a similar answer pattern. In general the answer “Not necessarily” was chosen by a low percentage of teachers and the answer “It should be” between two-thirds and three-quarters of the teachers. Note that teachers consider that OER should be available for free and it should allow modifications. Surprisingly, the issue that receives less consideration is

licensing. This can be critical, because as it was highlighted, if no license is provided, copyright restrictions prevail.

IV. EDU-AREA

Edu-AREA is a Web platform whose goal is to promote teaching innovation. The approach to achieve it is to provide an environment where users can participate, share and collaborate during the preparation and use of their educational materials. This platform was described in previous papers [20, 21].

Edu-AREA provides users with typical OER storage and sharing functionalities. In addition, it also includes online editing functionalities for some types of educational resources. In Edu-AREA, OER are grouped and managed in accordance to two categories: (i) Resources, about what can be used, and (ii) Plans, about what can be done.

Different categories of Resources, digital or otherwise, are further recognised: (i-a) documents (text, images, sound, video, etc.); (i-b) software applications; (i-c) hardware devices; (i-d) guests, people from outside the school that can be involved in an educational activity; and (i-e) trips, places or events from outside the school that can be visited. Some of these Resources can involve source files, such as documents, but others clearly not, such as guests and trips.

As for Plans, several categories are also identified: (ii-a) Activities, as the basic building blocks; (ii-b) Lesson Plans, made up of Activities focused on the achievement of certain learning goals; and (ii-c) Courses, made up by several Lesson Plans; etc. All these types of Plans may include a reference to the Resources involved.

In Edu-AREA we do not support users editing any of the Resources online, but just storing and sharing them, because there already exist very good and specialized tools for the different types of documents (e.g., images, videos).

FIGURE II. . ANSWERS TO THE QUESTION “IF YOU HAD TO DESCRIBE THE OER CONCEPT, HOW WOULD YOU DO IT ...?” IN A SURVEY AMONG 565 TEACHERS

Nevertheless, in the case of Plans users are allowed to modify them as actual OERs, remixing and editing them online. Moreover, CC licenses are automatically controlled in order to detect possible incoherencies.

Here, the main focus is on the features related to the support of the openness principles related to OER. This involves to support the creation, modification and reuse, the management of licenses and also to provide attribution and recognition.

A. Creating, Modifying and Reusing OER

Edu-AREA includes functionalities to support the 5 Rs rights [22]. Namely: retain, reuse, revise, remix and redistribute. Users can make a copy (clone) of any of the resources publicly available in the platform. This copy belongs to the user that requested the cloning. Users can also revise any resource, and they can redistribute their resources. As for the reuse and remix features, we need to make some considerations depending on the nature of the resource: Document (assets), Lesson Plans or Activities and Courses. In addition, it is important to indicate that users in Edu-AREA can choose to maintain their resources in a private state, not visible to other users. At any time, they can change the visibility to public and the resource will become visible to everybody as an authentic OER.

1) Documents

A Document refers to any piece of information that can be contained in a file, like a slide presentation, a video clip, a sound record, a questionnaire, etc. Documents in Edu-AREA cannot be directly online edited in the platform. There are available many tools to edit these documents, some of them even online. When Edu-AREA was designed, it did not make sense to provide an editor for each one of the possible document types in Edu-AREA platform. In order to support Documents in Edu-AREA from the openness perspective, it was decided to manage two different kinds of elements related to documents. First, a “Product”, that can be included in the platform or referenced, being the document in a external location. For example: a video in Vimeo, a presentation in Slideshare, a PDF in Dropbox, etc. Second, “Source” files of the Document. This is shown at Fig. III. At the top of the figure, several options are available to include the Document view (Url, Snippet or File). At the bottom, source files can be included. In this way, a user who wants to reuse or remix a Document provided by other user can easily get the source files, download them, edit them and modify the document or create a new document reusing some of the parts. This facility is not available in almost any of the platforms analysed at section III.B.

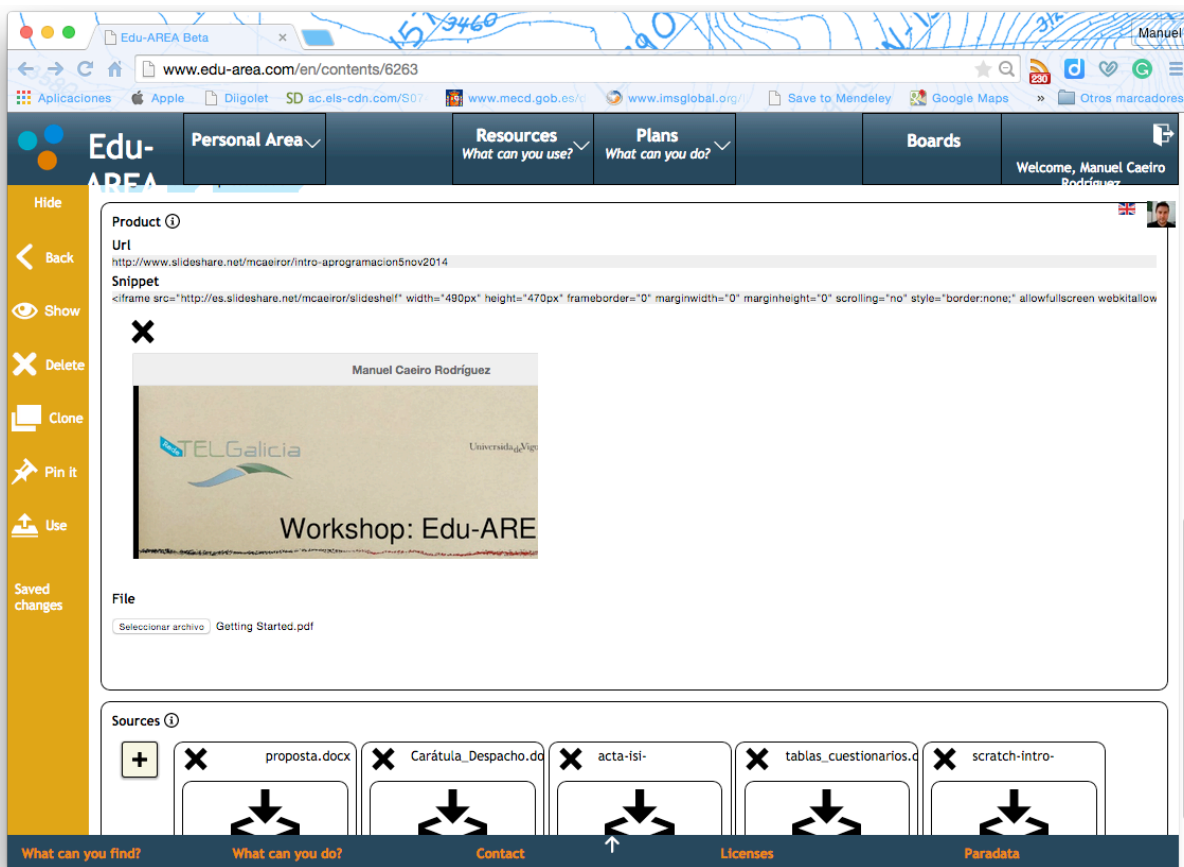

FIGURE III. SCREENSHOT OF EDU-AREA RELATED TO A DOCUMENT. PRESENTATION AND SOURCE FILES CAN BE INCLUDED

2) Lesson Plans and Activities

Lesson plans and Activities can be edited and remixed online in Edu-AREA. The platform provides templates to support the arrangement of Lesson Plans and Activities. Each template has a specific arrangement of text fields, text areas, item lists, etc. All these fields can be edited online. In addition, Lesson Plans and Activities can include other resources, such as Documents. This inclusion is managed as a “transclusion”, a concept that indicates a copy of a document inside other. These resources cannot be edited directly online in the platform, but as explained in the previous section. In any case, they can be remixed online directly.

3) Courses

The Course concept, or experience, can be considered as a step forward in the development of the open concept around OER towards a kind of “living” concept. The idea is to allow users to provide observations, evidences and reflections about the use of the OER in a real educational experience. For example, attaching pictures or videos of the students while playing an educational game, or commenting about the more difficult parts. This information can be very valuable for other users and we would like to promote its collection and sharing.

B. Licensing under Creative Commons

Edu-AREA provides their users with a mechanism to license correctly their works. In this way, teachers can share OERs with the certainty that they are not infringing any copyright law. In addition, as we have explained, they are required to license the resources. This is very important, because if a resource is not licensed it cannot be reused by

others. To the best of our knowledge, no platform in section III.B provides the licensing controls discussed.

It is important to have a clear view of some concepts managed in Edu-AREA and the way in which Creative Commons (CC) licenses can be managed on them. Documents may be licensed under CC. Lesson Plans and Activities may also be licensed under CC terms, but as they may include Documents, specific issues may be involved in their licensing. These issues appear when adaptation, collection and combination of resources have to be considered.

1) Assigning Author Attribution

When creating a new element, after assigning the correct license, if the user is not the original author, he/she should assign the proper attribution to the real author. To do this, the user must choose the No option as an answer to the question “Are you the original author?” located just below the image of the license. Right after choosing “No”, two input text boxes are shown and for the user to introduce the author’s name and the author’s URL.

In case of an adaptation, the right attribution is automatically assigned to the resource (cf. Fig. IV). Both original author and the author who made the adaptation appear in the attribution, with their correspondent links. The title of the “adapted” resource has a link to the Edu-AREA section where it was created, a link to the Creative Commons license is also included with every license, and a link to the author’s profile page in Edu-AREA or any other URL provided is also included.

FIGURE IV. CLOSE-UP OF LICENSE AND AUTHOR ATTRIBUTION IN SHOW VIEW OF A DOCUMENT

2) Assigning Licenses to Derivative Works

The platforms described in section III.B do not provide any assistance to users while choosing a license for adaptations, collections or combinations. The user needs to know the rules and valid options, and this can be quite complex and cumbersome.

In Edu-AREA the licenses that can be assigned to a derivative work are controlled and checked by the system in adaptations and combinations. In this way, if the user tries to assign a license that is not in accordance to the licenses of the included elements or to the license of the original work, an alert is triggered and the action is aborted. Similarly, if an element with a license not in accordance to the license assigned to the combination wants to be added by the user, an alert is triggered and the action is aborted. This is continuously checked by the system to always maintain the licenses under the CC compatibility rules.

A key issue is that in case the user is the author of some of the works to be adapted or combined, the CC license requirements are no longer applied.

C. Linking Resources

Another feature included in Edu-AREA devoted to promote the openness principles in Edu-AREA is automatic referencing. This corresponds to the generation of links among resources in accordance to their use. For example, if a document is included in a lesson plan, this will be annotated in the document. As a result, given a document, users could see where it has been included. Similarly, links about adaptations are also included, so given a resource we could go to the “parent” and “child” ones.

These links are related to the concept of paradata, as data about the usage of a resource. For each Resource, paradata are maintained as adoptions, adaptations, views, comments, tags, communications to social networks and annotation into Boards. We are trying to develop algorithms to provide quality indicators of the resources taking into account these paradata. Quality concerns are a main barrier for users that wonder about adopting OER.

V. CONCLUSIONS

This paper discusses about the contradictions in the way the Open Movement is being developed in the educational domain. There are several initiatives related to this movement that demonstrate a variety of interests and points of views. The differences are more relevant if we consider the proposals in relation to initiatives in other fields. From our point of view is necessary to open a debate about the existing platforms and to define clearly the functionalities to provide an appropriate support to the Open Movement.

The paper provides some data to understand the development of the Open Movement and OERs. Functionalities available in existing platforms and results of a teacher survey are presented. These data highlights the different points of view. In addition, we introduce the Edu-AREA system where our views and proposals towards OERs are embodied. We consider that the Edu-AREA functionalities promote an innovative change in the educational culture towards a more open approach, similar to the already successful open software culture.

Edu-AREA is proposed in a transversal way, for any field, but we think it can be specially valuable for Engineering and STEM education promoting a more active role by teachers and the sharing of proposals. Teaching innovation can be largely supported by technology, and this is directly an opportunity to approach students and teachers to these fields, supporting the technology literacy. In addition, the consideration of applications and devices as educational resources is very important for STEM and engineering. Many educational practices in these fields involve the use of these elements and they should be easily integrated in the lesson plans and courses.

One of the main tasks related to the future of Edu-AREA is its evaluation. We plan to organize some teacher events, such as hackatons, in order to populate the platforms with real OERs by real teachers. Then, we will promote the use of the platforms by these and other teachers and eventually we hope to arrange some communities of interest. The experience of these teachers using the platform will be surveyed in order to get an evaluation.

ACKNOWLEDGMENT

This research has been co-funded by the Galician Regional Government under project R2014/029 "*Research Networks: TELGalicia*", the European Regional Development Fund (ERDF) and the Galician Regional Government under project GRC2013-006 (Consolidation of Research Units).

On the Effectiveness of Using Midterm Examinations Strictly for Formative Feedback

Robert M. O'Connell

Department of Electrical and Computer Engineering
University of Missouri
Columbia, MO, USA
oconnellr@missouri.edu

Abstract—Research shows that, when it is conducted properly, formative assessment can have a significant impact on student learning. Examinations administered throughout the course, defined here as midterm exams, can be used effectively for formative assessment. However, misconceptions about the differences between the purposes of formative and summative assessment often lead to faulty application of midterm exams for summative assessment. The purposes of this paper are to clarify the pedagogical differences between exams used for formative and summative purposes, and to present data that illustrate that when midterm exams are used strictly for formative purposes, they can significantly enhance student learning, as measured by student performance on summative final examinations.

Keywords—*formative assessment; feedback; examinations.*

I. INTRODUCTION

The purpose of this Work-in-Progress paper is to present and discuss the results of an on-going study to quantify the benefits of formative midterm examinations. By “midterm examination” is meant any examination given during the semester or quarter during which the course is being taught, excluding the final, summative examination. Formative assessment is, by definition, used to provide feedback to both instructors and students in order to enhance student learning and produce greater achievement of learning outcomes [1 - 3]. In [4] the effectiveness of various forms of formative assessment are analyzed via surveys of students and faculty. Summative assessment, on the other hand, is used to measure how well students have achieved one or more learning outcomes, and it is used to determine an associated grade. It is not used for feedback to improve student learning. Although the most common form of summative assessment is the final examination, some instructors structure their courses in units, and do a summative assessment after each unit. In that model, each unit of the course is essentially a self-contained mini-course.

Midterm examinations are often used for both summative and formative purposes. For example, in a course having two midterm exams and a final exam, the midterms may each be used to determine ten to twenty percent of the final grade (while the final exam, laboratory scores, homework, and other items determine the remainder of the grade). This is the summative component. At the same time, the results of the

midterm exams are often used to provide feedback that helps students improve their learning in anticipation of the final exam. This is the formative component.

This dual usage of the midterm exams is problematic for two reasons. First, learning outcomes are usually expressed in terms of what students should know and be able to do at the end of the course. By assigning permanent credit to midterm exams, the instructor either rewards the student prematurely (if he or she does well on the exam) or penalizes him or her unfairly (if they do poorly), because the learning outcome explicitly gives them until the end of the course to demonstrate achievement of the outcome. In many countries outside the U.S., there are no midterms, only the summative final exam. This practice is consistent with the learning outcome statement. Secondly and perhaps more importantly, formative assessments work best when students can take risks and make errors without fear of penalty [1]. For the instructor to provide useful feedback, it is helpful to know the students' incorrect thought processes. Midterm exams with a summative component discourage students from taking such risks and thus deny the described feedback opportunity.

This difficulty raised the question as to whether midterm exams, used properly for formative purposes, would be effective at improving student learning, as measured by performance on summative final examinations. Thus, while adapting the teaching and learning strategy known as team-based learning (TBL) to basic electrical engineering courses [5 - 7], an important change to the basic process has been to use strictly formative midterm exams. In the following sections, the manner of using formative and summative exams in those TBL-based courses will be described; and formative and summative assessment data from the two most recent offerings of one course and the four most recent offerings of another one will be presented and discussed. In all cases considered, the student scores were significantly higher on those portions of final exams that corresponded to earlier midterm exams; and that when formative midterm assessments were not used for certain (the final two) learning outcomes, the scores on the summative final exam were significantly lower than those portions of the exam for which there had been an earlier formative midterm exam.

II. COURSES AND ASSESSMENTS

For this paper, average midterm and final exam scores from

the four most recent offerings of a required junior-level course in electric circuit theory and from the two most recent offerings of an elective senior-level course in electric power systems were analyzed. Each course has six intended learning outcomes [1] (ILOs). Briefly, in the electric circuit theory course, they are that by the end of the course, students should be able to analyze linear circuits containing operational amplifiers and transformers (ILOs 1 and 2); analyze RLC circuits in the time- and complex frequency domains (ILOs 3 and 4); and determine the impulse and frequency responses of simple passive and active filters (ILOs 5 and 6). In the electric power systems course, students should be able to use the per unit concept to calculate power in balanced three-phase systems (ILOs 1 and 2); calculate the physical properties and electrical behavior of three-phase transmission lines (ILOs 3 and 4); and use the method of symmetrical components to analyze unbalanced three-phase systems.

In all six offerings of both courses, achievement of the first two ILOs were assessed formatively with a midterm exam approximately one-third of the way through the semester, and similarly for the third and fourth ILOs approximately two thirds of the way through the semester. Ideally, a third formative midterm exam should also be administered for the final two ILOs, but that would occur at the end of the course, just a few days before the comprehensive summative final exam. This usually places an excessive labor burden on the instructor, so in the six course offerings used in this study, the third midterm exam was not administered.

Originally, the midterm exams were used formatively in the strictest sense. That is, the exams were graded to provide instructional feedback, returned to the students, and reviewed in class carefully, thus providing both instructor and students with the immediate opportunity to correct misconceptions and improve student learning in preparation for the course grade-determining final exam. Scores from the midterm exams had no bearing on final grades. That practice encountered two practical problems, which were identified in student course evaluation surveys [5 - 7]. The first was that many students would simply not take the midterm exams seriously or prepare well for them, because their scores didn't contribute toward the final course grade. Impending tests or even graded assignments in other courses (where scores contributed to the final grade) often took precedence over the formative midterm exams in the TBL-taught courses. The second problem was that many students objected to the heavy grade-determining emphasis attributed to the summative final exam and the test anxiety associated with such a format.

To solve both problems, a compromise was adopted, by which, if a student's score on the portion of the final exam corresponding to a specific ILO is higher than the corresponding score on the earlier formative midterm exam, the final grade for that learning outcome is determined solely by the final exam score. If not, however, then the final grade for that outcome is determined by the average of the two scores. This treats the midterm exam scores as a back-up of sorts in case of a "bad day" on the final exam or a portion thereof. The effectiveness of this solution was illustrated in

student course evaluation surveys [5 - 7], which showed that, before instituting the compromise, 69% of students in the TBL-taught courses studied seriously for the formative midterm exams and only 32% of them were comfortable with the heavy emphasis given to the summative final exam. Since introducing the compromise, over 90% of students in those courses now treat the formative midterm exams seriously and are comfortable with the final grade-determining policy. This compromise was used in all six course offerings analyzed and discussed here.

III. DATA AND DISCUSSION

The data in question are given in Tables I and II, respectively, for the electric circuit theory course and the electric power systems course. The first two columns of each table give the semester of the course offering and the number of students completing the course that semester. The fourth and fifth columns of each table show, respectively, the average scores on the midterm exam and the portion of the final exam corresponding to the pair of ILOs identified in the third column. (The data were combined in ILO pairs this way to simplify instructor work load.) The sixth column (Percent Change a) shows the percentage change in the scores in Columns 4 and 5. Thus, for example, in the electric circuit theory course in Spring '13, the class average on the portion of the final exam corresponding to ILO pair 1,2 (0.762) was 26.2% higher than the class average on the earlier midterm exam on the same two outcomes (0.604). All twelve percent

TABLE I
DATA FROM ELECTRIC CIRCUIT THEORY

Semester	No. of Students	Course ILOs	Midterm Average	Final Exam Average	Percent Change a	Percent Change b
Spring '13	42	1,2	0.604	0.762	+26.2	
		3,4	0.736	0.750	+1.9	
		5,6	-----	0.667		-11.8
Fall '13	52	1,2	0.619	0.874	+41.2	
		3,4	0.619	0.793	+28.1	
		5,6	-----	0.671		-19.5
Spring '14	42	1,2	0.613	0.817	+33.3	
		3,4	0.632	0.760	+20.3	
		5,6	-----	0.662		-16.1
Fall '14	45	1,2	0.601	0.777	+29.1	
		3,4	0.603	0.678	+12.4	
		5,6	-----	0.634		-12.8

TABLE II
DATA FROM ELECTRIC POWER SYSTEMS

Semester	No. of Students	Course ILOs	Midterm Average	Final Exam Average	Percent Change a	Percent Change b
Spring '13	39	1,2	0.629	0.736	+17.0	
		3,4	0.704	0.827	+17.5	
		5,6	-----	0.649		-17.0
Fall '14	27	1,2	0.604	0.686	+13.6	
		3,4	0.709	0.790	+11.4	
		5,6	-----	0.644		-12.7

change values in Column 5 are positive, with an average value of 21.0%, which suggests that the strictly formative midterm exams may have helped to improve student learning.

That suggestion is further supported by the negative percentage change values given in the final column (Percent Change b) of both tables. As stated above and shown in Column 4, midterm exams were not given for the ILO pair 5,6 of either course during any of the course offerings in question. The average scores on the portion of the final exam for that ILO pair are shown in Column 5; these values are smaller than the mean value of the two portions of the same final exam for ILO pairs 1,2 and 3,4 by the percentage given in Column 7. In the Spring '13 offering of electric circuit theory, for example, the average scores on the final exam for ILO pairs 1,2 and 3,4 were, respectively 0.762 and 0.750, with a mean value of 0.756. The average score on the same exam for ILO pair 5,6 was 0.667, which is 11.8% smaller than 0.756. Similar results were obtained for each of the six course offerings described in Tables I and II, with an average negative Percent Change b value of 15.0%.

V. CONCLUSION

In the six course offerings studied, final exam scores for ILOs 1 through 4 improved by an average of 21% over earlier midterm exam scores on the same ILOs; and final exam scores on ILOs 5 and 6, which had not been formatively assessed prior to the final exam, were an average of 15.0% lower than the mean value of the final exam scores on ILOs 1 through 4. These results suggest that midterm exams, used properly for formative assessment, can be effective at improving student learning, in response to the above-stated question.

Further supporting evidence for this conclusion will be obtained by administering formative midterm exams after the

third segment, i.e., ILOs 5 and 6, of each course, and examining how that exam affects the data in Tables I and II. This will require solving the above-mentioned end-of-semester practical problems.

The important features of this work to the engineering education community are that it underscores the error in trying to simultaneously use an exam for both formative and summative purposes, and it suggests that, when midterm exams are used correctly for formative assessment, they can have a significant positive impact on student learning.

Abstract—The U.S. Department of Education (DoE) asserts that one way to improve student achievement is to consider competency-based learning. The DoE describes competency-based learning as “a structure that creates flexibility, allows students to progress as they demonstrate mastery of academic content, regardless of time, place, or pace of learning.” Competency-based learning focuses on outcomes and skill-sets. Students are encouraged to learn in a way that allows them to employ reproducible skills sets to generate tangible outcomes.

Our group is early in an initiative to provide alternative learning environments in STEM higher education. The group consists of faculty from several academic units including liberal arts, libraries, and technology. One of the learning experiences currently being tested involves the tight coupling of all forms of communication and information literacy with technological skills and concepts. We develop an integrated learning experience that cultivates learner’s capacities of interpersonal communication and social and cultural awareness in a seminar environment.

We will describe our process of generating competencies from AAC&U inspired rubrics and how these were mapped to learning outcomes and learning activities in the seminar environment. The institutional (and in some cases legal) constraints associated with the spirit of competency-based learning will be discussed.

I. INTRODUCTION

Students acquiring STEM degrees often graduate school academically prepared in their fields; business leaders however have been stating that they often lack the more intangible qualities such as teamwork, critical thinking, communication skills, and ability to manage interpersonal relations [1], [2]. These “soft skills” are tightly coupled with professional performance and career growth.

Derek Bok has claimed “it is impressive to find faculty members agreeing almost unanimously that teaching students to think critically is the principle aim of undergraduate education” [3]. However, several recent reports cast doubt on the effectiveness of universities in delivering this goal. For instance, the 2011 book *Academically Adrift* claimed 21st century graduates are woefully underprepared for the workforce in regards to these “soft skills” [4].

Furthermore, these so-called soft skills are all connected to basic interpersonal communication skills, commonly referred to as oral and written communication, and their close

counterparts, listening and reading. Such skills are not merely “add-ons” to a STEM job; they can make the difference between a successful and a failing team, career, or even corporation. In the last decade there have been efforts such as Project Kaleidoscope by the Association of American Colleges and Universities (AAC&U) to advance broad-based systemic innovation to build and sustain strong undergraduate education in the STEM fields [5].

Our group is in the early stages of an innovative initiative to provide alternative learning environments integrated with competency-based components at the main campus of a traditional undergraduate residential STEM higher education university. The group consists of faculty from several academic units including liberal arts, education, libraries, and technology. The mission of the group is to create learning experience that enhance learners capacities of interpersonal communication and social and cultural awareness in a seminar setting. Transferrable skills, such as inquiry and analysis, design, ideation, and quantitative analysis are also cultivated in a studio environment. In addition to focusing on integrating the liberal arts and libraries into STEM environments, we have embarked on designing an architecture for the implementation of competency-based learning.

This paper describes the design and implementation of a competency-based architecture for learning and assessment. The paper first describes our Polytechnic initiative by articulating its vision and key values. Section III then discusses the design of our initial competency-based system for learning and the assessment of student work. Early results are presented in section IV, then the paper concludes in section V with a discussion of observations conclusions, and plans for future work.

II. THE POLYTECHNIC INITIATIVE

“The Purdue Polytechnic is an educational initiative aimed at creating an exemplar of the undergraduate education of the future” [6]. The initiative was proposed in the summer of 2013 and has been supported by the President and Board of Trustees of the university. The Polytechnic was initiated in the College of Technology (now called the Purdue Polytechnic Institute) with several strategic partners within and outside Purdue. Internal partners include the College of Liberal Arts,

the Libraries, and the College of Education. The initiative has also benefitted from cooperation by the Mathematics and Physics and Astronomy departments in the College of Science. External partners have included Olin College [7], the University of Illinois Urbana Champaigns iFoundry program [8], and the University of California San Luis Obispo's SUSTAIN program [9].

The Polytechnic is motivated by the conviction that undergraduate education has become misaligned with the needs and aspirations of the students and the demands of future economies such that nothing short of a significant overhaul will make a substantive difference. In this paper we articulate the values, the guiding principles, and the signature characteristics of the Polytechnic undergraduate education.

A. Values and Characteristics

The vision and several characteristics unique to this new program were established as a portion of the guiding principles the faculty kept in mind while developing the learning experiences for the first year cohort that arrived in the fall of 2014. In particular, some of our values include valuing diversity, learning, and experiences, student autonomy, and goal setting [10]. For the new program this means program and faculty roles would focus more on working with the student to provide opportunities for each one to pursue a particular interest that furthers the understanding of a situation or location and helps the student explore possible future careers or areas of more in-depth study.

The core values and strategies of the program are:

- 1) An architecture that supports the student in exploring and identifying a contemporary issue around which they design their learning plan combining technology with other fields of study.
- 2) Self-paced learning that allows the students to learn as fast as they can without barriers and as slow as they need without penalties.
- 3) A focus on learning outcomes educational attainment ensuring that students graduate when they can demonstrate expertise in a set of key competencies. The competency-based approach is also the vehicle for this aspect.

In addition, the learning experiences for the program were conceived of as a spiral of developing knowledge and skills, where learning opportunities continually bring students back to the same types of activities with expectations of additional skill in applying those skills and demonstrating knowledge application to particular situations.

III. COMPETENCIES AND BADGES

A. Competencies

Focusing on learning outcomes and demonstrable skills, the group made the programmatic choice to evaluate student work via a methodology based on competency. The AAC&U VALUE rubrics [11] formed the foundation of several competencies that have been adopted into our university core learning outcomes [12]. We took this as opportunity to create a new learning experience that encompassed the competencies of

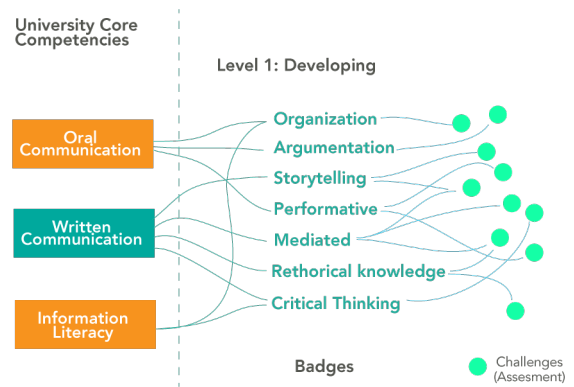

Fig. 1. Competency Map

Oral Communication, Written Communication and Information Literacy. Instead of having each of these competencies as separate courses (as it is traditionally done), we designed a new integrated learning experience called Culture, Communication, & Digital Narratives.

Figure 1 shows how the core competencies (oral communication, written communication, and information literacy) were mapped to 7 different sub-competencies. The sub-competencies were defined as a collaborative effort between a group of faculty from English, Communications, Technology, and Libraries. They represent combinations of learning outcomes from traditional courses which also map to rows in the VALUE rubrics. For example, the storytelling competency shown in figure 1 maps to rows in the oral communication rubric (Figure 2 while also mapping to rows in the written communication rubric shown in Figure 3.

We created an environment where these competencies were learned and practiced concurrently, where learning how to write effectively is not done sequentially after or before learning how to speak or design web mediated messages or web-pages. Students learn how to write while they learn how to integrate written messages in online multimedia delivery vectors or how to adapt them for oral delivery.

B. Badges

Digital “badges” were developed using our OpenPassport system [13], a derivative the Open Badges system developed by Mozilla [14]. While very similar to Open Badges, OpenPassport is currently restricted to local users.

Badges are certificates of competency mastery. They break down the learning material into discrete, yet coherent, modules, each attached to a specific skill-set or body of knowledge that result in a clear ability to analyse, understand, or perform a skill or procedure effectively and timely. Our use of the OpenPassport badge system differs from other online learning management systems (LMS) such as the Open Learning Initiative (OLI) [15] in that we used OpenPassport more as a repository for student deliverables and a means for assessing and providing feedback. Students rarely actively interacted

ORAL COMMUNICATION RUBRIC

Definition

Activity of conveying meaningful information verbally; communication by word of mouth typically relies on words, visual aids and non-verbal elements to support the conveyance of the meaning. Oral communication is designed to increase knowledge, foster understanding, or to promote change in the listener's attitudes, values, beliefs, or behaviors.

	Proficient 3	Emerging 2	Developing 1
Organization	Organizational pattern (specific introduction and conclusion, sequenced material within the body, and transitions) is clearly and consistently observable and is skillful and makes the content of the presentation cohesive.	Organizational pattern (specific introduction and conclusion, sequenced material within the body, and transitions) is clearly and consistently observable within the presentation.	Organizational pattern (specific introduction and conclusion, sequenced material within the body, and transitions) is intermittently observable within the presentation.
Language	Language choices are imaginative, memorable, and compelling, and enhance the effectiveness of the presentation. Language in presentation is appropriate to audience.	Language choices are thoughtful and generally support the effectiveness of the presentation. Language in presentation is appropriate to audience.	Language choices are mundane and commonplace and partially support the effectiveness of the presentation. Language in presentation is appropriate to audience.
Delivery	Delivery techniques (posture, gesture, eye contact, and vocal expressiveness) make the presentation compelling, and speaker appears polished and confident.	Delivery techniques (posture, gesture, eye contact, and vocal expressiveness) make the presentation interesting, and speaker appears comfortable.	Delivery techniques (posture, gesture, eye contact, and vocal expressiveness) make the presentation understandable, and speaker appears tentative.
Supporting Material	A variety of types of supporting materials (explanations, examples, illustrations, statistics, analogies, quotations from relevant authorities) make appropriate reference to information or analysis that significantly supports the presentation or establishes the presenter's credibility/authority on the topic.	Supporting materials (explanations, examples, illustrations, statistics, analogies, quotations from relevant authorities) make appropriate reference to information or analysis that generally supports the presentation or establishes the presenter's credibility/authority on the topic.	Supporting materials (explanations, examples, illustrations, statistics, analogies, quotations from relevant authorities) make appropriate reference to information or analysis that partially supports the presentation or establishes the presenter's credibility/authority on the topic.
Central Message	Central message is compelling (precisely stated, appropriately repeated, memorable, and strongly supported.)	Central message is clear and consistent with the supporting material.	Central message is basically understandable but is not often repeated and is not memorable.

Adapted from AAC&U Core Value Rubrics

Fig. 2. Oral Communication Rubric [12]

WRITTEN COMMUNICATION RUBRIC

Definition

Written communication is the development and expression of ideas in writing. Written communication involves learning to work in many genres and styles. It can involve working with many different writing technologies, and mixing texts, data, and images. Written communication abilities develop through iterative experiences across the curriculum.

	Proficient 3	Emerging 2	Developing 1
Context of and Purpose for Writing <i>Includes considerations of audience, purpose, and the circumstances surrounding the writing task(s).</i>	Demonstrates a thorough understanding of context, audience, and purpose that is responsive to the assigned task(s) and focuses all elements of the work.	Demonstrates adequate consideration of context, audience, and purpose and a clear focus on the assigned task(s) (e.g., the task aligns with audience, purpose, and context).	Demonstrates awareness of context, audience, purpose, and to the assigned tasks(s) (e.g., begins to show awareness of audience's perceptions and assumptions).
Content Development	Uses appropriate, relevant, and compelling content to illustrate mastery of the subject, conveying the writer's understanding, and shaping the whole work.	Uses appropriate, relevant, and compelling content to explore ideas within the context of the discipline and shape the whole work.	Uses appropriate and relevant content to develop and explore ideas through most of the work.
Genre and Disciplinary Conventions <i>Formal and informal rules inherent in the expectations for writing in particular forms and/or academic fields (please see glossary).</i>	Demonstrates detailed attention to and successful execution of a wide range of conventions particular to a specific discipline and/or writing task (s) including organization, content, presentation, formatting, and stylistic choices	Demonstrates consistent use of important conventions particular to a specific discipline and/or writing task(s), including organization, content, presentation, and stylistic choices	Follows expectations appropriate to a specific discipline and/or writing task(s) for basic organization, content, and presentation
Sources and Evidence	Demonstrates skillful use of high-quality, credible, relevant sources to develop ideas that are appropriate for the discipline and genre of the writing	Demonstrates consistent use of credible, relevant sources to support ideas that are situated within the discipline and genre of the writing.	Demonstrates an attempt to use credible and/or relevant sources to support ideas that are appropriate for the discipline and genre of the writing.
Control of Syntax and Mechanics	Uses graceful language that skillfully communicates meaning to readers with clarity and fluency, and is virtually error-free.	Uses straightforward language that generally conveys meaning to readers. The language in the portfolio has few errors.	Uses language that generally conveys meaning to readers with clarity, although writing may include some errors.

Adapted from AAC&U Core Value Rubric

Fig. 3. Written Communication Rubric [12]

with the system in ways that provide immediate or near immediate feedback, like walking the learner through a problem as is often the case in other systems like OLI. Rather, most

formative and many summative assessments were conducted using performance-based theories and methods consistent with those in [16].

Figure 4 illustrates what the learner sees when logging into the system. Here there are 33 badges available to the learner. Badges seen in the figure are those related to a seminar learning experience described later. Figure 5 shows a particular badge in Information Literacy. Here one of the challenges is exposed showing the required activity along with resources attached to the badge for learners to study and work with to demonstrate their level of competency. Also notice there are five challenges that the students must demonstrate successfully to earn the badge.

The development group encountered struggles in determining the 'size' of badges, where size denotes the quantity of content a particular badge or competency should incorporate. There was a hope of achieving a certain amount of uniformity across different courses in the size of the badges, despite development by multiple faculty members in different fields. After many conversations, the notion of one badge equaling one credit hour seemed to be the most acceptable to faculty, addressing concerns, and is supported through other CBE structures such as Western Governors University - Indiana [17]. The more discussion around competencies, badges, and credit hours, the more the one credit hour equal to one badge seems to make sense, as most 3 credit classes have between 3 and 9 learning outcomes, so there appeared to be a natural fit between one or more learning outcomes and a badge that would encompass that content. Thus we were able to map learning outcomes to badges in a way such that badges could be grouped in logical ways to map to traditional courses.

Figure 6 illustrates the badge/challenge arrangement for a competency in Fundamentals of Imaging Technology. This series of three badges was mapped to the learning outcomes of a similarly named freshman level course in Computer Graphics Technology. Note that several of the challenges contain "OR" clauses, meaning that students had the choice to complete these challenges in ways that stimulated their individual intrinsic motivation.

During development, the badges each contained between 2 and 5 challenges. The idea is that competencies and the badges attached to them are not simple constructs, but complex skill sets and abilities that need to be defined and practiced before mastery is to be achieved. For badges, a challenge is a particular activity or artifact that needs to be completed to succeed at the challenge. Once all the challenges for a particular badge are earned, then the badge itself is earned.

In addition to the size of the badge, an agreed upon measure of success was necessary for determining that a student achieved a particular competency. In the initial implementation, the faculty agreed that the threshold of achievement would be an A, so if a student succeed in completing all the challenges for a particular badge, they had an A for that competency. In a parallel fashion, successfully completing all badges for a course or learning experience meant the student earned an A for that course.

The logic of this approach is that mastery is for every given level of competence is a binary phenomenon: you either demonstrate it or not. To avoid the disqualification of the students if the challenges are too high, badges and competencies are structured on three levels: developing, emerging, and proficient, which correspond to the benchmark, milestones and

capstone levels shown in figures 2 and 3. Most competencies are demonstrated at each of the three levels and badges are awarded to certify the progress from one level to another.

IV. EARLY RESULTS

As stated earlier, assessments were performative in class in some cases while others were more in the context of written feedback. Formative assessments were also continuously provided during class time. In most instances, student work took many submissions before it was assessed as meeting a sufficient level of competency to be judged appropriate for collegiate work at a developing level for particular skills. An example of written feedback to a student submission demonstrating rhetorical knowledge looked like

"You did add comments, and this is good, but say a bit more about the principles. What is rhetorical about this? Are you talking about Aristotle's rhetoric? Can you connect it to Barthes' study of an image? How about the readings/principles you were given? Don't describe the image (the reader can see that), but discuss the design principle that creates a context, describes a story, etc."

In this case the submission was "reset" so the student could try again. Often the student and faculty would review work prior to submission but it became clear that first year students are not accustomed to a situation where work could be continually returned for revision and refinement. Students were generally not accustomed to having submissions returned for additional work. The current primary education system trains our students to get work completed on time, turn it in, and just accept the grade received as the course moves on to new material. This is the attitude and process a competency-based education model is intentionally designed to challenge.

Conversely, when a student's work was approved the assessor (faculty) would also provide feedback and recommendations for continued improvement.

"I like the feminist thread you've chosen this semester, great job. You certainly cover the basics of ethos, pathos, logos – that's certainly sufficient. I would challenge you in the future to really delve into a text, pick out the nuances of On Rhetoric (ask yourself, why has this two hundred page text been studied for thousands of years, certainly not for three simple concepts e, p, l...)."

It is important to note that in the example above the student has demonstrated a "developing" level of mastery of the competency of rhetorical knowledge. The developing level represents attainment equivalent to completing a similar learning outcome or small set of outcomes at an "A" level in an entry level (freshman) course in written composition.

V. OBSERVATIONS AND CONCLUSIONS

One struggle with implementing a competency based education model in a traditional university is how to fit the expected average of 15 credit hours per semester and 30 credit hours per year of schooling. There is a learning curve to getting students accustomed to this model of working. It is not uncommon for the first semester or two to be lower earning through the credit hours / competency lens, while later years far out earn the traditional model of 15-19 credit hours in a

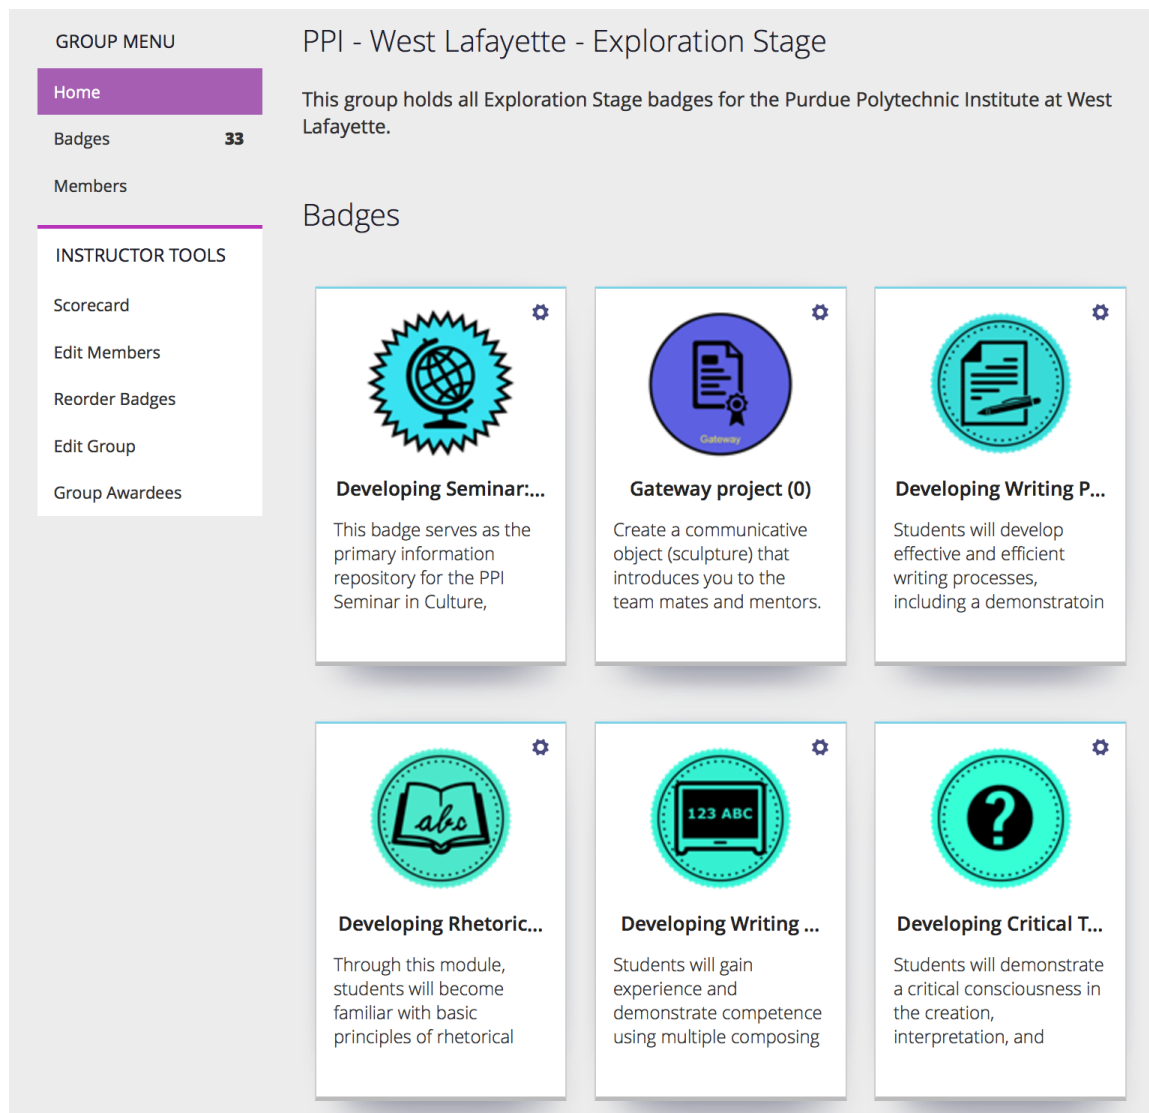

Fig. 4. Open Passport

semester. When trying to develop a new system like this that still has students and faculty restricted by a semester model that requires particular credit hour milestones to be met for student scholarships, faculty teaching load assignments, and similar administrative task, there is a challenge in balancing diverging requirements.

Another struggle, which in some ways also stems from needing to fit within the larger structure of an existing university, is the number of students who did not complete work during the first semester. The amount of incomplete work was due to a need for more time and more revisions on particular assignments to meet the threshold of the work submitted showing actual learning gains equivalent with an A in a traditionally structured class. Allowing the room for the learning to take place through additional revisions has added stress for several students as the workload has increased in the second semester while they try and stay on track with the university expectations and meet the learning expectations for the competency based program.

Badging systems are generally not a good substitute for a comprehensive learning management system. As a faculty, for example, we discovered there is no consistently clear place to maintain a course syllabus and organized class readings in a badge structure, particularly if the badge challenges are written so they can be achieved through submission of several different artifacts, potentially from different learning experiences (classes). To keep badges more general, information and resources for particular course activities needed to be presented and stored in another mechanism. Since we were not using another system, we created an umbrella badge that was used a resources container and was not expected to be earned by students. The syllabus and a variety of course readings were attached in this space.

Additionally, our badging system showed all available badges in a given group. Since the students in the first semester of this learning experience had a variety of introductory discipline specific courses available to them, and students were expected to complete all of the badges in all of the disciplinary fields, the list of outstanding work to be completed for a

Developing Information Literacy

☆ Get started

This badge certifies students' competency in using information appropriately to complete tasks. It corresponds to the university core curriculum foundational outcome in information literacy.

☆☆ Challenges

- Exploring a Topic ▾

For this challenge, you will turn in your explorations of a topic as you develop a research question.

You will be submitting the following to meet this challenge: Mind Map, Preliminary Environmental Scan, and a Refined Research Question.

Learning Outcomes

This badge certifies the information literacy core competency outcomes in the context of the PPI framework. Students will meet competencies in the following areas:

Seek: Identify a learning need and effectively locate material to address that need

Evaluate: Determine quality and relevance of sources selected

Apply: Use information gathered in an appropriate manner, neither claiming too much or too little from the source used, to help solve a problem

Document: Acknowledge the work of others appropriately and completely; ethically access and use information

Fig. 5. Information Literacy Badge

student was misleading, as all of the challenges for badges in the group were presented, whether a student needed to succeed at those particular challenges or not.

A. Epilog

During the spring semester of 2015 it became apparent that while mapping competencies at our level of granularity was both feasible and tractable, it was clear that this was a large challenge in terms of the many to many relationship between very granular competencies and the large number of courses available to students on our campus. Looking forward

to version 2.0 of our architecture, we are planning to decouple competencies from courses, thereby allowing learners to take advantage of traditional and other means of scaffolding their knowledge and skill so they can demonstrate higher order cognitive and meta-cognitive capabilities in the form of a smaller number of broad competencies like design thinking, systems thinking, effective communication, and ethical reasoning. We plan to continue developing learning environments in studio and seminar formats geared toward making the connections between learning in traditional environments and demonstrating broader competencies in the context of open-ended, real-world problems.

Systems Thinking Skills of Undergraduate Engineering Students

Shaobo Huang, Karim Heinz Muci-Kuchler, Mark D. Bedillion, Marius D. Ellingsen, Cassandra M. Degen

Department of Mechanical Engineering
South Dakota School of Mines & Technology
Rapid City, United States

Abstract— It is widely acknowledged that systems thinking skills (STS) are critical competencies that enable engineering students to solve problems, communicate, use data, and design components and systems, with greater success. Yet few studies have focused on examining the ST survey of engineering students in higher education. This preliminary study is aimed at investigating the STS of undergraduate engineering students and comparing the effectiveness of the instruments used to assess those skills. The primary research question is: how can we effectively measure the STS of engineering students?

Data were collected via a Background questionnaire and a Systems Thinking (ST) questionnaire that 117 engineering students finished, as well as a basic Systems Engineering diagnostics activity (SEDA) that 23 sophomore engineering students completed. Cross-comparisons were conducted between the ST survey and the SEDA to test the validity of the survey questions. Both quantitative and qualitative analyses were employed to assess the degree of STS of the engineering students that participated in the study. The findings from the current study contribute to the knowledge and assessment of undergraduate engineering students' STS.

Keywords—*Systems thinking; systems engineering; engineering undergraduates*

I. INTRODUCTION

Developing high performing, cutting edge products and systems requires engineers that, in addition to being proficient in their particular discipline, have a solid background in product development, systems engineering, and systems architecting [1-3]. Although many engineering programs in the US provide an introduction to the engineering design process itself in the context of a formal course, the development of system-level thinking skills is seldom emphasized in the undergraduate curriculum [4-12]. As a consequence, most engineering graduates are ready to do the technical calculations needed to design a specific component or simple product but struggle to design well-functioning products or systems of moderate or high complexity [13-18]. The lack of exposure to the concepts and tools of systems engineering and systems architecting frequently leads to system integration issues that demand design changes late in the development process. Unfortunately, those "last minute" design changes usually result in sub-optimal or degraded system performance and substantially increased cost.

Relatively few studies related to assessing and improving systems thinking skills (STS) were found after conducting a literature search in commonly-used literature databases. Among the notable works, Lammi [19] investigated the STS of high school students through an engineering design challenge by collecting data from engineering design sketches and interviews. Huang[15] reported that he successfully used systems modeling as a cognitive tool to enhance the STS of 15 graduate students. Davidz [2] conducted structured interviews and background surveys with senior engineers to research the enablers, barriers, and precursors to systems thinking development in engineers. The results showed that experiential learning and a supporting environment at work are primary factors that enhance engineers' systems thinking development. However, none of the studies found were focused on undergraduate engineering students and all of the assessment instruments used required someone with expertise in systems engineering to measure the students' systems thinking skills.

While STS are included in the ABET criteria for engineering programs, there is a dearth of literature on effective means of assessing undergraduate students' engineering STS. Systems engineering skills are implicitly evaluated in design classes when assessing project success; however, such evaluations are subjective and vary greatly between evaluators. What is needed is validated assessment instruments that can objectively assess students' competence in systems engineering; these instruments can then be used to guide the design and evaluate the effectiveness of curricular changes.

The work presented here is part of an effort to address the lack of study of STS in undergraduate students and the need for STS assessment tools that can be used by non-experts. The primary research question of the study is "*How can we measure the STS of engineering students?*" and this work-in-progress paper presents the authors' initial efforts to develop assessment instruments for that purpose.

II. SYSTEMS THINKING AND ENGINEERING

Good STS is crucial for the design of successful products and systems. Some elements of engineering design practices have been widely employed in engineering education to improve students' understanding of engineering concepts and principles, to develop students' "ability to apply knowledge of mathematics, science, and engineering," to train students to "function on multi-disciplinary teams," and to help students be

familiar with design processes. It is now clear, however, that a systems perspective is necessary to respond to the dynamic environment caused by the globalization of the economy, technological developments, and increasingly interdisciplinary collaborations [20-21]. This need for systems engineering skills is reflected in the ABET requirement that the curriculum of accredited engineering programs must allow students to “carry knowledge further toward creative application ... Engineering design is the process of devising a system, component, or process to meet desired needs [22].”

There is still little penetration of systems engineering instruction into the undergraduate engineering curriculum, and the result is a group of young engineers that, while competent in the design of components, does not have the knowledge and skills needed to deal with the interactions and tradeoffs that are inherent in the design of complex systems. Design of systems such as cars and aircraft require much system-level thinking and architecting before component design may commence. For practical reasons, students cannot design systems of such complexity during their academic careers. They can, however, be exposed to the design and analysis tools from systems engineering that can be brought to bear when faced with such challenges, and they can be provided with opportunities to practice with these tools on projects of lower complexity levels. One of the authors’ long term goals is to infuse the undergraduate curriculum with systems engineering education, starting at the freshman year.

III. METHODOLOGY

Two assessment instruments were developed and used for the study presented in this paper: 1) A systems thinking (ST) questionnaire, and 2) a basic Systems Engineering diagnostics activity (SEDA). This section provides summary information about the characteristics of both of those instruments.

A. ST Survey

To develop a survey instrument to measure undergraduate engineering students’ STS, meta-analyses of literature were conducted with the guidance of the research question: What are the primary components of systems-level thinking? The following subscales were identified as the primary features of system-level thinkers based on engineering education curriculum and students’ experience in the U.S.

Thinking Holistically: Identify and understand connections and interactions among the elements/ components/ subsystems in a complex system. A system-level thinker does not focus on components of a system in isolation but views them in the context of the system’s performance, including interactions with other components.

Interdisciplinary Knowledge: Understand the value of various disciplines, interpret a system from multiple perspectives beyond the engineering level, and conceptualize problems from a broad range of viewpoints [23-24]. For example, when solving engineering problems, it is essential to be aware of the environmental, marketing, economical, ethical, and cultural issues and their impacts on the selection and implementation of the designs.

Optimization: Consider system improvement and balance with tradeoffs while developing, selecting, and finalizing design solutions. The tradeoffs include, but are not limited to, technical challenges, cost of developing and maintaining, operation, schedule, and environmental constraints.

Communication and Interpersonal Skills: Effectively communicate and/or collaborate with people involved with the whole system, such as other engineers, colleagues in different departments, and customers. Communication and interpersonal skills are critical personal traits for systems thinking development in engineers [25-26].

The overall structure of the survey is a 30-item 6-point Likert scale (1: Strongly disagree; 2: Disagree; 3: Slightly disagree; 4: Slightly agree; 5: Agree; 6: Strongly agree) questionnaire. It has subscales with 6-10 items per subscale. To control acquiescence and minimize non-substantive responding, at least one item per subscale is reversely coded. One male M.S. and one female Ph.D. student were involved in reviewing the items. The items were adjusted according to the students’ feedback before being implemented in this preliminary study.

B. Systems Engineering Diagnostics Activity (SEDA)

A toaster was selected for the basic systems engineering diagnostics activity (SEDA) because the majority of the students were expected to be familiar with its purpose, appearance, and primary function. To avoid any disparities that could result due to varying degrees of familiarity with graphical tools used for the schematic representation of systems, a table was used instead of a concept map for this activity. One author lead the activity while another author observed the class.

Figure 1. Pegboard with Toaster Components

First, the class instructor spent about 20 minutes presenting to the students a series of pictures showing the disassembly of a toaster. Then a pegboard with all the toaster components was introduced (see Figure 1) and a list of all the toaster components was provided. A table template was then given to the students to complete. Using the information mentioned above, the students were asked to name the subsystems that comprise the toaster, identify the components that form each subsystem, and list the other subsystems that interact with each subsystem listed explaining their interactions.

IV. DATA COLLECTION AND ANALYSES

A. Quantitative Data (ST Survey)

Collection: Students in four undergraduate mechanical engineering courses at freshman to junior levels at a 4-year engineering college participated in the ST survey using Qualtrics, an online survey platform. Only students who finished at least 85% of the survey questions were included in

this study. The missing data were replaced by the overall mean of the individual's responses.

Analyses: Statistical descriptive analyses were employed to analyze the quantitative data using Stata 13. Reliability of the survey instrument was calculated with Cronbach's alpha. Cronbach's alpha reflects the internal consistency of the survey questions, that is, whether the questions in one subscale are closely related [27].

B. Qualitative Data (SEDA)

Collection: A total of 30 students in a sophomore-level Engineering Mechanics Dynamics course participated in the systems engineering diagnostics activity (SEDA) described in the previous section. Seven (7) student responses were excluded because they either did not identify interactions among subsystems or they collaborated on the activity and provided identical results. Four datasets were collected from each student's responses to four items: 1) naming the subsystems (Item 1), 2) listing the components involved in each subsystem (Item 2), 3) listing other subsystems that interact with a specific subsystem (Item 3), and 4) explaining the interactions of the other subsystems that interact with a specific subsystem (Item 4). Considering the many valid ways the toaster subsystems could be defined, a depth of grouping (minimum/maximum number of subsystems) was not required.

Analyses: Five mechanical engineering faculty independently evaluated the students' performance during the system engineering diagnostics activity. A student could receive one point if he/she provided reasonable responses, as perceived by the faculty, to Item 1 (naming the subsystems), Item 2 (listing the subsystem components), or Items 3 and 4 combined (identifying the interactions among subsystems). Consensus is achieved for each aspect assessed if 80% (4 out of 5) faculty assigned the same grade (1 or 0).

Summing the individual grades assigned by the five faculty evaluators to each aspect that was assessed, the total grade that a student could receive ranged from 0 to 15. A sophomore-level student was considered to have high performance in systems thinking skills if his/her total grade was higher than 10, moderate if between 8-10, and low if below 8.

V. RESULTS

A. Quantitative Data (ST Survey)

A total of 117 students finished the ST survey online. As shown in Table 1, over 85% of the students were males and most students did not come from homes where the parents were engineers or scientists.

Table 2 shows the reliability coefficients by subscales in the ST survey.

Table 1. Student demographics

Particip- ants	Gender		Parent is an engineer or scientist	
	Female (%)	Male (%)	Yes	No
ME 110 (N = 26)	1 (3.8%)	25 (96.2%)	4 (15.4%)	22 (84.6%)
ME 210 (N = 20)	1 (5.0%)	19 (95.0%)	4 (20.0%)	16 (80.0%)
ME 221 (N = 23)	0 (0%)	23 (100%)	3 (13.0%)	20 (87.0%)
ME 322 (N = 15)	2 (13.3%)	13 (86.7%)	1 (6.7%)	14 (93.3%)
ME 352 (N = 33)	4 (12.1%)	29 (87.8%)	5 (15.2%)	28 (84.8%)
Total	117			
*ME 110:	Introduction to Mechanical Engineering			
ME 210:	Statics of Mechanisms			
ME 221:	Dynamics of Mechanisms			
ME 322:	Machine Design			
ME 352:	Introduction to Dynamics System			

Table 2. Reliability Coefficients of the ST survey

Subscales	Cronbach's Alpha Value	Sample Item
Thinking Holistically	0.65	Testing a design in the laboratory cannot guarantee its functionality when it is used in a real environment.
Interdisciplinary Knowledge	0.67	What I am learning as an engineering student is relevant to politics or economics.
Optimization	0.60	Risk assessment is not necessary until the end of the project.
Communication and Interpersonal Skills	0.65	It is more difficult to communicate with students from non-engineering majors than with engineering students.

B. Qualitative Data (SEDA)

All students defined between 4 and 9 subsystems for the toaster; while 18 (78.3%) students listed 6 or more. The majority of the students (70%-100%) identified the following five subsystems: packaging, exterior covering, electronic, heating, and interior support.

Consensus among the evaluators was achieved for 56.5% of the students on naming the subsystems (Item 1), 47.8% for listing subsystem components (Item 2), and 82.6% for identification and explanation of subsystem interactions (Items 3 and 4 combined). Table 3 shows the distribution of students' systems thinking skills.

Table 3. Distribution of students' systems thinking skills

Systems Thinking Skills	High	Moderate	Low
Number of Students	4	8	11

Of the 4 students with high systems thinking skills, only one missed assigning a component (out of a total of 32) to one of the subsystems that he/she identified. Three (3) of the 8 moderate-skilled students, and 4 of the 11 low-skilled students, didn't assign at least one component to one of the subsystems that they identified. Almost 70% of the students that participated in the systems engineering diagnostics activity had at least one component listed in multiple subsystems.

C. Cross Comparison

The results of the SEDA were used to categorize and aggregate students' responses to the ST survey. Students with high, moderate, and low systems thinking skills were compared in terms of their average responses to the subscales of the survey (Figure 2). The results of the ST survey basically align with those of the SEDA: students recognized as low in their systems thinking skills in the SEDA also received the lowest scores in most of the subscales in the ST survey.

Figure 2. Cross validation of ST survey

D. Discussions and Future Study

This paper presented the preliminary results of a study aimed at assessing the systems thinking skills of undergraduate engineering students. Cronbach's alpha values and a systems engineering diagnostics activity (SEDA) were used to provide a preliminary test for the reliability and validity of the ST survey. Initial results from both the ST survey and the SEDA showed that there is a need to improve the systems thinking skills of engineering students.

E. Systems Thinking (ST) Survey

The Cronbach's alpha values, ranging from 6.0 to 7.0, indicate low internal consistency of the survey questions. Two reasons that can affect the Cronbach's alpha values are discussed below. First, the survey was answered by engineering students from the freshman to the junior levels. Although the influence from the background of the parents was controlled in the analyses, student responses to survey questions in the same subscale can vary significantly depending on their prior exposure to the product development processes in courses that they have already taken. Second, considering the complexity of engineering systems and the different phases of the product development processes, 6 to 10 questions for each subscale could be insufficient. In this regard, Cronbach's alpha increases with the number of items in the scale [27].

F. Systems Engineering Diagnostics Activity (SEDA)

The authors noticed four factors during the systems diagnostics activity that can impact the results. The factors are discussed in the following paragraphs.

First, the activity assumes that all the students are sufficiently familiar with the main functions and components of a toaster. However, the authors found that several students were unfamiliar with the purpose of certain components. For example, while conducting the activity more than 5 students asked for additional information about the location and/or function of some components.

Second, the pictures of the process of disassembling the toaster and the list of components provided to the students may have influenced the responses of the participants. For example, during the activity none of the students missed the packaging subsystem. This was most likely the result of showing pictures of taking the toaster out of the box and including the packaging materials in the list of components. The authors feel that without that input, some students would have missed that subsystem since they don't view the packaging as part of the product. It is important to keep in mind that for products like a toaster, the design of the packaging is part of the product development effort.

Third, communications among students could have affected the responses provided by some participants. Due to the limited time available during the class session, many students continued working on the activity after class. Although student responses that were almost identical were excluded from this study, it is possible that some of the responses used in the analyses were influenced by informal interactions among the participants.

Finally, assessing systems thinking skills using the SEDA can be subjective since the grades assigned to the items that were evaluated are affected by the experience of the evaluator and can be significantly influenced by external factors.

VI. FUTURE STUDY

To address the issues mentioned above, future studies will: 1) include more questions in each subscale in the ST survey; 2) use the updated ST survey to collect longitudinal data from students taking the same course with the same instructor but in different semesters; 3) provide students with a list of components that includes a picture and, when deemed appropriate, a brief high-level description of the general purpose/function of each component; 4) strategically group students in small teams and analyze teams' responses to the ST survey and the SEDA; and 5) evaluate students' responses to the SEDA by comparing them with typical responses of practicing engineers with systems engineering expertise. Finally, structural equation models will be developed to investigate the impact of engineering courses on students' systems thinking skills.

An analysis of the provision of context within existing remote laboratories

Tania Machet, David Lowe
School of Information Technologies
The University of Sydney
Sydney, Australia

tmac2470@uni.sydney.edu.au, david.lowe@sydney.edu.au

Abstract— Laboratory work is a well-accepted component of science and engineering programs. One emerging trend has been the increasing utilisation of remotely accessed laboratories, where the students can remotely monitor and/or control physical apparatus, typically across the internet. This supports greater flexibility of access for students as well as the possibility of sharing of facilities between institutions. One additional benefit is greater flexibility in designing the learning context within which the laboratory can be positioned. As the interaction is computer mediated, it becomes simpler to modify this interface and hence change the laboratory context.

Research has shown that context can have a significant effect on learning outcomes, students' retention of information, engagement with learning and on knowledge transfer from one domain to another (see, for example, [1],[2]). Despite this there has been little consideration given to understanding contextual information provided in laboratories in general and remote laboratories in particular.

In this paper we report on an analysis of contextual information provided within remote laboratories. Consideration is given to the ways in which the contextual information provides a connection between the real-world concepts being explored and the laboratory as a proxy for those concepts. The analysis shows that there is a diverse range of approaches and representational forms and suggests a new taxonomy that may be useful in describing the context found in laboratory activities for future analysis and design.

Keywords—laboratory; remote; context

I. INTRODUCTION

All learning occurs within a context, irrespective of whether that context has been actively constructed or is an incidental or unintended consequence of either the learning activity or the learner's history. The nature of the context and how this context relates to the concepts being learnt has been widely shown to have an effect on learning outcomes [3], [4]. Whilst this effect has been studied in a number of disciplines and over a range of different types of learning activities, we are specifically interested in how context can be used in laboratory activities – an area in which there has been relatively little written.

In previous work [5] it was argued that the provision within laboratory experimentation of an explicit domain context that can clarify the relationship between the experimental apparatus and a real-world situation which it can represent, could potentially support improved learning outcomes. In particular, this is based on the development of a clearer understanding of the relationships between the aspects of reality being investigated, the laboratory apparatus that is acting as a proxy for that reality and the conceptual model that describes some aspect of that reality.

Contextual elements that aim to clarify these relationships between the laboratory, its underlying model and the real world (including, importantly, where the relationships break down) are present in many laboratory activities but often their inclusion is done without systematic consideration of the design of these elements.

In order to begin reasoning about context in laboratories it would be beneficial to analyse existing laboratory activities to determine the different forms and functions that exist in the contextual elements of a range of laboratories. This would support the development of a framework that can be used to analyse and subsequently strengthen contextual aspects of existing laboratories as well as design contexts for new laboratories in such a way as to support laboratory learning outcomes.

Remotely accessed laboratories which, by necessity, have computer mediated interfaces, have provided educators with the opportunity to modify lab interfaces and supply contextual information in new formats (as opposed to laboratory notes and instruction). The literature presents a number of learning activities using remote labs that have been enhanced in such a way to support learning outcomes, however few of these specially look at the nature of the context provided [6]. Remote laboratories provide a suitably varied range of contextualisation to begin this analysis.

In this paper we look at the types of contextual elements that are relevant to laboratories, and the ways in which these might be classified. We begin by analysing existing literature to determine how context is currently described, with a particular emphasis on considering science education. Focusing on domain context, the ideas are then applied to a diverse range of remote laboratories in order to develop a

taxonomy that can be used to describe contextualisation within labs and provide the basis for future work in the analysis and design of contextualised laboratories.

II. CONTEXT

An appropriate discussion on context will need to be based on an understanding of the types of contextual elements that are relevant to laboratories, and the ways in which these might be classified.

Approaches in the literature range from identifying broad contextual categories (e.g. social or historical contexts [7]) to discussions on the effect on learning outcomes of specific contextual elements [8]. In earlier work by the authors [5] literature on contextualised learning was analysed, resulting in the definition of two broad categories of contextual information. The first is situational context, or those factors that relate to the environment within which the learning is occurring but which are independent of the specific learning tasks. An example of this might be learning taking place in the context of a noisy classroom setting. The second form of context is domain context, or those contextual elements which have a connection to the concepts that form the focus of the learning activity being carried out. An example of this form of context might be studying the concept of acceleration due to gravity in the context of a skier on a ski slope.

This paper is specifically interested in investigating the domain context of laboratory learning activities, considering how an enhanced understanding of the domain context in laboratories can eventually lead the inclusion of sensibly designed contextual information into lab activities in a way that improves learning outcomes.

A. How is context used in learning?

Context and related concepts have been studied within the educational literature for a considerable period. As an early example, Ausubel's theory of "advance organisers" [9], whilst not explicitly referring to context, does provide a mechanism for exploring context, albeit a context that has a direct subsuming relationship to the concepts being explored. Of particular interest is the notion of comparative organizers, which are used to activate existing knowledge schemas and hence "to increase discriminability between the new ideas and the previously learned ideas by pointing out explicitly the principal similarities and differences between them" [10]. We can conceive of an explicitly provided context as a form of advanced organizer.

Novak [11] takes this a step further, introducing the concept of a cognitive bridge:

"Cognitive bridges are short segments of learning material that provide guidance to the student as to which concepts in his cognitive structure might best be employed to learn meaningfully. They also help to signal what will be the key concept(s) in the new material and how these may bear a subordinate or superordinate relationship to concepts the learner already possesses."

In other words, in the setting of laboratory experimentation, we can recognise that an explicit domain context can, in effect,

act as a cognitive bridge, priming the learner to make associations between the laboratory concepts that are evidenced in the experiment and broader concepts in the scientific domain being explored and which are part of the learners existing knowledge, but which are not explicit in the experiment.

Often these associations are the result of analogical reasoning [12]. For example, a deforming beam in a physics experiment might be described analogously as a bridge across a river, thereby priming the student to think of a load on the beam as a car crossing that bridge. Considering a provided context as a form of cognitive bridge is useful in that we can then draw on the insights provided by Novak in relation to the design of these cognitive bridges. For example, Novak indicates (based on the underlying theory from Ausubel) that *"the crucial test for meaningful learning is the ability to solve relevant novel problems ... We see, then, that problem-solving ability derives from cognitive structure differentiation and that it is concept specific"* [11].

Kokinov's [2] classification of context also has parallels with Novak's cognitive bridge. Kokinov approaches context from the point of view of how the state of the environment is perceived and then internal representations of this are constructed. Kokinov discusses the role of three different processes involved in the mental construction of context and which are in turn affected by the context: perception; memory; and reasoning processes. "Perception-induced" context is that contextual information available through the current perception of the environment. This is potentially of most interest to us as it is this aspect that we have most control over. "Memory-induced" context is information obtainable from memory and previous context representations that are recalled. "Reasoning-induced" context is information derived through reasoning. Learners will use these context representations in the learning process [2],[13].

The approaches that Novak and Kokinov take to classifying context allow us to better appreciate how context is used by students in learning. These frameworks provide a link between the nature of the context and the learning process that occurs when students complete contextualised learning activities. However, whilst these frameworks provide useful insights we have to look further to find a means for determining the specific contextual elements that are relevant for a particular learning activity, or how these contextual elements relate to the concepts under study.

B. Which contextual elements are useful?

Numerous researchers have considered what information or artefacts may play a role in providing a context to learning activities.

Ausubel [10] provides clear indications for the type of information that is useful for advance organisers, that is that they provide introductory material that is "at a higher level of abstraction, generality and inclusiveness" than the content being learnt. Novak [11] goes on to identify several additional aspects that are relevant for context design: *"the advance organizer ... should ... serve to link the new information to be learned with existing concepts in cognitive structure. ... They*

also help to signal what will be the key concept(s) in the new material and how these may bear a subordinate or superordinate relationship to concepts the learner already possesses."

Klassen's [7] approach looks at which broad categories of contextual elements are relevant within specific activities. Klassen describes context in learning as including practical, theoretical, social, historical and affective context. Based on these categorisations, and how each factor can be influenced, Klassen developed the Story-Driven Contextual Approach (SDCA). He argued that learning can be contextualised by providing a "story". Delivered by a narrative, the story provides focus and motivation. Students then engage in self formulated or teacher supplied investigations involving a number of activities, all of which take place within the five types of contexts being supplied by the story and the students' own knowledge, ideas and experience.

Klassen's work provides insight into the different elements that construct the total context and how they can be categorised, as well as broadly arguing for a specific approach (contextualisation through narrative). It does, however, lack an effective mechanism for determining the specific contextual elements that are relevant for a specific laboratory, or how these contextual elements relate to the concepts under study. This is an aspect that is important in supporting the design of specific laboratory activities.

Van Oers [14] takes a different approach. Rather than considering context as any element that affects the interpretation of concepts, Van Oers looks at how content (or meaning) and context are related, describing two functions of context in learning. These functions are to support the "*particularization of meanings*" and to "*provid[e] for coherence*". Context particularises meaning by supplying additional information that focusses the learning on the appropriate interpretation of the concept being learnt and aims to eliminate ambiguities or possible misinterpretations not appropriate to the specific meaning. Context can provide coherence by relating content to a "larger whole" so that the knowledge is not restricted to a particular meaning or situation.

Van Oers distinguishes three different approaches that can be taken towards how context is related to the meaning being sought, each of which aim to achieve the two main functions of context.

- Using pre-existing cognitive structure as an anchoring point for embedding new material so that it can provide particular meaning and coherence. In this case Ausbel's advanced organisers are "externalisations of elements of cognitive structure" [14, pp.476].
- "Situation-as-context" - A meaningful experienced situation, one that makes "human sense", provides particularisation and coherence.
- "Activity-as-context" - Context is "embeddedness in activities".

Barab et al. [15], similarly to Van Oers, focus on the relationship between scientific formalisms (the focus of the learning) and the situations of use which provide a context for

those formalisms. Consideration is given to the nature of the relationship between the formalism and the "context of use".

A formalism may be directly experienced by the learner such that the meaning is inherently bound up with the specific instance. In this case the formalism is considered to be embodied by the context of use. Conversely, if the formalism is drawn out of, and understood as a separate concept from the specific instance in which it might be explored, then it is considered to be embedded. Embedding and embodying the formalism can be said to achieve Van Oers' function of "particularizing meaning". Once the formalism is further related to other contexts of use, beyond the one in which might have been originally learnt, then it is considered to be abstracted. The context that provides an abstracted formalism provides Van Oers' "coherence" by placing the content being learnt within a larger representation of reality.

Barab et al. further describe that the specific relationship between the formalism and the context of use can be either explicit or implicit.

Whilst Barab et al. [15] commence with a similar objective to that described in this paper – specifically "to establish a rich context through which scientific formalisms are embodied, embedded, and eventually abstracted" – their focus shifts to exploring the extent to which narratives can fulfil this purpose. Their work nevertheless provides some interesting insights into the design of contexts – represented as design principles that assist in embedding/embodying formalisms into authentic contexts of use:

- Establishing embodiment that provides a clear and legitimate role that gives value and meaning to actions;
- Illuminating context-context relations;
- Fostering of an analytical stance through encouraging a sense of participation;
- Development of multiple representations of formalisms, potentially through derivative contexts.

Barab et al. acknowledge that there is a balance that needs to be achieved when designing contextual elements for a curriculum between the "quality of the context" and the "quality of the formalism". The context can be detailed at the risk of being distracting (or noisy) and the formalism can range from explicit (and potentially quite formal) to implicit (and potentially inefficient).

C. How can context be represented?

The diverse approaches to classifying and defining what makes up context illustrate the wide range of contextual elements that are present in many learning activities. Narrowing this down to domain context still allows for context to be represented in a number of ways.

Looking at all laboratories, the equipment itself always provides domain context for the activity. The investigation of scientific models can often be done using different experiments and equipment, for instance the Inverse Square Law of radiation intensity at a distance can be investigated using a radioactive radiation source, or a light source. The selection and design of the equipment that makes up the laboratory

serves to particularise the learning by focusing the student on a specific interpretation of the concept under study. The laboratory, as a proxy for reality, represents only a small part of the real world and the instance it embodies exists in a broader domain context.

For instance, if we chose to investigate the Inverse Square Law using a radiation source, the laboratory equipment focusses the learning on the application of the model to radioactivity, but by itself provides no context linking the experiment to real world radiation sources, such as naturally occurring radioactive minerals, or radiation within a nuclear power station. Additionally, the laboratory equipment does not capture the alternative applications of the model, nor the limitations of the model were it to be applied in the real world, such as the fact that in reality there is always background radiation sources and radiation absorption. It is this link to existing knowledge and experiences of students, and an illumination of new information the model provides and how it can be applied, that context should aim to achieve. Existing remote laboratories provide contexts that differ in what type of real world context is being highlighted to student.

Many laboratory activities have associated learning material that may include diagrams, supplementary reading material, instructions, or links to information sources (such as videos and books) that provide further examples and details of the application of the model and can serve to provide further context. This scaffolding provides a cognitive bridge to existing knowledge or situates the learning in a broader frame, providing coherence. The computer mediated interface of remote laboratories can provide rich and varied contextual information to students during the laboratory activity, and it is of interest to consider how these can be represented.

Remote laboratories exist with a simple camera and control panels as the user interface, through highly realistic virtual representations of real control and measuring equipment, to laboratories that are fully embedded within virtual worlds. It is expected that context representation in remote laboratories would fall along a spectrum such as the mixed reality continuum [16] with the real equipment at one end and a completely virtualised, non-realistic, stylised or abstract representation at the other.

The ideas presented here on how context is used in learning and how contextual elements can be designed and represented provide a starting point for analysing context within existing remote laboratories. The next section will look at five different remote laboratories and identify the contextual elements by determining whether they fulfil any of the functions of context (van Oer's functions of particularisation and coherence, or Novak's concepts of cognitive bridge) and how this is achieved. These will then be described in terms of how they are represented: where they fall on a spectrum of 'realism', how closely the context elements are related to the model being studied and what the nature of this connection is. The analysis will be used to derive a taxonomy for describing context in laboratories and so contribute to the field.

III. LABORATORY ANALYSIS

Five different remote laboratories were selected for analysis from the literature as representative of the wide range of laboratories that exist. The first is a remote Hydroelectric Energy laboratory hosted at the University of Technology, Sydney (UTS) and its associated lesson to teach the concept of energy transformations to high school students [17]. Secondly, we will look at the Circuit Warz project which is a game based remote laboratory teaching electrical and electronic theory and principles, specifically in this case the principles of positive feedback in op-amps [6]. Thirdly, we will take a look at NetLab at the University of South Australia (UNISA) which aims to teach circuit design and analysis [18]. Further, we look at the UTS Inclined Plane laboratory and, lastly, at the Virtual Chocolate Factory [19].

A. Hydroelectric Energy Experiment

The LabShare remote Hydroelectric Energy laboratory is hosted at UTS and accessed via the Sahara laboratory sharing platform. The remote laboratory can be used to study the principle of the conversion of kinetic energy of flowing water into electrical energy. The lab consists of pump which lifts water to fill a tank, another pump which the student can control to force water into a pipe where the flow rate is monitored. The flowing water rotates a turbine (Pelton wheel) connected to an electromagnetic generator and falls into a lower tank where the first pump lifts it up again. The electrical output of the generator is used to power the LEDs placed in a model house. The LEDs can act as a digital monitor of power output, or as the load for the generator's output circuit depending on the laboratory lesson.

When conducting the laboratory, students log on remotely to the lab and will typically have access to: a live video stream of the real equipment with multiple views showing the water flowing, the real gauges and valves and the LEDs within the model house; a simulated control panel that allows students to manipulate the second pump and thereby change the water flow rate and simulated gauges which mirror the measurements of the real equipment gauges. All these are displayed within a web browser by the Sahara lab sharing platform (though the videos can be dragged to different positions). This is illustrated in Fig. 1 below.

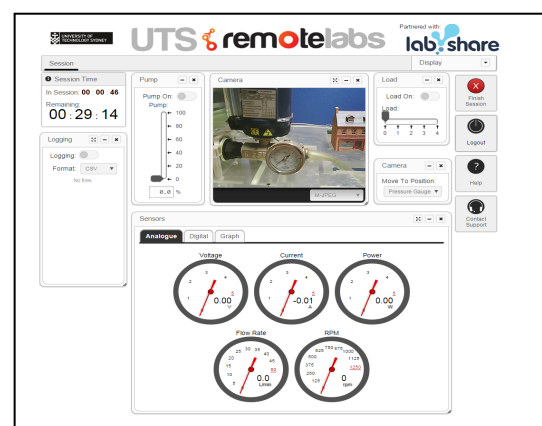

Fig. 1 Hydroelectric Energy Remote Laboratory (screenshot obtained on April 24, 2015)

Students also have a lesson plan with assessment questions and an illustration of other forms of energy conversion. The diagram is shown in Fig. 2.

Fig. 2 Excerpt from Hydroelectric Energy conversion lesson (obtained from <http://www.labshare.edu.au/catalogue/lessondetail/?id=7&version=1> CC BY 3.0)

1) Identifying the domain context elements

The concept under study is the basics of the theory of energy transformation. Domain context therefore, in this case, is those contextual elements throughout the laboratory activity that relate to the understanding of energy transformation. Probing the lab activity to determine which contextual elements fulfil the functions of particularising and providing coherence, allows us to identify and further assess the domain context elements. The following contextual elements can be argued to comprise the domain context:

- The laboratory equipment presents a scaled and simplified model of a real world hydroelectric power generation.
- The visual of moving water, turning wheel and lit LEDs explicitly illustrates a number of the energy conversions in the system with real-time video.
- The user interface presents a simulated control panel, gauges and LEDs. The user can see analogue, digital or graphs of the outputs of the gauges.
- Information provided with the lesson plan.

2) Describing the domain context elements

The elements that provide the context for this laboratory can be considered to fall into two categories. First is those contextual elements that are included within the lab equipment itself, represented physically in the form of the model house, the flowing water and the LEDs turning on and off which. These are displayed to the user very realistically in the form of the video panel showing the live video feed of the equipment. They provide an illustrated use case of the energy transformation. The model house included in the equipment extends the context by situating the energy conversion example into its real world context (that is energy conversion in hydroelectric power stations can result in lights turning on in a home).

The simulated control panel, gauges and LEDs however, are augmentations. The controls for the experiment are simplified to buttons and sliders which turn the motor on to

selected values and off again. The gauges are stylised representations of gauges showing the actual values measured. The simulated LEDs are also stylised representations. The layout makes control of the lab and visualization of the output simple and clear but they do not replicate real measuring or control equipment. There is limited representational ‘integration’ between the simulated controls and the real equipment – simulated gauges show the actual gauge readings but their physical representation is not connected.

In this case, the lesson plan explicitly illustrates different use cases of energy conversion with the use of the picture shown in Fig. 2.

This laboratory is typical of many labs that have control and display panels that mimic the laboratory equipment.

B. Circuit Warz

This laboratory aims to teach students the electrical and electronic theory using game based learning within an immersive, collaborative virtual world. The lab is set within Second Life and consists of students forming teams, taking quizzes and competing in designing oscillator circuits. It is considered a remote laboratory because the environment is linked to real hardware and the teams are working with physical circuits [20]. The game is set within an arena and each team has to answer quiz questions before competing against other teams to see who is most accurate at biasing the oscillator to achieve target peak-peak voltage and waveform periods. A screenshot is shown in Fig. 3.

Fig. 3 Circuit in virtual game arena (screenshot obtained from <https://www.youtube.com/watch?v=2Y3ghidy0j8>)

1) Identifying the domain context elements

The concept under study is the basics of the principle of positive feedback in op-amps. The contextual elements which meet the functions of particularising and providing coherence identify the domain context elements:

- The quiz used to provide feedback on the theory via multiple choice questions.
- The stylised resistors and capacitors which illustrate the real equipment that exists.
- Markings on the arena showing the op-amp circuit and where the resistors and capacitors sit in the circuit.
- The display boards showing the how accurate the value calculations for each team were.

2) Describing the domain context elements

This laboratory investigates positive feedback in op-amps by allowing students to manipulate values in an op-amp circuit

and seeing the results but it does not provide either specific use cases for op amp or alternative effects of these components in other types of circuits. The context in this laboratory serves to engage students more closely with the content and understand the components that make it up in more detail.

This laboratory does not display any of the real equipment to students. It is only the feedback from the actual values that show that the students are working with real hardware. The circuit however is displayed graphically in the arena with a schematic circuit diagram. Stylised resistor and capacitor objects are used in the virtual world for students to manipulate. Interaction with the resistor and capacitor components in selecting their values is not as it would be in the real world and does not reflect the physical form of the underlying hardware. No measurements are displayed during the game (such as oscilloscope measurements, though these are available for other laboratory activities within the environment).

In the Circuit Warz example the ‘integration’ between the controls and the real equipment is complete but hidden. Students manipulate the virtual world which effectively configures real hardware to their specifications but there is no distinction between the controls and the hardware as none of the real equipment is visible.

This laboratory is unusual in not providing a visual of the real remote equipment. It is representative of a small number of labs and appears from the interface very much like a simulation laboratory (although the real equipment values will affect how students learn from the lab).

C. Netlab

NetLab is a remote laboratory developed at UNISA. It consists of an interactive, collaborative environment designed to support experiments in electrical engineering such as circuit design and analysis. NetLab has a user interface that allows the design of circuits using a range of variable value components that can be dragged, configured and connected. There are a number of instruments that can be connected within the circuit and these are represented by very accurate images. Users can manipulate the controls of the measurement equipment through their virtual representations. The circuit builder interface and oscilloscope panel are illustrated in Fig. 4.

1) Identifying the domain context elements

The components that make up the domain context for this experiment must support circuit design and analysis: They are:

- Circuit components available for circuit design represented by symbols and icons.
- Highly realistic instrument panels.
- Live camera feed.

2) Describing the domain context elements

As for the Circuit Warz remote laboratory, there is no close connection with the execution of the circuit design in the interface and the underlying hardware in this remote laboratory. The live camera feed does however link the activities performed in the remote lab with the real hardware being manipulated.

Also, a characteristic of this laboratory is the very realistic instrumentation panels that exist and allows students to manipulate the components similarly to real world components.

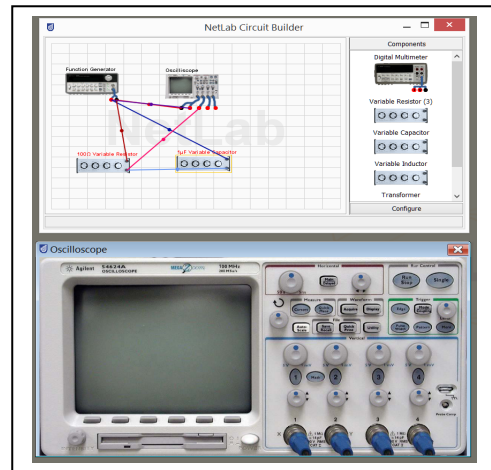

Fig. 4 Screenshot of a NetLab Session (obtained April 27, 2015)

The equipment and the context allows students to explore a range of circuit designs, placing the concepts of electrical circuits in a broader range than only a single configuration of components (as for Circuit Warz). There is no information supplied within the context of the real world application of these circuits however.

This laboratory is representative of a small number of proprietary labs that have been developed. Much work has been done to make the computer interface look and perform like real world controls.

D. Inclined Plane

The inclined plane experiment at UTS is a remote lab accessible through LabShare’s Sahara lab sharing platform. The lab consists of inclined plane with a track that allows sliding blocks to move along it when it is tilted. Students can select the blocks (each of which have different materials in contact with the plane) and the angle of the plane. They are able to take measurements of the block velocities and can therefore work out coefficients of static and kinetic friction, as well as calculation of acceleration due to gravity or calculation of the value of gravity. The inclined plane is shown in Fig. 5.

1) Identifying the domain context elements

Looking specifically at the calculation of acceleration due to gravity as the underlying model that can be investigated using this lab equipment within a laboratory activity, the following domain context elements can be identified:

- Laboratory equipment.
- Live camera feed provide particularisation.

2) Describing the domain context elements

This remote laboratory provides a use case for acceleration due to gravity. There is no additional context that allows the user to link the model for acceleration to other applications, nor is the inclined plane linked to similar real-world examples such as a playground slide or a skier down a slope.

The video feed supplies a real-time view of the equipment that is not augmented in any way with contextual information. The controls and output display are clear but not similar to real world measurement or control instruments.

Fig. 5 Inclined Plane (obtained from http://www.labshare.edu.au/library/past_rigtypedetail/?id=3&version=1)

E. Virtual Chocolate Factory

The Virtual Chocolate Factory [19] is a “virtual mirror” world of a real-world chocolate factory and its processes. The virtual world replicates the factory and includes real time data from sensors within the actual factory and real-time video from the factory. It was designed to be used, amongst other things for trainees to learn about the machines and processes within the factory. A screenshot is illustrated below in Fig. 6.

Fig. 6 Screenshot of Virtual Chocolate Factory (image obtained from vr.fxpal.com, Maribeth Back, FX Palo Alto Laboratory)

1) Identifying the domain context elements

Looking specifically at how the Virtual Chocolate Factory can be used to teach trainees about equipment and processes, the following domain context elements can be identified:

- Real time data from the real chocolate factory displayed in “Data Spots” (floating text in a transparent cloud next to the model the sensor is attached to).
- Live video from 10 cameras in the real chocolate factory.
- Faithful virtual replicas of machines and buildings are modelled in the virtual world.

2) Describing the domain context elements

The Virtual Chocolate Factory context provides a complete environment for the use of the processes and procedures being taught. While it does not expand the information to use in

other factory environments, the context situates the learning in an environment in which it will be used by replicating the factory in the virtual world.

The live video feeds link the virtual context and the data streams to the actual factory floor and the real world environment in which the knowledge will be used.

This laboratory is unusual in the level of fidelity and integration between the real world being measured and the remotely accessible learning environment.

IV. DISCUSSION

Having looked at a number of remote laboratories, we can see that although there are many common elements to how context can be presented, the degree to which this implementation is done varies greatly. The authors would suggest there are a number of descriptors that can be applied to laboratories that can capture the nature and depth of the context-content relationship. These are:

- Function – how the context fulfills the function of particularising or providing coherence.
- Fidelity - how realistic the representations of real world objects are.
- Level of Integration – how much integration is there between the three facets of context, content and the real equipment.

These descriptors only serve to provide a coherent way to analyse the laboratory content and make no judgement on the suitability or appropriateness of each. What level of each of these descriptors is ‘best’ is very dependent on the learning objectives being targeted within the learning activity. In some cases, the particularisation function of context best serves the key learning outcome such as in the Virtual Chocolate factory where trainees are expected to learn about the very specific machines and processes in the factory. In other cases, such as the Hydroelectric Energy experiment, it is hoped that students learn the broader concept of energy conversion than just the specific use case being investigated within the lab. The learning objectives of the laboratory will play a large role in the form that the context takes and which function it aims to fulfill.

A. Function

In the laboratories examined here, the laboratory equipment itself often provides a context which particularises the learning content to a specific use case. The lab equipment is a proxy for the real world and its form identifies which real world aspect of the model under investigation it aims to represent. In the case of the Inclined Plane experiment, this context is not expanded further by other domain context elements, however labs such as the Virtual Chocolate Factory and the Hydroelectric Energy rig do provide domain context that situates the laboratory equipment in a wider real-world scenario for which it is acting as a proxy. The context provides information about the real world environment for which that lab is a proxy that is not obvious from the lab equipment itself. We can consider this type of information to be *environmental domain context*.

Environmental domain context adds information linking the laboratory equipment and its underlying model to the real world environment for which it acts as a proxy.

The Hydroelectric Energy experiment is the only one with the associated lesson plan details. This shows that additional context has been supplied in the form of a diagram illustrating more use cases for the concept of energy conversion. This type of domain context provides an *alternative expression* of the model. While the lab equipment itself is a proxy for a small portion of the real world, domain context which provides an alternative expression provides coherence by linking the model under study to other real world scenarios.

Experiments such as NetLab provide contextual information that allows students a more in depth understanding of the concept under study. The range of components and the realistic nature of the instrument panels highlight aspects of circuit design not obviously available in experiments such as Circuit Warz. This type of contextual information serves to clarify the model under study, providing information not obvious from the equipment alone. This can be considered *elaborative domain context* where additional information serves to elaborate on the phenomenon under study.

To illustrate these ideas, we can consider a remote radiation laboratory as an example. The lab measures radiation intensity at a distance from a source to investigate the Inverse Square Law model. The lab equipment itself will provide the context of looking at this model specifically as it applies to radioactive sources. Examples of the types of context that could be added to provide further particularisation or coherence are:

- Environmental domain context: situating the lab in a virtual nuclear reactor links the lab to the real world environment for which it is a proxy.
- Alternative expression domain context: enhancing the remote radiation laboratory with other examples where the Inverse Square Law applies, perhaps by adding a microphone and illustrating how sound volume decreases with distance.
- Elaborative domain context: the user could be supplied with a dynamic model of radioactive decay to illustrate that while the Inverse Square Law is a good approximation, it does not take into account the stochastic nature of radioactive decay in the model.

B. Fidelity

How realistic are the representations of real world objects being presented as contextual information to students? On one hand this can be purely symbolic, such as the circuit diagram in the Circuit Warz experiment. On the other extreme are the incredibly realistic instruments mimicked in NetLabs and the models used in the Virtual Chocolate Factory. Fidelity of representation is a spectrum running from the symbolic or abstract representation, through a range of scaled or stylised representations, to a realistic copy of the real world environment.

C. Level of Integration

What stands out in the analysis of the labs here is how varied the level is of content integration into the context

provided. In many cases the lab equipment itself provides some domain context and these are obviously intertwined. In Barab et al.'s description, the lab equipment 'embodies' the content under study. For additional scaffolding context that is provided however, there is, once again, a continuous spectrum that runs from the extremes with labs like the inclined plane experiment on one hand and the Circuit Warz experiment on the other.

The Inclined Plane experiment context is provided the camera view of the equipment and the control panel which is designed for remote control of the equipment and not to mimic and real world object. The context supplied by these user interface elements is not linked by any additional information to the content under study. The only context that is linked to the content is the laboratory equipment itself which fully embodies the concepts under study.

On the other hand, the Circuit Warz context completely subsumes the real equipment to the extent that there is no realistic representation of the underlying hardware. The content itself is also completely integrated into the Circuit Warz game format – there is no interaction with the equipment other than through navigating through the game format.

In between these lie the laboratories such as the Hydroelectric Energy rig. While closer to the Inclined plane side of the spectrum, the Hydroelectric Energy laboratory includes a model house and stylised representations of the controls and gauges that link the real equipment to the context being supplied in the user interface. The graphics show real equipment values and this can be seen in the video panel too.

Closer to the fully integrated end of the spectrum is the Virtual Chocolate Factory. While the virtual world replicates the chocolate factory very realistically, the user interface provides a link to the real equipment by the use of live camera feeds and the display of live data.

V. CONCLUSION

Having analysed existing remote laboratories in terms of the form and function of the context provided, this paper has shown that there is a taxonomy that can be applied to describe the range of context found in labs.

Context fulfills its functions of coherence and particularisation by adding information in the form of environmental, alternative expression or elaborative domain context each of which address a link between the real world, the laboratory equipment and the model under study. Additionally, a wide range of representative forms was found ranging from purely symbolic to very realistic. This fidelity in the representation is related to but distinct from the level of integration between the remote laboratory equipment and its context. Laboratories ranged from immersive virtual worlds, to labs that mimicked hands-on labs in their form.

These three factors of function, fidelity and level of integration describe a large range of remote laboratories. Future work would attempt to apply this taxonomy to other remote laboratories including lesson plans and utilise the taxonomy in the design of context for new laboratories.

Mankato, MN USA

Abstract—Four years of student feedback from participants in a sponsored scholarship program is evaluated to assess perceived benefit of program activities that go beyond awarding scholarships. The program is structured to help students develop professional skills such as communication, teamwork, job readiness, and goal setting in a context that allows for formal and informal mentoring. Annual themes often related to current issues affecting society provide a setting to motivate these skills. Results show that students value skills and experiences outside of their major requirements. This work describes the program and its process for continuous improvement and provides insights into student willingness to participate in personal and professional activities on top of rigorous STEM major requirements.

Keywords—professional development; mentoring programs; active learning; multidisciplinary teams

I. INTRODUCTION

Providing STEM students with professional skill development in the traditional classroom setting has proven challenging due to time constraints and basic curriculum requirements. Technical professional skills, such as resume development and interviewing ability, are often met by a university's career services department, through workshops and individual coaching. Non-technical professional skills, such as interpersonal collaboration and decision making, can be met through various extra-curricular programs. A student interested in professional skill development must take the initiative to seek out these experiences outside of the classroom environment.

The Mentored Academic Experience (MAX) program was implemented at Minnesota State University, Mankato, which is a comprehensive university in the Midwest, to provide both technical and non-technical skill development in a community setting that fosters student engagement. This multidisciplinary peer mentoring support system was developed in conjunction with scholarship and program funding provided by two National Science Foundation (NSF) S-STEM grants. The MAX Scholars program was launched in 2007 with the first S-STEM grant (DUE-0631111) that provided funding for 67 students from 2007-2011. A renewal grant awarded in 2011

(DUE-1060659), has funded 76 students in total, including 17 also partially funded under the first grant.

Since its inception in 2007, the MAX Scholars program has supported students financially through scholarship funding and developmentally through a one-credit seminar. The weekly seminar helps scholars with the familiarization of university support services; allows participation in multidisciplinary discussions addressing broad academic and career issues; and promotes building connections with other scholars from diverse STEM disciplines. Multidisciplinary, investigative team projects are the main avenue of professional development in the weekly seminar. In addition to the weekly seminar, faculty mentoring is provided and peer mentoring is developed. These supports add dynamic avenues of professional development by providing more individualized feedback, as well as creating unique leadership opportunities.

A small group of faculty oversees the seminar, administers the program, and selects the scholars. Each academic year, the scholars cohort consists of 26-30 students with the proportions being approximately 1/3 sophomore, 1/3 junior and 1/3 senior. Cohorts remain diverse, as defined by the program criteria, with students majoring in many different STEM disciplines. Also represented are a diverse mix of gender, race, religious affiliations, socioeconomic backgrounds, and cultural experiences. Our program has demonstrated past success in addressing issues important to STEM fields and accreditation boards, such as functioning on multidisciplinary teams, understanding ethical responsibilities, developing a sense of the global and societal context of STEM work, and supporting the idea of life-long learning [1-4]. Qualitative data from 2014 was analyzed and pointed to the importance of this complementary educational experience that was outside of student major requirements. Students have commented positively on a range of experiences including: learning necessary professional skills for multidisciplinary team functioning, developing a feeling of connectedness to the broader science community, and valuing faculty-mentoring for professional and personal development [5].

Over the years, the program has developed and adapted through a continuous improvement process that revolves around faculty observation, reflection and received feedback.

The authors gratefully acknowledge the support of the National Science Foundation, award numbers DUE-0631111 and 1060659.

One aspect of the feedback is end-of-semester evaluations which have informed the changes to support overarching program goals. In this work, we present a brief quantitative analysis of survey results over the past four years, and a qualitative analysis of the short answer survey responses to the improvements implemented each semester. These results provide insights into programmatic best practices that complement traditional classroom experiences to support the academic, professional, and personal development of STEM students.

II. PROGRAM DESCRIPTION

A. Overview

The goals, structure, and continuous improvement process of the MAX Scholars program serves second-, third-, and fourth-year students majoring in mathematics; biology; chemistry; physics; information technology; electrical, computer, civil, mechanical and integrated (general) engineering; and automotive, computer, electronics, and manufacturing engineering technology. Students in the multidisciplinary cohort are awarded a \$5,000 scholarship, which is renewable for up to three years. Eligibility is based on demonstrated financial need, but selection priority is given to students who help create a diverse scholar cohort.

The multidisciplinary nature of the program extends to the program administrators as well. Faculty mentors have represented various disciplines, such as biology, computer science, computer information science, engineering, engineering technology, math, and English. In addition to the faculty, a graduate assistant from the Department of Experiential Education helps coordinate the seminar and other activities. The inclusion of a diverse mix of faculty and staff serves as one structure that supports MAX program goals. The specific intervention of including a graduate assistant in education was implemented as a result of the continuous improvement process, which is one of the structures used to support overall program goals (Table I).

Some major structural changes throughout the history of MAX have included adding distance students in an off-campus program 280-miles away, adding an annual retreat, increasing the number of majors eligible for the program, and funding a half-time graduate assistant. These changes were implemented to directly support community development, student engagement, and professional development.

TABLE I. PROGRAM GOALS AND STRUCTURAL SUPPORTS

Program Goals	Community development
	Increase student engagement
Structural Supports	Personal/professional development
	Weekly seminar
	Multidisciplinary group projects
	Annual retreat
	Mentoring

Yearly themes serve as the main catalyst for achieving program goals through the outlining structure (Table II, which includes changes discussed later in the paper). In 2014, the annual retreat, the weekly seminar, and group projects revolved around the theme of water. The annual retreat consisted of a 2.5 day bus tour in southern Minnesota to experientially explore water issues in the region. The group studied stream ecology on the Minnesota River, sustainability via riverboat on Lake Pepin, and land use research at a Discovery Farm. As part of the weekly seminar, students worked in multidisciplinary teams to explore water issues, which was proposed in a Pecha Kucha presentation and culminated in a research poster. Group projects covered topics such as desalination techniques, hydraulic fracking, and bottled water.

TABLE II. YEARLY PROJECT THEMES & IMPLEMENTED CHANGES IN THE MAX SCHOLARSHIP PROGRAM FOR THE ANALYZED YEARS

THEME	Major Changes Implemented
2010-11: Natural Disasters & Impact on Society	Fiction: <i>I Robot</i> by Isaac Asimov Conference attendance (Nobel Conference, local alternative energy conference)
2011-12: Sustainability & This I Believe statements	2 of 4 faculty on sabbatical or leave; 1 interim mentor participated Distance students included All eligible STEM majors included in the program Began annual retreat Graduate Assistant support began (10 hours per week) Non-fiction: <i>This I Believe: The Personal Philosophies of Remarkable Men and Women</i> edited by Dan Gediman & Jay Allison
2012-13: Election Process & Major focused Ethics Case Studies	Elevator speeches Initiated ethical framework Non-fiction: <i>The Immortal Life of Henrietta Lacks</i> by Rebecca Skloot
2013-14: Garbage & Personal Finance	Required meetings with assigned faculty mentors Ethics embedded in project work Phone interviews Non-fiction: <i>Young, Fabulous & Broke</i> by Suze Orman
2014-15: Water & Leadership	Theme of water strongly integrated into retreat to support information gathering during group time Included faculty mentor from Technical Communication Non-fiction: <i>Leadership for Engineers: The Magic of Mindset</i> by Ronald Bennet & Elaine Millam

B. Structures Supporting Goals

1) *Weekly Seminar*: The curriculum increases familiarity with university resources, provides useful information about a variety of personal and career issues, and fosters relationships with students and faculty across disciplines. In order to promote overall program goals, the seminar has

expanded from a traditional classroom seminar to include more topic-based, free discussion time for students to learn from each other. Topics such as time management, study skills, and work-life balance have been incorporated to increase personal and professional development. Guest presentations from additional faculty and staff, industry partners, or alumni scholars supplement the topic based curriculum. Community development is fostered through team building activities that focus on teamwork and leadership skills. The overall adaptive structure of the weekly seminar is motivated by best educational practices, especially for a diverse STEM community [6-11].

Emphasizing active learning in the MAX program has been a priority for program administrators and supervisors. The weekly seminar focuses mainly on activities, panel discussions, and group project work. In a meta-analysis of STEM education literature, Scott Freeman, et. al. found that active learning improves student performance. A consensus definition of active learning was created for their analysis: *“Active learning engages students in the process of learning through activities and/or discussions in class, as opposed to passively listening to an expert. It emphasizes higher-order thinking and often involves group work.”* [12] The MAX seminar provides this type of learning experience for the interdisciplinary cohort.

Another active learning approach is based on David A. Kolb’s experiential learning theory (ELT). A four-part “learning cycle” is used for understanding the learning process: 1) Concrete Experience, 2) Reflective Observation, 3) Abstract Conceptualizations, and 4) Active Experimentation [13]. The MAX weekly seminar is the underlying structure that provides the basis for applying ELT in multidisciplinary group work throughout the semester and on retreats. Group projects, which address issues related to S-STEM fields, serve as one type of experience students engage in with the program. Students reflect on the quality of work, leadership skills, and the overall group process. Feedback is conceptualized and the group adjusts and actively experiments in order to reach stated goals.

2) *Multidisciplinary Group Projects*: Scholars use their developing technical experience to analyze different societal issues in teams. Students grow both personally and professionally by developing collaboration, leadership skills, and technical communication skills. Project themes, content, and presentation expectations change every year in order to present students with novel challenges and increase student engagement. In 2011, students began working in geographically dispersed teams after a distance cohort was added. This experience continues to help students develop collaboration skills that are necessary for the geographic dispersion seen in the current workforce [3].

3) *Annual Retreat*: The annual retreat was implemented during the same academic year that the distance cohort was added in order to allow for community, personal, and professional development. Retreats help build community amongst scholars through face to face project work, industry tours, and social activities [3]. In 2012, the group also participated in structured team building activities in order to

develop communication skills and build trust amongst the group. In 2014, the retreat introduced the year’s theme by examining sites around Minnesota to learn about regional water issues.

4) *Mentoring*: As an essential facet of the MAX program, students are assigned a primary faculty mentor who is closely related to that student’s field of study, and returning scholars serve as role models and peer mentors for the new scholars. Faculty mentors meet with their mentees at the beginning of each semester and throughout the academic year, which provides an avenue to help students create and achieve both personal and professional goals. These meetings also allow faculty to remain aware of student engagement. When more majors were added in 2011, there became fewer opportunities for peer-mentoring amongst students within academic majors. In response, the weekly seminars regularly break up for discussion into groups clustered by major or academic year, as well as by affinity relationships based on common experiences such as hobbies, learning styles, and research vs. industry experiences.

Mentoring in the MAX program provides students with another form of social support which serves as an avenue for communal reflection on goals and career options. Research on the outcomes of mentoring have looked at entire student populations, as well as focusing on minority or underrepresented groups. There is a great deal of literature on mentoring available (e.g., [14,15] for reviews), but it has specifically been linked to an increase in student retention rates, self-efficacy and program satisfaction. Additionally, students’ adjustment to college has also been found to be positively linked to frequency of mentor meetings for underrepresented students [16,17].

C. Continuous Improvement Process

The continuous improvement process is informed by feedback collected throughout each year, which results in applying specific and timely interventions to the supporting structures of MAX. This process works to improve the overall quality of the program while maintaining organizational goals. Feedback is gathered through faculty observation and reflection, end-of-semester surveys, large group seminars, individual meetings between students and their mentors, and students’ reflection journals.

Each semester, the faculty mentors and graduate assistant observe weekly seminars and reflect on what is working well and where improvement is needed. Weekly faculty meetings allow for planning, assessment, and the initiation of interventions when necessary.

An annual assessment meeting serves as a forum for faculty to discuss major changes for the next program year. Some yearly additions have included a “common read” to connect students through a shared reading experience; the annual retreat to support community development; yearly themes to increase student engagement; and phone interviews to increase professional development. Refer back to Table II for an outline of major changes made to the MAX Scholars program over the past four years.

Since the beginning of the program in 2007, end-of-semester surveys have measured student outcomes in relation to program goals and outcomes influenced by supporting structures. The survey includes 19 Likert scale items and between three and four open-ended questions. In the fall of 2014, an additional end-of-semester assignment allowed students to reflect more thoroughly about questions that related to program goals. This assignment helped students internalize their learning over the semester, and provided a more in depth look into individual student experiences [5].

III. METHODS

A. Research Questions

What aspects of the program are, according to the students, most beneficial? This is a key question for the continuous improvement process. Providing value to the students can increase engagement and participation. Since these are typically highly engaged students who are willing to work hard in their education, creating a safe space of learning that is motivated by having a learning experience rather than a grade is valuable. The flip side of examining responses to this question looks at aspects that are missing from responses. It is possible that students are not finding some of the MAX activities valuable, even though faculty or alumni/ae recognize the value in these activities. An approach for improving the program would seek to find how those activities could be better presented to support student engagement in activities that might not seem to have immediate benefit to the students.

In general, are students receiving the program positively? This question is addressed in the context of the four key areas of relationships, working with goals, mentoring and professional skills. While students may experience other aspects of the program, these four areas address the programmatic goals of community development, increasing student engagement and personal/professional development.

B. Procedures

Data was collected from 151 end-of-semester student surveys of MAX Scholar seminar participants from spring semester 2011 (the last semester of first S-STEM grant) to fall semester 2014 following procedures approved by the Minnesota State University, Mankato Institutional Review Board. Descriptive statistics of all semesters is reported to provide an overall view of student experiences. Fall and spring data from three academic years (2011-2012, 2012-2013, and 2013-2014) were used to qualitatively map student experiences. All surveys consisted of 19 Likert scale questions and three qualitative questions. Several students did not complete the additional qualitative responses, which resulted in the collection of 92 qualitative responses (out of 103 in the examined set) for mapping to programmatic areas and annual themes. Qualitative questions asked students about aspects that were most beneficial, areas for improvement, and other thoughts they wished to share with the faculty mentors. Student data from Likert questions was included even if they did not complete all 19 questions ($N=151$). See Table III for Likert questions and descriptive statistics. Further quantitative

analysis, including changes across years and perceptions and experiences by class year is left for future work.

C. Qualitative Mapping

The open ended responses to the surveys were coded by the authors for positive, neutral and negative responses related to key programmatic areas: professional skills, goals, mentoring, relationships, project experiences, team/group work, and comments related to the semester or annual theme. Five coders worked independently to evaluate semesters or academic years. A set of eight response samples was used to assess reliability across coders. Inter-rater reliability was suspect, and researchers noted that responses that indicated a request for more of a particular type of programming were coded as negative.

To address these concerns, one researcher coded all years to ensure reliability. Data was analyzed thematically and a priori codes were used that corresponded to the goals and activities of the MAX scholars program: *relationships, mentoring, personal goals, groups/collaboration, research project, and professional skills*. During analysis, two other codes emerged: *guest speakers* and *interaction with students located at the Iron Range Engineering* program, a five hour drive away. Within each theme, comments were labeled as *positive, suggest change/increase, and suggests other change*.

IV. RESULTS

A. What aspects of the program are, according to the students, most beneficial?

Analysis of the qualitative responses to all questions show that 42% of the respondents indicated that they enjoyed the professional skills activities, which consist of lectures, guest speakers, and assignments designed to help students learn to write resumes and job application letters, present technical information to various audiences, and participate in job interviews in person and on the phone. Responses to which aspects of the program were beneficial include:

"I feel the MAX program is an excellent program. It has helped me reach outside my comfort zone and grow as a person. I now feel more educated and confident in my interview skills and finances as well as more aware of ethical issues."

"I feel the resume writing workshops really improved my marketability to the workforce."

"The resume and interview skill building lessons were very beneficial to me, and have helped me already in pursuing a career."

Analysis also revealed that 34% of the respondents had positive remarks about the relationships that they were able to develop with their peers in the program. Yet 11% indicated that they wanted more interaction with their peers at IRE and that the teleconferencing measures in place were not quite satisfactory. Responses to which aspects of the program were beneficial include:

"Working with students in different majors with different backgrounds and/or degree completion levels."

TABLE III. DESCRIPTIVE STATISTICS OF LIKERT QUESTIONS

Questions	Fall semester		Spring semester	
	Sample Size	Mean (Standard Error)	Sample Size	Mean (Standard Error)
I have improved my connections to faculty members in the MAX program.	79	4.04 (0.09)	72	4.28 (0.08)
I have improved my connections to faculty members in my academic program.	79	4.04 (0.10)	72	4.22 (0.10)
I have improved my connections to other students inside the MAX program.	79	4.37 (0.08)	72	4.33 (0.084)
I have improved my connections to other students inside my major.	78	4.10 (0.09)	72	4.28 (0.09)
I have improved my connections to other students outside my major.	79	4.00 (0.09)	71	4.08 (0.09)
Summary: Relationships	79	4.11 (0.05)	72	4.24 (0.06)
I have outlined goals for my academic year that will move me towards my ultimate career goals.	79	4.30 (0.07)	71	4.38 (0.08)
I have outlined goals for my academic year that will move me towards my ultimate personal goals.	79	4.27 (0.07)	71	4.34 (0.08)
I have met the goals I outlined for this semester.	79	3.67 (0.095)	72	3.94 (0.10)
I feel I will meet the goals I outlined for the academic year.	79	4.05 (0.08)	72	4.15 (0.10)
Summary: Goals	79	4.07 (0.06)	72	4.21 (0.07)
I have experienced being mentored by a faculty member in the MAX program.	79	3.99 (0.10)	72	4.01 (0.10)
I have experienced being mentored by a faculty member in my academic program.	79	3.91 (0.10)	72	3.86 (0.12)
I have experienced being mentored by a student in the MAX program.	79	3.24 (0.12)	72	3.35 (0.12)
I have experienced being mentored by a student in my academic program.	79	3.30 (0.12)	71	3.51 (0.14)
I have experienced being a mentor to other students in the MAX program.	79	3.43 (0.11)	72	3.57 (0.12)
I have experienced being a mentor to other students in my academic program.	79	3.75 (0.11)	72	4.06 (0.10)
Summary: Mentorship	79	3.60 (0.09)	72	3.73 (0.08)
In the MAX program I have developed my resume writing skills.	79	4.27 (0.10)	72	4.28 (0.10)
In the MAX program I have developed my skills in interviewing.	78	3.74 (0.12)	72	4.13 (0.11)
In the MAX program I have developed my skills in organizing information.	77	3.94 (0.10)	70	4.03 (0.10)
In the MAX program I have developed my skills in presenting information.	76	4.00 (0.10)	71	4.21 (0.09)
Summary: Professional skills	79	3.99 (0.09)	72	4.16 (0.09)

“The entire idea of meeting other students that have the same academic background and goals was a huge benefactor to me. It was very nice to see that others cared about the well being of MnSU as well as its community.”

“I also found it very beneficial to interact with students within my major who are juniors and seniors.”

Responses indicating a desire for more/better interaction with the Iron Range Engineering Program include:

“A trip back up to Iron Range. It would be fun. Last year it was a large bonding experience.”

“I think the overall idea of the students in both places interacting is a good one, but it is very hard to implement. Talking over Skype and the ITV camera can make conversations difficult when it is hard to hear.”

15% enjoyed guest speakers, and 7% requested more guest speakers in the future. Responses concerning guest speakers include:

“I greatly enjoyed the times when a member from one of the various departments of the university came to present a concept (such as philosophy and physics). These gave me a unique insight I might not have otherwise developed.”

"I really enjoy hearing from previous scholars or other people who are working in related fields or chose to continue studying. It not only gives me information but drive as well."

"Involve more industry people and speakers to talk about the project we are working on. Or to talk about how to go about pursuing a career."

"I would suggest we host people who work in the science field so that we can ask them career questions."

Although 12% found the mentoring beneficial as described in their qualitative responses, four students requested more mentoring and direct involvement by the faculty. Responses addressing mentoring include:

"The ability to connect with important faculty members in a stress-free setting."

"I appreciate the mentors' efforts to make this class engaging, interesting and beneficial to the students in terms of professional and personal development."

"A way to improve the course overall would be providing more information about the mentors. I would like to see a faculty panel where we could ask any question to the mentors. It would be interesting to see how the mentors got to be where they are today."

One of the issues in planning seminars that some students may participate in for two or three years is deciding which activities are worth repeating each year, such as resume development, team projects, and common reads, and which might not be, such as having the faculty talk about themselves too often. One change addressing this request was that faculty do brief presentations on their technical and personal backgrounds at the beginning of the academic year.

All key aspects of the program were mentioned by students, although the development of goals and work reflecting on the process of meeting them, done in small groups in seminar, were the least commented on in the qualitative portion of the survey.

B. In general, are students receiving the program positively?

The descriptive statistics shown in Table III indicate a general positive response to questions about the program. No questions are reverse coded, so there is the potential for a positive bias in the responses. However, when students do not like some aspect of the program, we do see a willingness to indicate that with responses of 1s and 2s. The highest response across all of semesters was related to the experience of relationships. This indicates that students are part of a developed community.

The area with the second highest response is goals. Since there are specific goal assignments, it is not surprising that they have developed goals. However, the higher value shows that even at the end of the semester and academic year, they are still connecting those goals to their career aspirations.

The biggest difference between fall and spring semesters is in the category of professional skills. This is in part due to programming since interview skills and practice are typically addressed in the spring semester.

V. CONCLUSION & IMPLICATIONS

This study provided insights to current student experiences in the MAX program, specifically finding which aspects of the program they find most beneficial. Students clearly saw the skills they developed as important and worthy of comment, but the highest Likert response was for experiences of relationships. This allows us to make conclusions about benefits to current students of the program, but does not allow us to know what is actually beneficial. Ascertaining overall program benefits will require inquiring about former scholars' experiences to find which experiences and skills were transferred to work life.

Professional skills were reported by students as the main benefit of the MAX program. Providing professional skill development while creating a supportive community through peer relationships and faculty mentoring has been a priority of the program. Responses showed that many students found relationships to be one of the main benefits of the program. Comments suggested frustration at the limitations that distance and technology placed on their ability to connect with peers. This can be addressed by providing technology training, having multiple backups available, and creating more opportunities for on and off-campus students to meet face-to-face.

Several students reported positive aspects of faculty mentoring in the program. Even though only a few requested more mentoring and interaction with the faculty, any requests for more interaction with faculty are taken seriously and have been addressed in following iterations of the course. Primary mentors and scheduled meetings at the beginning of the semester were responses to this feedback.

Guest speakers have been used throughout the history of the program in order to further develop a specific year's theme. Students responded positively to guest speakers and some requested more interactions.

Many programs are available to support community development, and career resource centers and some major courses offer job search support. Few programs combine these factors, especially in a multidisciplinary setting. Our evaluation shows that the MAX scholar program meets the goals of community development and personal/professional skills development, with engaged students actively participating in a weekly, co-curricular seminar.

Given these results, addressing development of professional skills in engineering programs could benefit from increased relationship building amongst students and their peers as well as with faculty mentors, whether within or across disciplines. Structures that support relationships as well as content delivery appear to be important to students. Providing a framework for reflection, specifically concerning goals, has a positive impact on students. Students benefit from active learning strategies used for professional skills, specifically resume building and mock interviews. Future work will investigate the long-term impact of relationships in a multidisciplinary setting with an alumni survey.

ACKNOWLEDGMENT

Along with the National Science Foundation support acknowledged on the first page, we gratefully acknowledge the feedback, support and engagement of faculty, graduate students and MAX Scholars who have participated in the program.

Abstract—Globally distributed group projects are becoming an attractive and increasingly common feature in computer science education. They provide opportunities for students to engage in activities that enhance both their technical skills and wider professional competencies with concomitant benefits for graduate employability. There have been some previous attempts to investigate these projects in terms of theories of technology use and collaborative learning, and this paper continues this process by examining globally distributed group projects from the perspective of salient issues in the fields of computer-supported cooperative work (CSCW) and computer-supported collaborative learning (CSCL). After detailing CSCW models that discuss the dimensions that characterise interaction and technology use in groups, we examine aspects of group learning from the perspective of theories of CSCL. Issues of cooperation versus collaboration, motivation for learning and models of group cognition are discussed in the context of two specific group projects. Analysis of these examples allows us to characterise behaviour within groups and provide insights that can facilitate the formation and effective development of project teams. This has important educational implications for the success of these distributed group projects.

Keywords—computer supported cooperative work; computer supported collaborative learning; globally distributed group projects; global software development education

I. INTRODUCTION

Collaborative group projects now have a well-established role in undergraduate Computer Science and Information Systems courses where they are used as the main educational setting for students to learn important professional competencies [1, 2, 3]. Over the last decade, prompted partly

by rapid globalisation in the computing profession, there have been attempts to integrate this kind of collaborative learning experience with opportunities for students to participate in authentic team working activities in geographically distributed settings. The technical and professional competencies developed in this type of learning environment have taken on greater importance as CS and IT education has responded to changing business practices within the industry. For example, the use of distributed software development models has now become the norm, while the implementation of large-scale information system projects often requires collaboration across considerable geographical distance and across conventional disciplinary boundaries [4]. Consideration of such factors has led to a recognition that student employability is significantly enhanced by participation in these type of distributed group projects, and as a consequence, there has been growing interest both in their operational aspects and in the particular learning activities around which they are built.

From an educational perspective, these projects present a fascinating environment in which to observe the interaction of students as they respond to a variety of novel and challenging situations. These may range from coping with intercultural differences in project management practices [5] to making decisions about the appropriation and subsequent use of collaborative technologies [6]. While specific projects throw up a variety of different problems, there are, nevertheless, common features which arise from the nature of the activity itself. The geographically-distributed nature of the project necessarily requires the use of some form of collaborative technology; the desire to provide students with an authentic experience of professional practice means that effective work processes are needed; the fact that these group projects are part

of a university programme promotes an emphasis on collaborative learning. While some work has been done investigating specific challenges to collaboration in these projects, there have been relatively few attempts to situate such learning environments within the broader educational framework provided by related research areas which also focus on collaborative work and group learning mediated by technology. Two such disciplines are Computer-Supported Cooperative Work (CSCW) [7] and Computer-Supported Collaborative Learning (CSCL) [8]. Both areas overlap with the practice of globally distributed group projects, although in different ways and with different emphases, and both can provide important insights into their design and successful implementation. In this paper, we investigate some of the issues that have arisen over a number of years in the operation of two different globally distributed group projects. The first is an established setting based on a collaborative information systems project, while the second is more recent and centres on a global software development task. We give a brief overview of the different projects as well as an account of relevant CSCW and CSCL research. We compare elements of each course unit from these perspectives and make suggestions for future iterations of the projects.

II. BACKGROUND

In this section, we provide a brief description of some of the main issues in the fields of Computer-Supported Cooperative Work and Computer-Supported Collaborative Learning that are relevant to our subsequent examination of international group projects. It is not our intention here in this paper to give a comprehensive account of either research field but rather to draw attention to those areas which we consider to be of use in the subsequent analysis.

A. Why CSCW/CSCL?

A major goal of higher education is to help students bridge the gap between theory and practice and perhaps, more importantly, between the types of convergent, highly structured learning exercises of the classroom and the reality of open-ended and less structured activities that they find in the workplace as graduate professionals. To do this, universities need to offer students opportunities to develop the competencies that professionals exhibit, which for those in the computing disciplines, include the ability to participate effectively in a globalised working environment, often using a range of information technology to assist productivity and facilitate collaboration.

For the university sector, this will involve the active search for, and purposeful cultivation of, pedagogical activities that foster the knowledge, skills and attitudes necessary for collaborative group working with colleagues at a local level, as well as in teams whose members may be separated by large geographical distances. To do this effectively inevitably involves the use of information technology. Early studies of technology assistance in education was based on individual learning. This has changed over the last 10-15 years as the importance of the social dimension to learning has been realised. In recent years, ICT in education has focussed on the way in which technology can facilitate such interaction.

Globally distributed group projects are a relatively recent phenomenon relying as they do on the use of information and communications technologies which have only become widespread in educational settings within the last twenty years. Whether in the context of an IT design and implementation group or a software engineering team, the geographical and temporal separation between individual team members brings a reliance on technology that impinges on the achievement of project goals in a much more critical way than with a collocated development team. The precise nature of the course aims and learning objectives of such projects will clearly depend on the specific context of the programme of studies in which each is situated. However, it is possible, even if only from a historical perspective, to draw some conclusions about what the underlying educational benefits of such activities are deemed to be. Firstly, they are set up to provide an environment in which students can attempt to gain an experience of work which has a higher degree of authenticity compared to more conventional classroom exercises. The authentic nature of these projects is often generated through the use of some kind of work-based learning pedagogy [9]. There is an emphasis on experiential learning [10] through mechanisms such as open-ended, problem-based and negotiated learning [11] and on the observation of, and reflection on, that experience [12] using reciprocal peer learning.

A number of observations can be made about this process. Firstly, the group projects' use of a work-based learning approach has a focus on both learning and on work (where by "work" we mean the technical, professional and social competences that are needed in graduate employment). Secondly, there is an irreducible cooperative or collaborative aspect to the learning. While there may be some variation on the cooperation/collaboration axis held by individual instances of a globally distributed group project, both the academic learning objectives and the development of work-based competencies are contextualised in terms of a collective approach rather than individual one. Together with strong reliance on a ICT infrastructure, this gives a characterisation of these projects in which information technology plays a critical role in support of team-based working and group learning. These are precisely the areas which CSCW and CSCL study and some researchers [13] have suggested that this overlap area of collaborative work-based learning will provide a key focus for such research in the future.

III. COMPUTER-SUPPORTED COOPERATIVE WORK

The growth in importance of globally distributed teams in major industries such as software engineering means that a large body of academic work has been developed investigating various issues and practices that lead to operational success. One component of this is a good understanding of the technological support structures that underpin communication across distance, and the way in which these structures facilitate collaborative work between individuals within teams. The field of Computer-Supported Cooperative Work (CSCW) [14, 15], is an attempt to systematise this research area and encompasses both the systems that are used to collaborate ("groupware") and the social component that such collaboration entails. Over the

last thirty years, it has developed into a mature research field which has given rise to important insights into the successful practice of globally distributed teams.

A. Factors Affecting Interaction: Matrix Models

One aspect of the research that has become widely known is its attempts to classify the independent components of interaction that are relevant to cooperative work. The most well developed of these is the so-called Space-Time diagram, usually just called the “CSCW Matrix”, devised by Johansen [16, 17] which became the de facto standard taxonomy with which to analyse tools and technology [18, 19, 20].

The work attempts to characterise cooperative systems according to time and spatial relationships. A cooperative or collaborative interaction is construed as having a time component which states when the interaction takes place, either synchronous or asynchronous, while its spatial component takes a locational classification, namely colocated or distributed. This therefore admits a fourfold decomposition with time and place axes which gives a matrix structure to the classification of technologies used in the interaction (see tab 1).

	Synchronous (same time)	Asynchronous (different time)
Co-located (same place)	Face-to-face meetings Live/IRL Classroom teaching	Shiftwork Shared representation, bulletin boards Shared workspaces, project walls
Distributed/ dispersed/remote (different place)	Parallel teaching, Dispersed collaborative teams Breakout rooms	Individual self-study Email Discussion forums, Wikis, blogs Content Management Systems

Table 1. The basic CSCW Matrix (Johansen, [16]; this version adapted from: Jørno et al, [21])

It is worth noting that, while ostensibly classifying interaction, the matrix is more commonly used to classify the temporal and spatial affordances of the technologies that enable this interaction.

While providing useful information in some cases, the overriding focus on the time and space characteristics of technologies may not give us useful information about the way in which those technologies actually contribute to the interaction, especially to elements of learning which may well be the primary concern. For example, as pointed out by Jørno, a telephone and a video chat both overcome geographical constraints and provide synchronous communication, but

grouping these technologies together does not really provide an insight into their different learning affordances.

Other classifications have been proposed (see Cruz et al, [22] for an extensive review). An interesting development is categorisation based on a technology’s mode of use rather than its properties. For example, Jørno et al [21] describe a “codification/articulation” matrix which uses a horizontal axis (codification) based the control mechanism that is used to achieve the maximum level of coordination among cooperating parties. This differentiates between central and decentralised control where centralised control is usually established through some form of leadership perspective while decentralised control is a more local and autonomous feature. An independent vertical axis is formed from a focus on the mechanism used to gain and exhibit proficiency. The axis differentiates between standardised articulation in which there are verifiable criteria for gauging success and attentive articulation in which evaluation is performed on a case-by-case basis, e.g. through some kind of mentorship or apprenticeship method.

B. Multidimensional Models of Interaction

The array structure of both the Space-Time CSCW matrix and the Codification-Articulation matrix arises from the abstraction of two orthogonal components from an analysis of the main features of a cooperative interaction. There are however, multidimensional models (where the number of dimensions, N, is greater than 2) that try to capture a broader conceptualisation and so extend the number of components considerably. One recent example of this is the Model of Coordinated Action proposed by Lee and Paine [23] which uses a seven dimensional framework of factors affecting interaction (see Table 2). The first two dimensions, “Synchronicity” and “Physical Distribution”, are essentially the time and location components of Johansen’s space-time matrix and are characterised by degrees of synchronicity and proximity respectively. The third is “Scale”, which is the number of participants involved, while the fourth is termed the “Number of Communities of Practice”. Here, Lee and Paine use a slightly unorthodox terminology and have extended Wenger’s original concept [24]. They put the idea of communities of practice to use as a measure of diversity, referring to the number of culturally distinct subgroups within the cooperative interaction. The concept of culture is taken to operate in both the macrocultural and microcultural sense, e.g. including subgroups based on ethnicity, as well as others based, for example, on the “work culture” found in different academic disciplines, or on shared personal histories or practices. Culturally homogeneous teams would be one end of this spectrum while the other would be extremely heterogeneous teams which would occur where the coordinated action of the group was greatly influenced by the expectations, norms, and practices of the individuals. The fifth dimension is “Nascence”: this attempts to encapsulate the degree to which the work of the group is static or changing and emerging over time, and denotes a spectrum of activities between routine tasks and those that are new to the group members or developing over time. The sixth dimension, “Planned Permanence”, tracks the intended permanence of the group itself, i.e. whether there

is an expectation that the collaborative action will be short-term or long-term. The last component is “*Turnover*” and refers to the relative stability of the participant makeup. It measures the rapidity with which participants enter and leave the group. This is different from both the Planned Permanence component, which is a characteristic of the group itself, and Nascence component which is a property of the production process for the collaborative artefact produced by the group.

Dimension	Continuum
Synchronicity	 asynchronous synchronous
Physical Distribution	 same location different location
Scale (number of participants)	 2 N
Number of Communities of Practice	 0 N
Nascence	 routine developing
Planned Permanence	 short-term long-term
Turnover	 low high

Table 2. Model of Coordinated Action (Lee & Paine, [23]).

The basic CSCW matrix has proved useful for describing the relationship between the affordances of technology and the process of cooperation but from a classification perspective, it is hampered by a reliance on just two components based on physical constraints. For our purposes, a more complex, multidimensional model, such as the coordinated action model proposed by Lee and Paine, which acknowledges the influence on interaction of factors other than synchronicity and proximity, would potentially provide a richer taxonomic framework to describe features of globally distributed group projects. It should be noted that we are not claiming that there is a unique attribution for each component for the group activity as a whole. Instead, each technology used to facilitate interaction will be represented on the synchronicity and location dimensions (in the same way that it is represented in one cell of the Space-Time matrix). The remaining dimensions would then provide a representation of the collaborative components.

The models and theories of cooperative and collaborative professional practice that underlie the field of CSCW produce valuable insights into the use of technology and its effect on group interactions. However, given the educational context of globally distributed group projects, it is natural to look to enhance these descriptions of cooperative activity with others which make specific reference the effects on learning. While CSCW does address some of these issues, especially in the context of organisational efficiency and workplace learning, it is a fact that the main focus is on the the design and use of technologies that affect groups, teams and networks. If, instead, we require a greater emphasis on the educational components of group work, we can turn to the related field of computer-supported collaborative learning.

IV. COMPUTER SUPPORTED COLLABORATIVE LEARNING

The subject matter for CSCL is how collaborative learning supported by technology can enhance the interaction of peers working in groups, and how collaborative technologies facilitate sharing and distributing of knowledge and expertise among community members. [25]. As with CSCW, we focus on a small number of issues with direct bearing on the globally distributed group projects rather than giving a general review of the background work.

A. Cooperation versus Collaboration

The first issue that should be addressed is the distinction made between cooperative and collaborative activities. According to Dillenbourg [26], “*in cooperation, partners split the work, solve sub-tasks individually and then assemble the partial results into the final output*”. By contrast, a collaboration is “*a coordinated, synchronous activity that is the result of a continued attempt to construct and maintain a shared conception of a problem*”, [27]. In collaborative situations, learning is a social process and individuals engage in group activities such as negotiation and sharing. These member interactions are themselves mediated by information and communications technology. This shift from cooperation, which can be performed as an individual activity prior to incorporation into a communal endeavour, to collaboration, which is fundamentally directed towards shared action is significant, and represents a important departure in a CSCL theory of learning. It also allows us to use it as a major classificatory tool for describing student activity in group projects.

B. The Issue of Motivation for Learning

A second issue suggested by approaches from CSCL is the origin of motivation for the collaborative work itself, i.e. what makes the learners feel they need to contribute to the work of the group. In their review of cooperative work and achievement, Slavin et al [28] identified four major theoretical perspectives on the achievement effects of collaborative work. The first two of these share a common emphasis on the importance of motivation as the key element in determining the success of a learning activity although they differ in ascribing to a source which is intrinsic or extrinsic to the group itself. The last two are more easily described in terms of cognitive development.

The underlying presupposition of the first viewpoint, sometimes called the *Motivational* perspective, is that it is the individual's desire to accomplish a task that is the single most important factor in accounting for group success. Group members are required to cooperate in order to further their own personal interests and consequently, when developing groups, there is an emphasis on building reward structures which promote alignment between the self-interest of the individual members and the stated aims and objectives of the group itself. Creating such cooperative incentive structures means that the only way group members can attain their own personal goals is if all the members of the group are successful. One interesting feature of this perspective is that individuals do not have to explicitly collaborate with other group members in order for the group to function effectively. It is the group members' behaviours in response to group oriented tasks that elicits praise or approbation based on the interpersonal reward structure that has been set up. The interdependence of group and personal goals is considered sufficient to induce students to act in ways that are conducive to group success. This type of individual motivation may lend itself more to cooperative ventures rather than full-blown collaboration (which may be a difficult goal to achieve in a globally distributed setting).

In contrast to the motivational perspective, which emphasises optimisation of cooperative performance as an extrinsic result of aligning group aims with that of individuals, the *Social Cohesion* perspective suggests that the effectiveness of individual participation in a group is mainly dependent on its level of social cohesiveness. Individuals contribute to group objectives insofar as they are drawn into its social structure and start to become intellectually and emotionally invested in the group. Instead of motivation arising from extrinsic factors such as external incentives and individual accountability, it is generated intrinsically as individuals come to see their own self-identity and goals, and that of their colleagues, as being bound up with that of the group. Again, this perspective has important implications for group formation and suggests that activities such as team-building that promote this sense of mutual interdependence are an important part of the group development.

While these two perspectives stress motivation (in either its intrinsic or extrinsic form) as the main explanatory factor for success in group learning, there are two others that can broadly be termed cognitive perspectives as they focus on the cognitive processes that occur when collaborative work takes place. The first of these was termed the *Developmental* perspective by Slavin and draws on the theories of developmental psychologists such as Piaget and Vygotsky to explain why interaction among team members would enhance learning. Both the Piagetian theory of learning through assimilation, accommodation and, finally, equilibration, and Vygotsky's theory of the zone of proximal development, involve an understanding of learning enhancement through interaction with peers. In the case of Piaget, interaction with other members of the group can provide occasions for disequilibrium, the basic prerequisite state for learning to occur, through cognitive conflict with previously learnt schemata. Vygotsky's theory also suggests that learning initially occurs through a social interaction which then leads to

a process of individual internalization and understanding. In both cases, group-based learning activities allow peers to provide feedback to individuals which encourages them to go beyond misconceptions (whether through a Piagetian or Vygotskian mechanism) and proceed to a more stable understanding of phenomena. In this context, group work provides an environment for members to gain an experience of peer communication which can enhance social learning skills such as participation, argumentation, verification and criticism [29].

The fourth perspective is that of *Cognitive Elaboration* [30]. In a similar way to the developmental perspective, this approach holds that, for learning to take place, new information has to be connected with related material held as prior knowledge. However, the most important driver for learning is considered to be the fact that collaborative interaction requires learners to explain their ideas and clarify potential misconceptions to other group members. This process of elaboration allows students to improve their understanding of relevant issues within the group and also serves to provide opportunities in which they can observe, and give and receive critical feedback from peers on learning strategies that are in use.

The point of discussing these four approaches to understanding motivating factors which lead individuals to contribute to the group is because they have implications for how project groups are created, how the learning activities are devised, how communications channels are set up and how the interaction among members are maintained.

C. Models of Collaborative Knowledge Building

A third element from CSCL research that we feel has an important bearing on the educational success of distributed group projects is its emphasis on group learning as a qualitatively different phenomenon compared to learning in individuals.

A key feature of collaborative learning is the process of knowledge building. Within the group, there will be elements of knowledge creation in multiple contexts. This is nicely illustrated in a diagram by Stahl [31] (Fig. 1.) which attempts to visualise the interdependent relationships between individual cognition and the process of "meaning-making" in small groups and again in the wider social context.

Much of the cyclic nature of knowledge creation is familiar to observers of how individuals learn in group projects. At the level of the individual, prior knowledge and beliefs, which are often tacit and held in a pre-articulated form, undergo some form of disequilibrium process when subject to the kind of experiences thrown up by group involvement. Some of this is dealt with at the individual level while some of it feeds into a new knowledge creation cycle involving rational discourse, argumentation, critical interaction with other members of the group as they go about their task. The key features here for the collaborative process are the articulation of the shared problem, discussion of different solution strategies, clarification of alternative viewpoints and the formation of a negotiated perspective with the other members of the team as a part of the production of whatever artefact the group task required.

Moving to a wider societal arena, the solution of the task then invites participation in a larger social context through the development of shared cultural perspectives such as professional competencies and institutional practices.

This view of different layers of value and meaning creation contributing to the goals of the group is a powerful one. While it may seem at first sight to be somewhat divorced from the practicalities of group activities, it nevertheless provides an underlying framework for understanding the many aspects of learning that emerge in these activities.

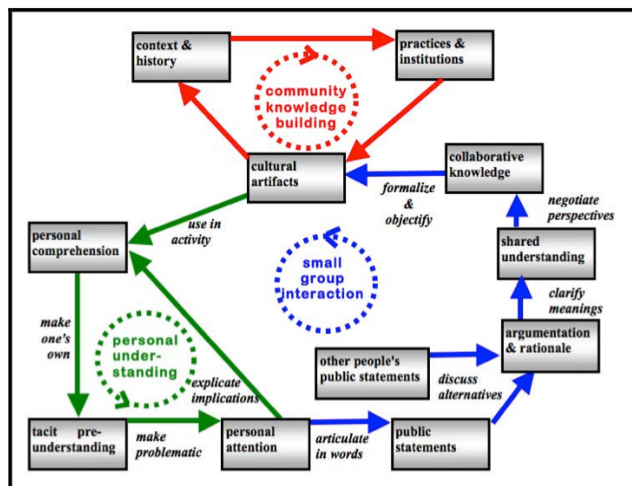

Fig 1. A Model of Collaborative Knowledge Building (Stahl, [31]; adapted from Stahl, [32], Ch. 9)

V. TWO EXAMPLES OF DISTRIBUTED GROUP PROJECTS

The objective of this paper is to use those aspects of the theories presented in the previous section to establish a framework for describing globally distributed student projects and appropriately characterising the salient features of the collaborative learning environments. We will do this in two cases. The first of these is the well-established "IT in Society" course unit which has been developed by Daniels and his collaborators at Uppsala University, Sweden, in conjunction with Rose-Hulman University, USA. The second is a newer collaborative course unit undertaken by computing science students at Robert Gordon University (RGU), Aberdeen, UK and their counterparts in the Indian Institute for Information Technology at Bangalore (IIITB), India. While the focus and content of the group project is different (the Uppsala /Rose-Hulman is an IT project whereas that involving RGU/IIITB students is a software engineering project), there are similarities in the approaches taken and with some of the difficulties which the newer collaboration has faced.

A. The Uppsala/Rose-Hulman Collaboration

The "IT in Society" course at Uppsala University was designed to meet demands from industry regarding improved communication competence among graduating engineers. This included the ability to work in heterogeneous groups and to

communicate in an appropriate and effective manner, both orally and textually. The course has had a focus on competencies from the very start, and had its starting point in the Open-Ended Group Project (OEGP) framework [35]. The focus on competencies is therefore explicit in the course and learning goals related to their development are found in the course description.

An element of international collaboration was introduced to the course in 2005 with a partner course unit called "IT in a Global Society", which was developed at Rose-Hulman Institute of Technology. The collaboration between these universities has been running for ten years, and has developed through the use of action research oriented series of changes [33]. Some examples of these are the introduction of personal learning contracts [2], written individual reflections [1] and speed dating exercises based on the constructive controversy theory [34]. The course has developed iteratively with a series of action research cycles each year as the teachers on both sides of the Atlantic are researchers in the area of computer science education. The course unit itself consists of an IT project and work-based learning activities that are related to understanding technological solutions in context and from a holistic perspective. Students are given a specific task, asked to investigate the background problem area, analyse and evaluate possible options and to suggest a solution. Design and implementation of software itself are not typically part of the project, even though some prototypes have been built to illustrate the proposed solution.
