The projects themselves are grounded in real-world applications and, since 2004, the client has been Uppsala County Council. Typically the client requires the students to address a problem in some area relevant for their current practice, such as eHealth. One example of this was an investigation into unauthorised use of medical records prompted by the Swedish Data Inspection Board which had demanded improvements to processes related to illegal intrusion. As a result of this, the students were given the task of investigating the problems of access control, looking at possible solutions inspired by other organisations, and suggesting improvements. Another example of a project in this area was an investigation into issues of "interoperability of eHealth" processes when integrating medical systems.

The class is introduced with a two hour lecture explaining the set-up of the course, where the learning outcomes are presented together with an explanation of the Open Ended Group Project's framework and the international collaboration. Most students have never worked in a project of this kind, and often have many questions regarding the requirements, tasks and set-up. During the initial lecture, the students are given documentation explaining the framework of the course, and the project requirements, e.g. that all groups must have weekly meetings with faculty, that meeting must take place when all international students can participate (which is difficult due to time differences) and that weekly meetings with the whole project and with the client are required. The open ended course setting requires the use of scaffolding for the students in order to work well. For example, two sets of individual meetings take place with all students regarding the nature of the learning contract that they write. The IT in Society course has not run

without problems, but has now reached a mature state where changes made are minor and related to circumstances, context and the students or faculty participating in the course.

B. The RGU-IITB Collaboration

The RGU-IITB collaboration is a globally distributed software engineering group project in which a development task is shared between students in Scotland and India. The project itself has now completed four main action research cycles. The first was an initial pilot, in which a small number of students from RGU undertook a software development task in collaboration with a similar number from IITB. This was done as an extra-curricular voluntary activity associated with a software engineering module. The second iteration involved six student volunteers from each institution and the task that they were asked to complete was credit-bearing. Assessment of the module involved examination of both the technical capabilities of the participants as well as their project management skills. The latter were assessed using a reflective journal which included entries made at critical points throughout the project. These journal entries were then reviewed, coded and analysed [35]. In addition to these, students were asked to complete an open-ended survey questionnaire which was used to elicit feedback from students on both the technical and project management challenges faced by participants. The third iteration involved a scaling up of the numbers in both institutions with an entire class of about twenty students from RGU and the same number from IITB. The groups comprised an equal number of students from each institution. Training on agile software development methods was provided to group members. The academic supervisors acted as product owners for the project using the scrum agile method. The product owners provided a prioritized list of the softwares functional requirements. However, the academic supervisors did not project manage the teams, as such. The fourth and latest iteration is ongoing at the time of writing but has reverted to a smaller number of participants mainly due to logistical difficulties associated with technology failure in the previous iteration.

The groups were responsible for establishing a project manager role, which was rotated through different group members during the project. Each of the groups had online meetings. Further, the decisions taken in such meetings were documented through meeting minutes. Each group was asked to produce the requirements and design documents, implemented software, testing results, and a project report. Interactions during group meetings were scheduled through timetabled class time as this simplified the process of arranging real-time conversations between group members. Groups were also encouraged to arrange additional meetings outside class.

Each of the teams was required to build a software application consisting of an online survey environment involving mobile phone client software for asking questions which was then collated into a server for storing survey results in a database. The quality of the final software deliverable was assessed and, together with an assessment of project management aspects of the activity, contributed to the final module grade.

VI. DISCUSSION

The basic classification scheme that we adopt is constructed from the features of CSCW and CSCL research that were elaborated in sections III and IV. The first element of this is a description of the potential for group activity in terms of the independent components that characterise the interactions. We choose to use a multidimensional continuum model ($N > 2$) rather than a matrix structure since the descriptive power of such a model outweighs the reduction in complexity that arises when restricting constraints to, say time and space factors. We therefore use the seven dimensional Model of Coordinated Action of Lee and Paine to describe the parameters that affect interaction and, by extension, the technologies that facilitate this interaction.

The second element of description is a determination of whether the activities of the group are cooperative or collaborative. This can be ascertained through identification of the mode of working of the individuals within the group. However, it should be noted that, for student projects with a remit to provide a positive educational experience (as opposed to, say, professional software engineering teams, where other commercial factors may be at play) it is proximity relations (together with the reliability of communications technology) that determine the extent of collaboration among the group members. This may mean, for example, that in situations where half the group members are collocated in one place and the rest collocated in another, genuine collaboration occurs only within each collocated subgroup. However, technological difficulties and the need for a positive attainment of learning goals in the course unit may mean that each collocated subgroup has its own specific learning objectives which can be fulfilled independently from those of the other subgroup. This would then tend to reduce the relationship between the two subgroups to one of simple cooperation.

A third characteristic of the interaction among the students is the motivation for learning. Intrinsic or extrinsic motivational factors, or developmental or elaborative cognitive factors may drive the learning and it is probable that this aspect is determined at the level of the psychology of the individual group member. For example, it is highly likely that some students will mainly be motivated by extrinsic factors while other will place more emphasis on a sense of belonging. Moreover, there will be a relationship between these motivational drivers and the cognitive factors described previously. Nevertheless, an understanding of the general disposition of group members in this area will enable the academic in charge to incorporate elements of appropriate scaffolding into the initial group exercises. Group goals could be clearly stated and shown to be aligned with individual learning objectives, or team-building exercises used to develop a sense of group identity. From a cognitive perspective, exercises which challenge hidden or unarticulated views might be appropriate as would some kind of peer interaction to promote elaboration.

Finally, while not part of the classification scheme per se, it is interesting to look at the knowledge creation cycles for both individuals and the group, as well as the way in which

completion of the group task relates to wider issues of professional competence and employability.

If we turn to the Uppsala/Rose-Hulman group project, we see that the relative maturity of project infrastructure allowed for some degree of regular synchronous communication, although asynchronous methods were used as well due to time-zone differences. The physical distribution dimension for students in Sweden and the USA was clearly distributed but this was mitigated by a collocation event at the start of the project when the American students visited Uppsala for a week to meet their Swedish counterparts. The number of people in the teams varied from year to year. The number of communities of practice, that is the measure of diversity within the project group was somewhat skewed since while the American contingent was relatively homogeneous from year to year, the subgroup from Sweden was often made up of a variety of nationalities as well as native Swedes. The task chosen each year was different and unfamiliar to the students comprising the project group. In terms of group structure, it was relatively short-term, lasting one semester but the students were expected to remain within the allocated subgroup.

The fact that there was an initial face-to-face meeting between members of the Swedish class and those of the American class meant that the potential to set up relationships which bound individuals to the group was much greater than if this had not occurred. Genuine collaboration was certainly possible while the subgroups were collocated and this may have continued after separation due to the availability of synchronous communications channels. Moreover, the greater potential for self-identification with group goals also meant that motivation intrinsic to the group was possible.

Examining the RGU/IITB group project, we find that although there was some use of synchronous technology, the difficulties with logistics, specifically with the network infrastructure at both RGU and IITB, meant that there was a much greater reliance on asynchronous technologies after the initial contact stage. The split between the two collocated subgroups in each development team also impacted on the technology used. The number of participants within each team varied with each iteration of the course and the make up of both the software development group and the collocated subgroups was culturally diverse leading to high scores on the number of communities of practice scale. The activity itself was unfamiliar to almost all students and the groups were clearly set up to be relatively short-lived, being dependent on the length of the module itself (twelve weeks). Finally, once the groups were set up, it was not anticipated that the membership would change and where this was not the case, the reason was because of lack of student engagement.

The two distinct locations for the software development subgroups meant that some collaboration took place at the local level but the main interaction between RGU and IITB students was cooperative. Finally, in terms of motivation for learning, there was little opportunity to build up personal relationships between members of the distributed teams and so the course relied on extrinsic factors such as compliance with

university assessment regulations to align group and individual learning objectives and so encourage engagement in the project processes.

VII. CONCLUSION

We have discussed in some detail a range of issues arising from CSCW and CSCL research which have an impact on our understanding of globally distributed group projects within a higher educational setting. These have been used to analyse the learning activities and use of collaborative technologies undertaken by group members and lead to a preliminary classification scheme for different aspects of the group project. The scheme was then applied to two examples of group project to see what insights could be gleaned from framing a discussion of their effectiveness in these terms.

We conclude by noting that, given the rapid spread of globalisation that has occurred in the world-wide Computing industry coupled with the advent of reasonably cheap and accessible communication technology, it is highly likely that universities will look with greater urgency to activities such as distributed group projects as a way of enhancing graduate employability in Science and Engineering industries such as Computing. Elaborating the nature and scope of those parameters that characterise the successful outcome of these projects will be extremely important as a step towards understanding the problem and so being able to control the learning environments using the technical infrastructure and appropriate pedagogies. We anticipate that this characterisation problem is one that will preoccupy academics in the future and this paper is a preliminary attempt to develop a framework in which this can be done..

A Quasi-Network-Based Fly-by-Wire Simulation Architecture for Teaching Software Engineering

Dan Tappan

Department of Computer Science
Eastern Washington University
Cheney, WA, USA
dtappan@ewu.edu

Abstract—Undisciplined cohesion and coupling undermine countless aspects of quality software. Students, however, unfortunately tend to gravitate toward such approaches. This system mitigates this problem by forcing them to communicate with their components through a well-constrained hierarchical virtual network of networks. The application is a dynamic, plug-and-play aircraft fly-by-wire system that processes a wide variety of commands to design, construct, and manipulate sensors, actuators, controllers, and communication buses concurrently in a flexible model-view-controller architecture. It successfully employs many systems-engineering concepts of modeling, simulation, visualization, and analysis toward the goal of instilling disciplined design, implementation, testing, and evaluation practices in students. In particular, it provides the pedagogical and programmatic frameworks for creating, executing, presenting, and analyzing meaningful test cases as part of formal test plans carried out in controlled experiments via scientific method. The system can be adapted relatively easily to countless other real-world multidisciplinary domains for reuse in other projects. Extensive results from classroom deployments show that students overwhelmingly benefit from this approach.

Keywords—software engineering; control system; simulation

I. INTRODUCTION

Software, by its flexible virtual nature, allows programmers to make quick and easy changes, at least compared to related physical disciplines like engineering. Unfortunately, without appropriate self-discipline, it is all too easy to produce messy spaghetti code with endless nasty interconnections. The equivalent rat's nest of wires in an electrical system would be immediately apparent to anyone, but in a software system, no such obvious red flags exist without first learning to recognize them. The goal of this system is to instill disciplined design, implementation, and testing practices in software-engineering students by forcing them to work within a Java model-view-controller architecture that behaves like a well-defined and protected physical plug-and-play network.

The overarching philosophy is to use a systems-engineering approach of modeling, simulation, visualization, and analysis respectively to build a solution, execute it in a controlled way, present the results visually, and analyze what they mean as part of testing and evaluation. The model, in particular, is a simplified aircraft fly-by-wire system that controls a variety of flight components in complex real-time ways. This context,

supported by background research, provided students in an undergraduate software-engineering course with a holistic understanding of the problem space such that they could create a corresponding clean implementation in the solution space. The objectives are typical of any software system: to separate the concerns, maximize cohesion, minimize coupling, and delegate responsibility appropriately. These considerations are further complicated by the need for uniform, safe, and repeatable concurrency among the components. Building and testing single-threaded code is difficult enough for most students; multithreaded (or the appearance of such here) absolutely requires a disciplined approach.

II. BACKGROUND

All control systems take inputs of some sort and produce corresponding outputs of some sort. In traditional (non-electronic) systems, the connections from the former to the latter are mechanical linkages like cables, pushrods, and shafts. For example, a car steering wheel directly drives the gearbox to deflect the front wheels. There is little possible dynamic variation in the operation, like changing the steering sensitivity based on vehicle speed, because the configuration of the static system is fixed. A “by-wire” system, on the other hand, translates the input from a sensor into an electronic signal that travels via a network to an actuator, which acts upon it as output. In this form, any amount of computer processing is now possible for dynamic real-time reconfiguration.

In a fly-by-wire system, the primary control sensors are located in the cockpit in the form of a stick or yoke, as well as pedals, switches, and levers. The actuators are located around the airplane. Fig. 1 shows a basic configuration, which also includes the engines and landing gear.

Fig. 1. Basic airplane actuators [1]

This work focuses on the behavior of the control system only, not on its effect on the airplane in flight. In other words, the airplane is basically stationary on a test stand. As a result, its degrees of freedom of motion and aerodynamics are ignored. For background, however, the elevators affect pitch (nose up or down) to change altitude; the ailerons affect wing roll to turn; and the rudder affects yaw to coordinate turns, much like the front wheel of bicycle does.

III. MODEL

This work uses a model-view-controller architecture. The model is the module that defines the machine being manipulated. The plug-and-play nature of the architecture allows it to accommodate other by-wire systems with relatively little difficulty. Further supporting this goal is the extensive use of well-established, reusable software design patterns [2]. For example, a subsequent offering of the same course used it as the basis of a toolkit for building and controlling heavy construction equipment. Follow-on work is planned for modeling railroads and railway equipment.

A. Datatypes

Significant, consistent anecdotal classroom evidence shows that students have a major problem with abstracting, maintaining, and manipulating data properly. Java primitives are appropriate in earlier low-level courses, but at higher project-based levels like software engineering, they lead to a proliferation of problems. For example, units, magnitudes, and limits are not applied consistently, error handling is inconsistent or almost nonexistent, and code bloats from haphazard attempts at reimplementing similar solutions in multiple places.

To mitigate this situation, the architecture provides a rich set of self-contained concrete datatypes for every kind of relevant data; e.g., Acceleration, AngleHorizontal, AngleVertical, FlapPosition, Identifier, Percent, Power, Rate, Speed, and many dozens more not directly in play in this paper. Each maintains its own error checking and helper methods for manipulating and converting it appropriately. This approach lends itself to convenient unit testing in isolation. It also reduces the burden of documentation; e.g., avoiding having to state and enforce everywhere that horizontal angles are in mathematical degrees (as opposed to navigational degrees or radians) because AngleHorizontal always uses this form.

Another consistent problem students have is with indiscriminate coupling and undisciplined, unprotected sharing of objects. Changing a mutable object in one place may have countless unexpected consequences throughout an entire system. To mitigate this problem, datatypes employ a functional paradigm, which makes them immutable. Any mutable action on them produces a new object via copy-on-write semantics [3]. It is therefore exceedingly difficult for students to interact with the system outside the prescribed network infrastructure, intentionally or not.

Finally, datatypes extensively use Java generics to constrain their application to appropriate contexts. Students are prone to hard-coding dangerous runtime casts and making decisions based on querying objects for their type with the

instanceof operator instead of properly utilizing the object-oriented principles of inheritance and polymorphism. Explicit casting should be avoided as much as possible in a dynamic, plug-and-play system.

B. Intervals

An interval is the data-structure equivalent of the presumed motive force that moves an actuator from one state to another. The basis is kinematics, or geometry in motion without regard to its causes [4]. Actuators play different roles and therefore have different state types, which the datatypes define, and intervals directly map onto and control.

An interval has implicit or explicit limits; e.g., a Percent interval always ranges inclusively from 0 to 100, whereas a Speed interval ranges inclusively from its specified minimum to maximum values. In all cases, the current state must always reside on the interval. It is impossible for a student to cause an inconsistent state without detection and notification.

Change in state as a delta is also configurable to account for slower or faster movement. In the linear variant, the delta never changes. In the nonlinear, it does so to account for acceleration or deceleration. Again, it is impossible to cause an inconsistent state. The interval always reflects a continuous function; e.g., it cannot achieve maximum delta without accelerating to that value by the rules. Likewise, it cannot change direction without decelerating to zero first. This behavior reflects the reality of the mechanical system that the interval represents.

An interval is like an operating-system process in several ways. A nonpreempting request submitted to it is queued for execution. For example, requesting it to go to maximum value and then immediately to minimum value would entail increasing to completion (with initial acceleration and final deceleration) and then similarly decreasing to completion. A preempting request, on the other hand, would cause the currently executing request to complete gracefully with deceleration to zero as soon as possible, followed by servicing the new request. A terminate request functions in the same way, except that it schedules no subsequent action. A cancel request kills the currently executing request immediately with no graceful shutdown. It is not an option for normal interaction because it violates the kinematics; i.e., infinitely fast deceleration from the equivalent of dividing by zero in

$$rate = distance / time \quad (1)$$

Fig. 2 notionally depicts the state and delta (top and bottom lines of each graph, respectively) for a variety of combinations of linear and nonlinear movement in increasing and decreasing directions with intervening terminate and cancel actions. To demonstrate the value of using the architecture-supported intervals over their own ad hoc implementations, the students had to solve the basic elements of this problem as a standalone proof-of-concept Java program. The results were telling: their solutions were overwhelmingly large, unmanageable hacks, not one worked completely, and the average grade was 11%. They said it was an extremely eye-opening experience and acknowledged the value of the orthogonal approach in this work: one solution applicable to many problems [5].

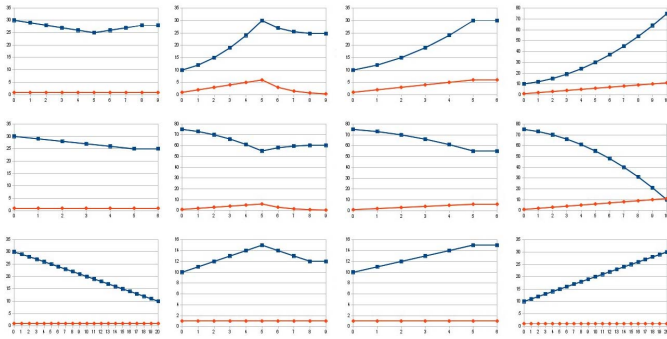

Fig. 2. Sample kinematics intervals

C. Buses

Every interval (as part of an actuator) resides on a communication bus that transfers requests. Three types of interval servicing are possible:

- *Oneshot*: service a request once, then expire automatically; e.g., instantaneous on/off actions.
- *Definite*: service a request until a specified end condition, then expire automatically; e.g., movement.
- *Indefinite*: service a request continuously, ending only upon a terminate or cancel request; e.g., engine rotation.

In addition, requests may specify in detail the timing of the interval servicing:

- *Lead time*: the amount of time that an interval should initially perform no action. This models initialization.
- *Duration*: the total amount of time that the request will be serviced. This applies to definite intervals only.
- *Frequency*: the rate at which actions are performed while being serviced. This allows them to operate at a fraction of the clock speed.

Requests are exactly that: *requests*. They are not imperative commands that must be honored (even though “command” is the conventional term used in flight control) [6]. In fact, the servicer decides how to process the request and responds to the submitter as follows:

- **IGNORED**: ignored and discarded the request because it was not considered applicable.
- **REJECTED_INVALID**: rejected the request, which normally would be serviced, but cannot be now because it is somehow invalid or inappropriate.
- **REJECTED_UNABLE**: rejected the request, which normally would be serviced, but cannot be now for some reason on the servicer’s side. The servicer may inform the requester when it is available again.
- **ACCEPTED_BLOCKED**: accepted the request, but it will be queued for later servicing because the servicer is busy.
- **ACCEPTED_SERVICING**: accepted the request, and it will be serviced immediately.

This handshaking approach was difficult for the students to embrace because they are used to shouting at their code imperatively to do what they want, and if it does not, then shouting louder. For example, one student admitted that his development process was to “[keep] throwing more code at the compiler until it shut up.”

D. Actuators

Actuators are the interval-based virtual mechanisms that cause the aircraft components in Fig. 1, as well as others, to change state appropriately. The presumed underlying motive force (electrical, hydraulic, pneumatic, thermodynamic, etc.) plays no role, only the resulting action. Section III.F addresses specific actuator behaviors in detail, especially in combination. In general, however, their data (what they are) and control (what they can do) adhere to the following constraints:

- *Rudder*: deflects left or right to an angle.
- *Elevator*: deflects up or down to an angle.
- *Engine*: changes speed as a percentage of maximum revolutions per minute.
- *Aileron*: deflects up or down to an angle; in roll mode, they are always paired antisymmetrically on the wings, so when one deflects, its counterpart deflects by the same amount in the opposite direction.
- *Speed brake*: deflects upward to an angle; on a real aircraft, separate dedicated actuators typically play this role, but for pedagogical reasons, ailerons do so here in speed-brake mode. There is no antisymmetry: all ailerons deflect upward to cause increased drag.
- *Main gear*: extends or retracts as a percentage of downward deployment.
- *Nose gear*: extends or retracts as a percentage of downward deployment, but also simultaneously rotates 90 degrees to stow sideways in the fuselage.
- *Flap*: deflects downward to an angle. As Fig. 3 shows, plain flaps rotate about a fixed point; for double-slotted flaps, this point moves backward, and the flap separates, requiring two coordinated intervals that are both simultaneous and sequential.

Fig. 3. Plain and double-slotted flap deployment [7]

E. Sensors

Whereas an actuator is an output device that changes state on command, a sensor is its complement as an input device to indicate this state by querying the actuator on command. Sensors do not play a significant role in the current manifestation of this work because the logger discussed in the next section already captures state data for analysis. Nevertheless, they do introduce interesting advanced safety

considerations into the flight-control system for future work on model reliability, for example.

For any number of reasons beyond the scope of this paper, a real-world mechanical system may erroneously exceed its specified design limits. An active preventative solution, in the form of a watchdog device, would immediately report any deviation as a fault [8]. A passive solution is also commonly present as mechanical stops that would physically prevent an actuator from exceeding its hard limits. However, it would still be possible to hit a stop and continue to try to move, likely resulting in wear or damage in the drive mechanism. A common hybrid approach is to monitor the actuator itself to see how hard it is working with respect to how much work it is performing: working hard with no effect likely means that it is at the limit, jammed, or otherwise interrupted. A garage-door opener is a good example.

F. Controllers

A fly-by-wire system is actually a hierarchical system of systems [9]. In this model, there is one master bus that runs from the cockpit throughout the entire aircraft, but no actuators are connected directly to it. Rather, it consists of controllers, which themselves have slave subbuses containing relevant actuators. This extra level of indirection allows for arbitrarily complex coordination at the receiving end (the actuators), where otherwise it would be the transmitting end (the cockpit) that would have to assume this responsibility. It also reduces bus traffic by sending consolidated requests to be interpreted, decomposed, and redistributed by the controllers as appropriate. The controllers are:

- *Rudder controller*: always contains a single rudder actuator on its subbus. A request to it (i.e., change deflection angle) passes untouched to the actuator.
- *Elevator controller*: always contains two elevator actuators. A request to it passes untouched to each.
- *Gear controller*: always contains two main-gear actuators and a nose-gear actuator. A request to it (extend or retract) passes untouched to each.
- *Flap controller*: contains an even number of symmetrically configured flap actuators, evenly distributed across the wings from left to right from the cockpit perspective. A request to it (downward deflection angle) passes untouched to each.
- *Engine controller*: contains any number of symmetrically configured engine actuators, distributed the same as flaps. A request to it (power percentage) has two interpretations. In gang mode, it passes untouched to each actuator; in isolation mode, it passes untouched to only the specified one.
- *Aileron controller*: contains an even number of symmetrically configured aileron actuators, also distributed the same as flaps. In standard roll mode, a request to it (upward or downward deflection angle) passes untouched to all actuators on the left wing, but the direction is inverted for the right wing. In mixed roll mode, the request addresses only the specified left

actuator, and the other actuators on the left wing deflect as a ratio of it, and likewise those on the right. (Section VII discusses this process in more detail.) Finally, in speed-brake mode, the request (deploy or retract) passes to all actuators to deflect upward to their maximum angle or downward to neutral, respectively.

Fig. 4 is an architecture for a typical two-engine passenger airplane, where L, R, and N respectively indicate left, right, and nose. Section V addresses the command generator.

Fig. 4. Typical bus architecture

Additional levels of indirection (i.e., controllers containing controllers) could also be added for complicated decision-making. For example, in flight the appropriate amount of yaw from the rudder depends on the amount of roll from the ailerons with respect to airspeed. An aileron request could issue a secondary rudder request [10]. Similarly, roll reduces lift, which may be compensated for by the pilot or the control system. In general, Boeing's approach, for example, requires the pilot to introduce more pitch as a separate intentional action, whereas Airbus's does so automatically [11].

Although not part of this work, controllers in conjunction with sensors could monitor the behavior of actuators in concert. Symmetric configurations must be in identical (or identically inverted) states at all times; otherwise, the aerodynamic effects could be catastrophic. Similarly, advanced coordination of an autothrottle is possible [12].

Other complex monitoring relationships are also possible, but are deferred to future work. For example, in combination with flight data, the flight-control system could determine the operating limits that the pilot is permitted to reach [4]. Under normal circumstances, operating in so-called Normal Law, the system does not allow the aircraft to enter a region of unusual or diminished flight control. For rare cases, Alternate Law relaxes these restrictions, but it still would not allow the aircraft to exceed its maximum operating limitations. Direct Law basically disables automated oversight altogether for exceptional cases and allows the actuators to be driven as if the control system were purely mechanical.

IV. VIEW

The view module of the model-view-controller architecture depicts the state of the system in multiple forms. Its plug-and-play nature allows other implementations to be added or substituted relatively easily.

A. Log

The most basic — but also most informative — view is text output to a log file. This view supports arbitrary logging of any aspects of interest, but the built-in output is generally sufficient for most analysis. The relevant details of each state at each clock tick go to a text file that directly exports to Excel. Fig. 5 shows an abridged form, which actually contains many more columns, as well as typically thousands of rows of events.

tick	time	code	action	bus	servicer_id	s#	request	request_id	status	response	t#
53	0.053	C	submit	bus1	gear_ctrl1	0	Service	gear_ctrl1#1	UNBOUND		
53	0.053	C	submit	gear_ctrl1_bus	gear_nose2	0	Service	gear_nose2#2	UNBOUND		
53	0.053	D	respond	gear_ctrl1_bus	gear_nose2	0	Service	gear_nose2#2	ACCEPTED_SERVICING		
53	0.053	C	submit	gear_ctrl1_bus	gear_main1	0	Service	gear_main1#3	UNBOUND		
53	0.053	D	respond	gear_ctrl1_bus	gear_main1	0	Service	gear_main1#3	ACCEPTED_SERVICING		
53	0.053	C	submit	gear_ctrl1_bus	gear_main2	0	Service	gear_main2#4	UNBOUND		
53	0.053	D	respond	gear_ctrl1_bus	gear_main2	0	Service	gear_main2#4	ACCEPTED_SERVICING		
53	0.053	D	respond	bus1	gear_ctrl1	0	Cancel	gear_ctrl1#1	ACCEPTED_SERVICING		
53	0.053	B	notify	gear_ctrl1_bus	gear_main1	1	Service	gear_main1#3	SERVICE		0
53	0.053	B	service	gear_ctrl1_bus	gear_main1	1	Service	gear_main1#3	BLOCK		
53	0.053	B	notify	gear_ctrl1_bus	gear_nose2	1	Service	gear_nose2#2	BLOCK		1
53	0.053	B	service	gear_ctrl1_bus	gear_nose2	1	Service	gear_nose2#2	SERVICE		
53	0.053	B	notify	gear_ctrl1_bus	gear_main2	1	Service	gear_main2#4	SERVICE		2
53	0.053	B	service	gear_ctrl1_bus	gear_main2	1	Service	gear_main2#4	SERVICE		
53	0.053	B	notify	gear_ctrl1_bus	gear_main2	1	Cancel	gear_main2#4	SERVICE		1
53	0.053	B	notify	bus1	gear_ctrl1	1	Service	gear_ctrl1#1	CANCEL		
54	0.054	B	notify	gear_ctrl1_bus	gear_main1	2	Service	gear_main1#3	SERVICE		3
54	0.054	B	service	gear_ctrl1_bus	gear_main1	2	Service	gear_main1#3	SERVICE		
54	0.054	B	notify	gear_ctrl1_bus	gear_nose2	2	Service	gear_nose2#2	SERVICE		4
54	0.054	B	service	gear_ctrl1_bus	gear_nose2	2	Service	gear_nose2#2	SERVICE		
54	0.054	B	notify	gear_ctrl1_bus	gear_main2	2	Service	gear_main2#4	SERVICE		5
54	0.054	B	service	gear_ctrl1_bus	gear_main2	2	Service	gear_main2#4	SERVICE		
54	0.054	B	notify	bus1	gear_ctrl2	2	Terminate	gear_ctrl1#2	TERMINATE		

Fig. 5. Abridged bus log

Not only does this log represent the states of the controllers and actuators, but it also shows the bus traffic. The communication process involves submitting a request and getting one or more immediate responses from its servicer. If the request is subsequently serviced, notifications are sent back to the requester for specified conditions like decelerating for arrival at the final state, arrival at the final state, preemption, and so on. This information could be exported to other applications to generate timing and UML sequence diagrams.

B. Graph Visualization

The textual form of the log file is richly informative, but it is not intuitively understandable. However, its structure not only exports natively to Excel for a tabular representation; its fields are also strategically organized to allow event chains to be plotted as line graphs. Fig. 6, for example, depicts the actions of a rudder actuator at the following key time points:

1. at initial position 0° neutral; command to 45° left
2. arrives; command to 45° right
3. arrives; command to 0°
4. arrives; command to 30° left
5. at 15° left preemptively command to 45° right
6. arrives

Fig. 6. Preemption test

Despite multiple requests, it is clear that at no time does the actuator find itself in an inconsistent state. i.e., above or below

the dashed lines depicting the physical limits. Moreover, the line represents a smooth, continuous function with no jerks or breaks through various acceleration, deceleration, and preemption actions. Such intuitive visual inspection is invaluable for testing and evaluation. Furthermore, mathematical analysis on the slope of the function would demonstrate that the performance remained within the specifications at all times.

C. Three-Dimensional Visualization

Visual representation in graph form is useful with respect to a localized part of the system like a single actuator or a group of related actuators. However, for a global systems-level view, three-dimensional visualization, as in Fig. 7, is far better.

Fig. 7. Actuator visualization [1]

As the next section discusses, actuator configuration is highly dynamic and need not correspond to any particular aircraft. As a result, the visualizer is stylized with oversize control surfaces that represent the appropriate actions, not necessarily the appropriate appearance. The visualizer can also depict metadata like physical limits and breadcrumb tracks showing a history of state changes.

This OpenGL-based Java tool has seen extensive use in the author's artificial-intelligence and software-engineering courses, related pedagogical research, and industry work as a general-purpose world viewer [13,14]. It is freely available at shelly.edu.

V. CONTROLLER

The controller is the user interface for building the model and running the simulation. It is based on a regular grammar that employs the Interpreter and Command design patterns [2]. The instructor's solution defines the parser with JavaCC, but the students had to design and implement their own with standard Java. This effort entailed thoroughly understanding the problem domain of the commands and their proper usage, as well as the solution domain of the API for the provided architecture. It strongly discourages head-first, brute-force coding by making such an undisciplined approach obvious and unpleasantly difficult.

A. Creational Commands

Creational commands define and build the actuators via the Builder and Factory design patterns [2]. Each contains a unique identifier, the interval limits, a delta value for changing state on the interval, and an acceleration for changing the delta value.

All eight of these commands (for aileron, elevator, and rudder actuators, etc.) have the following form:

```
CREATE RUDDER id WITH LIMIT angle
      SPEED speed ACCELERATION acceleration
```

B. Structural Commands

Structural commands define and build the controllers from the actuators created above. Each contains a unique identifier and the actuators. The controllers with a fixed number of actuators are:

```
DECLARE RUDDER CONTROLLER id1
      WITH RUDDER id2

DECLARE ELEVATOR CONTROLLER id1
      WITH ELEVATORS id2 id3

DECLARE GEAR CONTROLLER id1
      WITH GEAR NOSE id2 MAIN id3 id4
```

The controllers with a variable number of actuators are:

```
DECLARE FLAP CONTROLLER id WITH FLAPS idn+

DECLARE ENGINE CONTROLLER id
      WITH ENGINE[S] idn+

DECLARE AILERON CONTROLLER id
      WITH AILERONS idn+ PRIMARY idx
      (SLAVE idslave TO idmaster BY
      percent PERCENT)*
```

All controllers must be added to the master bus:

```
DECLARE BUS id WITH CONTROLLER[S] idn+
```

And finally the configuration is locked to prohibit further creation or structural commands and to authorize most behavior commands:

```
COMMIT
```

It is at this point that students perform any late consistency checks to verify that the system is configured properly before any manipulation of it can occur. For example, the number of engines and their properties must mirror each other on the wings. From a practical design standpoint, such a check cannot be done earlier while the engines are still being added because the process is sequential. Determining what can be done immediately versus deferred for later, as well as how, is an important part of software design thinking [15].

C. Behavioral Commands

The behavioral commands send requests across the master bus to be interpreted by the appropriate controller(s):

```
DO id DEFLECT RUDDER angle LEFT | RIGHT
DO id DEFLECT ELEVATOR angle UP | DOWN
DO id DEFLECT AILERONS angle UP | DOWN
DO id SPEED BRAKE ON | OFF
DO id DEFLECT FLAP position
DO id SET POWER power
DO id SET POWER power ENGINE id
DO id GEAR UP | DOWN
HALT id
```

D. Miscellaneous Commands

The miscellaneous commands manipulate the execution of the simulation. The first set affects the system clock:

```
@CLOCK rate
@CLOCK PAUSE | RESUME | UPDATE
```

Especially important for testing is the capability to wait a fixed amount of time. The preemption tests, in particular, need to be timed exactly. Manually issuing a command would result in inconsistent results over multiple runs. The command is:

```
@WAIT time
```

Finally, commands may be supplied in text files for execution as scripts, which greatly simplifies repeatable testing:

```
@RUN "filename"
```

VI. CONTROLLED EXPERIMENTS

The primary goal of this work is to instill disciplined software-development behavior in students. However, it also naturally serves as an effective platform for systematically evaluating the performance of a model by using scientific method in controlled experiments as follows:

1. Design and carry out an experiment (a test) to investigate something of interest.
2. Visualize and analyze the results.
3. If the results are unsatisfactory, perturb one and only one parameter in the experiment and rerun it.
4. If the new results are more promising, continue down this line of investigation; otherwise, either perturb the parameter in a different way or reset it and perturb a different parameter.
5. Continue to refine the model until the results are satisfactory.

Consistent with the primary goal, students gain valuable experience with discovering patterns and building mental models that connect causes to effects [16]. This approach reduces the amount of random, uninformed generate-and-test cycles, which generally allows students to be more productive by getting better results with less effort.

VII. RESULTS

The students' project consisted of three parts: implement the parser, implement the controllers, and execute a detailed test plan. The results of the first two parts were straightforward because this system does not allow them to deviate much from proper coding principles. The third part—testing and evaluation of the entire system—is the emphasis here. The deliverable required a formal report describing the test plan and its results. Each of 27 experiments addressed eight points, where 1–4 related to planning, 5–6 to execution, and 7–8 to presenting the results:

1. The rationale behind the test; i.e., what it was testing and why it mattered.

2. A general English description of the initial conditions.
3. The commands for (2).
4. An English narrative of the expected results.
5. The actual results with at least one graph showing the most representative view of the states.
6. A snippet of the actual results from the log file with a supporting explanation, including statistics, metrics, and graphs, as appropriate.
7. A discussion on how the actual results agreed with the expected results, or if they disagreed, a hypothesis on why.
8. A suggestion for how to extend this test to address related aspects of potential interest.

The results themselves are not as relevant here as what the students learned from them, but the following examples help convey how they learned it. Fig. 8 depicts the behavior of a three-engine configuration (where the dashed lines overlap). At time point (1), all three engines were commanded to increase power from 0 to 70%. Upon reaching this target at (2), the center engine was commanded to reduce power back to 0%. At (3), while the center engine was still decreasing, all three were commanded to go to 100%, which took until (4) to achieve.

Fig. 8. Engine manipulation

Determining correctness (testing) and evaluating performance (optimization) require three critical components: the expected results, the actual results, and a meaningful way to compare the two. All too often students lack one, two, or even all three of these. While the technical act of acquiring such data is necessary, it alone is not sufficient to make sense of the data. Students must have a firm understanding of the subject matter and its context within the problem domain. The pedagogical approach in this work provides endless opportunities to ground the programmatic exercises to reality in order to help students develop and improve their critical-thinking skills in computer science.

For example, experiments in engine manipulation could be better understood by knowing that it is normal procedure for pilots of many commercial airliners to spool the engines initially to 50% power on takeoff and then wait until they all reach this point before going to full power. The natural variability in engine performance does not guarantee exactly the same behavior simultaneously, which could have adverse effects on controllability during the takeoff roll. With this knowledge, students may realize that they are not just generating graphs; they are generating graphs that mean

something, and if that something is not what it should be, then they have considerable insight into what may need fixing.

Another example in Fig. 9 shows a complex example of mixing eight ailerons with different performance properties in roll mode. At (1), with all ailerons at their neutral position of 0 degrees, the master aileron (M) is commanded to deflect upward to 45 degrees. The slave ailerons on the same wing move upward as a ratio of its movement, while those on the opposite wing correspondingly do so downward. Upon reaching 45 degrees at (2), the master is commanded downward to -40 degrees, which is achieved at (3). The graph convincingly shows that all ailerons remain antisymmetrically synchronized at all times.

Fig. 9. Aileron manipulation

Fig. 10 shows the same ailerons acting in speed-brake mode. Starting again from neutral 0 degrees at (1), the eight ailerons deflect upward to their maximum limit of 90 degrees, which is achieved by all by (2). The master is then commanded to -20 degrees in roll mode, which results in behavior analogous to that in Fig. 9. The details of the action are beyond the scope of this paper, but again, the graph clearly demonstrates them to the students, who have the theoretical and practical foundation to know how to interpret it.

Fig. 10. Speed-brake manipulation

Finally, Fig. 11 shows a four-flap configuration, where two types of flaps differ in performance slightly. At all times through a variety of actions, the flaps of the same type remain synchronized, and the two types act appropriately with respect to one another. Such insight into the behavior of a complex system is invaluable in testing and evaluation.

Fig. 11. Flap manipulation

Reporting and evaluating the results of human subjects in work of this scope must be summarized due to limited space. However, it is based on a significant breadth and depth of objective and subjective measures including anecdotal observation, individual contributions from a background survey, 11 assignments, and 10 anonymous weekly assessments, as well as individual and team contributions from 18 project status reports, a project reflection, a team evaluation, a self-evaluation, and a course evaluation.

Most telling, 90% (28 of 31) of the participating students indicated that the graphical form of the test report directly contributed to a better understanding of what their code was actually doing, where they otherwise would have had less confidence in their results. Overall, the students rated the project 4.6 out of 5 (excellent).

VIII. FUTURE WORK

Almost any complex physical system is characterized by input, processing, and output that could map to this architecture. For reuse in future projects, it should accommodate more complex interval behaviors, as well as other sensors, actuators, and controllers. Of particular interest within this application are detecting and handling faults and managing operating laws. For a graduate-level course, especially for software quality assurance, the evaluation framework based on controlled experiments could be significantly expanded for richer analysis. In particular, the introduction of probability would contribute to a powerful stochastic Monte Carlo methodology.

IX. CONCLUSION

This work mitigates the common problem-solving strategy of many students who undermine the design of a system by indiscriminately throwing more code at every issue they

encounter. The hierarchical quasi-network-based architecture effectively prevents them from communicating with their components by any means except the prescribed ones. Its datatype-oriented interval framework safely and elegantly manages complex physical behaviors concurrently. This unified approach, combined with an overarching framework of modeling, simulation, visualization, and analysis, further provides a disciplined strategy for creating, executing, presenting, and analyzing meaningful test cases as part of formal test plans based on a sound methodology of controlled experiments via scientific method. Extensive results from a classroom deployment support the conclusion that students overwhelmingly benefit from this approach.

Abstract— While the initial course in linear algebra plays a decisive role in an engineer's basic formation, it is often marked by high rates of student failure and dropout and thus constitutes an important issue in the field of engineering education. The present study aims to enhance the teaching and learning processes in the first phase of linear algebra in engineering curriculum, viz., matrices, systems of linear equations, notions of vectors, and line and plane equations. To address this end, a methodological teaching proposal, Peer Instruction (PI), is proposed to improve student comprehension, classroom interaction, cooperation among peers, and assimilation of fundamental concepts. The PI method was applied in the initial phase of a linear algebra course in the undergraduate Chemical Engineering program at the Federal University of Ceará, Brazil. To measure student prior knowledge, a conceptual pre-test was conducted. Subsequently, eleven 2-hour classes were taught using PI, and a final exam was then conducted. Comparison of pre- and post-test results shows significant increase in student performance. The incremental increase in student-teacher and student-student interactions played a significant role in methodology's success.

Keywords—Peer instruction; linear algebra; engineering education; active learning; previous knowledge.

I. INTRODUCTION

Failure rates among first-year engineering students are increasingly encountered in universities worldwide [1]. A contributing factor to these high rates is the inadequacy of the students' academic background in mathematics [2].

In general, students have difficulty in relating previous knowledge to new concepts that will be learned at university. In this regard, basic abstract concepts in linear algebra, a core course in the engineering curriculum, merit special attention. Linear algebra provides a foundational language for mathematical modeling of a broad number of problems. Thus mastering these concepts is crucial to the education of future engineers [3].

Such basic concepts from secondary education such as matrices, systems of linear equations, notions of vectors, and line and plane equations, form a set of prerequisites for the proper understanding of linear algebra [4]. Accordingly, it is critical that students master these concepts in order to develop their abstract thinking in linear algebra; otherwise major difficulties are certain to arise [5-6]. Providing an appropriate background to students should help them overcome barriers between the abstract and real worlds. Such initiatives foster a better understanding of linear algebraic concepts to the benefit of students' academic studies and subsequent professional careers.

The conventional teaching method, based on lectures given by an instructor addressing a class of passive students, has proven ineffective for linear algebra courses. It fails to motivate students and makes it more difficult for them to absorb abstract concepts, as evidenced by the unsatisfactory learning rates found in evaluations [5].

The present study applies a teaching method, Peer Instruction (PI) [7], to support alternative teaching and learning processes for fundamental concepts of linear algebra in the context of the engineering curriculum. PI's immediate benefits include increased motivation and interest in the subject.

The PI method was developed by Eric Mazur, a professor of physics at Harvard University [7]. Its objectives are to motivate students' class participation, their collaboration with their peers, and, in particular, their assimilation of fundamental concepts in linear algebra.

The PI methodology was implemented throughout the Linear Algebra course taught in the program of Chemical Engineering at Federal University of Ceará (UFC). The purpose of this study, however, is to analyze student performance improvement solely in the initial phase of the course, in which basic mathematical concepts, viz., matrices, systems of linear equations, notions of vectors, and line and plane equations, are taught. Since these concepts customarily

This work was financial supported by CAPES (Coordination for the Improvement of Higher Education Personnel) - an Agency of the Brazilian Ministry of Education, and CNPq (National Counsel of Technological and Scientific Development).

are part of the secondary curriculum, students are expected to have previous knowledge of them. This is why analyzing the performance data restricted to the initial phase of the course is an effective way to assess PI's success.

Accordingly, it should be understood that references to the initial phase of the linear algebra course encompasses the previous knowledge acquired in secondary education.

The study finds that using different materials and alternative instruction strategies, based on PI, in teaching fundamental concepts of linear algebra enhances students' learning experience. This is particularly meaningful in regard to the initial phase of the course. Mastering these foundational concepts has a decisive impact in assimilating abstract ideas from the latter part of the course. Increased motivation has also been observed.

The study is divided into four principal parts. The introductory section consists of a brief history Peer Instruction and its systematization, while the second describes the implementation of PI techniques in teaching the initial phase of a linear algebra course. The third section presents the study's results and analysis, and the concluding section offers some thoughts about the study's result, implications, and further dimensions to be explored.

II. PEER INSTRUCTION

In the early 1990s, Mazur developed Peer Instruction as a teaching method to help his students improve learning in his introductory physics course. In view of its effectiveness [8-10], PI is now used in diverse courses in many countries [11-16]. Despite its international success, however, PI has not been sufficiently explored in linear algebra instruction in Brazil. In this study, Didactic Engineering (DE) [17] is combined PI to develop an efficient mechanism to teach the first quarter of linear algebra courses. This is the principal innovation presented in these pages.

PI's fundamental objective is to promote student engagement and cooperation in class, as well as the assimilation of fundamental concepts. The conceptual idea behind the method is to induce students to appreciate the importance of discovering for themselves the bases of theories covered in the classroom, thus honing their abstract thinking skills.

A PI lecture organizes its contents under critical topics. For each key concept, a brief explanation of about 10 minutes is provided, followed by a conceptual question using a multiple-choice format. Students are encouraged to think through their answers for 1 to 2 minutes, and then respond by a show of hands, flashcards, or electronic devices (clickers) directly connected to the instructor's computer. Subsequently, the instructor registers their responses for comparative purposes.

If at least 70% of the students select the correct answer, the instructor briefly discusses it without taking a further poll. As a rate below 30% implies students misunderstood the concept, the instructor explains it in further detail, often using another approach. Subsequently, the instructor poses another conceptual question. Ideally, students should answer it

correctly between 30 and 70 percent, implying that the question is challenging but not out of reach. In this situation, students are asked to discuss their responses with their peers, and endeavor to convince them to adopt their own answer. Simultaneously, the instructor should move around the classroom to foster fruitful discussions.

After two to four minutes, it is time for the next round of polling; if most students select the correct answer, the instructor can move on to the next topic; otherwise, he or she may elect to explain the question, analyzing each response. Fig. 1 summarizes the PI process [10].

Another important aspect of PI is that it requires students to prepare for class beforehand. Students must read material assigned by the instructor before coming to class. Such material might include text, videos, or bibliographic references that re-enforce the basic concepts to be discussed in the next class. Just-in-Time Teaching, developed by Novak, Gavrin, Christian, and Patterson [18], is used to incentivize such reading. Students are required to study the material, answer questions related to the complexities of the concepts, and provide their responses to the instructor by the deadline. For example, the instructor might ask, "Did you find anything difficult or confusing in the reading? If not, what did you find most interesting?" The goals of reading assignments are to encourage students to prepare for class, bolster student motivation, and provide the instructor sufficient time to adjust in-class activity to address students' difficulties.

As Mazur's experience confirms, Peer Instruction's successful implementation does not depend on the polling system. Fundamentally, PI is a student-centered teaching methodology that emphasizes the concepts of and provides a proper environment for peer discussion and collaboration. The instructor plays a role as a facilitator in the teaching-learning process, helping students' through their difficulties [19].

Vygotsky's theory empathizes that cognitive development is based on social interaction [20]. This concept is embodied in the Peer Instruction method, since the instructor, who plays the role of mediator in the learning process, seeks to stimulate student interaction. This enables student to actively participate and effectively cooperate with their counterparts, thereby increasing their own comprehension. These initiatives yield teacher-student interaction, student-student interaction, and a new interaction with previous knowledge.

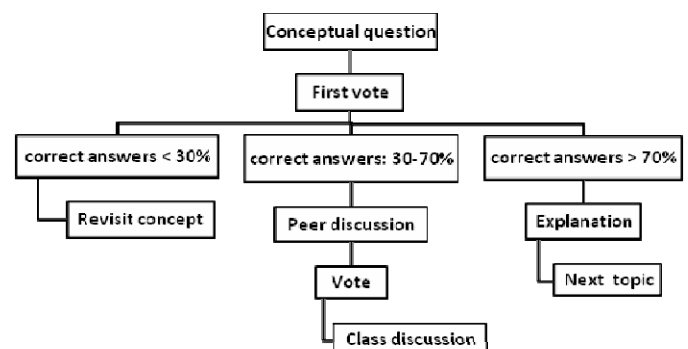

Fig. 1. Peer Instruction implementation process.

According to Ausubel's learning theory, to attain new knowledge, students must link it to relevant facts they already know [21]. When a new concept relates to existing knowledge gained in the classroom, the student will be better equipped to transform the knowledge into meaningful learning to be applied outside that milieu. Reading assignments have provided students the prior knowledge required for the absorption of a new concept. Hence, this methodology favors learning where students connect new content to pre-existing knowledge thereby generating meaningful learning.

III. METHODOLOGY

This study is based on the Peer Instruction method. The Just-in-Time Teaching method was applied as a reading incentive and the Didactic Engineering, methodology developed by Michèle Artigue [17], provided support in the organization, observation, and analysis required to prepare classes [22].

A. Learning Outcome and Course Description

The purpose of the lectures is to provide students with a sound background to the concepts of the initial phase of the linear algebra course. Their goal is to enable students to identify and solve linear equations, using matrix systems, highlighting geometric associations and physical interpretations. The reading assignments and conceptual and test questions are designed to meet expected learning outcomes described in Table I.

The study was conducted in a linear algebra course in the Chemical Engineering program at the Federal University of Ceará. Of the 70 students enrolled in the course, 64 were taking it for the first time. Student ages ranged from 17 to 21 years. There were 22 females and 58 males in the class.

The two-hour class met twice weekly. The lectures comprised 64 hours, of which 20 were dedicated to covering fundamental concepts required for the study of linear algebra. Table II shows the topics covered during the lectures.

TABLE I. EXPECTED LEARNING OUTCOMES

	Following the respective lecture, students should be able to:
S1	Identify types of matrices
S2	Operate matrices
S3	Distinguish between matrix and real number properties
S4	Solve linear equations using matrix systems
S5	Compute determinants of matrices and understand their importance in solving linear systems and inverting matrices
S6	Geometrically interpret solutions of linear systems via vectors, lines, and planes
S7	Write elementary mathematical proofs.

TABLE II. COURSE DESCRIPTION (INITIAL PHASE)

Lecture	Description
1	Explanation of study's methodology; Diagnostic pre-test
2	Matrix operations
3	Systems of linear equations Homogeneous systems
4	Row reduction and echelon forms Gaussian elimination
5	Inverse matrices and their applications
6	Determinants
7	Adjugate matrices
8	Vectors in n-space
9	Line and plan equations
10	Post-test

B. Peer Instruction Implementation

On the first day of class, the study's methodology and how it would be implemented in the class were introduced to students. The importance of their active participation and the need for pre-class reading was highlighted. Students reacted positively to the study's methodology and implementation.

A diagnostic pre-test, consisting of 10 true-or-false questions, was conducted to evaluate students' previous knowledge of basic concepts critical to the study of linear algebra. The same test was re-conducted subsequent to the lectures to assess student assimilation of these concepts.

Following the Just-in Time Teaching protocol, the reading material and assignment related to the content of their next class was periodically sent students via the university's Virtual Learning Environment, Sistema Integrado de Gestão de Atividades Acadêmicas (Integrated Academic Activities Management). The material provided was carefully designed to effectively and efficiently summarize a broad spectrum of online literature and content [23-27]. As an incentive to completing the pre-class reading, the assignments constituted 10% of the student's final grade. This credit was received by student solely on the basis of effort. An exam covering a significant number of conceptual questions was administrated at the conclusion of the initial phase.

The JiTT method recommends that students submit their completed reading assignment prior to class. However, such a task would hardly be in practical due to local constrains. Alternatively, the instructor used an alternative protocol from the Didactic Engineering methodology [17].

The students' completed assignments were received at the beginning of, rather than prior to, class. To compensate for this discrepancy, in preparing the lecture, the instructor predicted probable difficulties in assignment completion, based on teaching experience and current literature. This strategy, viz., a priori analysis, is part of DE's second phase [17].

In accordance with the final stage of DE, viz., a posteriori analysis and validation, following each class, completed assignments were analyzed by the instructor and compared with the anticipated results. Drawing on this analysis, the

instructor began the next class with a review of content inadequately assimilated as evidenced by the completed assignments.

Guided by the PI method, at the beginning of class, each student received a set of four cards for use in the polling process. After a brief discussion of the reading assignments and supporting material, the lecture main topic was divided into subtopics, followed by conceptual questions selected to advance the students' critical reasoning. The questions and multiple-choice answers were adapted from books and websites related to the course. Each question covers a specific concept or a property to be discussed in class [14, 23-26].

Following the PI strategy, the instructor presents a brief explanation of the content and poses a conceptual question to initiate the polling process. Students respond to the question without consulting textbooks or any other external sources.

If 30% to 70% of students answer a given question correctly, peer discussion in small groups of approximately two to three students is initiated. The groups are assigned with the goal of confronting students with different answers. After about 4 minutes of group discussion, the instructor polls the class again, explains the correct answer, and presents the next component of the lecture.

On the other hand, if the initial poll indicates that less than 30% of the class answered the question correctly, the instructor briefly explains the concept further, using a different approach. Subsequently, the instructor discusses each response to the question, guiding them to analyze them appropriately and thus arrive at the correct answer.

In the case where the rate of correct answers exceeds 70%, the instructor may elect to re-poll the class, following a peer group discussion as previously described, rather than simply moving on to the next topic. When this route is taken, the percentage of correct answers in the second poll generally surpasses 90%. This clearly indicates that the class has generally assimilated the lesson and there is no need for further clarification.

Student evaluation was performed continuously throughout the course. Student grades were based on reading assignments, class participation and the post-test. To validate the evaluation of the PI methodology, the test content was identical to that of the pre-test administered at the course's onset. Comparison of the results of the pre- and post-tests yields an accurate analysis on the progress of a student's knowledge and the success of the instructional method.

IV. RESULTS

In this section, the results obtained from the implementation of Peer Instruction during the initial phase of a university course in linear algebra are presented and analyzed.

A. Conceptual Questions

During the initial phase of the linear algebra course, a total of 20 conceptual questions were posed. To build student confidence and motivate them to participate in class, the difficulty level of the questions was gradually raised. Student responses were compiled on a worksheet for future analysis.

Of the 20 conceptual questions posed in this period, only 3 fell below the 30% threshold for correct responses in their initial poll. On the other end of the spectrum, 6 questions exceeded the 70% bound. Thus 55% of the questions fell within the 30% to 70% of range of correct responses sought by the PI method in their first round.

Review of responses indicated that questions involving matrix multiplication properties generated considerable doubts and discussion among students. Table III exemplifies one of those questions. Its initial polling generated a correct response rate of just 10%. An analysis of each potential response was carried out. Most students did not distinguish between the rules governing matrix multiplication and those applicable to the arithmetic multiplication of real numbers. This is a basic anticipated ability, as noted in Table I, S3. The question prompted a particularly stimulating discussion among the class, intensifying student's buy-in and motivation for active, collaborative participation in the course.

Student collective engagement in solving problems was not limited to this question. Indeed their increasing integration in addressing all questions was evident throughout the e period studied. Within a stimulating atmosphere, it was common to witness students attempting to convince their peers that their responses were correct. The increase in correct responses after discussion is illustrated in Fig. 2.

Peer discussions reflected progressive improvement in the rate of correct answers, as students became more confident in explaining their ideas to one another. A cooperative atmosphere pervaded the classroom.

B. Reading Assignments

In the initial phase of the course seven reading assignments covering matrices, linear equations systems, vectors, lines, and planes equations were completed.

Each assignment began with the question: "What did you find difficult or confusing about the reading? If nothing was difficult or confusing, what did you find most interesting?" This helped the instructor identify the principal challenges facing students.

Despite expected previous knowledge concerning these topics, students encountered substantive difficulties as evident in their completed pre-class assignments. A potential contributing factor could well be deficiencies in abstract mathematical reasoning.

TABLE III. CONCEPTUAL QUESTION ON MATRIX PROPERTIES. (correct answer :d)

- If a square matrix A is such that $A^2 - 4A^3 = 0$, then,
- a) $A^2(1 - 4A) = 0$
 - b) $A = 0$ or $A - 4A^2 = 0$
 - c) $\frac{A^2}{A^3} = 4$
 - d) none of the above.

Fig. 2. Percentage of correct answers before and after discussion.

In this regard, particular attention should be accorded a question testing math proof testing ability presented in Table IV (see also, Table I, S7). An overwhelming majority of 90% of students failed to find the correct solution. In light of this result, the instructor provided another explanation of the concept, using a different approach, but not providing the solution. The question was then resubmitted as a reading assignment. In this second round, 75% of the students answered the question correctly. To re-enforce the learning experience, the instructor asked a student to present their solution on the blackboard. Students reacted quite positively.

C. Assessment of Student Learning

The diagnostic pre-test was administered to 60 students (85% of all enrolled students) on the first day of class. The test, described in Table V, consisted of 10 statements covering the secondary-school level concepts integral to understanding linear algebra. Students were asked to rate each statement as follows: T (true), F (false), DC (unknown content), NE (never studied) or NC (have studied content but cannot solve) content). For the purposes of this analysis, the last three designations were regarded as blank responses.

The data, depicted in Fig. 3, indicate that nearly 65% of students missed or did not know the answers of the statements, indicated a low-level of previous knowledge of these critical concepts. None of the questions produced a correct response rate above 57%. For the most essential topic, i.e., vectors and lines, only 19% of the students provided correct answers.

The same questions used as the diagnostic pre-test were given as the post-test at the end of the study period. A total of 58 students took both tests, and their aggregate data were used to compare student performance in the pre- and post-tests.

TABLE IV. READING ASSIGNMENT WITH VERY HIGH FAILURE RATE

Given a square matrix A and λ a scalar. Show that if and only if $Ax = \lambda x$ for some vector

TABLE V. PRE-TEST APPLIED IN A STATEMENT FORMAT

Question	Concepts	Statement	Goal ^a
1	Transpose matrix	The transpose of a lower triangular matrix is a lower triangular matrix.	S1
2	Multiplication of matrices	The product of the matrices $A(2 \times 3)$ and $B(3 \times 2)$ is a square matrix 2×2 .	S2
3	Properties of the matrix product	If a square matrix C is such that $C^2 - C = 0$, then $C(C-1) = 0$.	S2;S3
4	Inverse matrix	If A is an invertible matrix, then $A^{-1} = 1/A$ where I is the identity matrix.	S3;S5
5	Determinant	$\det(AB) = \det(BA)$, where A and B are square matrices.	S5
6	Geometric interpretation of a linear system	A linear system of two equations and two variables does not have solution when their graphs are parallel lines.	S4
7	Linear system	A linear system of three equations and five variables has solution.	S4
8	Vector	The length of every vector is a positive number.	S6
9	Line	The intersection between two planes is a line.	S6
10	Plane	The intersection of three planes cannot be a single point.	S6

^a Goal Learning according to Table I.

Fig. 3. Answers given to pre-test.

Fig. 4 portrays the rate of correct answers in the pre- and post-tests. It shows a significant post-test increase in correct responses for each question. Question 4, e.g., generated a 60% increase in its correct response rate. In regard to vectors and line equations, the most critical questions in the pre-test, post-test responses represented increases in correct responses rates of 38% and 33%, respectively.

The statistic t-test was used to determine whether there was a significant difference in students' pre-test scores, prior to the course's onset, and their post-test scores, following the initial phase of their instruction. As shown in Table VI, the p-value is 0.000 and t is 13.380. Since $p < 0.05$, the results are statistically significant. In other words, there was a significant increase in average score in student performance.

TABLE VI. MEAN ANALYSIS OF PRE- AND POST- TEST

	N (sample)	Mean	Std Deviation	t-test ^a	Sig (2-tailed)
Pre-test	58	3.293	1.5448	-13.840	.000
Post-test	58	6.638	1.4228		

^a. Result obtained using SPSS software.

Fig. 4. Frequency of correct answers of pre and post tests.

Fig. 5 illustrates the overall result of students' performance in the pre-test and in the post-tests taking into account the frequency of the total number of correct, incorrect, and blank responses for each question.

The results of this comparison show a considerable improvement in student performance. As illustrated by Fig. 5, there was a 38% increase in the number of correct responses, a 6% decrease in incorrect responses, and a 31% decrease in the number of blank responses. The latter figure demonstrates the significant growth in knowledge acquired by students in the linear algebra course using the Peer Instruction methodology.

Fig. 5. Aggregate test results

V. CONCLUSION

Students were constantly encouraged to participate in class and share with others their solutions to the questions and the manner in which they arrived at them. Their positive response to such encouragement and their active participation enabled them to enrich their understanding of critical concepts in linear

algebra and to discuss them with confidence with their peers, thus contributing to their educational progress.

The results further demonstrate that the Peer Instruction methodology contributes to students' development of their abstract thinking capacities and facilitates collaborative learning, skills which will better equip them for their professional careers. This stands in contrast to the record of traditional approaches to education that too often regard students as passive recipients of infused content.

Research covering the methodology should continue to be developed to systematize its classroom application. In this regard, in a forthcoming work, the authors will present further analysis of the results noted herein and conduct a study of more complex conceptual questions. In addition, an evaluation of PI's application throughout the entire course will be undertaken and the perspective of students to this innovational instructional methodology will be analyzed.

ACKNOWLEDGMENT

The authors would like to thank Professor Barros Neto, Dean of the Technology Center, for giving the opportunity to them in applying Peer Instruction in the undergraduate Chemical Engineering program, from the Federal University of Ceará, as well as, to thank the students for working with them.

An Integrated Curriculum for Internet of Things: Experience and Evaluation

Simon G. M. Koo
Jesuit Liberal Arts College
Hong Kong
Email: simonkoo@ieee.org

Abstract—While most universities have courses in computer networks, embedded systems, and other related topics, few have courses dedicated to the uprising area of the Internet of Things (IoT). During the Fall quarter of 2014, Santa Clara University offered a graduate-level course on Internet of Things, whose curriculum was designed using an integrated approach in order to reflect the inter-disciplinary nature of the topic. The course composes of a series of lectures, which are taught by the instructor and guest lecturers, and a laboratory component.

In this paper, we will first define the description and the learning outcomes of the course, followed by our design rationale. We will then present the curriculum in details, and show the weekly schedule. We will also include a list of reference materials used in the course for easier adoption. Since the course is accompanied by a series of hands-on laboratory projects to enrich the learning experience, we will describe the design and development projects in details, including the vehicles used and the assessment criteria. Finally, we will present the feedback and comments received from the students as a form of initial evaluation of the performance of the course.

I. INTRODUCTION

The Internet of Things (IoT) has become the most hyped technology entering 2014, and according to Gartner Inc. [1], there will be nearly 26 billion devices on the IoT by the year 2020. The vision of the IoT has evolved due to a convergence of multiple technologies, ranging from wireless communication to the Internet and from embedded systems to micro-electromechanical systems (MEMS). This means that the traditional fields of embedded systems, wireless sensor networks, control systems, automation (including home and building automation), and others, all have contributions to enable the IoT [2]. The Internet of Things is also expected to have at least five to ten years before reaching “plateau of productivity,” and more and more universities are interested in offering courses on this subject (Figure 1).

However, while most universities have courses in computer networks, embedded systems, and other related topics, few have courses dedicated to the uprising area of this uprising area. During the Fall quarter of 2014, the author designed and the Department of Computer Engineering at Santa Clara University offered a graduate-level course on Internet of Things, whose curriculum adopted an integrated approach to reflect the inter-disciplinary nature of the topic. The course composes of a series of lectures, which are taught by the author as the principal instructor, and by some guest lecturers from the industry. The course also has a laboratory component.

The remaining of this paper is organized as follows: we will

first outline the basic description and the learning outcomes of the course, followed by the curriculum in details. We will also show the weekly topic schedule, and include a list of reference materials used in the course for easier adoption. Since the course is accompanied by a series of projects to enrich the learning experience, we will describe the design and development projects in details, including the tools used and the assessment criteria. Finally, we will present the feedback and comments received from the students as a form of initial evaluation of the performance of the course.

II. BASIC COURSE INFORMATION

In this section, we shall present the basic information about the course, which includes the catalog description of the course, its learning outcomes, and textbook and reference materials used.

A. Course Description and Learning Outcomes

The following course description is excerpted from the syllabus and was presented to the students on the course catalog:

This course introduces the design principles of the Internet of Things (IoT) and their device and infrastructure-related architectures, technologies and protocol frameworks that aimed at enabling the formation of highly distributed and ubiquitous networks with seamlessly connected heterogeneous devices. Student will learn to design and analyze such networks in order to support the development of intelligent services with given performance requirements in a variety of application domains. In particular, students will learn about the major architectures and paradigms for the Internet of Things, and protocols at the different levels of the IoT stack and also will learn to map those concepts with the OSI model by means of access layer (including sensor, vehicular and cellular networks for machine-to-machine communication) and network layer (with particular emphasis on IPv6-based solutions), and analyze their performance. The course will also introduce technologies and protocols at the service and application layers, which enable the integration of embedded devices in web-based, distributed applications. Students will get the notions for service creation, customization, execution and deployment in distributed IoT heterogeneous environments.

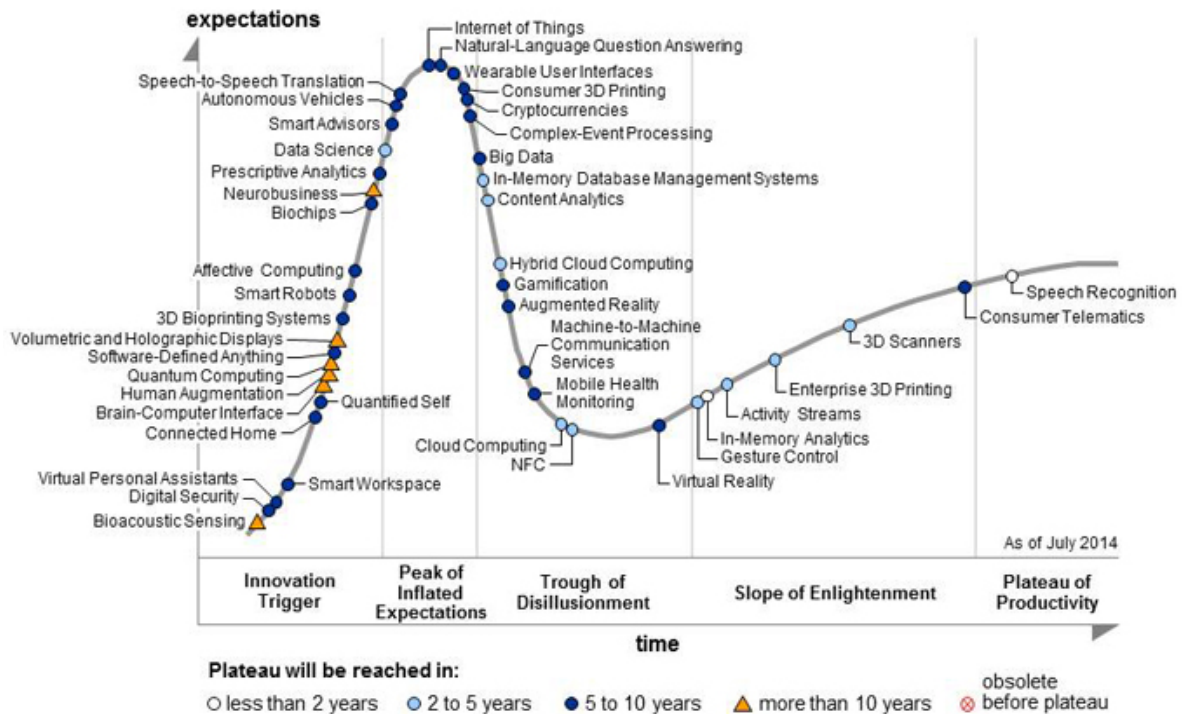

Fig. 1. Hype cycle for emerging technologies, 2014, according to Gartner Inc.

As a graduate-level topic course, conventional assessment vehicle may not be suitable to properly assess the learning outcome of the students. Besides, a significant portion of the learning outcomes were put on “design,” which calls for programming and implementation projects. In addition, it is very important to prepare graduate students on their literature survey skills and their academic writing skills, so after considering all these factors, we adopted the following grading scheme:

- A midterm written exam: 20%
- Programming project: 20%
- Industrial design project: 25%
- A survey paper: 35%

In order to better manage the instructions and facilitate the assessment, we also identified a set of learning outcomes for the course using techniques presented in [3] and shown to the students for their references:

Upon completion of this course, students should be able to:

- 1) *Characterize the Internet of Things (IoT) and enumerate its distinctive characteristics.*
- 2) *Demonstrate understanding of IoT and major machine-to-machine (M2M) communication protocols.*
- 3) *Demonstrate understanding of network layer support of IoT.*
- 4) *Design solutions for integrating smart objects into IoT framework(s).*

5) *Design IoT services and evaluate and analyze performances of IoT systems.*

Santa Clara University runs the quarter system, and there are ten weeks in each quarter. The week-by-week topic of coverage is presented in Table I:

TABLE I. WEEK-BY-WEEK LIST OF TOPIC FOR THE IoT COURSE AT SANTA CLARA UNIVERSITY

Week	Topic
1	Introduction to Internet of Things (IoT): Review of networking fundamentals.
2	Introduction IPv6: Motivations and current status. Structure of the IPv6 protocol and addressing and prefix notation. Introduction to Scala.
3	IP for Smart Objects: motivation and main challenges. IEEE 802.15.4.
4	Introduction to OpenIoT: Open Source Platform for the Internet of Things and Services.
5	RPL: IPv6 Routing Protocol for Low-Power and Lossy Networks.
6	6LoWPAN architecture. Issues in determining IPv6 links in LLNs and illustration of the undetermined link-addressing model. IPv6 addressing in 6LoWPAN.
7	Prototyping embedded devices and physical designs on IoT.
8	ZigBee: Architecture, device profile, and applications.
9	The Constrained Application Protocol (CoAP): features, interaction model, messages and request/response sub-layers, packet format.
10	Issues on designing of a complex IoT architecture: security, micro- and macro-mobility, and proxy communications.

Each week students will be assigned readings to the topics of that weeks, and programming and industrial projects are assigned in between. The course readings assigned had a significant impact on the students’ preparedness to work on their final survey paper.

B. Textbooks and Reference Materials

1) *Books*: Internet of Things is really a new topic from a coursework perspective, so there are not a lot of established textbooks in the area. Due to this reason, the course did not have a required textbook, and instead, we listed some reference books that are discussing the latest trends of Internet of Things to the students. Among them, McEwen and Cassimally [4] and Hersent *et al.* [5] were most often referred to as a general competency text, while Hagen's book on IPv6 [6] is the *de facto* reference when the topic was discussed. The course also required students to work on projects using *Scala* (more details on projects later), so the *Scala* book by Odersky *et al.* [7] becomes another important reference book for the students. Other useful reference books include the books by Vermesan and Friess [8], [9] and Bassi *et al.* [10].

2) *Journal and Conference Articles*: Exposing students to academic writing is also an important component of a graduate-level course. To supplement the lack of textbooks, we have identified several survey and position papers on IoT ([11], [12], [13], [14], [15]), and some design and framework papers on the topic ([16], [17], [18]). In addition, papers on the topic correspond to the weekly schedule are also assigned as referencing materials to supplement the lectures.

III. COURSE ACTIVITIES AND ASSESSMENT

Each week the primary course activities were lectures. A written midterm exam was given on the fifth week of the course to test the students' foundation knowledge about Internet of Things. In addition to the midterm exam, three more vehicles were used to assess the students' competency in the topic, and we will describe each of them in this section.

A. Programming Project

Programming projects are smaller scale, class projects requiring students to implement and realize Internet of Things components. On the cloud platform level, Internet of Things are going to be dealing with a large number of devices, so we chose to require students to use the programming language *Scala* as the language for their projects. *Scala* was designed by Martin Odersky at the École Polytechnique Fédérale de Lausanne (EPFL) beginning 2001. It is an object-functional programming language for general software applications, which has full support for functional programming and a very strong static type system. This allows programs written in *Scala* to be very concise and thus smaller in size than other general-purpose programming languages. Many of *Scala*'s design decisions were inspired by criticism of the shortcomings of Java [7]. The name *Scala* is a portmanteau of "scalable" and "language," signifying that it is designed to grow with the demands of its users [19].

The project we asked the students to build is a user interface to register, manage, and control the behavior of different sensors, and the application is running on a cloud server. The criteria of assessing the registration service project include how scalable and how robust the design and implementation are, as well as how user-friendly and easy-to-use the interface is. Through this exercise students are exposed to the design of the Internet of Things frameworks, and prepare application-level server processes to run on these frameworks.

B. Industrial design project

Another major component of the course is an industrial design project. It is a large-scale design project partnering with two Silicon Valley-based company, Dew Mobility and ARM, as well as EU-based OpenIoT project [20]. Students were instructed to build industrial-grade projects using the equipment and the design requirements from the aforementioned groups, and they were given a theme "Assisted Living" to build their Internet of Things applications upon. Each group of three to four students were given five weeks to design and implement their project, and they are required to submit a proposal with a schematic during the first week and a final report by the end of the project. Students were also required to give a formal presentation to the industrial partners.

C. Survey Paper

Each student was required to write a survey or tutorial paper on an Internet of Things topic of their choice, with the approval of the instructor, due by the end of the quarter. It was emphasized to the students that a survey or tutorial paper is not the same as a white paper or product review, and the main content of the paper should follow the guidelines listed below:

1) Introduction

- Discuss the background
- Summarize the surveyed research area and explain why the surveyed area has been studied.
- Summarize the classification scheme you used to do the survey.
- Summarize the surveyed techniques with the above classification scheme.

2) Survey details

- Present the surveyed techniques using the classification scheme in details. The use of tables and figures are recommended. It should be noted that tables and figures are NOT a substitute of the descriptive text.
- Identify the trends in the surveyed area. Give evidences for your decision.

3) Conclusions and possible future work

- Summarize the conclusions of your survey.

4) References

- List all the citations referenced in your paper. Points will be deducted for each dangling reference (i.e., the reference not cited in the main text).
- The final paper should be formatted using IEEE conference proceedings style using L^AT_EX.

We also made previously published student survey papers, either on Internet of Things ([12], [21], [22], [23], [24], [25]) or other related topics ([26], [27], [28]), available to students for their reference, so that they have a better idea about how a survey paper should be written.

IV. REFLECTION AND CONCLUSION

In this paper we presented our design of a new graduate-level course on Internet of Things, an emerging topic and yet

no proper curriculum was available. We have also provided a list of references for other instructors who want to adopt the syllabus. Most students enrolled in the course find the programming project and the industrial design project very interesting and most fulfilling, while the survey paper provided an opportunity for them to engage in formal research and literature survey. The overall experience of the students were positive.

A similar version of the course is being offered by the Computer Science Department of California Polytechnic State University, San Luis Obispo, during spring of 2015. All the industrial partners continue to support the course the way it was first offered, and made improvement to some of the materials based on students' feedback from the last offering. Further evaluation and assessment information will be available once the course concluded.

ACKNOWLEDGEMENT

The author would like to thank Mr. Shivakumar Mathapathi from Dew Mobility for arranging guest lecturers for the course and overseeing the industrial design project, Mr. Michael Koster from ARM Inc. for supplying the course with sensor hardware and all the hours he put in to help the students, and Dr. Martin Serrano for providing technical support on OpenIoT for the students.

Using an Interactive Animated Tool to Improve the Effectiveness of Learning CPU Scheduling Algorithms

Sukanya Suranauwarat

Bangkok, Thailand
sukanya@as.nida.ac.th

Abstract—CPU scheduling is one of the most important topics in operating systems courses. However, the main problem in learning CPU scheduling from textbooks is that textbooks usually simplify the illustration of CPU scheduling algorithms by using an unrealistic process execution model. They also do not give concrete examples when discussing complex algorithms. As a result, students are not able to gain insight into exactly how the algorithms work in real-world operating systems. To address this problem, the author developed an interactive Java-based software tool that uses graphical animation to convey the concepts of various CPU scheduling algorithms for a single CPU. While many existing animation tools were designed to be closely aligned with the content in traditional operating systems textbooks, this tool is uniquely designed and different in a number of respects. In this paper, the impact of the tool on student learning is measured, analyzed and discussed in detail. The tool has been used in two sections of the operating systems course at the author's institute, and has demonstrated effectiveness in assisting student learning of CPU scheduling algorithms.

Keywords— *Educational Software; Animation Tool; Computer Science Education; CPU Scheduling Algorithms; Operating System*

I. INTRODUCTION

Modern general-purpose operating systems allow multiple processes to coexist in the systems. In a single CPU system, only one process can be running on the CPU at any one time. When more than one process is ready to run, the operating system must decide which one is to run first and for how long. The part of the operating system that is responsible for making this decision is called the scheduler and the algorithm it uses is called the CPU scheduling algorithm. A large number of CPU scheduling algorithms were designed in the past especially in the early days of operating system development, and several of them are described in operating system textbooks [1]-[7]. However, the main problem in learning CPU scheduling from a textbook is that textbooks usually simplify the illustration of CPU scheduling algorithms by using an unrealistic process execution model. They also do not give concrete examples when discussing complex algorithms that use more than one scheduling algorithm such as Priority Scheduling and Multilevel Feedback Queues. As a result, students are not able

to gain insight into exactly how the algorithms work in real-world operating systems.

To address this problem, the author developed an interactive Java-based simulator that uses graphical animation to convey the concepts of various CPU scheduling algorithms for a single CPU including First-Come, First-Served (FCFS), Round-Robin (RR), Shortest-Job-First (SJF), Shortest-Remaining-Time-First (SRTF), Priority Scheduling, and Multilevel Feedback Queues (MLFQ) algorithms. The simulator was designed based on knowledge gained from experiences in implementing a couple of CPU schedulers in the BSD kernel [8, 9]. The simulator is unique in a number of respects. First, it uses a more realistic process execution model — the execution of a process consists of alternating CPU bursts and I/O bursts, as opposed to a simplified model used in textbook examples — only one CPU burst per process. Through a graphical user interface of the simulator, the user can configure several sets of processes easily and use them in observing simulations of various CPU scheduling algorithms. Second, the simulator graphically depicts each process' state versus time. The state of a process describes the current activity of that process such as “the process is waiting for an I/O operation to complete” or “the process is currently using the CPU”. Various events can cause a process to change states; the simulator shows these events. Using this representation, it becomes much easier to understand what is going on inside the system, why, at any given time, some processes are candidates for a CPU allocation and some are not, and why the currently running process can or cannot continue to use the CPU. Third, the simulator allows the user to practice and test his understanding of the concepts studied in two ways. The first is by making a prediction about which process will be allocated the CPU next and why, and the second is by making his own scheduling decisions and receiving immediate feedback.

The critical question is whether the simulator is effective in aiding students in learning CPU scheduling algorithms? An opportunity to measure its usefulness in two sections of the operating systems course at the author's institute was taken. In this paper, the impact of the simulator on student learning is measured, analyzed and discussed in detail. The result of the statistical analysis using a t test to compare the means indicated

that using the simulator does increase student performance in a statistically significant way.

The remainder of this paper is organized as follows: section 2 discusses related work, section 3 gives a brief overview of the simulator, section 4 evaluates the simulator's impact on student learning, section 5 discusses the evaluation results, and section 6 draws some conclusions.

II. RELATED WORK

In this section, some animation tools for learning CPU scheduling algorithms that others have developed are discussed.

English and Rainwater [10] developed several animations using Adobe Flash and used them as part of their lecture in an operating system course. Among these animations, four of them are used in teaching FCFS, RR, SJF, and Priority Scheduling algorithms. The animations are also accessible through the web [11] for anyone to use. However, the user is not allowed to create his own set of processes or set scheduling parameters like time slice. In other words, the predefined set of processes and the predefined scheduling parameter are used, and the same animation plays over and over again.

The CPU scheduling simulators developed by Tran [12] and Ham [13] support all the algorithms the author's simulator supports except the MLFQ algorithm. Unlike the tool developed by English and Rainwater, both of these tools let the user create a personal set of processes. However, the tool developed by Ham is more flexible, because time slice in the tool developed by Tran is program coded and taken as 1 or 4 for each set of processes.

The animations displayed by the above tools were designed to be closely aligned with the content in traditional textbooks about operating systems. Therefore, all the above tools use the simplified process execution model similar to those found in textbooks, that is, each process consists of only one CPU burst. Since tradition textbooks show the result of each scheduling example using a Gantt chart, the above tools also use a Gantt chart to animate which process is using the CPU at what time. This approach makes the simulation results look very similar to the results of scheduling examples in textbooks.

The MLFQ Scheduling Algorithm Simulator [14] is a tool that supports only one scheduling algorithm, as the name implies. To the author's knowledge, this simulator is the first tool that attempted to use a more realistic process execution model, that is, it allows each process to alternate CPU bursts with I/O bursts, in a simulation. While the author's simulator allows the user to set the CPU and I/O bursts of a process to any value, the MLFQ Scheduling Algorithm Simulator fixes all the I/O bursts of a process to one value. The MLFQ Scheduling Algorithm Simulator displays animation using Gantt charts for both CPU and I/O activities. However, it reports I/O usage in a composite Gantt chart with little hint as to how multiple simultaneous I/O requests are handled. This can confuse the user. In other words, the Gantt-chart approach is not appropriate to represent the animation when the execution of a process consists of alternating CPU bursts and I/O bursts. Rather than focusing on the resource usage as the Gantt-chart approach does, the author's simulator focuses on

the processes' states, how long processes are in each state, and the events that cause them to change their states. Using this approach, the user will be able to gain insight into exactly how the algorithms work, that is, the user will be able to understand what is currently happening to the processes and why the currently running process can or cannot continue to use the CPU. Also, the author's simulator gives the user the choice of sharing I/O devices with FCFS queues or using unique I/O devices for each process. In addition, the author's simulator animates I/O activity to help the user understand the specific outcome for multiple simultaneous I/O requests.

Recently, a tool called AnimOS CPU Scheduling Simulator [15] has been developed. This simulator supports all the algorithms the author's simulator supports. It also allows each process to alternate CPU bursts with I/O bursts. Although it is the newest tool, it does not give the user as much flexibility to create a personal set of processes as the author's simulator does. That is, it allows the user to set all the CPU bursts to a single value and all I/O bursts to a single value. Although, the AnimOS CPU Scheduling Simulator also gives the user an option to specify a range of values, it randomly assigns a value in the range to a CPU burst or an I/O burst of a process during the simulation. This makes it very hard for the user to be able to predict what will happen at any one point of time during the simulation. The AnimOS CPU Scheduling Simulator animates how each CPU scheduling algorithm works in a somewhat similar manner to the author's simulator. In the author's opinion, the author's approach or a similar one is most appropriate way to present the animation when a more realistic process execution model is used.

Finally, none of the existing tools provide a similar functionality as the author's simulator that allows the user to make a prediction about which process will be allocated the CPU next and why and to make his own scheduling decisions.

III. OVERVIEW OF THE SIMULATOR

In this section, the implemented simulator is briefly described, in order to provide sufficient background for the paper. The detailed description of the simulator can be found in [16]. The simulator is written using Java 6 and has two operating modes: simulation and practice modes. Each mode is briefly described below.

A. Simulation Mode

Fig. 1 shows two snapshots of the simulator during a simulation in simulation mode. Within a simulation-mode tab, the user can select which algorithm to be animated through a drop-down list box located in the top left section. For each selected algorithm, the predefined set of processes and the predefined scheduling parameters will be loaded so that the user can start watching the animation immediately. The user can modify the predefined set of processes or create a new set of processes. Also, the user can view or change the predefined scheduling parameters.

The bottom area of the front snapshot in Fig. 1 contains the buttons that allow the user to control the animation. The user can start and stop the animation whenever he wishes by clicking on the "Start" and "Stop" buttons. Alternatively, the user can choose to trace the algorithm step by step, in order to

understand the details of the algorithm, by repeatedly clicking the “Next” button. Note that the user can use this step-by-step function of the simulator to practice and test his understanding of the concepts studied. In this case, the user should predict which process will be allocated the CPU next and why before clicking the “Next” button.

The bottom half of the front snapshot in Fig. 1 shows the *display area* that accommodates the animation that demonstrates how the selected algorithm works. The left side of the display area is the *state-diagram view* which displays the different states in which processes can be at different times. A process can be in one of the three states: running, ready, and waiting. A process is in the running state if it is currently using the CPU. A process is in the ready state if it could use the CPU if it were available. A process is in the waiting state if it is waiting for some event to happen, such as the completion of an I/O operation, before it can proceed. The right side of the display area is the *timeline view* which displays a colored block for each unit of time a process spends in any state. The color of the block which corresponds to one of the colors in the state-diagram view is determined by which state the process is in. During the animation, various events may occur and cause a process to change its state. Details about the event can be viewed in the “Event Message” panel.

In the simulation of Fig. 1, a user-defined set of processes, which is summarized in the process table located under the drop-down list box of the algorithms, was used. The user-defined set of processes contains processes A, B, and C, all of which have the same priority of 2 and arrive at time 0. When two or more processes have the same priority, the simulator puts them in the ready queue for that priority in alphabetical order. Process A requests only one burst of 10 units of CPU time. Processes B requests a burst of 1 unit of CPU time, then blocks on I/O for 4 units of time, then requests a burst of 1 unit of CPU time, then blocks on I/O for 6 units of time, and then requests one last burst of 1 unit of CPU time. Process C requests a burst of 5 units of CPU time, then blocks on I/O for 4 units of time, and then requests one last burst of 3 units of CPU time. Note that processes B and C are using different I/O devices in this simulation. When I/O devices are shared among processes, they will be scheduled on a First-Come-First-Served basis.

In the simulation of Fig. 1, the MLFQ algorithm is selected. The MLFQ algorithm chooses a process to run from the highest-priority, non-empty ready queue. When more than one process is in such a queue, the RR algorithm is used to schedule among them. The MLFQ algorithm also varies the priority of a process based on its observed behavior. Therefore, the scheduling parameters of the MLFQ algorithm are the length of time slice and the conditions for increasing/decreasing a process’s priority. In this example, time slice is set to 3 time units and any process that has just returned from its I/O will have its priority raised by one. In the state-diagram view, the priority levels of the ready queues are displayed in front of the queues and the ready queue with

higher priority level is placed over the one with lower priority level. Since the maximum number of processes is limited to four, the maximum number of ready queues is four.

Fig. 1 gives two snapshots of this scenario. The front and the back snapshots are at time 15 and time 16 respectively. The state-diagram view of the front snapshot shows the state each process is in at the beginning of time 15. That is, process A is in the running state while processes B and C both are blocked in the waiting state for their I/O requests to complete. The timeline view shows that processes A, B, and C have been in the current states since time 11, 9, and 11, respectively. As reported in the “Event Message” panel, at time 15, two hardware interrupts have been generated indicating that the I/O operations requested by processes B and C have been completed, and the priorities of processes B and C have been raised to 4 and 3 respectively. At this point, process B becomes the process with the highest priority; therefore, it preempts the CPU from process A and runs next. Various events occurring at time 15 cause all the processes to change their states; the state-diagram view will show such transitions. As shown in the timeline view of the back snapshot, all the processes spend a unit of time in their new states.

B. Practice Mode

The user can open a practice-mode tab by clicking the “File” menu and then clicking “New Practice”. To reduce the time the user has to devote to learn how to use the simulator, a practice-mode tab has been designed to look as much like a simulation-mode tab as possible. The major differences between a simulation-mode tab and a practice-mode tab are as follows. First, there is no state-diagram view in a practice-mode tab. Second, the timeline view of a practice-mode tab does not contain the speed-control slider, but instead, it contains the “Display Answer” button. Third, the timeline view and the “Event Message” panel become editable so that they can be used as interfaces for the user to predict when and for how long each process is in a particular state and why it is in that state.

Since the timeline view is editable in practice mode, clicking the blocks under the timeline will change the color of the blocks. The user can predict which state each process is in for each block under the timeline by repeatedly clicking each block until the color corresponding to the predicted state is displayed. The color green, yellow, and red are used to represent running, ready, and waiting states respectively. This feature allows the user to visually predict which state each process is in for each block of time. The user can also predict why the processes are in the states he predicted by checking relevant checkboxes and filling in the missing information in the “Event Message” panel for each time.

At any time while in practice mode, the user can check whether his answer is correct or not by clicking on the “Display Answer” button, which causes the answers to be displayed in the timeline view.

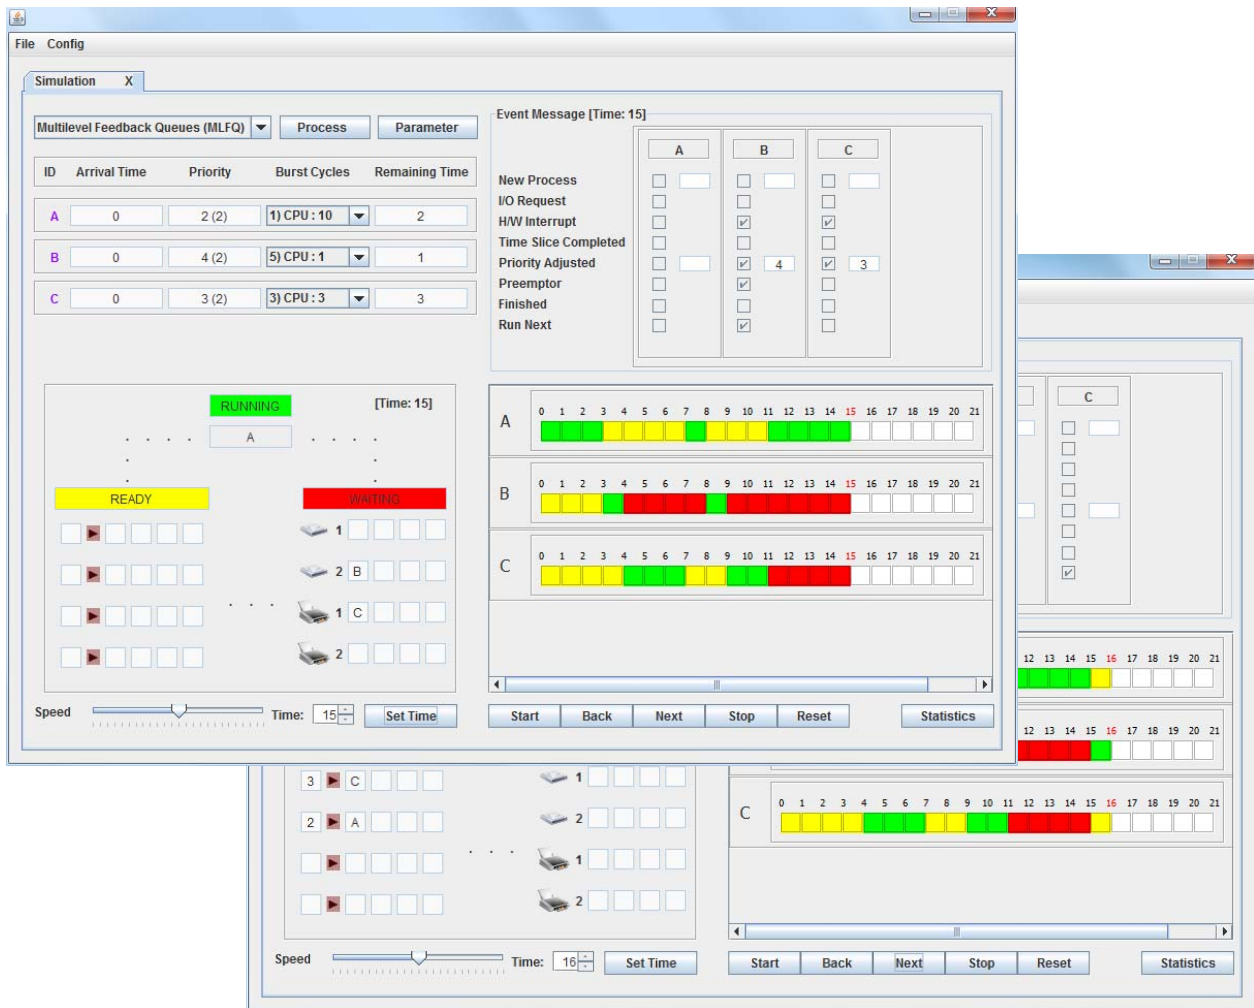

Fig. 1. Snapshots of the simulator during a simulation using the MLFQ algorithm.

IV. EVALUATION

The true usefulness of the simulator designed as a supplement to an operating systems course is in its effectiveness in aiding students in learning the concepts of CPU scheduling algorithms. The simulator was used in two sections of the operating systems course at the author's institute. The sample for the effectiveness study consisted of 37 students enrolled in one of the two sections of the operating systems course. Both groups of students took the operating systems course in the same semester but different sections. First, a section (control group) was randomly assigned to only use the textbook to learn CPU scheduling. The other section (simulator group) used the textbook and the simulator. The reason for selecting by clusters was to single-blind the control group to the simulator given to the other group. Once students were assigned to a group, all of the students were given a pretest; students who scored above twenty-five percent were excluded from the sample. The reason for excluding students was to block for students with some prior knowledge of CPU scheduling; six students were excluded for prior knowledge, one for withdrawing from the course.

After blocking for prior knowledge, nineteen students in one section ($n=19$) were in the textbook group (control group) that learned CPU scheduling only from the textbook. Eleven students ($n=11$) were in the simulation group (experimental group) that learned CPU scheduling from the text and through using the simulator. Students in both sections were given pretests and posttests. These tests assessed the same objectives but used different data. They consisted of basic and complex scheduling problems; complex scheduling problems involved using either Priority scheduling or MLFQ algorithm. Two experiments were conducted using basic and complex scheduling problems respectively and are discussed below.

A. Experiment 1

Our null hypothesis for the first experiment is that reading the textbook only and reading the textbook along with using the simulator will generate the same results — students in both groups will learn the basics at the same rate. First, all students were tested to establish a baseline. After that, the control group ($n=19$) was assigned to read the textbook over the next week while the simulator group ($n=11$) read the textbook and used the simulator during the same time. The two groups were then

retested on the same material with similar questions. The results are shown in Figs. 2 and 3. Fig. 2 shows the confidence intervals (CI) for the means of both groups. Fig. 3 shows the numerical summary for the two-sample t test outputted by Minitab.

Fig. 2. The confidence intervals (CI) for the means of the control and the simulator groups in Experiment 1.

Group	N	Mean	St Dev	SE Mean
Control	19	0.163	0.112	0.026
Simulator	11	0.382	0.281	0.085

Difference = mu (Control) - mu (Simulator)				
Estimate for difference: -0.2191				
95% upper bound for difference: -0.0602				
T-Test of difference = 0 (vs <): T-Value = -2.48				
P-Value = 0.015 DF = 11				

Fig. 3. The numerical summary outputted by Minitab for the two-sample t test in Experiment 1.

When tested on basic problems, the control group had a mean improvement of 16.3 points out of 100 points whereas the simulator group had a mean improvement of 38.2 points, as shown in Fig. 3. When the improvement of the two groups was compared a p-value of 0.015 was calculated using a two-sample t test; with an alpha of 0.05, this means that the null hypothesis was rejected. The alternative, that the simulator group improved more than the control group on basic problems, was accepted. In Fig. 2, the data for the confidence intervals is graphed; the point estimate of the improvement was calculated to be 0.219 or 21.9 points on a 100 point scale. This

means that the simulator group improved about twice as much as the control group.

One area of interest was how well will students do at problems beyond the textbook? In other words, how well will students do the basic problems when the execution of a process consists of alternating CPU bursts and I/O bursts as opposed to the basic problems when the execution of a process consists of a CPU burst only? The data is displayed in TABLE I and in Fig. 4; from the table the simulator group outperformed the control group on average by 22 points out of 100. Although the simulator group did not improve as much when doing CPU and I/O problems as they did when doing CPU only problems; a two-sample t test generated a p-value of 0.015 which implies that the simulator helps students learn to solve more difficult problems better than just using the textbook.

Fig. 4. The boxplots of the improvement of test score between the control and simulation groups when testing with the basic problems with CPU only, and when testing with the basic problems with CPU and I/O in Experiment 1.

B. Experiment 2

Our null hypothesis for the second experiment is that reading the textbook only and reading the textbook along with using the simulator will generate the same results — students in both groups will learn complex concepts at the same rate. First, all students were tested to establish a baseline. After that, the control group (n=19) read the textbook while the simulator group (n=11) read the textbook and used the simulator. The two groups were then retested on the same material with similar questions. The results are shown in Figs. 5 and 6. Fig. 5 shows the confidence intervals (CI) for the means of both groups. Fig. 6 shows the numerical summary for the two-sample t test outputted by Minitab.

TABLE I. DESCRIPTIVE STATISTICS: BASIC PROBLEMS WITH CPU ONLY AND WITH CPU AND I/O

Group	N	Mean	SE Mean	St Dev	Minimum	Q1	Median	Q3	Max
Control	19	0.1632	0.0256	0.1117	0.0200	0.1050	0.1150	0.2100	0.4250
Simulator	11	0.3823	0.0847	0.2810	0.0600	0.1050	0.3600	0.6650	0.9250

TABLE II. DESCRIPTIVE STATISTICS: COMPLEX PROBLEMS WITH CPU ONLY AND WITH CPU AND I/O

Group	N	Mean	SE Mean	St Dev	Minimum	Q1	Median	Q3	Max
Control	19	0.0947	0.0355	0.1548	0.0000	0.0000	0.0150	0.1450	0.5950
Simulator	11	0.493	0.118	0.390	-0.100	0.050	0.570	0.870	0.955

When tested on complex problems, the control group had a mean improvement of 9.5 points out of 100 points whereas the simulator group had a mean improvement of 49.3 points, as shown in Fig. 6. When the improvement of the two groups was compared a p-value of 0.004 was calculated using a two-sample t test; with an alpha of 0.05, this means that the null hypothesis was rejected. The alternative, that the simulator group improved more than the control group on complex problems, was accepted. In Fig. 5, the data for the confidence intervals is graphed; the point estimate of the improvement was calculated to be 0.398 or 39.8 points on a 100 point scale. This means that using the simulator helped students learn complex topics at a rate up to 5 times as fast as just using the textbook. It appears that this simulator helps students to apply what they read in the textbook to problems beyond the difficulty of the textbook examples.

Looking at TABLE II and Fig. 7, this data from the complex problems broken down between the problems when the execution of a process consists of a CPU burst only and when the execution of a process consists of alternating CPU bursts and I/O bursts. The data shows the limitations of studying just from a textbook. From the table, the simulator group outperformed the control group on average by 40 points out of 100 on complex problems. Also with the exception of a few outliers, the control group got zero on the complex problems with CPU and I/O bursts which shows a distinction between that group and the simulation group. This implies that the simulation group may have learned to adapt their learning to a variety of situations rather than rote memorizing a specific set of problems.

Fig. 5. The confidence intervals (CI) for the means of the control and the simulator groups in Experiment 2.

Two-sample T Test for Improvement on Complex Problems				
Group	N	Mean	St Dev	SE Mean
Control	19	0.0947	0.1548	0.0355
Simulator	11	0.493	0.390	0.118

V. DISCUSSION

In the past two decades, a number of visualization and animation tools have been developed and used in many areas of computer science education [17]-[20]. While the achievement of learning outcomes as a result of using visualizations and animations has been mixed, there is evidence indicating that carefully designed visualizations and animations can have beneficial learning outcomes. For example, engagement of the learners' attention [21]-[23] and the ability to control the visualization [24] appear to be key factors in building effective visualization and animation tools. Keeping these in mind, the simulator was designed with two operating modes: simulation and practice modes. In either mode, the user has control of the inputs. In simulation mode, the user controls the pace of the simulator such as the speed of simulation. In simulation mode, the user is encouraged to predict which process will be allocated the CPU next and why, and in practice mode, the user is asked to make his own scheduling decisions and receives

immediate feedback. Incorporating these research-based ideas — engagement and control — leads to greater student engagement, which results in deeper mastery of the course objective - understanding CPU scheduling.

Since other existing tools do not provide the level of engagement nor the degree of control like the author's simulator does, learning CPU scheduling algorithms using those tools might not be as effective.

VI. CONCLUSION

As an aid to the study of CPU scheduling algorithms for a single CPU, the author developed an interactive Java-based simulator that demonstrates the concepts of various CPU scheduling algorithms through animation. The author designed the simulator based on knowledge gained from experiences in implementing a couple of CPU schedulers in the BSD kernel and from research-based ideas in building effective animation tools — engagement and control. There are two operating modes for the simulator; the first is simulation mode and the second is practice mode. In simulation mode, the user can watch the simulation straight through from the beginning until the end, or watch it step-by-step. The user can also use this step-by-step function of the simulator to practice and test his understanding of the concepts studied. In this case, the user would predict which process should be allocated CPU next and why before moving to the next step. In practice mode, the user can predict when and for how long each process is in a particular state and why it is in that state through an easy-to-use graphical user interface, and check whether his answer is correct or not with the simulator at any time during practice.

The simulator was used in two sections of an operating systems class at the author's institute. A pretest and posttest were given to two groups of students — the group (control group) that learned CPU scheduling only from the text and the group (simulator group) that learned CPU scheduling from the text and through using the simulator. The pretests and the posttests consisted of basic scheduling problems and complex scheduling problems. The complex scheduling problems involved more than one scheduling algorithm such as Priority Scheduling and Multilevel Feedback Queues. When tested on basic scheduling problems, the simulator group improved a little more than twice as much as the control group. When tested on complex scheduling problems, the simulator group improved approximately 5 times as much as the control group. Therefore, the simulator appears to be effective in aiding students in learning CPU scheduling algorithms. The results also implied that the simulator helps students apply what they read in the textbook to problems beyond the difficulty of the textbook examples.

The current version (version 2) of the simulator will be made available to any interested instructor or student who sends a request by email.

Abstract—Matrices are important tools for many fields, and used in solving systems of linear equation. Technological tools are available to work with matrix operations, but still students avoid using matrices, specially in early stages. Moreover, they limit the use to solving linear equations. Using the field of electrical circuits, this paper introduces the advantage of looking at the systems of equations and solutions from other perspectives, thereby motivating students in the process of mathematical tasks. This approach is illustrated with examples.

I. INTRODUCTION

Application of matrices in solving systems of linear equations, has been in place for long time. Their use date back to the second, perhaps fourth century BC [1]. Applications are present in most scientific and engineering fields. Therefore, matrices are introduced in pre calculus books, for example [2].

But most students avoid matrices, mainly because of the tedious mathematical procedures for solving systems with three or more equations. Many books introduced MATLAB, Mathematica, or other software tools to work those systems. But then, again, fail in motivating students because, first, this requires the student to have tool available, and second the procedures usually focus in only solving the systems of equations.

Concerning availability of the tool, this is no more an excuse. Most graphical calculators have matrix capabilities that equate those of the above mentioned packages. Besides, students also have access to matrix calculations online [3].

But students need more motivation. One way of doing it is by showing applications where the advantage is highlighted not only by the easiness in equations' solving, but on how to set up the equations and see how this allows interpretations that facilitate the learning process, help them in simplifying steps, and so on.

To achieve this goal, it is necessary bring to the attention of students another way of looking at equations and matrix operations, that is, to adopt another perspective. This is precisely the goal of this paper.

No new theoretical results are presented. A previous work mentioned one of the techniques presented here for calculating two-port parameters [4]. This paper further extends the work in other ways. Specifically, by bringing up some properties

that have long been under appreciated in the sense that they are mentioned as mere properties.

I do not claim that the approach is original, since perhaps the reader has already used it, or find it quite obvious. Yet, my teaching experience indicates that it is not obvious for students, and neither for all practitioners. All I can say is that I have not seen elsewhere the approach taken here and used to motivate students. Namely, that of linking the properties with the settings of the equations and with the reading of the numerical results. This was one of the educational motivations behind [5].

This paper uses circuit analysis of resistive networks to illustrate the approach. But the perspective can be generalized to any field where systems of linear equations are used.

As a final remark, it should be emphasized that the author does not pretend to displace or diminish the importance of hand analysis in teaching. In fact, without theoretical fundamentals developed through these skills, the use of matrices becomes more a burden than a help.

II. MATRICES AND LINEAR EQUATIONS

Matrices and systems of linear equations are intimately associated. To simplify discussion and space, three variables are used for convenience in (1) without loss of generality. The system of equations

$$\begin{aligned}a_{11}x_1 + a_{12}x_2 + a_{13}x_3 &= b_1 \\a_{21}x_1 + a_{22}x_2 + a_{23}x_3 &= b_2 \\a_{31}x_1 + a_{32}x_2 + a_{33}x_3 &= b_3\end{aligned}\tag{1}$$

can be expressed in matrix form as

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} = \begin{bmatrix} b_1 \\ b_2 \\ b_3 \end{bmatrix}\tag{2}$$

This form is abbreviated as

$$\mathbf{A} \mathbf{x} = \mathbf{b}\tag{3}$$

. Here the 3x3 matrix \mathbf{A} is the coefficient matrix, and \mathbf{b} the vector of “knowns”.

In abstract form, we denote an $m \times n$ matrix as $\mathbf{A} = [a_{ij}]_{m \times n}$, where a_{ij} is the general notation for the element in i -th row and the j -th column.

Observe that in expression (2), row i of \mathbf{A} shows the coefficients of the variables in the i -th equation, while column j shows the coefficients for variable x_j along the different equations. This remark, as trivial as it may seem, is not usually noticed by students, but is essential for the goals of this paper.

Another important remark, is that $\mathbf{A}\mathbf{x}$ alone, without the equal sign, is the set of linear combinations that constitute the left hand sides of (1)

The solution for (1) is expressed in matrix form as

$$\mathbf{x} = \mathbf{A}^{-1} \mathbf{b} \quad (4)$$

In the vector that results from this operation, row j is the solution for x_j . Another trivial but useful remark to consider later.

Up to this point, this is what is usually done in most basic undergraduate courses when it comes to use matrices. Now, let us exploit elementary matrix theory a little more to take advantage for applications.

A. Matrix operations and properties

Let us bring up known definitions and properties which are useful for our purposes. No demonstration is given.

1) *Multiplication of a scalar and a Matrix:* If b is a scalar, and $\mathbf{A} = [a_{ij}]_{m \times n}$, then the multiplication of the scalar by the matrix is defined as

$$b \mathbf{A} = \mathbf{A} b = [b a_{ij}]_{m \times n} \quad (5)$$

That is, every element in the matrix is multiplied by b .

2) *Multiplication of a Matrix and a vector:* The multiplication of the matrix \mathbf{A} and the column vector \mathbf{x} , which represents a set of linear combinations like that to the left of the equal signs in (1), can be expressed in another form as

$$\mathbf{A}\mathbf{x} = \mathbf{A}^{(1)} x_1 + \mathbf{A}^{(2)} x_2 + \dots + \mathbf{A}^{(n)} x_n \quad (6)$$

where $\mathbf{A}^{(m)}$ is the m -th column of the coefficient matrix \mathbf{A} and x_1, x_2, \dots are the elements of vector \mathbf{x} .

This property further justifies the previous observation that the columns of matrix \mathbf{A} are associated to variables.

3) *Multiplication of Matrices:* Let us express a matrix displaying its column vectors as

$$\mathbf{B} = [\mathbf{B}^{(1)} \quad \mathbf{B}^{(2)} \quad \dots \quad \mathbf{B}^{(n)}]$$

Then the matrix multiplication $\mathbf{A}\mathbf{B}$ may be done as

$$\mathbf{A}\mathbf{B} = [\mathbf{A}\mathbf{B}^{(1)} \quad \mathbf{A}\mathbf{B}^{(2)} \quad \dots \quad \mathbf{A}\mathbf{B}^{(n)}] \quad (7)$$

Combining the information from (6) and (7), it is possible to affirm that in a multiplication such as $\mathbf{A}^{-1}\mathbf{B}\mathbf{x}$ where \mathbf{x} is a vector, the columns of $\mathbf{A}^{-1}\mathbf{B}$ have already information necessary. This will be partial or complete depending on the vector elements.

Again, although the above mathematical results are well known [6], the above comment observing the relationship of columns with elements of a vector is important to read results according to our objectives. That is, the application of these

observations to make matrices attractive and more useful to students for applications.

III. APPLICATION TO A FIELD: LINEAR RESISTIVE CIRCUITS

Linear resistive circuits are used in this section to illustrate the use of the above properties. The approach is applicable to many other fields.

A. Proportionality

Let us start by associating well known properties of linear circuits to the operations. First consider circuits containing only one source, as illustrated in Fig. 1(a).

Fig. 1. a) One source circuit; b) Multiple sources circuit

Denote this source in general as z . It may be a voltage or current source. With the background that students already have from Algebra, it is easy to demonstrate early in a circuit course, that the circuit equations can be written in the form

$$a_{i1} x_1 + a_{i2} x_2 + \dots + a_{in} x_n = b_i z$$

In a very early demonstration, any matrix method used here would make use of sparse matrices, since most of the coefficients a_{ij} and b_i will be zero. This is the so called Tableau Formulation [7], and the variables are element voltages and currents.

The objective of presenting students with such theory at this point is not necessarily having a method of calculation, but to exploit the characteristics explained before, which for all purposes become useful even for analysis methods not involving direct work with equations but with other procedures such as parallel-series reduction. Later, the variables and coefficients will depend on the method used to set up the circuit equations. Variables x_j will depend on the method used, and may be unknown voltages, or currents, unknown node potentials, loop currents and so on.

Combining all equations, and because of (5), we can say that the system can be written in matrix form as $\mathbf{A}\mathbf{x} = \mathbf{b}z$, yielding the solution

$$\mathbf{x} = \mathbf{A}^{-1} \mathbf{b} z \quad (8)$$

As a consequence, we can state the following

Principle of Proportionality: In a linear resistive circuit with one source z , every voltage or current, x_j is of the form $x_j = k_j z$, where coefficient k_j does not depend on the source value z

Although it appears trivial, it is in fact a property that is exploited in textbooks, but without showing the relationship. Let us see how this result can be used.

First, it shows that linear resistive circuits satisfy the homogeneity principle for linear systems, which states the following:

Homogeneity Principle: In a linear system, if $x = f(z)$ then $f(kz) = kf(z)$

Hence, it provides a mathematical proof to a concept that is usually presented in axiomatic form in basic circuit textbooks.

But, there are also practical consequences from the numerical point of view. Let us state three interesting ones for students and practitioners:

Network functions: If the signal source in Fig. 1(a) is identified as an input, z_{in} (voltage or current), and a signal -voltage or current - is identified as an output x_{out} , then x_{out}/z_{in} is a network function. It is a transfer function if both signals are in different elements, and port function if both are in the source, with the relative directions shown in the figure.

These functions receive names such as equivalent resistance (V_s/I_s), equivalent conductance (I_s/V_s) and so on.

The principle of proportionality tells us that if the signal has a value of 1 A or 1 V, then the numerical value of the output is equal to the desired network function. This result provides a purely numerical method to find the function. Compare this result with the traditional teaching: "Insert an arbitrary source and solve for the output. Then divide by the source". Moreover, in the same process we can find *all* functions in just two steps.

Furthermore, if for some reason or other you have already done the calculations, the principle can be applied by directly dividing by the desired input.

Finally, unlike ideas that sometimes students have or are told, the source can be of any type. It is the division what matters!

Working symbolic and time function sources: When the source z is symbolic, that is, has no numerical value, the principle of proportionality states that we can assume a unit value, and simply multiply the result by z . Hence, no need to have symbolic algebra in your tool!

Also, for a source of the type $Kf(t)$, where K is a numerical constant, you make the source equal to K , and multiply the final result by $f(t)$.

Last but not least: From the point of view of calculations, the principle of proportionality means that for solving for one source value allows us to find the currents and voltages for any other source value. Also, changes in source value that are needed to adapt one signal to a specific result can be done without further circuit analysis.

We illustrate the above remarks with an example.

Example Assume that in a circuit with a 30 V source, using the terminology illustrated in Fig. 1(a), $I_s = 2$ mA, $I_k = 5$ mA and $V_j = 4$ V. Then for a symbolic source V_s , we have then $I_s = (2/30) \times 10^{-3}$ Vs, $I_k = (5/30) \times 10^{-3}$ Vs and $V_j = (4/30)$ Vs.

Here, we have divided by 30 to obtain the numerical value for a 1 V source, and then multiplied the symbolic Vs.

We keep further examples for the next section, where these approaches are combined with superposition.

B. Superposition

Now take a circuit with multiple sources, such as the one shown in Fig. 1(b). Again, in an early stage in a basic circuit course it can be shown that any equation of the circuit can be written as

$$a_{i1}x_1 + a_{i2}x_2 + \dots + a_{im}x_m = b_{i1}z_1 + b_{i2}z_2 + \dots + b_{in}z_n$$

All equations can be written then in matrix form as

$$\mathbf{A} \mathbf{x} = \mathbf{B}^{(1)} z_1 + \mathbf{B}^{(2)} z_2 + \dots + \mathbf{B}^{(n)} z_n = \mathbf{B} \mathbf{z} \quad (9)$$

where \mathbf{A} is the coefficient matrix of order $m \times m$, $\mathbf{B}^{(j)}$ is a column vector of order $m \times 1$.

Notice that if all z 's are zero, except z_h , then (9) reduces to

$$\mathbf{A} \mathbf{x}_h = \mathbf{B}^{(h)} z_h \quad (10)$$

which has the same form as (8).

From the practical point of view of numerical calculations, we see that solving (9) we have

$$\mathbf{x} = \mathbf{A}^{-1} \mathbf{B} \mathbf{z} \quad (11)$$

In this expression, $\mathbf{A}^{-1} \mathbf{B}$ has all the information concerning the individual contributions of the sources and thus what we need to obtain the desired results is there. The j -th column shows the contribution of source z_j . Therefore, multiplying by \mathbf{z} becomes a matter of choice in many applications.

If all or part of the sources are numerical, we can incorporate the value into the source. In vector \mathbf{z} , if multiplication becomes necessary, we use the value of 1 for that source. Thus, we can discriminate among the different contributions by simply assigning columns instead of additions in the setting of the equations. On the other hand, for symbolic sources, we use unit values, and for sources of the type $Kf(t)$ we can incorporate K in the column or not, as desired. Examples of application of these principles are given in the next section. For the moment, let us look at some theoretical amenities.

An immediate consequence of (9) is the following result:

Let x_j be a current or a voltage in a linear resistive circuit with sources z_1, z_2, \dots, z_n , then

$$x_j = k_{j1}z_1 + k_{j2}z_2 + \dots + k_{jn}z_n \quad (12)$$

where k_{jh} can be obtained by making all sources except z_h equal to zero.

Again, this becomes a formal proof that these circuits comply with the additivity property of linear systems:

Additivity Principle: In a linear system, if $x = f(z)$ then $f(k_1z_1 + k_2z_2) = k_1f(z_1) + k_2f(z_2)$

This is precisely why these circuits are said to be linear! It also provides a useful property:

Extended proportionality Let x_j be a current or a voltage in a linear resistive circuit with sources z_1, z_2, \dots, z_m , with

$$x_j = x_{j1} + x_{j2} + \dots + x_{jm}$$

where x_{jh} is the value that results when all sources except z_h are off. Then, for the set of values $\{k_1 z_1, k_2 z_2, \dots, k_m z_m\}$ the response will be

$$x_j = k_1 x_{j1} + k_2 x_{j2} + \dots + k_m x_{jm} \quad (13)$$

Let us illustrate this result with an example before proceeding to the next section.

Example A circuit has three sources: $V_1=2$ V, $I_2 = 4$ mA, and $V_3 = 1.8$ V. The response of interest is a current i_o . The following results are known:

- When I_2 and V_3 are turned off, $i_o = 2.8$ mA.
- When V_1 and V_3 are turned off, $i_o = 4.7$ mA.
- When V_1 and I_2 are turned off, $i_o = 6.5$ mA.

How can we express i_o as a function of the sources?

Solution: What we do is to express i_o as the sum of contributions without realizing the addition, normalize for unit input values and then multiply by the corresponding symbolic values:

$$i_o = \frac{2.8 \times 10^{-3}}{2} V_1 + \frac{4.7 \times 10^{-3}}{4 \times 10^{-3}} I_2 + \frac{6.5 \times 10^{-3}}{1.8} V_3$$

That is

$$i_o = 1.4 \times 10^{-3} V_1 + 1.175 I_2 + 3.61 \times 10^{-3} V_3$$

IV. EXAMPLES

The usefulness of proper setting up of equations will show hot interpretation of results are easier and faster. Not only time is saved, but also results are examined to bring up applications.

A. First example

For the circuit of Fig. 2, find the nodal voltages and the power generated by sources using superposition.

Fig. 2. Example using superposition

We can write the matrix equation separating the sources instead of writing one total value, already including the voltage source current I_s .

$$\begin{bmatrix} 1 & \frac{1}{1600} & \frac{1}{32000} \\ 0 & \frac{51}{1600} + \frac{1}{4000} + \frac{1}{12000} & -\frac{1}{4000} \\ 0 & -\frac{1}{4000} - \frac{50}{1600} & \frac{1}{4000} + \frac{1}{2200} + \frac{1}{32000} \end{bmatrix} \begin{bmatrix} I_s \\ V_2 \\ V_3 \end{bmatrix} =$$

$$\begin{bmatrix} \frac{12}{1600} + \frac{12}{32000} & 0 \\ \frac{12 \times 51}{1600} & 0 \\ -\frac{12 \times 50}{1600} + \frac{12}{32000} & 0.004 \end{bmatrix}$$

The solution, found with any matrix handling tool, yields

$$\begin{bmatrix} I_s \\ V_2 \\ V_3 \end{bmatrix} = \begin{bmatrix} 492.1 \times 10^{-6} & -293.9 \times 10^{-6} \\ 11.87 & 63.2 \times 10^{-3} \\ -1.093 & 8.142 \end{bmatrix}$$

From this matrix, we can say that when the current source is turned off, the first column applies to I_s , V_2 and V_3 . Also, when the voltage source is off, the second column applies. We can add both columns to obtain the total $[I_s \ V_2 \ V_3]^T = [198.2 \times 10^{-6} \ 11.93 \ 7.049]^T$. The power generated by the voltage source is $p = (12 \times 198.2) \mu\text{W} = 1.38 \text{ mW}$, and that of the current source is $(4 \text{ mA})(7.049 \text{ V}) = 28.2 \text{ mW}$.

Up to here, the only novelty consists in a faster solution because the sources have been dealt with separating columns for them. Let us look now why the solution tells us much more than that.

To simplify our discussion, let us show three different situations:

- (a) when the current source is 1 A,
- (b) when the voltage source is 1 V, and
- (c) when both sources have unit values.

The three are derived directly using the “extended proportionality” property mentioned before. All we need to do in the previous solution is to divide by 12 the first column in cases (b) and (c), and by .004 the second column for (a) and (c). This exercise is only to show how looking at the matrix results give us interesting information. We have:

$$\begin{bmatrix} I_s \\ V_2 \\ V_3 \end{bmatrix}_A = \begin{bmatrix} 492.1 \times 10^{-6} & -73.48 \times 10^{-3} \\ 11.87 & 1.8 \\ -1.093 & 2035 \end{bmatrix} \quad (14)$$

$$\begin{bmatrix} I_s \\ V_2 \\ V_3 \end{bmatrix}_B = \begin{bmatrix} 41.01 \times 10^{-6} & -293.9 \times 10^{-6} \\ 0.989 & 63.2 \times 10^{-3} \\ -91.09 \times 10^{-3} & 8.142 \end{bmatrix} \quad (15)$$

$$\begin{bmatrix} I_s \\ V_2 \\ V_3 \end{bmatrix}_C = \begin{bmatrix} 41.01 \times 10^{-6} & -73.48 \times 10^{-3} \\ 0.989 & 15.08 \\ -91.09 \times 10^{-3} & 2035 \end{bmatrix} \quad (16)$$

Notice that in fact we do not need to work these matrices for the exercise that follows. It has been done here just for the sake of clarity.

Case A: Since the current source is 1A, we can interpret $V_3 = -1.093 + 2035 I_x$, where I_x could be any value for the current source. The first term corresponds to the case when $I_x = 0$, i. e., an open circuit. Hence, it is the open circuit voltage between node 3 and ground, also known as Thevenin's Voltage. On the other hand, the second term corresponds to the case when the source voltage is 0. Therefore, the resistance seen by the current source is 2.035 kΩ. In conclusion, the row

corresponding to V_3 provides us the Thevenin's voltage and resistance at that port.

Case B: Now the voltage source is 1 V. Following a similar reasoning to Case A, the row for I_s shows the information for the Norton Equivalent seen by the voltage source. The input resistance is $1/41.01 \times 10^{-6} \Omega = 24.34 \text{ k}\Omega$. The Norton, short circuit, current is $293.9 \mu\text{A}$. The change of sign obeys to the direction of I_s .

Case C: Both sources have unit values. Therefore, with a change of name for I_s as I_1 , we can say that

$$\begin{aligned} I_1 &= 41.01 \times 10^{-6} V_1 - 73.48 \times 10^{-3} I_3 \\ V_3 &= -91.09 \times 10^{-3} V_1 + 2035 I_3 \end{aligned}$$

In other words, the inverse hybrid parameters can be read as the submatrix formed with the rows for I_1 and V_3 , with port 1 at node 1 and the other port at node 2.

As it can be seen from these cases A, B, and C, proper setting up of equations results in finding out that there is a lot of information available and easy to read.

B. Second example

Assume that in the circuit of Fig. 3a, the initial voltage $v_C(0) = 2 \text{ V}$. Let us find the transient response of the capacitance voltage and current, the node potentials, and current I_s for $t \leq 0$.

Fig. 3. A transient example using superposition

One traditional way of doing this is by getting the Thevenin Equivalent seen by the capacitor (see Fig. 3b) to find the time constant $\tau = CR_t$. In this circuit, simple analysis introduced in the textbooks yields

$$v_c(t) = V_t + (V_o - V_t)e^{-t/\tau} \quad I_c(t) = \frac{1}{R_t}(V_t - V_o)e^{-t/\tau}$$

for $t \geq 0$.

Usually, from this result, two circuits are then analyzed. However, it is possible to proceed as follows with the information already available.

To obtain the Thevenin equivalent seen by the capacitor, we can substitute this one by a 1 A current source. The topology would be the same as in Fig. 2, and this was done in Case A, where the equivalent circuit was read from the solution (14). Therefore,

$$R_t = 2035\Omega; \quad V_t = -1.093 \text{ V}$$

and

$$\tau = R_t C = 2.034 \text{ ms}; \quad \frac{1}{\tau} = 491.6 \text{ s}^{-1}$$

With this information,

$$v_c(t) = -1.093 + 3.094 e^{-491.6t} \text{ V}$$

and

$$I_c(t) = -1.52 e^{-491.6t} \text{ mA}$$

Now, the substitution theorem [8] states that if the current entering a port from another two-terminal element is known, a current source with the known value may substitute the two-terminal element. In other words, we can go back to Fig. 2 and use for the current source the value $-I_C$, the sign being because of the direction. No need to repeat the analysis. Just take again (14) and multiply the second column by 1.52×10^{-3} , obtaining

$$\begin{bmatrix} I_s \\ V_2 \\ V_3 \end{bmatrix}_A = \begin{bmatrix} 492.1 \times 10^{-6} & -111.7 \times 10^{-6} \\ 11.87 & 24.01 \times 10^{-6} \\ -1.093 & 3.094 \end{bmatrix} \quad (17)$$

This result should be interpreted as

$$\begin{aligned} I_s &= 492.1 - 111.7 e^{-491.6t} \mu\text{A} \\ V_2 &= 11.87 + 24.01 \times 10^{-6} e^{-491.6t} \text{ V} \\ V_3 &= -1.093 + 3.094 e^{-491.6t} \text{ V} \end{aligned}$$

V. CONCLUSION

The purpose of this paper has been to bring up to our attention the convenience of looking at the setting of equations and interpretation of results with a renovated perspective. In particular, two properties were brought to show how applications stem out faster. By doing so, not only are we capable of deriving fast and convenient methods for solving problems where matrices are used, including the interpretation of results, which is what makes an engineer an engineer. We can also motivate students to see matrix applications with renovated interest and better appreciate the tools available.

The field to illustrate the approach was that of linear resistive circuits. Similar procedures can be applied in other fields. Also, other considerations such as transformations, mapping, etc., may be introduced as criteria to approach problems. The important point here is to associate tools with applications in such a way that results have immediate meaning in the branch of interest.

How Many Points Should Be Awarded for Interactive Textbook Reading Assignments?

Abstract—New college engineering textbooks and other online learning materials use activities like interactive questions to engage students and improve learning. Some such materials use a "safe" learning approach where activity solutions are readily available to students, as opposed to being graded like a homework assignment. Instructors have inquired how few course points are sufficient to ensure students complete such assigned activities. Furthermore, some wonder if assigning course points might lead students to "cheat the system" by revealing solutions to quickly earn points, rather than earnestly attempting to answer the questions. We analyzed behavior data of 1,394 students in 8 engineering classes at different colleges. We found that surprisingly few course points—just 5 or 10 points, and as few as 2 points—were sufficient to achieve over 90% average completion of activities by students. For comparison, assigning no points yielded only about 50% completion. Furthermore, we found that assigning points had only a minor impact on students earnestly attempting to answer questions, versus showing themselves the answer first, with earnestness changing only modestly from 92% to 86% when points were assigned.

Keywords—reading assignment; reading earnestness; interactive textbook; course points; homework; cheating the system, online learning.

I. INTRODUCTION

Engineering and other subjects increasingly use interactive textbooks and other online learning material from academic groups [12][14][15] and companies [5][9][19][20]. Interactive textbooks contain activities such as embedded questions that teach and reinforce the subject matter. Instructors commonly require such activities by assigning some homework points for completing the "reading". Reading completion is sometimes required before lectures, leading to more engaged students, and optionally supporting a "flipped" classroom.

We have developed such online learning material for several computer science/engineering subjects, presently used at over 250 colleges. The material emphasizes a "safe" learning environment where question solutions are available to students via a simple button click, where students can attempt questions as many times as desired without penalty, and where showing an answer incurs no penalty.

Given that courses have numerous items for which course points are awarded (exams, labs, projects, quizzes, written homeworks, etc.), a common question from instructors is how

few points are sufficient to cause students to complete the assigned readings. Furthermore, another question is whether assigning points might cause students to just show themselves the answers to quickly earn those points, i.e., to "cheat the system".

Our material includes multiple questions types, including true/false, multiple choice, short answer, and definition matching. Figure 1 shows three short-answer questions, which provide a hint if an incorrect answer is entered, or an explanation if a correct answer is entered. The user can reveal the answer by clicking the "Show answer" button.

Fig. 1. Three short-answer learning questions on integer arithmetic with the question and feedback on the left-hand side, and input field on right-hand side. User entered the correct answer for question 1, an incorrect answer for question 2, and showed the answer for question 3.

#	Question	Your answer
1	13 / 3 ✓ 4 3 divides into 13 four times, yielding 12 with remainder 1 thrown away.	4 Show answer Check
2	4 / 9 ✗ How many times does 9 divide into 4?	 Show answer Check
3	(5 + 10 + 15) * (1 / 3) 0 1 / 3 performs integer division, evaluating to 0. Thus the entire expression evaluates to 0. Correct expression would be (5 + 10 + 15) / 3.	 Answer shown. Show answer Check

Short-answer questions can be used to measure reading earnestness because if a student just shows the answer without first attempting an answer, then the student is clearly not trying. Reading earnestness could also be defined for true-false and multiple-choice questions by comparing the student's correct answer rate to the expected correct answer rate if guessing. However, that approach is prone to more data noise due to some earnest student activity appearing as guessing, whereas short-answer questions have an explicit button. Thus, this study focuses on short-answer questions.

II. BACKGROUND

Reading assignments improve students learning [1][11][16]. For example, in an engineering design course, students who were assigned textbook reading were more sophisticated in their problem solving strategies for a given problem than students not assigned the textbook reading [1]. Though students believe the course textbook is important for learning [4], researchers have found that many students tend to complete assigned readings only while preparing for an exam, whereas completing the reading as scheduled [2][6][7][8]. Such postponement may hamper a student's ability to understand lecture material as presented, and other assignments during the course's progress. The effectiveness and usage of textbooks have been published more for psychology education than engineering education; hence, the reference to some psychology education works. However, textbooks are commonly used and assigned for reading in engineering classes.

Researchers have developed subjective metrics to measure student perspectives of textbooks [3][10][11]. For example, Gurung [11] developed the Textbook Assessment and Usage Scale (TAUS) to measure students' textbook evaluations. TAUS includes over 20 questions that a student answers after having used a textbook. The questions ask about the quality of specific elements (e.g., Figures and Tables) and whether the placement of the specific elements was appropriate and visually appealing. In contrast to the subjective metrics previously developed, this paper introduces an objective metric that measures a student's reading diligence.

Numerous academic groups [12][14][15] and companies [5][9][19][20] are developing interactive textbooks for engineering. Open Learning Initiative offers free courses that come with an interactive textbook that includes multiple choice questions and interactive activities that are recorded [15]. Learning with Python [12] includes a programming environment, practice questions, a code visualization tool, and videos. For Dummies eLearning includes multiple choice quizzes at the end of sections [9]. Zyante's zyBooks include animations, interactive tools, and practice question sets [20]. zyBooks record student activity, and contain a student and instructor dashboard for monitoring activity. Many instructors assign homework points for completing readings according to a particular schedule, to keep the students up to date in the course and have them come to lecture better prepared.

Numerous online homework systems have evolved in recent years, such as MyMathLab (Pearson) [13], WebAssign [17], WebWork [18], etc. Those systems are mainly intended for homework submissions. Solutions are typically not available, or a solution may be viewed but then a new problem is generated. Such systems differ from the online "reading" activities that are growing in popularity and are studied in this paper.

III. PROPOSED METRIC: EARNESTLY-COMPLETED READING

Instructors commonly assign reading assignments with the intention that students will diligently read the assignment. We introduce the metric *earnestly-completed reading* to quantify a student's reading diligence, which is how much of the assigned

reading a student spent time working through, as opposed to skimming through. Earnestly-completed reading is a combination of two metrics:

- *Reading completion* – The percentage of assigned activities that the student completed. For a short-answer question, the question is completed if a correct answer was eventually submitted for that question.
- *Reading earnestness* – Of the completed assigned activities, the percentage of activities that the student earnestly completed. For a short-answer question, the question is earnestly completed if the student attempts the question before eventually possibly showing themselves the answer. An attempt is a submission with more than whitespace. An unearnest completion is when the student shows the answer before attempting.

Earnestly-completed reading is then defined as:

$$\text{earnestlyCompleted} = \text{completion} * \text{earnestness}$$

Figure 2 shows the relationship between the amount of reading assigned, completed, and earnestly-completed. Figure 2(a) is for an assignment worth some points; Figure 2(b) is for an assignment worth no points. Ideally, a student would earnestly complete the entire assigned reading.

Fig. 2. Relationship between the amount of reading assigned, completed, and earnestly-completed for an assignment (a) worth points and (b) not worth points.

IV. PARTICIPANTS

We initially considered 26 classes across 23 universities for potential inclusion into our analysis. We tried to find a group of classes with similar reading assignment structure. We used the following inclusion criteria to mitigate potential confounding factors:

- Used an interactive textbook by zyBooks [20] and required the textbook for the class.
- Used the textbook for reading assignments regularly throughout the term.
- Assigned points proportional to completion, such as completing 50% of the reading earned 50% of the

points, as opposed to a threshold beyond which students receive full credit.

- Used a scheme with a single deadline per assignment, as opposed to awarding more points before lecture than after lecture.
- Contained at least 30 students in the class.

We found 8 classes meeting all the inclusion criteria. The 8 classes were offered in Fall 2014 and contained a total of 1,394 students. Table I shows the number of students per course points awarded. We determined the number of course points by a survey given to the instructors of the classes.

TABLE I. NUMBER OF CLASSES AND STUDENTS ACROSS THE COURSE POINTS AWARDED.

Points awarded	Number of classes	Number of students
0	2	250
2	1	54
2.3	1	437
5	1	380
10	1	69
17	1	90
20	1	114

V. RESULTS AND DISCUSSION

We classified each class by points awarded, such as 0, 2, 5, or 10, including merging 2 and 2.3 points awarded. Then, we compared the categories with respect to reading completion, reading earnestness, and earnestly-completed reading.

For each points awarded, we computed the average reading completion, average reading earnestness, and average reading earnestly-completed, which are defined as follows for each points awarded:

- Students are numbered $1 \dots n$
- C_i : Reading completion by student i
- E_i : Reading earnestness by student i
- Average completion: $\frac{\sum_{i=1}^n C_i}{n}$
- Average earnestness: $\frac{\sum_{i=1}^n E_i}{n}$
- Average earnestly-completed: $\frac{\sum_{i=1}^n (C_i \times E_i)}{n}$

The average earnestly-completed averages the earnestly-completed per student, as opposed to multiplying the average completion by the average earnestness, which would yield a different statistic.

Table II shows the average student reading completion and reading earnestness, and student earnestly-completed reading for a given points awarded.

TABLE II. AVERAGE STUDENT READING COMPLETION, EARNESTNESS, AND EARNESTLY-COMPLETED PER POINTS AWARDED. 5 TO 10 POINTS HAD THE HIGHEST READING EARNESTLY COMPLETED.

Points awarded	Average completion	Average earnestness	Average earnestly-completed
0	53%	92%	50%
2	90%	86%	77%
5	93%	89%	83%
10	94%	95%	89%
17	88%	72%	64%
20	94%	86%	80%

For reading completion, nearly any number of assigned points—as little as 2 course points—seemed sufficient to achieve completion of about 90%. Note that 100% completion is not expected due to some students skipping low-value items like readings, homeworks, or even quizzes, and due to some students who drop the class but remain subscribed to the material. As such, 90% completion is quite high. The conclusion here is that students merely need a small number of points to tip the scales in favor of students taking the time to do the reading activities.

With respect to earnestness, the student earnestness remained quite high, around 86% for classes that awarded some points for reading (versus 92% for classes that awarded no points). This value is also quite high, because not all "Show answer" clicks are due to not trying; some are due to legitimately not knowing how to answer a question. As such, one sees that awarding points seems to have little impact on earnestness.

Of course, such earnestness is dependent on the quality of the questions. We have observed in the past that questions that are confusing or unreasonably hard have low earnestness ratings. Likewise, questions that are viewed by the student as repetitive/drill have lower earnestness. Via earlier analyses, we have eliminated most of both such kinds of questions from our material.

Based on these findings, we recommend assigning between 5 and 10 course points for reading completion. Although 2 points seems to be sufficient, we note that such a small number may be viewed as odd by students. More than 10 points is reasonable but may not be necessary, with such points being reserved perhaps for assessments (written homeworks, quizzes, exams, projects, etc.).

Many factors other than the number of points awarded can affect completion and earnestness. For example, a class that is on a topic for a particular major and taken mostly by students in that major is likely to have higher completion and earnestness; such was the case for the class awarding 10 points, for example. In contrast, a class that is taken mostly by students in a major differing from the class' topic are more likely to be less earnest due to not being as vested into learning the subject matter; such was the case for the class awarding 17

points (a class on programming for non-computing majors). Other factors may include: the instructor explaining the benefits of the reading assignments; the instructor painting the reading material in a positive light such as, “This is modern learning material that’s been shown to really help students learn.”; the amount of workload that the class gives; and the quality of the lectures.

Future work may seek to account for the instructor, such as including many different instructors in each point awarding category. Future work also includes continued data collection and analysis to determine other impacts on completion and earnestness. A similar analysis of student work completion and earnestness may be conducted with massive open online courses, commonly referred to as MOOCs.

VI. CONCLUSION

Interactive learning material is becoming more readily available to instructors as a replacement to a textbook. A common question is how many points should be awarded to insure the students complete the reading assignments. We found that very few points are sufficient to yield high completion rates of about 90%, while earnestness remained high. Based on the analyses, we recommend awarding between 5 and 10 points for reading completion. Awarding fewer points may be viewed as odd by students and awarding more points may not be necessary.

Combining MATLAB[®] Simulation with Telecommunications Instructional Modeling (TIMS[™]) in a Senior Level Communications Course

Dr. Richard J. Hartnett and Dr. Paul B. Crilly
Department of Engineering, Electrical Engineering,
U.S. Coast Guard Academy, New London, CT 06320
richard.j.hartnett@uscga.edu

Abstract— In this work we present some of our successes in combining MATLAB[®]-based simulation methods with Telecommunications Instructional Modeling (Emona-TIMS[™]) experimental methods to enhance student learning in a senior-level communications systems laboratory. While faculty have discussed the relative merits of simulation versus real experimentation in recent years, we find that combining these approaches has multiple advantages: (1) A TIMS[™] based approach (where we have chosen to use “real-world” demodulated audio from local radio stations as the local message signal) makes students feel that they are engaged in “real-world modulation/demodulation;” (2) The TIMS[™] based approach inherently reinforces a “concept map” (block diagram) view of communications modulation and demodulation; (3) The MATLAB[®] simulation approach forces students to think about how to perform a proper simulation (e.g. set appropriate sampling rate, set appropriate specifications for digital filter design for envelope detector or discriminator, etc.) for both analog and digital simulation; and (4) The MATLAB[®] simulation approach sets a starting point for our students as they pursue software defined radio (SDR) communications applications in some of their senior design projects. We find synergy in combining the two pedagogical approaches in most of the labs in our communications systems course, and this typically results in enhanced student comprehension.

While more formal assessment will be conducted over the next two years, at this point we know from course feedback that students very much appreciate both learning tools. Students commonly remark that the TIMS[™] really highlights the “big picture,” and helps them understand what to expect before they start the MATLAB[®] simulations, while coding up the MATLAB[®] simulations gets them “into the weeds,” and gives them the tools to test out ideas that support their senior projects.

Keywords—electrical engineering education, communication engineering education, student experiments

I. INTRODUCTION

As faculty who teach undergraduate courses in the Electrical Engineering major, we routinely search for ways to enhance student learning and excitement for the subject matter. Sometimes students appreciate seeing simulations, while other times they appreciate experimentation, and the debate continues as to the appropriate mix in undergraduate education [1], [2].

Some researchers have commented [3] that a TIMS[™] based experimentation approach (in a very similar course as ours) garnered high marks for student satisfaction, and students acquired more skill and confidence in experimental methods. Our experiences are consistent with these observations. In our work, however, we suggest that a mix of simulation and experimentation has multiple advantages, and we take this approach in our senior-level undergraduate electrical engineering course called Communication Systems.

We see that an “experimental” TIMS[™] based approach [3] makes students feel that they are engaged in “real-world modulation and demodulation.” Furthermore, the very nature of the TIMS[™] based approach (where every TIMS[™] module has a specific function) [4] is a self-reinforcing “concept map” or block diagram view of the entire modulation/demodulation process.

We also see value in having our students do MATLAB[®] simulations, because such (digital) simulations force students to grapple with the details of setting up a proper simulation (e.g. setting appropriate sampling rate, using reasonable vector lengths for use in an FFT, design of an appropriate digital filter for use as a frequency discriminator, etc.) Since many of these same students are also learning about software defined radio (SDR) concepts for use in their senior projects, we see merit in our students understanding how to perform MATLAB[®] and Simulink[®] simulations.

We find synergy in combining the two pedagogical approaches in most of the labs in our communications systems course, and our experience suggests this results in enhanced student comprehension. Typical student comments are that the TIMS[™] experiments help to reinforce the concept maps for modulation/demodulation, and MATLAB[®] simulations force students to learn how to do proper simulations, while forcing them to recall information from previous courses.

Preliminary assessment suggests that students gain considerable insight from both the MATLAB[®] simulations and TIMS[™] experiments, however more formal assessment needs to be garnered over the next two years.

II. OVERVIEW OF OUR EQUIPMENT SUITE FOR COMMUNICATION SYSTEMS LAB

The primary equipment suite used for our Communication Systems labs is shown in Figure 1. Equipment listed from top to bottom include: EMONA TIMS-301, Agilent DSO 6034A Digitizing Oscilloscope, Agilent 89410A Vector Signal Analyzer, Agilent 33220A Function Generator, Rolls 35 Watt Stereo Power Amplifier, an AM/FM tuner, and stereo speakers. The general strategy for our labs is that students use low frequency sinusoidal and digital signals from the EMONA TIMS-301, and relatively narrow-band audio signals (demodulated audio) from the AM/FM tuner output, as message signals, as they study various modulation and demodulation methods in each lab. Labs using our primary equipment suite include Review of Fourier Series, Amplitude Modulation and Demodulation, Frequency Modulation and Demodulation, Pulse Code Modulation, and AM Single Sideband Modulation and Demodulation. Here we will focus on three labs: Amplitude Modulation/Demodulation, Frequency Modulation/Demodulation, and AM Single Sideband Modulation/Demodulation.

Fig. 1. Communication Systems laboratory primary equipment suite

In addition to the primary equipment suite, students have access to Windows 7.0 work stations where they are able to transfer data from the Agilent 89410A Vector Signal Analyzer to MATLAB[®] for later analyses. Students also have access to laboratory computers in order to perform the MATLAB[®] coding portion of each laboratory.

III. AMPLITUDE MODULATION (AM) AND DEMODULATION

This lab consists of several parts: (1) A MATLAB[®] study of AM generation, (2) a MATLAB[®] study of envelope detection, (3) a MATLAB[®] study of I & Q demodulation, (4) a TIMS[™] study of AM DSB-LC (large carrier), (5) a TIMS[™] study of AM DSB-SC (suppressed carrier), and (6) a TIMS[™] study of demodulation using product detection methods.

A. Studying AM using MATLAB[®]

Students are asked to write a short MATLAB[®] M-file which generates an AM (DSB-LC and DSB-SC) signal, with carrier frequency of 3kHz, a sinusoidal modulating frequency of 100Hz, a modulation index of 0.2 (for DSB-LC), and a sampling frequency of 50kHz. After successfully generating this signal and viewing it in both the time and frequency domains, they learn how their plots change as a function of modulation index and modulating frequency. They are also asked to consider why the sampling rate was chosen to be that value for purposes of simulation.

Students then use MATLAB[®] to demodulate the signals (using I&Q demodulation and envelope detection for the DSB-LC, and product detection for the DSB-SC.) They perform graphical comparisons of the original message and demodulated waveform, and draw conclusions based on their observations. Student feedback tells us that the MATLAB[®] simulations teach them a lot about how one can write code to perform simulations and test ideas.

B. Studying AM Using TIMS[™]

Students then use TIMS[™] to generate AM DSB-SC, using the audio oscillator as a (low frequency) sinusoidal message signal, and a 100kHz carrier. They use an analog multiplier on the TIMS[™] to generate the AM signal, and they view the DSB-SC signal at a center frequency of 100kHz in the frequency domain. They vary the amplitude and frequency of the low frequency sinusoidal message signal, and observe the effects in both time and frequency domains. At this point we have the students switch the message signal, from the low frequency sinusoidal message, to the (demodulated) audio signal coming out of the FM tuner, and they observe the DSB-SC signal in both the time and frequency domains.

Finally, we have the students demodulate that signal, by routing the DSB-SC signal to a “multiplier” module (which performs the function of a product detector), and then to a low pass filter module. The “multiplier module” multiplies the DSB-SC signal by a (variable) phase shifted carrier on the TIMS[™], and students learn about the importance of aligning the phase of the carrier and the local oscillator during product demodulation. The output of the “multiplier module” is sent through a low pass filter on the TIMS[™], and the output of the low pass filter is routed to the audio amplifier and speakers, so students are able to listen to their demodulated audio, while observing all signals in the time and frequency domains.

At this point, students begin adjusting the low pass filter bandwidth and gain, and begin shifting the phase of the local oscillator. Student feedback suggests that they very much appreciate the full sensory immersive experience of the

TIMSTM portion of this lab, as it helps them to remember important concepts.

IV. FREQUENCY MODULATION (FM) AND DEMODULATION

This lab consists of several parts: (1) A study of FM using the Agilent DSO 6034A Digitizing Oscilloscope, Agilent 89410A Vector Signal Analyzer, and the Agilent 33220A Function Generator, (2) a MATLAB[®] investigation of FM demodulation from I & Q data, (3) a MATLAB[®] generation of FM and demodulation via a frequency discriminator, and (4) a TIMSTM investigation of FM modulation and demodulation using Phase-Locked Loop (PLL) demodulation and frequency discriminator demodulation methods. Here we will focus on parts (2)-(4).

A. Studying FM using MATLAB[®]

After students study FM signals in both time and frequency domains using a signal generator, oscilloscope, and dynamic signal analyzer, they learn about three methods for FM demodulation: (1) Demodulation from base band In-Phase and Quadrature (I&Q) data, (2) Demodulation using a phase-locked loop (PLL), and (3) Demodulation using frequency discriminator techniques.

For FM demodulation from I&Q data, we ask students to turn to MATLAB[®] for additional insight. We provide them a MATLAB[®] data file (.mat file) that is a “baseband” I&Q signal (commonly referred to as a “complex envelope” for the FM signal), sampled at 25kHz, and we ask them to demodulate and play the resulting audio file.

As we present in class, if one is presented with “base band” in-phase (I) and quadrature (Q) data, a classic way to perform FM demodulation is to perform operations on the vector $I+jQ$. We tell our students since FM is a form of “angle modulation,” it seems logical to examine the angle of the vector $I+jQ$ in order to begin demodulation. We ask students to develop a simple function in MATLAB[®] which will perform the desired demodulation. Recognizing the “angle” function provides a return argument from $-\pi$ to π , we ask them to consider “unwrapping” the angle of the $I+jQ$ vector to avoid discontinuities. Finally, we remind them that they are not interested specifically in the “angle” of $I+jQ$ (in radians), but more interested in changes in that angle as a function of time (instantaneous frequency – radians/sec). After some thought (and considerable coaching), they come up with a single line of code that accomplishes the desired demodulations: $y = \text{diff}(\text{unwrap}(\text{angle}(S)))$, where S represents the baseband $I+jQ$ vector. At that point they use the MATLAB[®] commands “sound” or “audioplayer” to listen to the message, and they usually take some time to think about why that methodology worked so well! Student feedback on this part of the lab is tremendous.

In addition, we have our students generate an FM signal with carrier frequency 5kHz, modulating frequency 100Hz, a modulation index of 1.0, with sampling frequency 22050Hz. That signal is then used as the FM signal input to a frequency discriminator (that they must design!), and the simulation is accomplished completely in MATLAB[®]. This portion of the lab requires that they remember something about digital filter

design (studied in earlier courses), and it requires that they design the filter such that the frequency of interest is in the center of the transition band of the filter they design. Students were less than enthusiastic in their feedback for this part of the lab!

B. Studying FM using TIMSTM

For this module, students use the Voltage Controlled Oscillator (VCO) module on TIMSTM to generate an FM signal at a 100kHz center frequency. Both the center frequency and the frequency deviation (VCO “gain”) can be adjusted on the VCO card. The “message input” to the VCO is taken from the demodulated audio from the FM tuner at the bottom of the equipment suite (from Figure 1), and we have the students generate a relatively narrow band FM signal (small modulation index). After students view the FM signal in both the time and frequency domains, we give them the assignment: demodulate that signal by building a Phase-Locked Loop (PLL) detector, and play the demodulated audio through the stereo amplifier and speakers.

At this point, students are initially confused, and I refer them to a standard block diagram for a PLL detector (Figure 2). We tell them that each block of the PLL diagram consists of one or two modules from the set of TIMSTM modules, and they then begin to build their PLL. We explain that the phase detector is implemented as a multiplier cascaded with a low pass filter, and the input to the PLL is the FM signal they just created.

Fig. 2. Basic block diagram of phase-locked loop (PLL) for FM demodulation.

To assist them in getting a working PLL, we advise them to follow these steps: (1) Make sure the VCO in the feedback path of the PLL is set to the same frequency as the center frequency of the incoming signal, (2) set the “gain” of the VCO in the PLL feedback path at roughly the same “gain” as the VCO that is generating the FM (relatively low), (3) make the low pass filter relatively wide in the feed-forward path of the PLL, and (4) lower the gain of the gain block in the feed forward path. At this point we explain to students that the input to the VCO block is the demodulated audio of interest, and we are interested in listening to that signal.

By slowly adjusting the VCO gain and the bandwidth of the low pass filter, students are usually able to get their PLL’s working perfectly within 15-20 minutes, and they feel such a sense of accomplishment when they can hear the demodulated audio output. Furthermore, they are always amazed to hear how perfect the demodulated audio sounds. At this point we have a “teachable moment,” and we ask our students to make the PLL “break lock” by (1) reducing the VCO gain or low

pass filter gain, (2) reducing the bandwidth of the low pass filter, or (3) changing the frequency of the VCO in the feedback path. By the end of the lab, students have obtained considerable insight into the workings of a PLL, and it is at that point we draw parallels for them between concepts they have seen in Computer Controls class (e.g. P, PD, PID controllers) and PLL demodulation. Feedback on this part of the lab is overwhelmingly positive, and students remark that they gained tremendous insight into PLL theory and operations from this lab experience. Assessment data taken from their FM lab reports and hourly exams also suggest that students have a more solid understanding of PLL concepts.

Finally, students disconnect their PLL TIMSTM configurations, and reconfigure the VCO that generates the original FM signal to a center frequency of 70kHz. Students then use the 60kHz low pass filter module from TIMSTM to implement a “frequency discriminator.” Since the center frequency of the FM signal now lies in the transition band of their low pass filter, they are generating a signal that varies in amplitude and frequency. By passing this signal to the “utilities module” (which has an envelope detector), students learn that they have performed FM detection by performing envelope detection on an “AM-like” signal. Again, they listen to the demodulated audio output, and again they are impressed at the audio quality.

V. AM SINGLE SIDEBAND GENERATION AND DEMODULATION

This lab consists of two parts: (1) A MATLAB[®] study of single sideband (SSB) amplitude modulation and demodulation, and (2) a TIMSTM investigation of single sideband amplitude modulation and demodulation.

A. Studying AM-SSB using MATLAB[®]

During the AM lab, students wrote MATLAB[®] code to generate an AM DSB-SC signal with a carrier frequency of 3kHz, and a sinusoidal message signal of 100Hz. Here they modify their code to produce the AM-SSB signal, either upper (“-”) or lower (“+”) side band, by using the equation

$$s(t) = A_c [m(t)\cos(\omega_c t) \mp \hat{m}(t)\sin(\omega_c t)] \quad (1)$$

where A_c is a scaling factor, $m(t)$ is the message, and $\hat{m}(t)$ is defined as the Hilbert transform of the message. Students write their own “Hilbert transformer” by using the “fft” function, multiplying positive frequency components by “-j” and negative frequency components by “j”, and then inverse transforming the result by calling the “ifft” routine. Using a sinusoidal signal for $m(t)$, students see that they can elect to generate either the upper or lower sideband signal by changing the sign on $\hat{m}(t)$ from equation (1). Students also see that they can multiply the SSB signal by a (coherent) carrier signal, low pass filter, and retrieve the original sinusoidal message.

B. Studying AM-SSB using TIMSTM

Using the TIMSTM modules (specifically the 100kHz sine/cosine waveform generators, the audio signal generator, and the quadrature phase shifter module), students generate an

AM-SSB (lower) signal at 100kHz using the Hilbert transform or “phasing method” discussed in class. Using the audio signal generator as the $m(t)$ initially, students view the SSB signal in both the time and frequency domains. After students are convinced that their phasing method is working, they use the audio signal from the FM tuner in the primary equipment suite, and view the results in both the time and frequency domains. At this point, students are impressed that this “phasing method” works so well in completely eliminating one of the sidebands. They finish the lab by using a product detector (with oscillator that is coherent with the carrier) in order to demodulate the AM-SSB signal. They route the signal output to the amplifier and speakers, and enjoy the resulting music.

Feedback from this portion of the lab suggests that our students appreciated both the MATLAB[®] and TIMSTM sections of the lab, and assessment results from lab submissions and exams suggests to us that student comprehension of AM-SSB concepts has improved over the last several years.

VI. CONCLUSIONS

We presented some of the ways we have combined MATLAB[®] based simulation with Telecommunications Instructional Modeling (Emona-TIMSTM) experimental methods to enhance student learning in a senior-level communications systems laboratory at the U.S. Coast Guard Academy. While relative merits of simulation versus experimentation have been debated over the years, our experience suggests that students very much appreciate that the TIMSTM based approach inherently reinforces a “concept map” (block diagram) view of communications modulation and demodulation. Furthermore, they also see value in doing MATLAB[®] simulation, because they see it as a first step towards testing senior project research ideas, and they see value in learning how to perform a proper simulation. Although we are in the early stages of assessment, we do see advantages in combining these two pedagogical approaches, based on student feedback and improved student comprehension.

MORE THAN JUST RIGHT OR WRONG:

USING CONCEPT QUESTIONS TO DISCERN STUDENTS' THINKING IN MECHANICS

Jeffrey L. Newcomer
Engineering & Design Department
Western Washington University
Bellingham, WA
jeff.newcomer@wwu.edu

Abstract—This paper outlines five concept questions from Statics and Mechanics of Materials from which instructors can easily learn about student thinking when the students select incorrect answers. These questions represent vertical transfer assessment tools and show the potential of using such questions. They can be used as part of a pre-test or in some other manner such as a warm-up exercise. The questions discussed here all show good correlation between students' answer selections and the misconceptions or specific difficulties that they are exhibiting with the concept covered in the question. Simply by assessing the answer distributions instructors can easily learn enough about student thinking to tailor instruction and classroom activities.

Keywords—concept questions; concept inventory; pre-test; warm-up exercise

I. INTRODUCTION

Concept questions have become a staple of assessing students' understanding of engineering fundamentals. Well-established concept inventories for Force, Statics, Dynamics, and other areas provide means to assess students' learning gains and understanding at the end of a class, and are often used to establish students' baseline understanding at the beginning of a class [1]-[4]. While there is no denying the value of using concept questions or concept inventories for summative assessment, there are also many opportunities to use concept questions for formative assessment that frequently go by the wayside. Concept questions with well-written distractors can have a strong correlation between students' specific difficulties and/or misconceptions and their incorrect answer selections [5]-[9]. Studying patterns in answer choices for select questions can give instructors insight into students' patterns of thinking while there is still time to address those students' specific difficulties in the class.

To determine patterns of student thinking in their selection of incorrect answers on concept questions, it is necessary to have students explain their answer choices in order to establish if correlations exist between students' reported thinking in selecting a specific answer and what those correlations are. Once correlations between student thinking and answer selection are established, an instructor can gain insight into the thinking of individual students or groups of students simply by studying the distribution of the answers to the question. This

technique can be very valuable when students answer concept questions or take concept inventories as pre-tests, and also when concept questions are used as warm-up exercises [10]. Warm-up exercises are a good complement or alternative to pre-tests, especially in cases such as with the Concept Assessment Tool for Statics (CATS, formerly known as the Statics Concept Inventory or SCI) where overall pre-test results on CATS correspond to random guessing and CATS includes symbols and terms that are not familiar to students at the beginning of a Statics class. In the case of CATS, the Force Concept Inventory (FCI) is recommended as a pre-test [6],[11]. Therefore, rather than give a pre-test that has dubious overall value as a measure of incoming student preparation, purposefully chosen concept questions may be given as warm-up exercises instead, and the same valuable information about students' thinking can be obtained.

This paper outlines four examples of Statics concept questions and an example of a Mechanics of Materials concept question for which studying students' explanations to their answers to concept questions has been used establish strong correlations between students' answer selections and the thinking that led them to that answer choice. The paper will also give examples where distractors do not strongly correlate with a particular line of thinking, and an example of how a small adjustment to a distractor was able to solve that problem and improve correlation between students' answer selection and their lines of thinking. In Statics classes the patterns of student answers to concept questions given as warm-up exercises was used to focus class discussions and exercises to address the specific difficulties that students' displayed through their answer selections [12]. The results of this approach were improved student conceptual understanding of the course material, which was established through the inclusion of concept questions on the final exam for the class and through the use of the CATS as a post-test. While there is still plenty of room for improvement, students in these classes scored well above national averages on concept questions involving equilibrium and equivalence with this approach [13]-[14].

II. TRANSFER, MISCONCEPTIONS, AND SPECIFIC DIFFICULTIES

Transfer is the term commonly used to describe a student's ability to apply knowledge gained in one context in a different

context. Fundamentally when students are asked to take a pre-test for a class, the instructor is trying to assess what Bransford and Schwartz refer to as students' "preparation for future learning" [15]-[16]. This concept from the modern transfer literature is one that acknowledges that novices might not initially be able to apply their knowledge from one setting in another, but if they are prepared to learn how to apply that knowledge in the new setting, they are well enough prepared to eventually succeed in the new setting. Relative to the traditional model of transfer, this is focusing on the student's perspective of the transfer, or actor-oriented transfer, rather than the expert's perspective [17]-[19]. This idea of actor-oriented transfer was further refined by Rebello et al. to differentiate between situations where a pre-existing knowledge structure can be applied, which they dubbed as horizontal transfer, and situations where the mental model must be created rather than referenced, which they dubbed as vertical transfer [20]-[22]. So giving students the FCI as a pre-test in a Statics class is an example of trying to assess their horizontal transfer ability from Physics, while giving students CATS as a pre-test is an example of trying to assess their vertical transfer ability. Using a pre-test to assess students' horizontal transfer ability is more likely to give an instructor a clear picture of students' level of preparation from a pre-requisite class, but less likely to give a clear picture of the specific difficulties and misconceptions the students have about the material in the new class than trying to assess their vertical transfer ability. While the aggregate score on a pre-test for horizontal transfer may provide more accurate information for comparative learning gains from the beginning of a class to the end of it, there is much to be learned from assessing students' answers to vertical transfer assessments in terms of being able to tailor class activities and assignments to address students' misconceptions and the specific difficulties that they exhibit. This dichotomy that exists between using pre-tests to try to assess students horizontal or vertical transfer ability is why alternate approaches such as using warm-up exercises to supplement pre-tests may be the best solution to uncovering students' misconceptions and the specific difficulties that they exhibit.

Misconceptions and specific difficulties are different types of problems students may have or exhibit when attempting to master new material or transfer concepts from one context to another. The term 'misconception' is commonly used in engineering education to describe an incorrect understanding that must be unseated and replaced with a correct understanding, but there is an alternative theory in Physics Education Research that student difficulties are influenced by context if not outright context dependent [23]-[28]. In this view students' incoming understanding is made up of bits of loosely connected knowledge referred to as phenomenological primitives (p-prims) [23]-[27] or facets of thinking [28]. These p-prims, or knowledge elements, are triggered by context; while they may individually be correct in some circumstances, they may be applied in the wrong circumstances or combined improperly to form incorrect conclusions. According to this view, students do not need to have misconceptions unseated; instead they must learn which elements are correct in which contexts. These elements provide building blocks for reaching the desired mode of thinking. In this terminology, instead of misconceptions, students exhibit "specific difficulties" [29] –

some more commonly than others. In order to design effective instructional material and techniques, one should take students' specific difficulties into account [30]-[31].

Misconceptions and specific difficulties are not mutually exclusive models, and they are both things that an individual student may exhibit. For example, a student assessing equivalence in a Statics class may enter the class with the misconception that an equivalent rotational system must maintain a center of rotation rather than moment equilibrium, and use that criteria to try to identify equivalent systems. The same student may also exhibit the specific difficulty of only assessing moment equilibrium in a static system when cued to do so. This may not be an indication that the student has the misconception that force equilibrium satisfies all equilibrium conditions, but that he or she has not developed a complete enough mental model to consistently assess moment equilibrium without a cue, although then he or she might only assess moment equilibrium when given that cue. It is common for students at the end of Physics, at the beginning of Statics, and, more common than one would like, at the end of Statics to conflate force and moment equilibrium, but without more information about those students' approaches and/or answer selections to equilibrium questions it may not be possible to determine if a student has a misconception or is exhibiting a specific difficulty that is linked to context or an incomplete mental model [7]-[8], [32]-[33]. Examining students' answers, and sometimes their explanations, to conceptual questions designed to assess students' vertical transfer ability can provide instructors with insight that will allow them to address the issues elucidated by those questions through class activities and assignments.

III. EXAMPLES OF INFORMATIVE CONCEPT QUESTIONS

Concept questions with well-posed distractors can tell an instructor quite a bit about students' approach to and thinking about a problem when the students' answers are incorrect. This section describes four concept questions that have been used in Statics and one that has been used in Mechanics of Materials to allow an instructor to discern and address students' incorrect thinking on the underlying topics. In all of these examples, students were initially asked to explain their thinking, which allowed the patterns of thinking to be correlated with the answers. Once the correlations have been established, the student explanations are no necessary, although requiring explanations does seem to engage the students in the problems a bit more. It should be noted, however, that it is common for students' explanations to not match their answer selections in up to 10% of responses, so this information is generally much more reliable for determining common patterns of misconceptions or specific difficulties in a group of students than the exact misconceptions or specific difficulties of an individual student [13].

The first three examples discussed below are from CATS and cover equivalence, free body diagrams, and equilibrium respectively. The fourth example is a matched pair of rigid body motion questions that were developed to see if students' ability to describe dynamic motion could be used as a measure of their preparation for learning Statics. The fifth and last example was developed for Mechanics of Materials to see how well students could apply stress and strain concepts from a pre-

requisite Introduction to Materials Science and Engineering course to rank order stress and deflection in simply supported beams with the same cross-sectional area, but with the beam's material distributed differently. All of these are examples of questions that can quickly give instructors reliable information regarding student thinking. Not all concept questions give such clear and consistent results as these examples, although sometimes only a small modification is required to improve the correlation between a distractor and the errors in thinking that students are exhibiting by selecting those answers.

A. Static Equivalence

Static equivalence is a concept for which students commonly exhibit one of the following errors: a) they assume that to maintain equilibrium the value of an applied couple must change if it is applied at a different location; b) they use a force to balance a change in the magnitude of a couple, but ignore force equilibrium; or c) they assume that there is a 'center of rotation' that must be maintained. Figure 1 shows a concept question from CATS that includes distractors that correlate well with students' explanations of those errors [7].

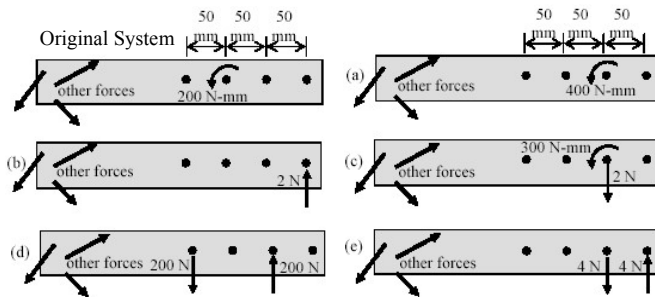

Fig. 1. Static Equivalence concept question from CATS

In this question students are asked to select the system that will maintain equilibrium for the original system (upper left image) with the 'other forces' shown on the left side of the bar when the 200 N-mm couple is replaced. The correct answer is (e), but at the start of statics students most commonly pick (d), the answer that maintains the presumed center of rotation. This misconception was also documented independently in the work of Brose and Kautz [9]. Students also frequently select (a), which changes the magnitude of the applied couple when its location changes, and (b), which maintains moment equilibrium, but ignores force equilibrium.

When studied in some detail in [7], this question showed good correlation with students' erroneous thinking and answer selection. 146 student explanations were coded for four different student errors: 1) assessing moment equilibrium without assessing force equilibrium, 2) stating that only couples can balance couples, 3) stating that the magnitude of a couple must change if it is moved, and 4) specifying a center of rotation. Of the 146 responses, 18 were too ambiguous to code for errors. For the remaining 128 responses that were coded: 26 of 31 (84%) students who answered (a) displayed error (3) and 11 of 31 (36%) displayed error (2), 28 of 28 (100%) students who answered (b) displayed error (1), and 39 of 46 (85%) students who answered (d) displayed error (4). 17 of 18 (94%) students of students who answered (e) gave a correct explanation.

Whether the issue is a misconception, such as maintaining a mythical center of rotation, or a specific difficulty, such as forgetting to assess force equilibrium, this question is a good example of a question that gives an instructor reliable information about student errors simply by knowing which answers students' selected. The information can be easily obtained whether the question is used as a warm-up question, as it was for the study in [7], or whether the information is pulled from pre-test responses if CATS is used as a pre-test. Once the answer distribution for a specific group of students is known, an instructor can use the information to tune class activities and assignments to address the conceptual errors and specific difficulties that are commonly exhibited in the class.

B. Free Body Diagrams

The static equivalence question outlined above is a good example of a relatively clean question for which students commonly exhibit a single error. In other cases, students may exhibit multiple specific difficulties or misconceptions, so to be effective, the question(s) used to assess that likelihood needs to be able to differentiate between two errors, but also allow for a student to exhibit both of them. Free body diagrams are an example of this. Two very common specific difficulties that students exhibit at the start of Statics are including internal forces and including indirectly applied forces explicitly. Figure 2 shows a concept question from CATS that includes one distractor for each of those errors individually, and one for those two errors combined [5],[7].

Fig. 2. Free Body Diagram concept question from CATS

In this question students are asked to isolate blocks 2 and 3 and the cord, D, that connects them. Answer (d) is correct. Answers (a) and (c) both include the error of inclusion of the internal force, and answers (a) and (b) both include the error of explicit inclusion of indirectly applied forces. This question is a good example of how a small modification can have a big impact on the information that can be gleaned from students' answer selections. The early version of this problem had a different distractor for (a) that contained a specific difficulty that almost no students exhibited [5]. At that time the students who selected (b) or (c) sometimes commented that none of the answers were correct, because they had to choose between including the force in cord D or the weight of block 4. When the distractor for (a) was changed to include both specific difficulties, it gave those students who exhibited both a way to do so on this problem, and it gave the instructor that information. Table I shows the change in answer distribution from the original answers to the answers shown in Figure 2.

TABLE I. COMPARISON OF ORIGINAL AND NEW ANSWERS

Answer	n	a	b	c	d	e
Original	35	0.0%	11.4%	54.3%	31.4%	2.9%
Modified	129	20.9%	4.7%	58.9%	13.2%	2.3%

Once modified, this question showed very good correlation between students' answer selection and their explanations [7]. The 129 responses shown in Table I were coded for two errors: 1) A force is 'missing' from the other choices, and 2) cord tension is equal to the weight of the object hanging directly off of it. In the 129 responses, 13 were too ambiguous to code. For the remaining 116 responses that were coded: 22 of 25 (88%) students who answered (a) displayed both errors (1) and (2), 6 of 6 (100%) students who answered (b) displayed error (2), and 65 of 66 (98.5%) students who answered (c) displayed error (1). 16 of 17 (94%) students who answered (d) gave a correct explanation. It is interesting that 22 of 30 (73%) of students who answered (a), (b), or (c) and displayed error (2) also displayed error (1), while only 22 of 89 (25%) who displayed error (1) also displayed error (2).

C. Equilibrium

The free body diagram question outlined above is a good example of where a question can be easily modified to provide instructors more specific information on student thinking. In other cases it is not possible to clearly discern all common student errors from a single concept question. Equilibrium assessment is an example of where this sort of thing can occur. There are five types of specific difficulties that students commonly exhibit when analyzing equilibrium: a) assess force or moment equilibrium, but never both, and only the latter when something in the questions cues that analysis; b) assess force and moment equilibrium as separate events that do not need to occur simultaneously; c) assume that a couple also contains an unbalanced linear force; d) always assess only force equilibrium; and e) always assess only moment equilibrium [5],[7]-[8],[33]. Figure 3 shows a concept question from CATS that includes one distractor each for specific difficulties (d) and (e), but with a distractor that conflates specific difficulties (a), (b), and (c).

Fig. 3. Equilibrium concept question from CATS

In this question students are asked, given the directions of the loads indicated, whether one, both, or neither of these bodies can be in equilibrium. The correct answer is that neither body I nor body II can be in equilibrium, and students who say so are almost always consistently assessing both force and moment equilibrium. Students who answer that body I can be in equilibrium but that body II cannot are almost always assessing only moment equilibrium, but not force equilibrium. Correspondingly, students who answer that body II can be in equilibrium but that body I cannot are almost always assessing only force equilibrium, but not moment equilibrium [7]-[8],[10],[33].

The largest study of this problem, [33], examined 289 student explanations to the problem from final exams at three different universities. There were 83 students (29%) who answered correctly, 82 of whom had answers that could be coded. Of those students, 94% correctly assessed force equilibrium and 90% correctly assessed moment equilibrium. There were 58 students (20%) who selected the answer biased towards moment equilibrium, 55 of whom had answers that could be coded. Of those students, 96% correctly assessed moment equilibrium, while 76% of them did not address force equilibrium at all, and another 7% only addressed force equilibrium on body II. There were 93 students (32%) who selected the answer biased toward force equilibrium, all of whom had answers that could be coded. Of those students, 96% correctly assessed force equilibrium, while 59% did not address moment equilibrium at all, and another 24% only addressed moment equilibrium on body I. The remaining 57 students (19%), of whom 55 had answers that could be coded, said that both bodies could be in equilibrium. Of those students, 56% addressed force equilibrium only on body I and 65% address moment equilibrium only on body II, so that at most 56% clearly displayed specific difficulty (a), while the remainder displayed specific difficulties (b), (c), or a combination.

The challenge is when students say that both bodies I and II can be in equilibrium they can reach that conclusion in multiple ways. One way for a student to reach this conclusion is to only assess moment equilibrium for body I, cued by the inclusion of the applied couple in the loading, and to only assess force equilibrium on body II, not cued to assess moment equilibrium due to the lack of an applied couple. Another way is for the student to assess force and moment equilibrium as separate, decoupled events. For example, for body II a student may say something to the effect that the forces as shown can satisfy force equilibrium, and then if the horizontal and vertical components of the force on the top right corner can be adjusted then the forces can also satisfy moment equilibrium. A similar

though reversed argument can be made using the force on the top left corner of body I. Finally, for body I a student may also indicate that the applied couple also contains an unbalanced force. In support of the argument that symbols like couples are inappropriate for pre-tests, this approach appears much more often at the start of a Statics class than at the end of it [7]-[8]. With that duly noted, however, the main point here is that all three of these, sometimes the second and third simultaneously, get captured by the same distractor, and there is not a simple way to parse out what the students' specific thinking is without getting more information. Given that at the start of Statics that almost as many students say both bodies can be in equilibrium as all of the other answers combined, this question is much more effective at letting an instructor know the rough fraction of students who struggle to assess equilibrium consistently, than the exact part of equilibrium with which they are struggling, which makes it a much better pre-test or early warm-up question for Mechanics of Materials than for Statics.

D. Rigid Body Motion

Using questions from the pre-requisite class, such as using the FCI to assess students' preparation for future learning in a Statics class implies that the students should all be comfortable with the symbols used on the assessment. Sometimes, however, there are interesting things to be learned by asking students to stretch outside of their pre-requisite course material. Here is an example of a dynamics question developed to explore whether students' ability to correctly assess the motion of unconstrained rigid bodies gives an indication to how well prepared students are to learn equilibrium concepts in Statics. The initial theory was that a student who recognized that an unconstrained body would both translate and rotate would be better prepared to master static equilibrium. Figure 4 shows two unconstrained rigid bodies lying on a frictionless surface and subjected to loadings that are designed to entice students to think translation first for the one on the left and rotation first for the one on the right, but that actually have resultant forces and moments that differ slightly in magnitude, but not in direction.

Fig. 4. Paired unconstrained rigid body concept questions

For a multiple choice pre-test or warm up questions, these two bodies are more easily asked as two questions, with the gist of each being will the bar: a) not move at all, b) translate without rotating, c) rotate without translating, d) rotate and translate, or e) something else, and, if there is interest in a deeper understanding of the rotation of the bars, one can add: if there is rotation, will it be around the end of the bar, center of the bar (i.e. center of mass for a uniform bar), or another point?

The idea was that students who recognized that both bars would both translate and rotate would be better prepared to correctly model and analyze statics equilibrium, but the results turned out to be somewhat different [34].

While the results to date are based upon a relatively small sample size of 92 students, the predictive outcome was potentially very useful. There were 83 students that applied a consistent model to their analysis of the two bars, and, as a group, they did well in Statics. There were 9 students that did not apply a consistent model to their analysis of the two bars, and they struggled in Statics. Specifically, even if the first bar was seen to translate or rotate and translate and the second bar was seen to rotate or rotate and translate the student proved to be well prepared to learn Statics; as long as the model was consistently applied the student registered learning gains. However, if either bar was indicated as not moving or doing 'something else', or if the first bar only rotated and the second bar only translated, the student struggled in Statics and showed minimal learning gains. The group of 9 students who struggled on the concept questions performed significantly worse than the other students on the equilibrium ($p = 0.082$) and equivalence ($p < 0.002$) concept questions on the final exam, and on CATS ($p = 0.004$), both overall and on the equilibrium section of CATS. The average learning gain on CATS from the pre-test to the post-test for the former group was 7.5 points (out of 27), while for the latter group it was 0.4. Although this does not give the same specific information as the questions outlined in the first three examples, it does provide instructors with a tool to identify students who are not well prepared for Statics.

E. Stress and Deflection (Strain) Relationship

Statics is not the only course for which well selected concept questions can give instructors useful information. While there is not a concept assessment tool for Mechanics of Materials that is analogous to CATS for Statics, there are concept questions for Mechanics of Materials that can be used as warm-up questions that can also give instructors valuable information about student thinking. One specific difficulty that students entering Mechanics of Materials often exhibit is that they do not have as strong of a mental model of the relationship between stress and strain as they do between forces and stress.

Fig. 5. Beam with cross-section options concept question

Figure 5 shows a figure for a pair of questions regarding the stress and deflection of a beam that is made of three joined planks. The top of the figure shows the beam loading, and the bottom shows the three possible configurations of the planks for the beam's cross section. The gist of what the paired questions ask for in this situation is to have the students rank order the amount of beam deflection for each possible cross section, with 'all the same' as one of the options, and then to do the same thing for beam stress.

When this question was used in a very small preliminary study, the students did a good job of properly ordering the relative amount of deflection for each configuration, but did not do a good job of ordering the stresses. 19 of 26 (73%) students got the relative deflections correctly ordered, but 14 of 26 (54%) students said that the beams would all have the same stress because they all have the same cross-sectional area, including 10 of the 19 (53%) who were able to order the deflections correctly [35]. In most instances of the pre-requisite Introduction to Materials Science and Engineering course, students are only introduced to direct stress, so it is not a surprise that many equate stress as being inversely proportional to area, but that roughly half of the one who recognized that the deflections would differ were unperturbed by the contradiction of the deflections being different while the stresses are the same is useful information for the instructor. These students may have even recalled that stress is directly proportional to strain in the linearly elastic region, but they were not able to apply that knowledge to the beam bending situation to realize that if the deflection (strain) differs so must the stress. It is another example of how relatively simple concept questions can be used to give instructors useful information regarding student thinking when put into a situation of vertical transfer.

IV. LESSONS AND CONCLUSIONS

All five of these questions or pairs of questions are examples of cases where students' thinking generally correlates well enough with answer selection for an instructor to be able to get good insight into a class simply by reviewing the answer distributions. The next step in the process, which is beyond the scope of this paper, is to find the activities that help students to get past their misconceptions and specific difficulties so that they develop appropriate and consistent mental models. Think-pair-share exercises are often helpful, but I have found in Statics that they are better when supplemented with physical explorations or computer animations that can also demonstrate the concepts in action. In addition, when discussing the answer distributions on a warm-up exercise, examination of why the incorrect answers that were popular are incorrect, and why they are attractive distractors, often seems to generate better class discussions than examining why the correct answer is correct.

There are no perfect solutions for helping all students to learn concepts like equilibrium and equivalence; the main point here is that instructors can ask students concept questions that give those instructors useful information about students' misconceptions and specific difficulties from answer distribution alone. There are a growing number of recommendations to use horizontal transfer assessment tools for pre-tests in order to be able to measure learning gains in a class from beginning to end. If measuring learning gains is the primary goal of giving

a pre-test, then this is good advice. However, using vertical transfer assessment tools, whether through pre-tests or some other method such as warm-up exercises, can provide instructors with information that is not available through the use of horizontal transfer assessment tools by showing instructors what misconceptions and specific difficulties students are exhibiting with the new material.

This paper has outlined five questions or paired questions that allow instructors to gain extra insight into student thinking from students' answer selections. Sometimes students strongly exhibit a single misconception or specific difficulty, as with the equivalence question described herein, and sometimes students might be prone to exhibiting more than one specific difficulty, as with the free body diagram question that was outlined. The important things are that the questions' distractors are set up to allow students to express their errors, and that the distractors are verified to confirm that students' explanations of their thinking match the intent of the distractor from the expert's perspective. If one or more of the distractors are a reliable indicator of student thinking, then the concept question or questions used can provide much more information than how often students selected a correct answer. Knowing that students' thinking on a concept is incorrect is far less useful than knowing the ways in which their thinking is incorrect.

The examples given in this paper are meant to just show the potential of what can be easily and reliably learned by well-structured, carefully selected, and thoughtfully used concept questions. This little set of questions is far from complete, and covers only a small part of engineering foundation courses. While some conceptual questions do not give much insight into student thinking, there are many that do or can with adjustments to their distractors. There is both plenty of room and much need to develop, test, and share questions that prove themselves to be useful for quickly assessing students' misconceptions and specific difficulties.

ACKNOWLEDGMENT

The author would like to thank Professor Paul Steif of Carnegie Mellon University for allowing questions from CATS to be used for warm-up exercises for Statics.

Abstract— Colombian Higher Education Enterprise Architecture is a framework for managing the system-of-systems lifecycle of Higher Education Programs. With this framework is possible to model scenarios about the government as a regulator of Higher Education services, the educational institutions as providers of higher education services and the different business and social sectors, and individual citizens as clients of higher education services. Under this perspective all the stakeholders can participate in the planning, development, transfer, use and control of all the products and services lifecycles of higher education in order to prioritize improvement alternatives and measure progress when it is moving towards excellence in training processes, research, innovation, development and knowledge transfer.

CHE²A is a supportive environment for the management of higher education as a public service, which hosts the vision of "Global Coalition Intelligent Network Services (-GIUNC -) to analyze and evaluate systematic, systemic and logistically, the characteristics of processes, outputs and outcomes and risks through key factors such as those proposed by the -GIUNC-itself, Registry of Qualification established by the Ministry of Education of Colombia or other similar factors established by national or international entities, from which, the stakeholders in the Higher Education services, interpret, evaluate, argue, propose, define, plan, implement and measure strategies, tactics and actions for improvement, innovation and development higher education programs.

CHE²A is a knowledge management system that is enriched by the experience of organizations and supports innovation in higher education toward a high performance service.

The approach set **CHE²A** does not advocate specific tools, methods or practices, but promotes a new way of thinking, to solve the great challenges of the interactions of technology, power, politics and economics made involves the general study design, complexity and systems engineering. Although these systems often exhibit behaviors systems of complex systems, however, not all complex problems fall within the scope of systems of systems.

This article presents the context, perspective and use of **CHE²A** through its models ontological, epistemological, methodological and regulatory that allow navigate the life cycles of products and services offered by higher education

institutions and all those entities benefiting from this results achieved.

Keywords—Enterprise Architecture; Agile Methods; Simulation; Serious Play; Maturity Models; Quality Assurance

I. INTRODUCTION

This paper presents a summary our processes of the research and development realized in the Laboratory of Integrated Organizational Systems (LASIO) using the framework "Enterprise Architecture with Agile Methods Model (ARTEMA)" for developing a Colombian Higher Education Enterprise Architecture prototype -CHE²A-, which it extends ours works of [7] [8] [9] [10] and the System Quality Assurance in Higher Education -SACES- used by the National Education Ministry of Colombia in recent years.

The Colombian Higher Education Enterprise Architecture prototype -CHE²A- is justified on framework for managing the Systems-of-Systems Lifecycle (SoSL) where we have established that a system should possess:

- An Enterprise Architecture [2][4][13][16][18] which represents the organizational and behavioral structure through integrated baselines of referential components and principles that guide their evolution.
- An Enterprise architecture [2] [18] which consists of building blocks organized in layers o views that encourage multidisciplinary work to engage and develop, with harmony, coherence and synchronization, institutional knowledge about continent and content around organization and behavior, which is observable by many holistic perspectives, for an efficient and flexible government through sustainable strategies, tactics and practices of continuing improvement, evolution and innovation.
- A sceneries views set [21] of organizational and functional capability models (executable architecture) that are composed of activities and these are in turn are decomposed operational architectures in which is possible to establish evaluation through simulations, virtually and physically, to analyze current capabilities or develop situational prognosis prior to the implementations and deployments of systems in order to verify, validate and communicate the relationship among complex structures of processes, stakeholders, rules, requirements and constraints, to improve design,

implementation, forecasting, deployments, and resourcing around systems, environment, technical, data and information about capabilities, services, products and outcomes.

- A set of principles [1] [2] [3] [5] [15] [17] to the learning and work collaborative (agile methods) to avoid the overhead and bureaucracy, solve problems, and promote participative adaptive of leadership, planning, management, development and transformation of the higher education.

This paper is organized as follows:

- **Processes Model of Leadership Organizational.** This section shows the building blocks that establish and locate the standards of structural, functional and operational practices with what is modeling the Colombian Higher Education Enterprise Architecture -CHE²A- ("what") associated to Administrative and Strategic Management, Tactical and Operative Administration ("how" through with lean-agile methods) associated with "where", "why", "when", "who", "how much" as reasons of feasibility and added value.
- **The Colombian Higher Education Enterprise Architecture Model.** This section describes the view of the Organizational Leadership Processes of Higher Education from the perspective of strategic, tactical and operational capabilities in three abstraction levels: High, Intermediate and detail, to particularize hierarchically capabilities. Additionally, there is a description of reference practices set to be used by the different institutions participants in the Colombian Higher Education System.
- **The Model Assessment of CHE²A.** This section describe the form of assessing compliance with standards defined in the CHE²A and its instances in order to monitoring and realizing continuous improvement associated with corrective (business continuity) and preventive actions (research, innovation and development) of calibration and adjustment in specifications (standards guides) and measuring instruments (smart metering).
- **Prototype Model for CHE²A.** This section shows the simplified tailoring of CHE²A as experimental reference of the organizational and behavioral practices in a educational component of a Higher Education Institution. This prototype has been developed within the CIDLIS and it represents a process lifecycle environment of research, teaching and learning about the courses taught in the E³T-UIS.
- **Conclusions.** This fragment recounts the retrospective assessment of the CHE²A research process regarding the lessons learned and future work to develop under this architecture.
- **Acknowledgment.** This part refers the gratitude to those stakeholders contributed in the development of this project.
- **References.** In last section it is referenced the bibliographic information underlying the approaches developed in this research.

II. PROCESSES MODEL OF LEADERSHIP ORGANIZATIONAL

The Processes Model of Leadership Organizational for develops CHE²A (Fig. 1) in its structure strategic, tactical and operational is organized into following steps:

Fig. 1. Process Model of Leadership Organizational

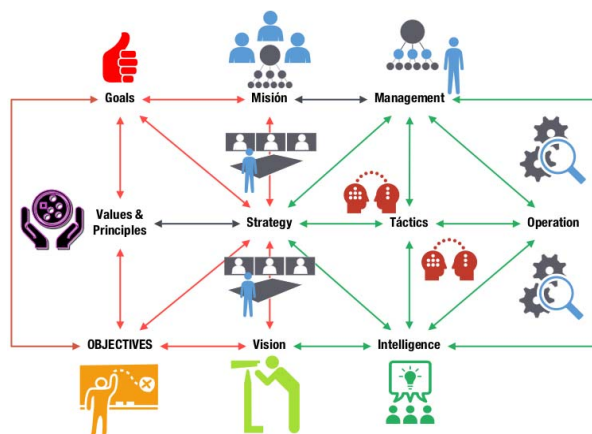

1. **Modeling.** In this step the experts model Higher Education sceneries through processes, capabilities and competences around Regulatory Institutions (Colombian State), Clients (Society and Sector environments) and Providers (Higher Education Institutions).
2. **Awareness (Consciousness).** In this second phase all experts agree together model and establish the SoS baseline:
 - a. Strategic thinking, capabilities, performance and regulatory standards for executing by the Regulatory Entities;
 - b. Goals, objectives, competences, politics, performance of managing human resources, innovation and development on the required knowledge and research needs of the different business lines of Clients; and,
 - c. The organizational objectives, commitment and social responsibility, and, development and environmental sustainability management on the services, research and knowledge transfer of higher education entities and regulatory institutions.

3. **Assessment.** In this third phase, it is realized the preparation, transfer, training and validation of instruments, products and services of the regulatory entity, clients and suppliers, that will be use during the assessment of Higher Education Ecosystem.

The process of monitoring and assessment of the evolution of the Higher Education Ecosystem (Fig. 2) require collect, analyze and evaluate compliance with the requirements of human resources, research, innovation and technological development, according with the strategic, tactical and operational goals and objectives about the management of educative products and services, committed between clients (sectoral environments) and providers (Higher Education Institutions) under the control of regulatory entity.

Fig. 2. Evaluation of Higher Education Environment

There are differences between the processes of monitoring and assessment about processes capability, events and risk situations in the scenarios of regulation, clients and suppliers. On clients, the analysis is done separately around processes and events. On the suppliers and the regulatory entities, the analysis is done mixed. This approach ensures transparency in the assessment. It should be reiterated that assessments meet simultaneous functions of regulation and improvement. The vision of the results of monitoring and assessment achieved sustains that:

- Client Entities judge and establish whether their products and value-added services are within their organizations and their clients. They judge and establish its needs and capabilities around the providers of Higher Education.
 - The Higher Education Institutions judge and establish whether human resources formed and the educational products and services generate value within their organizations, social networks, citizens, environment and industry.
 - The Regulatory judge and establish if the provides results of certification, accreditation, inspection and monitoring add value to the organization itself as a system-of-systems compounds by institutions of Higher Education, Business, Citizens and the state itself.
4. **Benchmarking.** From the result of assessment, it is possible to perform a comparative measurement between client organizations and higher education institutions

around the factors in the models of processes, capabilities, risks, inputs, outputs and outcomes. The comparative measurement environment could generate classifications around factors and provide new challenges and opportunities for improvement, innovation and development to match products and services, offered and received among all committed conglomerates.

5. **Performance.** Got Benchmarking, it is possible to establish action plans that lead the development of new strategic, tactical and operational for each type of participant in the Higher Education Ecosystem.

III. THE COLOMBIAN HIGHER EDUCATION ARCHITECTURE

"The Colombian Higher Education Architecture Model" (Fig. No. 3) is corresponding to the Process Model of Leadership Organizational with three abstraction levels: High, Intermediate and detail.

A. High Level of CHE²A

High Level of CHE²A consists of an essential element called Administrative Management, from which three building blocks emerge: Strategic, Tactical and Operational Administration. Each of the components is proposed as a means of skills (capacities) and capabilities to the different organizational perspectives for providing holistic common interpretations for those stakeholders in the higher education ecosystem. The model is deploying from the intelligence perspective for decision making supported by the direction and leadership through planning, monitoring and control of tactics actions around the educative architecture, providing logistics, manage resources and knowledge, and capture information, for and from, the operation, to improve, research, and develop, under continuous processes of optimization approach.

1) Administrative Management (Direction & Leadership).

The Administrative Management view include the capabilities of analytical thinking (creative thinking, decision making, learning, problem solving and systems thinking), behavioral characteristics (ethics, trustworthiness and management), body of knowledge about the products and services of the principles, practices, problems, solutions and organization of higher education programs, communication and interaction capacities and capabilities to support decision taking, facilitation, leadership and teamwork. This component is tactically supported by the tactical administration for implement strategies and operations, for transforming the current state of the mission towards the vision, achieving objectives and goals under the framework of organizational values and principles. All the capabilities described are inherited by all entities in the architecture model.

2) Tactical Administration (Institutional Management Knowledge).

The Tactical Administration view includes competences to Institutional Knowledge Management. This component manage the Educational Architecture to support, supply, monitor and control all the organizational activities and functional logistics around knowledge, communications, technology, economy, people and performance of the Administrative, Strategic, Operational, and itself. The Tactical

Administration view is nested in three levels of management: Establishment, Transfer and Monitoring of resources. It should be noted that all the components of CHE²A have the same lifecycle pattern: Feasibility, Initiation, Leadership and Decision Making, Monitoring and Control, and Clouse out. This pattern corresponds to agile methodology process which is characterized by a gradual and iterative delivery oriented by opportunity, courage, commitment, teamwork, problems solving, adaptive planning and continuous improvement

Fig. 3. Colombian Higher Education Architecture Model View

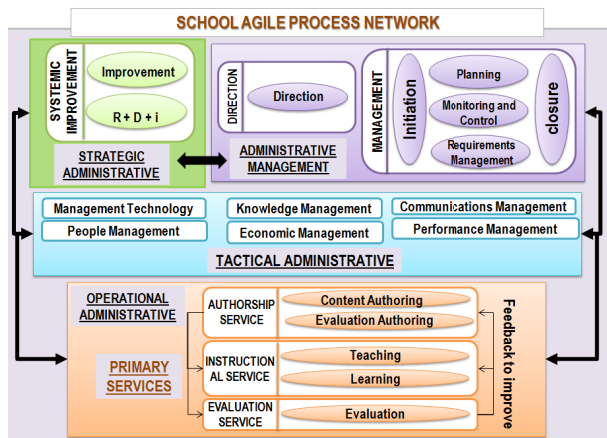

Fig. 4. Intermediate level of CHE²A

3) Strategic Administration (Research, Innovation & Development).

The Strategic Administration view include competences for improving the system as a whole, from the architecture to the environment and functional analysis studies, information on the specifications and the behavior of the processes developed by the organization. The performance of this component is supported and directed by Tactical Administration under the supervision and vision, leadership and direction of the Administration Management. The principal competence of this entity is the intelligence and educative Analysis (business analysis) for developing portfolios, plans, programs and

projects to produce goods and services to the Tactical Administration, who will integrate and deploy it. It is very important to note that the Strategic Administration supplies test and transfers all its products and services to the Tactical Administration, because this entity who manage the knowledge and the architecture (CHE²A) of research, innovation, improvement and development, around each of the architectural components carried out by the organization.

4) Operative Administration (Transfer, Teaching & Learning).

The Operative Administration view includes the capabilities corresponding with the bodies of knowledge of each of the educational programs offered. The Operational Administration develops the institutional mission that must be specified in all logistical architecture and the infrastructure and media resources, knowledge, and goods and services, with a focus on sustainable development provides to its environment. Its functionality depends on the Tactical Administration. The process follows the same mechanics of the other components already described but adapted hierarchically to all activities (features), operations and tasks of teaching and learning. It is important to reiterate again that the lifecycle of each process is associated with the already pattern of agile methods, emphasizing that the Operational Administration should be based on logistics provided by the Tactical Administration and also provide it, information from processes performance, and problems and incidents management that affect or may affect the continuity of the processes, to provide corrective and preventive actions for future improvement to be developed by the Strategic Administration.

B. Intermediate Level of CHE²A

The second level presents the view of breakdown of the capabilities associated with the Administrative Management and the Tactical, Strategic and Operational Administration (Fig. No. 4 and TABLE I). This level is the basis to support the actions of higher level about knowledge, capacities, skills, tools and techniques to fundament assessment of managers, analysts, researches, teachers, instructors, authors, mediators, students and other stakeholders associated with humans, knowledge, technology and infrastructure resources [6] [14] .

C. Detail level of CHE²A

This Detail level presents a capabilities breakdown view of the High (first) and Intermediate (second) level (Fig. No. 5) about specific areas of knowledge, capacities, skills, tools and techniques to fundament assessment of managers, analysts, researches, teachers, instructors, authors, mediators, students and other stakeholders associated with humans, knowledge, technology and infrastructure resources.

This level is considered variable because it must be tailored specifically to the alleged philosophical conditions within the autonomy of each of Higher Education Institutions. Under this interpretation the level includes the ontologies (superstructures, structures and infrastructure of higher education), the epistemology (Body-of-Knowledge) and methodology

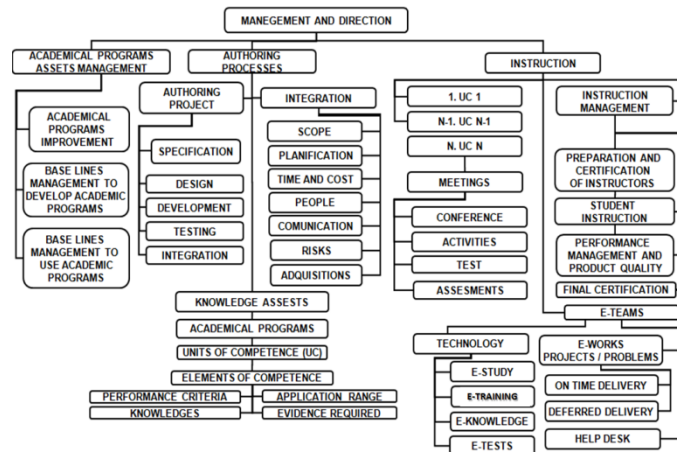

(capabilities, technologies, techniques, instruments, tools and skills) for using by all the stakeholders of each institution.

TABLE I. Intermediate level of CHE²A

Processes		
Capabilities	Capacities	Knowledge Competences (Maturity Level)
Administrative Management	Direction	1. Decision Analysis & Making (3) 2. Causes Analysis (5) 3. Educational Strategic (3)
	Management	4. Requirements Management (2) 5. Educational Planning (2) 6. Educational Monitoring/Control (2) 7. Risk Management (3) 8. Educational Quantification (4)
Operational Administration	Authoring	9. Requirements Definition (3) 10. Educational Design/Development (2) 11. Educational Verification (3) 12. Educational Validation (3)
	Instruction	13. Instruction Service Delivery (2) 14. Instruction Service Continuity (3) 15. Incident Resolution/Prevention (3)
	Evaluation	16. Evaluation (3)
Tactical Administration	Quality Assurance	17. Educative Architecture Enterprise (2) 18. Knowledge & Configuration Management (2) 19. Measurement and Analysis (2) 20. Educational Analysis (2) 21. Quality Assurance (2) 22. Training (3) 23. Communications Management (3) 24. Performance Measurement (4)
Strategic Administration	Systemic Improvement	25. Definition and Improvement (3) 26. Research, Development & Innovation (5)

As an example we describe how often we have developed this level in our experimental tests.

Fig. 5. Detail level of CHE²A

1) Detail Ontology level of CHE²A (Structure)

The Ontology of CHE²A follows the guidelines set for the two levels previous through an integrated administration management and tactical, strategic and operative administration that it is represented in "Management and Direction" [7] [8] [9] [10]. The components that emerge in this structure correspond to operative processes: Knowledge assets management: Authoring, Development and Maintenance:

- The Knowledge Asset Management Processes follows the guidelines to academics improve under Strategic Administration and baselines management following the guidelines developed by Tactical Administration.
- Authoring Processes, is covered by Strategic, Tactical and Operative Administration, for designing and making

teaching-learning modules and evaluations under the vision of competency-based formation using agile project management as a support tool to develop products and services of competence specifications, performance criteria, knowledge, applications and the establishment of evidence required to certify skills acquired; design and production of teaching-learning objects that are seen as technological applications of reusable components supported by human resources; verification, validation and integration of components; a integral improvement process for resources, content, practices and the same authoring. Authoring Processes also includes development, management and maintenance of knowledge, to make them consistent, permanent and relevant.

- Instruction and Evaluation Processes is established for following learning sequences through teamwork activities to solve problems through agile methods. The student projects are supported by a tutor, a coach and several assistants. These projects are charged with overseeing all activities of the students. Instruction Processes may include certification procedures and, eventually, be linked to each course; a fact that makes feasible the continuous monitoring practices of certified human resources and allows continuous improvement processes directly into formation development.

2) Detail Epistemology level of CHE²A (Performance)

Established the ontology [11] [12] the next step is validate and constitute criteria of truth to admit, raise and study cognitive phenomena that occur when observing how it is generated, builds, defines and institutionalize the knowledge and its own and emergent concepts, types of knowledge possible and the criteria that justify or invalidate, and the degree to which each criterion is true between the knower and the object known. In short, establishing and studying the conditions of production and validation of knowledge object as technological product applicable to the value chain of the educational process.

3) Detail Metodology level of CHE²A (Method).

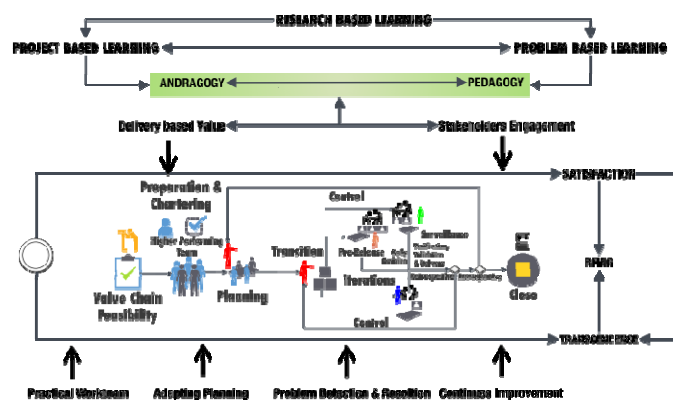

The methodological pattern is based on the scientific method for explaining phenomena; establish relationships between facts, and state guidelines grounded in principles and values that explain the phenomena and obtaining, with this knowledge, useful applications to the community.

By example, the CIDLIS² use the educative process pattern methodology which has three paradigms of learning (Fig. 6): Problems, Projects and Research [19][20], established under the principles of Andragogy (teaching techniques aimed at educating adults) and Pedagogy (teaching techniques geared toward education, as intrinsic phenomenon of the human species) developed to raise the continuous delivery of value supported by the commitment of all internal and external stakeholders that are associated with an higher education process. This process is clocked by stages. Each stage requires integrally inputs required to produce products and achieve a gradual iterative training in which knowledge and skills using proprietary techniques and tools for each phase of training.

Particularly in all phases of the teaching-learning activities covering:

- The intellectual domain (cognitive system) in which the learner receives direction and training
- Emotional and physical domain (emotional system) in which the learner, with the support of an educational coach and a facilitator, publicly confronts his learned achieved in the cognitive system.
- The practical domain (emotional system) in which the learner, with the support of educational assistants and facilitators, get experience, skill and maturity as a practitioner.
- The domain creative (expression system) in which the apprentice is delegate to perform own creations.
- The autonomous domain (Integrated system) in which the learner is leadership, free and critical, to make their knowledge practices.

Fig. 6. Example of Teaching & Learning Methodology of the Detail level

Others examples of methodological patterns used by the CIDLIS² are (Fig. 7): teamwork, adaptive planning (considering that educational outreach is variable in time), the detection and resolution of problems and continuous improvement, as elements which result in a work-oriented agile projects to realize practices and versioned deliveries supported in small iterative partial products that enable the gradual improvement of maturity and development of products, knowledge, and human and technological resources, necessary for the development of an educational process. The iterative cycle is set at multiple levels according to the Organizational Leadership Processes of CHE²A, following the specifications and requirements prioritized by value and opportunity for each of the required products to be delivered just in time to allow coexistence and synchronization processes related with products and authors, teachers, learners, administrators and other roles established in an educational process.

IV. THE MODEL ASSESSMENT OF CHE²A

The CHE²A and its implementation have two assessment tools (Fig. 8) the Integral Assessment Method of Interactions and Communications and The Integral Organizational Assessment Method.

Fig. 7. Example of Teams Developing Methodology of the Detail level

The Methods follows the principles of Standard CMMI[®] Appraisal Method for Process Improvement (SCAMPISM) [22] extending to aspects of cost, time and performance. The methods produce benefits around insight into an organization's capabilities by identifying the strengths and weaknesses of all current processes relative to CHE²A reference model to prioritize improvement plans, focus on improvements that are most beneficial to the organization given its current capabilities and risks processes level.

Both methods follow the same sequence of steps with roles and responsibilities assigned but with adaptation according to each assessment object; Plan and Prepare (Analyze Requirements, Develop Plan, Select and Prepare Team, Obtain and Initial inventory of Objective Evidence and Prepare for Appraisal Conduct), Conduct Appraisal (prepare participants, examine, document, verify and validate objective evidences, validate preliminary findings and generate results) and Report Results (deliver, package and archive results)

A. Integral Assessment Method of Interactions and Communications

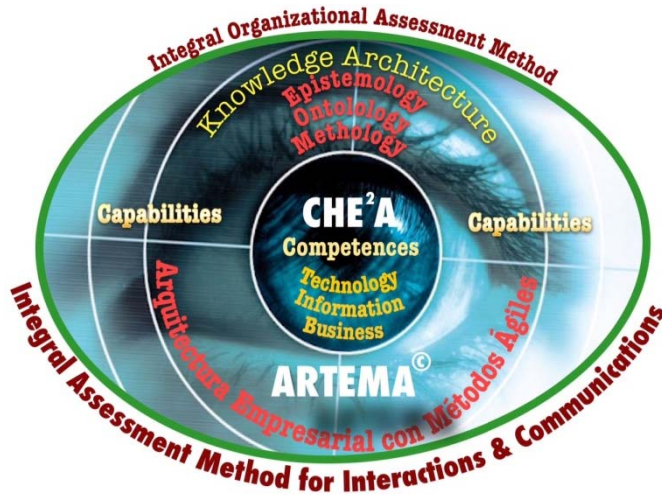

The first assessment method of CHE²A and its instances evaluates the characteristics of attitude and aptitude of interaction and communication capabilities to determine the quality and trustworthiness ethics of organizational and performance integrity respect to ontology, epistemology and methodology, capabilities and competencies of leadership, direction, administration, teaching, learning, facilitation, negotiation and teamwork. With this assessment becomes consciousness in matching CHE²A and reality environment to organizational and functional behavior to be aware for knowing and doing. This situation permits constructs intelligent measurement instruments (standards patterns of calibration and adjustment of specifications for measurement) to monitor and realize continuous improvement associated with corrective (business continuity) and preventive actions (research, innovation and development).

B. Integral Organizational Assessment Method

The second assessment method of CHE²A and its instances is supported in the validity of the results of the first assessment and evaluates the characteristics of attitude and aptitude of capabilities around the Educational Knowledge (principles and practices, environment, organizational and solutions of knowledge) to determine the quality, trustworthiness, suitability and ability to know, build, transfer, do, teach and learn how to work with knowledge in the different social and sectoral environments. With this assessment becomes consciousness in matching CHE²A and reality environment to organizational and functional behavior about knowledge. This situation can also constructs intelligent measurement

instruments to monitor and realize continuous improvement associated with corrective and preventive actions.

Fig. 8. CHE²A Assessment Methods

V. PROTOTYPE MODEL OF CHE²A

This section presents a prototype model of CHE²A. This modeling has required develop a vision of the current state of Colombian Higher Education in order to build a basic environment of analysis and validation.

A. The current state of Colombian Higher Education View.

The System of Higher Education in Colombia is comprised of three interrelated subsystems: Evaluation, Information and Development. With these systems the Higher Education Institutions are regulated by two major moments, one mandatory, when created, and other, voluntary when institutionally accredited under 10 quality factors (TABLE II).

TABLE II. Higher Quality Factors for Higher Education Institutions

Qualified Register Factors		
Id	Description	
1	Institutional Mission and Project	x
2	Students	x
3	Teachers	x
4	Academics processes	x
5	National e international Visibility	x
6	Research and Artistic Creation	x
7	Pertinence and Social Impact	x
8	Self-evaluation y Self-regulation	x
9	Institutional Welfare	x
10	Organization, Management & Administration	x
11	Academic Support Resources and Physics Infrastructure	x
12	Financial Resources	x

Similarly, academic programs of Higher Education are regulated in two stages, one mandatory, must fulfill 15 quality conditions (TABLE III) to be granted the Qualified Registry, and other, voluntary, getting demonstrate compliance with 10 factors high quality(TABLE IV).

The accreditation of institutions and programs are complementary. The first is oriented towards the institution as a whole; the second considers its integral parts or key components. With which, the Quality Assurance System is based on the National System of Higher Education that indirectly influences the curricular compositions and organizational structures under the support of competences according to the job performance information of graduates proportionate by the Labor Observatory about market needs.

With which, as a whole, the system are pretending create a self-regulating system with permanently seeks improvement processes.

TABLE No. III. Qualified Register Conditions

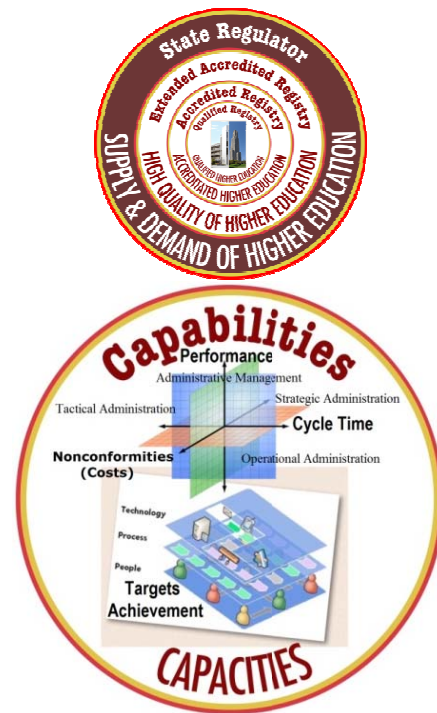

Id	Factor	
1	Name of Program	x
2	Justification	x
3	Curricular Content	x
4	Organization of Academic Activities	x
5	Research	x
6	Relationship with the External Sector	x
7	Teachers	x
8	Educational Media	x
9	Physical Infrastructure	x
10	Selection and Evaluation Mechanisms	x
11	Academically and Management Structure	x
12	Culture of the Self-evaluation	x
13	Program Graduates	x
14	University Welfare	x
15	Sufficient Financial Resources	x

In conclusion, while the Colombian state (Fig. 9) as regulator establishes general standards of regulation that induce curricular and organizational structures, it is necessary to define frameworks that provide comprehensive guidelines for the development of higher education, where the bodies of knowledge are determined as units of reusable composition (inputs, outputs, tools and techniques, and personal or organizational skills) for each of the capabilities offered in educational services.

TABLE IV. Accredited Register Factors in Colombian Higher Education

Id	Factor	
1	Mission, project and program	x
2	Students	x
3	Teachers	x
4	Academic Processes	x
5	Visibility	x
6	Research, Innovation & cultural	x
7	Institutional Welfare	x
8	Organization, administration & management	x
9	Impact in the middle	x
10	Physical & Financial Resources	x

Fig. 9. The current state of Higher Education in Colombia Versus CHE²A

B. Basic environment of analysis and validation.

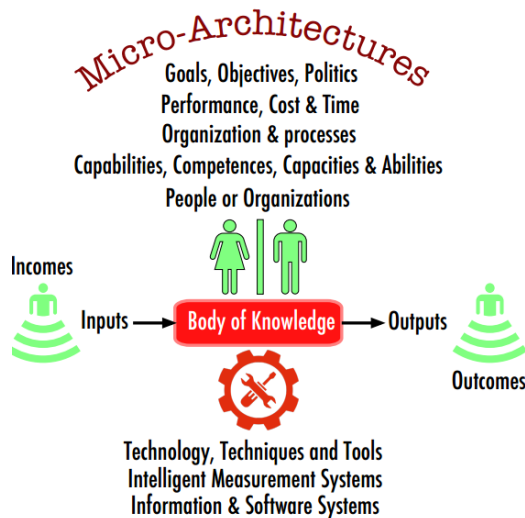

The basic architecture environment has been developed in the last two years about the undergraduate and graduate courses taught by CIDLIS at E3T-UIS. They supported in the school model Agile (Fig. 4 and Table I) were structured and integrated the CHE²A in High and Intermediate layers and the teaching-learning detail level was constituted by three components (micro-architectures) (Fig. 10 and 11); Bodies-of-Knowledge of Project management, Quality Engineering and Statistics for Engineers.

Assessed the results of the experimental period of use CHE²A (Table V), it appreciate that assessed the results of the experimental period implies that the culture of all stakeholders in higher education is still not prepared for the proposed changes, however, development and simulation and prototyping of architecture is useful for estimating and induce the development of a portfolio of projects associated with the entire higher education ecosystem, including the internal and external environments to higher education; administration, teachers, managers of infrastructure and knowledge, providers, alumni, state, productive sectors, and in general, all the community concerned.

Table V. Technical Data Sheet of experience with CHE²A

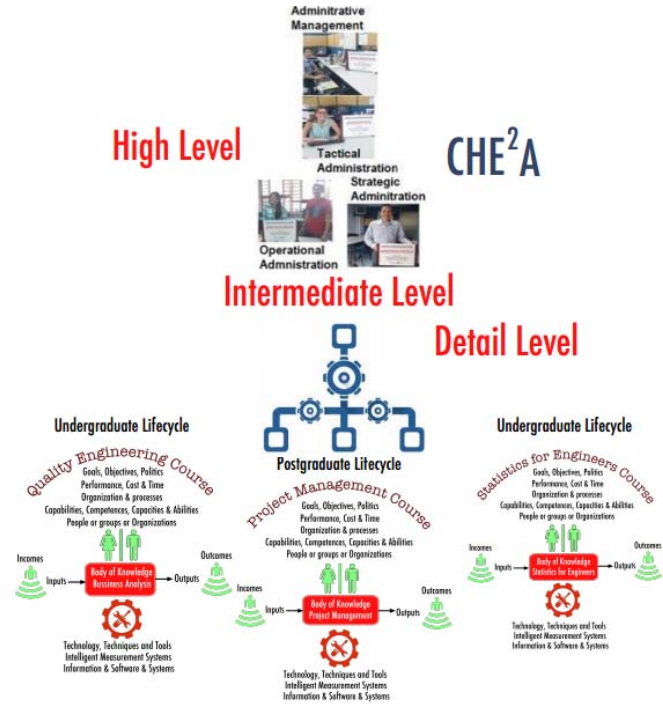

Resources	Quantity
Students	254
Teachers	3
Students approved	240
Students disapproved	14
Hours accompanied by teacher	704
Undergraduate courses	11
Postgraduate courses	6
Administrative Management	2
Tactic Administration	1
Strategic Administration	1
Operative Administration	1
Assistant Personal	9
Average grades in undergraduate courses (About 5)	3.5
Average grades in undergraduate in postgraduate courses	4.5

Fig. 10. CHE²A Knowledge Units

The instance of the CHE²A as pilot developed drove along the stakeholders to establish the results of leadership, management and administration, teamwork, value creation, engagement, problems identification and resolution, and continuous improvement.

Fig. 11. Examples of CHE²A Bodies-Of-Knowledge Micro-architectures

VI. CONCLUSIONS

The conclusions are presented from the organizational, performance and methodological perspective and future work.

Lessons learned from CHE²A and its implementations enhances the Teaching-Learning exercise to create a dynamic, agile and collaborative learning integrated with the environment, fact that motivates and creates value for all those involved in the educational process.

The achievements of CHE²A has been benefits, all the components and its instances has been translated into the creation of a discipline to internalize the processes and principles of performance and accountability, it must be sustained in models as CHE²A, always previous to any development, for doing actions reliable of leadership with all the teamwork and being whole integral organizations.

Future CHE²A argues to extend the model to the scenarios of simulation to work components as units on which their structures and behavior is not known, in order to perform intelligence to create collaborative environments supported by systems of systems.

ACKNOWLEDGMENT

We express our thanks to the students of the courses: Quality Engineering, Projects Management and Statistics and Probability for Engineers of Electrical, Electronics and Telecommunications Engineering School of the *Universidad Industrial de Santander*, who actively participated through its projects and feedbacks without it would not have been possible to perform this experiment. Also, we express our appreciation

to the staff of the Center for Information Technology and Communications (CENTIC) and CIDLIS facilitators because without your support we would not be able to do this exercise.

Abstract—Higher education has emphasized global education as a strategic goal over the past few decades, yet little empirical data has been collected to inform the decisions of global education. Engineering schools have integrated global experiences into programs with limited knowledge regarding the effectiveness of their program planning and capacity for supporting internationalization. Research is needed regarding strategies that support effective global programming and how outcomes of these strategies can be evaluated. Through three separate studies, this research addresses how engineering educators may implement, assess, and evaluate effective global engineering education programs. Using concept mapping, the first study will engage international engineering program facilitators to develop a framework that highlights effective global engineering education strategies and their evaluation. Data Envelopment Analysis will then be utilized to measure the relative effectiveness of global engineering education programming strategies using indices and outcomes identified in the framework. Using Latent Profile Analysis, the third study explores engineering global preparedness patterns among undergraduate engineering students as well as evaluates the relationships of engineering global preparedness with different student, institutional, and global programming variables. The anticipated results of this research are evidence-based global engineering programming strategies and systematic evaluation methods for international engineering program facilitators and educators.

Keywords—*global engineering education; engineering global preparedness; concept mapping; data envelopment analysis; latent profile analysis*

I. INTRODUCTION

Engineers in academics and industry are recognizing the importance of preparing the current and next generations of engineers to be successful in the new global economy [1]–[3]. National commissions and scholars have noted the impact of globalization and the implication for continued U.S. economic leadership [4]–[6]. To this end, engineering global preparedness has become an important educational outcome, with educators believing that success in a global context requires students to acquire specialized knowledge and develop new skills and attitudes. Engineering programs have increasingly emphasized global education programming as a

core piece of their strategic goals over the past few decades, investing substantial resources to increase participation in global experiences, both curricular and co-curricular, with the expectation that a student who participate in such experiences will become more globally prepared. Engineering schools integrate global perspectives and experiences into programs through a variety of offerings (both curricular and co-curricular) but are often operating with limited knowledge regarding the effectiveness of their program planning strategies and the organizational capacity for supporting the internationalization process. Most evidence as to how global programming impact engineering students is anecdotal, without much empirical evidence to guide educational practice [7], [8].

There is a lack of rigorous research regarding global engineering programming strategies and the fervor to globalize engineering programs has focused primarily on the development and less on evaluation [9]. Empirical research is needed regarding the strategic planning and outcomes evaluation of global engineering education programming strategies. Through three separate, but integrated, studies this proposed research addresses how engineering educators may implement, assess, and evaluate effective global engineering education programming (GEEP) strategies. The objectives of the three studies are as follows.

First, develop with international engineering program facilitators a conceptual framework via a logic model that identifies effective global engineering education programming strategies and outcomes. In doing this, we will establish essential inputs and outcomes for successful global engineering education programming, and distill feasible mechanisms for assessment and evaluation. A participatory, integrative mixed methods approach, called Concept Mapping [10], will be employed.

Second, based on the results of the conceptual framework, conduct a cross-institutional quantitative study of 30 engineering schools across the U.S. to analyze the relative efficiency of global engineering education programming strategies. Data Envelopment Analysis (DEA) [11] will be used to construct specific benchmarks for evaluating the performance of individual global engineering programs. This will be useful to engineering educators not only in measuring

efficiency of different program strategies, but also guiding them how that could be accomplished.

Third, build upon these findings by adopting a finite mixture models approach to discover undergraduate engineering students engineering global preparedness development patterns as well as evaluate the relationships of engineering global preparedness with student backgrounds, institutional constraints, and global programming strategies. Specifically, Latent Profile Analysis (LPA) [12] will be applied to a data set containing undergraduate engineering students' demographics, prior international experiences, and global preparedness. LPA has significant theoretical and practical advantages over traditional techniques when analyzing multidimensional data like global preparedness [12].

Figure 1 outlines the proposed research framework. To achieve these objectives, the following primary research questions are explored: (1) What are effective global engineering education programming strategies, and how can we empirically identify and assess the mechanisms for effectiveness within the engineering discipline?; and (2) How can we formulate evidence-based global engineering programming strategies that are robust to the diverse backgrounds and experiences of undergraduate engineering student populations and engineering programs?

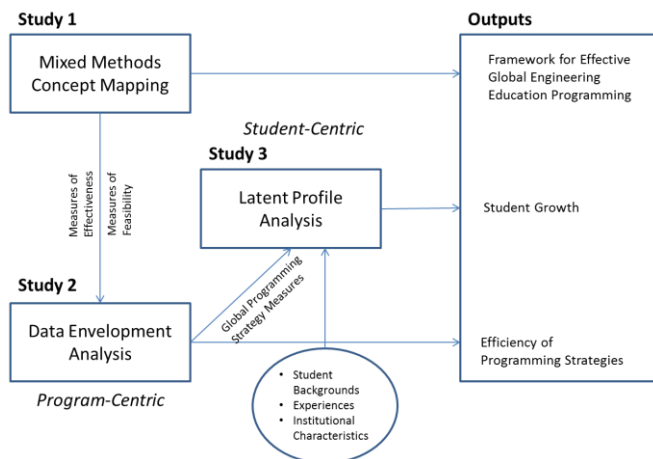

Fig. 1. Research Framework

II. RELATED WORK

A. The State of Global Engineering Education

Accreditation bodies, national engineering organizations, and government agencies have recognized the importance of global competence in today's globally interconnected world. The American Society for Engineering Education's (ASEE) Green Report (2010) has called for colleges to adapt curricula to incorporate "an appreciation of different cultures and business practices, and the understanding that the practice of engineering is now global"[13]. Engineering programs recognize the need to equip graduates with the right skills to stay globally competitive, and many schools have begun making efforts to incorporate global learning experiences into their program structure. Parkinson provides an overview of 24

exemplary programs [14], noting that a few have goals to increase their number of graduates with an international experience. Research, however, has indicated that international learning experiences are not necessarily predictive of students' engineering global preparedness. The beneficial effects of global engineering programming such as study abroad on engineering global preparedness may be a more popular narrative than an empirically grounded claim due to methodological shortcomings in prior research. A more comprehensive and integrated approach to enhance development of global preparedness in engineering students is necessary to meet the changing needs of society world-wide. As engineering programs continue to invest heavily in global education programming efforts, it is critical to determine whether these investments can be expected to produce their intended results and what strategies best produce these results.

B. Global Engineering Education Programming (GEEP) Framework

The Center for Internationalization and Global Engagement (CIGE) provides analyses of critical international education issues and supports the internationalization of higher education through a broad range of programs and services[15]. The Global Engineering Education Programming (GEEP) framework in Figure 2 is an adaptation of CIGE's Model for Comprehensive Internationalization, which is defined as a strategic, coordinated process that seeks to align and integrate international policies, programs, and initiatives, and positions colleges and universities as more globally oriented and internationally connected [15]. This framework will be used as a guide and leverage point for the construction and interpretation of the conceptual framework.

III. STUDY 1 - CONCEPT MAPPING OF GEEP STRATEGIES AND OUTCOMES

Concept mapping is a integrative, mixed methods approach for organizing the ideas of a group or organization, to bring together diverse groups of stakeholders and help them rapidly form a common framework that can be used for planning, evaluation, or both [10]. The approach integrates qualitative individual and group process with multivariate statistical analyses to help a group of individuals describe ideas on any topic of interest and represent these ideas visually through a series of related two-dimensional maps [16].

This methodology will be used for the development of both GEEP strategies (planning) and outcomes (evaluation). This concept mapping study will involve a group of 30+ stakeholders drawn from across key groups associated with current global engineering programming across the U.S. These participants will brainstorm planning strategies and outcome evaluation criteria, resulting in two sets of concept maps. These maps will be interpreted together to generate a conceptual framework for GEEP strategies. Study 1 will address the following research question: what are the key strategies when designing and implementing effective global engineering education programming, and how the effectiveness of these strategies be evaluated?

Fig. 2. Global Engineering Education Programming framework Adapted from Center for Internationalization and Global Engagement (CIGE) Model for Comprehensive Internationalization [15]

Stakeholders will first brainstorm a large set of statements relevant to GEEP strategies and outcome evaluation. Each stakeholder will sort the statements into piles based on perceived similarity, and rate each statement on 'Importance' and 'Feasibility'. Engineering program information on the type of school, size of engineering program, and other mitigating factors will be captured.

Multivariate analyses will be conducted that includes two-dimensional multidimensional scaling (MDS) of the unstructured sort data, hierarchical cluster analyses of the MDS coordinates, and then a computation of average importance and feasibility for each statement and cluster of statements. Finally, the group of stakeholder will interpret the maps through a structured interpretation process designed to help them understand the emergent strategies and outcomes; and label them in a substantively meaningful way [16].

The GEEP stakeholders interpret a series of maps that reflect item and cluster similarity and scale ratings, pattern matches (pairwise comparisons of cluster ratings across criteria such different stakeholder groups or rating variables, using a ladder graph representation), and go-zones (bivariate graphs of statement values for rating two variables within a cluster, divided into quadrants above and below the mean of each variable, showing a "go-zone" quadrant of statements that are above average on both variables). The stakeholder group will then discusses ways to utilize the final GEEP concept maps, pattern matches, and go-zones to enhance program planning and evaluation.

Using program theory [17], the resultant concept maps will be used to develop a model of how effective GEEP strategies work and how these strategies influence immediate outputs and through them, longer-term outcomes. Logic models are consistent with this emphasis, and typically show environmental factors, inputs, outputs, and outcomes for a program in a graphic form [18]. The logic model will be used to identify and develop GEEP outcome evaluation questions and a resulting GEEP evaluation instrument.

IV. STUDY 2 - BENCHMARKING GEEP AGAINST BEST-PRACTICE USING DATA ENVELOPMENT ANALYSIS

Data envelopment analysis (DEA) is a mathematical programming based approach for measuring the relative effectiveness of decision making units (DMUs) that have multiple inputs and outputs [19]. DEA can be viewed as a multiple-criteria evaluation methodology where DMUs are alternatives, and the inputs and outputs are two sets of performance criteria where inputs are to be minimized and outputs are to be maximized. The assumption here is that there is a conceptual or experiential relationship between the outputs

and inputs. The DEA linear program provides optimal weights on DMUs used as references to benchmark each DMU being evaluated to obtain an objectively identified efficient peer group [11]. In Study 2, the efficiency of global engineering programs in utilizing GEEP strategies (inputs identified in Study 1) will be measured. The inputs and outputs used in the proposed model will be the result of the conceptual framework and the results of the GEEP evaluation instrument designed in Study 1. The following research question is addressed: Can we systematically compare the effectiveness of different global engineering education programming strategies and how can we use this information to benchmark against best-practice? This study will be useful to engineering education policy makers not only in measuring the efficiency of different GEEP frameworks, but also in guiding them how that could be accomplished.

The inputs and outputs of the model will be the key strategies and outcomes identified in Study 1, and outlined in the conceptual framework and measured via the GEEP evaluation instrument. The Banker, Charnes, and Cooper (BCC) model of DEA is proposed to combat the perceived faulty assumption of constant returns to scale among global engineering programs. The BCC model takes into account the possibility that small global engineering programs may not be able to operate as efficiently larger ones, or in other words, variable returns to scale [20]. In addition to measuring the efficiency of each global engineering program, efficiency will be decomposed into the contributions of output factors. The efficiency measures will show the global engineering programs whose strategies have been utilized inefficiently and the decomposition will help determine future areas of improvement.

The weights obtained from the DEA linear program model have been used to represent the importance of the input and output factors, with the rationale that more favorable factors tend to have larger associated weights. However, weight restrictions are often imposed that constrains the weights of favorable factors to small values. To investigate the importance of a factor and its contribution to the efficiency score, a cluster analysis will be explored to distinguish the dissimilarity of the global engineering programs with respect to the efficiency contributions of the specified outputs/outcomes.

A further analytic step is to seek statistically the DEA efficiency scores by regressing the efficiency scores of each global engineering program with the controllable inputs of the BCC model described above. It is natural then to model them using a censored (tobit) regression, which is designed to estimate linear relationships between variables when there is either left or right censoring in the dependent variable. This follow-up methodology is being proposed as a way of exploring the associations between the DEA efficiency scores of global engineering programs and the GEEP strategies that are employed.

V. STUDY 3- LATENT PROFILE ANALYSIS AS A TOOL FOR UNDERSTANDING GLOBAL PREPAREDNESS PATTERNS

Of particular importance to global engineering research is engineering students' preparedness for global workforces (i.e.,

engineering global preparedness). To this end, the third study aims to profile undergraduate engineering students on different levels of engineering global preparedness as well as evaluate the relationships of engineering global preparedness with different student, institutional, and global GEEP strategy variables (discovered in Study 1). The following research questions are addressed: (1) Can we identify and examine different patterns of engineering global preparedness among undergraduate engineering students?; and (2) How do global engineering education programming strategies affect global preparedness development patterns, and how can we use this information to inform engineering practice regarding curricular and co-curricular globalization strategies?

These questions are addressed by employing Latent Profile Analysis (LPA), a type of latent variable mixture model, which has significant theoretical and practical advantages over traditional techniques when analyzing multidimensional data like global preparedness [12]. The goal of LPA is to identify clusters or patterns of observations that have similar values on latent indicators.

The purpose of study 3 is to identify the typical global preparedness profiles of undergraduate engineering students from 15+ universities across the U.S, resulting in a sample of roughly $N = 4,000$ students. Fifteen of the engineering programs involved in studies 1 and 2 will be the programs included in the LPA. Additionally, the LPA solutions obtained will be compared using different conceptualizations of global preparedness. LPA solutions obtained using a 2-, 3-, and 4-factor model of global preparedness will be explored to better understand if more complex conceptualizations were need to better differentiate students global preparedness patterns. Two primary steps will be used to accomplish the goals of Study 3. First, LPA will be used to classify engineering students into clusters with separate sets of analyses being conducted, one for each conceptualization of global preparedness. Second, hierarchical logit models will be constructed to examine the extent to which profile membership relates to student, institutional, and global programming variables. The extent to which profile membership relates to global experience patterns will be pursued to determine if solutions based on more complex conceptualizations of global preparedness can more accurately predict global experience participation and interest.

VI. CONCLUSIONS

The impetus behind the development of international engineering programming has been the perception that engineering has become a global profession [21]. As a result, engineering programs now have a responsibility to design effective and sustainable global preparedness development strategies for their engineering student populations and, in turn, evaluate the outcomes of these strategies. Results from the proposed research provide understanding regarding sustainable development of engineering global preparedness and broadens the knowledge base about the construction, implementation, and evaluation of global engineering education programming.

Abstract— Employers worldwide are seeking engineers who possess a more complete professional skillset that could be useful in the constantly changing globalized economy. For this reason, engineers are expected to have leadership, communication, and teamwork skills, in addition to analytical skills. Furthermore, they are also expected to have attributes of global competency, which would help them thrive in the global workforce. A plethora of information and studies exist on undergraduate students and how institutions are helping students increase their global competency through methods such as international exchange and study abroad programs. Despite these efforts, there is little information on engineering doctoral students and methods for increasing their levels of global competency. Doctoral students are at the forefront of scientific and technological innovation and discoveries, so it is critical that they are trained to work effectively in diverse environments. This study comparatively examines the intercultural experiences of a) engineering Ph.D. students from the U.S. who traveled abroad, and b) international engineering Ph.D. students who traveled to the U.S. Findings indicate that students tended to prepare themselves for travel abroad in various ways, and that negative experiences of domestic students abroad are related to a mismatch between pre-travel expectations and actual experiences. International students more frequently mention cross-cultural differences, and those with greater levels of support tended to report easier adjustments. Findings can be applied toward helping U.S. and international academic institutions identify strategies to develop graduate students' global competency levels.

Keywords—doctoral students; global competency; study abroad; international experience.

I. INTRODUCTION

The world we live in is a vastly interconnected place. Each country is intertwined and dependent on other parts of the world. Countries will continue to become even more interconnected in the future, and this calls for universities to prepare their students to enter a globalized workforce through enhancing students' global competency levels. While an important concept, many different definitions of global competency have been proposed. One definition of global

competency is the ability to communicate effectively and appropriately in intercultural situations [1, pp. 247]. Based on this definition, global competency would depend on the individual's awareness, skills, and mindset in one's specific cultural setting. For example, specific aspects of global competency can include world knowledge, foreign language proficiency, cultural empathy, ability to work effectively with individuals from different cultures, and ability to practice one's profession in an international setting.

Historically, engineering degrees have been intensive programs in math, design, theory, and physics while classes for developing other skills that would lead to global competency have been viewed as tangential to the engineering curriculum [2]. This phenomenon also holds for engineering graduate studies, where programs commonly promote a high technical preparation while leaving aside other professional skills [3-5]. However, by the time they join the workforce, graduate students will be required to work effectively doing research or performing in industry within an internationalized framework. Some of the problems needing global collaboration have been listed in the National Academy of Engineering's Grand Challenges of Engineering, such as making solar energy economical, providing access to clean water, and engineering better medicines [6]. Therefore, increasing global competency in graduate engineering students is paramount to their success and the future of our society.

This study considers two groups of graduate engineering students: a) domestic U.S. students and, b) international students enrolled in U.S. institutions. We collected qualitative data from interviews including a variety of questions to investigate aspects of students' global competency development: understanding of other's world views, cultural self-awareness, adaptability and adjustment to new cultural environments, open-mindedness, second language proficiency, international experience, leadership, and other relevant information. The goal of this research is to gain more knowledge regarding the experiences of graduate students as they transition and work in a foreign country using a comparative framework between the two groups of students.

II. BACKGROUND

There is some history behind the birth of the need of global competence among engineers. Up until the last few decades, engineering education worldwide has dealt primarily with preparation to work in one's own country [7, pp. 433]. An increase in globalization and mobility in working engineers, as well as concerns with economic competitiveness and employability of engineers has required countries to reevaluate what competencies are needed for an engineer working in such diverse environments. In the United States during the 1990's, engineering education shifted accordingly to creating more flexible engineers to work internationally through establishing new accreditation criteria for engineering programs [7]. European nations have begun preparing their engineers to be mobile and transition to working throughout the entire European Union. Latin America has followed as well by placing more emphasis on global competency in engineers' education [7]. Therefore, the development of global competency is currently an essential quality of engineers.

Nowadays, global competency is a widely discussed topic, and because it has multiple aspects, multiple definitions have been put forth. Deardorff, for example, looked into how people think of and define global competency [1, pp. 242]. Participants in her study were asked to rate multiple definitions of global competency, and broad definitions were more widely accepted. The definition most highly favored was: "Knowledge of others; knowledge of self; skills to interpret and relate; skills to discover and/or to interact; valuing others' values, beliefs, and behaviors; and relativizing one's self. Linguistic competence plays a key role." Her study showed that although global competency is hard to define and is constantly changing, it is important to continue assessing students' global competency levels and the best way to do so is through a mixture of qualitative and quantitative measures [1]. This study uses a qualitative approach to analyze the development of global competence skills among engineering students.

There has been a lot of research on identifying the best strategies to promote global competence among engineering undergraduate students. Universities everywhere are finding ways to prepare their students for practicing in an international workforce, therefore they are interested on finding such strategies. Lohmann et al. [8, pp. 119] have discussed how engineering programs are finding ways to incorporate language preparation, coursework in global studies, and transnational design. In addition, many universities offer a co-major or dual major program in which students earn two bachelor degrees, one in engineering and the other in liberal arts or international studies. Other options include certificates in international engineering and many institutions also encourage international experiences, where the most common form for engineers is research or study abroad [8]. Downey et al. present more information on global competency in engineering students and show that international experience is one of the best ways to instill global competency [9, pp. 111]. International enrollment specifically pushes students out of their comfort zone and immerses them in another culture for a longer period of time. Other methods of increasing global competency are international projects, international work placement, international field trips, and integrated class experience.

Although there is still debate about which strategies are more efficient.

Within the analysis of students' experiences abroad, it has been shown that short-term periods of study abroad positively affect the development of intercultural sensitivity [10]. However, there is also evidence that longer periods of stay have more significant and enduring impact on students [11]. Also, Douglas and John-Rikkens have shown that the difference between a student's point-of-origin and the location of a study abroad program would have a positive effect on the students' development of worldmindedness, defined as "the extent to which individuals value the global perspective on various issues" [12]. Therefore, these factors have been already pointed out for consideration when students' decide the international endeavors they may undergo.

Even though the research on understanding the effects of students' experiences abroad is vast, it is mainly focused at the undergraduate level. However, the experiences of graduate students may differ from those of undergraduates, since graduate students tend to be older, have different academic expectations, are involved in research, and may have different worldviews and understandings. Therefore we should consider these differences when analyzing the development of global competency skills of graduate students.

It is important to start analyzing these effects on students at the graduate level since they will be also facing the challenge of joining a global workforce. Gearon [13] has pointed out that graduate students should seek having international experiences that would make them more competent professionals. He mention the efforts of different institutions supporting graduate students achieving this goal in the areas of medicine, law and engineering [13].

Furthermore, in engineering, the proportion of international graduate students tends to be larger than in the undergraduate population, therefore we must consider the potential differences in their experiences developing global competence due to their international status. Research has shown that international sojourners have usually lower adjustment rates than domestic U.S. students when relocating at U.S. universities [14], but to the best of our knowledge there is no literature on these differences at the graduate level.

Some studies have explored how the international experiences affect graduate students; however, these analyses have been mainly focused on international students in the U.S. [15-16]. For example, in the qualitative analysis performed by Jiang, Chinese engineering graduate students were interviewed to understand their intercultural learning process during their time attending U.S. graduate schools [16]. The results showed that even though the students were exposed to a high diversity of cultures and people, they did not to recognize any changes in their mindset in terms of their "values and beliefs, prejudices and stereotypes." The students reported that language barriers and cultural differences were their main challenges to engage in inter-cultural interactions [16]. They also reported detraction from looking for opportunities to interact with individuals outside of their comfort zone because of the presence of a strong peer-network of other Chinese students. In the academic aspect, students also reported to be challenged to adapt to the

independent learning style, and struggling with the lack of instructions or guidance [16]. Other studies have explored the experiences of Indian engineering graduate students in the U.S. in terms of their acculturation [17] and shifts in their own cultural expectations [18]. The analysis of the experiences of international graduate students in the U.S. has also include exploring the factors determining the students' levels of satisfaction with their academic programs and their social relationships [19]. Perruci and Hu reported that the level of contact with U.S. students, language skills and perceived levels of discrimination were strongly correlated with the student' level of academic satisfaction [19].

On the other hand, the analysis of the experiences of U.S. domestic graduate students abroad it is also very limited. Sciaky et al. [20] based on the claim that "graduate students who gain experience practicing science outside the U.S. will be better prepared to participate in [the] global scientific community" analyzed the experiences of about a dozen graduate students going abroad for research experiences and conclude that the challenges they faced were generally overcome and outnumbered by the perceived rewards.

Analyzing both groups of students: domestic U.S. students going abroad and international students in the U.S. would have value due to the different perspectives and challenges they hold. Therefore, further study is needed to show how global competency can be developed among engineering students at the graduate level considering both of these groups.

Thus, by examining comparatively international graduate engineering students attending U.S. institutions as well as domestic graduate engineering students in the U.S. we envision to contribute to the current body of knowledge that is more focused on the global competency gains of undergraduate engineering students. Finally, we aim to contribute identifying strategies to effectively increase these global competencies among all graduate engineering students. It is envisioned that these strategies will inform program administrators, graduate programs, and key stakeholders to make decisions aligned with preparing engineering graduate students for working in diverse environments.

III. METHODS

We conducted interviews to delve deep into students' global experiences. We administered these interviews to graduate engineering students at a large, research-intensive Midwestern university. The respondents vary in their engineering discipline. We interviewed four domestic U.S. graduate students who traveled abroad for conferences or research. For comparison, we interviewed eight international students who traveled to the Midwestern institution for graduate studies. After conducting the interviews they were transcribed by a private third party, we analyzed the transcripts using open-coding and thematic analysis in Dedoose software. We considered this method appropriate for the exploratory nature of this research.

IV. ANALYSIS AND RESULTS

A. Experiences of U.S. Domestic Students Abroad

We interviewed four domestic graduate engineering students, three men and one woman. Their lengths of stay varied between one to three weeks abroad for reasons such as an international conference or conducting research. The three research questions that were used to build the interview protocol, were the following:

- 1) *How do students prepare for their international experience?*
- 2) *How would they describe their experience?*
- 3) *How relevant are their experiences to their personal and professional network?*

In this section the evidence gathered from the analysis of the students' responses are summarized according to these research questions.

a) Preparation to go abroad

Besides the academic preparation (preparing a poster or a presentation), the students reported on preparing themselves through self-led online research about the things to avoid doing while in the host country. They expressed a concern on being respectful of the host culture. Students were not really interested in preparing for the language in the host country, since their stays were relatively short and all the people involved in the events they attended were able to speak English at a certain level. However, the student with the longest stay reported challenges to navigate the city due to these language limitations. They also reported doing some research about the touristic attractions in the host country since they considered these trips "*once in a lifetime*" opportunities.

b) Assessment of experiences

Students reported their experiences in terms of the differences they perceived between the U.S. and the country they were visiting. We classified these differences as neutral, positive, negative. The neutral differences were those where the students did not express positive or negative feelings attached to them. Their reflection on these differences can help them assess their own graduate experience compared to those students in the host country and reflect on the weight of their cultures into their work styles. The neutral differences students found by the students between the U.S. educational or research experience and that in the host country include:

- a) ***Cultural structures and the relevance of hierarchies***, for example, a student talking about the structures in the host country mentioned: "*the culture is very, very polite and you're very respectful of anyone who; a) is older than you, or b) has a position above you. So, it was really important like even just speaking to someone that you were very conscious of that and respectful.*" Acknowledging that this may be different from the style in the U.S. where students can often refer to professors

by their first name if that is the way they introduce themselves.

- b) **Work structures**, students perceived that graduate students in the host country worked longer than they usually do and that they are more dependent in supervision, and
- c) **Security levels**, students perceived that research institutions in the host country had higher security standards than those in U.S.

The identification of these differences can help establishing more efficient and successful research partnerships or work relationships in their future careers.

The positive experiences reported included academic growth due to the exposure to researchers from different places giving feedback to their work. Furthermore, they cited that their exposure to a different culture was something they enjoyed. As visitors they also got a good impression of the locals as they were always helpful towards tourists. It is envisioned that these positive experiences could help to set expected outcomes to plan the foreign forays for other students.

The few negative experiences they reported could be related to high expectations that the students were holding before going abroad. The student with the longest stay mentioned that the people in the host research laboratory did not have time for him, and that there was no specific project for him to work on. Another student reported how his expectations about the neatness of the host city were high; in consequence, seeing a relatively dirty and overpopulated city was something unexpected and disappointing. The exploration of these negative experiences helps noticing the relevance of setting realistic expectations before going abroad and can help on making recommendations to avoid the recurrence of similar episodes for future students.

c) Relevance of Their Experiences to Their Personal and Professional Networks

Students reported that they found it useful to meet different professors that may be helpful later in their career, as connections or potential employers. However, when questioned about other types of professional networks built, one student reported that he aimed to keep in touch with the people he met at the hosting institution but he did not succeed.

B. Experiences of International Students in the U.S.

We interviewed eight international graduate engineering students to obtain more in-depth information surrounding their global competency and experiences in the U.S. (six men and two women.) Students interviewed were from Colombia, Brazil, India, Pakistan, and China. The following three research questions were used to build the interview protocol for international students:

- 1) *What is the student's background and what were their experiences before moving to the U.S. to study?*
- 2) *What types of interaction do they have with U.S. citizens and U.S. culture?*

3) How has studying in the U.S. affected their future plans and career goals?

The interview transcripts were analyzed using thematic analysis. In this section, we present the main four themes emerging from the analysis. We also consider some suggested implications for the challenges to improve global competency among international students.

a) Stronger focus on differences than similarities

Interviewed international students consistently seemed to highlight cultural differences more often than similarities. Two interview questions asked them to compare their experiences in the US to their experiences at their home country, although did not explicitly use the word "differences." Only one question asked them to highlight their differences between their experiences as international students to other international students from different countries of origin. However, within this analysis, students mentioned differences between cultures ten times more than they commented on similarities. Students mentioned various differences between cultures as well as in their academic experiences.

Cultural differences that were mentioned when they compared their experience in the U.S. to that in their countries were:

- People in the U.S. seem more independent, having their own personal space and privacy, and a generally self-driven culture.
- The U.S. is more culturally diverse, especially in a university setting.
- There are higher levels of awareness about social issues pertaining to gender and race within the U.S.

Students also mentioned differences in academia, for example, some students mentioned that they like the academic system in the U.S. and that they have access to more resources through it. All over, most students mentioned they have more opportunities academically in the U.S.

It is important to recognize cross-cultural differences as these students have done, but this tendency of disregarding similarities between cultures may represent a limitation in developing global competency. One student reflected on the importance of recognizing cultural differences and trying to understand and learn from those differences mentioning: *"Listening and being aware of the differences is the first step in trying to establish a good process of adaptation and... it's a lot of listening instead of reacting and reflecting and acknowledging the differences. That helps me to adapt or adjust to new culture."*

Miville et al. [21], presented the construct of *universal-diverse orientation* (UDO) which reflects "an attitude of awareness and acceptance of both the similarities and differences among people." They developed a tool (the Miville-Guzman Universality-Diversity Scale, MGUDS) that has been extensively validated in different versions to measure global competence among different professional areas [22]. It has also been used to measure global competence among engineering students [23-25].

From the UDO definition, we can observe that acknowledging and appreciating similarities can be equally important than the appreciation of differences. Therefore, helping students start recognizing and valuing similarities between their culture and the culture in the host country would play a role in increasing their global competency and being ready to transition into the global workforce. Universities are advised to take action accordingly, and try to find ways to shape graduate engineering students' comfort with differences and enhance their appreciation of differences as well as their appreciation of similarities between cultures.

b) Relevance of family ties and support

Our interview protocol only contained one question mentioning family explicitly: "How did you prepare yourself to live in the U.S.? For example, mentally, legal/visa issues, talking with friends or family, financially/scholarships, etc." Although it was only prompted to be discussed once, participants talked about family ties throughout other portions of the interview. We may infer that those who mention their family more frequently have greater levels of support from their family, which helps them in the transition to moving to another country. For example, previous research on Latino families, that may be applicable to other types of families, shows that better family functioning and emotional support provided by family members leads to lower rates of depression and greater emotional adjustment in college students [26].

Family ties may lead to higher levels of global competency in different ways. Family trips and vacations may expose the students to the U.S. or other countries and inspire them to travel and live abroad later in life. Trips to the United States, or other English speaking countries, also give students a chance to practice and develop their English skills, which may give them more confidence that they can successfully live and study in the U.S. on their own. Furthermore, family may offer financial support that allows the student to study in another country. International students have greater fees to study at U.S. institutions, not to mention extra expenses due to travel. Having financial support is very helpful in assisting with the transition to another country. Although we acknowledge that families able to afford vacations abroad may be part of higher socioeconomic status in their country, a deeper analysis of the composition of graduate students in terms of their socioeconomic level and their dependence on other types of funding (e.g. scholarships, loans, etc.) could strengthen our conclusions on this type of family support.

Family offer a network of support for the student as they transition into another country and culture. A caring family may give the student the encouragement needed to make the move to another country. In addition, students can also turn to their family connections for advice after arrival in the host country. Furthermore, having family to turn to during times of distress makes the new atmosphere much more manageable. Having the support of family in the country of destination may be another factor influencing global competency. Many participants mention that they have family living in the United States, and that as graduate students they visit these family members. These trips within the U.S. increase their rate of cultural exchange.

Furthermore, some students have spouses living with them in the United States, which gives them another person to share this experience with and rely on. These findings are consistent with Poyrazli's, who showed that married international students would have higher levels of social support [27]. Having a spouse gives the student another person to go out and be involved in American culture with and attend outings and cultural events that the person may not have gone to alone. Having close family members' best interests in mind may make the person more willing to try new things and immerse themselves in the offerings of the new culture. In addition, university organizations can play a role in fostering these familial ties. One student mentioned his experience being paired up as an international student with a family in the U.S. for cultural immersion, having the opportunity to explore the culture through sharing different events such as Thanksgiving. This student's experience shows that students can get involved with other families aside from their own to increase their global competency and expose them to more cultural events. Family support may be a factor in higher levels of global competency and adaptation to the change of a new culture.

c) Networks of Support/Advice

A strong network of support and advice may lead to easier adjustment to a new culture. Cohen and Willis [28] found evidence of the use of social support (perceived as interpersonal psychological and material resources) as a buffer against stressful and potentially adverse situations. This was named the "buffering model" [28]; our results are somewhat aligned with this model. The amount of advice and mentorship the students received varied. Students mentioned many things that they got help with or needed advice on: paperwork and legal issues, housing choice, U.S. customs, and transportation, for example. The student expressing the highest number of difficulties while his graduate studies received little advice before their departure and also had less mentorship in the U.S. These findings are consistent with those of Poyrazli [27], who demonstrated that international students with higher levels of social support had less acculturative stress.

Most students received extensive advice before they arrived in the U.S. Many students received help with legal paperwork and their application to graduate school as an international student. These students received advice on how to survive here as well: safety, transportation such as bikes and cars, and where to live and what kind of apartments to rent. All of this preparation will make a student more adept at adjusting to the new culture. The positive impact of social support on cross-cultural adjustment was also studied by Adelman in the late 80's [29], when she analyzed how the informal networks of support positively impacted the cross-cultural adjustment of sojourners before departure and after their initial entry to the visiting country. In this context, a student mentioned that the support received from networks of friends helped them adjust socially: "*My friends and my colleagues have helped me figure out how to mingle with the American and become more a citizen of this country.*"

Many students in our sample were supported financially through their home institution or through some other type of funding. Having less worries about money in a foreign country

may make the transition easier for these students. Some students are already professors at their home institutions and are receiving financial support through these universities. Two students reported being funded through the Fulbright Program, which in addition to financial support gave them extensive preparation and advice on the transition to the U.S. One of them mentioned: *"They help you through the whole process. All the exams, all the tests...."* This positive impact of the Fulbright program is an indicator of its success in its intention to prepare global scholars that "advance international education and access to education worldwide" (www.fulbrightonline.org). Fulbright and other programs alike have played a significant role on promoting the global competency of engineering students in the U.S. through supporting and promoting studying abroad experiences [30].

Students also mentioned academic support, such as academic advisors. Many of these experiences are shared by the students with higher levels of global competency. The student reporting the most challenging financial difficulties in his time at graduate school expressed the need for someone to guide him by commenting: *"I think every student should have somebody who guides them. It's especially important for international people who come into this new environment. They're trying to adjust to this new setting and trying to understand what is going on. I wish I'd had a mentor."* Every student would benefit greatly from more mentorship and advice about the transition to living in another country, both before and during the transition.

d) Participation in U.S. culture/hobbies

From our analysis, we can infer that students that most frequently mentioned involvement in U.S. culture were those describing having better experiences. These results support literature reporting that international students' interactions with members of the host culture help them achieve better adjustment outcomes [31-32]. The student reporting the most frequent interaction with U.S. citizens and therefore U.S. culture, mentioned social activities such as hanging out with friends, cooking and hosting dinners for friends, going to the bars, and playing in a band.

Many students mentioned hanging out with friends, joining sports teams or collegiate clubs for example as part of their participation in U.S. culture. Interestingly, the two participants with the most negative experiences during their time at the U.S. reported having more solitary hobbies such as reading, doing research, bible study, or orchestra. One of these students commented on his opinion about not needing to interact with new people by saying: *"You don't need to approach others to officially like.... other cultures. If you just feel good, why do you need to change yourself?"* In general, students that did not interact with the U.S. culture did so because of lack of time, unease in such situations, language barriers, or lack of information on campus social events. Some research has been done to study the limitations of international graduate students on improving their intercultural learning process in the U.S. For example, Jiang [16] explored the experiences of Chinese graduate students in engineering programs in the U.S. and found that language barriers and cultural differences were their main challenges to engage in intercultural interactions, as well

as the existence of a strong peer-network of other Chinese students that helped them stay in their comfort zone [16]. These findings present universities with some suggestions on how they can engage international students. For example, universities can increase communication about campus events to engage international students.

Another finding from our research is that all of the participants have changed their hobbies since their arrival in the U.S. Some reasons cited for these changes were: moving to a different type of city (metropolitan area to the country), changes in weather patterns that force them to stay inside more. Students also reported increased levels of stress, either from moving to another country or from high requirements from their graduate program that forced them to take on easier and more relaxing hobbies. Students also mentioned changes in amounts of free time, however some reported more free time and others reported less free time. All of these changes in lifestyle have forced the students to find different hobbies in the U.S. that fit into their new schedules. How well students adjust to these differences may contribute to their levels of global competency.

Interestingly, every participant mentioned fitness, sports, and working out as a priority in their lifestyles. Participants mentioned a variety of hobbies such as swimming, martial arts, soccer, biking, working out, intramural sports, basketball, and attending and watching professional sports games. It has been documented that being active is a great way to relieve stress [33], and may be even more important for students adjusting to a new culture. One participant mentioned that her interaction with sports has helped her endure the culture shock. Furthermore, joining an intramural sports team may be a great way to start interacting with U.S. citizens. Since all of our participants mentioned fitness as a part of both their lives at home and in the U.S., it may be beneficial to create strategies considering this fact to promote the interaction of international and domestic U.S. students such as fitness clubs or sports leagues.

C. Comparing U.S. domestic and international graduate students experiences

It is important to relate the experiences of domestics abroad to that of international students in the U.S. For example, both groups of students frequently detailed differences between their country and their host country. Domestic U.S. students reported differences were analyzed to a greater depth, and we classified them as neutral, positive, or negative. This pattern was also seen in international students, however it was not reported in the scope of this paper. We suggest that both groups of students need help in drawing similarities between cultures which may help them with their adjustment. Another similarity we found is that both groups reported preparation before their trips. However, the domestic U.S. students often reported self-led preparation because of their relatively short length of stay.

On the contrary, international students preparing to live abroad for a longer period of time ranged from self-led to receiving extensive mentorship and advice before and during their move. Because the international students were preparing for a longer

stay, they often received more help. Also, the U.S. students did not prepare to speak the host country's language, whereas many of the international students coming to the U.S. reported studying and practicing English. We found that both groups would benefit from greater preparation and mentorship. Additionally, both groups reported making network connections or having academic opportunities in their travel experiences. It appears that the international students made more long-lasting connections, which can be explained by their longer lengths of stay. However, both groups reported overall academic benefits from their travels. This shows that international travel is indeed beneficial to students' academic growth and global competency development.

V. DISCUSSION

This work explored how the experiences of graduate engineering students influenced their development of global competency. This was performed through students' interviews. First, our analysis of domestic U.S. students going abroad explored how they prepared for it, how their experience was, and how relevant were these experiences for them. Students explored the culture in the host country before traveling to guide their behavior appropriately. They reported positive gains in their academic development and were highly reflective on the different structures in both culture and working styles between the U.S. and the host country. The negative experiences reported by students could be linked to unrealistic expectations they previously had.

Second, the analysis of international students in the U.S. gave evidence of different areas to consider for harnessing the acquisition of global competency. Students were more likely to talk about cultural differences than connect similarities; we consider that the reflection on similarities would improve the development of global competency and would enhance students' adaptation to the host country. Another result was that students with greater family ties as well as networks of support, both in the U.S. and their home countries, had greater levels of global competency. Parallel to this, there was a positive correlation between access to networks of support and levels of global competency. These networks can be really helpful for the demanding transition of living abroad. Furthermore, every participant in our study frequently mentioned sports or fitness as an integral part of their lives, even though their hobbies had changed from the time they lived in their home country.

There were no identifiable themes related to students' plans other than that most of the international students planned to return to their country of origin either after finishing their degree or after obtaining some professional experience in the U.S.

There are different limitations to this study that should be considered. First, we conducted the analyses with a relatively small sample of students from only two different engineering graduate programs. Second, our sample of international students was composed from students coming from only 5 different countries. Five interviewees were from South America, which could represent a bias towards the Latino experience in the U.S. and could represent lack of

generalizability to students coming to the U.S. from other countries. A more varied group of interviewees from different countries and more graduate programs could help to overcome these limitations.

VI. CONCLUSION

Our work can be summarized with three main findings. First, domestic students regularly prepared themselves for their experiences abroad through self-led preparation in order to be culturally appropriate. Furthermore, the few negative experiences they reported are connected to higher expectations formed before their trips. Therefore, better advising from mentors that have had experiences abroad would be useful to avoid having unsatisfied expectations.

International students studying in the U.S. frequently discussed cultural differences rather than similarities. These students tended to have low comfort with differences. These two traits may be a hindrance to building global competency. Universities are advised to help students in findings cross-cultural similarities and become more comfortable with differences. Additionally, international students with greater support from family, friends, and mentors had better adjustment outcomes. Universities are advised to help foster these relationships both before and during international students' traveling experiences.

VII. IMPLICATIONS AND FUTURE WORK

Our results about the experiences of domestic students abroad imply that it is important that sponsor organizations, as well as academic advisers and mentors, help students develop realistic expectation about their future experiences abroad. Academic advisors have usually been more exposed to international experiences, therefore could support students in this manner.

Our research shows that graduate engineering students are more likely to perceive cross-cultural differences rather than similarities. Our work also shows that students have low comfort with these differences. We suggest that universities take action accordingly and find ways to foster cross-cultural understanding and increase comfort with differences between graduate engineers. The evidence found about the relevance of family ties in the development of global competency would imply a possible strategy for universities to help students develop this trait. Cultural exchange programs that pair up international students with U.S. families have proved to be an efficient strategy to help speed up students' acculturation. Higher support to these type of programs would be suggested.

The development of different networks of support or advice would be an invaluable resource to adapting students in the U.S. Promoting structures of incoming advisors or student committees to help students before and after arrival could have a good impact on alleviating incoming students' burden. Our findings present universities with many suggestions on how they can engage international students in U.S. culture. For example, universities can increase communication about campus events to engage international students. Universities

can promote sports leagues as a place for cross-cultural engagement as well as a way to release stress that comes with the transition to another country.

Universities should enhance their graduate engineering students' international experiences in a way that those trips contribute to the development of global competency in a better way. Our studies show that students need to increase their appreciation of these diverse experiences and also their comfort with cultural differences.

Future endeavors on this research line will include longitudinal analyses of the development of global competency among graduate students, gathering data from different institutions, as well as different programs and among students going abroad to or coming to the U.S. from a wider variety of countries.

A Semester-Long Study Abroad Model for Engineering Students

The Unified Project Approach

Abstract— Study abroad programs have nearly doubled in the last ten years. Studies show that students who study abroad are better prepared for success in their respective fields of interest. This is no less true for engineering students. But engineering schools have been very slow accepting the challenge of providing study abroad opportunities to students, due perhaps to the rigidity of most engineering curricula which were developed in the last century. This trend is changing, however. The largest increase in students studying abroad are STEM students – in 2012/13 9% overall were from STEM disciplines and 2/3rd of these were engineering students. Many universities offer short-term study abroad programs for engineering students designed to be held during the summer. These short-term programs strive to accommodate those who cannot afford to delay their coursework. It can be suggested that semester-long programs provide greater cross-cultural benefits but providing a study abroad curriculum that fits the stringent engineering requirements can be difficult. The College of Engineering at The University of Oklahoma has developed an engineering study abroad program that offers key engineering courses chosen to fit a wide variety of discipline-specific engineering curricula. The key to success in any program is faculty involvement. In order to promote faculty involvement the course work is broken into concentrated four-week blocks taught by different engineering instructors, providing an opportunity for professors with active research programs to share their current expertise with the students in a foreign setting. In order to provide a cohesive educational experience, a Unified Project is developed that has components that relate to each course and which takes advantage of opportunities offered by the host country. This study model is expected to provide smooth transitions from one concentrated course to the next, while providing the students with the cross-disciplinary and cross-cultural experience that engineers will need to compete on a global marketplace.

Keywords—*Study Abroad, concentrated block study, unified project, Engineering Study Abroad*

I. INTRODUCTION

Undergraduate engineering students remain underrepresented in study abroad programs across the United States. This is a result of many factors, which often lead to the omission of a study abroad experience in engineering

programs. Major factors include the sequential nature of coursework, rigorous curricula, accreditation constraints, pressure to maintain high grade point averages, access to professional internships, and funding opportunities. Yet the refrain continues across the higher education community that our responsibility and charge is to graduate students with international awareness, cross-cultural skills and sensitivity. Indeed, future employers see this as a necessity under the paradigm of a global economy. This is clearly expressed by Ken Kohrs, former vice president of the Ford Motor Company, and quoted by Parkinson in [1]. Globalization is a key theme in all disciplines and engineering represents a key area where international cooperation may be the underpinning to technology access across the globe [2]. If modern stereotypes of engineers have any basis in reality, our engineering students would benefit greatly from the development of greater international awareness and cross-cultural skills.

II. PURPOSE OF PROGRAM DESIGN

A. Initial Program Alignment

The University of Oklahoma (OU) College of Engineering (CoE) has been engaged in promoting study abroad experiences for engineers for several years, with courses being offered in both summer programs and a full fall semester regimen. Study abroad for engineers is a growing effort amongst US universities [3,4] with many different approaches. In keeping with national trends, the most popular options among students are summer programs that do not disrupt the required course sequences that occur during the regular academic year [5]. But students and educators alike acknowledge that the truly transformative study abroad experiences occur in programs of significant duration, cultural immersion, and required adaptation [6]. Therefore, the most widely submitted study abroad requests among our students begin with an inquiry for a semester-long program that offers the right set of engineering courses that permit them to stay on track, yet provides the opportunity for a transformative global experience.

Toward this end, over the three fall semesters of 2012, 2013, and 2014, the CoE developed an engineering curriculum

approach at our flagship program in Arezzo, Italy, that fit within a myriad of academic issues or needs. The first issue was to offer engineering courses with broad appeal to attract greater student involvement. Engineering disciplines have become highly compartmentalized, making it difficult to offer a series of engineering courses that provide degree credits for engineering students from different disciplines. Careful consideration was given to selecting courses that were common to most engineering disciplines, such as Statics and Engineering Statistics. Other courses were selected for their popularity and flexibility in topic design. In particular, OU offers a course called Measurement and Automation that deals with data collection, sensor analysis, and measurement theory. Because computerized data collection and analysis are fundamental to all modern engineering disciplines, multiple small projects are easily constructed to which students can relate their studies. A fourth course offering provides an elective engineering credit in the area of technology history. The Disruptive and Innovative Technologies Ideation course examines the historical scientific context in which major technological shifts have occurred, and is well-suited for the cross-cultural environment of study abroad.

Another issue was the cost-effective deployment of faculty to lead the courses in Arezzo. There is a significant cost required to accommodate three or four professors for an entire semester in a foreign setting. A secondary constraint in this regard was the need to ensure ABET accreditation criteria were properly accounted for to ensure proper student credit toward their degree. It was essential to send faculty who have continually been vetted by the university's accreditation efforts. However, most engineering faculty have active research programs requiring significant time commitment. Indeed, typical engineering faculty work breakdown suggests that 40-50% of their time is allocated to research. Thus it is difficult for a professor with an active research program to commit to being out of the country for an entire 16-week semester. To alleviate this problem, a block course method was incorporated in which a single three-credit semester course in engineering was taught in a concentrated four-week block. This provided for a single housing solution for the engineering professors, while also alleviating the need for them to attain work/teaching visas required by Italian law. This model has reduced program costs for the CoE, but has also promoted involvement of faculty with active research areas. This is essential in promoting global engineering education environments because these faculty are most familiar with the current state of technology and can best relate the course work to both the local venue as well as broad intercultural engineering issues.

A final issue to address was the need to form a connection between the relevance of studying engineering subjects abroad with the international experience. Although engineering curricula are still fairly rigid in their requirements, ABET accreditation is changing the focus of assessment to include abilities such as *communication skills* and *teamwork* [7]. General education requirements are intended to help satisfy these less objective skill sets, and it is important to offer to the engineering students general education courses in areas of their interest, such as the history of science, engineering as a

business or the impact of technology. Because OU already had a study abroad program in Arezzo, it was an ideal environment in which to form a partnership between the humanities and engineering. Each engineering student is required to take a one-semester Italian class that introduces the practical aspects of the language, as well as a cultural analysis of the local environment. Because ABET accreditation concerns are not an issue in general education courses, this course is taught by local educators who are well-versed in Italian culture. Moreover, students are encouraged to take the Art History course offered each semester. Even when they choose not to officially enroll in this course, students are required to attend the field trips as a guided opportunity to explore other cultures, both current and historical. The engineering professors also attend the field trips and, after the Art History professor finishes a discussion, the engineering professor initiates a discussion on engineering elements of interest. So while the art history professor may discuss the artistic merits of a statue, the engineering professor may discuss why or how the statue is similar to a cantilever beam, or they may discuss the room itself. In this manner the engineering and liberal arts students learn that their worlds are interconnected and are much richer for it.

B. Modified Engineering Study Abroad Design

After establishing the program and acquiring feedback for the first semesters, several modifications are being implemented for the fall of 2015, and are the subject of this Work in Progress (WIP) paper. While the concept of block scheduling for engineering courses received positive feedback from both professors and students, one shortcoming that was identified was the need to provide a smoother transition between the concentrated areas of study. The initial test of the new structure is designed around the original four courses: Engineering Statics, Engineering Statistics, Measurement and Automation, and Disruptive and Innovative Technologies and Ideation. However, the structure of the model is the focus of this WIP and we expect it to be extendable to other course offerings. The future structure is detailed in the following paragraphs.

III. UNIFIED PROJECT APPROACH TO STUDY ABROAD

The intense four-week block schedule for engineering courses in the OU study abroad program can make the transition from one course to another rather abrupt. While the students enjoy getting to know each professor in a small classroom environment, which is extended through field trips and other community activities in which all study abroad participants take part, the discontinuity between courses is sometimes difficult for the students. To address this shortcoming, we have designed the engineering curriculum to provide a unique, full-semester project experience that unifies the disparate topics being taught. Synchronizing four different faculty members over several different engineering disciplines is made possible by a new emphasis on pre-departure organization both on a curricular and logistical level.

The *Unified Project* approach relies both on flexible course content and order of instruction. The project concept is intended to encompass several engineering disciplines because this is a hallmark of engineering projects that students will face

in the workplace. Indeed, many projects require a breadth of knowledge that should be reinforced during a student's college years, rather than after the fact once they face the situation as a practicing engineer on a project team. The courses taught and the material studied are detailed in order below.

A. Measurement and Automation

Analysis of data based on theoretical development requires some type of data set to be most effective. This is the premise of experiential learning. Toward this end, the concepts of measurement through data acquisition, data analysis, and control are studied first. This process leads to the acquisition of a set of data that can be studied in the Engineering Statics class. Necessarily, these data should be related to structures, so sensors common to structural analysis are studied. During this course students are exposed to the concepts of sensor types, bandwidth, sampling rates, dynamic range and resolution. The four-week block culminates in the acquisition of data related to a structure or sculpture of historical significance. This not only prepares the students with a data set for the following courses, but begins to associate the local culture with the engineering activities. In the fall 2015 semester we will acquire data on Michelangelo's *David*, a statue of some historical significance.

B. Statics

Statics is an engineering course required in several engineering disciplines, making it a useful course for a study abroad program. In an historical setting such as the OU Arezzo campus, much of the related material is architectural in nature. This environment provides a plethora of opportunities to study the theory of statics and examine extant examples to promote a practical understanding of what is traditionally merely classroom-only theory. The four-week block in Statics culminates in a practical application of lecture topics to the structural model data collected during the Measurement and Automation block. In the fall 2015 semester the data the students collected for Michelangelo's *David* will be used to compute the centroid and determine the weight of the statue. This will lead to calculations of gravity and lateral forces plus shear moments, culminating in a discussion on stress and the engineering limitations of Carrara marble.

C. Engineering Statistics

Engineering Statistics is a required course across most engineering curricula for good reason. Measurement is always subject to error, and the processes being measured generally have a random component. Although measurement and process error is briefly discussed in the Measurement and Automation block, particularly from the filtering aspect, the underlying statistical theory is not discussed. However, the data sets collected in the Measurement and Automation block are prime examples of the information corrupted by measurement error. This provides a rich data set to which statistical theories can be applied as they are developed in lecture. Also, the students have an understanding of data collection methods at this juncture, so the Statistics professor has an opportunity to collect other measurement sets for analysis.

A unique feature of study in Europe is the transportation infrastructure, particularly the train systems. American

students are much less familiar with this mode of travel which is extremely commonplace in Europe. Train schedules have profound statistical qualities based on usage patterns and this provides yet another opportunity for connecting the engineering theory, application, and local culture. This particular study is the quintessential study-abroad experience.

D. Disruptive and Innovative Technologies Ideation

The final four-week block is devoted to a course developed at the University of Oklahoma called Disruptive and Innovative Technologies and Ideation. This is an elective engineering course available to all engineering majors. This class studies the engineering principles of major technology shifts and their impact on society. Clearly, the Italian Renaissance created some significant technology shifts, and while the course is not restricted exclusively to Italian contributions, it provides the substrate to discuss some of the technology used earlier in the semester, and to analyze how the disruptive technologies around the world have affected Italian culture. This course provides engineers with an opportunity to expand their professional and ethical horizons in an intercultural environment that, it is expected, will create a deeper understanding of how technology and culture intersect. In the fall 2015 semester we will discuss how Michelangelo's *David* is an expression of art, but also an expression of Florentine engineering technology; and, when coupled with its originally intended setting of the Duomo of the Santa Maria del Fiore cathedral, it is an expression of power.

E. Semester Outline

Figure 1 shows the general progression of coursework through the semester. Each four-week block constitutes a 3-credit hour engineering course, meaning students can attain 12 credit hours designed to be applicable to each individual engineering degree. The classes meet for a total of ten hours each week, which is divided into three days. This ensures that the required contact hours are satisfied and allows time to develop theory and discuss application during each class. However, it also provides the students time to be involved in the other course offerings that are the cornerstone of expanding the engineer's cross-cultural literacy. Indeed, ensuring that the engineering students participate in the broader social context of study abroad is essential to their experience.

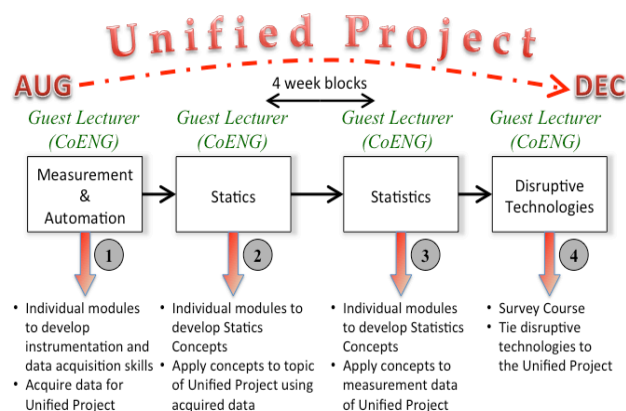

Figure 1 Engineering Course Progression for Unified Project

IV. CULTURAL EXTENSION IN ENGINEERING

It is a hallmark of US study abroad programs to integrate the student into the local or host culture and its history. Though the pervasiveness of this concept is fundamentally a representation of its importance, it should be noted that some students report that they did not feel integrated. OU engineering students are given ample opportunity to integrate via local language exchanges, engineering-based internships, volunteer activities, as well as via guest lecturers. Although engineers are often considered to be single-minded and unaware of more social, “right-brain” issues, understanding the relationship between art, culture, and technology is well within their grasp. The OU Arezzo campus offers an Art History course that studies some of the world’s classic artworks in the first person. This is a particularly effective time in history for engineers to study art, as many of the Renaissance artists studied math and science extensively, developing some fundamental concepts that are taught as fundamental ideas in art, and STEM, classes today. Perspectivism, optics, and the geometry associated with it were essential products of the Italian Renaissance. Moreover, the tools of science were artistic works themselves, and it is a seminal experience for the engineers to be exposed to these works of art and make that connection between culture and science.

V. CONCLUSION

The University of Oklahoma College of Engineering Study Abroad program in Arezzo, Italy, is a growing program that has a unique structure designed to expand the involvement of both engineering students and faculty. The concentrated block-study model provides the opportunity to engage a greater variety of professors who might not otherwise feel they can afford to spend an entire semester abroad. Our Unified Project model delivers a series of courses that have a

logical connection that enhances the semester-long studies that the students experience, while providing them with a solid set of engineering classes that can be counted toward their degree. This is essential to promote semester-long study abroad so that students do not have to worry that they will lose a semester in terms of graduating on time. The first offering of the Unified Project model will occur in Fall 2015. Assessment methods are being developed to measure the qualitative and quantitative results, and will be reported when available. We believe the growing program numbers are indicative of a successful program, and the Unified Project will provide that next step in the university’s goal of expanding study abroad opportunities to all undergraduates.

Learning Philosophies: A Glimpse into Students' Approaches to Learning

Natascha M. Trellinger and Michael C. Loui

School of Engineering Education

Purdue University

West Lafayette, IN, USA

ntrellin@purdue.edu, mloui@purdue.edu

Abstract—A learning philosophy, as discussed in this paper, is a collection of beliefs about how one learns and approaches learning activities and tasks. Learning is often studied from the instructor's point of view, but learning from the student's perspective is not examined much. A baseline understanding of how students learning philosophies might be disclosed and interpreted are described by the nineteen student responses to an open-ended survey in an undergraduate elective course titled "Engineering in Global Context." The findings suggest implications for course and curriculum design in order to promote higher levels of thinking and to develop appropriate epistemological beliefs. Partially through the lenses of Bloom's Taxonomy and Schommer's Epistemological Dimensions, this paper offers a glimpse into students' conceptions about learning.

Keywords—Learning Philosophy, Bloom's Taxonomy, Epistemological Dimensions

I. INTRODUCTION AND LITERATURE REVIEW

Classrooms are steadily transitioning to being more student-focused than ever before. Course design and pedagogy have truly begun to engage students in active learning by incorporating the students' thoughts and opinions into classroom activities [1]. However, course design and pedagogy could be improved by better understanding what students are thinking about their learning. Do they like being actively engaged in discussions in class? How do they know they have mastered the material? Instructors have many ways to increase student engagement and to assess student learning, but both instructors and students would benefit from better understanding students' perspectives about their own learning.

An instructor likely has a teaching philosophy, or conceptions about teaching and how students learn. Often associated with a teaching statement, a teaching philosophy consists of an instructor's beliefs, attitudes, and perceptions about teaching. Much research has examined instructors' thoughts on student learning [1]–[3], instructors' thoughts on teaching philosophies [4], [5], and students' thoughts on teaching philosophies [6], but little if any research has examined students' thoughts on student learning.

A student's beliefs, attitudes, and perceptions about learning might be considered a learning philosophy. Similar to a teaching philosophy, a learning philosophy would describe how a student thinks about the act of learning, its purpose, and how one actually learns. As universities strive to produce

competent engineering graduates, what these graduates think about their approaches to learning and their thoughts about mastering the material is often not considered in the design of courses.

Adult learning theory can also help us make sense of the college student. It is common for students to develop into adult learners during the undergraduate years. Here, adult learner refers to someone "who (1) has an independent self-concept and who can direct his or her own learning, (2) has accumulated a reservoir of life experiences that is a rich resource for learning, (3) has learning needs closely related to changing social roles, (4) is problem-centered and interested in immediate application of knowledge, and (5) is motivated to learn by internal rather than external factors" [7, p. 5]. Adult learning theory can be even better understood by considering the states of development as Perry does.

Perry [8] examines the development of the dualistic thinker into the multiplicitic thinker. Often, undergraduates begin their university studies thinking dualistically about the nature of knowledge, believing there is always one correct answer and that knowledge is handed down only by authorities. Multiplicitic thinking, as Perry describes it, evolves through nine stages to where students become comfortable and reach a view that accepts knowledge as an ongoing, complex and evolving process [8].

Ideally, students graduate from college with an understanding of multiplicity of worldviews and an ability to engage in life-long learning. The ability to gauge and self-direct learning and understand what and how one should learn, and to know when something has been learned, are skills harbored as multiplicitic thinkers and lifelong learners. Studying students' learning philosophies might help us better understand how to guide students to achieve these goals.

In this study, we use Bloom's Taxonomy and Schommer's Epistemological Dimensions to understand what students said about their learning. Bloom's Taxonomy, which was revised by Anderson and Krathwohl [9], presents a hierarchy of cognitive thinking and the structure of knowledge. Instructors can use Bloom's Taxonomy to define learning objectives and the skills and abilities the course will provide [9]. The structure of these cognitive processes is organized from lower-level skills to higher-level skills: Remember, Understand, Apply, Analyze, Evaluate, and Create, respectively [10]. While assignments might make evident to the instructor the

level at which students are performing, students are likely unaware of how they are performing in relation to Bloom's Taxonomy.

Schommer [12] examined students' thoughts about the nature of knowledge, or their epistemological beliefs. Built upon Perry's Theory, these epistemological beliefs are generally thought of as "what individuals believe about the source, certainty, and organization of knowledge, as well as the control and the speed of learning" [11, p. 293]. Schommer identified the following four epistemological factors that might hinder college and university students as they work toward higher level thinking skills and abilities:

1. *Innate ability*: The ability to learn is determined at birth
2. *Quick learning*: Learning occurs in a short amount of time or not at all
3. *Simple knowledge*: Knowledge is best characterized as isolated facts
4. *Certain knowledge*: Knowledge is unchanging

Schommer found that students who exhibit these beliefs had poor comprehension skills. Holding on to these beliefs might hinder students from developing and gaining higher-level thinking skills and appropriate epistemological beliefs [12].

This study aims to examine students' thoughts and beliefs about their learning and study practices. As previous work has shown, examining an instructor's teaching philosophy can be very useful for addressing classroom improvement. However, the students' perspectives and beliefs about learning, or learning philosophies, have not been examined in much detail. We believe this information can be extremely useful to instructors and students alike in making courses more effective. This work contributes to the understanding of students across many learning spectrums (Bloom's, Schommer's, and Perry's). It also helps us better understand the transition to and development of adult learners. Furthermore, this work builds upon previous work by examining themes that fall beyond the two frameworks used.

Our findings, in addition to previous research, seem to suggest that students are initially comfortable as passive learners. Although students enjoy discussion in the lower-level engineering course described in this paper, they are not truly able to gauge and direct their own learning. We believe the lack of self-directed learning skills implies that educators and instructors need to purposefully include scaffolding for students to reflect on their learning and development into life-long learners, and in this case, successful professionals in engineering or other fields.

II. BACKGROUND

At Purdue University, ENGR 20100: Engineering in Global Context is a course that can satisfy a requirement for the Global Engineering Minor, can satisfy the general education requirements for undergraduates, or can be taken as an elective. ENGR 20100 was first offered in the Spring of

2014 and has been taught three times. The development of the course was informed by the Engineering Cultures content and model originally developed at Virginia Tech [13]. ENGR 20100 is the only course in Purdue's College of Engineering that explicitly considers the historical, social, and economic aspects of engineering. Student feedback has guided topic selection and course foci over the three course offerings. As a reading-, writing-, and discussion-based course, it differs from most typical engineering courses. Further information about challenges associated with getting official approval for the course can be found in a prior conference paper [14].

Below are the course description and course learning outcomes as defined in the syllabus, emphasis added to present verbs that correspond to Bloom's Taxonomy:

COURSE DESCRIPTION This course examines how engineering is intertwined with larger economic, social, cultural, and technological dynamics in an era of intensified globalization. Its major goals are to help you understand and appreciate what engineering is, how engineers are trained, what engineers do, and how engineering and society interact. The course approaches these themes through discussion of: the relation and interaction of engineering, science, technology, and society; the historical origins and development of engineering as a profession; diversity issues in engineering and other STEM fields; engineering in cross-national/cultural contexts; and contemporary challenges related to globalization, ethics, and sustainability. In summary, the course is designed to help students *understand* [Understand level of Bloom's Taxonomy] what it means to identify as, and/or work with, engineers. Recitation sections and/or independent projects provide further opportunities to expand your knowledge and improve your skills in relation to the major course topics and themes.

COURSE LEARNING OUTCOMES Students who successfully complete this course should have the ability to: 1. *Describe* [Understand] and *evaluate* [Evaluate] the specific kinds of knowledge and methods typically employed by engineers, including in comparison with other professional fields, 2. *Understand* [Understand] the historical development of engineering education and the engineering profession in the United States, 3. *Recognize* [Remember] how national differences are important in engineering work, including by *comparing* and *contrasting* [Apply] different national histories, cultures, and styles of engineering, 4. *Explain* [Understand] the significance of diversity in engineering education and professional practice, including by *evaluating* [Evaluate] competing perspectives on diversity in different historical and sociocultural contexts, 5. *Understand* [Understand] contemporary trends and issues related to globalization, ethics, social responsibility, and sustainability, and *interpret*

[Apply] their significance in relation to engineering education and practice, and 6. *Demonstrate* [Create] written communication capabilities at the level of “emerging” or higher (as defined by the Purdue Core Curriculum guidelines).

The course meets three times a week for 50 minutes, for which students are often assigned readings of 5 to 15 pages in length. There are frequent (approximately once per week) reading quizzes whose main purpose is to check for reading comprehension. There are six homework assignments (described below), a midterm exam and a final exam. The classroom is a mixture of lecture and discussion. A sample homework assignment, which is required to be at least 600 words, is presented below, emphasis added to again highlight verbs related to Bloom’s taxonomy:

This assignment begins with you reading Stuart Leslie’s article “Charles F. Kettering and the Copper-cooled Engine”, which highlights a struggle between two different engineering perspectives working to design and produce a copper-cooled engine for General Motors.

For this assignment, you will *apply* the “Engineering Problem Solving with People” framework to systematically *analyze* the two major perspectives in this case.

- After reading the article, write a one-paragraph *summary* of its content.
- Next, adopt Kettering’s perspective and in approximately one paragraph *describe* his location (organizational, geographical, etc.), knowledge (including skills, expertise, etc.), and desire (personal and professional goals).
- Now turn to the perspective of the manufacturing engineers and production staff, and in another paragraph *describe* their location, knowledge, and desire.
- Finally, in a concluding paragraph *develop* your own critical assessment of this case, including what you think were the biggest gaps in perspective between the two main stakeholder groups. Make sure you discuss how such issues might be remedied or addressed, and by whom.

With assignments that consider social and environmental implications, such as the one above, ENGR 20100 provides an appropriate context to explore student learning philosophies in engineering. As skills associated with reading and writing are particularly important in engineering fields, it is exciting to see how students develop and gain those skills through the voice of the students themselves. In this study, we examine the learning philosophies of students in ENGR 20100 as an effort to provide insight into their approaches to learning for the course.

III. METHODS

This work is guided by the following research question: **What are students’ learning philosophies in the context of ENGR 20100: Engineering in Global Context?**

We found the context of ENGR 20100 to be particularly appropriate for examining the learning philosophies of engineering students. In comparison to problem sets and note-taking, which are common course activities in engineering courses, the course activities in ENGR 20100 largely comprised of reading, writing, and discussion. The contrast naturally allowed for us to ask students to compare their study and learning approaches, highlighting the variation in cognitive levels and development between courses.

It is important to examine a course at this level and context since so much research is focused on freshman and senior engineering and design. The context of global engineering provides a fresh perspective and comparison for engineering students’ learning philosophies.

A. The Participants

The participants were the students enrolled in ENGR 20100 during the Spring 2015 semester. There were 25 students, of whom 19 took the survey and gave consent to allow the use their de-identified responses for this research project. The whole class consisted of seven females with a mixture of academic level ranging from freshmen to seniors. While most of the students were in engineering or computer science, a few students were in other disciplines, such as business and industrial management.

B. Tasks and Procedures

As part of the ENGR 20100 course grading, course surveys count for 5% of the final grade. Completing these surveys results in a binary completion grade: students were graded solely on whether they completed the survey, and not based on the content of their survey responses. The mid-course survey included two questions asking about how the course was going thus far, and for any recommendations for improvement. Additionally, the survey asked the following questions, the responses to which are the data for this study. As can be seen, student responses to these questions would provide useful insight for an instructor of any course. Some of the questions were inspired by Maryellen Weimer’s work [15].

1. How do you prepare for class sessions in this course?
2. Is how you prepare for this course similar to or different from how you prepare for other courses? Explain.
3. What do you do when you read the assigned texts for this course? (Take notes, formulate questions, skim, re-read, etc.)
4. How do you know if you’ve mastered the material for this course, other than a grade?

5. How do you know if you've mastered the material for other courses, other than a grade?
6. Think about the best course you ever had. What were some characteristics of the course that made it the best?
7. I learn best when... (complete this thought)
8. I feel most confident as a learner when... (complete this thought)
9. Classmates compromise my attempts to learn when... (complete this thought)

Qualitative data were collected from students in the form of open-ended survey responses so that we could see what students said about their learning in their own words. These questions ask students what they do with their study time in this course and what they think about themselves as learners. The data was collected following appropriate guidelines and approvals for human-subjects research.

C. Analysis

Student responses were analyzed using exploratory content analysis [16] to allow for themes to emerge naturally. Through discussion, the authors came to agreement about the emergent codes. These themes were then clustered using thematic analysis [16] to see what themes and concepts were common among the class as a whole. Next, the themes were deductively analyzed through the lens of the conceptual frameworks of Anderson and Krathwohl (Bloom's Taxonomy) and Schommer (Epistemological Dimensions). The researchers continued to meet and compare their results until a consensus on the coding framework was reached.

IV. RESULTS

Student responses were thematically clustered into three major themes. The first theme centers on items relating to Bloom's Taxonomy. The second theme relates to conceptions about learning according to Schommer's Epistemological Dimensions. And finally, a third theme clusters other noteworthy comments and remarks made by the students that do not fit into the two conceptual frameworks. Results related to each theme are presented in the sections that follow.

A. Bloom's Taxonomy: levels of thinking and mastery

Students were asked to think about their conceptions of mastery of material for the ENGR 20100 course as well as for other courses. Students largely described mastery in ENGR 20100 at the Remember and Understand levels in Bloom's Taxonomy. For example, in response to Question 4: "How do you know if you've mastered the material for this course, other than a grade," students responded:

"When I can discuss about a topic I know I understand it."

"If I have an understanding of the topic capable of teaching others."

"If I can contribute to Friday class discussions."

"I can tell based on how easily I can think of answers to questions presented by the instructors."

"If I can answer the questions on the power point correctly, then I assume that I understand the material."

"When I can remember the information I review in my head."

Only a few students went beyond the Remember and Understand levels of Bloom's Taxonomy. However, a couple students described mastery in ENGR 20100 as being able to connect and compare various course concepts, which is associated with the Apply level:

"If I can start back at engineering in England, Germany, and France, and tell the progression of thought and how it stemmed to the United States including where it is today (especially in a global perspective)."

"If I can pinpoint changes in my thought process regarding international engineering from now and the past."

Students' responses to Question 5, "How do you know if you've mastered the material in other courses, other than a grade", differed from their responses about the ENGR 20100 course. Here students generally defined mastery at the Apply level in Bloom's Taxonomy. For example, students described mastery in other courses, which are likely engineering science courses, as being able to apply knowledge with confidence and to real-world situations:

"If I can apply the knowledge outside of class with complete confidence."

"If I can solve problems similar to the problems given in a real world setting."

"For mathematical courses, I know I've mastered the course when I can apply what I've learned to a real-life situation."

One student described a still higher cognitive level of Bloom's Taxonomy as an indicator of mastery – Create:

"If I could solve problems or create problems without looking back at the textbook, I think I did master the material."

Similarly, responses to Question 8: "I feel most confident as a learner when... (continue this thought)", centered around

similar themes as the responses to Questions 4 and 5. The students described feeling confident when they were able to discuss, explain, and apply the material, and when they were able to get the correct answer. Some examples of these themes are:

“I am able to understand a concept and explain it to others clearly.”

“I understand the material and can apply it to other applications.”

“I am able to talk with others to discuss the material.”

“I feel most confident as a learner when I apply my current knowledge and I am correct or I am able to figure out what I did wrong and what I need to fix in order to get the problem right.”

Moving from levels of thinking to the content of what students are thinking gives us even more of an understanding of other components students’ learning philosophies include.

B. Schommer’s Epistemological Dimensions: Quick and accurate problem solving

Student responses also revealed evidence of two of the four dimensions described by Schommer, namely *quick learning* and *certain knowledge*.

Students described mastery in other courses as being able to apply knowledge to solve problems quickly and correctly. While effortlessly solving a problem is not equivalent to quick learning, the emphasis students put on easy problem solving is substantial. For example, in response to Question 5: “How do you know if you’ve mastered the material in other courses, other than a grade”, student responses included:

“I know I’ve mastered the material in a course if I use the information I learned in that course easily, as if it is now something that is a natural part of me and I do not need to think excessively about how to do it. For example, after Calc I, I can take simple integrals and derivatives quickly and without much hesitation.”

“I can work out problems of the same type of nature without having to really think about it.”

“If I can select any problem set from any point during the term and complete them with accuracy.”

“I can tell based on how easily I can discuss the material with peers.”

And additionally, in response to Question 8: “I feel most confident as a learner when... (continue this thought)”, one

student felt confidence when answering questions or following a lecture came with ease:

“I can answer all the questions a professor asks in class correctly and/or can follow the lecture very easily.”

In line with Schommer’s epistemological dimension of certain knowledge, one student also described how believing the instructor contributed to personal confidence as a learner. For example, this student reported feeling most confident as a learner when:

“I am sure that the person telling me something is telling the truth and that I can trust their knowledge.”

While examining student responses through the lenses of Bloom and Schommer, responses that did not fit into those frameworks still provide glimpses into what we can learn about student learning philosophies. The additional themes that resulted from our analysis are described next.

C. Other Themes

A number of student responses did not fit in line with either Bloom’s Taxonomy or Schommer’s Epistemological Dimensions, but nonetheless turned out to be interesting findings. These two themes were engagement with the readings and best course characteristics.

a) Engagement with readings: In ENGR 20100, students read articles and other publications in preparation for course sessions and for assignments. Question 3 asked students what they do when they read the assigned texts, even giving some suggestions such as take notes, formulate questions, skim, and re-read. The students described the activities of reading, re-reading, skimming, taking notes, and highlighting. Not one student described formulating questions, and no students suggested additional activities while reading. Some students offered reasons or explanations for their behavior. For example, some students skimmed long readings and others took notes on what they perceived to be important concepts:

“If the pages are not long, I would take notes for the points I think are important. Also for the assignment. If the reading is long, I would skim most of it.”

“I usually read the texts in their entirety. I will take notes if I think I will forget things.”

“When I read the assigned texts for this course I usually try and retain as much information as I can, but a lot of times that takes too long and I will just end up skim reading the texts.”

"I first read the assignment completely, then take notes on any insights I have so that I can remember them later. On the day of the discussion, I typically skim the assignment once more to ensure I can remember details."

Here, we are able to see what students are actually doing and thinking when they are assigned a reading. Next, while we know the instructor for a course plays an important role, we will see what students like about their best instructors and courses.

b) *Best course characteristics:* Question 6 asked students to consider the best course they have ever had and reflect on what characteristics of that course made it the best. The students responded about interest in the material; an engaging, clear, and organized professor; opportunities to practice what they were learning; and having an appropriate work load. For example, some responses that demonstrate each of the themes described above include:

"The instructor's explanation was clear, concise, and easy to follow. The instructor's handwriting on the blackboard was neat and clear. The class was very organized and [the instructor] supplements students with enough resources such as course slides, sample exams, and lecture notes. The topics covered were interesting and intellectually stimulating."

"Some characteristics include: professor/student interaction, enjoyable learning, relatable and interesting material."

The material was engaging and hands-on. Also, a lot of discussion and interaction between students and teachers made it feel like a comfortable environment."

"Characteristics include lots of time to practice during class and when the professor/TA has easy to access office hours."

One final theme examined the difference between learning goals and beliefs. It is important to recognize that while sometimes a learning goal heavily depends on the context, as will be described next.

c) *Learning goals vs. learning beliefs:* Some students expressed goals for ENGR 20100 that might not necessarily reflect their usual learning beliefs and goals. For example, in response to Question 6, "Is how you prepare for this course similar to or different from how you prepare for other courses? Explain," two student responses were:

"I prepare for this course very differently from my other courses. I took this class to fill a requirement and it is not one of the classes I'm interested in, so I

do not spend as much time working for this class as I do my core classes."

"Other courses are more relaxed in the way that I am a senior so I do not have to worry about doing the reading and can do it whenever I want."

Bloom's Taxonomy and Schommer's Epistemological Dimensions helped us make sense of a lot of student responses to questions about how they study and learn. Additionally, some responses that dealt with other aspects of learning conceptions were also explored to help us understand the idea of learning philosophies even more holistically. Possible interpretations and implications of the results can provide ways of implementing these findings into the classroom, and are discussed below.

V. DISCUSSION

The Bloom and Schommer frameworks provided useful ways to make sense of the data. However, the emergent thematic analysis that was conducted was beneficial to uncover other themes that emerged that did not fit in with the aforementioned frameworks. Since there has not been much work about students' learning and study practices, this work gives a preliminary understanding about students' perceptions.

The responses to Questions 4 and 5 about mastery revealed some interesting implications about the relative skill levels relating to reading and writing versus math, science, and engineering skills. In ENGR 20100, a reading- and writing-intensive course, students believed that they had mastered the material only if they had achieved the Understand level of Bloom's Taxonomy, whereas in presumably technical courses, students defined mastery as achieving the Apply level. One especially interesting point is that before students took the survey, they had completed two homework assignments that had required higher level thinking skills, including Evaluate and Create, but there was no evidence that students were aware of these higher level skills in their definition of what counted as mastery in the course.

The contrast between students achieving the Understand level in ENGR 20100 and the Apply level in technical courses on Bloom's Taxonomy might demonstrate to us as educators that engineering students largely perform at lower levels in more reading- and writing-based courses. If engineering students really perform at much lower levels in reading and writing tasks than problem solving tasks, there are significant implications for students to achieve the necessary and desired outcomes for graduation and advancing one's career.

Schommer's Epistemological Dimensions appeared only a few times within the students' responses in the form of quick leaning and certain knowledge. The fact that students still harbor these beliefs about the nature of knowledge demonstrate that they might not be moving towards more advanced and higher-level thinking. Again, if students are holding on to inaccurate beliefs about knowledge, there are useful implications for students moving forward and advancing, since developing a full and appropriate understanding of knowledge is necessary as engineers.

An explanation for why students' cognitive levels of mastery might be higher for other courses is likely due to practice – these students have been practicing technical problem solving and analysis in many of their courses. Additionally, students commonly believe that engineering does not require the skills of reading comprehension and effective writing. These beliefs may lead students to aim for lower levels of mastery for the ENGR 20100 course than for technical courses. Another possible explanation considers students who are purely taking this course to fulfill a requirement. These students may greatly value reading and writing but did not for this particular course.

The students also brought up how ENGR 20100 was “different” than other courses they usually take (namely technical courses), but then also discussed that they learn best in discussion-based courses. In general, many engineering courses are lecture-based with less discussion and other active learning. Since students in this study really valued discussion, we suggest that engineering students would benefit from the inclusion of discussion practices in their technical engineering courses.

The students' descriptions of good professors aligned well with what other research says about the characteristics of excellent instructors [17]. This consistency suggests that the participants in this study are similar to students in other studies. This similarity suggests that the findings in this paper regarding levels of thinking in reading and writing based courses are probably generalizable to similar courses at other universities. The questions used in this study would likely provide useful and insightful information to instructors, but might benefit from alterations as described below.

Although these findings and implications are interesting and can aid more student centered teaching, it is important to note some limitations of this study. The work would have been strengthened if students were given a more thorough understanding to the context of what was being studied. Focus groups and interviews could potentially have deepened our understanding of student conceptions about their learning. Furthermore, students' investment in this assignment was likely minimal. Students who are interested in self-reflection and considerations about their learning may have provided more thoughtful and complete interpretations about their learning. On the other hand, students who were taking this course purely to fill a requirement may not have had much interest in providing insightful responses to a course survey. More information about student demographics could have also provided deeper understanding about student motivation and how those are linked to student learning philosophies, although it is important to note that academic level and age do not necessarily map to higher levels of thinking or more accurate epistemological beliefs [7].

VI. IMPLICATIONS AND FUTURE WORK

Tools such as Bloom's Taxonomy and Schommer's Epistemological dimensions can illuminate areas of learning where students need further practice and skill development. Students reported to be performing at lower levels in a course that is largely reading- and writing-based as compared to their

technical courses, but the engineering profession requires higher levels of thinking for reading, writing, and communication to be successful. If these skills are addressed and improved, developing well-rounded competent engineers will become more realistic.

A student survey such as the one described in this paper can be extremely valuable to instructors and can potentially improve course alignment. Course alignment, in this case, means making sure there are clear connections between the content that is being taught, the way it is assessed, and the way it is taught (pedagogy). In line with adult learning theory, acknowledging student learning philosophies can help make courses more meaningful to the students. For example, one of the goals of this course is to support students as they develop as globally competent professionals working on cross-cultural teams. They were encouraged to discuss and analyze global situations through class discussion and homework assignments. Students were also often provided with the freedom to tailor their assignments to their particular interests. Seeing their comments about how they know they have mastered the material and that they like the discussions with their classmates reinforces that this goal is being met for some of the students.

This work might be enhanced if Bloom's and Schommer's concepts were integrated more into the survey itself. If students are asked to think in the terms of Bloom and Schommer, we might better understand their own interpretations of their learning philosophies through these frameworks. While the findings from this work might provide details about the various scales and levels of thinking, it would be interesting to make students more aware of these scales and levels so that they have the opportunity to better understand their development as adult learners.

Additionally, it would be valuable to understand what instructors and professors think of the learning philosophies of their students. Future work will include interviews with faculty that include a discussion about what was said in the survey responses and thoughts about how this new knowledge could be included in course design.

VII. CONCLUSION

By understanding students' learning philosophies through a research perspective, college students and instructors alike will begin to understand students' ways of thinking about their learning. When instructors understand the beliefs and practices used by students, they can adjust their teaching techniques to the benefit of the class. The survey questions utilized in this study can be used as a tool to gain insight into students' approaches to learning. Learning philosophies are an underexplored research area that needs further study at all levels of engineering education. This work provides one example of a specific instance in a particular context.

ACKNOWLEDGMENTS

We thank the instructor for ENGR 20100, Dr. Brent Jesiek, for allowing us to collect this data and share the results with the engineering education research community. We also thank Brandon Fulk for his support and comments throughout the project process. This project was completed under Purdue University IRB Protocol Number 1502015757.

Abstract—Mathematics continues to be a major hurdle for engineering students. The authors presented results of a pilot precalculus summer program at FIE 2014. In the current paper, we examined longitudinally the results of the institutionalized version of the precalculus summer program over four years. Students who scored less than 22 on the Mathematics Placement Exam could either a) participate in the personalized precalculus program (PPP) or b) take the fall precalculus course. The research question for this study was: How well did the students who took the PPP perform in the precalculus and engineering calculus course sequence compared with the students who did not participate in the PPP? The PPP included an online study plan with practice problems in common areas of difficulty in algebra and trigonometry and required online tutoring sessions for 30 hours over a six-week period for the first three years and the same number of hours over a three-week period for the fourth year. For this paper, we analyzed the trends over four years of the program to determine whether participants are progressing successfully through the engineering calculus sequence.

Keywords—calculus, engineering education, mathematics placement, summer program

I. INTRODUCTION

The gap between college acceptance and readiness remains. Yearly, almost 60% of eligible college freshmen discover they are not ready for university studies [1]. After enrolling, they realize it is necessary to enroll in remedial non-credit bearing courses in English or mathematics. In college remedial education programs, early successful intervention helps students, the institution, and society succeed all together [2].

Concern about the number of students requiring remediation has been evident for quite a few years, and the number of remedial courses that need to be offered, especially at the post-secondary level, has increased. Remedial courses

are an important and utilized component of higher education in the United States [3; 4; 5]. These courses have been offered in almost all U.S. two-year community colleges to students for writing, reading, and mathematics (below college algebra). Unfortunately, now four-year post-secondary institutions are also finding it necessary to offer a large number of remedial mathematics courses. Every year, over two million students enroll in remedial education courses in U.S. colleges and universities [6]. In the fall of 2000, 22% of freshmen entering American colleges were required to enroll in remedial mathematics courses [7]. Those numbers are increasing; 24% of students in four-year colleges and 38% of students in community colleges enrolled in remedial courses in 2006. Of all the remedial classes, mathematics had the largest enrollment [7]. In fall 2003, more than 65,000 students in Texas were enrolled in remedial mathematics courses [8].

Remedial courses are costing colleges more than they produce in revenues [9]. From 1995-2000, the number of freshmen registered in remedial courses remained the same; however, the number of courses they took grew from 28% to 35% [7]. Citizens are burdened by paying taxes twice for the same courses these students took in high school. One estimate of the total cost, including tuition, fees, and local taxes, for the 2000-2001 year was \$462 million [10].

In addition to the expenses incurred from remedial education tuition, there are also costs associated with families and the economy in general. During 2006, the U. S. lost \$2.3 billion in revenue due to the fact that “remedial reading students are more likely to drop out of college without a degree, thereby reducing their earning potential” [11]. Across the U.S., college graduates can expect to earn \$1.2 million more in average salary over a lifetime than a non-college graduate [8].

In addition to concerns about the costs associated with post-secondary remedial education, there is controversy surrounding the usefulness of remedial mathematics classes. While previous researchers have found the effectiveness of remedial programs in encouraging students to persist and succeed in credit-bearing courses [12; 13; 14], other researchers [15; 16; 17] have found that remedial courses can be a roadblock impeding students, or their supports are short-term and do not translate into successes in credit-bearing courses. Research results have demonstrated mixed results with remediated students as well. Another group of researchers have found that remediation can be detrimental to success; at the same time, others revealed there were adverse consequences in particular settings while there were positive effects in others [18; 19]. Students who start remedial work in one of the higher levels tend to perform like students who are not remediated [20; 21]. Students who need precalculus remediation in degree programs that require calculus generally graduate after four years at a rate of about 70%, compared to 80% for students who enroll straight into calculus [22].

Remedial mathematics courses have the highest rates of failure; thus, students are not succeeding in mathematics, which inhibits them from reaching their educational objectives [6]. Using data from the Beginning Postsecondary Students Longitudinal Study and the associated 2009 Postsecondary Education Transcript Study, a statistical analysis of factors contributing to STEM attrition was conducted. Findings showed that taking lighter credit loads in STEM courses in the first year and taking less challenging math courses in the first year increased retention in STEM fields [23]. An NSF STEP Grant [24] required students to attend a 3-contact-hour recitation session every day, in addition to the class lectures. These remedial techniques increased STEM retention in fields such as engineering. Unfortunately, if students needed to enroll in remedial mathematics before enrolling in mathematics courses required for their degree plans, their time to graduation took longer, and the probability of finishing their degree was less. In the U. S., about 20% of students who successfully finish a remedial program earn a four-year degree in a six-year time frame; at the same time, nearly 50% of regular students are expected to graduate in that same time frame. Whether or not a student dropped out was a predictor of their need for college remediation [8].

Engineering majors at Texas A&M University are required to be enrolled in Engineering Calculus I at the same time or before their first engineering course. Students who had to enroll in precalculus after they enrolled in the university were almost one semester behind in a demanding major program with few opportunities to achieve in the mathematics classes, thus preventing their admission into upper level engineering classes. Reference [25] has acknowledged that employing remedial technology programs can bolster student learning and can serve as a positive influence on instructors' skills when working with students. Instructional technology programs including WeBWork [26], math and engineering supplemental tutorial sessions [27], and an online homework system – MasteringEngineering [28] – have been used to eliminate the learning gaps of students. These programs demonstrated positive results in bolstering mathematics skills and the self-confidence of students in beginning engineering classes.

The current study is based on a previous study [29] in which participants were enrolled in a bridge program for 30 hours with a tutor and an on-line course that lasted three weeks. After the program students were allowed to retake the placement test with the hope that they would now score a 22 or above and be eligible for Engineering Calculus. By the end of the program, mean student scores on the placement exam increased by 8 points and the standard deviation was reduced by 50%, negatively skewing the distribution.

II. PROGRAM DESCRIPTION

Reference [30] noted that “self-perceptions of competence begin to decline in Grade 7 or earlier” and show up more in mathematics. Reference [31] found that only some students are able to control and direct their own studying. Some students need assistance developing study skills. Without help, these students end up only “employ[ing] task-specific strategies such as preparing for tests” [32]. Reference [30] found that “learning environments that are intellectually challenging and supportive of individual progress and mastery” and that students “who feel self-efficacious about learning or performing a task competently are apt to participate more readily, work harder, persist longer when they encounter difficulties, and achieve at higher levels”.

The Personalized Precalculus Program (PPP) project is about mathematics remediation, retention, and keeping students on their academic track. The purpose is to remediate students needing precalculus help for Engineering Calculus I before their first semester in college.

The typical student is admitted during his/her senior year. If the student declares a STEM major, he/she is required to take the online Mathematics Placement Exam (MPE), a 33 question precalculus examination that is a good predictor of Engineering Calculus I success [33]. Currently, students with a score of 22 or higher are automatically admitted to Engineering Calculus I. Students with scores in the 14-21 range are given the opportunity to take the PPP. Students below this score must take precalculus or college algebra. This affects about 4,200 students during a typical fall term, of which more than 800 are destined for precalculus.

There are numerous other reasons why placing students in precalculus is undesirable. 1) Many (if not most) students forced to take this course enter it believing they already know the material, and it is true they have probably seen most of it. This creates a negative attitude toward learning. 2) Students have a low success rate (~51%). 3) Students forced to take the course suffer (in their own minds) something of a stigma at not being allowed to take Calculus I, and sometimes resentment builds. 4) Often precalculus students' classmates say the course has little value, reinforcing some of the factors above. 5) In most STEM majors, students taking a precalculus course are locked out of their normal program and can be delayed in graduation for as much as a year.

There are two other large groups of students of about 300 each that are at risk, and both are Calculus I bound. The first of these will eventually earn a D or F (or W) in the course. Often these students are lost to their STEM aspirations or must repeat Calculus I. The second are those that will eventually earn a C.

Aside from those dropping from STEM at this point, this group continues to Calculus II, but their grade point average is typically 1.3 on a four point scale. Thus, more STEM majors are lost.

The PPP course materials have been placed on WebAssign, a commercial assessment and course management tool. The student pays \$150 to take the course, almost enough to make the program self-sustaining. It is completely online. The materials consist of videos of math topics, a complete precalculus text, and a variety of quizzes the student must take to advance in the program. So, for purposes here, imagine the PPP to be an essentially complete precalculus course, where participants are required to complete various components. The program is personalized in that students are not necessarily required to complete all of the materials in the course. The test they take at the beginning of the course identifies which of the four main areas they need to complete. Experience over several years has shown that students are generally deficient in all the same areas originally identified to be included in the program. Within each of the areas, they take quizzes. If they do not score at least 70%, they are expected to continue practicing the algorithmic problems in that topical area. This feature personalizes the program throughout the students' time in the course. A bar that turns from red to yellow to green indicates their progress through the material. The mathematical components such as trigonometry are exactly those for which the typical calculus student has the greatest trouble.

The operations of the PPP are complex. In the next paragraphs, the main components are sketched out, including tutoring, format, and recruiting. Enrolled students are divided into cohorts of at most twenty. They are assigned a tutor and live, online meeting times with the tutor. Tutors are carefully selected for qualities related to teaching calculus to beginning students and for their excellence at truly communicating with students. The communications factor is extremely important, as the online environment can promote passivity. Therefore, tutors must be able to engage students in the learning process. A fully online program without a tutor would likely not succeed, as most students are essentially unable to learn mathematics independently, videos, applets, and other assists notwithstanding. Indeed, it has been shown a large percentage of entering students lack useful direction with specific study methods, which includes self-study [34]. In fact, had they been able to learn well from the textbook alone [35], they would have been able to attain the cut score to enroll in engineering calculus. The online system contains algorithmic problems, providing an almost endless supply of practice problems with immediate feedback on the answer [36]. Videos of similar types of problems are available to support them when they continue to have difficulty with the problems. Additionally, students have access to the tutor in the online sessions and through email. The tutor not only explains problems with which students are having difficulty, but also provides an opportunity for engaging in "practices of negotiation and interpretation" that enables students to transfer the use of mathematics knowledge to different situations [29].

As for the PPP duration, the course format has been changed somewhat over the five years of its operation. Originally, it was viewed and taught as a six-week course,

meeting three times per week. This format was somewhat unsuccessful in retention though good in results. Beginning in 2014, the sessions have been condensed to about three weeks to improve retention. The number of student-tutor contact hours have remained essentially the same, however. This has proved far more successful in PPP retention, though success results are still under study.

Students completing the program are encouraged to take the MPE once again, with the vast majority now placing into Calculus I. The first question to ask is how well do these students perform? In fact, those placing into Calculus I complete the course at the same rate as those in their MPE grade-class. Previous analyses proved such students succeed at a substantially lower rate if they are placed into calculus without the PPP intervention [37; 38].

The perennial problem with the PPP program has been recruiting students to enroll. All recruiting is done by email with an online enrollment site. Note the program is completely voluntary. This cannot be changed. It is online when the student is still at home; it is taken during the summer when many students work at various jobs. For a couple of years the enrollment remained at less than one hundred. However, in our most recent application (2014), more than 250 students enrolled. This is evidence of student perceived value of the program, of student's understanding they may need help in mathematics, of the encouragement of college advisers to students, and to the reasonable costs for this service.

III. PURPOSE AND RESEARCH QUESTIONS

The mathematics sequence for engineering students is critical to their success and enrollment in upper level engineering courses. In a prior paper we reported the results of student success in Engineering Calculus I in one academic year at the beginning of the program [37]. The summer program described was designed to improve students' algebra and precalculus skills before retaking the MPE so that they could begin on track for their engineering courses. As the program has evolved through institutional changes in student advising, additional support resources, different tutors, and different groups of students over four years, modified research questions needed to be asked.

The research question for this study was: How well did the students who took the PPP perform in the precalculus and engineering calculus sequence courses compared with the students who did not participate in the PPP?

IV. METHODOLOGY

Before enrolling in mathematics courses at Texas A&M University, students were required to take the MPE. An opportunity to participate in the PPP was offered to students who scored below 22, with the hope that they could improve their MPE scores enough to enroll in Engineering Calculus I their first semester and begin on track with the engineering course sequence. The 23,237 students who enrolled in Precalculus, Engineering Calculus I, II, and/or III during the fall or spring semesters from Fall 2010 through Fall 2014 were study participants.

Random assignment for the study was not possible because it would require offering some students the opportunity to begin on track in their engineering studies while denying the opportunity to other students who did not meet the cut score on the MPE by requiring them to take Precalculus in the fall. The best research design possible was to compare performance of those who enrolled in the PPP with similar students who did not enroll.

In this study, we examined not only the results from the first semester of calculus, but also subsequent courses in the engineering calculus sequence. The question under consideration was whether PPP participants continue to be at least as successful through the sequence as non-PPP participants. Data analyses consisted of recommended methods [39; 40; 41; 42]. The recommendation for data analysis is to report findings in a way that promotes meta-analytic thinking so that conclusions can be drawn across studies [43; 44]. Therefore, in addition to correlational analyses across subgroups, non-sample size dependent estimates of importance were used. Data were analyzed using 95% confidence intervals and Cohen's d effect size estimates. Data confirmation follow-up was scheduled for the semester following post-secondary matriculation. Confidence intervals represent the results by providing a measure of variation around the point estimate, which provides a clear picture of accuracy of that estimate. Narrower bars indicate greater precision, which is heavily influenced by sample size.

V. RESULTS

There was a valuable and powerful influence of PPP on grade when considering the first mathematics class. The mean grades were nearly identical and were not statistically significantly different. The effect size Cohen's d was nearly zero, meaning that the PPP students were just as likely to succeed in Engineering Calculus I as those students not needing remediation. However, the effect dropped off marginally in the second course (151) and fell precipitously in the two subsequent courses. When considering that, even for the initially qualified students, the average score (1.97) was below passing, but for the PPP group the average grade (1.2) was markedly low. The residual effect of PPP was not helpful in improving performance of PPP students in mathematics courses beyond Engineering Calculus I.

Fig. 1. Comparison of Academic Performance by Participation/Non-Participation in PPP

We examined how PPP impacted female performance and likely persistence in a 4-course sequence. It was evident that the mean female score started out relatively equal to males and became relatively constant with earning a passing grade and, on average, there was a likelihood of persevering because the average score met the 2.0 cutoff for matriculation into a subsequent class. The average female score exceeded that of males. While the mean difference between males and females was small, the male mean was below the 2.0 cutoff for matriculation into the subsequent mathematics class. Note that in Figure 2 the 0 represents females, and 1 represents males.

Fig. 2. Performance by Gender Across Courses for PPP Participants

VI. CONCLUSIONS

There are several reasons for offering a program like the PPP: leveling the playing field for those students with less adequate prior knowledge from high school; keeping students with weaker math backgrounds on track for graduation in a calculus engineering sequence; and improving the performance of at-risk students in their calculus sequence. Any pre-college program can contribute to leveling the playing field, if only by

allowing students more time to adjust to the differences college life offers and providing them a glimpse of the expectations in college courses. Many students were able to save time and money and begin calculus on track during their first semester. However, overall, PPP students taking Engineering Calculus I in their first semester did not perform as well in terms of grades as those taking it second semester. One of the reasons for this result could be the adjustment from high school. All students have some adjustment pains, and the “weaker” PPP students may well have performed better in the spring because they decoupled the stress of first semester college and the stress of a rigorous course like Engineering Calculus I. Other differences are not likely in our case: many of the same teachers teach Calculus I both fall and spring semesters. Before the final exam, the course has three common exams constructed by faculty teaching the course, leading to very similar faculty expectations from semester to semester. This finding aligns with research on the effect of study skills on student performance and with the previous study over the results from the program in 2011 alone [43].

Like most programs, the PPP has undergone changes over time. In the original offering, only students scoring above a minimum threshold (MPE score of 16) were allowed to participate. This minimum score was eliminated in subsequent years. Students were able to circumvent the registration system and register for Engineering Calculus I even if their MPE score fell below the minimum cut score on the MPE. After the first two years, students were blocked from registering for calculus I if they did not meet the minimum cut score on the MPE. A few students could still have bypassed the registration block if they were able to convince advisors that their scores were not representative of their *real* knowledge. Finally, in 2014, the PPP was reduced from a six-week program to a three-week program. The jury is still out on this change. A comparative analysis of the six-week and the three-week PPP will begin following the 2015 offering. Additionally, because students who perform marginally well in the first course are at high risk for failure in subsequent courses in the engineering calculus sequence, bridge programs for continued support throughout the sequence have been initiated. Studies about the effects of those programs are in progress.

First in the Family:

A Comparison of First-Generation and Non-First-Generation Engineering College Students

Dina Verdín, Allison Godwin
School of Engineering Education
Purdue University
West Lafayette, Indiana 47907
dverdin@purdue.edu, godwina@purdue.edu

Abstract—This study investigates first-generation and non-first-generation engineering undergraduates' math/science identities, subject-related interests, and career plans. First-generation students are an understudied, but growing population. Understanding how these self-beliefs and background factors affect students' engineering choice can help widen pathways into engineering which continues to be defined as “pale and male.” Additionally, identity has predictive value for practical outcomes like engineering choice in college. The data for this study comes from the nationally representative Sustainability and Gender in Engineering (SaGE) survey completed by 6,772 college students who enrolled in first-year English courses at 2- and 4-year colleges across the U.S. Data were analyzed using t-test and chi-square tests for linear and dichotomous outcomes respectively. Our results show differences in first-generation students' identities, interests, performance/ competence beliefs, and family support for science. These differences can serve as a stepping stone towards understanding the trajectories of first-generation college students in engineering. By understanding underrepresented students' identities, performance, and backgrounds, specific strategies can be developed to support these students in our engineering programs.

I. INTRODUCTION

The President's Council of Advisors on Science and Technology have stated that there is a significant need for recruiting and retaining more engineering students [1]. However, a longitudinal study of students' academic records at several large engineering institutions showed that students who matriculate into engineering have higher persistent rates than those in other areas of study, highlighting that the deficiency of engineers is not due to retention but recruitment. In large part, first-generation students attend 2-year institutions and transfer into 4-year engineering programs at higher rates than non-first-generation students [2], [3]. Engineering has lower migration rates into the discipline after the first year than other fields; students who do not matriculate into engineering in their first semester have a lower chance of going into the field later on in their academic careers [4]. Combined, these trends differentially impact first-generation students than their peers who are not first-generation.

The changing demographics of the United States, in terms of college enrollment, demonstrate an upward trend in the enrollment of first-generation college students in higher education. Although there are few recruitment or outreach efforts directly targeting this growing population of first-generation college students interested in engineering, this demographic offers a significant contribution to the nation's engineering workforce [5]. Additionally, students from diverse backgrounds can improve the quality of solutions for engineering problems through alternative perspectives [6]. This argument for increased diversity in engineering appeals to the improvement of engineering outcomes. An additional need for diversity in engineering takes a social justice perspective, that access to engineering and the social and economic capital that an engineering career offers, as well as the solutions generated, should be representative of the U.S. population [7]. With an increasing number of first-generation college students entering universities, and the need for more engineers [8], this population has the potential to improve the variety of who is represented in engineering and offer unique perspectives to help solve important engineering challenges.

While first-generation students have potential to increase the size of the engineering workforce, they face many educational obstacles. The experiences and challenges that first-generation students face in the higher education system demands further research attention. The U.S. Department of Education classifies first-generation college students as those who came from families where neither parent obtained a four-year college degree [9]. These students are disproportionately Latinos and African-American students and have greater missed opportunities in the quality of their mathematics education [10], [11]. In the 2007-2008 academic year, the National Center for Education Statistics reported the following percentages of college students whose parents had a high school diploma or less: 25 percent of White parents, 32.2 percent of Asian parents, 35.6 percent of Native American parents, 45 percent of African-American parents, and 48.5 percent Latin American parents [12]. Previous studies found that poor classroom and academic climate, low academic achievement, difficulty with conceptual understanding, low self-efficacy, inadequate high school preparation, lack of interest, alternative career goals, and minority status increased students' chances of leaving engineering [13]. These trends make first-generation students a high risk population for attrition in engineering.

This material is based upon work supported by the National Science Foundation under Grant No. (1036617). Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

The educational system in America has been regarded as an “engine of social mobility that provides equal opportunities to all deserving students, irrespective of their previous background, upbringing, or life circumstances” [14, p. 1178]. However, sociologists have argued against this belief of upward social mobility through open opportunities for education [14]. In fact, the higher education culture in America creates “social reproduction,” which constructs, retains, and recreates inequalities amongst groups based on access and equity patterns that limit participation of minority groups. Social class inequalities are created by institutions of higher education through their middle- and upper-class cultural norms of independence, which do not take into consideration students who come from working-class backgrounds, typically possessing norms of cultural interdependence [14]. First-generation students are likely to face this cultural disconnect in higher education due to their lack of social capital. Social capital as defined by Bourdieu is “the sum of the resources, actual or virtual, that accrue to an individual or a group by virtue of possessing a durable network of more or less institutionalized relationships of mutual acquaintance and recognition” [15, p. 2]. In large, social capital not only encompasses income and socioeconomic status, but also inequalities of resources in the public education system [16]. These factors differentially affect first-generation students based on family structure. Students from first-generation families have lower parental education level than their peers that often defines their own socioeconomic status. Lower socioeconomic status families typically have less access to quality schools and teachers based on the locations in which they live. Additionally, the community values of first-generation students are not always directed towards the pursuit of a higher education. All of these factors, as well as community values, have an influence on students’ academic achievement [16].

National studies have reported academic under preparation for first-generation college students who are typically falling behind their non-first-generation peers [14], [17], [18]. Certain privileges accessible to non-first-generation college students, such as parents with first-hand knowledge of the college process and procedures, study skills, and mentors in the college system are not present for first-generation college students [17], [19]. Previous research studies have reported that first-generation college students typically come from lower socioeconomic status household, are less prepared academically, have lower high school and college GPAs and lower SAT scores, have not participated in honor programs, have a part-time student enrollment status, have dependents, have geographical constraints with regards to college choice, and have greater drop-out rates when compared to non-first-generation students [7], [9], [11], [13], [15]. Additionally, first-generation college students often come from high schools with low college enrollment rates, have peers who are not college-bound, and have a lower understanding of what college is about, and possess less knowledge about the expectations of students in college and how to prepare for their first term compared to their peers [22]. The cultural mismatch first-generation students face in the higher education system is an unseen disadvantage that can hinder their performance, thus systemically reproducing differences in academic achievement and maintaining existing social hierarchy [14]. All of these factors naturally disadvantage this group’s ability to see engineering as a possible career in college.

Family encouragement and interest have proven to foster academic achievement for students, even after controlling for socioeconomic status. Parents can enhance their student’s interest in mathematics and science by helping their student see the importance of these courses, as well as emphasizing their importance in future careers [23]. Interest in mathematics and science as possible careers declines for many students at an early age. However, a recent study found that parental encouragement was more affective in increasing test scores than having parents who attending parent/teacher conferences or having at home resources (i.e. books, magazines, video games) [23]. These findings illustrate the importance of having family members that support students’ STEM interests.

While there is significant research highlighting average differences between first-generation students and their peers on background factors, there has been a dearth of research on how first-generation students’ attitudes and self-beliefs impact choice of major. The aim of this study is to examine differences between mathematics identity, self-perceptions of mathematics performance, and STEM-related interest for first-generation and non-first-generation college students in engineering and how this may influence career plans. Math was chosen as an area of interest because connections between math and choice of engineering have been found for STEM students [24], [25]. Math and science academic ability were also found to be significant predictors of admission and retention in engineering, while college student’s self-confidence in math and science has been found to be a strong predictor of short-term and long-term persistence in engineering. However, a significant percentage of first year students are entering engineering with weak mathematics preparation [26]. For these reasons, understanding first-generation students’ attitudes and self-beliefs can be an important part in understanding how to recruit and retain this population in engineering.

II. THEORETICAL FRAMEWORK

Identity has been researched in a wide range of theoretical perspectives and contexts including psychology, sociology, anthropology [27]. In recent years, identity has been used as an analytical tool for studying issues around theory and practice in education [28]. People have multiple identities that are connected to their performances in society. Role identity is an authoring of one’s self in a particular context (e.g. in an engineering discipline) and how this concept remains changes over time [29]. As a student’s identification with a particular field or subject grows, a student can begin to develop agency to make positive changes in their world based on who they see themselves to be. An individual’s agency along with societal structures, which may also constrain an individual’s possibilities [30], interact to develop students’ authoring of themselves and the impacts they can make in their world.

This research is focused on students’ role identities as a “math person” or a “science person.” The theoretical framework, used in this work, is constructed of three dimensions of students’ self-beliefs that are central to their development: students’ perceptions of their own performance/competence, beliefs that they are recognized by others, and their perceived interest in math or science. The performance and competence dimensions are not independent of each other [31]; students who believe that the

can do well on course assessments (i.e. performance) respond similarly to items measuring their beliefs about being able to learn content knowledge (i.e. competence) as measured by confirmatory factor analysis [25]. A longitudinal study conducted by Cass et al. [32] found these dimensions of mathematics interest, performance/competence and recognition significantly predict choice of engineering career, irrespective of SAT/ACT math scores and background factors (i.e. parental education as a proxy for socioeconomic status). Students with a high level of self-perceived academic competence tend to persist at higher rates, have a greater chance of adopting mastery and/or performance approach goals, understand the material at a deeper level, and have better study skills [33]. Interest in the subject matter plays a key role in choosing engineering; students should have an understanding of the field of engineering in order to be attracted to it and have opportunities to develop their identity around engineering. The recognition factor of identity is related to the individual's beliefs that are recognized externally by professors, other students, and parents as an engineering student. This conceptual framework has been previously researched to identify students' physics and mathematics identity [25], [29], [31], [32], [34].

In addition to a role identity framework, students' career outcome expectations from Social Cognitive Career Theory (SCCT) were examined. SCCT has been widely used to investigate choice of engineering as a career. This theory is based on a social cognitive approach originally introduced by Bandura [35]. SCCT is founded on the triadic reciprocal relationship between personal and physical attributes, external environmental factors, and over behavior included in social cognitive theory. This model, first proposed by Lent, Brown, and Hackett [36], features three interlocking models including interest development, choice of career, and performance (described by self-efficacy) developed from previous work by the authors as well as a meta-analysis of current vocational career models and research. Outcome expectations, job aspects students' want in their future careers (e.g. making money, supervising others, etc.), are impacted by students learning experiences and self-efficacy and have an effect on interests, career goals, and choice actions related to students' career decisions. These aspects can tie identity theory via interests and performance/competence beliefs with career choice by understanding how first-generation student differ in what they hope to gain in their future careers.

III. RESEARCH QUESTION

Utilizing these frameworks, we worked to address the following research questions:

How are first-generation college students different when compared to non-first-generation college students on: 1) family support and background factors; 2) math and science identity; and 3) career intentions?

IV. METHODS

The data analyzed in this study comes from the nationally representative Sustainability and Gender in Engineering or SaGE (engineering.purdue.edu/ENE/Research/SaGE_survey_God

[win 2014](#)) survey completed by 6,772 college students (55% female) who were enrolled in first-year English courses at 50 different 2 and 4-year colleges across the U.S during the fall semester of 2011. The colleges and universities were drawn from a stratified random sample taken from the National Center for Education Statistics (NCES). The development of this survey has been extensively addressed in previous studies [25], [29], [37] and thus will be briefly explained in this paper. The development of the SaGE survey was organized into three main sections: 1) a literature review to identify factors that may influence increased enrollment in engineering, 2) an extraction of items from previous national studies (FICSS, PRiSE, and FICS-Math) and, 3) open-ended responses from 83 high school science teachers across the nation via a survey administered on-line. The final survey consisted of 47 questions (i.e. anchored scale, multiple choice, and categorical responses) regarding students' career goals, high school science and math experiences, science enrollment and achievement as well as demographic information. This survey has been used in other studies to identify factors that influence students' attitudes towards engineering careers using the construct of mathematics and physics identity [25], [37], [38], as well as to investigate the association between engineering and sustainability-related topics in students' experiences [39]. To compare differences between first-generation students and their peers, pairwise comparisons were conducted for each of the research question topics. The data were analyzed using t-test and chi-square tests for anchored and dichotomous outcomes, respectively. Effect sizes were calculated by Cohen's d and Cramer's v for t-test and chi-square comparisons, respectively. All statistical analyses were conducted using the R programming language statistical software system [40].

V. RESULTS AND DISCUSSION

Students who reported their male and female guardian or parent had completed a "bachelor's degree" or "master's degree or higher" were coded as non-first-generation students (4,206), and students who reported both male and female guardian or parent with "less than a high school diploma," "high school diploma/GED," or "some college or associate/trade degree" were coded as first-generation students (1,057) as consistent with the U.S. Department of Education's classification. Students who indicated "don't know" for both parents were eliminated from the study (1,509). First, the student demographics for first-generation and non-first-generation students were examined via descriptive statistics to understand the students encompassed in the groups. Latino/a students comprised a significantly larger portion of the first-generation students (30% versus 12%, $v = 2.68$) and Caucasian students comprised a significantly larger percentage of the non-first-generation students (84% versus 53%, $v = 1.43$) when compared using chi-square contingency table tests. This finding confirms the same trends as national reports that the first-generation population is a majority of students from Latino origins [41], [42].

A group comparison, using Welch's t-test, was conducted to find differences in academic performance of first-generation and non-first-generation students prior to college using an academic performance index, which is a scaled measure from 0 to 1 of students' prior high school course taking, level of course, and standardized tests scores [39], [43]. Non-first-generation students had a significantly higher academic performance average (55%) than first-generation students with an effect size of $d = 1.87$ ($p < 0.001$). This data set demonstrates the lack of academic preparation first-generation college students have received, which is consistent with previous research findings reporting lower academic achievement when compared to non-first-generation students [14], [17], [18]. This difference in students' academic performance begs the question of whether instructors and administrators need to

focus more on supporting this population before the transition from high school to college. As well, research indicates students come from low socioeconomic status and are more likely to be from underrepresented groups. When asked if English was the primary language spoken at home, the data also revealed first-generation students were less likely to solely speak English at home ($p < 0.001$) with an effect size of $v = 2.07$.

Students were asked to rate the importance of the following outcome expectations for their future career satisfaction anchored from 0 ("not at all important") to 4 ("very important" – see Table II). First-generation students demonstrated significantly higher interest than their peers in "applying math and science" in their future career, as well as interest of "developing new knowledge and skills." First-generation students also reported, on average, higher interest in careers related to mathematics and engineering compared

TABLE I. FUTURE CAREER INTERESTS AND EXPECTATIONS

Statement	Average for First-Generation	Average for Non-first-generation	Significance [§]	Effect Size (d)
Outcome Expectations for Future Career (0-"Not all important"; 4-"Very important")				
Q1a: making money	3.42	3.28	***	0.68
Q1d: supervising others	2.24	2.13	**	0.17
Q1e: having job security and opportunity	3.58	3.53	*	0.10

to a higher science interest for non-first-generation college students.

Contrary to some previous literature indicating that fewer Latino and African American students were interested in mathematics careers [23], these results offer encouragement for finding ways to recruit more and diverse students in engineering. But, they also highlight potential challenges for first-generation students, their instructors, and administration in supporting these students academically in engineering programs. While recruitment strategies based on these attitudes and interests offer opportunities to persuade first-generation students to choose engineering in college, specific strategies to help these students navigate their engineering education and be successful in their programs are needed. We must not only recruit talented students with diverse backgrounds into engineering, but also promote their success and retain them in engineering careers. To maintain America's global competitiveness, we need innovative engineers capable of solving large, complex, global problems [44], [45]. These much needed future engineers will have to come from new sources of talent, including the growing population of first-generation students in higher education. There is a significant need for not just more engineers [46], [47], but a more diverse workforce of engineers which can lead to greater innovation [6].

Research studies have also suggested that STEM-interested students with low socioeconomic status choose engineering more often than science [29], [48]. In one study, students with lower socioeconomic status were also more likely to have taken Calculus in high school and had, on average, higher SAT math scores [48]. These students may focus on mathematics because they were encouraged by their school's guidance counselors who recommend a solid career in engineering for students talented in STEM [48]. This option may be more often prescribed because students with a degree in engineering can regularly earn more than their peers in entry-level positions with only a bachelor's degree. Often, careers in science or mathematics require additional education for graduates to be successful.

First-generation students reported a higher interest in "having an easy job," than non-first-generation students. Since first-generation students in this study reported demonstrating a significantly higher interest in applying math and science to their future career, we initially questioned first-generation students' understanding of the mathematics and engineering fields. While this may be one reason for both the desire to apply math and science and have an easy job were reported by these students, other explanations exist. These students may have a different perception about the concept of "having an easy job" as being less physically labor intensive. For many first-generation students, their parents are manual laborers or agricultural workers. Having "an easy job" may equate to working in an air-conditioned building, making higher amounts of money, and using their intellect and education as the basis for their employment. Future qualitative work can explore these student perceptions about career expectations. . While studies suggest that students with at least one engineering parent, have greater chances of choosing an engineering major [26], [49]–[51], first-generation students who do not have parents that are in the engineering field, may be persuaded to pursue careers that offer significant economic capital and require higher academic training than

the ones their parents possess. First-generation students may find a connection between engineering and a manual job their parent may hold. For example, in some of our previous work, one first-generation student spoke about his parent's job as the reason he wanted to enter the military and major in electrical engineering. This student's father was a veteran, but worked in appliance repairs. The student made the connection between his father's job and an engineering discipline so that he could "following in his father's footsteps" while pursuing an advanced degree [49].

Additionally, engineering students with lower socioeconomic status are less likely to be encouraged by their science teachers than their peers [48]. On average, non-first-generation students reported having a greater interest in science with an effect size of $d = 0.30$ ($p < 0.01$) than first-generation students. A study claims that "well-rounded" students, those who typically have a higher socioeconomic status, tend to have greater family encouragement towards science [48], our findings also validate this claim.

Our analysis suggests that first-generation students show a slightly greater interest in "having job security and opportunity" ($p < 0.05$). This finding may be consistent with their higher interest in careers in engineering and math. One study reported that students may be more likely to persist towards earning an engineering degree, regardless of any "negative views about certain aspects of engineering education," if they strongly believe an engineering degree will improve career security [26, p. 366].

Chi-square tests were conducted to analyze group differences in family interest in and support of science and mathematics (see Table II). Although first-generation students had high levels of interest in mathematics and mathematics related fields, these students reported lower levels of family support in mathematics. The lack of support in math and science, for first-generation students, may also account for the highly significant difference in reporting that these topics were "not a family interest." Having non-college educated parents equates to lacking social and/or cultural capital, which can undermined access to resources (i.e. math/science tutors) given to first-generation students. At the same time, this lack can lead to less informed decisions about the need to excel in the mathematics and science fields [52]. Research has demonstrated that parental beliefs and expectations can promote academic achievement in mathematics for students [23], [53]. A prior study reported that students whose parents met with mathematics teachers, counselors or attended training workshops on how to support student's mathematics skills made greater gains in mathematics than those who did not [53]. This kind of parental involvement in students' academics may be a challenge for first-generation students with parents that primarily speak a language other than English in the home. Students may be experiencing a difficult time translating mathematics terminologies to their parents, thus making it more challenging for the parents to provide support. Layered on top of the complexity of non-English speaking families are different cultural understandings the role of school in students' lives and how parents interact with this institution [54]. For some immigrant families, parents may not expect to have a lot of interaction with the teacher because that is not a common practice in their home country. The difficulty is often not only linguistic (schools regularly employ translators) but can also include working conditions (e.g.

multiple jobs) which do not allow parents to participate as readily in school activities. As well, some parents also have little schooling themselves, which creates a disconnect in understanding the role teachers in the American school system play in their children's lives. Some parents were even said to be "sensitive about the issue and aware of their own limitations in the eyes of their children" [54, p. 151]. However, this ethnographic study points out that life circumstances had prohibited these immigrant parents from receiving a formal education rather than explicit decisions not to pursue additional education opportunities [54]. Additionally, parents might not be aware of alternative ways of helping their student, such as tutoring services or online resources, to name a few. Parents may also be working long hours or have work schedules that conflict with their students' homework time. So, there are complex dynamics at play that can vary significantly and require different types of interventions. Efforts to support this population will require educators to actively engage with these students, as well as provide resources for parents to become involved in their student's academics.

The reported lack of family support towards math and science may hinder first-generation students' perceptions of themselves as math and science people. One of the most important subconstructs of identity theory is feeling recognized by others as the type of person who can fulfill a particular role (e.g. science person, math person, engineer, etc.). We found no significant differences in students' self-beliefs of performance/competence in math and science or feeling recognized by others in those areas. While differences in interest were found, with higher interest in math for first-generation students and higher interest in science for non-first-generation students, interest is only one subconstruct of identity. Other work has shown that believing that other see them as a "math person" or "science person" (e.g. recognition) is the most important factor for identity development [24], [25]. In order to begin to understand first-generation student's math identity, further research is required to uncover how this math interest is developed and who, if anyone, recognizes students.

These results are, overall, consistent with findings from several previous qualitative studies on first-generation students. However, these results offer insight into how students see themselves as math and science people (identity) and how they differed in expectations for career from their peers. First-generation students are similar in many ways to their peers. While non-significant results were not reported in this study, other identity subconstructs in math and science recognition and performance/competence beliefs were not any different between the two groups compared.

In utilizing a cross-sectional study design, the data gathered have some strengths: large statistical power, national representativeness in the sample, and the ability to test hypotheses surrounding events that were introduced to students naturally rather than through an intervention. This study design also has certain weaknesses, notably including the inability to draw causal conclusions. Rather, results are correlational in nature. The results do indicate substantial correlations between student responses and students' choice of major, but further work is necessary to indicate a causal direction to these relationships. For example, first-generation students may be interested in STEM-related careers because they see it as a way to "apply math and science" as an

outcome expectation, or they may want to "apply math and science" because they have chosen a STEM-related career that does so. The direction of the effect cannot be determined from the data collected in this study.

VI. CONCLUSION

These results show significant differences in first-generation students' career outcome expectations, interest in math and science, career interests, and family backgrounds as compared to their peers. These differences have some implications for high school guidance counselors, college instructors, and engineering education researchers. When advising students for entry into college, ensuring that first-generation students have an understanding of the expectations and types of careers that they could possibly pursue in engineering could improve the match between students' interests and career outcome expectations. This approach could also improve retention of these talented and diverse students within engineering programs. In designing curricula or pedagogy, mapping how engineering meets desired outcome expectations (inventing/designing things through the engineering design process, developing new knowledge and skills, and doing hands on work in classroom environments through CAD drawing, prototyping, gathering data, etc.) could improve students' desires to continue in engineering. This work also highlights the needs for educators and schools to partner with first-generation students' parents to provide the support and resources that these families need. Finally, this research highlights areas of research in how first-generation students are prepared to enter college, how they choose engineering, and what factors can help support identity development in this group of students. Our future work will begin to explore these areas through mixed methods research.

ACKNOWLEDGMENT

The authors would like to thank the participants of the Sustainability and Gender in Engineering for providing the data used in this paper.

Abstract— With the increased acceptance and inclusion of engineering as an area of study at the K-12 and the proliferation of outreach activities intended to increase students' interest in pursuing degrees and careers in engineering, first-year engineering students are increasingly arriving in university engineering programs with significant prior exposure to engineering content and practices. In this study, using a combination of a survey and follow-up transcript analysis, we explored the relationship between students' participation in pre-college engineering activities and their academic performance in their first year of studying engineering at a large research university. We found no significant relationships between either the type of pre-college engineering activity or the level of participation and students' grades in their first-year engineering classes. We did identify several trends in the data that suggest other areas of study, as well as changes to the data we request from students regarding their pre-college experiences.

Keywords—pre-college engineering, first-year engineering, K-12, persistence

I. INTRODUCTION

Pre-college engineering is growing. This growth is evident in the proliferation of pre-college engineering programs and activities, the inclusion of engineering knowledge and practices in state and national educational standards, and a growing acceptance of engineering as part of the K-12 curriculum. Popular programs such as the Project Lead The Way curriculum and FIRST Robotics competitions attract large numbers of students each year. Engineering is featured prominently in the *Next Generation Science Standards* [1], which guide the development of state science standards that in turn influence what students are expected to learn in the K-12 classroom. Engineering is already included in the educational standards of many states, although the implementation of engineering and level of integration in the K-12 curriculum varies significantly between states [2], [3]. As the acceptance of pre-college engineering programs continue to grow, increasing numbers of young people will be exposed to engineering ideas and practices.

The pre-college study of engineering presents numerous benefits. These include increased awareness of engineering and the work of engineers, a valuable context for the promotion and growth of mathematics and scientific knowledge and applications, the development of engineering habits of mind

and thinking modalities that can help solve problems encountered in everyday life, increased technological literacy, and interest in pursuing engineering as a career [4]. Although limited in their ability to establish causal relationships, many studies have shown that exposure to pre-college engineering activities in formal and informal educational settings can influence students' decisions to pursue a degree and career in engineering [5]. However, relatively little is known about the relationship between pre-college exposure and students' subsequent academic performance in an engineering degree program. The present study seeks to address this gap and explore the connection between pre-college engineering programs and students' first-year of studying engineering at a large public research university.

II. BACKGROUND

Students who have participated in pre-college engineering programs tend to perceive lasting benefits of participation in their university engineering studies. These perceived benefits include increased technical knowledge and abilities, increased comfort with engineering design, and improved professional skills such as the ability to work on a team or communicate technical ideas [6], [7].

Prior quantitative research on the effects of pre-college engineering is limited, and tends to focus on either Project Lead The Way (PLTW) or FIRST Robotics (FIRST), the two largest pre-college engineering programs in the country. PLTW is a series of elementary, middle and high school classes, with a variety of courses focused on different engineering disciplines available at the high school level. FIRST Robotics is a series of robotics design and build competitions, with different events targeted at elementary, middle, and high school programs and generally implemented as an extra-curricular activity.

With over 6,500 schools in all 50 states offering one or more of its courses, PLTW is the largest provider of pre-college engineering curricula in the United States [8]. Research on the effects of participation in PLTW courses are mixed, with most studies showing a positive relationship between participation in the program and students' decisions to pursue further study in STEM fields and increased achievement in their chosen degree programs compared to students that have not participated [9]. A large study utilizing propensity score

This work was supported by NSF Grant #EEC-1265216

matching to compare students that have participated in PLTW to students who have not found that the PLTW students scored higher on statewide mathematics assessments, were more likely to be college-ready, and more likely to pursue higher education [10]. Another large study found that PLTW participants were more likely to enroll in STEM degree programs, but did not measure students' performance in those programs. Studies that have looked at persistence of PLTW students have found no significant difference in persistence [11]. Overall, existing research on PLTW suggests positive effects on high school performance, but do not establish a strong relationship between participation and college performance [5].

Studies of FIRST Robotics are more limited, and show a high rate of interest in and tendency to pursue engineering degrees, but with little information on students' performance or persistence in their chosen degree programs. Evaluations of the outcomes of participation in FIRST Robotics competitions [12]–[14] found that students were more likely to pursue degrees and continue on to careers in STEM fields than students who had not participated in the program. Other research has shown that participants in FIRST robotics teams who were involved with specific aspects of the competition such as design, building, or documentation aspects of the competition were more likely to pursue STEM majors than team members who had not participated in those aspects of the competition [15]. A small sample of FIRST alumni who went on to serve as mentors for FIRST robotics teams attributed numerous benefits to having participated in the program such as increased technical skills and competence and knowing how to work on teams [7]. To summarize, while several studies have shown students participating in FIRST programs were more likely to pursue further study in engineering or other STEM fields, relatively little is known about how the students fared in their degree programs or if a relationship exists between participation and success in undergraduate engineering.

Other related studies connect pre-college engineering experiences to positive outcomes for students studying engineering. Participation in technology or engineering classes or interest in an engineering-related hobby such as computer programming or robotics can have a positive effect on university engineering students' self-efficacy, which may lead to increased achievement [16]. Engineering-focused high schools can also increase students' self-efficacy and interest in pursuing further study in engineering [17]. However, none of these studies explore differences in grades between pre-college engineering participants and non-participants.

Given the lack of research on university engineering program success and its relationship to pre-college engineering participation, this study seeks to answer the following research questions: 1) Is there a relationship between participation in different types of pre-college engineering programs (formal classes, extracurricular activities, enrichment programs, etc.) and students' academic achievement in their first-year of engineering studies? 2) Do students who have participated in a greater number of pre-college engineering activities have higher academic achievement in their first year of engineering studies?

III. METHOD

To explore these questions we developed a survey [18] and administered it to students in four sections of the First-Year engineering course at Purdue University. At the same time, we obtained consent from a portion of the students completing the survey to access their academic records to explore the connection between pre-college engineering participation and students' grades in the two classes that comprise the first-year engineering program, along with their grades in their first two calculus classes. The original survey link was sent to 470 students, with 411 students completing the survey. Of those respondents, 301 were domestic students, and of those students 230 consented to allowing access to their academic records. We administered the survey in Fall of 2013, and in Fall of 2014 retrieved the academic records of the students and connected this information to their original survey responses.

In this study, we examined the relationship between pre-college engineering participation and four courses in the first-year engineering sequence. Engineering 1 is taught in sections of 120 students, with students working in consistent teams of 4 students through the semester studying engineering design, analysis, ethics, diversity, and developing professional skills. Engineering 2 continues the study of design via a curriculum organized around learning MATLAB. The Calculus 1 and 2 courses are taught through the mathematics department, and have curricula consistent with the offerings of these courses at most universities.

To analyze the data, we conducted independent samples T-tests using SPSS to compare differences in mean grades in the aforementioned engineering and calculus courses. We conducted two sets of analyses. The first focused on exploring differences between students who had participated in various types of pre-college engineering programs compared to students that had not participated in those programs. The types of programs we compared were classes in elementary, middle, and high school, extracurricular activities, summer camps, university-sponsored pre-college engineering programs, and an "Other" category for students who had experiences that they felt were connected to engineering but did not fit in any of the provided categories. The second analysis also used independent samples T-tests to compare the mean grades of students differentiated by the number of pre-college engineering activities that they reported.

IV. RESULTS

Tables 1 and 2 show demographic information for the participants in this study, and suggest that the sample is representative of the overall demographics of First-Year Engineering at the University.

TABLE 1: GENDER OF DOMESTIC RESPONDENTS (N=226)

Gender	Count	Percent
Female	58	26%
Male	168	74%

TABLE 2: RACE/ETHNICITY OF DOMESTIC RESPONDENTS (N=225)

Race	Count	Percent	Percent of First-Year Engineering Students
White	177	79%	80%
Asian	28	12%	7%
Hispanic/Latino	13	6%	5%
Multiple/Other	4	2%	Not tracked
Black/African American	3	1%	3%

Table 3 shows the number of students interested in the various engineering disciplines available at the University, sorted by the average number of activities reported by the respondents. Significant variation exists in the number of reported pre-college engineering activities, ranging from around three activities for students interested in electrical or computer engineering to 1 activity for students indicating interest in Agricultural, Biological, Biomedical, or Industrial Engineering.

TABLE 3: MAJOR AND AVERAGE NUMBER OF PRE-COLLEGE ENGINEERING ACTIVITIES (N=226)

Major (number of respondents)	Average number of activities
Computer Engineering (15)	3.1
Electrical Engineering (14)	2.9
Interdisciplinary / Multidisciplinary Engineering (5)	2.4
Mechanical Engineering (64)	2.3
Nuclear Engineering (8)	2.1
Aeronautical and Astronautical Engineering (31)	2.0
Chemical Engineering (26)	1.9
Undecided (7)	1.7

TABLE 4: DIFFERENCES IN MEAN FIRST-YEAR COURSE GRADES BY CONTEXT OF PRE-COLLEGE ENGINEERING PARTICIPATION

Course Mean Grades and Sample Sizes						
Context		%	ENGR 1	ENGR 2	Math 1	Math 2
Elementary School	Y	4.4	3.50 (10)	3.00 (10)	3.00 (9)	2.30 (10)
	N	95.6	3.67 (219)	3.11 (200)	2.78 (199)	2.57 (198)
Middle School	Y	18.3	3.62 (42)	3.15 (40)	2.92 (37)	2.50 (41)
	N	81.7	3.67 (187)	3.09 (170)	2.76 (171)	2.57 (167)
High School	Y	66.8	3.65 (153)	3.14 (142)	2.84 (141)	2.57 (139)
	N	33.2	3.67 (76)	3.03 (68)	2.66 (67)	2.55 (69)
Extracurricular	Y	32.3	3.57 (74)	3.04 (69)	2.79 (69)	2.47 (69)
	N	67.7	3.70 (155)	3.13 (141)	2.78 (139)	2.60 (139)
Summer Camp	Y	17.5	3.55 (40)	3.23 (35)	2.59 (38)	2.60 (36)
	N	82.5	3.68 (189)	3.08 (175)	2.83 (170)	2.55 (172)
University Program	Y	14.8	3.65 (34)	3.07 (28)	2.63 (29)	2.53 (29)
	N	85.2	3.66 (195)	3.11 (182)	2.81 (179)	2.57 (179)
Other	Y	16.6	3.58 (38)	3.14 (35)	2.63 (31)	2.74 (36)
	N	83.4	3.68 (191)	3.10 (175)	2.81 (177)	2.52 (172)

Mean (Sample Size) no differences significant

TABLE 5: DIFFERENCES IN MEAN FIRST-YEAR COURSE GRADES BY AMOUNT OF PRE-COLLEGE ENGINEERING PARTICIPATION

Course Mean Grades and Sample Sizes					
Participation		ENGR 1	ENGR 2	Math 1	Math 2
1 or more activities	Y	3.65 (178)	3.10 (163)	2.79 (160)	2.55 (164)
	N	3.69 (51)	3.11 (47)	2.76 (48)	2.60 (44)
2 or more activities	Y	3.60 (118)	3.16 (108)	2.82 (106)	2.57 (108)
	N	3.72 (111)	3.05 (102)	2.75 (102)	2.55 (100)
3 or more activities	Y	3.61 (70)	3.22 (65)	2.70 (63)	2.50 (66)
	N	3.68 (159)	3.06 (145)	2.82 (145)	2.59 (142)
4 or more activities	Y	3.59 (39)	3.25 (36)	2.63 (34)	2.38 (38)
	N	3.67 (190)	3.07 (174)	2.82 (174)	2.60 (170)

Mean (Sample Size) no differences significant

Civil Engineering (13)	1.7
Environmental and Ecological Engineering (5)	1.6
Materials Engineering (7)	1.6
Agricultural Engineering (4)	1.0
Biological and Food Process Engineering (2)	1.0
Biomedical Engineering (13)	1.0
Industrial Engineering (12)	0.8

Table 4 shows comparisons of the mean final course grades in the respondents' first-year engineering courses and first two semesters of calculus, separated by the context of pre-college engineering participation. Significant variation exists in the level of participation in each of the contexts, ranging from 66.8% of respondents indicating that had done engineering activities in a high school class to only 4.4% of the sample indicating exposure to engineering in an elementary school class. Note that many of the respondents will be included in multiple comparisons, as they have had exposure to engineering in multiple contexts. All of the mean course grades were comparable between each of the engineering contexts, and this combined with the relatively small sample sizes for several of the contexts led to no significant differences in the means as measured using an independent samples T-test.

Table 5 shows comparisons of the mean final course grades in the respondents' first-year engineering courses and first two semesters of calculus, separated by number of pre-college engineering activities. Similar to the engineering contexts, we did not find any significant differences in the means between the groups using an independent samples T-test.

In addition to the results shown in the tables, we conducted a one-way between groups analysis of variance to explore the effect of pre-college engineering participation on course outcomes in the first two engineering courses and math courses included in the first-year engineering curriculum. Participants were divided into groups according to their level of participation (Group 0: 0 activities; Group 1: 1 activity; Group 2: 2 activities; Group 3: 3 activities; Group 4: 4 or more activities). We did not find any statistically significant differences in any of the final course grades for any of these groups.

V. DISCUSSION

Although the differences are not significant, students with increased pre-college engineering participation tended to have higher grades in Engineering 2. This may be indicative of the relationship between prior programming experience and increased performance in this programming-focused class, and suggests that future surveys should more strongly focus on identifying the content of the students' pre-college engineering experiences, as this may have a more measurable effect on course outcomes.

Students who participated in significant numbers of pre-college engineering activities also tended to have lower grades in their math course, although again these results are not statistically significant. This may suggest that although these students were highly engaged in their engineering activities, they may have been less focused on their studies in general. This is not necessarily bad, as it suggests that pre-college engineering activities may have some success in recruiting students into engineering who might otherwise be deterred by lower grades in their math and science courses. This suggests a need for a future study that includes more information on students' pre-college academic performance to explore this hypothesis.

VI. CONCLUSION

The results of this study suggest that minimal relationships exist between students' participation in various types of pre-college engineering programs and activities, and their academic performance in their first-year of engineering studies. The results also suggest that we need to make changes to the survey instrument to explore students' exposure to various types of engineering content as opposed to the types of activities that they participated in.

As the students described in this paper complete their second years of study and decide to continue towards the completion of their engineering degree programs or leave engineering to pursue a different degree, we will be able to explore the relationship between pre-college engineering programs and persistence in undergraduate engineering.

Abstract— Engineering Mechanics (Statics) is a challenging sophomore course and an essential prerequisite for many branches of engineering. Unfortunately, the Statics course often becomes a gatekeeper course for numerous engineering students. This paper focuses on the process and the tools developed for effective identification of at-risk students in the Statics course. Effective early identification of at-risk students allows for timely interventions and for the informed use of teaching resources. In this paper, the authors describe the methods employed to effectively identify at-risk student and accurately assess students' mastery of prerequisite material. Moreover, the authors describe herein the interventions employed to improve student success. It is argued that the described activities have increased and will continue to increase student engagement in learning and their persistence to pass the Statics course. Preliminary assessment results show promising accomplishments in addressing knowledge and student retention and engagement.

I. INTRODUCTION

Investigations of students' academic preparedness [1]–[2], study practices [3], and engagement with their own learning process have been useful in identifying students at risk. At-risk student in this paper is used to describe students who are considered to have a higher probability of failing specific lower level STEM gatekeeper courses. Drawing from the literature, the identification of at-risk students in lower-level engineering courses in this project is based on assessment of student prerequisite knowledge retention, student past performance, and student self-efficacy. This section describes some of the most common ways to identify students at risk and the importance of early educational interventions.

A. Early Identification of At-Risk Students Based on Prerequisite Knowledge Retention

STEM curricula are structured in such a way that students are required to satisfactorily complete the prerequisite courses before progressing in their degree program. It has been well established that the assessment of students' prior knowledge and understanding of prerequisite concepts is an effective tool to establish the appropriate level at which to begin instruction in a specific course [4]. In many cases, STEM programs rely only on students passing the prerequisite courses for admission into the advanced courses. However, issues with

knowledge retention of prerequisite material are commonly observed and reported in the literature [5]. Thus, diagnostic testing has become more widespread in colleges and universities [6].

Identification of at-risk students based on prerequisite knowledge is especially relevant for lower-level engineering students. In fact, Efimba et al. [7] concluded that prerequisite knowledge is a more important factor in determining student's success in a sophomore engineering course for underclassmen than for upperclassmen (i.e. the achievement of underclassmen was directly related to prerequisite knowledge). The study suggested that upperclassmen are more likely to work to compensate for deficiencies in prerequisite knowledge and that underclassmen are more likely to need additional measures to enhance their achievement. Stated by Mills et al. [8], a newly implemented Civil Engineering curriculum was mainly focused on project-based and problem-based learning. The authors show the effectiveness of the new curriculum to be the best way to satisfy industry needs, without sacrificing knowledge of engineering fundamentals. They concluded that the engineering industry and academics are more familiar with concepts of projects in professional practices than with concepts of problem-based learning.

B. Early Identification of At-Risk Based on Past Performance

Even though knowledge retention may be a valid concern, a student's past performance record provides an early indication of whether she/he is at-risk. For example, Levin and Wyckoff [8] determined that an effective freshman year model to identify the best predictors of retention is using grades in Physics I, Calculus I and Chemistry I; and in a sophomore year model, the best predictors of retention were grades in Calculus II, Physics I and Physics II. Zhang [10] found out that high school GPA and math SAT scores were positively correlated with engineering graduation rates for all universities for which data were available. Interestingly, verbal SAT scores correlated negatively with odds of graduation, the consistency of this outcome for seven out of eight universities makes this observation even more notable. Several other studies [11]–[16] have identified at-risk students in engineering programs based on the students' high school

GPA, SAT and ACT scores, college GPA, and passing grades in the freshman engineering courses, among other predictors.

Some of the previous studies, however, usually presume students are completing prerequisite coursework at the institution and do not necessarily consider the impact should they be transferred from early-college programs or two-year institutions. Preliminary work was previously conducted by the authors to determine if there were definitive correlations between success in Statics and performance in prerequisite courses. The results were highly inconsistent. This was attributed to the fact that at The University of Texas-Pan American (UTPA) students can transfer in or receive credit for Calculus I and Physics I – the prerequisites for Statics – through various means that introduce high variance in the results. Some of the options include the credit for high scores on either the Advanced Placement (AP) or International Baccalaureate (IB) Exams. Other means are far less consistent, however. Students can transfer credit from the regional two-year institutions, which have dual enrollment agreements with school districts to offer early-college programs directly at the high schools sometimes employing existing high school educators credentialed to offer courses for college credit. Assessments and curriculum for these courses are not standardized. Though UTPA does collect data regarding whether course credit was attained by exam or transfer credit, with regards to the transfer credit in particular, it cannot parse where or how the course was administered.

Some studies have suggested combining student past performance with retention of prerequisite knowledge and/or ongoing performance in the course to identify at-risk students. For example, Huang [18] indicated that in engineering dynamics, a sophomore-level course, many students perform poorly because they lack solid mathematical skills and good understanding of concepts and principles. The most useful predictor variables in dynamics were the cumulative GPA, three prerequisite course grades, and the first exam score in the course, allowing sufficient time for the instructor to implement educational interventions during the rest of the course [18]. Furthermore, to better assess student prior domain knowledge, a pretest prior to the start of the dynamics course and homework grades were suggested to be included in future studies as predictor variables [18]. Other programs have significantly invested in technology to track students beyond the traditional online homework system. For example, Steif and Dollar [19] developed a learning dashboard (LD) computer system in Statics as part of the Carnegie Mellon Open Learning Initiative to allow instructors to track on-line learning activities and to estimate needed skills and concepts for students to master Statics. Another study has been performed to identify how organization of a student's solution to problems in Statics relates to correctness of the work and can be used as indicator of at-risk students [20], [21].

C. Early Identification of At-Risk Based on Self-Efficacy

The majority of the reviewed studies focused on early identification of at-risk students based on prerequisite knowledge and/or past student performance; however, there is recognition in the literature of other missing factors.

Besterfield-Sacre et al. [22] mentioned that students' attitudes are important in the perception students have about engineering and their self-assessed abilities; however, educators have focused more on assessing the mastery of content knowledge and skills. The perception of engineering, motivation, confidence, competency, retention, and persistence is affected by these attitudes [22]. Many students need a reality check to conceptualize their own responsibility and what is required of them to obtain an engineering degree; some students lack certain skills and level of maturity (e.g. time management, how to talk to professors and ask for help) that instructors might take for granted [22]–[24].

Albert Bandura [24], [26] defines self-efficacy as “people's beliefs about their capabilities to produce designated levels of performance that exercise influence over events that affect their lives.” Increasing a person's self-efficacy for a specific challenge will have a direct impact on achievement [27]. Also, Denzine [27] mentioned that engineering education researchers are focusing on the topic of achievement motivation. Developing motivated, self-directed, or self-regulated, students allows for self-regulatory learning with the benefit being students self-monitor thoughts, feelings, and behavior to achieve the goal. Zajacova [28] conducted a study on first-semester freshman students to demonstrate the relationship between academic self-efficacy and stress and its effects on students' grades and persistence; suggesting that that self-efficacy is a better predictor of success than stress. Instructors and mentors can help students modify their learning strategies to lead to college and lifelong positive benefits [28]. It is suggested that instructors must consider providing frequent feedback to students to develop self-regulating behavior and help them to understand their learning process. Self-efficacy develops with experience and time and it is not a fixed personality characteristic. College students should have a learning goal orientation, which is a malleable state, rather than a performance goal orientation, in order to have positive effects on learning, motivation and achievement [24].

The identification of at-risk students based on past performance has been combined and/or compared with assessment of different aspects of student self-efficacy. For example, the Pittsburgh Freshman Engineering Attitudes Survey (PFEAS) has been used to measure incoming freshmen attitudes during registration and SAT score was used to measure initial preparedness [28]. The PFEAS was used to measure students' attitudes toward an engineering career and their self-assessment about confidence in study habits and communications skills. The most important predictor factors that were identified included preparation (SAT), academic ability (high school rank), and confidence in study habits (PFEAS) [28]. Allen et al. [30] analyzed the effects of academic performance, motivation and social behavior on the third-year retention, transfer and dropout from college. If the reason for students to drop out is clarified and studied, they believe that the intervention programs and supplemental instruction can serve students better.

D. Importance of Early Educational Interventions

Successful early interventions increase student learning and decrease student attrition and frustration. In fact, the literature suggests that by improving the performance during the first term of students at risk, the chance of successful completion of the engineering programs increases [31]. For example, the provision of supplemental instruction for at-risk students has been found to be effective in improving the grades of such students [32]. However, the success of some teaching/learning methods, such as problem-based learning, depends on student's self-efficacy and team collaboration [33]. Blat [34] indicated that supplemental instruction (SI) focuses on high-risk courses ($> 30\%$ students failing) not on high-risk students, and that SI is not a remedial program. SI is recommended to promote and facilitate collaborative learning, with specially qualified and trained peer leads that do not work problems for students but teach students how to learn.

There is evidence that early educational interventions are especially important for lower-level students. For example, Knight [35] determined that engineering students who take a first-year engineering projects course are significantly more likely to be retained at the third, fifth, and seventh semesters than their peers who do not take the course. This is accredited to the impact of active hands-on pedagogy, developing student learning communities, early experiences of the human side of engineering, self-directed acquisition of knowledge, mentoring, and the success orientation of the course. Thompson mentioned that many newcomer students simply do not know how to look at themselves as learners, think about how they learn, set goals, actively apply strategies, and monitor themselves as they make progress [36]. The degree of self-regulation required at the college level is frequently not what students are used to. Instructors must do more than prepare lectures, they must address students' processing skills.

There is evidence that the process of selection, implementation, and fine-tuning of early educational interventions is not trivial. For example, a study determined the effectiveness of 4-hour as opposed to 3-hour version of a traditional Statics course [37]. The additional hour involved a mandatory problem session. After controlling for factors such as SAT Math scores, Calculus I grades, and Chemistry I grades, to identify at-risk students, it was found that the performance difference on the final exam between those who took the 3- and 4-hour sections of the course was statistically insignificant implying that the additional hour was not effective. Another study [38] demonstrated the effect of small group learning on success of undergraduate students in science, mathematics, engineering and technology courses.

E. Statics: Lower-Level Engineering Gatekeeper

Fig. 1 indicates the main topics that are associated with student learning outcomes in the Statics course in our department, shown in the order covered in class. One of the main difficulties students face in Statics is retention and integration of knowledge in all these topics to develop adaptive expertise skills to apply the learned concepts and

procedures to solve a variety of engineering mechanics problems.

Fig. 1. Main topics studies in Statics.

As baseline information, the passing and failing rates of students that took Statics taught by the same instructor in the regular semesters from the Fall 2006 to Spring 2011 semesters are as follows. Students that passed the course got A, B, or C grades and the average passing rate during such time was 60.7%. Students that dropped were about 14.3%; therefore, about 25% of students got D or F grades. With a different instructor, the average passing rate remained at about 60% until the Fall 2013 semester (before early educational interventions). However, the students who dropped the course increased up to $\sim 25\%$. Students drop the course due to different circumstances along the semester: deficiency in algebra and trigonometry, too much work, too many courses, missing homeworks and classes, and lack of commitment to be persistent and overcome frustrating experiences.

II. AT RISK STUDENT EARLY IDENTIFICATION

This section describes the methods selected to identify students at risk (based on prerequisite knowledge, past performance, and self-efficacy) in this study and the early interventions to be studied [Fig. 2].

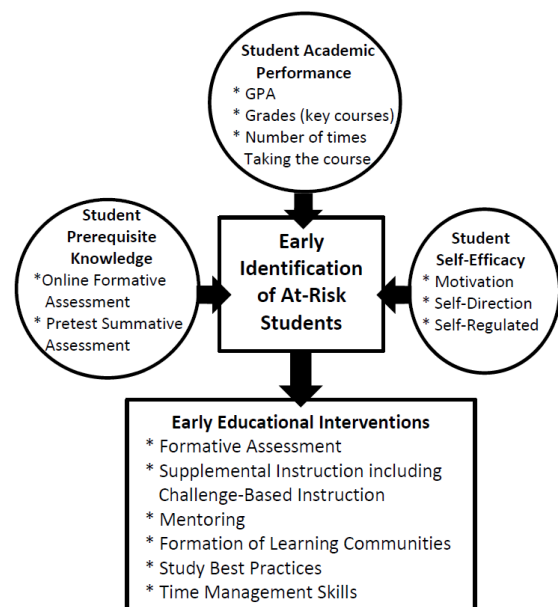

Fig. 2. Early Identification of At-Risk Students and Intervention.

The use of frequent online formative assessments is being promoted in gatekeeper courses to keep students actively learning outside of the classroom, solving problems to master the material, and abreast of their current knowledge mastery. Assessments were prepared in Statics for students to review prerequisite material at the beginning of the course. Figs. 3-4 show sample online questions, prepared with Respondus and implemented on Blackboard, about algebra, trigonometry, calculus, and physics. The online assessments provide students with quick feedback to test and improve their knowledge in prerequisite topics as well as in new concepts studied in the course. An important goal of these online assessments is to encourage students to study out of the class time and apply the concepts they are learning to reinforce knowledge retention and at the same time to emphasize the importance of such knowledge. It is estimated that the perception and the interest of the students about what they are learning improves through these online assessments. In fact, students have shown increased engagement in learning and perseverance to pass the class because the majority try multiple attempts in order to improve the online assessment grades and to practice more problems. Online assessments are graded automatically and provide immediate feedback to the students. In each question, students get random values from a range previously determined by the instructor; therefore, it is usually the case that different students do not get the same values. Also, not all students get exactly the same questions. However, preparing online assessments is a complex task that requires developing, testing, and implementing the assessments, ideally involving relevant real-life applications to make a positive impact on the students' understanding of concepts.

Fig. 4 shows an example question used in the online assessments that are given to the students at the beginning of the semester to review prerequisite topics. Notice that this example shows the feedback students receive when answering either correct or incorrectly. As the online assessments are improved, it is expected that the feedback becomes more elaborated so that students might be directed to study specific sections of the textbook, to study information from a web page, to watch a video, or other remedial action. Reviewing these topics is an essential step at the beginning of the Statics course. Fig. 4 illustrates a question about Physics to review for the pretest in which students need to determine the horizontal and vertical components of a force vector. These online formative assessments present multiple advantages, including the randomly generated parameters that allow assigning different system conditions to each student.

One important fact that might become a drawback of online assessments in comparison to written homework assignments or in class or recitation session assessments is that the students' complete work is not revised by a grader. Therefore, the required steps in the procedure to solve online problems, such as drawing complete free body diagrams and finding the equilibrium equations are not directly being evaluated; instead, it is expected that students attend the instructor's office hours or mentoring sessions (when

available) to get help to answer any online assessment questions. In such case, it is important to allow students to perform the assignments in multiple attempts to obtain the best possible grade, to ask questions before the next attempt, and to practice solving more problems. Consequently, it is important that the students take ownership of their learning process by asking questions and being persistent to complete the online assignments.

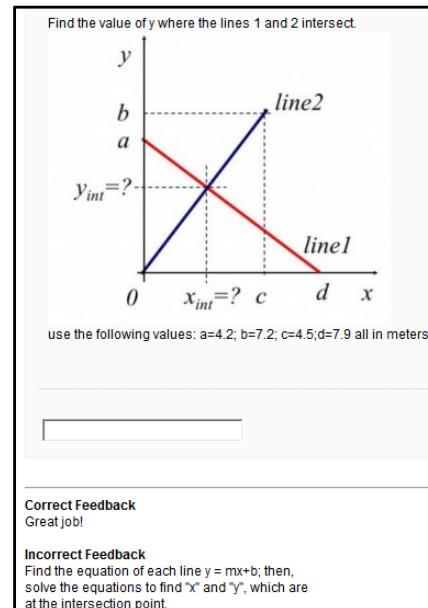

Fig. 3. Online question example to review prerequisite Trigonometry material.

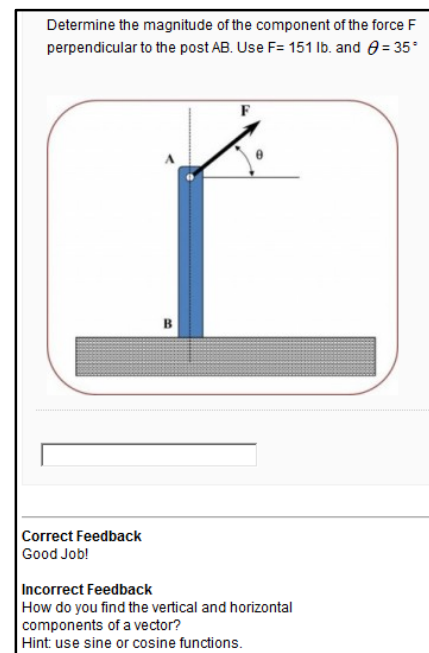

Fig. 4. Online question example to review prerequisite Physics material.

III. SAMPLE INTERVENTIONS

The first step in the intervention was to develop online assessments for students to review prerequisite material. After

that, a pretest was prepared to identify strengths and deficiencies of students at the beginning of the course. The next intervention step was to identify the best study practices to use as guidelines for students to be successful in the gatekeeper courses. Supplementary instruction in the form of mentoring sessions was also provided to help students solve homework. Online formative assessments were developed to engage and help students to persistently study to retain and integrate knowledge and apply it to solve problems throughout the semester. Another intervention in the gatekeeper courses consists of developing challenges with real world context problems to motivate students to learn the material and acquire adaptive expertise. Consequently, it is expected that by combining best study practice guidelines, online assessments, real world context challenges, and peer-led mentoring sessions, student performance and passing rates in the gatekeeper courses will be improved.

Expectations and Guidelines for Students to be engaged in the Gatekeeper Courses: In collaboration with the Center of Excellence in STEM Education at UTPA, a website is being designed to help faculty and students to achieve academic excellence. The instructors of gatekeeper courses are encouraged to make students aware of the purpose and importance of the following course materials, resources, and best student practices:

- Considerations to prepare and to explain the syllabus;
- Importance of note taking and record keeping;
- Time management tips;
- Taking full advantage of office hours;
- Solving homework and solution format;
- Benefits of attending mentoring sessions and mentors' benefits;
- Advantages and disadvantages of team work and study groups; and
- Creating and implementing challenges and promoting adaptive expertise

Identifying At-Risk Students at the Beginning of the Course: Several tools were developed and implemented to identify at-risk students at the beginning of the gatekeeper courses. It is estimated that supplementary instruction, such as mentoring, could benefit at-risk students that are willing to work hard, study, ask questions, and dedicate time to learn and master the material in the course.

As shown in Fig. 2, the specific factors that were taken into account to identify at-risk students are:

- Grades on first assignments to prepare for pre-test;
- Pre-test grades;
- GPA and performance in pre-requisite courses;
- Class repetition due to failure or drop; and
- Survey to determine motivational, socio-economic, and demographic factors.

The purposes of students preparing for the pre-test and taking the pre-test are to make them aware of the need to retain previously acquired knowledge; another purpose is to identify those students that might be at-risk at the beginning of

the courses due to insufficient mastery of prerequisite knowledge. So far, it has been determined that, when well designed, there is a correlation among the results of a pretest and the final grades in the Statics course. Hence, it is important that the instructors of gatekeeper courses develop activities to engage students to review and study prerequisite material because it could be a determinant factor in the success or failure of the students in the course. As the courses progress, most students usually assume that new concepts are not very difficult to understand because they can follow the instructor's explanation in the lectures. However, difficulties arise for some students when making decisions needed to adapt and apply the acquired knowledge to solve different or more complicated problems.

Implementation Process: In order to prepare the students for the pretest (i.e. prerequisite material evaluation), the developed online formative assessments were assigned to students the first day of classes. The pretest, which has been refined for a number of years, is usually administered during the third class of the semester (i.e. second week). Besides having questions about prerequisite material, the pretest contains questions about students' previous academic performance (e.g. GPA, grades in pre-requisite courses, number of times taking the courses) to help identify at-risk students. At the same time, students completed an online survey to determine student self-efficacy and motivation and to try to capture socio-economic and demographic factors. Based on student pretest performance (e.g. pretest grade <70) and these other factors, students at risk were identified and were asked to attend mentoring sessions led by trained upper level students to discuss and clarify any doubts about class, homework, or projects.

IV. PRELIMINARY RESULTS

The project began in Fall 2013 with development and refinement of the previously described instruments. The results in Statics in the Fall 2014 semester about the online assessment developed to review prerequisite material is presented in Table 1. It was determined that 44 out of 45 students completed the online assessment at least one time. During the first attempt, the average grade was 44; 41 students attempted to solve the assessment a second time and the average grade was about 57%; 33 students attempted to solve it a third time and the average was about 69%; 18 and 13 students attempted it for a 4th and a 5th time, respectively. The average number of attempts the students tried on the first online assessment was 2.5. This shows that the formative online assessments engage students and make them persistent to study and try to obtain better grades. The overall average, considering the final grade as the highest grade of all five possible attempts of this assessment, was 80.8%.

Table 1. Results of the first online assessment.

	Grade on HW1	Attempt #1	Attempt #2	Attempt #3	Attempt #4	Attempt #5	Attempt #6
Number of Students	44	44	41	33	18	13	5
Average grade (%)	80.8	44.0	56.9	68.8	70.5	76.9	76.0

The results showed that there is a strong correlation among the results of a pretest and the final grades in the Statics course. Previous to this study, the authors found out that the implementation of prerequisite assessment instruments without allowing students to review the material did not provide useful information about at-risk students or predicted success in the course. Therefore, it is important that the instructors of gatekeeper courses develop activities to engage students to review and study prerequisite material before assessing them in such topics. Fig. 6 shows that a student who failed the course (final grade < 70) would have scored roughly lower than a 68 on the pre-test. In other words, a score of 68 on the pretest would, on average, lead to a final grade of 70, and with 95% confidence, it is estimated that the final grade would be between 65 and 75. A similar result was obtained between the pretest and the results on the exam 1 in Statics.

Even though these preliminary results need to continue being verified in future semesters and different courses, it is expected that well-designed pre-tests and prerequisite assessments could be accurate predictors of student performance in the course. The pre-test results not only provide important information to the instructor, about the students' preparation and knowledge of prerequisite material, but they also reinforce students' understanding of the need to review and further master prerequisite material in order to be properly prepared for the new course.

Fig. 5. Correlation between pre-test and Exam 1 (top) and final course grade (bottom) [Fall 2014]

Figs. 7 and 8 shows the correlation of the final course grade and the results in exam 1, the students' GPA, and grades in prerequisite courses (Calculus I and Physics). However, a

model was obtained after a series of diagnostic tests (e.g., normality), with no major violations of the procedure assumptions, so a basic ordinary least squares regression model was used. From the model results, the only significant predictor of final grade was the pretest. The GPA was significant originally, but, when pre-test was included as an input factor, it became no longer so ($P > |t| = 0.6$). We believe this is because a vast majority of variation in GPA outcomes is determined by non-mathematical classes (e.g. English, Sociology, Political Science, History, etc.) students encounter in the general curriculum and the fact that the GPA includes only UTPA coursework. Hence, key prerequisite courses are not included into the calculation of the GPA if credit is transferred from another institution.

Fig. 6. Correlation between GPA and exam 1 (top) and final grade (bottom) [Fall 2014].

The pre-test was a strong predictor of final course grade, however ($P > |t| = 0.05$). The pre-test is a direct measure of math/engineering fluency so it is therefore the more reliable predictor of course outcome. With the help of the grant's evaluator, a consent form and a socioeconomic, motivational, and demographics survey, both approved by IRB, were prepared and implemented in the courses. Student self-efficacy and motivation was estimated at the beginning of the semester by an online survey performed by the Center for Survey Research at our institution. The survey inquiry students about their interest in learning engineering, getting good grades, career advantages, discoveries, enjoyment of learning, and scoring high on test and course grades. Fig. 9 shows that students that score 38/50 or less on the motivation survey are at-risk of getting a final grade in the course that is less than 60%. The data are suggesting that any student scoring a 40/50 or below on the pretest motivation scale should be flagged for intervention.

In terms of demographic factors, the instruments showed that 93% of the students were underrepresented Hispanics and that 19% were female. About 40% of the female and male

students were identified as at-risk and attended mentoring sessions. The results showed that the mentorship program has a positive effect, especially for students with GPAs greater than 2.5. Female students have a slight declining performance from pretest to final grade. Fig. 10 shows the relationship between pretest-final grade improvement (i.e. the difference between the final grade score and the pretest score) and mentorship with GPA controls during the Spring 2015. It is important to mention that a number of students who were not identified as at risk requested permission to attend the mentorship program.

Fig. 7. Correlation between prerequisite course grades (Calculus top and Physics bottom) and Statics final grade [Fall 2014].

Fig. 8. Correlation between motivational survey and final grade [Fall 2014].

Fig. 10. Difference between Statics Pretest and final grade [Spring 2015].

Finally, the Statics course passing rate in the Spring 2014 (56 students with an online review average of 68 and a pretest average of 70), Fall 2014 (45 students with an online review

average of 80 and a pretest average of 83) and Spring 2015 (63 students with an online review of 70 and a pretest average of 70) were 75%, 71% and 61% respectively (including students who dropped the class). The authors expect that the results depend on, among other things, the number of students in the course and prior preparation as determined by the online assessments and pretest average. In the aforementioned semesters, interventions, including peer mentoring, had a significantly increase (~10%) in the number of student receiving a final grade of A or B.

V. CONCLUSIONS

This paper focused on the process and the tools developed for effective identification of at risk student in the Statics and other gatekeeper courses. In this study, early identification of at-risk students led to interventions with supplementary instruction activities, such as mentoring sessions, challenges, online assessments, attendance of office hours, and awareness of best study practices. Based on lessons learned, the semester started with a review of important prerequisite material needed to succeed in the course. A review of trigonometry, algebra, calculus and physics concepts was performed during the first lecture. Following the review, online assessments were used to provide instant feedback to students about areas of weaknesses where additional review is needed. An in-class pre-test is then implemented to assess the same prerequisite topics but with slightly different contexts to determine whether or not the students actually understood and mastered the prerequisite concepts. Identification of students at risk is then based on student prerequisite knowledge (e.g. pretest results, pretest online assessment), student past performance (e.g. GPA, the number of times taking the course, and grades in the prerequisite courses), and/or student self-efficacy. Among other things, a direct correlation was found between the results in the pretest and the student final grade in the course. The mentoring sessions were recommended to all students in the course; but, they became mandatory for at risk students.

In addition, the developed early at-risk identification system allowed the instructors to determine the preparation of the students at the beginning of the semester to tailor the instruction during the semester. It is argued that the described activities have increased and will continue to increase student engagement in learning and their persistence to pass the Statics course. Preliminary assessment results show promising accomplishments in addressing knowledge and student retention and engagement.

For at-risk students, the results of the interventions not always generate expected positive results. Some students have difficult schedules and/or poor time management skills; they do not complete the online homework, put no effort to attend office hours or mentoring sessions, and end up struggling and no passing the course. Different strategies are being implemented to motivate students. The instructors continue creating or adapting more online assessments and challenges to integrate knowledge. In each gatekeeper course, there has to be a plan for mentoring activities and training of mentors.

Future work in this project consists of completing the evaluation of results in Statics, Electrical Circuits I, Statistics, Computer Science I, Calculus I, and Chemistry I and adapting, developing, and implementing the materials required to perform the proposed interventions in the corresponding gatekeeper courses. This project is ongoing and it is in the middle of the second year of a total of five years. In the future, it will be important to complete and analyze the results of the pretest, surveys, and concept inventory required to identify at-risk students in several gatekeeper courses.

ACKNOWLEDGEMENTS

The authors would like to acknowledge the financial support of the National Science Foundation Science, Technology, Engineering, and Mathematics Talent Expansion Program (STEP) Graduate 10K+ program (grant number DUE-0311349) with special funding from Intel and General Electric, under which this project was carried out. We would also like to thank the UTPA Center for STEM Excellence (C-STEM) and its director, Dr. Cristina Villalobos, for assistance and support. Moreover, we thank the UTPA Center for Survey Research and its director, Dr. Jessica Lavariega Monforti and Dr. William Donner for assisting with evaluation and data collection.

Abstract— Many domestic and international students arrive at college lacking the skills needed for academic careers in engineering or engineering technology. To support academic progress and develop essential skills, TECH 101, Engineering Technology Fundamentals, was proposed, approved, and funded by the School of Engineering and Technology at a large urban public university. The course offered students the preparatory skill development needed to begin an engineering or engineering technology major. TECH 101 facilitated a completely different approach, utilizing a very rare collaboration. Course design and implementation were championed by an experienced engineering technology instructor and a uniquely qualified faculty member whose background includes both transition to college expertise as well as second language acquisition. Drawing the two diverse skill-sets together resulted in context-based activities closely integrated with hands-on technical work, as well as development of a technical vocabulary and English language skills. A small group of learners participated in the initial course offering in the fall of 2014. This Work In Progress paper will explore the unique technical and preparatory course components that promote the support of underprepared domestic and international students.

Keywords—retention, remediation, engineering education

I. INTRODUCTION

In 2005, a joint report from the National Science Foundation and the National Academy of Engineering [1] framed the priorities for improvement in academic institutions involved in engineering education. The group warned that, in order to meet the demands for engineering graduates, remedial coursework must be available and well-crafted. In addition, the report encouraged educators to incorporate engineering concepts into developmental education. However, the dearth of scholarly research associated with discipline-specific remedial educational experiences in engineering and engineering technology seems to document that few institutions heard this decade-old warning.

At some colleges and universities, especially less-selective institutions, many students arrive on campus lacking the academic and personal skills required for success in engineering or engineering technology programs. The typical support solution for these deficiencies is to require enrollment in developmental mathematics and English courses, guided by

placement tests [2]. As a result, the academic pathway toward enrollment in discipline-specific courses may be a long one. Student attrition during the remedial period may be substantial [3].

Vincent Tinto, the student retention theorist, has asserted that student access without support is not opportunity [4]. This perspective may lead educators to conclude that admitted students should receive highly engaging and academically appropriate support services that could promote growth, persistence, and achievement. Utilizing research results [5] associated with persistence factors identified in student populations in engineering technology served by urban public institutions, discipline-specific developmental coursework seemed to be appropriate approach to promote academic success. Important conclusions from the literature shaped the intervention, including personal goals centered around both degree attainment and discipline understanding, academic collaboration (as opposed to social connections), strong faculty relationships, and adaptability surrounding the student's academic role. All of these factors collectively can be generalized by a sense of belonging and a sense of purpose.

Donna Riley, in a March, 2015 *Prism* article stated, "Four-year institutions must no longer cherry-pick students able to withstand engineering's 'rigors'." [6] The prominent National Science Foundation-affiliated author strongly advocated for a "resource-rich" environment that includes substantial academic support. In addition Riley held the provocative position that "there is no situation from which one can 'never' become an engineer." Riley's stance strongly supports the notion of intertwining remedial content embedded in discipline-specific material and activities.

With a desire to support underprepared learners admitted to an urban public university, two faculty members identified and designed the delivery of a discipline-integrated support course to engineering and engineering technology learners, as a supplement to additional developmental mathematics and English coursework.

II. COURSE OBJECTIVES AND DESIGN

TECH 101 was created to cultivate fundamental analytical and communication skills for students who were unable to meet the pre-requisites for the first technical course in the engineering technology curriculum, TECH 105, Engineering Technology Fundamentals. TECH 105 requires students are ready for freshman composition and pre-college algebra. Many learners were international students or who may have graduated from an underperforming high school. As a result, participants in the first TECH 101 generally lacked a basic knowledge of mathematics or the ability to communicate effectively in English, either written or spoken, or both. In addition, engineering learners could utilize TECH 101 in order to maintain full-time enrollment while enhancing technical skills and progressing toward technical courses required in the curriculum.

While academic skill building was inherent in the course design, objectives related to the exploration of the role of a college student associated with the common practices, codes, values, and interactions associated with the collegiate culture, were integral to the successful delivery of TECH 101. The instructors hoped to cultivate the positive attributes of resilience and adaptability in TECH 101 learners. Factors associated with persistence were tightly woven into the discipline-specific material.

Course objectives were designed to align with the expectations of coursework in TECH 105. In collaboration with the freshman engineering technology instructors, the following course objectives were identified:

After completion of the course, the student should be able to:

- Create graphical representations of data
- Describe and define common metric prefixes
- Demonstrate basic unit conversion applications
- Identify and apply the scientific method to the investigative process
- Communicate the results of a scientific experiment using a generally accepted lab report format
- Create written technical reports using WORD software
- Create fundamental spreadsheets and use them to solve basic problems
- Use spreadsheet software to create graphs and charts
- Develop an effective technical vocabulary
- Describe and apply the concepts of effective teamwork
- Demonstrate an ability to meet deadlines and instructor expectations.

To promote successful completion of the course objectives, several key course components were identified including the use of weekly vocabulary words, a question of the day, a student presentation, written examinations, and laboratory reports.

A. Question of the Day

The question of the day technique utilized a scientific prompt drawn from the *Science Teacher's Activity-a-Day* [7] and the *Science Question of the Day* [8]. This process fostered group collaboration and brainstorming to determine a solution to the prompt. The course instructor guided the investigation by careful evaluation of each word in the question. The questions were often tied to the fundamental concepts associated with the laboratory experience planned for the week. The students' effort in arriving at a solution to the question of the day served as preparation for the vocabulary and scientific theory needed for the weekly topic and hands-on experiences.

B. Vocabulary Words

Each week, five words were provided to the students, typically associated with the technical concept under examination. For example, during the lesson associated with observations and the scientific method, vocabulary words included observation, bias, appearance, quality, and quantity. Flash cards were utilized to reinforce understanding, with time spent explaining how flash cards should be incorporated into study techniques. The students utilized multiple online dictionaries to evaluate the various entries for the word and assorted meanings, utilizing context to be able to determine the appropriate definition, and choosing the most succinct definition; which allowed them to practice their summarizing skills as well as using contextual clues to define new words.

Vocabulary words served as models to explore the concepts of context, homophones, and online translator tools. Learners were guided through the examination of dictionary entries to identify the particular meaning most likely to be associated with TECH 101 content. An example of this process was undertaken for the term "mass," utilized in the density content area, a challenging term for some international students. An online dictionary was consulted and the various meanings explored. The definition as a Christian service was discussed as well as the dictionary labels such as "related to medicine." Students were guided to evaluate and select the appropriate meaning.

C. Reflective Discussion

Throughout the course, open discussion between both instructor and learners as well as among students was highly encouraged. In the beginning of the course, it was explicitly explained that this was a safe space for questions and for practicing English. A supportive environment among peers was encouraged and fostered, which lead to students being very open to class discussions and supporting each other when questions arose. Diminishing the power distance between students and professor was a vital step in promoting role understanding, behavioral expectations, and overall course success.

Discussions were always conducted with the instructor seated with the students facilitating, but not leading, the communication. Often, the students would rely heavily on the instructor to answer questions, expecting immediate answers instead of working out a solution individually or collectively. Once this was noted, the instructor would set up a hands-on

activity, facilitate the necessary discussion, and then excuse herself for a period of time. The students were left to work together and solve problems without the intervention of the instructor. This proved very successful. The students became excellent problem solvers on their own, and became proud of their work and new-found abilities.

D. Laboratory Reports

Formal and written laboratory reports developed skills associated with summarizing, communicating technical terms in English, and conveying data. The requirement demanded significant attention to detail, comprehension of faculty expectations, and ability to meet deadlines. Throughout the semester, assignments increased in depth and complexity, building on previous understandings.

The instructor was surprised at the significant deficit in computer literacy. Course laboratory reports offered students task-specific activities to promote fundamental skill building including keyboarding, work processing commands and techniques, access to online data storage, and functions within course management software. Careful emphasis to cultivate computer literacy was an essential course outcome in order to promote success in future courses.

III. HANDS-ON ACTIVITIES

Hands on activities were crucial. Experiences were drawn from a variety of resources including The Sourcebook for Teaching Science [9], resources at the Discover Engineering website [10], and Engineering World Health [11]. Some of the experiential learning projects are described in this section.

A. Density of a Tootsie Roll

In the pre-work for this experience, the vocabulary words of the day explored the terms in the density equation. The question of the day dealt with how and why density should be calculated and the students practiced using and understanding the formula. As part of the lab, the students used the formula $D=M/V$ to calculate the density of different sized Tootsie Rolls. They made a hypothesis about whether the size would affect the density and then used scientific language to explain their results. The students also used very simple unit conversions with the scales. Learners were introduced to tools to help convert and understand the difference between English and Metric Units, as the international students were unfamiliar with English Units.

B. Paper Airplane

This experience was completed at the beginning of the semester and primarily focused on clear communication skills and attention to detail, but was integrated with engineering design. Students were tasked with designing a paper airplane that would fly the farthest of any in the class. They were then asked to write instructions for the instructor to create a paper airplane exactly like the one they created. A competition took place to see whose plan flew the farthest and then to see if the instructor's version was identical to the original. A final discussion after the laboratory helped the students understand

the need for clear word choices. In addition, learners postulated how their instructions could have been improved. The need for engineers to possess excellent written communication skills was also discussed.

The written instructions and a summary of the findings were the written deliverables for this activity.

C. Tower Project

This lab engaged students in engineering design, formal written communication skills, and a basic understand of the potential social impacts associated with the discipline of engineering. The discussion for this lab was comprised of research the construction of towers around the world and the race to build the tallest building. A visit to the website for the Burj Khalifa building [12] sparked interesting discussion, as the international students were very familiar with this building in Dubai.

Once students were familiarized with the positive and negative social impact of engineering design, specifically the design of the tallest building in the world, they began their own design of 'towers'. The students were each given a box of toothpicks and unlimited mini marshmallows. They were tasked with building the tallest tower, the minimum height had to be 12 inches, and it had to withstand a breeze of a fan. They concluded this experience with a written report.

D. Robot Arm

Students were given a box of various office supplies and were tasked with building a robot arm that would pick up a cup holding paper clips and empty this cup into another cup roughly one foot away. This experience included little discussion and preparation as a way to help the students hone their design and teamwork skills. The vocabulary words for the week were centered around team work.

Students were given the basic instructions for this lab and were left alone for approximately 15 minutes to begin their design process. After that time, they were shown a short video of students who had previously completed this project and were allowed more time to work on their design. Learners met the objective and concluded the class with a discussion about their work together and how teamwork might be challenging in a professional engineering environment. Students completed a written laboratory report as homework.

E. Estimating

Somewhat surprisingly, this experience was noted as a favorite by the class members. The objective of this lab was to explore the importance of estimating within the engineering discipline, and to practice using basic tools of measurement. Discussions began with brainstorming how and why engineers should have well-honed estimating skills. The lab work required a variety of estimating skills, including estimating weight, length, height, and number of objects. Students completed a worksheet where they estimated several objects such as number of objects in a jar, the temperature of the classroom, the width of the classroom, the height of their instructor, etc. Next learners took actual measurements of these items. Finally, students wrote a reflection describing

what they learned as well as why estimating skills are important for engineers. The following class, the instructor offered some suggestions on how to best complete the estimates required for the activity.

IV. OBSERVATIONS

The students in Tech 101 were all studying different engineering technology disciplines, which created a wonderfully diverse environment for discussions and teamwork. Students were extremely conscientious and engaged in the learning process, which resulted in fruitful discussions and thoughtful responses in their written lab reports and reflections.

The greatest challenge for learners in this course was the successful completion of the written report. The first lab report of the semester was completed step-by-step as a class; with each student submitting his individual report. Each week, students were tasked with completing more of their lab report on their own.

The students experienced difficulty when asked, at the end of the semester, to name all parts of the lab report. Upon reflection, this course should have included an entire class period devoted to the written report, the importance of understanding its different sections, and how to produce a quality product. Because this is an important fundamental skill for engineering students, special consideration should be given to this skill in a remedial setting.

The course activities promoted a deeper understanding of the role of a college student (in the United States), especially the responsibilities, expectations, and the keys to success in the engineering and engineering technology disciplines.

Four students began the course, one student withdrew from the university. Of the three remaining students, all are still enrolled in their majors and successfully completing TECH 105.

V. CONCLUSIONS

Upon completion of TECH 101, students were asked their opinions and concerns both in a formal, anonymous course evaluation and as part of a class discussion. All students in the class agreed that they found the course beneficial and taught at a speed compatible with their learning, even if they had been hesitant to enroll initially. Throughout the course, the improvement in confidence of the students was noticeable, as was the production and success in course assignments.

A familiarity with the jargon and tools used in an engineering classroom supports and encourages the underprepared student, especially those who are studying in a

foreign language. This course provides those skills in a nurturing setting where students can test their new-found skills in authentic, discipline-specific environments, which is a best practice for second language development.

In future semesters, the instructors will fine-tune the course content, with special emphasis to maintain relevancy to the current student population. The Tech 101 pilot demonstrates that discipline-specific developmental coursework fosters both technical fluency as well as college-student role understandings in a highly satisfactory way. Learners enjoyed the hands-on activities and responded to the escalating instructor expectations. Initial findings suggest that TECH 101 supports student success once learners begin engineering or engineering technology curricular coursework.

ACKNOWLEDGMENT

The authors appreciate the administration of the School of Engineering and Technology as well as University College at IUPUI for their willingness to support innovative approaches to engage underprepared learners.

Abstract—Peer Led Team Learning (PLTL) is a nationally recognized curriculum enhancement strategy adopted in various forms by over 150 universities and colleges across the United States. Consistent with the outcomes and the vision of ABET Engineering Criteria 2000 and the National Academy of Engineering Engineer 2020, PLTL prepares students to work in teams; apply knowledge of mathematics, science, and engineering to solve problems; communicate effectively; engage in life-long learning; and develop leadership skills. Published PLTL program data have shown that using peer leaders in small group workshop settings boosts performance in critical first-year courses including core math, science and engineering courses. The PLTL model promotes the growth of critical workplace skills for students and peer leaders such as working in teams, listening, critical thinking and leadership. This paper will present the basics of the PLTL instructional model, including sample materials developed for engineering workshops. Consideration of the practicalities of the six critical components will be discussed: integration of the workshop component into the course structure, involvement of the teaching faculty, training and supervision of the peer leaders, creation of challenging materials, and provision of appropriate institutional resources.

Keywords—first year; engineering; retention; peer-led team learning

I. INTRODUCTION

In the United States, engineering programs suffer high rates of attrition. Among students who start as freshmen in engineering, only 57% complete baccalaureate degrees in engineering [1]. Attrition from other STEM disciplines is also high: “less than 40% of US students who enter universities with an interest in STEM, and just 20% of STEM-interested underrepresented minority students, finish with a STEM degree” [2]. The importance of promoting greater success among would-be engineers has been a long-standing concern in numerous reports issued by governmental agencies or appointed task forces, especially with the recent call to graduate “10,000 more engineers a year and 100,000 new teachers with majors in STEM” [3]. According to a study commissioned by the Association of American Colleges and Universities (AACU), Liberal Education and America's

Promise (LEAP), and other organizations [4], employers need employees who know how to communicate across diverse cultures and can work in teams of diverse groups, are knowledgeable about science and technology, are able to reason analytically, write clearly, and demonstrate creativity and innovation. These practices promote flexibility in working on multi-disciplinary solutions to complex problems.

Despite these calls to action, the U.S. has a “leaky pipeline” in engineering. Universities have implemented various efforts to improve retention and increase recruitment in the engineering fields. Numerous studies have identified reasons for attrition from engineering, such as excessive coursework and diminished interest [5], poor teaching and advising [6], and lack of confidence in mathematics and science skills [7]. To meet accreditation requirements, undergraduate engineering programs include a substantial number of mathematics and science courses, typically concentrated in the first two years of studies. “The math-science death march,” a phrase coined by Goldberg [8], refers to calculus, chemistry, and physics courses frequently required prior to taking engineering courses, as well as the slew of engineering science courses in the second and third years of engineering programs.

Although academic performance might be a factor for some first-year students, persisters and nonpersisters earned similar grades[9]. Most attrition from engineering occurs at the end of the first year, but attrition during the second year is still significant. Even for students who survive first-year courses, second-year core engineering courses can present barriers to persisting. These core courses, in the first and second years, provide excellent opportunities for the application of peer-led team learning.

II. THE PEER-LED TEAM LEARNING MODEL

Peer-led Team Learning is a “curricular structure” [10] developed in the early 1990s originally to improve college students’ pass rates in chemistry courses. In addition to the traditional lectures by faculty, a course includes a weekly

scheduled workshop, led by a peer leader, a student who has previously completed the course successfully. The PLTL model is characterized by six “critical components” which were developed through extensive evaluations of workshop programs that worked best when all six components were present [11]. These six critical components are:

- 1) Peer-Led Workshops are integral to the course.
- 2) Instructors are involved in the selection of materials, training, and supervision of peer leaders, and they monitor the progress of workshops.
- 3) Peer leaders are selected, trained, and supervised to be skilled in group work as facilitators.
- 4) Workshop materials are appropriately challenging, directly related to course methods of assessment, and designed for small group work.
- 5) Workshops are scheduled and held once a week for two hours, contain six to eight students per group, in space suitable for small-group activities.
- 6) The Peer-Led Team Learning program is supported by the department and the institution with funds, course status, and other support so that the program has the opportunity to be adopted across courses and disciplines.

PLTL workshops provide students with a collaborative learning environment, mentoring relationships, and effective learning strategies which encourages student retention in STEM majors. Beyond supporting student learning, PLTL helps undergraduate students develop as leaders. The peer leaders, trained as facilitators of learning, serve as role models and guides to the academic culture.

Where peer-led workshop strategies have been implemented, data on student performance have shown significant improvement in the pass rates. These improvements have averaged 12-15% increase of ABC grades, fewer withdrawals, and other measures of student performance in the first-year courses that are requisites for engineering majors. These results are demonstrated, for example, in general chemistry at Washington University [12]; University of Puerto Rico [13]; University of Texas at El Paso [14], and Kennesaw State University [15]; organic chemistry at Portland State University [16] and University of Rochester [17]; biology [18]; and pre-calculus at New York City College of Technology, CUNY [19]. Computer science as a discipline, in an effort to attract more students, especially those not yet well-represented, has used PLTL as a best practice by two consortia: one focused on recruiting more women, led by the University of Wisconsin, Madison [20]; and one focused on Hispanic students at eight Hispanic-Serving Institutions [21].

Examples of the incorporation of PLTL in engineering courses are not yet prevalent. At the University of Rochester, use of workshops for several years in an electrical and computer Engineering (ECE) course intended for mechanical engineering and optics majors, joins the long list of STEM and social science courses that incorporate peer-led workshops at

this private research-intensive university. Those non-ECE majors must complete a course in circuits, and data over five years found a positive correlation between final course grade and workshop attendance [22]. At Northwestern University, all engineering students in their first year must complete a four-quarter sequence, Engineering Analysis, which “integrates math, science and computer programming with engineering applications” [23]. Attendance at optional peer-led workshops correlated with successful completion of the required four-course sequence. Findings indicate that a workshop program using undergraduate leaders is an appropriate model for increasing students’ academic success in freshmen undergraduate engineering courses.

A. General Chemistry at the University of Texas at El Paso

At the University of Texas at El Paso, 33% of students taking first-semester general chemistry intend to be engineering majors. PLTL Workshop provides an innovative strategy for enhancing and increasing 1) student success in courses, 2) retention at the university, 3) successful completion of and timeliness to graduation. Because of the gatekeeper nature of the first semester general chemistry course (CHEM 1305), the PLTL program at the University of Texas at El Paso has led to a dramatic increase in the number of science and engineering students successfully progressing into STEM majors. Since this Peer-Led Team Learning Workshop Program was implemented in the year 2000, the Program has significantly improved the passing rate in CHEM 1305 by almost 20%.

An added benefit of the UTEP PLTL program is the development of professional skills: Over the past fifteen years, Peer Leaders have been first authors for almost two dozen publications and first authors on more than 110 posters and oral presentations made to international, national, and regional audiences. These experiences dramatically benefit the careers of the Peer Leaders and provide meaningful work experience enhancing professional skills and significantly contributing to the career objectives for the Leaders involved. Fig. 1 shows the number of students passing general chemistry.

Fig. 1. Number of Students Passing General Chemistry I (CHEM 1305) at the University of Texas, El Paso, 1994-2009.

B. Introduction to Electrical and Computer Engineering, at the University of Illinois at Urbana-Champaign

The Department of Electrical and Computer Engineering at the University of Illinois at Urbana-Champaign offers two majors and one minor: bachelor of science in computer engineering, bachelor of science in electrical engineering, and a minor in electrical and computer engineering. Beginning in the fall of 2007, PLTL was implemented in ECE 110, Introduction to Electrical and Computer Engineering. ECE 110 is a large course with 300 to 400 students per semester that is required for first-year students majoring in electrical and computer engineering, and for students majoring in general engineering. Students should have completed or be concurrently registered in a first semester calculus course. ECE 110 introduces selected topics in circuits, electronics, and digital systems: topics that are often taught in second-year engineering courses at other universities. ECE 110 was developed in the early 1990s to give first-year students an engineering design experience [24].

The PLTL workshops were implemented as optional 90-minute sessions “supervised study sessions,” in specific time periods on Sunday afternoons and evenings. Students who elected to participate in the PLTL workshops were randomly assigned to learning teams in one of their available time periods. The peer leaders or “team leaders,” as identified by the Urbana-Champaign program, comprised graduate teaching assistants and undergraduate “graders” already assigned to ECE 110, and unpaid undergraduate volunteers; more than half of the leaders were volunteers. New team leaders attended a two-hour training session at the beginning of each semester, and most attended thirty-minute weekly meetings throughout the remainder of the semester. Team leaders were responsible for administrative duties, such as sending e-mail messages to their teams, and recording student attendance.

Workshops were held in classrooms, with two teams working at separate chalkboards in each classroom. Whenever possible, an experienced leader led one team and a new leader led the other team in the same classroom; this arrangement enabled the new leader to obtain help from the experienced leader. During each weekly workshop, each learning team collaborated to solve four to eight difficult problems selected from ECE 110 examinations given in previous semesters (see sample problem in Fig. 2). These problems were more challenging than routine homework problems: their solutions sometimes required understanding of basic concepts, analysis of complex situations, and the creative application of knowledge to unusual situations. The problems included circuit design and logic design problems that had multiple solutions.

Students who regularly attended PLTL workshops earned higher scores on the final examination than did other students [25]. Further, regular attendees enjoyed social benefits such as making new friends, networked support structures, and increased confidence with their school environment.

Johnson and Loui [26, 27] analyzed the experiences of fourteen peer leaders who kept weekly reflective journals: each

leader wrote a journal entry after each PLTL workshop. Initially the leaders worried about their own limitations. As the semester progressed, the leaders faced operational challenges and tried to encourage cooperation within their teams. The leaders adjusted their teaching methods, and they began to appreciate intellectual diversity. By the end of the semester, they reported increased self-confidence and interest in teaching in the future.

ECE 110 was completely redesigned in 2014 and became a 3-credit course; the current enrollment is more than 400 per semester. Workshops are still offered on weekend afternoons and evenings; most students live nearby or on campus so weekend workshops fit into their schedules. One of the ECE 110 instructors takes responsibility for preparing all problems used in the workshops in each semester. This instructor supervises the graduate teaching assistant who coordinates the peer leaders, to ensure that everyone understands these materials and the rationale for the selection of the problems. The College of Engineering currently provides space for the workshops in the engineering library. The Department of Electrical and Computer Engineering provides funding for the undergraduate graders who serve as peer leaders. It has allocated funds from internal grants to develop a new workshop-style discussion section in the fall of 2015 that targets students from underrepresented groups, including students from rural high schools.

Fall 2008, ECE 110 Problem 2. Written by Michael C. Loui.

The kinetic energy of a Toyota Prius car is 53 kilojoules (kJ) when it travels at 20 miles per hour (mph). The car’s regenerative braking system has a generator that converts the kinetic energy into electricity, which recharges the battery. We model the battery as a 290 V ideal voltage source and a $0.06\ \Omega$ resistor. Starting from a speed of 20 mph, the brakes are applied at time $t = 0$, and the current $I(t)$ from the generator decreases linearly from 30 A to 0 A at time $t = 4$ seconds (sec).

- Write a KVL equation that relates V_r and V_g .
- Determine the value of V_g when I reaches 0. **Explain your reasoning.**
- Determine the average SRS power P_{avg} for the 290 V voltage source between 0 and 4 seconds. **Show your work.**
- Determine the total amount of energy returned to the voltage source and the efficiency of the regenerating system in this case.

C. *Statics, at New York City College of Technology, City University of New York (CUNY)*

The Department of Construction Management and Civil Engineering Technology (CMCE) of New York City College of Technology (City Tech) at CUNY offers associate degree programs in Construction Management Technology (CM) and Civil Engineering Technology (CE). All freshmen students in CMCE are required to complete Statics as a prerequisite to their design courses. Students should have completed college algebra and trigonometry and be concurrently registered in a first-semester physics course. The statics course provides an introduction to the concepts of force, equilibrium, section properties, load pattern distribution and equilibrium. About 60 to 90 students enroll in statics each semester.

PLTL was implemented in Statics in spring 2012 in an effort to increase student performance and decrease withdrawal rates. PLTL workshops in Statics are one hour in length and take place outside of the classroom. Workshop attendance contributes to the students' grade; students who are not able to attend can complete a supplementary assignment. Peer Leaders complete a one-credit course in Peer Leader Training in their first semester; in addition, all Peer Leaders are expected to attend weekly leadership seminars, which form the basis of a community of practice [28]. The workshop modules are designed to be reflective of the lecture topic but are at a more challenging level than the examples done in class.

Prior to the implementation of PLTL, the average percent of students passing with a C or better was about 50%. This percentage has increased steadily from 52% in spring 2012 to 79.5% in fall 2014 and the withdrawal rate has decreased from 33% in spring 2012 to 16.5% in fall 2014.

PLTL workshops provide civil engineering technology students with a collaborative learning environment, mentoring relationships, and effective learning strategies. The program has been successful for both participating students as well as for the peer leaders. Since 2012, of the 12 peer leaders for statics, 11 have been retained in the engineering program. Peer leaders have presented at the Peer-Led Team Learning International Society conferences (pltlis.org), as well as at regional conferences.

From 2012 through spring 2015, PLTL was incorporated in some but not all sections; starting fall 2015, a one-hour workshop component will be integrated in all sections of statics. The CMCE department has been instrumental in supporting curriculum change and securing funding to pay the Peer Leaders. Sections are taught by full-time as well as adjunct faculty, therefore the level of involvement varies with the type of faculty assigned to the course. City Tech peer leaders undergo training during their first semester. Fig. 3 shows student performance in statics and Fig. 4 is a problem developed for statics workshop.

Fig. 3. Student performance in Statics.

Fall 2015 CMCE 1115 Workshop Problem. Written by M.Villatoro and R. Mason.

Given: A load test is required on Pile X, this load test will indicate whether the pile can hold 1000 lbs of load in compression. The load test frame is setup as follows.

Required: Determine the reaction force created in Piles A and B due to the 1000 lbs force on Pile X.

Given: The 5 ft wall is supported on a W12x26 girder spanning 16 ft between 2 supports. The line load produces by the wall is 2 kips per linear ft.

Required: Determine the reactions at the two temporary support blocks. Be sure to include the weight of the girder.

Fig. 4. Sample problem for peer-led workshop in CMCE 1115, at NYC College of Technology, written by M.Villatoro and R. Mason.

III. DISCUSSION

PLTL has proven successful in applications for STEM courses in universities across the nation. Students in STEM courses perform better with the incorporation of peer-led workshops; implementations in engineering and technology courses help students succeed as have implementations in science and mathematics courses. The three case studies presented provide a summary of the PLTL application, and the data indicating the improvement of student performance and withdrawal rates. Each application incorporates the six critical components at varying levels. The ability to incorporate all six critical components effectively is a function of various elements including institutional support, uniformity across sections, and time required for supervision and preparation. The adherence to the PLTL model's critical components helps campus programs gain from others' experiences with continual trends in improving grades, persistence, and retention. Where the administration does not support faculty's efforts, the PLTL program will not become embedded in helping students learn through discussion, and collaborative problem-solving.

PLTL introduces students to working as a team, developing communication skills, and working with diverse learners, preparing students to be successful engineers in accordance with Engineer 2020 [29] and ABET EC 2000 [30]. The Engineer of 2020 urges the engineering profession to recognize what engineers can build for the future through a wide range of leadership roles in industry, government, and academia--not just through technical jobs. Some of the desired attributes developed through PLTL include analytical skills, creativity, practical ingenuity, flexibility, leadership, and lifelong learning.

IV. CONCLUSION

Arendale [31] notes that, "the highest level of student outcomes occurs when a comprehensive learning system is integrated throughout the course learning experience." PLTL is an effective learning system which provides new experiential learning dimensions, not only for students, but also for the peer leaders, who gain leadership and other skills. PLTL provides students with the learning tools and supportive environment critical to the success of students.

As PLTL is introduced to more engineering and technology courses, studies investigating how it can develop students' teamwork and communication skills, to satisfy ABET Criterion 3, could be conducted. What aspects of the PLTL model are essential in achieving these outcomes? How can the incorporation of peer-led workshops be designed to promote these attributes?

The many studies conducted on student performance with PLTL have shown improvements in retention, whether in the sciences, mathematics, and engineering courses. What is the logic model, or mechanism, by which PLTL promotes retention? Working with Tinto's theory of academic and social integration [32], peer-led workshops may offer alternative mechanisms to learning communities. What conditions of

peer-led workshops foster improved retention in groups that are underrepresented in engineering?

Unlike homework problems in science courses, problems in engineering courses can also involve design. These design problems are difficult for beginning students because they have multiple solutions and require judgment in making tradeoffs. Can the experience of solving design problems through PLTL in first- and second-year engineering courses prepare students for month-long and semester-long design projects in subsequent courses? PLTL is an excellent platform in which to apply design problem exercises.

The implementation of Peer-Led Team Learning in engineering courses is in a nascent stage. Its continued adoption will support students' learning in the first year courses in mathematics, science, and engineering, thus forestalling the "death march" in those courses, and fostering the necessary critical thinking [33] needed in engineering. PLTL can be key to improving retention in the engineering majors, and be vital to responding to the needs of the nation's workforce.

Abstract— This work in progress explores how instructional strategies and technology use were related to engineering students' affinity toward a class. Instructional strategies, such as contextual problem-based learning and teamwork, can increase student interest in a topic. Additionally using different technological tools affects student interest and learning. However, instructors can be challenged to encourage and maintain student interest, which makes this study worthwhile to pursue. To our knowledge, there is a dearth of engineering education research exploring the relationship between instructional technology, instructional strategies, and engineering students' course favoritism. This study aims to fill this gap by identifying effective instructional strategies and the use of educational technology that helped make a class engineering students' favorite.

Keywords—*instructional strategies; educational technology; student interest; course favoritism*

I. INTRODUCTION

It is reasonable to speculate that students learn more and are more motivated to learn in their favorite classes. Therefore, to identify and implement effective instructional strategies that help increase student favoritism for a class is a worthwhile goal. If students are more motivated to complete coursework, they learn or perform better [1, 2]. In searching the literature, we did not find any research study that specifically explored the relationship between instructional strategies and engineering students' favorite classes. Some instructional strategies identified in general, such as problem-based learning [3] and teamwork [4], make classes more motivating or interesting. However, to our knowledge, there is no set of specific instructional strategies that are proven to be effective in increasing student favoritism for a course.

Generating and maintaining student interest in the class or topic is a critical component of favorite classes. Interest refers to "focused attention and/or engagement with particular events and objects" [5, p. 169] so we can actively process the important and relevant information. Generating and maintaining student interest can contribute to creating optimal

learning environments [5], which we argue should be considered when developing and implementing learning activities. Student interest in learning can be promoted via effective instructional approaches [5] and the use of educational technology [6]. There is a lack of research on motivational effects of instructional strategies and the use of educational technology on students' affinity toward a class. Likewise, few studies explore effective instructional strategies and the use of educational technology in engineering students' most favorite classes. Our study aims to fill this gap by identifying effective instructional strategies and the use of educational technology that helped make a class engineering students' favorite. We asked the following research question: What kind of instructional strategies and technology were used in engineering students' most and least favorite classes? We aimed to identify the instructional approaches and tools used in engineering students' most and least favorite classes.

II. LITERATURE REVIEW

A. Instructional Strategies

Some specific course instructional strategies may motivate student learning and engagement. For example, problem-based learning (PBL) can motivate students in applying what they have learned to solve real world problems [7]. Through PBL, instructors can encourage students to seek out new information and generate new knowledge based upon their prior knowledge. Students engaged in problem-solving demonstrate greater focus and attention to learning as well as engage in deeper cognitive processing [3]. Problem-solving also provides engineering students with hands-on activities, which helps develop and sustain interest [8].

Similarly, service learning that combines instruction/learning with meaningful community service helps prepare students professionally [9]. Service-learning provides students hands-on opportunities to gain skills and knowledge that may otherwise not be obtainable in their classes. Through service-learning, students are motivated to gain effective communication and project management skills [10].

Additionally, group projects or teamwork can develop student interest in subject content through the need for autonomy, competence, and social relatedness [11]. In group projects, students engage and interact with others, which allows interest to be modeled and remodeled, such as one develops an interest because of one's peers [4]. Friendly competition within a team or between teams can also promote interest in some subject topics. A meta-analysis of college students studying STEM subjects found small group work has a significant positive effect on academic achievement and motivation [12].

A study by Dartmouth University reported that engineering alumni's favorite classes involved problem-solving, service-learning or teamwork [13]. The participants also reported enjoying transferring theory to practice through solving real-world problems in their favorite classes.

In addition to specific instructional strategies that can help develop student interest in subject matter, there are some general approaches that can build student interest in learning. Krajcik and Mamlok-Naaman [14] suggest organizing instruction around a driving question rather than topics. This practice emphasizes the relevance of the material (driving questions) to real life. Using driving questions to organize instruction helps pull relevant information together, which facilitates application of learning [14].

Likewise, learner centered teaching approaches increase student interest in instructional material. Ellis, Rudnitsky and Scordilis [15] found that learner centered instruction in teaching introductory engineering mechanics could help students become more committed in the field of engineering.

B. The Use of Educational Technology

As educational technology becomes an essential element in teaching and learning, students' interest and motivation can be affected by the use of technology in their classes. Appropriate use of technology in the classroom can increase student interest [6] and can enhance students' learning [16]. For example, visualizations and simulations not only help generate students' interest but also allow students to better use evidence and data during their scientific inquiries [17]. Technology, especially technology-based student-centered learning, has the potential to optimize student learning [18].

Technology can be used to support learner autonomy, i.e. taking charge of one's own learning [19], and to encourage more active and deeper learning [20]. For example, providing technology-supported instruction in the form of motivational emails and links to supplementary instructional materials (such as videos) increased student motivation to learn [21]. Students who received supplementary motivational instruction perceived that they could take charge of their own learning and displayed more self-directed learning than students who did not receive supplementary motivational instruction. Similarly, educational games were found to be effective for learning and motivation in the context of learning computer concepts [22]. Educational technology may enhance student learning and attainment for learning, providing resources and learning platforms (such as Blackboard and Coursera) for independent learning and team collaboration [23]. Despite the promise of technology tools to engage and motivate, it is important to note that they are just

tools, a means to accomplish an end goal. Therefore, educators need to focus on the learning processes (such as collaborative learning) instead of the tools [24].

III. METHOD

We created a survey containing a combination of selected and free-response items which we invited engineering students to complete. The survey included items asking the participants' to share their most and least favorite classes and justifications for their ranking of the courses, the major instructional approaches used in the courses, and the technology used in the courses. The survey also included demographic questions and Likert-scale questions asking students to rate the usefulness of the instructional strategies and use of technology in their most and least favorite classes. An invitation to participate in the online survey was sent to more than 500 undergraduate students in the College of Engineering at a Western university. Ninety-five students (73 men, 22 women) completed the survey. Participants included undergraduate engineering students from various engineering program areas such as mechanical and biomedical engineering, electrical engineering, materials science engineering, civil engineering, computer science (in the college of engineering), and construction management (in the college of engineering). The average age of the survey respondents was 25, 12 respondents were freshman, 26 were sophomores, and 26 and 27 were juniors and seniors respectively.

IV. RESULTS

Research Question: What kind of instructional strategies and technology were used in engineering students' most and least favorite classes?

According to the survey results, a variety of instructional strategies were adopted in students' most favorite classes including lecture (100%), live demonstration (65%), individual problem solving (63%), group problem solving (58%), full class discussion (54%), group discussion (49%), and laboratory experiments (35%) (see Table I). Only one most favorite class had adopted all seven of the above instructional strategies. The majority of participants believed the instructional approaches adopted in their most favorite class helped their learning. Similarly, a variety of instructional strategies were adopted in students' least favorite classes. However, it seemed that more least favorite classes had adopted less interactive (discussions) and less hands-on (labs) approaches.

Results showed that a variety of technology tools were used in students' most favorite classes including PowerPoint presentations (100%), video/simulation during class (71%), online homework system such as Masteringphysics.com and Webassign.com (48%), clickers (classroom response system 23%), relevant videos used outside of class (46%), Blackboard discussions or online discussion forums (23%), mobile devices (e.g. iPad, tablet computer, smart phone 17%), Blackboard quiz/test (17%), and recorded lectures provided by course instructors (17%) (see Table II). Only two most favorite classes

did not use any other technology except for PowerPoint presentations. In the most favorite courses, more participants believed the use of technology outside of the classroom was helpful for their learning compared to those in the least favorite courses. However, more than half of the participants held a neutral attitude (neither helpful nor harmful for their learning) towards the use of technology in their most favorite class.

Most participants' most favorite classes incorporated several instructional strategies (see Table I). Similarly, most participants' most favorite classes included several technological tools (see Table II). Results also showed that a variety of technology tools were used in students' least favorite classes (see Table II). However, the percentages of the use of technology in students' least favorite classes were less than those of the most favorite classes. The Ns in Table I and II stand for the actual number of responses for that particular item choice.

TABLE I. INSTRUCTIONAL STRATEGIES IN THE MOST AND LEAST FAVORITE CLASSES

Instructional strategies	Most Favorite (%) N=71	Least Favorite (%) N=62
Lecture	100	90
Live demo	65	15
Individual problem solving	63	3
Group problem solving	58	23
Full class discussion	54	23
Group discussion	49	16
Lab experiments	35	10

TABLE II. TECHNOLOGY ADOPTED IN THE MOST AND LEAST FAVORITE CLASSES

Technology/ tools used	Most Favorite (%) N=52	Least Favorite (%) N=62
PowerPoint presentations	100	53
Video/simulation used in class	71	27
Online homework system	48	42
Other relevant videos used outside of class	46	16
Clickers	23	21
Blackboard discussion	23	16
Mobile devices (e.g. iPad, tablets, smart phone)	17	11
Blackboard quiz/test	17	23
Recorded lectures	17	6

In the most favorite classes, 97% of students (36 out of 37 responses) considered the instructional approach helped their learning, and only one responded the instructional approach was neither helpful nor harmful. About 32% of participants (22/69) considered the use of technology in class helped their learning, and 68% participants (47/69) considered the use of

technology neither helped nor harmed their learning. In the least favorite classes, 73% students (24 out of 33 responses) considered that the instructional approach harmed their learning; only 2 responded the instructional approach helped their learning; and 7/33 participants considered neither helpful nor harmful. Only 3% of participants (3/87) considered the use of technology (including both in and outside the class) in their least favorite course helped their learning, while 13% participants (11/87) considered the use of technology harmed their learning; and 84% participants (73/87) considered the use of technology neither helped nor harmed their learning.

VI. DISCUSSION AND CONCLUSION

In our study we explored instructional strategies and the use of technology in engineering students' most and least favorite classes. Most participants considered the instructional approaches in their most favorite class helpful. Specifically, problem solving, hands-on activities, demonstrations, and discussions were found to be positively linked to most students' favorite classes. Instructional approaches are closely related to learner satisfaction and supportive course instructors, which are critical to generate and or sustain students' interest in the course. However, few students considered technology use helpful in their most favorite classes, which means the use of technology in those most favorite classes did not necessarily motivate the students to learn. Therefore, effective use of technology in engineering classrooms needs to be improved.

Although instructors play an important role in implementing the instructional strategies and technology tools, our study did not consider the impact of instructor in student's most favorite and least favorite classes. From the overall differences between participants' responses to the same instructional strategies and technology tools in both most and least favorite classes, we could see a clear trend with respect to our findings (see Table I and II).

Our study has some limitations. First, the survey relied on self-report data, which may be subject to bias of participants when recalling their most and least favorite courses. Second, the relatively low sample size may limit the generalization of the study. Future studies on exploring the relationships between instructional strategies and the use of technology with engineering students' favorite and least favorite classes from different types of institutions are needed. Nevertheless, the findings of the study can provide some practical guidelines on supporting students' interest via effective instructional strategies and use of technology (part of the instructional strategies). Future studies on how instructional strategies and the use of technology have the potential to help instructors learn how they can generate interest in those academically unmotivated students as well as sustain interest in students who are initially motivated. Different instructors could implement the same instructional strategy differently. For example, some instructors explain and discuss their PowerPoint slides while others just read their slides. Future studies may need to include the impact of instructors in such studies.

Is this “transfer shock”?

Examining the perceptions of engineering students who articulate within the Irish higher education context

Abstract—“Transfer shock” is a well-known phenomenon during the process of articulation, when students move from short-cycle applied programs to more academic longer-cycle study programs. In the US context this problematic transition has been observed in students transferring from community colleges into the traditional university system. In Ireland’s binary higher education structure, one set of institutions, known as Institutes of Technology (IoTs) allow for this transition to take place entirely within individual institutions. This paper is part of an ongoing investigation into one such IoT, where engineering students who achieve high grades at the end of 3-year (so-called Level 7) “ordinary degree” programs frequently transfer into the 3rd year of 4-year Level 8 “honors degree” programs, with surprisingly successful outcomes. One surprise derives from the fact that the students who enter Level 7 engineering programs are deemed at the outset to be academically less able, particularly in mathematics, than those who go directly into Level 8 programs from secondary school. Relatively little work has been done on this transition to date. In the 3rd and 4th year of many honors engineering programs within this institution it is not unusual to have 30-50% of the students coming from an ordinary degree background, the majority from within the institution itself – with others transferring from other IoTs in Ireland. Previous research has shown that students from this background initially struggle in the 3rd year of the honors degree program when compared with students who have proceeded directly through the honors program, before going on to successfully graduate. Can this be attributed to ‘transfer shock’; even though most of these students are continuing in an institution and with faculty that they are already familiar with? In order to examine this phenomenon we interview students from several engineering disciplines at various points in this transition. We explore the perceptions of the students regarding this transition and, based on the information coming from the interviews, we conduct a large scale survey to be administered to articulating students across engineering programs in the institution. The preliminary results of this survey are also presented here.

I. Introduction

For several decades many higher education systems across the world have been attempting to respond to the increasing demand for graduates. One method has been to encourage articulation, which is the transfer of students at the end of short-cycle applied programs into more academic degree programs at universities. In the US context this process sees students moving from community colleges [1], while in the UK students may complete a foundation degree [2] or a Higher National certificate or diploma [3] at a further education college before transferring to a university. Articulation can give students from non-traditional backgrounds, who may be economically disadvantaged; or from the first generation of their family to enter higher education; and mature students, the opportunity to gain an honors degree through this indirect route. However, the process is not without difficulty and many students who undertake this route drop out before attaining their goal or experience problems in coming to terms with the new institutional culture they encounter. This set of problems has been referred to as “transfer shock” and studies in the US and the UK have sought to analyze its effect [4], [5]. The phenomenon typically results in a dip in grades for a period after transition to university [6], [7], [8], and is thought to be attributed to the adjustment to the new “institutional habitus, including staff attitudes and relationships (community), teaching and learning strategies (curriculum) and social spaces (campus)” [9]. One solution suggested by Greenbank is to offer both short-cycle applied and honors degree programs in the same institutions [2]. This is where the Irish higher education system may have an advantage.

Ireland’s higher education system is said to be binary. On one side are the seven traditional universities, the oldest being Trinity College Dublin which was founded in 1592. On the other side are 13 Institutes of Technology (IoTs), set up originally as regional technical colleges to support the training and educational needs of their local areas. Then there is the Dublin Institute of Technology (DIT), which straddles both

Keywords—*articulation; transfer shock; engineering students*

sides of this divide¹. It grew from a group of technical colleges, founded in the late 19th and early 20th centuries to deal with vocational training and education, into a fully independent institution, established in 1993. Today DIT is a member of the European Universities Association and has degree-awarding powers up to doctorate level. Its so-called “ladder system” (see Table 1 below) allows a student to begin by completing an apprenticeship or short-cycle applied certificate program (known as Level 6 in the National Qualifications Authority of Ireland’s framework (NFQ) of levels in the Irish education system [10]) right through to a doctorate at Level 10 – all within the same institution. This, surely, is the ideal place in which to examine whether transfer shock can be avoided during the process of articulation.

Table 1 Explanation of NFQ Levels [10]

NFQ Level	Explanation
Level 6	Advanced Certificate
Level 7	Ordinary Degree
Level 8	Honors Degree
Level 9	Masters Degree
Level 10	Doctoral Degree

A research group of faculty who teach students of various engineering disciplines at DIT has been examining the experience of articulation from 3-year engineering technology programs (at Level 7) into the 3rd year of 4-year Level 8 degree programs. This research has shown that some articulating students do indeed struggle, particularly in mathematics, when they move from Level 7 to Level 8 but that the majority recovers sufficiently to graduate with, on average, a grade higher than students who came directly through the four years of Level 8 programs [11]. This paper sets out to explore students’ own perceptions of their transition, their awareness of experiencing transfer shock, or otherwise, their motivations, difficulties and successes. Following on from the analysis of interviews with a group of currently articulating students, a survey has been created and administered to a larger group from the same engineering disciplines. Both the interview and survey analysis will propose an answer to the question of whether these students perceive transfer shock as something that has affected them during their transition into an honors degree program.

II. Background to the study

The traditional route into a level 8 degree program in engineering in Ireland requires students at the end of their second-level schooling to achieve high proficiency in mathematics, as the professional body for engineers, Engineers Ireland, stipulates a minimum of grade C at higher

level in the State Leaving Certificate examination. The numbers taking the higher level mathematics have never exceeded 25% of the examination cohort and this has greatly restricted potential entrants to level 8 engineering programs. One solution provided by DIT and other IoTs has been to provide less theoretical programs requiring a lower level of mathematics on entry – these are the 3-year Level 7 degrees, known as Bachelor of Engineering Technology, from which many students go on to articulate into the 3rd year of Level 8 programs at DIT. Recent research into the expectations of students starting out in a Level 7 program in mechanical engineering in 2013 shows that at least 73% of them intend to transfer to a Level 8 program after graduation [11]. This is very different to the expectations of, for example, Scottish students in equivalent programs, only 13% of whom had decided at the start of their studies that they would want to articulate later [5].

Despite their proven weakness in mathematics, students articulating from Level 7 and graduating in 2009 and 2010 have been shown to have averaged a mark of 62% while, surprisingly, their direct entry colleagues with high mathematics competence at the outset achieved an average mark of only 53% [11]. This was in spite of research showing that, within the first semester after articulating, many former Level 7 students had had difficulties passing their first math modules in the honors program [12]. In order to be allowed to articulate, these students had been required to attain an average of 60% in their final grades at Level 7. They then appeared to allow their marks to dip for a semester or year after transferring to Level 8 before outshining their direct entry colleagues in the final year towards obtaining their honors degree.

Students who graduated from 2011 onwards have not been required to attain such a high grade at Level 7 in order to be permitted to articulate. Since then the average mark on entry to the 3rd year of the Level 8 degree program has been reducing year on year so that in 2013 the average mark of entrants was 51%. Perhaps not surprisingly in this case, the grade advantage of former Level 7 students on graduation from Level 8 has also reduced – now their final marks are on a par with their direct entry colleagues [13]. This is not to forget that such students, coming into DIT with weak mathematics skills and completing their level 7 programs with mediocre results, are nonetheless graduating with similar grades to those who entered with high math competence directly into the 4-year Level 8 program, admittedly by taking one year longer to do so.

The dip in results that has been observed immediately following transfer into Level 8 programs, as discussed above, mirrors the phenomenon of transfer shock seen in students moving from one institution to another. However, these students are not moving to an unfamiliar institution. In fact, in many cases they encounter the same faculty members teaching similar modules in the same environment as before they

¹ This binary division ignores private colleges and specialized education and art colleges, for example.

articulated. As was seen earlier, many of those who start out at Level 7 fully intend to transfer to the Level 8 program as soon as they are permitted to do so – so where does the difficulty lie? The only way to discover the answer to this question was to ask the students themselves.

III. Methodology

This section of the paper outlines the methodology applied to answer the research question as to whether articulating engineering students perceive “transfer shock” as something that has affected them during their transition from a Level 7 program into a Level 8 program. Included are the details and justification of the research method used; the profile of the participants; the research protocol, ethical considerations and how the results were obtained and analyzed.

A. Research Method and participant profile

This study utilized a number of methods, namely a qualitative approach in the form of one-to-one interviews conducted by faculty members, some of whom lecture on Level 7 and/or Level 8 engineering programs, and follow-up quantitative research by means of an anonymous online survey. Given the complex nature of “transfer shock” the qualitative approach was applied first to gather insights on the “how” and “why” of student experiences in order to enable common themes to be identified. The quantitative approach was to investigate whether these identified themes or issues could be generalized to the larger articulating engineering population. As it was thought the information may be sensitive, the online survey was anonymous and only general profiling data was gathered from participating students as outlined in the next sub-section. This approach is similar to that taken by Greenbank [2] and Winter and Dismore [9].

Students enrolled in the 2014/2015 academic year from both 3rd year and 4th year stages of Level 8 programs were considered. While previous research had concentrated on mechanical engineering students [11], this study gave an opportunity to include civil, structural and manufacturing & design engineering students. The total cohort available was 105 students across all four disciplines. Students were asked to volunteer to participate in the face-to-face interviews with three students selected from each category, and where possible, across the range of academic performance. Overall, 13 student volunteers were separately interviewed – a breakdown of their profile is shown in *Fig. 1*. For the online survey, 41 students took part giving a response rate of 39%. The breakdown in *Fig. 2* shows more 3rd year than 4th year participants in contrast to the qualitative study.

A review of recent literature on the difficulties encountered by articulating students identified four main problem areas, [2], [4] [5], [6], [8] and [9]. These can be categorized as: community (both inter-student and student-faculty member relationships); curriculum (work load and learning styles); culture (expectations set by faculty members, class attendance,

assignment submission guidelines and class interaction) and campus. The last category was not a factor in this study given that all those interviewed came from the same institution and did not have to deal with a new campus environment.

Fig. 1. Qualitative Participant Profile in 1:1 interviews

Fig. 2. Quantitative Participant Profile of online survey

B. Approach to conducting the research and analyzing results

The categories were used as a guide during the semi-structured interviews to ensure students considered all aspects of their transition. Faculty did not interview any student from their own discipline and the recorded interviews lasted on average 15-20 minutes. Prior to the commencement of the interview students were asked to read an information sheet outlining the parameters of the study and they also signed consent forms. It was clearly stated that they could conclude the interview at any stage.

A detailed review and analysis of the transcripts of the interviews identified themes that formed the basis for the online survey. Focus was put on the categories of culture, community and curriculum as well as specific terms such as “grades dipping” in an attempt to find evidence to support previous research that had shown particular difficulties in the first semester after transferring into Level 8 [11]. Howieson’s research on articulating students in Scotland [5], which involved a large questionnaire of approximately 50 questions, also provided a useful source for the final online version,

which was chosen for ease of development and administration of the survey responses. There were 10 questions in total, with initial questions designed to gather information on student profile and their own expected performance for the end of this academic year. Most questions were structured using a Likert 5-point scale with a comment section provided for respondents to explain or justify their selection. A final open-ended question required students to sum up their overall transition experience. All students currently studying on Level 8 programs in civil, structural, mechanical and manufacturing & design engineering received an email requesting those who entered through a Level 7 program to participate in the anonymous online survey. The quantitative data received from the survey was exported and a graphical analysis was completed. The comments provided to support the selection made by the students was examined in order to help understand their responses more thoroughly.

iv. Results

This section presents briefly the qualitative and quantitative data from the research conducted through the face-to-face interviews and the online anonymous survey. Analysis and discussion of these findings will be presented later.

A. Qualitative Results

Five main themes were identified from the interviews: a dip in grades; the expectations of faculty; class integration; study behavior and challenges related to the content of the Level 8 programs. The students' perception of whether their performance dropped as measured by the grades they attained in the first year of transition was mixed overall, with some having experienced a drop in grades while others claimed no effect or even increasing grades at Level 8. The content of the program was perceived to be delivered at a faster pace and more in-depth theoretical aspects were explored. In relation to the expectations of faculty, one key finding was that students perceived more self-directed learning was expected and that a higher quality and depth of analysis was required for Level 8 success. There was little "hand-holding" observed as compared with Level 7 programs. Effective peer-learning and an overall positive interaction between Level 7 articulating students and the existing Level 8 cohort was noted. With regard to study behavior, students indicated that an adjustment was required to balance the workload, giving less time for ongoing study and more time needed for continuous assignments because of the greater workload in Level 8 programs. On the other hand, transitioning students felt they had benefited from their experience of having already completed a final year project at Level 7 and that this increased their ability to plan assignments and projects on the honors program.

B. Quantitative Results

From the online survey, 38% of students stated that articulating was very easy or easy, but the majority (62%, Fig. 3) found it either somewhat challenging or difficult. Many

commented on the fact that some repetition of module content enabled a smooth transition, while comments made in relation to the increased workload evidenced a more challenging aspect of the transition process. The academic performance of the articulating students was mixed, with 57% stating they were successful or very successful with another 30% stating they were somewhat successful. Only 14% felt they were unsuccessful, explaining that they were mentally exhausted or experiencing a lack of motivation (see Fig. 4). Eighty percent of participants responded to the question regarding specific difficulties with module content, with a quarter not finding that any specific content was challenging. Modules that were mentioned as challenging were mathematically based. A higher volume and level of theory was highlighted as a problematic aspect of transition but there was an even spread over other modules based on individual abilities, preferences or learning styles.

Many students perceived no or only minor differences (57%, Fig. 5) with respect to the teaching styles of faculty between Level 7 and Level 8. Students supported their opinions by commenting that they felt more self-learning was expected and in Level 8 a hands-off approach was more evident. Also, it was mentioned that fewer practical "worked through" examples were given at Level 8 with a greater focus on theoretical knowledge proving somewhat more of a challenge to understand. The majority of students found that they had to change their study habits a lot or at least to some degree (62%, Fig. 6) to deal with the Level 8 workload. Predominantly, their comments suggested that there was less time available for study due to projects and group assignments. More personal focus and interest in the program was indicated by some whilst others, now in their 4th year of the Level 8 program and 5th year overall, just wanted to pass and get finished at this stage. Due to their heavy workload, end of semester study rather than consistent study throughout the semester was the main observation here.

A Cronbach Alpha test was carried out to determine the level of internal consistency of responses between the student perceptions of transfer challenge and successful transfer based on their academic performance. The calculated Cronbach alpha value was 0.495. This value indicates that there is a low level of consistency which is evident in some responses. For example, some students considered that the transfer was easy, but were unsuccessful with regard to academic performance.

Fig. 6. Students' perception of the difference in their study behavior

Fig. 4. Students' perception of how well they transitioned based on their academic performance

Fig. 5. Students' perception of the difference in teaching styles by faculty members

v. Analysis and discussion

This paper set out to answer the question: do articulating students perceive transfer shock as something that has affected them? This question was analyzed using quantitative and qualitative data and was examined under several themes which now provide a useful framework for discussion of the results. The themes were derived from students' comments collated during interviews with faculty. It is worth observing, however, that these themes fit well with those already identified in research by Winter and Dismore [9] – which are: community, curriculum and culture.

A. Dips in grades

Thirty percent of the interviewees stated that they were somewhat successful in articulating, while only 14% felt they were unsuccessful. Fifty seven percent said they were successful. Since this study involved both 3rd and 4th year students, the findings of this study could be assumed to compare favorably with results from previous studies, [12] and [13], which show that, while identifying initial difficulties in transferring, these appear to be resolved at the end of year 4, when articulating students are on a par with direct entry colleagues in terms of average grades. When grades did not dip the reasons given included the intensity of effort required to complete the Level 7 programs and the level of difficulty at Level 8 not being significantly greater than in Level 7. In contrast, reasons given for grades dipping included a lack of motivation and that the “difficulty was so high”.

B. Faculty expectations

While 57% of respondents perceived only minor differences or some differences in the teaching styles of faculty, comments collated from the interviews show faculty expectations are perceived by some students to be quite different at Level 8. The following quotes emphasize the need for self-directed learning:

- “You have to do a lot more research yourself.”
- “Even the likes of printed out notes, that was left up to yourself.”
- “Left to your own devices.”

Other comments emphasized the faster pace and higher intensity of the requirements of the Level 8 program:

- “It’s just tough to keep up with everything.”
- “There was a significant increase in the workload.”
- “We are expected to up our game.”
- “Maths moved at a slightly quicker pace.”

C. Class integration

Comments made during interviews indicated that students consider integration of former Level 7 and Level 8 students to pose no problems. Comments include “there is not a huge difference between the way they do things and the way I do.” While initially “we would sit on either side of the room”, in semester 2 one student observed “more mixing going on”. Several students perceived the mix to be advantageous to both articulating and traditional Level 8 students, commenting that they “spur us on” and “some of the stuff I would have done in Level 7 and they wouldn’t have touched on, I’d help them with that, and other students would help us with stuff we hadn’t done.” Hence, the positive experience and advantages of peer learning are evident.

D. Study behavior

The majority of students found that they had to change their study habits a lot or at least to some degree (62%) in order to deal with the Level 8 workload. Predominantly, their comments suggested that there was less time available for study due to projects and group assignments. Additional comments collected during interviews indicate again that students feel the Level 7 experience has given them an advantage over their Level 8 colleagues because “we have done a final year project before, we have a good idea of what is needed” and “from the first final year we did, we were slow off the mark, we won’t let that happen again.” Some overlap with the theme of faculty expectations is evident here, with one student commenting “you are being asked to think about

what you are doing ... and see if you can come up with new ideas.”

E. Challenges related to content

Eighty percent of participants responded to the question regarding specific module content challenges, with a quarter not finding that any specific content was challenging. More than 50% of respondents said the transfer to Level 8 was either somewhat challenging or difficult. Some modules (with high theoretical and mathematical content) were highlighted by some as posing difficulties – “it’s a lot more in depth”. Further, the importance of regular attendance at lectures was highlighted – “even if you have covered it before, you have to be in the vicinity to pick things up again”, while other students commented on the amount of repetition between Level 7 modules and their corresponding Level 8 modules. Some saw this as an advantage, especially in the more theoretical modules – “that kinda eased the transition”, while others complained. It was noted that this problem is specific to some engineering disciplines and not to others.

A recurring challenge highlighted by respondents was the volume of assignment work required. Answers included comments like “it’s tough to keep going” and “a significant increase in workload”, “the biggest challenge is to try to get them all done on time”. One student recommended that “people in Level 7 need to be notified more about how difficult Level 8 is”. Another student, however, commented that the “pace increased slightly”.

IV. Conclusions

Previous research at DIT [11] has shown that some articulating students do struggle when they move from Level 7 to Level 8. Other recent research [12] shows that, while students initially struggle with their math modules, their final average marks are on a par with their direct entry colleagues [13]. The purpose of this paper has been to explore students’ own perceptions of their transition, in particular their awareness of experiencing transfer shock or not, their motivations, difficulties and successes. The question this study set out to answer was: do articulating students perceive transfer shock as something that has affected them?

Whilst 38% of students in the online survey stated that articulating was very easy or easy, 62% found it somewhat challenging (38%) or difficult (24%). This provides the clearest indicator of transfer shock. Analysis of the interviews shows that a significant proportion of students do perceive challenges and significant changes in transferring from Level 7 to Level 8 – which concurs with previous studies. The difficulties identified by students correspond to the themes such as faculty expectations, study behavior and content challenges. Integration of former Level 7 and Level 8 students is seen by many interviewees as advantageous, with one

cohort being able to help the other, thereby demonstrating the positive experience of peer learning.

Another indicator of transfer shock is that of academic achievement or dips in grades. The academic performance of the articulating students was mixed, with 57% stating they were either successful or very successful and another 30% stating they were somewhat successful, whilst only 14% felt they were unsuccessful. This divergence in student perception of academic performance could be explained by the fact that the cohort studied as part of this paper includes both 3rd year and 4th year students. It is our contention that the 4th year students have either recovered from the challenges faced in transferring or, indeed, have forgotten that they ever experienced challenges in the first place. This view is supported by findings from a parallel study [13] which shows that the final marks of articulating students are on a par with their direct entry colleagues. The Cronbach Alpha test performed on the internal consistency of responses could indicate the presence of transfer shock also.

Finally, while adjusting to a new campus cannot be considered a factor in contributing to transfer shock in this study, since students articulate within the same campus, it might well ease the articulation process, as suggested by Greenbank [2]. This is validated by analyzing the comments captured by students who responded (38%) that they found the transfer between level 7 and level 8 as 'very easy' or 'easy'.

Further research into articulation of DIT engineering students is planned. Areas to be focused on will include:

- The practice of peer learning between articulating and direct entry students.
- The extent to which faculty expectations differ between Level 7 and Level 8 programs.
- Has Ireland set the correct drivers for its Level 8 engineering programs?

WhatsApp with Learning Preferences?

Imelda Smit

Information Technology Department
North-West University (Vaal Triangle Campus)
Vanderbijlpark, SOUTH AFRICA
imelda.smit@nwu.ac.za

Abstract—Systems Analysis and Design is a second year subject offered as two modules. It forms part of the Information Technology course at the North-West University's Vaal Triangle Campus. As part of an initiative to create varied opportunities for students to learn, the lecturer creates instant messaging groups on WhatsApp; a forum created to allow communication between peers. It is designed to allow students not having access to Internet away from campus, access to peers while preparing for formative and summative assessment.

Felder and Silverman developed five dimensions of learning preferences, each with two sections. Their research built on the research of Kolb, Meyers-Briggs and Jung. The dimensions include: perception where learning takes place in an intuitive way or by sensing; input which may be visual or verbal; organizing which may be inductive or deductive; processing where students learn through active participation or on their own through reflection; and understanding in a sequential or global way.

The WhatsApp environment was included in students learning repertoire to allow for differences in learning preferences and to enable students to get answers to questions while away from campus. With WhatsApp being a social media platform, we may assume that students who learn actively will be more inclined to use it. Since text is used to communicate, we may suspect that verbal learners will also benefit. Pictures can be sent, which may assist visual learners. In this way, it may be argued that most learning preferences can be addressed in a conversation group.

Are these assumptions true? Does instant messaging address most learning preferences? This paper will attempt to identify students from the different learning preferences by analyzing the WhatsApp conversations among them. Other questions that will be answered from this research include: How good is student participation – how many students prefer not to be part of a conversation group for learning, and how many would stay, but only to read conversations between peers?

Keywords— *learning preferences, WhatsApp groups, Systems Analysis and Design*

I. INTRODUCTION AND CONTEXT

Systems Analysis and Design (SA&D) is offered as a second year subject in the Information Technology course offered at the Vaal Triangle Campus (VTC) of the North-West University (NWU). It is offered over a year as two modules.

Students are diverse; black, white, Indian, colored, foreigners; male and female make up the classes that grew from 50 students in 2011 to 125 in 2014. Many students are

from disadvantaged backgrounds, magnifying the importance of using resources to its full capacity.

Students find the subject difficult for various reasons, including the fact that the subject is not as structured as mathematics and programming (in which they normally excel), but fuzzy; it includes a lot of material to be made sense of and the lecturer expects them to work in groups while it is the first time they are exposed to closely working with and relying on their peers. To help all students to participate to their full capacity, many resources are utilized and made available to students. These include eFundi, a Learning Management System (LMS) with all resources and information uploaded in one place. Since 2014 study guides were replaced by SmartGuides, which are downloadable to any device and are used to guide students through every study unit. Videos on difficult concepts support the text book. Various formative assessment opportunities exist to create formative feedback opportunities and allow students to build a solid participation mark. A group project teaches students to work in groups to support one another and learn from one another.

Since students consistently find the preparation for semester tests the most difficult and stressful activity, the compilation of instant messaging (IM) groups were introduced to allow students to communicate with one another and get feedback from peers or the lecturer – immediately. When the initiative was introduced, Blackberry Messenger (BBM), MXiT (a South African development) and WhatsApp were used to ensure that all students have access, but since the middle of 2013 only WhatsApp is used, since most students have access to it. It was found that group sizes should be fairly big to ensure active communication on a variety of topics. Here the developments in IM implementations assisted its use for our purpose – when the project started in 2012, the three IM applications used (BBM, MXiT, WhatsApp) allowed between 15 and 25 people per group, this was extended with subsequent upgrades of WhatsApp to 50 in 2013 and 100 in 2015. Bigger groups generate lots of communication, streamed 24/7 as students work on different schedules. This did create problems for some students who left the groups when the discussions got momentum. Since the early days some time is taken to make group members aware that posts need to be made with care and that one may silence a conversation while focusing on studies or sleeping – current applications allows it.

In the subsequent sections the following topics will be addressed, namely the formulation of the problem, a background on learning preferences, a discussion of the research project, the learning preferences identified from the WhatsApp conversations and finally, the concluding remarks.

II. PROBLEM FORMULATION

An obvious potential advantage of the use of IM in learning is that factors that normally hinder collaboration and group work are minimized when using this technology. Irrespective of geographical distances, students are able to interact with their lecturers and classmates, both synchronously and asynchronously.

The disadvantages of online discussions emerged through a study by reference [1] who reported that some participants preferred a face-to-face format to the more limited social interaction of an online learning environment. Reference [2] again, found the limited flow in dialogue and the absence facial expressions and gestures that occur in face-to-face contact, limited the impact of discussions. It was also found that some students were intimidated by having to put their thoughts in writing [3].

To counteract some of the disadvantages mentioned reference [10] reports that the use of emoticons, for example “:D” or “😊” to show emotion, small verbalizations like “lol” (which means “laugh out loud”) or “yea” are used to sustain conversational flow and also to demonstrate understanding. This enables the student to build rapport and establish common ground.

To what extent do WhatsApp conversations, as a teaching and learning tool, support the different learning preferences?

During the first semester of 2012, IM platforms (BlackBerry Messaging (BBM), WhatsApp and MXit) were introduced to support students’ learning. Students were asked to indicate the platform they already use to socialize, so platforms were utilized based on their popularity among the students. Initially IM was used to make concepts covered in SA&D available to students – on their cell phones. It was thought that this would allow students to familiarize themselves with concepts anywhere, anytime. This experiment was not received well by students and they suggested that it would be better if the platforms could rather be used to support them in preparing for semester tests and examinations.

The suggestion was implemented during the latter part of the same semester, using the same platforms. Groups were formed according to the restrictions of each platform, and the number of students using each platform. The lecturer created groups from information supplied by students on a voluntary basis. Students were invited to join at any time and they could delete the conversation at any time. For this reason figures supplied in Table I below are only estimations – numbers changed on a continuous basis as students were added and removed themselves. In addition to the voluntary basis on which the interaction worked, technology is not stable, cell phones break, they get stolen and, especially in the early days upgrades left one with a virgin IM tool – all groups and conversations were lost.

Students were prepared that they were supposed to help one another, although the lecturer would clarify issues when she felt students go astray.

During the first semester of 2013, it was noticed that MXit lost its popularity among the students (only one student used it)

and although BBM was still popular, all students using it also used WhatsApp. This situation called for the decision to only use WhatsApp – which allowed groups of up to 50 students at that time. This decision was supported by the fact that MXit made use of advertisements to supply an income stream – a model that can distract attention from the work at hand. On the other hand, BBM allowed students to choose their own names – which made it difficult for the lecturer to identify the person talking. BBM was also only supported by a BlackBerry phone in the initial years. The lecturer felt that WhatsApp was accessible by all smartphones, it focused on conversations only, it supported the sending of pictures to support conversations and it was easy to identify students.

TABLE I. CLASSES AND STUDENTS USING IM IN SA&D

<i>Year</i>	<i>Class size</i>	<i>WhatsApp</i>	<i>BBM</i>	<i>MXiT</i>
2011, S1	50			
2011, S2	44			
2012, S1	82	23 (2 groups)	19 (1 group)	23 (1 group)
2012, S2	70	20 (2 groups)	15 (1 group)	18 (1 group)
2013, S1	110	45 (1 group)	18 (1 group)	1 student
2013, S2	86	42 (1 group)		
2014, S1	126	93 (3 groups)		
2014, S2	78	64 (2 groups)		

In addition to the groups listed in Table I, a new group was formed after the first examination was written at the end of each semester. The NWU allows for a second opportunity examination for students not able to write the first examination, or failing it.

In the next section learning preferences are scrutinized to set the scheme for evaluation the students’ learning preferences on the IM platform.

III. LEARNING PREFERENCES

Reference [4] studied students in the engineering field and identified five learning dimensions, each having two focuses. This information is reflected in Table II that follows on the next page.

The answers to five choices may define a student’s learning preference [4]:

1) The type of information the student preferentially perceive is either sensory which includes sights, sounds, physical sensations; or intuitive which includes possibilities, insights, hunches.

2) The sensory channel through which external information is effectively perceived may be visual, including pictures, diagrams and demonstrations; or verbal, including words and sounds.

3) The organization of information with which the student is most comfortable is either inductive, where facts and observations are given, underlying principles are inferred; or deductive where principles are given, consequences and applications are deduced.

4) The student’s preference regarding processing of information, which may be actively through engagement in

physical activity or discussion; or reflectively through introspection.

5) The student's progression towards understanding, which may be sequentially, occurring in continual steps; or globally, occurring in large jumps, holistically.

TABLE II. LEARNING PREFERENCES ADOPTED FROM REFERENCE [4]

<i>Dimension</i>	<i>Focus</i>	<i>Description</i>
Perception	Intuitive	Uses existing knowledge framework to scaffold new concepts and find relationships, little attention to detail.
	Sensing	Experiment with new concepts, like to do examples to learn, build on facts.
Input	Visual	See new concepts in pictures, diagrams, demonstrations, graphics. Color attracts them.
	Verbal	Learn through words, whether written or verbal, hearing and explaining to others enhances remembering.
Organization	Inductive	Reasoning progresses from particulars to generalities.
	Deductive	Reasoning progresses from principles to consequences.
Processing	Active	Summarize new concepts, participate in discussions with peers; or explain to peers.
	Reflective	Needs time alone to think about new concepts. Learn on their own.
Understanding	Sequential	Linear lessons offered in short successive sessions, increasing in difficulty.
	Global	First sees the bigger picture, then the detail and its relationships. Relates new concepts to current knowledge and understanding.

The index of learning styles, developed by references [5, 6], addresses only the last four categories in its questions, namely input, organization, processing and understanding.

Reference [7] stresses the fact that no learning preference is preferred to another. They are simply different. Each has its own strengths and weaknesses. Lecturers should equip students with the skills associated with each preference.

With the above statement in mind, it is also true that for a professional person to function effectively in a work environment; requires working well in all learning preference modes [8].

It is the opinion of the researcher that is especially true in SA&D, because of the fact that the discipline requires people skills and technical ability and requires of the professional to draw from a variety of tools to be able to do the job well. It is therefore also important to develop a well-rounded young professional with regards to learning preferences.

IV. RESEARCH PROJECT

Interpretive research is a research paradigm that allows a researcher to understand the research environment [9]. This research project has the goal to understand through determining whether IM conversations allow students along the learning preference spectrum to use it as a learning tool.

WhatsApp history is downloadable through electronic mail. It lists conversations, indicating the person talking, the time and the date. For the purpose of this paper students are protected and their identities are not made known. Pictures that were sent are not shown on the history. This conversation data was analyzed to decide which learning preference a student likely prefers. Snippets of conversations are used to illustrate and motivate this.

For the purpose of this paper, the communication in the WhatsApp group created for the second opportunity examination of the first semester of 2013, are used for analysis purposes. The group was fairly small – it consisted of 18 students, but was made up of a group of students motivated to pass the subject module.

The second opportunity examination group was created on 2 July 2013, the examination was scheduled for the afternoon of 5 July 2013 and the group dismantled on 14 July 2015. It included almost 400 conversation lines.

The basic structure included the following:

- The **formation** of the group by the lecturer. The group is named and a group photo that may be changed by any participant is uploaded. The students are prepared regarding the purpose of the group. Missing members are named to enlist the help of the members in getting them on board.
- Six **topics** were discussed, of which the longest covered almost 135 conversation lines. They included the following:
 - Topic 1: Expectation management.
 - Topic 2: Gantt charts.
 - Topic 3: Object-oriented analysis.
 - Topic 4: Use-cases.
 - Topic 5: Cross life-cycle activities.
 - Topic 6: Entity relationship diagrams.
- **Administrative issues** were addressed during these topic conversations. Administrative issues addressed, included the following; arranging a face-to-face examination preparation session and clarifying the purpose of the second examination.
- Establishing the **scope** of the paper. Although the scope of the paper includes all the subject module outcomes, allowing students to speculate on the chances of a question being asked may help them to enter the examination being more confident.
- **Unwind** from the pressure of the examination, directly after the examination. Four members left the group immediately after the examination was written. The rest stayed on to talk about the experience writing the examination and to keep tabs on the assessment progress. Most students left the group after their marks were made available.

These categories may be compared to the work done by reference [10], where four conversation types were identified, namely:

- 1) A shared understanding and the construction of meaning, where peers talk only for the purpose of establishing common ground.
- 2) Displays of intimacy and making fun for the purpose of building relationships.
- 3) Labor division in the creation of artifacts (or answers) – something that was not found regularly in this research.
- 4) Sharing of feelings regarding work completed, their lecturer(s) and peers.

It may be noted that the first two points were almost absent in the SA&D conversations. This may be because of the fact that these students worked together in groups and knew one another quite well when the group was formed.

Labor division (point 3) did occur during the discussion of topic 2, although it was initiated by the lecturer.

The fourth point also occurred after the examination was written when students speculated on their chances of passing.

In addition to the four conversation types mentioned by reference [10], discussion of the topics mentioned occurred, which was very encouraging.

The WhatsApp group had 15 members. This supported the claim that the students were motivated to do what was necessary to pass the module. Only 9 students actively participated in the discussions. The other 6 students only “listened in” and did not say anything. It is hoped that these students learnt while reading even though they were not participating.

Of the 9 students who interacted, 4 students participated by using the forum only to solve administrative problems. It is hoped that these students were set at ease and could therefore focus on their studies. One student only participated while the scope was discussed.

The WhatsApp conversations included the discussion of 6 topics among the lecturer and 4 students who made meaningful contributions. From the analyses, deductions can be made to determine whether IM as a teaching and learning tool accommodates most learning preferences.

V. LEARNING PREFERENCES IDENTIFIED IN WHATSAPP CONVERSATIONS

Referring to Table II in Section III and Section III in general, the four dimensions used to determine learning preferences, namely input, organization, processing and understanding, builds on one another, where the input represents the way learners prefer to view new information; organization refers to how they would integrate this new information with what they already know; processing refers to how they prefer to interrogate the new information to convert it to knowledge and understanding refers to how they would likely look at the world – using a bird’s eye view or seeing details as important.

Keeping this building block categorization in mind, the data of the four students who participated in a meaningful conversation about the material to be examined was analyzed. Tables III, IV, V and VI show the evidence as compiled by the researcher.

TABLE III. LEARNING PREFERENCES STUDENT A

<i>Student A</i>	<i>Classification</i>		<i>Example from conversations</i>
Input	Visual	Verbal	Topic 2: (<i>advised another student to watch a video on the topic</i>) “Theres a video on how to do gantt and pert diagrams. Check it out it will help u.”
Organization	Inductive	Deductive	Topic 2: (<i>figuring out the critical path</i>) “Subtract the others from the critical path, since its the longest, we dnt want negatives.”
Processing	Active	Reflective	Active participation during the topic 2 discussion.
Understanding	Sequential	Global	Topic 2: (<i>attention to detail</i>) “I also think the nodes shud b there even thou we dnt write anything on them”

From her conversations, student A is perceived as a *visual* learner who watches the videos provided, she derives at conclusions regarding what she sees (*inductive*) to help her organize the information. She is an *active* learner who likes to interact with others while processing information. Although her understanding is difficult to assess, her attention to detail categorizes her as a *sequential* learner.

TABLE IV. LEARNING PREFERENCES STUDENT B

<i>Student B</i>	<i>Classification</i>		<i>Example from conversations</i>
Input	Visual	Verbal	Topic 3: “Mense, could yal please explain the inheritance relationship ... hw to draw the second part of it”
Organization	Inductive	Deductive	Topic 2: (<i>figuring out what a dummy path is</i>) “Yah ... bt wt mkes the path to b a dummy path???”
Processing	Active	Reflective	Active participation during the topic 1, 2 and 3 discussions.
Understanding	Sequential	Global	Topic 2: “Ka gantt u draw bars not lines ... ke pert dt uses lines to connect paths ... a path ka gantt is represented by a bar ...”

From her conversations, student B is perceived as a *verbal* learner, since she only uses only words to communicate; she makes deductions from the examples discussed (*inductive*). She is an *active* learner who likes to interact with others while

processing information. Her understanding is assessed as *sequential*, since it is clear that she gives attention to detail.

TABLE V. LEARNING PREFERENCES STUDENT C

<i>Student C</i>	<i>Classification</i>		<i>Example from conversations</i>
Input	Visual	Verbal	Topic 2: Uploaded a picture.
Organization	Inductive	Deductive	Topic 2: (<i>loads Gantt example, then interrogates it</i>) "In my Gantt chart how do I represent two paths that connects to one point, like Mam say path E 2 B, C?"
Processing	Active	Reflective	Topic 2: (<i>after an explanation by another student</i>) "Yes I agree with u, ohk let me try figure it out..thank neh"
Understanding	Sequential	Global	Topic 2: (<i>attention to detail</i>) "I am not sure I get u, on node activity diagram I do get I can connect the parts, but in my Gantt chart I have to shade the days my project will take place, so I am puzzled on how we do dat in Gantt Chart."

From her conversations, student C is perceived as a *visual* learner who likes to draw conclusions from the examples discussed (*inductive*) to help her organize the information. She is a *reflective* learner who prefers to spend time on her own to process information. Although her understanding is difficult to assess, her attention to detail categorizes her as a *sequential* learner.

TABLE VI. LEARNING PREFERENCES STUDENT D

<i>Student D</i>	<i>Classification</i>		<i>Example from conversations</i>
Input	Visual	Verbal	Topic 5: (<i>another student asked where to find information on cross-life cycle activities</i>) "It's on chapter 3's slides."
Organization	Inductive	Deductive	No evidence.
Processing	Active	Reflective	No evidence.
Understanding	Sequential	Global	Topic 5: (<i>another student asked where to find information on cross-life cycle activities</i>) "It's on chapter 3's slides."

From his limited interaction, student D is perceived as a verbal learner. He gives no indication of his preferences regarding organization and processing of new information. The fact that he knows exactly where the information his peer is requesting is to be found, categorizes him as a sequential learner.

VI. CONCLUSION

For the purpose of this paper a fairly small group of students were selected. They were part of a WhatsApp IM group preparing for a second opportunity examination. Their conversations were analyzed to determine their learning styles as displayed in their conversations.

From the analysis of the conversations an IM application like WhatsApp may be categorized as a useful tool to assist students in their preparation for assessment. Table VII attempts to use a heat map approach to indicate how useful WhatsApp may be as a tool to accommodate learning preferences when preparing for assessments.

TABLE VII. IM'S CAPACITY TO ACCOMMODATE LEARNING PREFERENCES

Does IMs accommodate learning preferences?		
<i>Dimension</i>	<i>Focus</i>	<i>Motivation</i>
Input	Visual	Since WhatsApp allows for the distribution of pictures, visual learning is supported.
	Verbal	Verbal explanations work well on WhatsApp.
Organization	Inductive	On WhatsApp it is easy to list examples and progress from particulars to generalities.
	Deductive	WhatsApp is not a teaching tool and therefore deductive reasoning will rarely happen..
Processing	Active	Any person may start a conversation, get inputs and discuss topics.
	Reflective	A cell phone can be put on silent or ignored.
Understanding	Sequential	The fact that more than one conversation may take place at the same time may confuse a person who understands sequentially.
	Global	Distribution of pictures like mind-maps may assist. Unfortunately little evidence could be found as proof of understanding.
Heat map clarification		
Not well-suited		Fairly well-suited
		Well-suited

In the conversations analyzed, little evidence was found of students' understanding and deductions had to be made. It may be that students prefer not to converse their progress towards understanding or that they progress towards understanding on their own, while studying and making sense of what was discussed on the IM platform.

Future research may include the following:

- To focus on a larger group of students with a bigger cohort participating actively. Such a study may include a larger variety of differences in learning preferences – with the accompanying proof in terms of conversations.
- The research may also be expanded to include teaching styles to match learning preferences. This may help students struggling to progress because of a mismatch with the lecturer's preferred teaching style.
- The delivery of a well-rounded young professional upon graduation may include the development of individual students' non-prominent learning preferences.

Mayagüez, Puerto Rico 00682

Dr. Amilcar A. Rincon-Charris
Mechanical Engineering Department
Inter American University of Puerto Rico, Bayamon
Bayamon, Puerto Rico 00957

Abstract – The purpose of this paper is to present an interdisciplinary research project in order to attract engineering students to the area of aerospace systems. The Puerto Rico NASA Space Grant (PRSGC) is a joint program between the University of Puerto Rico-Mayagüez (UPRM), the Inter American University of Puerto Rico-Bayamon (UIPRB) and other educational institutions. The desired impact of the project is to promote interdisciplinary research in the area of aerospace systems with the collaboration of graduate and undergraduate students from electrical, mechanical and computer engineering departments. As an example of the progress obtained through interdisciplinary research, this paper will focus on the Electronic Power Supply (EPS) developed of a CubeSat by both the UPRM and the UIPRB. CubeSats are miniature satellites designed for space science explorations. Due to their low cost and reduced size, not only have they earned an eminent position in the field of space exploration but they have also become a reliable tool for space education. The multidisciplinary process consists of the design, simulation, and construction of each the CubeSats EPS. This collaboration has helped create ties between UPRM and the UIPRB.

Index Terms – *CubeSat, aerospace, interdisciplinary research, study programs, electrical power supply*

I. INTRODUCTION

It is evident that research and development has become an essential part of a large number of engineering universities for its significant contributions to society [1]. Despite the global impact research conveys, it is mostly a closed group effort. Specific groups (companies, organizations, universities, departments, etc.) work towards achieving a single objective in order to create a positive impact. Engineering research should no longer be constrained to single agencies; interdisciplinary efforts should aid in accomplishing global objectives. Recently universities have adopted interdisciplinary approaches, collaborating with other institutes in order to expand ideas and improve teaching methods [2]. As part of the PRSGC, engineering departments from different universities in Puerto Rico have merged together in order to design and construct Puerto Rico's first functioning CubeSat. This project is considered to be interdisciplinary due to its use of the diverse aspects performed by the different fields of engineering. The PRSGC is composed of the UPRM, the UIPRB as well as other educational institutes in Puerto Rico. Fig. 1 illustrates a diagram of the different universities, agencies and departments that are collaborating in this project.

Fig 1: The collaborators in the NASA Space Grant Consortium. Certain projects focus on the collaboration between different educational institutions in Puerto Rico.

The PRSGC is an opportunity to encourage collaboration between different universities in Puerto Rico while at the same time promoting a higher degree of learning. The PRSGC focuses on enhancing Puerto Rico's research, education and workforce in the fields of Science, Technology, Engineering and Mathematics (STEM). With this in mind, the participating universities are encouraged to collaborate in different projects in an interdisciplinary manner. For this reason UPRM along with the UIPRB are collaborating in aerospace related projects to create a platform for students to work on. Some of these aerospace related projects involve unmanned aerial vehicles and small satellites. One of the steps taken to strengthen the aerospace program of both the UPRM and UIPRB is to combine both their curriculums. As an example of the progress obtained through interdisciplinary research, this paper will focus on the results obtained through the collaboration of the UPRM and the UIPRB.

This article is organized in the following manner: section II describes the academic background of the UPRM and UIPRB as well as their collaboration. Section III gives a general description of the selected aerospace project. Section IV describes the projects methodology and expectations from each engineering field. Section V describes the educational impact the project had on students. Finally section VI presents the conclusions obtained.

II. ACADEMIC BACKGROUND AND COLLABORATIONS

The UPRM is a public university located in the municipality of Mayagüez, Puerto Rico established in 1911. UPRM offers 52 bachelor's programs, 28 master's programs and 5 doctoral programs. Moreover, it has been accredited by the Middle States Commission on Higher Education (MSCHE) since 1946 and by the Accreditation Board of Engineering and Technology (ABET), ranking among the top 10 U.S. universities in the field of engineering. The Electrical and Computer Engineering (ECE) Program currently has nearly 1,100 students which represents nearly 10% of the whole UPRM's student population and more that 20% of the UPRM College of Engineering' student population. Also, the ECE Department's research and graduate programs involve 14 laboratories, groups and centers, more than 40 graduate-level courses, 49 faculty members with PhD degrees, 2 adjunct professors, nearly 1,100 undergraduate students and over 60 graduated students. At present, the ECE Department offers BS and MS degrees in ECE and a PhD in computer informatics science and engineering.

The ECE Department offers several areas of specialization that could be applied to aerospace systems: control systems (e.g. trajectory optimization), electronics (e.g. IC for energy harvesting), power electronics (e.g. high density power supplies for satellites), computing systems (e.g. cyber security), and communications (e.g. wireless communications). Also, collaborations between the Mechanical Engineering (ME) Department and the ECE Department have resulted in a minor in Aerospace Engineering. Table I shows examples of the foundation courses offered by the ME Department. Table II shows examples of ECE and ME elective courses that are offered as part of the aerospace program.

The UIPRB is a private university located in Bayamon, Puerto Rico, established in 1956. With an enrollment of about 5,000 students, UIPRB offers undergraduate programs with emphasis on technology, engineering, aviation, computer and science. Its BS programs in Industrial, Electrical and Mechanical engineering are also accredited by ABET. Its ME program is designed to train students to develop the knowledge and abilities needed to function as an efficient professional in the fields of energy and aerospace by providing students with the opportunity to hone in on the necessary skills required to become successful in the aerospace industry.

One of the UIPRBs largest contributions is their research facilities, which are designed for aerospace testing; ground station laboratory for communications systems, thermal analysis laboratory equipped with thermal oven and a vacuum designed for testing space conditions. The university also possesses a control systems and electronics laboratory as well as a clean room. Table III illustrates the UIPRBs aerospace programs and courses.

TABLE III: UIPR-BAYAMON AEROSPACE PROGRAM

Program	Course	Description
Minor Aerospace Engineering	MECN 3974	Aerospace Experience I
	MECN 3973	Aerospace Experience II
	MECN 3975	Space Mission Analysis and Design
	MECN 4301	Aerospace Materials
	MECN 3545	Gas Turbines and Propulsion systems
	MECN 3350	Aircraft Design and Performance
Master of Science in Mechanical Engineering with concentration in Aerospace	MECN 6210	System Engineering
	MECN 6220	Advance Structure Engineering
	MECN 6230	Aerospace Dynamic
	MECN 6300	Advance Control System
	MECN 6260	Advance Mechanical Vibration

The UIPRBs curriculum and facilities in combination with the UPRMs courses is the key to developing successful projects in the field of aerospace. Undergraduate courses from the UIPRB such as; MECN 3974 and MECN 3973 provide UPRM students with the fundamental in the field of aerospace. Graduate design courses like MECN 6230 are also incorporated into lectures in order to gives students a better understanding of aerospace dynamics.

For the fall semester of 2014, the ECE Department of UPRM provided the graduate courses of INEL 6085 and INEL 6066. These courses were used to introduce the concept of aerospace applications into the curriculum and shared with faculty and students from UIPRB. Both of these courses incorporated the subjects of solar energy and power supply design, two topics that are essential for the aerospace applications. The final projects for these courses were also related to aerospace and were presented to students and faculty from both universities. For the spring semester of 2015, a new course, INEL 6995, was created and added to the graduate curriculum for the sole purpose of continuing this interdisciplinary collaboration between universities.

III. THE CUBESAT PROJECT

A CubeSat is a miniature satellite originally designed for space science exploration. Conceived as an educational tool, they have managed to challenge traditional satellite standards and are recognized for their potential utility by space and research agencies around the world [3]. The design and construction of a satellite is a multidisciplinary effort, involving aspects of all fields of engineering [4]. It is not expected that a single group should design and construct the entire CubeSat. For this task to be achieved it is essential to involve several groups, from different institutes and disciplines [5], [6]. These CubeSat projects are primarily led by universities and non-US space groups. In most cases government agencies have sponsored the development of these projects through organizations such as; NASA, National Science Foundation, and the Department of Energy [7].

CubeSats are mainly composed of several units; an on-board computer, control and communication systems, among other measurement devices. In order for these units to operate it is essential that their power is supplied by an EPS. The interconnection between the EPS and other subsystems is the key in developing a well-functioning CubeSat [8]. The UPRM, in collaboration with UIPRB are tasked with designing the EPS for the Space Plasma Ionic Charge Analyzer (SPICA) CubeSat. This is achieved by joining together the electrical, mechanical and computer engineering departments. The wide variety of courses and facilities from both universities will help students develop an EPS prototype for the CubeSat. Fig. 2 shows a Computer Aided Design (CAD) 3D model of a standard U2 CubeSat design, illustrating some of the most vital parts of the EPS developed by students.

Fig 2: Standard 2U CubeSat diagram. CubeSats are small scale satellites composed of several subsystems. They are designed to provide easy access to space science education and space science exploration.

IV. PROJECT METHODOLOGY

Through the PRSGC, graduate and undergraduate students from UPRM and UIPRB collaborate in the project. This project organization is based on similar Cubesat schemes from other successful institutes that have managed to create an impact in their communities [9], [10], [11]. This university uses a project group structure composed of three groups; Project Management Group, Supervisor Group, as well as several other Project Groups. The supervisor group is composed of the supervisors of the different project groups tasked with providing guidance to each group. These groups are overseen by a steering committee composed of each member of the project groups and the professor acting as project manager.

A similar project organization is adapted for this project joining together faculty, industrial affiliates and students. Faculty members are involved in supervising the overall development of the project. They provide students with course work, articles and related material that may guide them in the right direction. Faculty members are aware that their participation in the project must not interfere in the student's leadership development. In addition, graduate advisors can become a part of the mentoring process. These advisors can range from professors to industrial affiliates. The team is organized in order place students in charge of the project. The team leaders or Systems Engineering Group, composed primarily of graduate students, are in charge of managing and keeping a constant flow of information between all engineering groups. They are also the bridge between students and advisors. Fig. 3 illustrates the organization of the team established by both the UPRM and UIPRB.

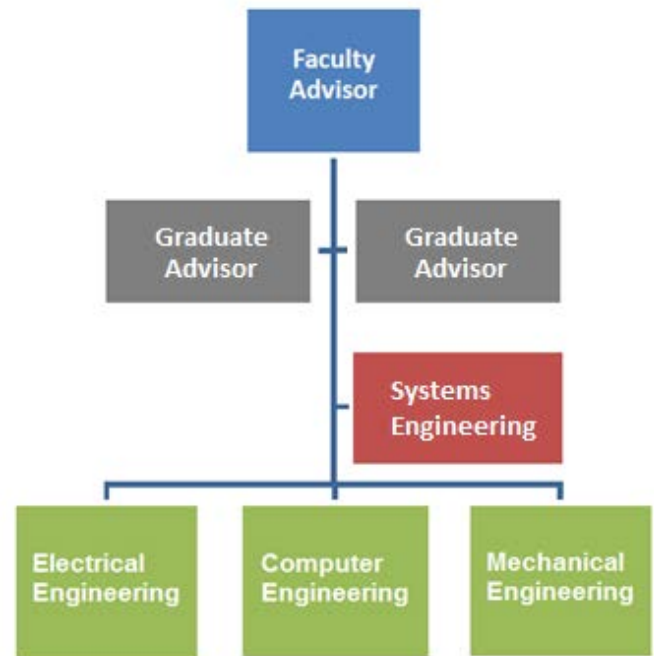

Fig 3: Team organization. Team includes faculty advisors, graduate advisors as well as the integration of each engineering discipline. The group is organized in a manner that students have the responsibility of leading the project.

Four teams are formed, each team consisting of students from both the UPRM and UIPRB. Each group specializes in a specific engineering field; electrical, computer and mechanical engineering. An additional group consists of one student member from each engineering field. Teams are student managed and are assisted by mentors and supported by industry specialists [12], [13]. This teaching method requires teams to work together, for the duration of several semesters, in order to learn the necessary skills required to complete their tasks [14]. Each one of these teams is expected to have a basic set of skills that play an essential part in the project with the purpose of teaching students new skills. However there are some basic abilities that students should possess in order to understand how to tackle obstacles that may occur during the course of the project.

A. Systems Engineering Group

The systems engineering group are the student team leaders of the project. They consist of one student representative from each engineering department. These students are the leaders of their respective engineering groups and are expected to be experts in their field. Their responsibilities are not limited to their engineering knowledge; they must also possess strong communication skills, leadership abilities and powerful project management skills. The main objective of this group is to promote interdisciplinary research among other groups. This group is also the bridge between the engineering groups and the faculty advisor. They must present results as well as the progress of the project.

B. Electrical Engineering

Electrical engineering students are required to have a solid background in circuit design and analysis. It is essential that the group possesses basic circuit analysis knowledge in order to understand the electrical characteristics of the topologies proposed for the EPS. An intense literary review of conference articles, journals and transactions help identify acceptable circuit designs. Once a series of circuit topologies are selected, students design, build and test them in order to identify which are more suitable based on the desired application.

C. Computer Engineering

The students from the computer engineering team are expected to have enough background in order to program microcontrollers (MCUs) and to be able to implement different types of algorithms. These students are prepared to attack any computational problems that may occur. Students are also expected to be familiar with software that can aid other groups by using simulation software or computer aided Printed Circuit Board (PCB) design tools.

D. Mechanical Engineering

Mechanical engineering students are suggested to have taken courses contained in the aerospace programs offered by the ME Department of UPRM and UIPRB. These students must be able to design small parts, structural hardware and other components required by the CubeSat infrastructure. These students are also expected to have basic skills related to CAD, and computer aided manufacturing (CAM) software, as well as computer numerical controlled (CNC) tools for milling machines.

Each group is assigned a certain task in order to identify what goals must be completed at the end of each semester. Table IV shows the organized teams and their respective responsibilities.

TABLE IV: TEAM AND TASK DISTRIBUTION

Field	Task	Description
Electrical Engineering	Design	The design process consists of selecting the suitable circuit topologies for the EPS. Once the design for the EPS is completed, electrical engineering students work alongside the computer engineering group in order to design the PCB layout using CAD tools.
	Construct	Students must construct a final EPS prototype that complies with the CubeSat weight and size limitations established by the mechanical engineering group.
	Test	The testing process involves characterizing the solar panels as well as validating the functionality of the EPS.
Computer Engineering	Design	This task requires basic programming knowledge of MCU in order to design the control system responsible for performing the MPPT and any additional control functions.
	Construct	The construction process consists of building a simulation for the entire EPS system including the CubeSats solar power array. This group also aids the electrical engineering group with PCB design software and the mechanical engineering group with CNC design tools.
	Test	Testing requires students to assure that the MCU is executing the correct algorithms for the control system as well as the MPPT.
Mechanical Engineering	Design	This task requires the design of small parts, structural hardware and other components required for the CubeSats infrastructure.
	Construct	The construction process requires the mechanical engineering students to work together with the electrical and computer engineering groups in order to manufacture the PCB for the EPS using CNC machine tools.
	Test	The testing process involves thermal and vibration testing in order to assure that the EPS can withstand deployments as well as the harsh conditions of space.

Although groups focus on their own tasks, students are encouraged to assist each other in order to promote interdisciplinary research. This in combination with the time shared in the laboratories helps create an exchange of information between the different engineering disciplines that promotes an interdisciplinary research environment [15], [16]. Because of the interdisciplinary aspect of the research project, there is a great number of professional skills learned between the students that is not learned in traditional classrooms. This skills help build the bridge between the learning and the social environment of the academia. Teams are encouraged to prepare presentations, reports and articles as well as attend conferences and workshops in order to teach them how to present their work to experts, professionals, and colleagues [17].

V. BROADER EDUCATIONAL IMPACT AND RESULTS

A beneficial impact obtained from this project is the experience students earn from working with relevant software in the field of engineering: MATLAB, Simulink, Multisim and LabView among others. These different software tools help simulate stress and space conditions that cannot be easily verified with theoretical calculations. In the ECE department of the UPRM, power electronics is generally applied to the subjects of motor control and renewable energy. This project has broadened the field of power electronics applications in the area of aerospace. A variety of DC/DC converters topologies, microcontrollers (MSP430, ArduinoUno, Propeller, Parallax, etc.) and MPPT techniques have been explored in order to meet the CubeSats specific needs. Another added incentive from this project is improving the students' hands-on skills and laboratory capabilities. Students learn how to design and print circuit boards. Fig. 4 illustrates a PCB design made with the Eagle software for the final version of the CubeSats EPS.

This project has provided student the experience of focusing on a variety of tasks while also allowing them to coordinate work between various groups from other departments and in the UPRM and the UIPRB [18]. It has motivated undergraduate students in the mechanical, electrical and computer engineering and computer science programs to embrace a multidisciplinary approach to engineering. Currently there are 42 students working directly on the CubeSat project. Notice the improvement in the design of the EPS. The initial prototype, although functional, is bulky and exceeds the CubeSats size limitations. In a period of half a year, the students have taken the design and transformed it into a robust, that complies with both size and weight limitations. The constructed CubeSat EPS prototypes developed over the course of the project are shown in fig. 5.

Fig 4: The 9cm x 9cm PCB design of the CubeSats EPS, developed by the computer engineering team of the UPRM. The project gives students the opportunity to learn new design software that is not traditionally taught in courses.

(a)

(b)

Fig 5: The developed CubeSat EPS Prototypes. (a) The initial EPS prototype developed for the first semester 2013-2014 with no weight or size limitations. (b) The second EPS prototype developed for the second semester 2013-2014 designed with the CubeSats restrictions.

Once the PCB is designed, it is manufactured using a CNC milling machine which traces the circuit paths on a copper clad. Electrical components as well as connectors are carefully soldered unto the PCB. The end result is a 9cm x 9cm EPS capable of charging the CubeSats battery as well as supplying the required voltages to the measurement devices. Notice how the EPS complies with the CubeSats weight and size limitations established by the mechanical engineering team.

The final product is tested with the use of a solar array simulator that aids in emulating the CubeSats solar panels. Although the construction of the EPS is a task assigned to the electrical engineering team, computer engineering students provide support by integrating the microprocessor unto the PCB. This included adding capacitors as well as the selection of voltage regulators (to supply power to the MCU) and adding a crystal oscillator. This is an example of how the electrical and computer engineering teams collaborated in order to achieve a common objective. This PCB design and construction approach has been adopted by other power electronics projects in UPRM and UIPRB [19].

In order to power the CubeSat, solar panels are located on each one of its sides. Mechanical engineering students designed and manufactured several solar panels, using triangular advanced, improved triple-junction Gallium Arsenide (GaAs) solar cells. These solar panels supply power to the loads while charging the battery of the CubeSat. Each solar panel consists of 24 GaAs solar cells. When the series and parallel connections are made between the solar cells, the result is a 9cm x 9cm solar panel. Fig. 6 illustrates the GaAs solar cells, solar panels that have undergone and the developed CubeSat casing which houses the EPS.

(a)

(b)

(c)

Fig 6: The GaAs solar panels. (a) The triangular advanced triple-junction GaAs Solar cell. (b) The solar panels constructed by the mechanical engineering students of the UIPRB. (c) The developed CubeSat casing with solar panels attached.

Once the solar panels were constructed, the electrical and mechanical engineering teams were tasked with their characterization. Based on the parameters obtained by the electrical engineering team, the computer engineering group simulated the solar panels in order to obtain their I-V and P-V curves. This is another example of how, the mechanical, electrical and computer engineering students all collaborate with each other in order to complete their task of constructing a GaAs solar panel model.

Finally, the solar panels were electrically connected to the input of the EPS and the control system was programmed unto the MCU. With the connections in place, the EPS system was inserted into the CubeSats housing and the solar panels were mounted unto the sides of the frame. This is another example of interdisciplinary research between the mechanical, electrical and computer engineering departments.

VI. CONCLUSION

An interdisciplinary CubeSat project between the UPRM and the UIPRB is discussed in this paper. The desired impact of this project is to establish collaborations between the engineering departments from different universities of Puerto Rico. In order to do this, the universities have selected a specific area of interest. Aerospace is an emerging topic in Puerto Rico that engulfs several fields of engineering. Cubesats in particular, are an interdisciplinary project that involves different aspects of all the fields of engineering. The UPRM and UIPRB are tasked with developing the CubeSats EPS. Students from electrical, computer and mechanical engineering from both the UPRM and UIPRB exchange course material in order to strengthen their universities curriculums.

This collaboration has influenced a growth in aerospace technologies in universities in Puerto Rico and has helped create ties between UPRM and the UIPRB as well as with agencies like NASA and PRIDCO. The efforts of all the universities participating in this project have proven that interdisciplinary research can have a great impact on students, while at the same time influencing institutions into adopting new courses and teaching methods. In general the learned resources could not only be applied to this project but to any other project, including topics outside of the aerospace and power electronics field.

It is expected that undergraduate students interested in pursuing a master's degree will base their thesis on this project. This will help prologue the participation of students in the project, while at the same time providing an additional incentive. The majority of students that have worked in CubeSat related projects in the past have been employed by companies such as: Texas Instruments, Honewell, Infotech aerospace services, Florida Turbine, Lockheed Martin and NASA. Students have also had the opportunity of participating in summer internships at high raking institutions and laboratories such as: Michigan State University, Ohio State University, University of Minnesota and Argonne National Laboratories.

ACKNOWLEDGMENT

The authors gratefully acknowledge the participation of the M_{inds}^2 CREATE Team at the University of Puerto Rico (UPR) and the Inter American University of Puerto Rico (UIPR) as well as the support of the Puerto Rico Industrial Development Company (PRIDCO) and the NASA Puerto Rico Space Grant Consortium (PRSGC) under grant number NNX10AM80H.

Abstract—This paper introduces a novel, supportive tool for engineering educators while making course adaptations. As pointed out in the 2013 FIE workshop “An Online Revolution in Learning and Teaching,” online learning is likely to impact every department and teacher in some manner. Other innovations impacting engineering educators include active learning, peer instruction, problem-based learning, and just-in-time teaching. When implementing change, educators are expected to present existing course materials in alternative formats. One resultant difficulty is visualizing, understanding, and judging the impact of various alternatives. Learning materials organization is often limited by delivery methods such as learning management systems that present material linearly. This project uses text analysis and graph transformation techniques to produce various alternatives allowing educators to envision ways changes can be effectively implemented in their courses. We demonstrate how temporal and topical relations between individual learning items can be extracted from existing courses and used to produce a graph that is an effective representation of the course. From this, graph transformations produce alternative organizations of course material allowing various solutions for educators to consider while redesigning their courses. This form of automated brainstorming stimulates out-of-the-box thinking, often producing options previously not considered.

I. INTRODUCTION

In an effort to meet the changing landscape of education many departments and universities are offering more online courses – a move that is likely to impact every department in some way [9]. This will require more instructors create on-line courses. Other innovations in instructional strategies are also widely impacting engineering educators [2] including peer instruction, flipped classrooms, problem-based learning, just-in-time teaching, and a variety of active learning strategies. Implementing any of these strategies requires changes to existing courses. Sometimes an educator is so familiar with the current course organization that it becomes a stumbling block for visualizing alternative options.

When anticipating change it is valuable to see how existing learning materials can be organized and used in new ways. The purpose of the ENABLE project is to provide assistance in making informed changes. ENABLE is not an acronym, rather a name that reflects the purpose to enable the implementation of quality educational strategies. The two major contributions of the current ENABLE system are that it:

- gathers information about the existing course and creates a graphical representation of the relations between the learning items, and

Fig. 1. CS0, Foundations of Computer Science Original Course Organization (upper). CS0, Initial Course Graph Relations (middle). CS0, Transformed Course Organization (lower).

- uses text analysis and graph transformation techniques to present alternative arrangements of the learning items.

As an example, consider the data from a sample CS0 course, Foundations of Computer Science, taught at Utah State University. The information about the learning items for this course was gathered from Canvas (a standard learning management system) and a graph was produced representing the current organization of the course; see Figure 1 (upper). This shows all the learning items for the course laid out in order across the days of the semester. Figure 1 (middle) shows the initial course graph constructed directly from the learning materials, and visually exhibiting the relations of interest: *precedes*, *occurs in*, and *includes*. The orange nodes (small, no fill color) represent the learning items. The orange edges between the learning item nodes are the *precedes* relations. The green nodes (larger with solid fill color) represent the topics. The green edges go between the topic nodes and the learning item nodes and represent the *occurs in* relations. The unit relations are expressed visually by locating nodes *included* in a unit near the same vertical location. Figure 1 (lower) shows the class material after text analysis and graph transformation by the ENABLE system. Note that this is one possible reorganization of the course. In

Fig. 2. Close up of small section of graph from Figure 1 (middle).

this transformation the learning items are organized by topic. Only the topically related *precedes* relations are included which allows a more clear separation of learning items by topic. The *occurs in* relations are all represented. In this particular transformation *includes* relations are not expressed. Due to the size of these graphs it is difficult to see the details clearly in this small of an image but the changes are significant enough that you get a sense of the differences the transformations make. Figure 2 shows a small section of the graph and allows the details to be more visible. This image shows a single topic node (solid circle) and three learning items (circles with no fill color). The learning item to the far right is an exam and the relations coming into this exam consist of four *occurs in* relations and three *precedes* relations. This is an ideal situation to apply the split exams transform that is discussed in section IV, Transforming the Graph.

II. DISCOVERY OF RELATIONS IN COURSE MATERIAL

Many types of relations exist between the learning items, but here we focus on three basic ones: temporal, topical, and unit coherence. These describe the chronological order, similarity of topics, and presentation organization of the learning items, respectively.

A. Identifying Temporal Relations

Temporal relations express the relation in time between learning items. The word *precedes* is used to express this relation. A learning item (Item A) *precedes* another learning item (Item B) when the due date of Item A is before the due date of Item B. These relations are transitive such that if Item A precedes Item B and Item B precedes Item C, then Item A precedes Item C. When all these relations are included on a directed graph the learning item at location k in the sequence has $k - 1$ in-edges and $n - k$ out-edges, where n is the number of learning items. These graphs are too cluttered to be informative. See Figure 3 (upper).

A simpler view of the temporal relations displays only the *precedes* relations that come immediately before a given node. This graph displays an edge from a node to the node it immediately precedes in time. This reduces the number of edges to $n-1$ and makes a much more readable graph. Since these relations are transitive, no connection is lost.

Fig. 3. Detailed Graph of *precedes* Relations (upper). Graph of immediately *precedes* Relation (lower).

See Figure 3 (lower). These figures are the graphs produced for the CS0 course.

The meaning of the *precedes* relation is limited. Learning items connected in this way are not necessarily related by topic or grouped in the same unit. Note that *precedes* does not mean it is a prerequisite. This relation expresses nothing more than how learning items are laid out in time in the original course.

By itself, the temporal relation seems trivial, and yet it is the predominant relation presented to students. An educator who has designed and implemented a course is aware of other relations between the learning items such as how they are grouped together to create a unit of learning, how they are related by a single topic or a group of topics, and prerequisite recommendations. Although the educator may consider these other relations more significant, the learning management systems currently available use the temporal relation as the dominant organizational aspect when presenting learning materials. Even when the module tool is used in Canvas to group learning items together into units, the student view presents learning items in a linear format based solely on temporal relations in the assignments page, the gradebook, and the syllabus.

When combined with topical and unit relations the temporal relations add some information. For example, if there are two assignments that cover the same topic and one precedes the other it is likely that there is a non-commutative relation between the two learning items and it is important that the first is completed before the other.

Not all items in Canvas have due dates. In the sample CS0 course, 8 out of 49 learning items do not have due dates associated with them. These undated learning items include lecture notes, videos, and frequently asked questions. It is likely these items are informational materials that are most beneficial when preceding other items in the same unit or other items of the same topic. As topics extend across a larger time period than units, associating the undated learning items with other items in the unit is preferred. These learning items are dated two days before the first dated item in their unit.

B. Topical Relations

To identify the topical relations the text of each learning item is gathered. Canvas provides a title and a text description of each learning item. These become the basis of the text. This text is analyzed to see if there is a link to a file. Canvas has a specific way of referencing files that have been uploaded making it possible to use text parsing and regular expressions to identify these references. Once a filename is found, the file extension is considered. Currently ENABLE adds .txt and .pdf files to the text description. Pdf files are converted to text before being added. Canvas has a category of items identified as quizzes. These contain questions in addition to the text description. For these types of learning items, the questions are added to the text description.

ENABLE uses a .txt file to store a series of topic lists. These lists contain topic words, word groups, and variations. Each line in the file represents a single topic. Individual topic variations are separated by a comma. The original list of topics for the sample CS0 course includes:

- <content>
- <html, structure>
- <attribute, attributes>
- <tag, tags>
- <element, elements>
- <publishing, host, publish, published>
- <careers, career, careers in cs, cs careers>
- <darpa>
- <history, cs history>
- <css, style>
- <hardware, system>
- <javascript, script>
- <functions, function>
- <textboxes, textbox>
- <using the web, use the web>.

The use of a list of topic variations allows different versions of the same word such as **publishing**, **publish**, and **published** to be counted as a single topic. Stemming algorithms [11] may be used to accomplish this same grouping. However, this list of topic variations allows entirely different words to be associated with the same topic. For example, the word **host** is included in the list with **publishing**. This allows the instructor a great deal of flexibility in associating a variety of words or word phrases with a single topic.

Using these lists of topic words, a term frequency vector is created for each learning item document. Term frequency (*tf*) is a count of how many times a term occurs in the learning item document [7]. The document in this case is the description of the learning item. This description includes any text available in Canvas or uploaded by the instructor. The frequency count of terms found in a topic list are combined to produce a single *tf* count for each topic.

When computing *tf* for all the terms in a corpus of documents, this process produces high-dimensional, sparse vectors [8]. Techniques such as the application of singular value decomposition (SVD) to a topic similarity matrix (i.e., spectral graph analysis) may allow the reduction of

dimension to make computationally intensive text analysis more efficient [3]. In the CS0 example here, the limited number of specific terms found in the topic lists produced *tf* vectors for which no dimensional reduction was possible.

This raw count of how many times a term occurs in a document can be more informative if it is weighted. The weighting approach used by ENABLE is *tf-idf*. *tf-idf* starts with the *tf* and then multiplies it by the inverse of the document frequency. The document frequency (*df*) of a term is the count of how many of the documents in the corpus contain that specific term. If the *df* is high, the term is very common so the fact that it shows up in a document is not as significant as a term that is less common. When the *df* is low, the occurrence of the term in a document is more significant. By multiplying *tf* by the inverse document frequency (*idf*) the resulting value results from a weighting based on the relative frequency of the term in the corpus. The ENABLE system computes *tf-idf* using log weighting of the *tf* count and log inverse frequency weighting on the document counts [7].

$$tfidf_{t,d} = (1 + \log(tf_{t,d})) \log\left(\frac{N}{df_t}\right)$$

A Pearson correlation was done between the *tf-idf* values of the topics. For each correlation that was greater than 0.8, the topics were considered for combining. In the sample CS0 course there was a correlation between the *HTML*, *attribute*, *element*, and *tag* topic lists. Combining these was obvious once the correlation pointed them out. These are all parts of the HTML language. The other topics that were highly correlated were *JavaScript*, *functions*, and *textboxes*. Although functions is a topic that exists outside of JavaScript, in the context of this course, functions are only discussed or used in JavaScript. This correlation made the instructor aware that their broader view of the computer science curriculum was reflected in this separation of topics and would best be adapted to fit the content of this specific course. This provided the instructor a fresh perspective informed by feedback from ENABLE.

This illustrates one of the many benefits of gaining another perspective when considering changes to current courses. This process of identifying correlations between topics provided new insights into possible changes to the topic lists. These insights were not recognized when the original topic lists were made. This process led to the reduction of topics from the original fifteen to the following ten:

- <content>
- <html, structure, attribute, attributes, element, elements, tag, tags>
- <publishing, host, publish, published>
- <careers, career, careers in cs,cs careers>
- <darpa>
- <history, cs history>
- <css, style>
- <hardware, system>
- <javascript, script, functions, function, textboxes, textbox>
- <using the web, use the web>.

C. Unit Relations

Units are a set of learning items that are grouped together. Unit relations come directly from the modules tool in Canvas. This tool allows an instructor to group learning items into units. Many different groupings are used. Some instructors group the material based on a textbook such as a unit for each chapter. Others use it to organize temporally such as one unit for each week in the course. Another approach is to organize by specific topic coverage. Current grouping in these modules reflects groupings that are in some way meaningful to the instructor. The unit grouping of learning items is used as the y-value in Figure 1 (upper and middle) and Figure 3. This visually shows how learning items are related by unit.

III. CREATING THE INITIAL GRAPH

A. Temporal Relations

When graphing the temporal relations the *precedes* relation is used. Nodes represent learning items and edges are the relations between them. This is a directed graph with the arrow of the edge on the node with the later due date, expressing that one node precedes the other node in time. To make the graphs more readable, these edges are labeled with *P*.

B. Topical Relations

To graph the topical relations, a bipartite graph is used with one set of nodes representing the topics and the other set of nodes representing the learning items. This is a directed graph with the arrow of the edge on the learning item nodes expressing that the topic *occurs in* the learning item. For readability, these edges are labeled *OI*.

C. Unit Relations

The unit relations represent a grouping of the current organization. This is represented as a bipartite graph with one set of nodes representing the units and the other set of nodes representing the learning items. This is a directed graph with the arrow of the edge on the learning item nodes expressing that the unit *includes* the learning item.

D. Combining the Graphs

The temporal and topical relations go well together since the temporal relations are entirely in the set of learning items. This combined graph includes all the topic nodes and learning item nodes with both the *precedes* and the *occurs in* edges included.

The unit relations are loosely expressed by using the unit value to compute the vertical location of the nodes in the starting graph. This provides a visual representation of how the learning items are grouped into units but does not include any edges that connect items in a unit. Figure 1 (middle) shows the graph structure produced for the learning materials in sample CS0 course when these relations are combined.

IV. TRANSFORMING THE GRAPH

Because ENABLE identifies alternative course structures that maintain the relations between learning items it becomes necessary to transform the graph while still keeping the meaningful relations intact. Graph grammars and graph transformation systems provide a means for doing this. There is much research and many successful applications based on the research in this area [4]. One of the application areas of graph transformation systems is model transformations. This area of model transformation has become important to the field of software engineering [1]. The models used in software engineering have enough similarities to the graphical representation of learning materials to allow model transformation as the graph transformation technique used by ENABLE. These similarities include typed nodes, node attributes, and edges that represent different types of relations.

For graph transformation, ENABLE uses AGG, a development environment for attributed graph transformation [6]. It is based on an algebraic approach to graph transformations. The implementation of this approach closely follows the formal, theoretical foundation of algebraic graph transformation and so provides validation support [5] and sound behavior concerning graph transformation [10]. AGG has non-deterministic rule and match selection but provides control of this with rule layers.

A. Defining Semantic Rules

Once the initial course graph is available, it becomes possible to begin a conversion process from a linear (chronological) style class organization to a more non-deterministic, multi-path organization of the learning items more suitable to online delivery. It is now necessary to determine the types of desirable transforms and their meanings. We begin with the consideration of how to eliminate unnecessary *precedes* relations.

We define a restraint as an unnecessary constraint between two items. Thus, restraints are removed in order to open up more possibilities for the relations between learning items. When removing restraints it is important to maintain the integrity of the course representation.

1) *T1: Topic-based precedes Elimination Rule:* The major restraint is the *precedes* relation. It restricts any change in the order of learning items. However, many of the *precedes* relations are not necessary and can be removed without changing the necessary relations. The first step is to remove unnecessary *precedes* relations. As discussed earlier, *precedes* relations by themselves have little meaning. The fact that one learning item comes before another provides only limited information. Now that the temporal and topical relations have been combined into a single graph the system can identify *precedes* relations that have no topical connections and can be removed.

If *A precedes B* and *B precedes C* and there are no common topics that occur in both *A* and *B*, the *precedes* relation from *A* to *B* can be removed. When removing this relation it is important to keep the relation that *A precedes C* and *B precedes C*. Note, however, that the net number of

Fig. 4. Graph Transformation to Eliminate Unnecessary *precedes*.

Fig. 5. Graph Transformation to Split Unrelated Exam Elements.

precedes relations is reduced by 1 as there was an implied $P(A,C)$ before the application of $T1$.

More formally, this can be stated as:

$$\text{if } P(A,B) \wedge P(B,C) \wedge \neg T \ni (OI(T,A) \wedge OI(T,B)) \\ \text{then remove } P(A,B) \text{ and add } P(A,C)$$

We call this the *Topic-based precedes Breaking rule (T1)*. Figure 4 shows a graphical representation of this transform.

2) *T2: Topic-based Exam Splitting Rule*: One result of building course organization based on temporal relations is illustrated by exams. Commonly, an exam is written to assess the material that has been covered over a specific period of time. For example, since the last exam or since the beginning of the semester. This time-based connection is not required for assessment. Therefore it is possible to divide the material assessed in an exam by topic. Separating the temporal grouping inherent in exams provides additional possibilities for change. The split exams rule is applied after the remove *precedes* rule has been applied. Enforcing this rule application order prevents any exams being split when preceding learning items are topically related. AGG allows the user to specify which rule layer a specific rule is in. It enforces rule ordering by applying all the rules in one layer before applying rules in the next layer. This, then, is another example of a restraint: when exams tie learning items together that are not related in any other way.

If A *precedes* Exam 1 and B *precedes* Exam 1 and there are no common topics that occur in both A and B , then Exam 1 can be split into two exams, Exam 1A and Exam 1B such that A *precedes* Exam 1A and B *precedes* Exam 1B, and A and B are independent of Exam 1B and Exam 1A, respectively. See Figure 5. This transform must be applied after $T1$.

Fig. 6. Learning Item Split Due to Too Much Material.

Fig. 7. Pressure Reducing Exam Split Transform.

Currently ENABLE applies both these semantic rules using graph transformations. There are additional meaningful transformations to be explored in the future work of this project, but we give them here to show the power of the approach.

3) *T3: Material Splitting Transform*: It may be determined from analysis of student success on homework problems and exams that there is too much material in some learning items. This leads to the transform shown in Figure 6.

4) *T4: Reduced Pressure Splitting Transform*: Another way to reduce the cognitive load for an exam is to split an exam temporally. This leads to the transform shown in Figure 7.

5) *T5: Change of Topic Detection Transform*: In a standard classroom setting, a sequence of material on one subject will eventually give way to a change of topic and a new set of materials. We believe that this can be detected in the initial course graph due to the overlap pattern of related topics among the learning items. For example, a learning item that sits at the end of a sequence of topic-related items, and at the start of a distinct topic-related set of items, is most likely a transition item. This leads to the transform shown in Figure 8.

B. Applying Semantic Rules to the Graph

In AGG, transformations are defined by a rule with three parts (as described in the transformations given above):

- LHS (Left Hand Side): specify the pattern to find in the graph.
- NAC (Negative Application Condition): identify any restrictions to be imposed on the transformation. This part shows results that are not allowed. If the transformation would produce this result, the transformation is not applied.

Fig. 8. Topic Change Item Split Transform.

- RHS (Right Hand Side): demonstrate what the pattern in the graph is to be after the transformation is applied.

These transformations embody the semantic rules listed above.

C. Applying T1: Topic-based precedes Elimination Rule

After the topic-based *precedes* elimination rule was first applied to the sample CS0 course, the instructor reviewed the resulting graph. Several unexpected findings were encountered.

1) *Learning Items with No Topical Relations*: There were five learning items that had no topic relations. Upon examination, two of the items were truly not related to any topic, an assignment in which students were to submit which team they wanted to be on, and the teacher evaluation. Both items were left unchanged with no topical relations.

The other three clearly were related to a specific topic but none of the terms in the topic list were found in the description. This could be remedied by using ENABLE's file upload tool that provides a way to add additional text to the description of a learning item. This also caused the instructor to consider the value of more frequently using the topic terms explicitly in the textual presentation of the learning items.

2) *Learning Items with Meaningless Topical Relations*: There were six topical relations that connected learning items to topics mistakenly. In five of these learning items, the topic words occurred but were being used in a more general way. For example, one of the topics is **content**. This is specifically related to selecting content when creating a web site. However, the word **content** was used in its more general way in three of the learning items. In the other case the instructions included a restriction to not use JavaScript which was a future topic. These relations were manually removed.

D. Applying T2: Topic-based Exam Splitting Rule

The first time the topic-based exam splitting rule was applied there were fewer exam splits than expected. Upon closer review it was discovered that the exam asked questions about a topic without using a topic word explicitly. This seemed pedagogically sound. For example, one question about computer science history was "Why was the invention of the integrated circuit important?" Although this question does not use the term **history**, it is clearly assessing the student's familiarity with the computer science history covered in the course. These missing meaningful relations can

Fig. 9. Course Graph After the Application of Transforms T1 and T2.

be included by adding text that includes the missing topic words to the description using ENABLE's file upload tool. This adds the text to the ENABLE system without altering the exam itself.

There was one case where the review of the exam exposed the possibility of adding a word to the topic list. The word **occupation** was used in the exam that covered careers in computer science. This word was also used in other learning items about the topic. It was determined that adding this word to the topic list would add clarity. Adding the term to the topic list resolved this missing relation.

E. The Resulting Graph

Figure 9 shows the result of the application of the transforms T1 and T2. The revised graph affords much greater leeway in the organization, presentation, and order of selection of material for the instructor and the student.

V. ALTERNATIVE ARRANGEMENTS

Once the T1 and T2 transforms have been applied, many of the original organizational limitations have been removed. This opens the way for alternative arrangements of the learning items.

A. Separating by Topics

The graph in Figure 10 shows the learning items organized by topic. This arrangement separates the learning items in several distinct topic groups. The large group in the middle reflects the interrelated nature of several topics. This provides a visualization of how topics are related and how they might be rearranged. There is no visualization of *includes* relations.

B. Adding Unit Clustering

The graph in Figure 11 is clustered by units. The similarity between the graph arranged by topic and this one indicates that the units in the original organization grouped learning items into units by topic. Order of the units is not restricted. There are *precedes* relations between the the five units in center of the graph. In the first and second grouping there are edges going in both directions.

C. Informing Change

There is information in these graphs that can be visually retrieved. Consider the following:

- How many topics occur in a specific assignment? This question can be answered by looking at how many *topic* edges come into an assignment. In the sample course, only one topic *occurs in* each of HW3, HW4, and HW7

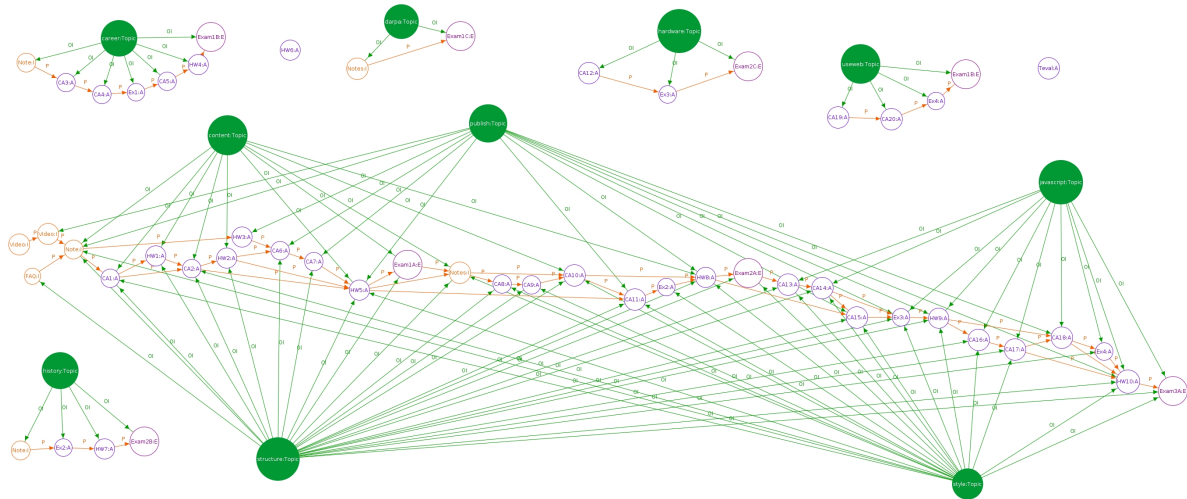

Fig. 10. Course Graph Arranging Learning Items by Topic

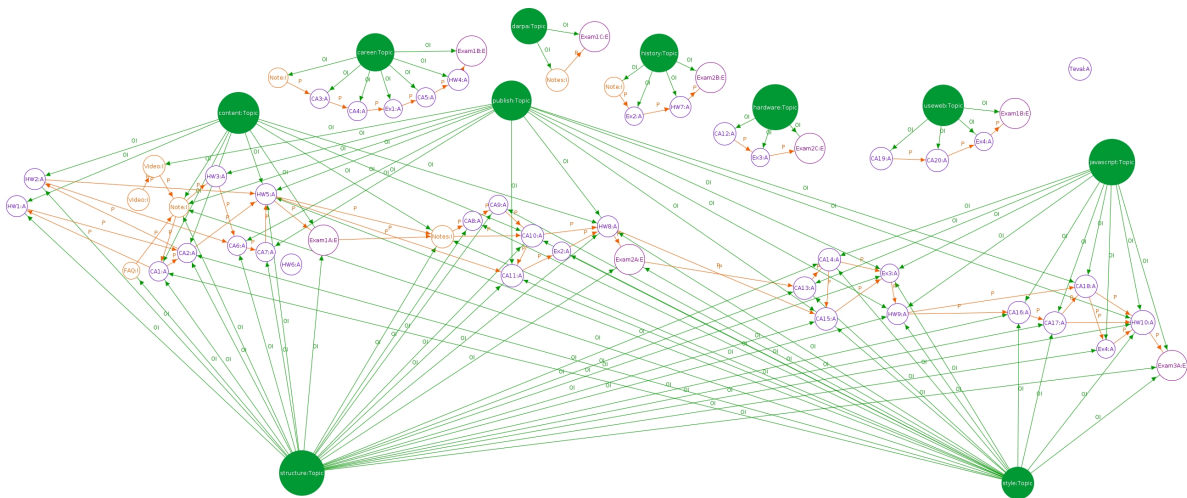

Fig. 11. Course Graph Arranging Learning Items with Clustering by Units.

while four topics *occur in* in each of HW5, HW8, HW9, and HW10.

- What units can be rearranged without interfering with *precedes* relations? The answer to this question can be found by looking at the *precedes* edges between unit clusters. For those units with no *precedes* edges between them the order can be changed without disrupting the temporal order restrictions expressed by these edges.

Having access to this kind of visual information has the potential to provide meaningful insights very quickly.

VI. CONCLUSIONS AND FUTURE WORK

We have developed an automated system that constructs an initial course organization graph based on information provided by Canvas, a standard Learning Management System (LMS). A variety of types of material are represented in the nodes of the graph and initially only their chronology is known. A detailed analysis of the materials based on the text

contained within each learning item allows a more informed representation which captures the topic relations among the items. A set of graph transformations is then defined which convert the (basically) linear structure of the course to a graph structure which makes evident the dependencies and independencies of the learning items. A specific test case, CS0, was transformed in this way to demonstrate the power of the method.

A. Validation of Results

The system is able to exactly reproduce the temporal *precedes* relations of all dated learning items. For those learning items that do not have a due date, a date is used that is related to the earliest date in the unit in which the undated item is included. It is also possible to extract and identify the Unit or *includes* relations in all cases where the modules tool in Canvas is used. No testing was done with courses that did not use the modules tool. It is anticipated

that input from the instructor would be required to identify unit relations if they are not identified in the LMS. Topical *occurs in* relations are produced from the text. In the example course the automated assignment of *occurs in* relations was correct in 472 of the 490 topic to learning item combinations. In eight cases none of the topic word variations was found in the learning item but they were in fact related to the topic. For nine combinations a topic word was encountered in the description but the learning item was not related to the topic. In one case the topic word was used to instruct the students to not use the topic on this specific assignment. These discrepancies were corrected with input from the instructor. Involving the instructor in the analysis process is one of the strengths of the ENABLE system. It not only improves the validity of the results but also improves the possibility of increasing the instructor's potential for understanding the possibilities for change.

Currently ENABLE produces eight different course maps based on the relations between learning items. Each of these graphs can be rearranged by the instructor to produce many organizations. The course maps have been designed to minimize the congestion of learning items and relations. The system does not, however, guarantee a minimum number of edge crossings. There is congestion of undated learning items as they are all positioned temporally at the beginning of a unit. This is a problem in one of the 13 units in the sample course. Another congested area is produced when exams are split. The due date and unit assignments are the same for each of the split exams. This locates them close together. These congested areas are easy to resolve by dragging the nodes to new locations. When the nodes are moved the connecting edges automatically move with them keeping the visual representation of relations intact.

B. Informing Change

This process of analysis and transformation provides insight for the instructor about a variety of ways the course materials can be organized. As the instructor sees existing course materials presented in a variety of ways their perception of the possibilities for making innovative changes like using peer instruction, flipping the classroom, adding blended learning, implementing more active learning, etc. is increased. This increase in possibilities facilitates change.

Information about the existing course is provided by each step in this process. The ENABLE system gathers existing information from what is available about the course in the LMS and represents it in a visual way. This sheds light on what students currently have available through their access to the learning materials in the LMS. The most significant finding was how entrenched the *precedes* relation is in the presentation of course material. This relation often adds little meaning to how learning items are related and yet it is the predominant organization strategy used when displaying information to students. When comparing the visual representation of that organization, see Figure 1 (upper) to the alternative organizations produced by ENABLE, see Figures 10 and 11, it is clear that there is significant room

Fig. 12. *precedes* vs. *prerequisite* Relations.

for improvement in how the educational community presents learning material to students. Although this first phase was designed to inform instructors about the many organization options available when making changes, the feeling of the authors is that the effort to develop a graphical, non-linear representation of a course could have significant impact on how the students perceive and interact with course materials.

C. Future Work

During the course of this work, we determined that even though the *precedes* relations have been restricted to those that have common topic relations, they still express limited information. We believe that a more informative relation is the *prerequisite* relation that expresses a recommendation that one learning item be completed before another learning item. The *precedes* relation limits the connections between learning items and does not allow flexibility in ordering. It is easy to identify cases when this representation is too limited to express how the learning items are actually related. For example, there may be several learning items that are designed to prepare a student to complete a particular homework assignment such as a lecture, a class activity, a video, and a reading assignment. Using *precedes* relations, a graphical representation would look similar to that shown in Figure 12. Representing it this way indicates a specific ordering between the learning items when in fact this ordering is not required.

In the future we hope to transform learning outcomes by (1) facilitating deep student learning in science and engineering by providing the student feedback resulting from behavior models based on monitoring paths taken through the online course graph and linking that to performance in the class; and (2) providing effective tools for the instructor to monitor the effectiveness of the course material and its organization. The innovative use of a Bayesian inference network, a technology currently applied in many intelligent systems, will be developed and applied in a real-world learning environment to create a predictive computational model for individual learners and educators. By identifying operational student learning processes it may be possible to detect how knowledge gaps are a consequence of less successful learning strategies and tactics. Developing learning strategies can be challenging, thus an effective learning environment to support this must be designed and developed. As a next step we propose to integrate a Bayesian inference network within the ENABLE system to provide synthesized data about learners' activities, behaviors, and performance.

Abstract— Relevance of a concept being taught to the real world is believed to contribute to an increase in the intrinsic motivation and engagement of a learner. Such relevance is often found lacking in learning material such as textbooks. Practical issues and problems one could face while learning or implementing new concepts are a means of establishing such relevance. In this paper, we propose a method to automatically augment learning material with practical questions about the concept being learnt. We use questions and answers from StackOverflow, a leading social Questions and Answers (Q&A) website to augment an electronic textbook interface, thus connecting the concepts being taught to the real world. For achieving this automatically, we first mine the textbook content to locate words and phrases which are likely to be the most important concepts on each page of the textbook. We then select only those words and phrases which appear as ‘tags’ in StackOverflow, typically defined by users while asking and answering questions. Using permutations of these tags as queries, we query the StackOverflow database to obtain relevant questions and answers to augment any given page. We present an interface to augment textbooks with such questions using the aforementioned method. We also present the results of a student survey examining the effectiveness of the augmentation in establishing relevance to their learning.

Keywords— Computer Science Education; e-learning; Relevance; Questions; StackOverflow; Augmentation

I. INTRODUCTION

Keller [1] defined *relevance* as a learner perception of whether the course instruction and content satisfies personal needs and/or career goals of learners. Studies show that establishing the relevance of what is being learnt to learners’ personal goals and experiences increases learner motivation [2-4]. One of the ten principles of good teaching derived by Kember and McNaught [5] after a study of 62 award-winning teachers was establishing relevance of the learning content to the learner. Another study by Ballantyne et al. [6] on 44 award-winning teachers reported that exemplary teachers often linked theory with practice in order to establish relevance. A good teacher can often make an important contribution in establishing relevance thereby increasing learner motivation. However, students often study on their own and may not get ready help from teachers. Also, not all teachers are good at establishing relevance of the learning material to the learner’s world.

Even though computer science has a pervasive presence in our lives with its diverse applications, computer science textbooks often primarily focus on its theoretical aspects. Large portions of computer science textbooks are dedicated to teaching theory and mathematical foundations of underlying concepts. Practical examples do appear, but they typically do not appear alongside the theory being taught. Due to this, a learner may miss the relevance of what is being learnt while learning from such textbooks. Kember et al. [7] found that a common cause reported by learners for lack of motivation was “purely abstract teaching, confined to theory”. As a result, a learner can get demotivated from such lack of relevance in learning material used for self-study.

Can relevance be established while learning from such material? Agrawal et al. [8] proposed augmentation of textbooks with content obtained from the internet to increase the effectiveness of textbooks. Gandhi et al. [9] proposed a design for augmentation of learning material such as textbooks and e-books in order to aid personalization. They mined content from the internet to populate ‘layers’ of relevant information for the concepts being taught. In their proposed electronic book interface, they placed such information besides the learning content so that it could be accessed as required by the learner.

Starkey [10] proposed integrating radiographic medical images when radiology students learnt pathology using preserved specimen. The augmentation helped establish the relevance of the pathology concepts to learners’ future vocation and led to a “positive impact on the learning experience”. In case of computer science, such relevance can be established through exposing undergraduate learners to real-life situations encountered by programmers, software developers and graduate students, which are the roles that they are likely to take up in future. We believe that such situations are often represented as questions and answers on social Questions and Answers (Q&A) websites such as StackOverflow [11].

In this paper, we propose ‘augmenting’ learning material such as electronic textbooks with practical questions and answers posed by real users in order to establish relevance of the learning material to real life. In specific, we use questions and answers posted at a popular social Q&A website called StackOverflow.

In specific, our contributions are:

- 1) We propose augmenting learning material such as e-textbooks with Q&A to establish relevance while learning,
- 2) We propose algorithms to automatically retrieve and recommend Q&A most appropriate to a given page of learning material, and
- 3) We present the results of a survey conducted with 48 undergraduate students to assess the effectiveness of the augmentation in establishing relevance.

II. STACKOVERFLOW AS A SOURCE OF PRACTICAL KNOWLEDGE

StackOverflow [11] is a free social Q&A for professional and enthusiast programmers with over 9 million questions asked and / or answered by over 4 million users. Users post questions about programming concepts on StackOverflow and other users answer these questions. The answers deemed best by many users get more number of votes thus automatically filtering bad quality answers or spam. Furthermore, users gain a reputation score as they consistently answer questions thus increasing the credibility of their answers [12]. Typical questions are related to practical application of programming and technology such as technology implementation, how-to procedures, concept explanation, code debugging and troubleshooting, review, and advice [13]. Users typically tag the questions with the concepts they are related to, thus allowing easy search [14]. The site receives over 6 million views per day from software professionals and students all over the world [15]. In fact, John Bishke, the education entrepreneur, termed sites such as StackOverflow as the “new Computer Science Departments”, where people went to learn and employers went to find more about potential employees [16].

Surakka [17] reported that subjects such as data structures, algorithms, procedural programming, object-oriented programming, software architecture and software engineering were rated to be the most important computer science skills by combining multiple studies with software developers, graduate students and teachers. StackOverflow has an abundance of Q&A related to these concepts. For example, Table I shows the number of questions in StackOverflow tagged using main concepts in data structures, an important skill for computer programmers [18].

StackOverflow has been used as a source of knowledge for assisting experienced as well as novice programmers. In two separate studies, Ponzanelli et al. [19] and Bacchelli et al. [20] proposed augmenting an integrated development environment (IDE) typically used for programming with StackOverflow

TABLE I. NUMBER OF QUESTIONS IN STACKOVERFLOW FOR IMPORTANT CONCEPTS IN DATA STRUCTURES

Concept	Number of questions tagged
Arrays	13,000+
Linked Lists	7,300+
Trees	7,700+
Stacks	4,900+
Queue	4,500+

Q&A. This allowed programmers to instantly view Q&A related to the program they were writing. Pai et al. [21] proposed automatically recommending StackOverflow expert users as mentors to novice programmers.

In this paper, we use the Q&A in StackOverflow as a means of relating the concept being learnt by learners to questions posed to real practitioners thereby establishing its relevance.

III. AUGMENTATION OF LEARNING MATERIAL WITH Q&A

We used the concept of textbook augmentation described by Gandhi et al. [9] to establish relevance during self-study. In order to demonstrate the concept, we used 14 pages describing 3 common topics chosen from 3 different textbooks as the base learning material used for augmentation. The topics were *multithreading* (a basic programming concept) [22], *database normalization* (a practical database concept) [23] and *Dijkstra's algorithm* (a theoretical concept) [24]. As a test prototype, we provided a web interface to the PDF versions of these pages with navigation controls. On the right side of the page, we provided a Q&A pane with links to questions from StackOverflow for the concepts being taught on the page. The prototype interface was web-based [25] and could be accessed

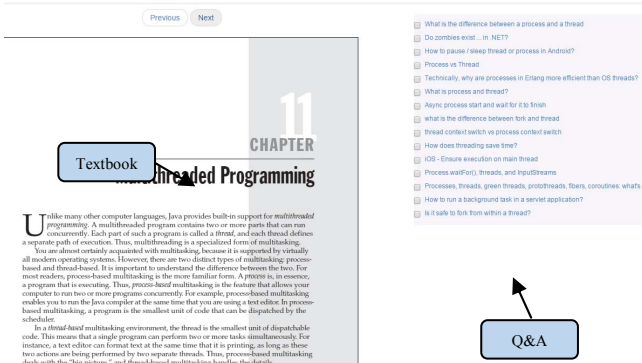

Fig. 1. Interface for augmenting textbooks with Q&A

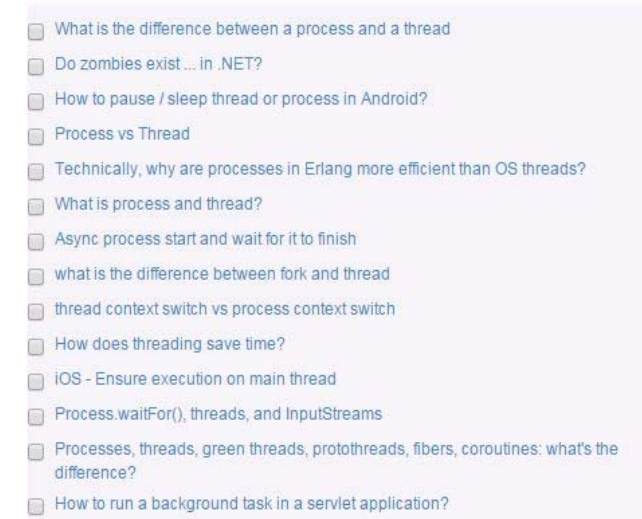

Fig. 2. Details of the Q&A pane automatically recommended for the topic *multithreading*

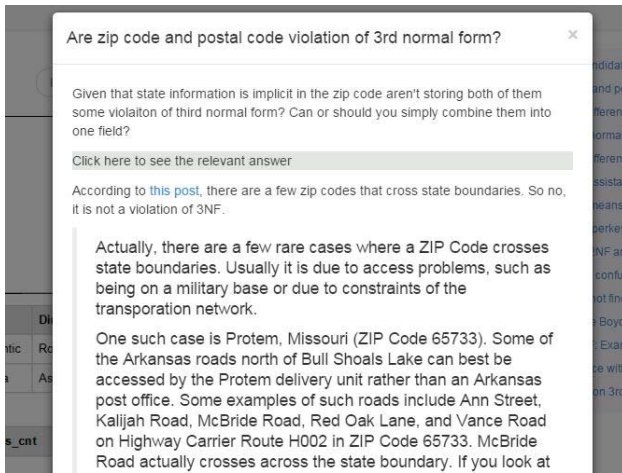

Fig. 3. Details of the Q&A popup window

in a browser as shown in Fig. 1. The details of the Q&A pane are shown in Fig. 2. Clicking on a question opened a popup window with the entire question. The answer was hidden to begin with for arousing learner curiosity. Clicking on the bar below the question revealed the top answer for that question in StackOverflow as shown in Fig. 3. The learner could also vote for a question she found relevant by clicking on the *like* icon.

IV. AUTOMATICALLY RECOMMENDING Q&A

Though we described the interface using limited learning material consisting of 14 pages, we devised an algorithm to automatically recommend Q&A and augment every page of any given computer science learning material available as electronic text. The algorithm consisted of the following two steps:

A. Find important concepts from each page

Since different learning materials can have different formats, we could not rely on formatting features such as headings and emphasis to extract keywords. Instead, we used a natural language processing approach prescribed by Liu et al. [26] for finding important phrases from the learning material.

As a first step, we extracted the text from the PDF files using PDFBox [27]. Then, we built a word graph for the given learning material. For this, we selected all unique single words and removed the most commonly occurring words such as *the*, *and*, *a*, *for* (also known as *stop-words*). We found what part of speech each word was using the Stanford part-of-speech tagger [28] and selected only adjectives and nouns. We created the word graph by connecting a pair of words with an edge if they co-occurred in a sentence. We then modeled the topics in the learning material using a technique called Latent Dirichlet Allocation (LDA) [29]. LDA represents documents as mixtures of topics and predicts the probability of words being associated with a particular topic. Using LDA by considering each page of the learning material as a document, we found the probability of a topic occurring in a document if a certain word occurred in the document.

Then using the word graph and the topic probabilities, we computed a Topical PageRank (TPR) score for each word, which indicated the importance of each word to different topics. This formulation used the PageRank algorithm [30] proposed by Page et al. which ranks a vertex in a graph higher if there are other vertices connecting to it. We computed the TPR by running PageRank on the word graph for each topic separately, while providing a bias towards the words contained in that topic.

The above exercise gave us a list of keywords (such as *multithreading* and *tree*) and their TRP score, but we also needed to find keyphrases containing more than one word (such as *binary tree* and *shortest path*). For finding such keyphrases, we adopted the approach prescribed by Agrawal et al. [8]. Using this, we first split the learning material in sentences and tagged every word with its part of speech. We used the following regular expression patterns to extract keyphrases (Note that *JJ* stands for adjective, *NN* for noun and *IN* for preposition):

1. $\{<JJ.*>*<NN.>+<IN><JJ.*>*<NN.>\}$
e.g. *depth of tree*
2. $\{<JJ.*>*<NN.*>+\}$
e.g. *random sampling, linked list*
3. $\{<NN.*>+\}$
e.g. *quicksort algorithm*

We then added the TPR scores for each keyword contained in each keyphrase to assign a total score to the keyphrase.

B. Query StackOverflow using these concepts to get Q&A for recommendation

First we created a search index for the entire StackOverflow repository containing 27 GB of data made available by StackOverflow [31]. We did not use the web service provided by StackOverflow for querying to provide flexibility, increase performance and avoid web traffic.

For each page of the learning material, we selected the top 10 keywords and keyphrases according to their TPR score. We then formulated queries using a mathematical combination of at most 6 words and at least 2 words from the top 10 list. This resulted in over 800 queries per page. Though only a few of these combinations yielded search results, they covered all possible combinations of keywords thus increasing the chances of retrieving appropriate Q&A. We combined the search results obtained for all the queries to obtain a unique set of Q&A as candidates for augmentation.

StackOverflow provides a mechanism for voting Q&A in positive (*upvote*) and negative (*downvote*) directions. The difference in the upvotes and downvotes is often regarded as the score for the question [32]. We used the same metric to rank the candidate Q&A and selected the top 15 questions for augmenting the page.

V. OBSERVATIONS ON RECOMMENDED Q&A

We found that for the aforementioned test learning material of 14 pages, 111 Q&A were automatically recommended by our algorithm. No related questions were found for 4 of the pages. This was because these pages either contained examples or lacked keywords important for the concept being taught. We manually analyzed the recommended Q&A and made the following observations:

1) *Questions catering to Bloom's taxonomy*: We found that the questions catered to lower-order as well as higher-order thinking skills prescribed by the revised Bloom's taxonomy [33]. For example, recommended questions such as *what is the difference between a process and a thread*, *can trivial superkey be considered as candidate key* and *what data structures to use for Dijkstra's algorithm in Erlang* were related to lower-order thinking skills such as *understand* and *apply*. Recommended questions such as *is it safe to fork within a thread*, *finding highest normal form of a relation of database* and *how to optimize Dijkstra algorithm for a single shortest path between 2 nodes* were examples of higher-order thinking skills such as *analyze* and *evaluate*.

2) *Interesting questions*: We found some of the recommended questions to be interesting and unexpected. Example of these were *how waterproof is a Swiss cheese*, *are zip code and postal code violation of 3rd normal form* and *do zombies exist... in .NET*. We believe that such interesting content can be useful towards arousing curiosity and increasing engagement in learners.

3) *Questions useful for job interviews*: We found that some of the recommended questions were questions often asked in job interviews. Examples of these were *how to find the distance between two nodes using BFS* and *what is the difference between fork and thread*.

4) *High quality answers*: While we found a rich variety of questions, we also found high quality answers to most of the questions. In many cases, they were interesting as well as accurate. We believe that this quality of curation is largely a result of the StackOverflow voting mechanism being used by a large number of active users.

5) *Almost no unrelated questions*: We found only one question which was unrelated to the learning material. This indicated that our automated recommendation algorithm worked well on the given learning material without needing any manual curation.

VI. EXPERIMENTAL STUDY USING THE AUGMENTED INTERFACE

In order to examine the efficacy of the proposed interface in establishing relevance of the learning content using StackOverflow Q&A, we conducted a classroom experiment with 48 undergraduate (senior, junior and sophomore) students of computer science. We asked the students to spend 15 minutes in learning from the aforementioned 14-page learning material augmented with Q&A. We then asked them to fill out a survey consisting of 12 questions assessing *relevance* and *preference* on a 5-point Likert scale (1 – *Strongly disagree*, 2 –

Disagree, 3 – *Neutral*, 4 – *Agree*, 5 – *Strongly agree*). The questions assessing relevance consisted of 8 statements such as *Learning with such accompanying Q&A will help me in my job interviews* and *In future I am likely to face such questions while doing my job*. The questions assessing preference consisted of 3 statements such as *The accompanying Q&A made my learning more interesting* and *I will prefer learning with such accompanying Q&A*. The last question *When am I most likely to use such a learning interface with accompanying Q&A* allowed multiple selection from 7 learning situations such as *In class*, *Exam preparation* and *Job interview preparation*.

We also recorded the learner activity during the experiment by recording the time that they spent on each accessed question and questions flagged as relevant by them.

A. Results of the survey

We found that a reverse coded question from the preference assessment was misinterpreted by some respondents, and therefore we had to discard it. Also, we found that 3 respondents had given the same rating to every question. So we discarded their responses from further analysis thus considering 45 responses for further analysis.

We found acceptable consistency in responses for relevance (Cronbach $\alpha = 0.72$) as well as for preference (Cronbach $\alpha = 0.8$). Fig. 4 shows the mean of responses for all the survey questions. We further grouped the responses together into two

Fig. 4. Mean rating for survey questions for relevance (blue bars) and preference (dark blue bars)

Fig. 5. Percentage of respondents agreeing to Q&A augmentation being relevant (blue bars) and to them preferring such augmentation (dark blue bars)

TABLE II. SPEARMAN'S RHO CORRELATION AMONG RESPONSES⁺

	Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10
Q1										
Q2	0.48**									
Q3	0.45**	0.32								
Q4	0.32	0.26	0.11							
Q5	0.23	0.42*	0.33	0.36						
Q6	0.06	-0.05	0.23	0.11	0.07					
Q7	0.21	0.29	0.17	0.03	0.07	0.18				
Q8	0.09	0.30	0.23	0.07	0.17	0.06	0.42*			
Q9	0.35	0.24	0.26	0.32	0.29	0.13	0.23	0.18		
Q10	0.54**	0.23	0.44*	0.39*	0.47**	0.06	0.18	0.18	0.61**	

⁺ The *relevance* questions are related to – Q1: Examinations, Q2: Job interviews, Q3: Job, Q4: Past experience, Q5: Future work content, Q6: Level of knowledge, Q7: Outcome, Q8: Freedom to choose. The preference questions are related to – Q9: Interest, Q10: Preference.

** $p < 0.001$, * $p < 0.01$.

categories, viz., Agree (corresponding to Strongly agree and Agree responses) and Disagree (corresponding to Strongly disagree, Disagree and Neutral responses). We grouped Neutral under Disagree to account for a possible central tendency bias wherein respondents tend to pick the neutral option in case they leaned towards disagreement. Fig. 5 shows the percentage of respondents agreeing to the Q&A being of relevance to them as blue bars, and that agreeing to prefer augmentation of their learning interface with Q&A as dark blue bars. In summary, we reported that 79% percent respondent agreed to the interface being relevant to them and 76% respondents agreed to them preferring the augmented interface for self-studying.

Table II shows the Spearman's rho correlation among the responses. The statistically significant correlations are denoted by two stars ($p < 0.001$) and one star ($p < 0.01$). We found moderate correlations between preference and Q&A being relevant to examinations ($\rho = 0.54$, $p < 0.001$), to future job content ($\rho = 0.44$, $p < 0.01$), to past experience ($\rho = 0.39$, $p < 0.01$) and to future job expectations ($\rho = 0.47$, $p < 0.001$). We also found a statistically significant moderate correlation between the aggregated relevance response and the aggregated preference response ($\rho = 0.49$, $p < 0.001$).

B. Analysis of usage patterns

We analyzed the learner activity in terms of the time they spent on accessing Q&A on each page as well as the Q&A they

Fig. 6. Percentage of learning time spent by learners on accessing Q&A

TABLE III. TOP Q&A IN TERMS OF TIME SPENT BY STUDENTS

Question	Time, min	Bloom's skill type
What is the difference between a process and a thread	13.8	Understand
Process vs. Thread	8.6	Understand
Do zombies exist ... in .NET?	8.0	Analyze
How does threading save time?	5.3	Analyze
How to pause / sleep thread or process in Android?	4.8	Apply
The best shortest path algorithm	4.6	Apply
How waterproof is a Swiss cheese?	4.2	Evaluate
Are zip code and postal code violation of 3rd normal form?	3.9	Analyze
Superkey, candidate key & primary key	3.8	Understand
What is the difference between fork and thread	3.8	Understand

^ indicates a higher order thinking skill as per Bloom's taxonomy

found relevant. We removed 2 outliers from the time data which corresponded to students leaving keeping the popup window open. We found that 45 students spent a total of 127 minutes on Q&A, which was approximately 18% of the total time spent on learning. Fig. 6 shows the percentage of learning time spent by students on accessing Q&A, ordered by the highest to the lowest percentage. We could not include data for 8 students who had chosen to take the survey, but not to register. We found the median percentage of time spent by students on accessing Q&A to be 13.6%.

We found that 91 Q&A out of 111 were accessed by students. Table III shows the top Q&A in terms of time spent by students reading them. It also lists the number of students who accessed the questions. We observed that these questions consisted of questions catering to both lower-order and higher-order thinking skills as defined by Bloom's taxonomy. They also consisted of interesting questions as well as questions which could be asked in job interviews. A question such as *how to pause / sleep thread or process in Android* also indicated that some students wanted to relate the concept being learnt to current and relevant technology such as mobile phones.

However, we found a contradictory trend while analyzing the student vote data. Table IV shows the top 10 questions according to the percentage of students voting for them as relevant questions. These Q&A mainly catered to lower-order thinking skills as per the Bloom's taxonomy such as *understand* and *apply*. This observation probably indicated that the learners' notion of relevance was related to practical and immediate learning goals such as understanding and applicability of the Q&A to familiar scenarios.

Fig. 7 shows the total time spent by students on each page. We found that during the experiment, most students primarily used the first page to assess the interface. Fig. 8 shows the distribution of average reading times for questions. The median of reading time was 0.38 min. We believe that such short time spent on Q&A is due to the time constraint of 15 minutes on students for assessing the interface.

TABLE IV. TOP Q&A IN TERMS OF STUDENT VOTES

Question	% of students	Bloom's skill type
What is the difference between a process and a thread	67	Understand
Finding kth-shortest paths?	58	Analyze [^]
Superkey, candidate key & primary key	58	Understand
Normalization - IDENTIFYING Transitive Dependencies	56	Apply
Process vs. Thread	49	Understand
Relations in 2NF and 3NF	49	Apply
How does lock work exactly?	47	Understand
The best shortest path algorithm	47	Apply
What is the difference between 3NF and BCNF?	47	Understand
How do you normalize one-to-one-or-the-other relationships?	42	Apply

[^] indicates a higher order thinking skill as per Bloom's taxonomy

VII. DISCUSSION

In this paper, we demonstrated that learning material can be made more relevant to learners by augmenting it with Q&A from social Q&A websites such as StackOverflow. In an experiment conducted using such augmented interface, we found a statistically significant correlation between perceived relevance of Q&A and learner preference for such an interface. We also found that more than 75% students preferred learning with such a learning interface. In specific, we found correlations between learner preference and perceived relevance of Q&A to examinations, future job content, past experience and future job expectations.

The aforementioned correlations could be attributed to learners' need for connecting theory to their world. For instance, using Q&A, they are able to imagine the content of their future jobs, scenarios related to job interviews, scenarios related to current and relevant technology, and their subsequent role as a practitioner. Analysis of the recommended Q&A suggests that StackOverflow Q&A offers a variety of questions addressing a variety of learning needs

such as higher order thinking skills, interview readiness and programming skills to satisfy the needs of a variety of students. We did observe a tendency of learners to choose questions catering to lower-order thinking skills such as *understand* and *apply* as per the Bloom's taxonomy. This indicates that for building relevance, immediate learning goals such as understanding a concept well and applying it to familiar scenarios need to be catered to in establishing relevance while learning.

In this paper, we also proposed an interface and a method for automated recommendation of Q&A from StackOverflow as an augmentation to any given learning material in computer science available as electronic text. This allows us to make the augmentation a part of learning management systems, electronic books and mobile study apps.

VIII. LIMITATIONS AND FUTURE WORK

The limitations of the work described in this paper include the relatively small number of students used for experimentation and the relatively short period of time for which they used the experimental interface. The time constraint in the classroom setup probably did not allow the students to explore the interface in detail and in a sustained self-study setting. In near future, we plan to conduct a similar experiment as a part of an online learning portal with a much larger set of students.

Also, a question is a construct that creates curiosity in a learner. We did not specifically examine the effect of curiosity in the experiment. Based on the classroom observations of students using the interface, we believe that curiosity also has an important role to play in the utility of Q&A and can be examined in future experiments.

In future, we plan to make the recommendations more personalized to learner interests. This might include classifying the questions into abstractions useful to learners such as *explanation*, *implementation*, *troubleshooting* and *suggestion* by refining the StackOverflow queries with verbs indicating question types as suggested by Allamanis et al. [34].

Blended Learning at Maths with Aerospace Engineering Freshmen

N. Llobregat-Gómez, J.-A. Morano, M.-D. Roselló, L.M. Sánchez Ruiz

Universitat Politècnica de València, UPV

Valencia, Spain

[<nllobre,jomofer,drosello,lmsr@upvnet.upv.es>](mailto:nllobre,jomofer,drosello,lmsr@upvnet.upv.es)

Abstract—Instructing mathematics to engineering freshmen is a challenge not only because of their diverse backgrounds but also because of their high skills in digital technology. For this reason, a new approach has been considered in Aerospace Engineering at Technical University of Valencia (UPV) which, in addition to master classes, includes assignments specially designed to achieve mathematical competencies in the first year. These assignments reinforce the learning process of students and increase their competencies before each assessment test. On the other hand PoliformaT, an educational platform developed by UPV, and based on the Sakai project, has facilitated to develop a flipped teaching methodology in the one hour lab sessions in the first year of Aerospace Engineering. Thus a blended learning methodology, a combination of computer technologies and face-to-face classes, has provided very good learning outcomes results for Spanish standards. We present some results concerning our first year Mathematics course in Aerospace Engineering and the opinion of the students about this blended learning methodology.

Keywords—Blended learning, Mathematics in Engineering Education, Assessment and Evaluation Strategies/Approaches Laboratory Experiences, Teaching & Learning Experiences in Engineering Education, First and Second Year Program

I. INTRODUCTION

One of the main objectives under the Bologna Process has been to avoid passivity in students when they are in the classroom. Instead, focus has been placed in getting the students to be part of their own learning process [1].

In order to encourage this active participation several methodologies have arisen, such as problem-based learning, flipped learning, collaborative learning, online learning, etc. Combining some of these and other methodologies we find how the so called blended learning emerges, so that students can learn on their own, alone or in groups, and always maintaining focus on the acquisition of specific competences during the learning process [2].

On the other hand, the competences and skills developed in the subject of Mathematics are basic in all Engineering studies and among them the skill of a proper use of mathematical software must be worked in a natural and active way. With this in mind the authors are taking advantage of the powerful software MATHEMATICA at Aerospace Engineering following a blended methodology for the classes.

Mathematics I is a compulsory and annual subject delivered in the first year of BEng Aerospace Engineering [3] at the

Higher Technical School of Design Engineering (ETSID acronym in Spanish) of the Technical University of Valencia (Universitat Politècnica de València, UPV). It has got 120 contact hours (12 ECTS) from which 75% of them correspond to Theory/Problems (TP) sessions and the remaining 25% to Lab practice (LP).

The methodology used involves a blended methodology since flipped classroom is partially used by students to prepare lab classes in advance, as detailed in Section II. Is in these lab sessions where the educational platform developed by UPV, PoliformaT becomes very helpful. In section III we analyze the results obtained in Mathematics I of BEng Aerospace Engineering during the academic course 2013/14. We also present the students' opinion about the blended methodology applied in the subject. Finally, in Section IV we discuss the results and the questionnaire with the students' opinion.

II. BLENDED LEARNING

Blended learning occurs when learning takes place through several channels such as, combining Internet and digital media with the procedures established in the classroom with physical co-presence of teacher and students.

A. PoliformaT, the UPV's educational platform.

The use of educational platforms can enhance learning opportunities. All of the platforms have many utilities, and we find especially useful the ones called 'self-developed' because they allow improvements in their specific purposes, aspects and tools according with the demand of its users. PoliformaT has been developed by UPV and it is based on the Sakai project [4]. Sakai is based on reliable and extensible educational software distributed under an open source license. We dispose of tools like 'Resources', 'Modules', 'Chatroom' or 'Forums' but some features of PoliformaT have evolved throughout users demands such as the interconnection between tools like 'Schedule', 'Announcements' or 'Messages'. Other improvements include 'Drop Box' that now enables to download students files by groups whereas previously the download was one by one; 'Gradebook' where now it is possible to add comments to each mark improving the feedback; 'Polls' that allows to query students anonymously about different issues. It has also been incorporated several changes in the editor of the 'Test&Quizzes' tool. It incorporates a text editor, what makes the work more efficient, especially in Maths. It is essential to allow the use of different fonts, paste text from other software, including images, and

Supported by Ayuda a Proyectos de Innovación Docente, PID-DMA-2014, Applied Mathematics Department (Technical University of Valencia, UPV) 2014; and Proyecto de Innovación y Mejora Educativa PIME B-24, Vicerrectorado de Estudios, Calidad y Acreditación (VECA), UPV 2014.

create formulas. Currently the inclusion of formulas is allowed from LaTeX although some unsolved technical issues appear in questions of 'Numerical Answer' type by the use of '{}'. They are reserved to contain the correct answer but LaTeX frequently uses it with some characters. Recently, PoliformaT has implemented TURNITIN as a software tool for faculty staff. TURNITIN software is aimed to prevent plagiarism and it allows instant revision of delivered works by searching for coincidences in multiple information databases through 'Originality check', 'GradeMark' and 'PeerMark' [5].

B. Traditional and in-class learning

For theory and problems classes we use a traditional in-class methodology with master lectures.

To reinforce the contents seen in theory sessions, students should carry out certain tasks to implement such content. These tasks are performed outside of the class and therefore can become *collaborative learning* without being the specific methodology of these tasks. The tasks have been carefully designed to complement and assist in the learning process, which is part of a *problem-based learning*. However, the tasks serve mainly to develop the skill of solving problems (plan, resolution and interpretation). New concepts do not appear while doing them.

C. Flipped learning and online learning

Some contents of Mathematics curriculum are incorporated directly into lab sessions which asses into the lab sessions are key issues. For these lab sessions, we use MATHEMATICA as computer algebraic system and the educational platform, PoliformaT.

The current methodology has been achieved through an evolutionary process from the initial lab sessions and their corresponding evaluation to a situation in which we are delivering the one-hour weekly lab class based upon the *flipped class* methodology.

A flipped classroom is a methodology in which students can choose their own pace in the learning process and teachers guide and help them. With this approach students can achieve deeper learning by working harder and making a personal commitment to the process [6-8].

With this methodology the standard lecture in-class format is replaced with opportunities for students to prepare, review, discuss, and investigate the course contents with the instructor during class. There are several ways to flip a class, the main idea under this perspective is that students review lecture materials previous to master class and then attend theoretical classes to develop learning activities with an instructor [9].

In [10] there is an interesting summary with hints about different strategies for flipping classroom highlighting:

- Assigning readings, following up in-class discussion or quizzing as well as providing videos and readings for students to review and promote forum discussions by instructors fostering an online or hybrid class.
- Capturing lectures from classes and providing the recordings for students review after class.

- Assigning reading material outside of class or in class, and require students to teach part of the class by some media.

These approaches allow having access to the material when students miss a class, follow the course up with this material and finally, for those who join the group later, facilitates the updating with the first lessons.

This inverse classroom involves changes in the teaching practice for both, students and instructors. Students should modify their passive attendance to the traditional lectures and the teachers must develop suitable material for the new flipped setting. Moreover students should be ready to discuss in class stirring the students' participation.

Depending on the level of technology and time available, a flipped classroom may or may not include this technological component (CAS, videos, ...). Our methodology makes a reasonable use of technology in line with the strategy described above. An important aspect for success is that students are evaluated each week about the material they have been working by their own, as explained below.

Each group of LP consists of about 25 students and with such a small group the potential of MATHEMATICA is exploited. Our flipped learning implementation has got three different stages: *pre-class*, *in-class* and *post-class*.

The work of pre-class stage is made outside of class and it relies on the educational platform PoliformaT by providing a guide with topics and exercises that students should prepare before the lab session. This guide also includes theoretical aspects that they need and must know and their related MATHEMATICA commands.

Each week there is a lab practice session, the in-class stage. This begins discussing with students the different elements of their prepared session. In a second part of the in-class session we host an assessment where freshmen have to solve individually some questions and exercises posed through the platform and assisted by MATHEMATICA. In these questions, the instructor is available to help students if they ask for it.

The third part of each session, post-class stage, starts once finished the assessment when students check their answers and qualifications and teachers can detect unachieved skills both in general and in individual cases. In such cases some reinforcing tasks are proposed pursuing that the students achieve this skill. For example, by suggesting the review of virtual laboratories [11] and videos [12] that explain certain contents or, proposing conducted exercises with appropriate supporting literature.

Moreover following this methodology, students and instructors monitor the students' learning progress. The marks obtained in lab sessions have got an influence on the continuous assessment of the students who also must perform semester exams individually.

D. Other activities to facilitate competencies achievement

Along with this weekly flipped classroom in lab sessions, the students were also required to make some assignments to promote the work of the subject. They have to solve this task

during one week. Each assignment includes, between others, questions related to:

- Math problems with some degree of difficulty.
- Engineering related problems.
- Open questions with no closed answer.

Assignments are performed in a non-controlled environment (NCE), and therefore there are always some doubts about their authorship. For this reason students are requested to take a multiple-choice test under a controlled environment (CE), in-class, related with the type of the assignment exercises.

During the multiple-choice test under CE students can even consult their home assignments, so the multiple-choice test is not standard. Students know that they will be awarded with the same positive (negative) absolute input in success (failure) case and with 0 input in case of no answer.

III. RESULTS AND STUDENTS' FEEDBACK

There were 126 students of Mathematics I in BEng Aerospace Engineering during 2013/14. This participation serves as reference for relative values and percentages. 5 out of 126 had less than two attendances, and were considered as non-participants of the experience

The students' performance was as follows:

- The average on the 27 weekly lab sessions was 8.7 with a deviation of 1.7.
- The 4.7% (6/126) of students did not take the LP semester exams almost matching the students with non-attendance at LP sessions. Without considering these 5 students, the percentage drops to 0.8%.
- The averages obtained in the LP semester exams were 5.6 and 7.6 with deviations of 2.0 and 2.4, respectively.
- The global mark of assignments, green in Fig. 1, was obtained by weighing these two results. Most students performed better under NCE than at class under CE, blue and red respectively in Fig. 1. In few cases we found divergence between both values what leads to intuit that they received aid in the NCE assignment.
- The 8.7% (11/126) of students did not take the TP tests which correspond to 4.7% of students not considering the 5 dropouts.
- The average scores obtained in the three TP tests were 6.1, 6.6 and 6.9, with standard deviations of 2.4, 2.6 and 2.1, respectively.
- Finally 88.9% (112/126) of students passed the subject, 92.6% without accounting the 5 dropouts.

Assignment Grading

Fig. 1. Grades obtained by each of the 119 students in an assignment composed of two parts: Performance in a non controlled environment (NCE) whose grade is in blue (▲) and a multiple choice test done in a controlled environment (CE MC) whose mark is in red (■) where the NCE task could be consulted - in this case no answers obtained 0 points and wrong answers subtracted 1 point -. For this reason some red marks are negative. In green (+) the global assignment mark (GM) was 65% of the NCE part and 35% of the CE MC test, whose minimum possible value was taken to be zero.

We got feedback from students about the blended methodology applied in the subject by using a PoliformaT's tool called 'Polls'. This poll consisted in several questions, related with the organization of the subject and other issues.

The first question was meant to know the actual time spent by the students in the pre-class stage. The results show that most students did not take more than two hours a week of preparation (see Fig. 2).

Another question tested his/her opinion about the efficiency of using the platform as a means of evaluating the answers and it also shows that this method improves or at least facilitates the learning of subject contents (see Fig. 3).

We also obtained their opinion about the possibility of finishing the TP sessions by doing some questions through PoliformaT. In this case most answered do not know perhaps because they cannot imagine the way that these questions would be (see Fig. 4).

Fig. 2. How many hours do you spend on average a week to prepare each LP session?

Fig. 3. Do you think that being assessed with PoliformaT at the end of each practical session is good for your learning process?

Fig. 4. Do you consider that it would be good for your learning process if each week you had to answer a quizz with PoliformaT about the concepts presented during the sessions of Theory-Problems?

In Figure 5, we show the students' opinion about the assignments and its importance in the learning process.

From the Poll it is clear that students do not have a negative perspective towards the use of a flipped methodology. Although the performance of this methodology has been developed only in LP sessions, its effects have had great influence on the results of TP. In our opinion this is mainly due to the constant review of concepts that students must carry out during the preparation of LP sessions.

Fig. 5. In what assignments are concerned, I think that...

IV. SUMMARY

When active learning is performed, students get activities, tools and approaches to the subject that together with their motivation, attention, etc. make that their learning process is performed through a creative attitude. In this paper we describe the initiative taken in a basic subject of first year as Mathematics in Aerospace Engineering with the aim of favouring this kind of active attitude among students from the early stages of their university studies.

By means of a blended methodology, combination of many other methodologies, very good outcomes in Spanish standards have been achieved. Results of first year Mathematics course in Aerospace Engineering have been presented, where 95% students attendees was achieved at the end of the course, all of them taking all exams, and where a success rate above 90% has been experienced which is far of being standard at Spanish Engineering studies.

In addition we have collected the opinion of the students concerning the different facets covered by the blended learning methodology used and discussed their results in this paper.

Abstract

International accreditation bodies monitor and accredit engineering programmes offered by tertiary institutions based on the high standards set forth by the Washington, Sydney and Dublin Accords. These accords stipulate specific graduate attributes like problem solving, investigation, modern tool usage, sustainability, ethics, teamwork, communication, management and life-long learning. Many of these attributes may be assessed by means of practical work done by students in a laboratory. This paper presents student perceptions about practical work done by freshman engineering students for a module termed, Digital Systems 1. The paper firstly considers the importance of practical work in an engineering environment and then discusses the significance of student feedback. It then sheds light on the research methodology used in acquiring data for this research. Finally the results are analyzed which indicates that South African engineering students really enjoy practical work done in a laboratory. Student further indicated that it helps them to fuse theoretical knowledge gained in the classroom, but prefer to work alone as opposed to in groups. A key recommendation from this study is to encourage more group work among freshman engineering students so as to strengthening the vital graduate attribute of teamwork.

Keywords— practical work; student perceptions; entry level subjects; theory; freshman

I. INTRODUCTION

Mahatma Gandhi once said [1], “A customer is the most important visitor on our premises. He is not dependent on us. We are dependent on him. He is not an interruption in our work. He is the purpose of it. He is not an outsider in our business. He is part of it. We are not doing him a favor by serving him. He is doing us a favor by giving us an opportunity to do so”. These words are very applicable to education, where students are actually the most important customers who become the most logical evaluators of the quality of a course. This novel notion of asking students to provide their perspectives on effective teaching and learning was first introduced in the late 1920's [2] and has grown steadily to the

point of being included as one of the criteria [3] used in measuring the academic performance of academics.

The Central University of Technology (CUT) [4] is home to approximately 13000 students and offers National Diplomas and Bachelor of Technology degrees in various faculties, including the Faculty of Engineering and Information Technology. These engineering based programs are accredited by the Engineering Council of South Africa under the guidelines of the Washington, Sydney and Dublin accords [5]. This accreditation is usually performed by examining the evidence of theoretical and practical work completed by students and facilitated by academics [5].

Practical work performed in laboratories provides great insight into the caliber and attributes of the graduates, and should be reviewed periodically in line with Industry needs. One key review of the practical work involves obtaining student perceptions of whether the work was enjoyable, beneficial, challenging and relevant to the theory covered in a classroom. Previous research has revealed that senior engineering students in an electronic communication course indicated that they really benefitted from the practical work scheduled in a laboratory [6]. Many of these senior students have been able to successfully enter the workforce after completing their practical internships with Industry related partners [7].

However, what are the perceptions of freshman engineering students towards practical work done in a laboratory? This paper aims to present these perceptions regarding practical work done in a computer systems engineering laboratory. The importance of student feedback is firstly presented along with how theory and practice may be integrated into a module termed, Digital Systems 1. The research methodology is then substantiated and the results are presented in a series of figures.

II. SIGNIFICANCE OF STUDENT FEEDBACK

Feedback can be conceptualized as information provided by an agent with the aim of improving or enlightening the recipient [8]. It cannot be a once off process, but needs to be a continuous cycle, an evaluation cycle [9]. The evaluation cycle suggested by Hounsell is shown in Figure 1. The first step here

is to define the context of the evaluation and then devise a feedback strategy. The third step is to gather feedback and analyze it. The fifth step involves agreeing on a remedial action and finally implementing the changes.

Fig 1: The evaluation cycle by Hounsell

In an educational environment, feedback can occur in many forms, with student feedback being a unique example. Student evaluation of teaching (SET) is seen as a way to measure teaching performance in higher education institutions [10]. The validity and reliability of student feedback have been studied in detail by many researchers, some of whom have come to the conclusion that it is indeed useful in evaluating teaching [11][12][13][14][15][16][17][18][19].

Research has further shown that student feedback positively impacts upon educators and their teaching ability [20]. Student feedback increases the likelihood that excellence in teaching may be recognized and rewarded, which surely provides motivation for instructors to gather and respond to this kind of feedback [16].

Perceived disadvantages of student feedback stem from the argument that there is no universal definition of effective teaching [2]. Other studies have commented on the correlation between a small sample size and its effect on valid student feedback [20] while the tendency to use grade inflation as a means to influence student feedback has also been noted [2].

Although disadvantages do exist in asking students to comment on the quality of a course, numerous advantages do exist in favor of it. However, student feedback should be sought to evaluate any changes that have been made to integrate theory and practice in a specific module.

III. INTEGRATING THEORY AND PRACTICE IN DIGITAL SYSTEM 1

Digital Systems I is a compulsory module for all Electrical Engineering students. This module usually comprises many freshman engineering students who have very limited prior laboratory experience. Many challenges exist in delivering a

freshman course [21] with one unique challenge relating to the large number of students attending a course [22]. In fact, average classroom sizes for this module range between 100 and 150 students per semester.

Digital Systems I is a Level 6 module according to the National Qualifications Framework [23] with 12 credits awarded to it. This means that students need to dedicate at least 120 notional hours to this module over a 14 week period. The purpose of Digital Systems I is to provide a basic introduction to the working of digital systems as contrasted to analog systems. The course aims to build a knowledge base for subsequent modules like Digital Systems II, III and Logic design III.

The specific learning outcomes of this module gives the freshman engineering student the ability to implement simple digital circuits, making use of different simplifying techniques and various digital devices. Student assessment focuses on building simple circuits for conversion between the various number systems, analysis of logic circuits, simplification using Karnaugh maps and building combinational logic circuits. All practical sessions are done in conjunction with the corresponding theory which is highlighted in Table 1.

TABLE I: Linking theory and practice in a Digital System I laboratory

UNIT	THEORETICAL CONCEPTS IN THE SYLLABUS	PRACTIAL ASSIGNMENTS IN LABORATORY
1	Introduction to Logic gates Gate	Identification of logic gates and their functions
2	Conversion from binary to decimal, to gray code, to hexadecimal, to octal and to BCD	Designing Binary to Gray and Gray to Binary converters
3	Boolean algebra laws and rules, De-Morgans theorem, Truth table construction, Standardization of SOP and POS terms, Boolean simplification using Karnaugh maps	Generating truth tables from logic circuits and redrawing the circuits using only NAND gates or NOR gates. Creating and building circuits from non-standard SOP/POS expressions
4	Combinational logic circuits	Designing 4 bit adder circuits using 7483 and 7486 IC's

Apart from the five practical experiments shown in Table 1, the students are required to do a practical test and a group assignment. The students submit their circuit designs on paper for the respective practical experiments and only construct their physical circuits after having their design assessed. The practical test is conducted after the conclusion of the 3rd practical experiment and focuses on reflecting on the previous experiments with a view to re-enforcing the graduate attributes of problem solving and investigation. Designing digital circuits to meet specific criteria and then investigating or evaluating their operation is assessed.

The group work assignment is completed after the 5th practical experiment. The students are split into groups of five where they are given a real-industry related scenario or

problem. The five students are then required to analyze the problem according to the theoretical concepts which they have acquired, design a circuit on paper as a probable solution, construct the circuit on a breadboard and then evaluate it to see if the problem has been solved. The practical mark (PM) of the students is calculated using the following formulae:

$$PM = \left(\frac{\sum(Assignments)}{5} \right) 0.5 + \left(\frac{\sum(Practical\ test + Group\ work)}{2} \right) 0.5$$

This PM is then used to calculate the course mark (CM) of the student. The CM also depends on the two written tests, namely the First test (FT) and the Main test (MT). The formula used for calculating the CM is as follows:

$$CM = (0.25 \times FT) + (0.35 \times MT) + (0.4 \times PM)$$

The PM has to be above 50% and the CM has to be above 40% for the student to gain entry into the final written examination. The final mark (FM) of the students is calculated based on marks scored in the main evaluation (ME) and the CM. The formula for the final mark is as follows:

$$FM = (0.6 \times ME) + (0.4 \times CM)$$

The formulae given above stress the significance of the practical work, which accounts for 40% of the CM. The practical assignments done in the laboratory consist of two main sections. The first section tests the theoretical knowledge of the student while the second section assesses their practical skills. In the theoretical section, the student has to prepare for the experiment. This can include drawing digital circuits, creating truth tables and answering theory questions relevant to the experiment. Each student is individually assessed prior to the laboratory session for the first section and the marks are captured on an MS EXCEL sheet.

The second section involves building the circuit using the different components provided to the students in the laboratory. This is done within the laboratory. Once completed, the student demonstrates the result to the lecturer or laboratory assistants. The student is assessed for the second time here based on the output of the circuit. The mark for the second section is added to mark of the first section on an MS EXCEL sheet to obtain the assignment mark. This mark is then used for calculating the practical mark (PM) described earlier. The written report of the theory work and practical work (with all marks attached) is stored in the laboratory for future reference.

IV. RESEARCH METHODOLOGY

An exploratory study is employed along with descriptive statistics involving quantitative analysis of the collected data. An exploratory design may set the stage for future research and usually involves only a single group of respondents [23]. Descriptive statistics are used as the results are interpreted with regard to specific freshman engineering students enrolled at CUT. Quantitative analysis is important as it brings a methodical approach to the decision-making process, given that qualitative factors such as "gut feel" may make decisions biased and less than rational [24].

The target population was restricted to freshman engineering students enrolled for Digital Systems I during 2014 ($n = 56$). An electronic response system (ERS) was used in a classroom environment to obtain student perspectives on specific questions relating to the practical work done in the laboratory. Closed-ended questions, featuring Likert scales, were used based on previous research which focused on student perceptions of practical work done in a laboratory [25][26]. Using this ERS in class ensured a high response rate, while the closed-ended questions did not require the participants to express lengthy views, as this is rather cumbersome with the ERS used to collect the results.

V. RESULTS AND DISCUSSION

The purpose of this paper is to present freshman engineering student perspectives of practical work done in a Digital Systems I laboratory. This is done by dividing the results into four sections. The first section focuses on whether the students were satisfied with the practical work. The second section focuses on whether the practical experiments helped students to better understand the course content. The third section focuses on whether the practical experiments were challenging and relevant to the theory presented in the classroom. The fourth section focuses on student recommendations regarding the practical work and on submitting their written practical assignments online via a learning management system.

The results for the first section revealed that 70% (40% strongly agreed and 30% agreed) of the students enjoyed the practical work. As a follow up question, the students were asked if they would recommend the subject to other students. Here, 50% (20% strongly agreed and 30% agreed) indicated that they would indeed recommend this subject to other students. These results are shown in Figure 2. This tends to suggest that the students were satisfied with the practical work, as enjoying and recommending a module are factors that may indicate student satisfaction [27].

The results of the second section are given in Figure 3. Here 86% (59% strongly agreed and 27% agreed) of the students agreed that Digital Systems I was a valuable learning experience while 65% (26% strongly agreed and 39% agreed) reported that the practical work helped them to apply new knowledge in solving engineering related problems. A further 81% (43% strongly agreed and 38% agreed) of the respondents indicated that the practical work helped them to better understand some of the theory given in the classroom. These results imply that the practical experiments are enabling students to understand and apply their newly gained theoretical knowledge in demonstrating the desired graduate attribute of problem solving which is prescribed by the International Engineering Alliance [5].

The next focus was on the relevance and difficulty of the practical experiments Figure 4 indicates that the majority of students (82% agreed) perceived the practical work as being relevant to the theory covered in the classroom. The practical work was viewed as challenging (70% agreed), but not too

difficult (12% agreed) by the majority of the respondents. This tends to suggest that the practical experiments have been

aligned with the theoretical instruction, thereby adhering to the principles of constructive alignment [28].

Fig 2: Student perspectives on practical work done in the Digital Systems I laboratory

Fig 3: Student perspectives on subject knowledge gained after completing practical experiments in the Digital System I laboratory

The results of the fourth section considered recommendations regarding the practical work and its submission via an online learning management system (see Figures 5 – 7). The results indicate that 66% of the students feel they need to do more experiments in the laboratory, while 78% believed that they needed more time doing the experiments. Students also expressed the view that they would prefer to work on their own (70%) in the laboratory.

However, this goes contrary to the desired graduate attributes of teamwork and communication prescribed by the International Engineering Alliance [5]. CUT also has regular advisory committee meetings with Industry who often indicate that African engineering students struggle to work in groups. This therefore suggests that more emphasis needs to be put on group work, where the academic needs to incorporate principles of collaborative learning [29]. Encouraging group

work at this early stage of these students intellectual development may reverse the eventual viewpoint of senior engineering students towards the importance of group work in Industry.

Figure 6 considers recommendations relating to the practical work. 23% of students want more access to the laboratory during the evenings, while some students did verbally indicate that they would like to access the laboratory more during the day. In keeping with the trend of working alone, only 19% of the respondents indicated that they would prefer working in smaller groups while 23% feel that more computer simulations should be included in the practical work. This could improve the student's ability to demonstrate the desired graduate attribute of modern tool usage [5].

Figure 6 further highlights that only 9% of students want to submit their practical assignments online. With the drive

towards a more Green Environment where paper usage and printing needs to be reduced, this recommendation is difficult to adhere to.

Fig 4: Student perspectives regarding the relevance between the practical and theoretical work

Fig 5: Student perceptions regarding frequency and duration of practical work

Fig 6: Recommendations from students to improve practical work

Fig 7: Feedback regarding why students would not want to submit their practical work online

Results of student reasoning for not wanting to submit their assignments online are shown in Figure 7, where no single overwhelming reason is provided. The predominant reasons are limited computer (19%) and internet access (19%). This could also be attributed to the fact that a good majority of students come from previously disadvantaged backgrounds [7]. However, limited e-skills of students also warrants attention (10 - 13% indicating that they have limited MS Word, PDF and general computer skills). A tutorial addressing this concern could be incorporated into the practical work thereby strengthening the graduate attribute of modern tool usage [5].

VI. CONCLUSIONS

The purpose of this paper was to gain insight into the perspective of South African freshman engineering students regarding practical work done in a Digital Systems I laboratory. The results indicate that the majority of student perceived the practical work to be enjoyable, beneficial, challenging and relevant to the theory covered in a classroom. This tends to suggest that the practical work is re-enforcing the theoretical knowledge of the students.

Students further recommended that the laboratories be opened for access after normal class hours and that the number of practical experiments be increased, with especial reference to more simulations. A possible recommendation would be to create awareness among students about specific online open computer laboratories and how to access them. Offices of lecturer assistants may also be moved to the laboratories in order to provide students with more opportunities to access the laboratories outside the normal laboratory scheduled time.

However, two key deficiencies were identified in that the majority of South African freshman engineering students do not prefer group work alone and in that these students are reluctant to submit their practical assignments online. Reasons for the latter include limited computer and internet access. A

recommendation should be to encourage CUT management to enter into partnerships with local Internet service providers to negotiate an acceptable Internet student package. As for the former deficiency, recommendations need to be made to academics to incorporate more group work into their practical instruction. Collaborative learning strategies need to be implemented. In conclusion, these results do suggest that freshman engineering students are fusing their theoretical and practical knowledge, experiencing a measure of satisfaction as they demonstrate the acquisition of important graduate attributes mandated by many accreditation bodies in the world.

ACKNOWLEDGMENT

Rangith Baby Kuriakose would like to thank CUT for the opportunity to engage in engineering education research.

Cyber-Infrastructure Support for the Integration and Analysis of Student Success Data

Wai Yan Elsa Tai, Ann Q. Gates, and Monika Akbar

Department of Computer Science

University of Texas at El Paso

El Paso, USA

wyetai@miners.utep.edu; agates, makbar@utep.edu

Abstract—Increasing enrollment and retention in science, technology, engineering, and mathematics (STEM) programs, particularly for students from underrepresented groups, has become a national priority. Institutions often have multiple funded and unfunded efforts that address student success and broadening participation. One challenge is that they are typically discipline specific with little interaction with complimentary efforts outside of the sponsoring department or college. Such isolation can hinder wider adoption of effective practices and the development of innovative programs based on lessons learned. This project, funded by the NSF Innovation through Institutional Integration program, focuses on defining the cyberinfrastructure and communities needed to support the discovery and integration of student-success projects. The paper is organized as follows: discussion of the motivation; presentation of the infrastructure and models created to connect data collected by various projects, units, and programs; and description of MetaShare, a metadata management system that captures metadata about artifacts in support of integration across projects.

Keywords—cyber-infrastructure; data models; expertise system; data discovery; community of practice; data integration; data management system.

I. INTRODUCTION

A national priority and a focus of many efforts supported through funding agencies is to increase the proportion of the U.S. population attaining college degrees, in particular students from underrepresented groups. This emphasis has given rise to a number of projects (also referred to as *initiatives* in this paper) that often target a particular discipline. While many of the initiatives have been successful, departmental silos and hierarchical structures have often made knowledge sharing and long-term support of effective practices difficult. To address this, the NSF Innovation through Institutional Integration (I³) program set interrelated goals [1] that include the following: increase synergy and collaboration across NSF-funded projects within and between institutions towards an educational environment where artificial boundaries are significantly reduced and the student experience is more fully integrated; expand and deepen the impact of NSF-funded projects and enhance their sustainability; promote innovative programming, policies, and practices that encourage the integration of STEM research and education; and encourage STEM educational or related research in domains that hold promise for promoting intra- or inter-institutional integration and broader impacts.

To meet the I³ goals, the University of Texas at El Paso (UTEP) proposed to build cyber-infrastructure, communication, and connection structures with a focus on broadening STEM participation. UTEP's I³ project has challenged faculty, administrators, and stakeholders to think strategically about the creative integration of NSF-funded awards. The I³ project has resulted in the development of the Expertise Connector website and Move Communities portal that connect expertise on campus. The focus of this paper is on the part of the I³ project that centers on the development of cyber-enabled technologies to document, share, and discover project information such as goals, activities, evaluation, and metadata, including relationships among projects that broaden participation in STEM fields at all academic levels.

After elaborating on the motivation and goals of UTEP's I³ project in Section II, the paper presents an overview of UTEP's efforts to build inter- and intra-institutional connections in Section III. Section IV describes the methodology for building the cyberinfrastructure that supports discovery, information and knowledge sharing, and inter- and intra-institutional connections. Section V describes the summary along with the preliminary results. The paper ends with future directions in Section VI.

II. MOTIVATIONS AND GOALS

The vision of UTEP's I³ project is to transform the university into one in which faculty are committed to sharing resources, collaboration is supported through recognition and rewards, effective initiatives are extended across the university, discussion among diverse faculty members and administrators stimulates new ways of student preparation and advancement in STEM areas, and proactive strategies are employed to identify effective avenues for sustainability. The project seeks to build the cyberinfrastructures for the university to establish a culture where sharing of practices developed by initiatives leads to innovation in the preparation of students for undergraduate research and graduate education.

Because investigators manage their own artifacts, e.g., publications, reports, workshop materials, outreach activities, and scientific data, they may be distributed across different repositories, such as Excel worksheets or databases, local computers, or servers. In addition, artifacts may be stored in various formats and different levels of granularity, which can complicate integration. Because provenance may not be

captured, data analysis can be challenging. Furthermore, initiatives often operate in isolation with little interaction outside the department or college. For example, Peer-Led Team Learning (PLTL) initiatives are run through the university's Entering Student Program, as well as the departments of computer science, chemistry, mathematics, and electrical and computer engineering. Each initiative collects its own data, performs its own evaluations and, as a result, may collect different types of evaluation data. Because of the difficulty in identifying who is doing what on campus, it is a challenge to compare or share data and ideas, which can hinder knowledge transfer and reuse. Initiatives are often not connected to broader institutional efforts, which makes wider adoption of effective practices and the development of innovative programs based on lessons learned more difficult.

Some of the related challenges that the university faces are the following: 1) the ability to track students involved in similar initiatives; 2) the ability to identify related efforts with the aim of determining their collective impact and institutionalizing efforts with significant results; 3) the ability for new initiatives to review recommendations for facilitating institutional assessment and evaluation and adopting existing instruments; and 4) the ability to collaborate and learn from other projects.

The expected outcomes of the cyberinfrastructure efforts reported in this paper are cyber-enhanced tools that facilitate discovery of student success data collected by initiatives across the university; a well-defined, efficient process for integrating data, which can be used to answer questions that promote understanding and adoption of effective student success practices; and mechanisms for identifying related initiatives and making recommendations to align related initiatives.

III. BACKGROUND

The proposed effort is defining a comprehensive solution supported by a change in culture at the university with support of upper administration and the development of cyberinfrastructure that connects people with tools to support collaborations. A key element of the project was the development of the Expertise Connector system [2] that publishes comprehensive information about researchers through information stored in Digital Measures (DM) (see Table 1). Through DM, faculty and professional staff enter their statement of expertise, keywords, links to their personal website and social network connections, and selection of aligned university's strategic areas. Research stories and associations with Move Communities (described next) are also part of a user profile. Because faculty and professional staff use DM for annual performance review, profile information is expected to remain current. The Expertise Connector is similar to other solutions such as Vivo [3] and Influent [4]. Both Vivo and Influent are intra-institutional approaches for discovering expertise. Influent bases the user profiles on publications garnered from Scopus. Influent, which is used by the UT System, also references Expertise Connector and vice versa.

The Move Communities infrastructure supported by Expertise Connector provides the ability for a researcher to

associate with a Community of Practice (CoP) in a particular area of interest. A CoP [5] is a group of individuals, who share an interest, concern, or passion, and who interact regularly to improve what they do. Move Communities connect people with people, people with experts, and people with information (e.g., resources on campus, related efforts, and effective practices). The intent is to encourage sharing and motivate action to address challenges and opportunities collectively. Example Move communities center on areas such as undergraduate research, cybersecurity, and engaged scholars.

Another critical component for making connections across the university is an infrastructure that facilitates documentation and management of metadata, i.e., data about the artifacts that result from research. Attaching semantics to the metadata distinguishes the I³ approach from others. Data-sharing in any context is facilitated by incorporating the attributes necessary to depict metadata typically done through standards. Rich metadata in such context promotes discovery, analysis, selection, aggregation or filtering, and reuse [6]. Data artifacts can be generalized through the definition of its class, meaning the data type of which they are members, associated standards, confidentiality policies, and formats used. The abstraction of such entities provides a re-usable structure that can detail metadata artifacts at a high-level, but provide enough information to ensure analysis-ready, interoperable artifacts [6]. Takeda et al. [7] proposed profile-based recommendations to suggest proper organization of data and assist in defining such things as related projects, standards, and instruments.

IV. METHODOLOGY

Fig. 1 presents an overview of the method used in defining the cyberinfrastructure. This section elaborates on each of the components.

A. Interviews

We interviewed university officials and evaluators to identify questions that potential stakeholders e.g., proposal writers, provost, deans, chairs, faculty, and staff, would be

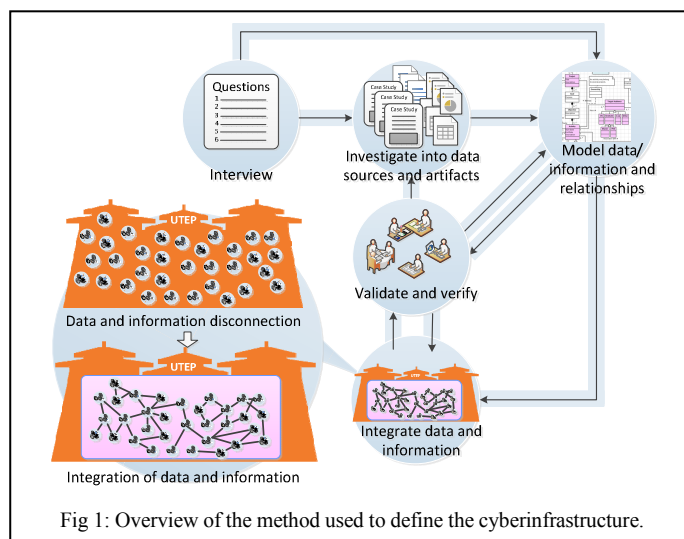

Fig 1: Overview of the method used to define the cyberinfrastructure.

interested in learning about student success and broadening

STEM participation. The following is a list of sample questions collected during the interviews:

- Which broadening participation initiatives are employed in academic programs that have significantly higher student retention rates of female students?
- For initiatives that address retention, what is the impact (e.g., retention in the major, retention in STEM, time to degree) within and across disciplines and departments?
- What are the differences in the PLTL approaches used in different departments?
- What are the impacts of PLTL on student pass rates?

B. Investigation into Data Sources and Artifacts

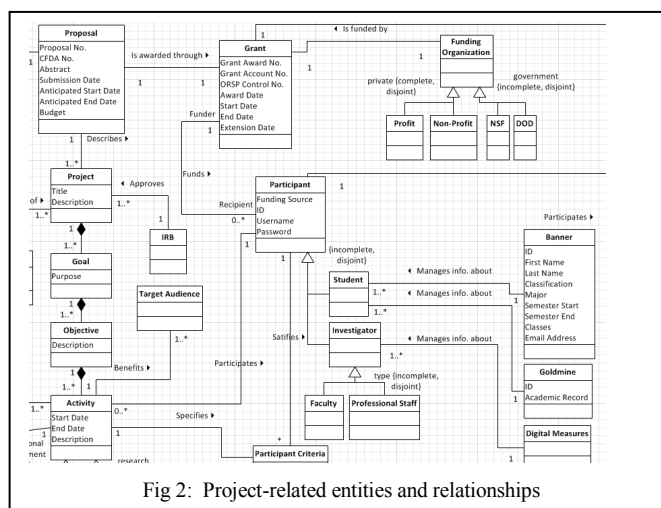

The motivating questions collected from the interviews guided our investigation into identifying various data sources and artifacts. Table 1 presents a summary of selected data sources referenced during the investigation process.

TABLE 1. Selected Data Sources

Source	Data and Artifacts
Banner	Banner manages student information.
Center for Institutional Evaluation, Research, and Planning (CIERP)	<p>The Common Data Report provides information about enrollment and persistence, transfer data, and student life.</p> <p>The Fact Book presents information about collection of frequently requested data: undergraduate and graduate student profiles, enrollment, and degrees conferred. Integrated</p> <p>The Integrated Postsecondary Education Data System Data Center Reports provides information about institutional characteristics, completions, enrollment, student financial aid, and graduation rates.</p> <p>CIERP conducts surveys to collect longitudinal data on different student perspectives and student reported information.</p>
Digital Commons	Digital Commons provides research and scholarly output submitted by faculty and graduate students of the individual university colleges, departments, and centers on campus.
Digital Measures (DM)	Digital Measures manages faculty members' professional activities and accomplishments for annual, tenure, and promotion evaluations.
Expertise Connector	Expertise Connector provides faculty and professional staff profiles, community profiles, center profiles, and research stories.
Goldmine	Goldmine manages students' academic history.
The Office of Research and Sponsored Projects (ORSP)	ORSP maintains full proposals submitted through the university and other information associated with awards.

C. Modeling of Data/Information and Relationships

The motivations for modeling sources of data and information are twofold: 1) the complexity of university systems and the lack of documentation of such systems make it difficult for faculty to know the primary sources of data and information; and 2) many investigators manage their own artifacts, resulting in the distribution of data and information

across different repositories. To address this, the project studied and analyzed data sources, data, and information managed by each data source. The analysis resulted in a set of Project-Data models using the Unified Modeling Language (UML) class diagram [8].

The project also analyzed the relationships among data and information to identify which motivating questions can be answered, determine the source for additional information needed to answer questions, and minimize areas of redundancy. Fig. 2 presents a snippet of the project-related entities and relationships managed by OSRP, the project investigators, and the metadata management systems.

In accordance with UML notation, a rectangle in the class diagram denotes an entity or concept, and an arrow represents a relationship among entities. Arrows are labeled with the name of the relationship. A triangle at the top of an unlabeled line denotes a generalization (“is a” relationship) with the tip of the triangle pointing to the parent relationship. A filled diamond denotes a composition. The notation “0..*” denotes a zero-to-many relationship and “1..*” denotes a one-to-many relationship.

To elucidate how the Project-Data models can support analysis, consider the following motivating question: “Which broadening participation initiatives are employed in academic programs that have significantly higher student retention rates of female students?” In order to answer this question, it is necessary to have access to information about students and projects. Using the Project-Data model, it is possible to determine which projects have broadening participation activities based on how they are tagged and, through the investigators associated with the project, it is possible to determine the academic programs involved. The ORSP is the primary data source for proposals and their associated data. As described in Fig. 2, a *proposal* may be associated with 1 to many *projects*. A *project* is comprised of 1 to many *goals*. Each *goal* is comprised of 1 to many *objectives*. Each *objective* is comprised of 1 to many *activities*, and each *activity* has 1 to many *target audience(s)*. Knowing who participated in an activity through the course number or the participant list, for example, we can harvest relevant information about each individual from Banner and Goldmine.

A question such as “What are the differences in the PLTL approaches used in different departments?” could be partially answered through analysis of *artifacts*, e.g., *evaluation reports*, and *activities*. Through discussions with faculty involved, for example in a CoP centered on peer mentoring, a deeper understanding of the differences could be obtained.

D. Validation and Verification

Information captured during the investigation, analysis, and modeling phases were validated and verified by domain experts through meetings in which walkthroughs and inspections of the Project-Data models were conducted. Validation and verification is an on-going activity as part of our continuous quality improvement model.

E. Integration of Data and Information

As depicted in Fig. 1, the Project-Data models serve as the foundation for developing MetaShare, a metadata management system designed to facilitate collaborations among researchers by guiding the documentation of project activities, metadata, and provenance. Furthermore, MetaShare supports analytical processing for data discovery and knowledge inference. The models described in Section IV.C were used to identify three key components of MetaShare that document the projects as well as integrate data generated from different sources. *Project* is the highest level of abstraction at MetaShare. Each project consists of *Activity* that accomplishes one or more project goals. At the lowest level of abstraction, MetaShare manages information about the *Artifact* - resources used, transformed, or produced by an activity.

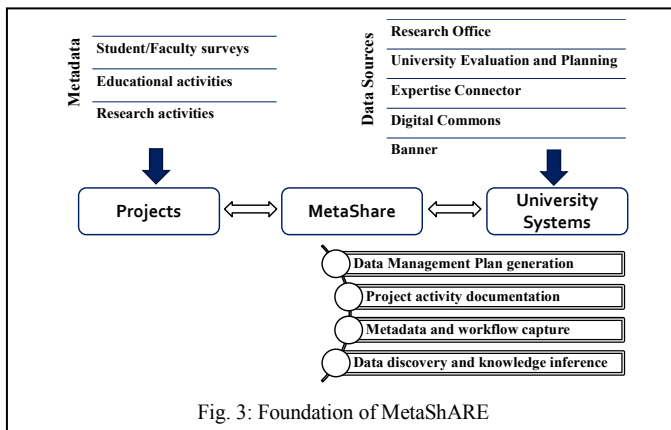

Fig. 3: Foundation of MetaShare

MetaShare connects to different data sources across campus as shown in Fig. 3, and it bridges the gap between projects and university systems. Currently, MetaShare connects with ORSP and DM. To facilitate data integration, MetaShare must map the attributes (fields) stored in different sources through a well-defined plan that includes standards and schemas to preserve semantic information. There are ongoing efforts [9], [10] to create standards to support data documentation and sharing, in particular with the requirement to define data management plans by many agencies. Most initiatives at the university, however, are rarely designed with the goal to share data. To address this challenge, the UTEP I³ project is working on a data-dependent, automatic mapping that takes the actual values of the fields to suggest a mapping

between data sources. Another challenge is the automatic identification of sensitive information that supports the process and policies related to data confidentiality. A successful integration of different sources will pave the path to generating effective set of queries that can help us answer the questions listed in Section IV.A. It will also help us to identify and recommend best practices for new initiatives.

V. SUMMARY AND PRELIMINARY RESULTS

To address the NSF’s I³ program goals, UTEP has defined the cyberinfrastructure that supports interactions among people through physical spaces, events that support in-person communication, and virtual collaborations supported by cyber-enhanced tools. In particular, UTEP has accomplished the following: the development of the Expertise Connector system to highlight expertise on campus, seed funds to support interdisciplinary research offered by the Provost’s Office, and an interdisciplinary (ID) network manager to support ID research and educational activities on campus hired by the Office of Research. The ID network manager also supports the development of Move Communities that operate as a CoP. The events for bringing researchers together have included the events sponsored by UTEP’s ORSP, such as the ID Research Symposium, Engagement Encounters, and Pop-Up meetings.

The UTEP I³ project team has identified the primary sources of data and information in support of student success initiatives at the University. Models have been created to illustrate the data and information that can be harvested and knowledge that can be derived from the primary data sources. The analysis of the models allowed us to determine what questions can be answered, identify the sources needed to access critical information, and detect potential areas for discovering new knowledge. The model has laid the foundation for developing a metadata management system, known as MetaShare, to support the ability of individuals to document relevant data, documents, and other artifacts derived from their efforts; generate data management plans; capture metadata and provenance; define workflows that elucidate how data was transformed; discover data/information and infer knowledge; and answer questions about student success.

VI. FUTURE WORK

The I³ project will be conducting two case studies in collaboration with CIERP. The first case study focuses on a large interdisciplinary research project that requires the integration and analysis of data from multiple sources. The questions center on trust and completeness. The second case study is centered on the Student Success Database managed by CIERP. As part of continuous quality improvement, the effort will include working with stakeholders to further refine the Project-Data models. We plan to evaluate the completeness of the models by developing a comprehensive set of questions and usage scenarios that are validated by stakeholders. We are also expanding the functionalities offered by MetaShare and extending MetaShare to incorporate semantic web technologies that support trust.

ACKNOWLEDGMENT

This work is supported by NSF grant HRD #1242122 awarded to CREST-funded Cyber-ShARE Center of Excellence at the University of Texas at El Paso and NSF grant DUE #0963648.

Defining Moments:

The Link Between Definitions of Teaching and the Desire to Teach

Yevgeniya V. Zastavker, Jeremy M. Goodman, Rebecca J. Christianson

Olin College of Engineering

Needham, MA

yevgeniya.zastavker@olin.edu

Abstract— In response to the well documented lack of highly qualified STEM educators in the United States, this work seeks to understand how to increase interest in K-12 STEM teaching among engineering students. This paper presents a preliminary framework and findings exploring factors that motivate the choice of a teaching career among the alumni of a small engineering college. In particular, it focuses on the relationship between the ways in which study participants defined “teaching” and “teacher” and their post-graduate interests and pursuits. Fourteen subjects participated in semi-structured, open-ended interviews designed to elicit an understanding of their definitions of teaching as well as the experiences and influences that shaped those definitions. Preliminary analysis suggests that participants with very narrow views of teaching and learning are averse to teaching, while those with broader definitions are likelier to engage in teaching, teaching-related careers, or consider them in the future.

Keywords—*Recruitment of STEM Teachers, Definition of Teaching, Teacher Motivation*

I. INTRODUCTION

In 2013, the US Department of Education released the results of the most recent administration of the Programme for International Student Assessment (PISA), which compared the performance of 15 year olds in mathematics, science, and reading in 65 education systems around the world. US performance showed no measurable increase from previous administrations of the assessment. Only 9% of US students performed at the top level in mathematics and only 7% in science, both of which are below the average national performance at this level among all countries taking part in the assessment. These results are also well below the performance of students in countries such as Singapore, China and Japan [1]. At the college level, the proportion of bachelor's degrees awarded in the science, technology, engineering and mathematics (STEM) disciplines is half that awarded in China and Japan [2-5]. Coupled together, the poor performance of K-12 students in STEM subjects and the lack of STEM college graduates adversely affect not only the supply of highly qualified employees in the growing technological market, but also the supply of future teachers, which compounds the cycle of poor performance in this area [2-7].

Despite increasing focus and attention on STEM subjects through the Next Generation Science Standards, the Common Core State Standards Initiative and state-level initiatives, there are not enough well qualified K-12 teachers to supply even

existing curricula, let alone support the reform and expansion of STEM education [1]. In a stark illustration of the problem, the National Taskforce on Teacher Education in Physics has concluded that less than half of the nation's physics and chemistry teachers hold degrees in those fields [6]. Yet even with White House calls for recruiting 100,000 new STEM teachers over the next decade, little progress has been made and little guidance is available for developing solutions to this problem [8-9].

In this paper we posit that understanding the development and evolution of undergraduate students' interest in and identification with teaching is a necessary first step toward designing and implementing new strategies for the recruitment of STEM college graduates into the teaching profession. Existing literature has sought to understand the retrospective motivations for in-service or in-training teachers [10-16]. Recently, a number of studies exploring graduate teaching assistants' identities vis-à-vis future teaching careers have added important insights into the educational landscape [17,18]. None, however, specifically address the development of initial motivation among engineering college students to enter the teaching profession in the STEM disciplines [10-18]. Understanding the experiences that underlie motivation and subsequent identification with teaching is a critical next step in learning how to build the STEM education workforce.

This work-in-progress paper seeks to characterize engineering graduates' construction of teaching as a profession as well as their interest in and/or actual pursuit of employment in education. This study is performed at a small undergraduate engineering school, which for the purposes of this work we refer to as Celadon College. Celadon offers only engineering degrees, embeds project-based learning throughout the curriculum, and has no formal K-12 teacher preparation program (see [19] for further description of the College). Despite this, our previous work indicates that Celadon's students are highly engaged with issues of teaching and learning. Celadon students and alumni demonstrate interest in teaching careers or enter teaching careers at a rate that is over double national averages for engineering graduates. Moreover, they participate nearly uniformly in informal peer teaching experiences, and exhibit a high level of pedagogical awareness [19].

II. METHODS

A part of a larger descriptive mixed-methods study, this work utilized a semi-structured, open-ended interview protocol

that was administered to fourteen participants who received their bachelor's degrees at Celadon between 2006 and 2014. The goal of the interview protocol was to allow study participants to reflect on defining moments in their undergraduate and pre-college careers that shaped their current understanding of teaching, the role of the teacher, and the process of teaching and learning. Participants were particularly encouraged to reflect on memorable anecdotes and personal influences throughout the interview.

Maximum variation purposive selection was used to sample from the respondents of our initial study to represent diverse graduation years, gender, and a broad variety of post-graduate experiences, including both teachers and non-teachers [20]. Most interviews were conducted via phone or Skype, with one interview conducted in person. Audio was digitally recorded for each interview and transcribed for further analysis.

Data was coded for important categories and themes [21-23]. Descriptive and analytical memos were then written to support the process of identifying emergent themes [24]. This preliminary work will be followed up with multiple layers of coding using the constant comparative method. Narrative summaries around further honed emergent themes will be used to form thematic matrices, with which to perform within- and across-case comparisons and as starting stages for an emergent theoretical framework [25].

III. PRELIMINARY RESULTS AND DISCUSSION

Preliminary findings indicate that how broadly graduates define teaching or what it means to be a teacher relates to their interest in becoming a teacher and engaging in teaching as a long-term pursuit. In what follows we describe how study participants discursively construct their own teaching identities through a carefully scaffolded inquiry about who a teacher (and a learner) may be and what rights and responsibilities a teacher (and a learner) may have. To date, we have identified a continuum, spanned by three broad categories, which describe how engineering graduates position themselves to act in relation to teaching within their ever-evolving individual story lines. We define those categories as *acknowledging differentiators*; *acknowledging experimenters*; and *active integrators*.

A. Acknowledging Differentiators

Acknowledging differentiators' definition of teaching greatly transforms and fluctuates throughout their interviews. Starting with a relatively rigid description of a teacher as an authority figure who "imparts knowledge or skills" to their students, *acknowledging differentiators* shift to a portrayal of their most memorable learning moments and construct a different situational interpretation of who a teacher may be. The two definitions are usually incongruent with one another. Therefore, *acknowledging differentiators* position themselves and their attributes with respect to these two definitions in a way that allows them to discursively justify their lack of interest in pursuing teaching as a career.

A typical example of how such a story line may develop is that of Shawn, a 2008 Celadon graduate and currently a Ph.D. student in civil engineering, who previously "spent five years as a sustainability consultant ... working with mostly Fortune

500 companies' sustainability departments to help them understand where the environmental impact of their products was and how they might improve that." Shawn originally defined teaching as an act of "convey[ing] information to somebody else in order to impart knowledge or skill to them that they can repeat." This definition seemed to align with Shawn's recollection of a time when he felt like a teacher,

... certainly many times in my role at the previous company where I was helping mentor new employees, sort of bring them on board and up to speed ... I've done a lot of workshops with clients on life-cycle assessment, sort of teaching them about the basics of life-cycle assessment and life-cycle thinking. ... so, it's sort of trying to convey that, um, that, like, insight or mindset or, like, perspective to somebody.

Throughout the interview Shawn continued to reformulate learning and teaching, subject to specific experiences or learning episodes he shared in response to the interviewer questions,

... coming from high school, where it was very lecture and theory based, going to Celadon, where it was very project based, particularly in the first year it was a very big shift in mindset to actually being able to, like, build stuff and do stuff rather than just memorizing things... I think that was certainly a very pivotal experience for me understanding what learning was and what teaching could be.

As a specific example of this "shift in mindset," Shawn recalled a time when his Celadon instructors responded to his question by "cryptically say[ing], 'I don't know. You should go try it out'." Although Shawn described this experience as "extremely frustrating," he also acknowledged it to be interesting and "probably helpful for building the sort of skills needed to explore something independently." It is this particular experience that allowed Shawn to articulate a drastically different role that an instructor may take, that of "creating an environment conducive to learning" where the skills to acquire and hone are "diagnosing and synthesis, creating new hypotheses, and ... the creative exploration."

This reevaluation of teaching and learning processes, however, seemed to diverge from Shawn's initial conceptions and, unable to find equilibrium between these two constructions, he reverted back to his original descriptions. At first, Shawn restored his definition of a learner,

I think it, it depends on which side of receiving of learning I'm on, like, the, the teacher, um, if you will, or the instructor, may be more interested in creating sort of a learning experience than in that imparting of knowledge. Um, whereas the instructee may be more aware of the teaching per se rather than the sort of creating something that's ripe for self-exploration...

Later in the interview, Shawn's characterization of teaching/teacher also recrudesced when, in response to a question about a time when he helped others learn, he

explained his role as a team leader on a human-powered vehicle team as,

less as conveying knowledge, and more about managing and collaborating. I just don't think of my role there as, um, teaching per se. Um, whereas at work, it was much more...like, there were sort of sets of skills that needed to be conveyed to student...

It is clear that Shawn attempted to discursively make sense of his experiences and rationalize his identity as a teacher vis-à-vis his old and new definitions of teaching and learning. Despite the evidence of the effectiveness of the newly outlined teaching and learning processes and the excitement about “teaching [the] stuff [he is] passionate about,” Shawn was unable to reconcile the two definitions. As a result, some of the characteristics that persisted in Shawn’s final construction of teaching and learning processes were the presence of an authority figure with content/skill know-how, imparting of knowledge and skills, and rigidity in the process by which this imparting takes place: the same things that he found less than useful for his own learning processes. Finally, and importantly, Shawn did not identify teaching in its own right as impactful,

I think that creating something somewhat tactile ... at the end of the day and see an impact [of it] ... is fairly important for me. And so, I think that rather than teaching as a career, having that impact in the private sector and creating the types of teams and relationships that I really enjoyed in the past is probably how I'll pursue that.

Shawn was able to acknowledge alternative ways of teaching but differentiated those as being used by others, for others, and in other environments. As such, an *acknowledging differentiator*, Shawn never defined himself as a teacher; teaching is what he could do, but not what he wanted to do.

B. Acknowledging Experimenters

Acknowledging experimenters' definition of teaching also greatly evolves throughout their interviews. Unlike *acknowledging differentiators*, these study participants evolve along with their definitions and find their new identity as teachers. This identity, although yet un-lived and with no explicit plan of being enacted, seems to be welcomed by all *acknowledging experimenters*.

As an example of an *acknowledging experimenter's* trajectory, Steph, a 2014 Celadon bioengineering graduate, who was about to start her first job as a designer, began her interview by describing teaching as “the opportunity to impart information on someone or to multiple people.” She then continued to elaborate by explaining that

[teaching] is when someone or something demonstrates knowledge or a skill for someone or something else. But it can be a two-way street. ... it doesn't have to be a teacher and student. It doesn't have to be people. ... it could be, you know, one professor or it could be a learning experience from each other as a collaborative group.

In rapid succession, Steph proceeded to expand her interpretation of teaching as a responsibility to influence others and their belief systems,

I think you have a whole influence... it's more than just knowing something and being able to share it. It's also understanding that students have their own belief system already ...as a teacher you need to both, um, influence in ways you want to and understand that students may not perceive [your goals] in the way you want to.

Soon after, when recalling a time when she felt like a teacher, Steph’s interpretation of teaching matured to include a need to listen, empathize, and individualize students’ experiences, while also simultaneously being able to step back and allow for an adventure that is an organic part of a learning process,

putting myself in [students'] shoes and trying to really understand what they're experiencing and trying to figure out where are they stumbling, what's the challenge for them ... every student...or every team had different dynamics and different ways they were working that I had to cater to ... while being cognizant of their team dynamics and trying not to mess with that, because [it] was [their] adventure.

This nuanced description of teaching, followed with an account of how simultaneously exhausting and rewarding her teaching experiences have been, led Steph to a somewhat surprising admission,

'Wow, I really kind of want to teach design.' Which is the whole, like, 'Oh, crap, education's throwing a wrench in what I want to do. Maybe I'll actually be a teacher, I don't know.'

Although Steph began the interview by declaring that she will be doing design work in the immediate future, her long term plans consist of “hopefully in the future go[ing] back towards biomechanics.” Nowhere in this declaration did she include a desire to pursue teaching as a career; yet, Steph’s discursive exploration of teaching and learning allowed for a construction of a new teaching identity, something that may allow for changing career goals.

An *acknowledging experimenter*, Steph’s positioning vis-à-vis a teaching career is based on active experimentation with the craft of teaching during her undergraduate experience and allowing for an epistemological shift in regards to teaching as a rich and enriching endeavor.

C. Active Integrators

Active integrators define teaching and learning processes in the most nuanced and delicate way and place creation of an environment where learning can happen at the core of their definition. For example, Tricia, a 2013 graduate who just earned her Master’s Degree in Education from another institution and became certified to teach high school physics, described the endeavor of teaching in the following way,

it's designing an educational experience for students. ... it's about creating an environment and a set of

conditions in which students will learn. So, it means ... creating structures and supports and guidelines that help students get to where you want them to be but also where they want to be. ... as a teacher, you have to have some goals and objectives of your own, but also students need some amount of freedom to make their own choices.

Later in the interview, Tricia explained that providing students with choices affords them agency and motivation to learn.

Active integrators described their evolution as learners and evolution of their definitions of teaching and learning. They shared their exploration into what it means to be an effective teacher and, in the words of another study participant, concluded that “the focus should not be on teaching at all. ... it should be on learning [as] focusing on teaching tends to focus on what the teacher is doing instead of what is happening with the person who is learning” (Christine, Class of 2007).

Through their journeys and through actively integrating their new experiential and discursive constructions of teaching and learning processes into their practice of teaching, *active integrators* were able to grow into their new identity and develop as supporters of the learning experiences of others. It is not surprising therefore, that the *active integrator's* identity converged on teaching: “I am a teacher. That is my identity,” shared Tricia.

IV. IMPLICATIONS AND CONCLUSIONS

While this is a work in progress, the preliminary analysis has yielded a potentially useful framework for understanding the orientation toward teaching among recent graduates of a STEM program. As is evident in the description of *active integrators* above, those who have already pursued a teaching career have developed more sophisticated schemas of how teaching is defined, identified with teaching as a profession, and constructed their own teaching identity through their self-defined and self-directed preparation to enter the field. As this study progresses to deeper levels of analysis, the exploration of the continuum between those who have no interest and those who may or do have interest in teaching but have not acted on that interest, particularly *acknowledging differentiators* and *acknowledging experimenters*, may yield greater understanding of the experiences that shape one's interpretation of and affinity to teaching. What are the cognitive and motivational processes that form one's identification with teaching and identity as a teacher? What experiences and discourses in one's undergraduate STEM environment that may contribute to development of self-esteem, self-efficacy, self-consistency, and self-regulation to support interest in and/or actual pursuit of employment in education? Through careful analyses of these questions, it may be possible to create an educational environment that facilitates development of pedagogical awareness and construction of teaching-related identities. By doing so, we may be able to shift students' interest and motivation along this continuum and foster the likelihood that they enter a K-12 teaching profession.

ACKNOWLEDGMENTS

This work was supported in part by a grant from the National Science Foundation (DUE-1156832) and Olin College of Engineering Summer Faculty Grant Program. All opinions expressed are those of the authors and not necessarily those of the National Science Foundation. We would like to thank undergraduate students Cecelia Auerswald, Yun-Hsin Chen, Adam Coppola, Doyung Lee, Margaret Lidrbauch, and Anne LoVerso for their contributions to this work. We would also like to thank other members of the research group, Dr. Jonathan D. Stolk, Alex Dillon, and students Lilia Chan, Pinar Demetci, Nitya Dhanushkodi, Ryan Eggert, Aditi Joshi, Madeline Perry, Caz Nichols, Cesar Santana, Robert Siegel, and Sarah Walters.

Abstract—InnoEscuela is more than a learning experience, a programmed methodology to implement courses related to Technology and Computing which follows an innovative way of teaching. The methodology focuses on Project-based learning and team work. Students organize themselves in teams which are called innovative enterprises and they have to **decide** to create a solution to a social disadvantage, technical problem, or any other kind of need **they perceive**. That's why the core of the courses is focused to practice the whole Technological Innovation process.

Keywords—InnoEscuela; project-based learning; innovation; technology; computing; secondary; pre-engineering; innovative enterprise; student-centered teaching; motivation.

I. INTRODUCTION

Spanish Education System is structured very similarly to other countries. A first stage of primary education precedes the Compulsory Secondary Stage, where students are 12 to 16 year-old. It is at this stage of Secondary Education, where the educational curriculum offers a compulsory nature subject, Technology, focused on the study of materials, systems, devices, electrical and electronic circuits and programming. Course implementation is addressed by the Project Method and quite often teachers use an entire school year to implement this methodology to get students to make a practical device.

InnoEscuela program is specially designed to be directly applied in Technology as an added value to the current course for several reasons. First, students have to find a need or a problem in their surroundings and generate ideas to provide a solution. They have to decide to go for the most value added project. Second, the solution must correspond to a technical innovation thus requiring a stronger team effort. Finally, the program meets educational values such as to work as a team, to behave as an innovative enterprise, to be concerned about the people living in the students town, to take care of the natural environment and ultimately, to be able to overcome any difficulty and failure when performing the project which would prime them in the entrepreneurial and innovation spirit.

II. METHODOLOGICAL BACKGROUND

InnoEscuela is an educational program designed to join in the same context of technology discipline, the use of ICT, entrepreneurship and innovation in a real world practical work which is technically and economically feasible, sustainable and viable. Due to its novelty in bringing together so many different education aspects, the program is a real educational innovation in itself.

Teaching principles of the program are backed up in the Project method. According to traditional historiography, the project method idea is an original development of the American Progressive education movement. It was thought to have originally been introduced in 1908 as a new method of teaching agriculture, but educator Dr. William H. Kilpatrick [1], of the University of Columbia, elaborated the concept and popularized it worldwide in his famous article, "*The Project Method*" in 1918.

Kilpatrick identified in 1921 the term project to refer to “.... any unit of purposeful experience, any instance of purposeful activity where the dominating purpose, as an inner urge, fixes the aim of the action, guides its process, and furnishes its drive, its inner motivation.”, being, currently, the most accepted definition of PM, from a training and teaching standpoint.

Nowadays, knowledge management is more diverse and more complex, just as economical and financial market procedures, enterprise supervision or industrial and production management. In this way, since Kilpatrick, many authors [2] have contributed with educational publications improving project method execution and methodological actions. This is the case of L.J. Waks [3], the author of a brilliant work that relates project method to learning methodologies for the digital era. In his work, Waks reinvents the project method by addressing its scope through six elements that, according to a

sequence, will create a timeline of actions to consider when implementing it. Waks explains these elements sequences as follows: i) First project dealing in the group; ii) Determination of project situation in a social context, iii) Assessment of incident learning potential relative to learners' needs; iv) Needs evaluation of background knowledge; v) Scheduling of project tasks and; vi) Continuum project assessment and learning integration

The first and second elements determine the importance of learner participation while the other four offer a frame for a teacher to determine his or her role as an integration core between project and learners, extending his or her participation from identifying the needs of learners to the teaching of needed skills in order to facilitate the tasks to achieve the completion of the project.

III. AIM AND OBJECTIVES OF INNOESCUELA

InnoEscuela initial feature stands in its perfect adequacy to the subject of Technology and Computing, as it is conceived from the official curriculum. The methodology development is according to project-based learning, following the stages of problem solving. Thus, it requires no special didactical adaptation as it integrates in the work that is currently done in standard Technology classrooms. InnoEscuela is however contributing to educational innovation since students are the owners and responsible of their project, thus receiving additional values than those expected from conventional education. The first is the consideration of the technological innovation as one key compulsory specification for students to apply in the design of a Project, which might be focused as a social entity or an enterprise. The way to work will be conceptually similar to what those organizations usually do.

In addition, the way the program has been conceived tries that students' work with a blended methodology which includes several educational resources such as interdisciplinary character, Project based learning process, Self-directed learning techniques and Resources-aided learning

IV. THE ROLE OF THE TEACHER IN THE PROGRAM

As mentioned above, the way to teach young students will not follow a pedagogical path in the same way as it's currently done, as teacher's behavior might have to change from considering the content the most important. At InnoEscuela, program teachers are required to stop being the main access point to knowledge and information. Teachers background at InnoEscuela optimally also includes some knowledge of how enterprises or organizations carry out their innovation projects. Teachers play a significant role as knowledge managers and drivers, simultaneously with their responsibility to provide students with knowledge as a tool. As students are in charge of acquiring and collecting the information from different sources, teachers must behave as a guide providing the proper observations in order to drive students through the best data sources and advising them with the best ways to use the data.

This does not mean that teachers interact with students in a passive way. Actually, at InnoEscuela teachers are the core of all the activities involved in the processes to achieve the objectives, helping to prepare the plan through which the student will carry out the sequence of steps. As a guide, teachers will determine what's called the "*moments of learning*", discrete times in which the team must hold a meeting to read, select, calculate, just to understand certain information items, receive a brief lesson to cover some knowledge need from the teacher, etc. In order to determine the functional structure of the teaching-learning process and the role teachers have to play, the five moments of learning model [5] has been implemented. The model fits to a scenario in which teachers are responsible of planning the times when these moments of learning can be triggered. The nature and features of each one are, as defined by Mosher and Gottfredson:

1. **Moment of learning #1: First learning.** Every time a new knowledge appears, teachers will become an instructor. The instructions can be offered as an explanation of new contents or could appear when students are doing information searches. The latter is more difficult to detect except if the teacher has given to students the proper guidance to find the information.
2. **Moment of learning #2: Deeping Learning.** The first approach to knowledge has been completed and, the understanding channel of a specific contents is open. This is the time at which, students are able to develop new comprehensive strategies by themselves, once a new conceptual scheme is understood. Students are also able to deepen in the contents being still guided by teacher's explanations.
3. **Moment of learning #3: Remembering or applying what's learnt.** The learning scheme is done and the concept has been acquired. Contents are available to be applied in a practical way and students are able to reproduce the meaning of the contents.
4. **Moment of learning #4: Learn when things change.** Change is something that the human mind is used to. In fact, to deal with changes, nature has provided us with coping mechanisms. At the time a change occurs, a measurable parameter is the speed of response from the teams. Subsequently, the adaptation will require new ways to perform in order to follow with the project. They could be new calculations or even, new requirement definitions.
5. **Moment of learning #5: Learn when things go wrong.** When something goes wrong at the implementation step, it means that some aspects have not been considered at all in the previous definition process. This means that in the design or productive stages, some concepts or ideas were missing. In this case, learning is divided into two phases. First is to find out the cause that induced an improper work by weighing several diagnosis alternatives for figuring it out. Second phase will starts when the error reason has been understood. Then a feedback to solve the situation will be to generate.

These circumstances won't appear just once in the whole process of the Project making. Most likely, they are expected to appear quite often. Now is when the profile of the teacher as a guide will be more important. Gallagher et al [8] defined the role of the teacher in a project environment as "*instead of being experts or didactic instructors, they become meta-cognitive coaches*", in close reference to the guidance role. As knowledge facilitators, teachers induce students to think about their own thinking when being exposed to the problems that a project contains.

From students' standpoint, instructions are received and provided by the teacher when a moment of learning appears and this can be considered as a kind of discrete driven learning. In fact, students are the contributors in every stage of the working process. They assume any technical problem, they give certain solutions and select the proper ones, and they create the suitable documentation to convert the idea into a planned development. The idea is discussed and improved to finally be implemented. This requires a previous knowledge of the materials and tools to handle.

This simple proposal allows obtaining some other benefits beyond the mere team work, like the destruction of barriers that society tries to impose about the gender. From a traditional standpoint, some tasks are associated to males and some others to females. In InnoEscuela, this separation does not exist given that the starting point is the equality of capabilities no matter the gender, leaving out any kind of prejudice.

Given how wide technological knowledge source is, InnoEscuela provides a feedback to other subjects in the same way it needs other subjects' knowledge as part of the instructional source. Cross-curricular environment does reinforce global learning as an additional benefit.

V. ORGANIZATION AND IMPLEMENTATION

InnoEscuela has been designed as a Technology and Computing subjects program and is split into different years: a first course for 12-14 year-old students, a second course for 14-15 year-old students in coincidence with 3rd degree of Spanish Secondary Compulsory Stage, and a final course for those students in the previous year to access to Baccalaureate stage. Independently from the different focus and level of difficulty of each course, four phases are common in the development of the three courses as represented in Figure 1.

Fig. 1. Key blocks applied throughout a year program

In the first common phase, design of the innovative idea, the team is constituted as an innovative enterprise and the students draw the work to develop throughout the year, taking inspiration from the needs that they perceive from the environment surrounding them and making up their mind to the most potentially valuable proposal as an enterprise. In the second and third common phases, students will prepare the planning and will build the innovative idea prototype, assuming quality assurance policies keeping in mind the potential customers/users of the final product. Finally, students will develop a product launch that consists in the design of advertising campaigns and other actions to show to other people their product and convince them to use it.

Since InnoEscuela is sensitive to young students' own ideas, a culture of protection of innovations is promoted in the program through workshop modules and the writing of a simulated patent application document. In this way, the Spanish Patent and Trademarks Office [12] is collaborating with InnoEscuela in the development and design of industrial and intellectual protection material adapted to the different age of our students.

VI. INNOESCUELA RESOURCES: INTERACTION FOR STUDENTS AND TEACHERS

In each course, InnoEscuela provides a series of digital resources and educational materials available in a digital platform. These resources are free to be printed and copied, at the time students can use digital versions to work within the team. The educational materials available are:

1. Student notebook in each Secondary compulsory education course (12-14, 14-15 and 15-16 year-old), in Spanish as well as in English. A composition of the covers of the three notebooks is represented in Figure 2.
2. Teachers planning for each of the three courses, including didactical explanations and assistance, pedagogical and technical recommendations and descriptions of the external resources, to let them behave as a program facilitator with their students.
3. Didactical workshops for each course. Some specific knowledge pills are provided in the way of electronic presentations in order to introduce new knowledge and to make possible a continuous progress. Some of them are the Innovation workshop, the Industrial and Intellectual Property workshop, Web programming workshop, Arduino workshop, etc..
4. Workshops self-assessment activities

Fig. 2. Covers of the students notebooks

To access to the digital resources, a web page has been created at <http://www.innoescuela.org>, also available by .com and .es domains. The web is also the way to access to the digital platform in order to facilitate:

- Access to teams/companies materials
- Communications among innovative enterprises with the teacher and with other enterprises
- Assessment of teams' activities
- Teacher control of how each enterprise progresses and its evaluation

One of the features of InnoEscuela Program is the progression of contents offered throughout the year courses in parallel with the contents of the subject of Technologies and ICT. The optimal scenario is the exploitation of the program since the first or second course (12-14 year-old). However, methodology allows new students' enrolment in the following courses or even teacher's discretion.

Physical spaces to be used in this program are the usual specific rooms where Technology and ICT students are working in, such as group classroom and Technology workshop or computers room. Teachers will be free to decide how to use these spaces depending on their criteria, the needs of the Technology and ICT department or the restraints given a multiple use by several groups.

VII. THE EVOLUTION OF INNOESCUELA THROUGHOUT THE SCHOOL YEAR: STEPS FROM THE IDEA TO THE IMPLEMENTATION

Students start to work in InnoEscuela at the beginning of Secondary school which involves a change to unknown contents and organization from the Primary (Elementary) school. In Primary school, they are used to deal with already defined contents while in Secondary school they will have to improve their skills and abilities in order to become competent in several areas of knowledge. InnoEscuela has been developed to guide students in the acquisitions of mainly technical skills but also about economics, organization, innovation, linguistic, mathematical, communication and marketing. InnoEscuela intends to prime in them curiosity to find out how things work through the observation of their environment surrounding them, and what needs do they find that might be covered. Observations and ideas must be however guided and assisted by the teacher, as it's quite possible for teams to become mind-blocked or they might propose not feasible enough solutions.

Student teams, incorporated as innovative enterprises, are acquiring concepts about Innovation and Company Organization from the beginning in order to be used in the problem solving process through finding their environment's needs. InnoEscuela will guide them throughout the process to include any type of innovative idea in their project to build a prototype, which will be quality-controlled, promoted and protected under an InnoEscuela-type patent document quite close to the official one of the Spanish Patent Office. The

contents for the 12-14 year-old students (1st-2nd degree) will guide students through the following steps or chapters:

1. *The innovative enterprise*
2. *Our Innovation*
3. *We select and develop the innovative idea*
4. *Preparing the manufacture of our innovative project*
5. *We promote our innovation*
6. *Protecting out innovative idea*

14-15 year-old students (3rd degree) are characterized by having developed basic skills and having acquired enough knowledge to face electro-mechanical projects. Besides, their skills in motor technology are quite mature and their abilities have been improved to face projects that require both intellectual efforts and practical implementation.

Thus, InnoEscuela program proposes a new challenge by incorporating electronics in their innovative projects. In this third course, new didactic workshops will be learnt and a more professional focus is applied since new knowledge is provided: planning the building of the project and promoting their innovative idea, object or system by programming a web site. Students will be developing teamwork by the following sequence of chapters in 3rd degree:

1. *The innovative enterprise*
2. *Our Innovation*
3. *Selecting and developing the innovative idea*
4. *We plan our innovative project*
5. *Putting into practice our works quality control*
6. *We design our web page*
7. *We protect our idea*

InnoEscuela provided methodology could be just applied once in one course or could be deployed into the four Compulsory Secondary education courses. We recommend the latter option as continuous work for several years enhances the innovation and entrepreneurship abilities and skills, reaching its highest level in 4th degree (15-16 year-old). The focus in this course maintains the simulation of working as a company, but slightly modifies the way to apply Innovation.

This course has a multifaceted approach that encourages business action towards research and development of innovative products using modern technologies such as using Arduino as an essential part of the project, accessing to Remote Labs in order to experience research simulations, preparing a business plan to address the mass production of the innovative device and deepening their knowledge of computer tools. This work plan in 4th degree will have the following sections:

1. *Introduction to research*
2. *Founding our innovative enterprise*
3. *We train as researchers to qualify for Innovation*

4. *We develop the design of our innovative product with Arduino*
5. *We build the designed innovative product*
6. *Spreading our innovative product in the web*
7. *We do our business plan*
8. *Can we protect our innovative product?*

As it can be observed, the course will start with works related to research activities as a new way to implement the teaching format of “*Learning by doing*” prior to the making of the innovative project. Once the product or Arduino-based system has been designed, students’ team/company has to assign responsibilities to members in order to simultaneously work with the innovations hardware implementation and the programming of the device according to the design specifications. In figure 3, a part of the team is working in the making of the external aspect of the innovation while the other members (Figure 4) are programming Arduino board using any of the Arduino programming development tools such as Arduino IDE, Scratch for Arduino (S4A) [7] or Visualino[8]. A second option selected by some other teams has been the use of Scratch for Arduino (S4A) as the preferred interface to develop the program of the innovative system.

Fig. 3. A moment of the hardware implementation of a team project

Fig. 4. Plants growing surveillance students project by using Arduino control system

VIII. A DIGITAL ENVIRONMENT FOR EDUCATIONAL PURPOSES: INNOESCUELA DIGITAL PLATFORM

InnoEscuela Digital Environment (IDE) is an additional resource implemented for those teachers who prefer to use electronic documentation instead of the students’ InnoEscuela

notebook to write in it. It has been developed through Moodle environment. Each team/company notebook has been digitally created with edition possibilities. At InnoEscuela we recommend to use the electronic version of documents to be able to upload them to IDE. Teachers are granted with a specific teacher user’s password to access to any documents from their students innovative enterprises in order to complete the evaluation, assessment and communication with them.

IDE has also been developed to provide asynchronous communication between teachers and their students innovative enterprises as well as among these enterprises themselves.

Fig. 5. A team programming and setting up Arduino firmware

Available to teachers is an optimal assessment tool and also a guide to follow the progress of their students. The main IDE features are represented in figure 5, and the 1st/2nd course (12-14 year-old) specific aspect of IDE is in figure 7.

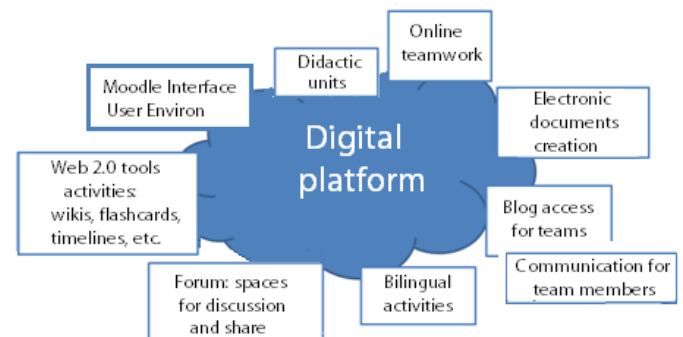

Fig. 6. Main features in the digital environ

To understand and get familiar with IDE, a user’s guide documentation has been created which is freely available to everyone, either current teachers or anybody interested in participating in the program.

With these assumptions, one of InnoEscuela development Partners, the Department of Electrical Engineering, Electronics and Control from Spanish University of Distance Education UNED, has developed the IDE as an e-learning application that responds to the needs described above.

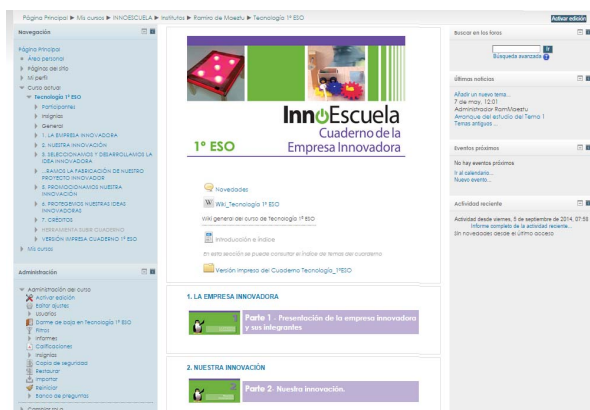

Fig. 7. Aspect of the IDE interface for 1st /2nd courses students

A review of existing e-learning platforms was performed. First approach was to know which type would fit better the needs of InnoEscuela program. As a final result, the application was developed as an e-learning platform whose main features are described as follows:

- Type of environment: **Moodle version 2.6**
- Operating system: **Windows Server 2008**
- Web support and Database Management System: **Suite Wamp 2.4**

Windows Server 2008 machine has been implemented on a virtual server with VMware technology. The main reason for this decision is motivated by two aspects. Firstly, the variable number of High Schools and Colleges expected to host in the environment and secondly, an expected large number of platform users working discontinuously will alternate periods of high usage with others of low utilization, requiring a robust behavior.

Based on these reasons, the use of a virtual machine is indicated to allow the variation of the main resources (processors, RAM, hard drives, etc.) in active work mode, avoiding to stop the services and being able to adapt to different IDE usage periods. In figures 8 and 9, some graphics of the performance of the virtual machine are represented. It can be observed that the virtual machine is suitably working according to the normal functions, which show that hardware is not a performance limitation.

Fig. 8. CPU performance of the virtual machine that supports the application

Fig. 9. Memory performance of the virtual machine that supports the application

When writtin this document, the IDE production stage is developed as follows:

- Number of courses = 54
- Number of users = 159
- Number of roles assignments = 155
- Number of messages in communication channels = 29
- Number of questions among users = 53
- Number of available resources = 364
- Average number of simultaneous participants = 2.71

A system of templates has been configured in order to create new courses and new categories when needed. Four profile categories have been created in the IDE, as represented in figure 10. Administrator is the highest entity in the IDE and is able to control any aspect of the Moodle environment which gives support to the application. The second level is the profile "Teachers" with complete capabilities to edit courses in which they are authorized to work and to create new courses inside the category.

Fig. 10. Existing profiles in the application

At the bottom level, non-edition permission have been created for the access of Teachers and Innovative Enterprises who respectively will be guest lectures and students' teams. The rights of these two profiles are restricted to access to the courses in user's mode which includes downloading and uploading teams/companies documentation and activities, downloading of didactic workshops, qualifications display and access to communication channels.

A thematical development of the courses has been implemented in the IDE following the same InnoEscuela

organization desing as from notebooks, being variable depending on the course. Each of the stages or parts of each course are shown individually paged.

Hierarchized categories structure have been created (figure 11) from a first split into High Schools and Colleges to the activities at the lowest entity item.

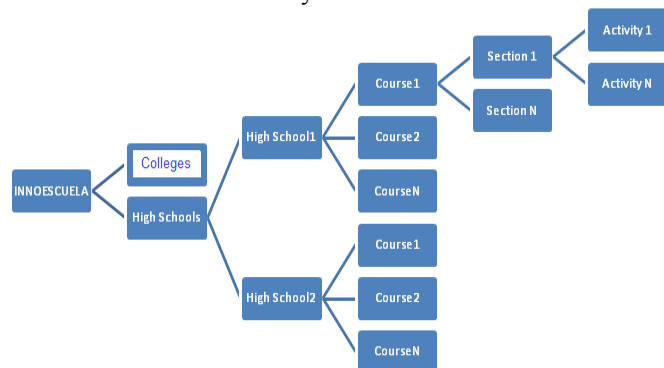

Fig. 11. Structure and categories in InnoEscuela application

The InnoEscuela Environment Development provides several capabilities according to the user's profile. The most significant are:

Access to IDE as an innovative enterprise:

- Access to the activities of downloadable content in each section of courses (Notebook and Workshops)
- Access to parts of the notebook that contain activities to be delivered to teacher
- Access knowledge tests applications (self-assessment tests)
- Access to general forums and specific course sections
- Access to Blogs and Wiki spaces by course
- Notification area, calendar per course and activity reports
- Internal messaging system, warning system events
- Access to Area profile settings to particularize their appearance and operation in the IDE
- Access to report of assessment scores and degrees in the courses where the team is involved.

Access to IDE as Teacher:

- Access to the activities of downloadable content in each section of courses (Notebook and Workshops) in edition mode in order to change aspects and contents.
- Creation of new topics in the events system and uploading of the activities schedule
- Wiki control in each course
- Deliveries assessment and control
- Edition of the evaluation system in each course
- Control of the attendance process of users
- Users groups control
- Display of permissions and control of his /her innovative enterprises
- Uploading of new courses and courses backup and restore.

IX. STUDENTS' EVALUATION AND ASSESSMENT

InnoEscuela is a program conceived under the premise of the active and permanent making of activities and tasks with a methodological design based on a sequence, that consists of starting a new task just when the previous task has been finished. Thus, the program will consider a type of continuous assessment of the activities developed by students' innovative enterprises.

Assessment will be applied through two areas:

- **Innovative enterprise scope.** It's recommended the use of the assessment plan provided in which evaluation criteria and assessment methods are identified.
- **Student personal scope:** Teachers may use as many assessment tools as they consider appropriate in order to assess the progress of the student in each of the stages according to their scope in each of the terms. Personal assessment of each student is recommended according to his/her progression as basic skills and competences [9] as described by UNESCO education programs, for which a specific section has been provided. Assessment and evaluation has been developed according key competences [10, 11], according to European Commission education policies and these have been also divided into sub-competencies and beyond, extended in specific descriptors. According to this assessment methodology, evaluation will be carried out and by extension, qualifications and grades.

According to the qualification system provided in InnoEscuela and available through the IDE, each teacher might decide the weight assigned to each task contained in each stage. However, a certain weight has been given as default for these assessment elements. A graphical layout of the qualification process has been represented in figure 12.

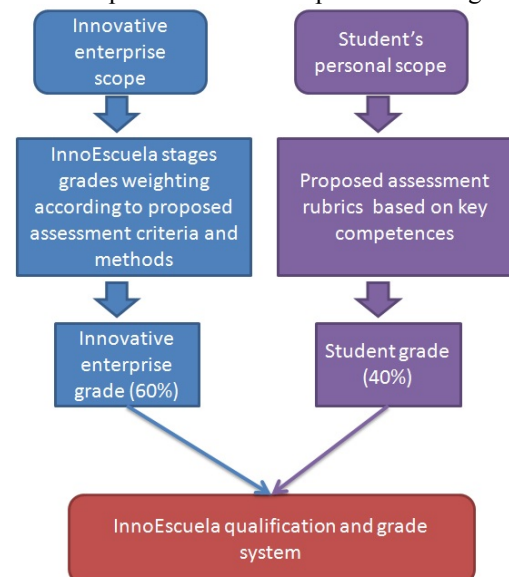

Fig. 12. Structure and categories in InnoEscuela application

It is recommended to apply a 60% of the final score to the innovative enterprise scope and a 40% to student's personal scope. Final score is left to teacher's discretion since he/she is the closest person to the subject. This means that the teacher will be able to determine the degree of scoring to apply to each InnoEscuela aspects and scopes, such as teaching of theoretical contents of the subject, use of Information and Communication Technologies, specific attitudes to face the work, use of English or Spanish as linguistic vehicle in order to make descriptions, evaluation of students' attitudes in the team and towards teamwork, etc.

Definitively, the application includes a delivery system to allow students upload the parts of the documentation for teacher to be able to correct and qualify the contents.

X. SOME PRELIMINARY DATA ABOUT STUDENTS' DEVELOPMENT

InnoEscuela is been applied for the first time in the 2014-2015 course. A number of 20 teachers of the Spanish territory are teaching Technology and ICT following the InnoEscuela program with almost 1,000 students aged from 12 to 16 year-old. At the moment of writing this communication, school year hasn't still finished and final scores haven't been graded.

However, in the past four year-courses, a pilot program has been carried out following the basis of InnoEscuela program. In this pilot experiences, some groups have been taught with the innovative methodology and have been compared with other students' groups who haven't applied the program. The evaluation of the pilot program has led us to design and create InnoEscuela since two main outcomes have been measured: an important improvement in final course average marks of 10% to 30%; and a great qualitative improvement in satisfaction and motivation in both teachers and students involved.

XI. CONCLUSIONS

InnoEscuela has been introduced as a program but also as a multiple source learning methodology to complement conventional teaching activities in courses related to Technology and Computing. InnoEscuela intends to contribute to technological innovation through a specific methodology that focuses on Project-based learning and team work. Students are organized in teams which are called innovative enterprises and they have to create a solution to a social disadvantage, a technical problem, or any other kind of need, with an only restraint: ideas to implement must content an innovation.

We, InnoEscuela creators, are proud of the final product and preliminar results since students recognize to learn more motivated, being crucial the ownership spirit of each creating team/company. Teachers involved in the program consider a

good proposal to transform the role of teacher from one conventional instruction-type to another that can be described as a guide or a facilitator of knowledge. The assumption of this new role permits to change the performance and efficiency of the teacher in class since he/she pay more attention to students development.

Acknowledgment

The authors would like to acknowledge the Spanish Education, Culture and Sports Ministry, in special to CNIIE to support InnoEscuela program, as well as to Cotec Foundation for Technological Innovation. We also thank to the Spanish Patent Office (OEPM) for the knowledge support and their collaboration in the program.

Arts & Bots: Application and Outcomes of a Secondary School Robotics Program

Jennifer L. Cross, Emily Hamner, Chris Bartley and Illah Nourbakhsh

Robotics Institute
Carnegie Mellon University
Pittsburgh, PA, United States
jlcross@cmu.edu

Abstract—Arts & Bots combines intrinsically creative craft materials, common robotics components, a custom programming environment and teacher professional development to create a flexible robotics intervention for secondary school classrooms. In order to engage students underserved by other robotics programs, Arts & Bots is oriented to support the creation of collaborative expression-focused robots, as opposed to more commonly implemented competitive task-focused robot activities. Specifically, Arts & Bots targets integration into traditional non-technical classes, such as literature and history, to reach a broader base of students than would be enrolled in elective technology programs. This paper describes three classroom implementations, including a secondary school poetry project. By including Arts & Bots in these core courses, we expose diverse students to engineering education activities such as hands-on experiences with computer programming, prototyping, and the engineering design process. We present our outcomes grouped within two primary themes: first, in Technological Fluency, we present students' self-reporting of concepts learned, confidence with technology, and breaking of technology stereotypes; second, in Complementary Non-Technical Skills, we present other skills students learned by participating in the Arts & Bots program.

Keywords—educational robotics; interdisciplinary education; technological fluency; secondary school engineering

I. INTRODUCTION

The diversity of new technological inventions is greatly affected by the creativity and background of technology developers. Considering the underrepresentation of women and minorities in STEM careers, it is evident that society is inadequately utilizing the creative capacities and diverse experiences that such underrepresented groups could contribute. In order to attract a wider diversity of students to pursue advanced training and careers in engineering, it is critical that students have pre-college experiences that allow them to practice engineering and help them to develop technological fluency.

Technological fluency is the ability to manipulate technology creatively and for one's own use; an idea espoused by our research [1] among many others [2] [3] [4] [5]. It is important to provide opportunities to develop technological

fluency to all students, yet the current practice of pre-college engineering education frequently limits engagement with engineering to a narrow population. In secondary school, engineering-focused extracurriculars often utilize high-intensity, contest-driven challenges as motivational hooks for students inspired by competition [6] [7]. Engineering and technology classes in secondary schools are usually offered as elective classes for students with pre-existing interest in engineering and technology. Unfortunately, these current approaches fail to reach students who are unmotivated by competitions or are uninterested in technology for its own sake.

Our intervention, Arts & Bots is aimed to engage a more diverse population of students, including those unmotivated or uninterested in existing technology interventions, in engineering practice. We look to achieve this through a robotics program that is focused on expression and communication over competition and that provides a non-technology context for technology use. The robot hardware kit, which is the basis for Arts & Bots, is designed to promote expressivity by combining intrinsically creative and gender neutral arts and crafts materials with commonly used robotics and technology components. Through programs like Arts & Bots, we believe it is possible to encourage a different style of student engagement than the status quo for secondary school engineering education and thus possible to attract a more diverse population of students to engineering careers.

II. ARTS & BOTS OVERVIEW

The Arts & Bots program started in 2006 with the goal of exploring the educational impact of expression-focused technology experiences. The Arts & Bots program initially began as an extracurricular intervention which aimed to diversify the Computer Science pipeline by engaging 11 to 14 year old girls [8] [9] [1]. At that time, others were also developing similar extracurricular programs for engaging students who were not interested in traditional robotics programs and competitions, by providing connections to robotics through creative interests, like music, art, and storytelling [10].

Following our initial implementation phase as an extracurricular program, we transformed Arts & Bots into an in-school intervention in order to reduce participant self-selection. By designing the Arts & Bots kit to enable craft-based building followed by choreographic programming, we

This material is based upon work supported by the National Science Foundation Graduate Research Fellowship under Grant No. (0946825) and the NSF Broadening Participation in Computing program under Grant No. (0940412). This work was supported in part by a Graduate Training Grant awarded to Carnegie Mellon University by the Department of Education (#R305B090023).

Fig. 1. Student built robots, from left to right, robot theater (I Know Why the Caged Bird Sings by Maya Angelou), arm model, and historical figure (Alexander the Great).

connected technological fluency to arts education, which is well-regarded and supported in school systems and by students who may not have strong prior experience with electronics. We focused efforts on integration with non-technical, core courses in order to engage students in engineering and programming practice who would otherwise avoid enrolling in a technical elective course or extracurricular activity.

The Arts & Bots hardware kit includes a large number of aesthetically-oriented outputs including DC motors, hobby servos, and tri-color LEDs along with various interaction-promoting sensors including IR distance, light, and sound level sensors. Craft materials are chosen by the educator to suit her desired project. By implementing affordances for sound, lights, and choreography, we enable Arts & Bots to be flexibly integrated into secondary school topics such as poetry. Additionally professional development training on Arts & Bots has repeatedly enabled teachers in such non-technological disciplines to directly implement Arts & Bots as expressive elements of their student assignments [11], enabling the summative evaluation of student attitudes and student knowledge gains as reported in this article. While prior publications have concentrated on the iterative participatory design of the Arts & Bots hardware [9] and software elements [12], this report focuses on the educational evaluation of Arts & Bots in 7th and 8th grade core disciplinary courses.

A. Arts & Bots Curriculum Examples

Through professional development, we train teachers to use the Arts & Bots hardware and software, and to develop their own project which integrates Arts & Bots with the goals of their discipline [11]. We provide three examples of this type of curricular project in different areas: poetry, health and history.

1) Poetry

The first example is a poetry project. Beginning in 2012, a small public, junior-senior high school began implementing Arts & Bots in their 7th and 8th grade Language Arts classes. In this class, teams of two to four students chose poems from a list preselected by the teacher for their vivid imagery. Over seven class days (roughly 14 contact hours), these students worked in groups to analyze the selected poem and design a robot theater (Fig. 1, left) which they build and program to represent their poem. Students recorded audio clips of themselves reading the poem and incorporated these clips into

the programs they wrote. The class was jointly instructed by the Language Arts and Gifted Support teachers.

2) Joints and the Musculoskeletal System

The second implementation example took place in a health and physical education class. Two 7th grade teachers taught Arts & Bots to a combined health and physical education class on joints and the musculoskeletal system beginning in 2014. Teams of students created models of human joints (Fig. 1, center) which they could “personalize” with clothing and accessories. Students chose a joint for their project: knee, shoulder, or elbow. Teachers provided a limited number and variety of materials with an emphasis on using recycling and recycled material. The project covered 15 class periods (roughly 12.5 contact hours).

3) Historical Figures

The last example is from a technology education teacher who implemented an Arts & Bots project with 7th grade students. The project was spread over the course of the school year (roughly 20 contact hours) beginning in 2010. The technology education teacher integrated content in history, English, science, and math classes that were co-taught with each content teacher respectively. Students selected a historical figure from a list provided by the history teacher (e.g., Hercules, Alexander the Great, Pharaoh Hatshepsut). In history class, the students researched the life of their chosen figure. In English class, students wrote a biography from the perspective of their individual. Finally, with support from the math and science teachers, students built robotic models of their historical figures (Fig. 1, right) and programmed them to act out the biography.

III. METHODS

A. Hypotheses

We wish to understand the ways in which creative robotics activities within a disciplinary context impact student learning, and in particular, how student technological fluency is affected by this inclusive approach to technology exposure. Technological fluency itself is governed by two factors: student attitudes toward technology, and student technical knowledge. Each form of change is insufficient by itself in catalyzing a shift in the overall student-technology relationship. Empowered attitudes are required for students to apply

knowledge. Knowledge is required for students to be effective in acting on their attitudes. Thus, we propose two specific hypotheses relating to enablers of student technological fluency:

1. Arts & Bots increases student grounding of technical knowledge and technical skills.
2. Arts & Bots increases student motivation and confidence to engage with technology.

In addition to fluency-centered hypotheses, an important goal for the Arts & Bots pilots stems from our desire support the technology of all students. We believe that the incorporation of creative robotics into disciplinary core courses has the capability to attract a more diverse student population to technology and, thus, to a pathway toward technological fluency. Our third hypothesis relates specifically to the nature of inclusiveness achieved with the Arts & Bots program:

3. Arts & Bots engages a broad demographic of participants, across gender and across prior technological exposure.

If these three hypotheses are supported by our evaluation, then we believe that Arts & Bots successfully meets the need for an intervention which improves the technological fluency of a broader population of students through a different style of student engagement than the current pre-college engineering education status quo.

B. Assessment Tools

We organized the evaluation of technological fluency into two primary surveys reflective of our hypotheses: Student Knowledge with Respect to Technology (Knowledge) and Student Attitudes with Respect to Technology (Attitudes). We also collected basic demographics information from students, including race, age, grade level and gender for addressing the broadening demographics hypothesis. Student learning and attitudes were assessed through pre and post surveys given to students before and after their Arts & Bots project respectively. A small subset of students was interviewed following completion of their Arts & Bots project.

1) Knowledge Survey

The Knowledge Survey consists of six short answer questions, nine multiple-choice hardware component questions phrased as analogies, six multiple choice software questions, and ten multiple choice systems engineering questions. The short answer questions were slightly different between the pre and post-test version. The systems engineering questions are adapted from [13] and include 10 items describing actions of devices and subsystems. The students were prompted to indicate whether each action is an “Input”, “Output” or “Processing” of the system (Table I). This paper presents results from two short answer questions and the systems engineering questions. Hardware and software multiple-choice questions continue to be tested and refined.

2) Attitudes Survey

The student Attitudes Survey consisted of 7 short answer questions and 35 Likert-type questions. The short answer questions were slightly different between the pre- and post-test

TABLE I. MULTIPLE CHOICE QUESTION DETAILS

Multiple Choice Questions	Details	
	Number of Items	Answer Choices
Attitude Scales: Please select the answer that shows how you feel right now about the statement. There are no right or wrong answers, just be honest.	35	NO! no Neither yes or no yes YES!
Systems Engineering Scale [13]: Below is a list of actions. Check off whether each action is an input of information, the output of information, or the processing of information.	10	Input Output Processing

version. The Likert-style questions have students rate agreement with various attitude statements with grade level appropriate options: “YES!”, “yes”, “neither yes or no”, “no”, and “NO!” (Table I). The Likert-style questions fall into four attitude subscales: Interest (9 items), Motivation (9 items), Curiosity (8 items), and Confidence and Identity (9 items). This paper presents results from three short answer questions and from the Likert-style questions.

C. Demographics

In this paper, we present data and analysis from 7th and 8th grade students experiencing their first Arts & Bots project. Data were collected from six schools: five public and one independent; a mix of rural (n=3), suburban (n=2), and urban (n=1). Data were collected in 13 separate classes. These classes included six 7th grade classes covering: Accelerated Language Arts, Advanced Math, History, and Technology Education; and seven 8th grade classes covering: Academic and Accelerated Language Arts. Data were collected between November 2010 and April 2014.

The number of students in the data samples below varies slightly due to a number of factors. First, student absences resulted in unequal numbers of Knowledge and Attitude Surveys as they are sometimes applied on consecutive class days depending on class structure. Second, incomplete data collection by teachers led to entire classes having only pre- or post- surveys collected. Finally, our survey tools undergo regular refinement and modification of wording thus items that were introduced more recently may have fewer responses.

The analysis in this paper excluded participants who did not meet the following two conditions: 1) were enrolled in a middle school class, and 2) were participating in their first Arts & Bots project. This led us to exclude data collected from 19 twelfth grade students who were considered outside the target class level and data collected from 6 seventh grade and 34 eighth grade students who had prior Arts & Bots project experiences.

There are Attitudes Survey data from 139 students in 7th grade and data from 73 students in 8th grade. Of those, 98 seventh graders and 55 eighth graders completed matching pre- and post- Attitudes Surveys. There are Knowledge Survey data from 140 students in 7th grade and data from 89 students in 8th grade. Of those, 100 seventh graders and 44 eighth graders completed matching pre- and post- Knowledge Surveys.

D. Analysis

Students were assigned unique subject numbers, and names were replaced by subject numbers throughout the data. The analysis methods used for the three types of survey items (short answer items, Likert-type attitudes items, and systems engineering items) are described below.

Short Answer Coding: Open-ended questions were coded independently by two coders, each an expert in robotics. Survey responses were randomly assigned survey ID numbers to make coding blind to student grade level and whether responses were from pre- or post- surveys, when possible. Responses could be assigned multiple codes if they expressed multiple unique ideas without overlap. Unless otherwise noted, coding was done on the full set of data, and inter-rater reliability was calculated for this complete set (Table II). The top response codes are provided in tables for the following four questions: “What was the best thing that you learned during the project?” (Table III), “Did you enjoy doing this project?” (Table IV), “How did this experience change how you think about technology?” (Table V), and “Should other students have this experience?” (Table VI).

Attitude Scales: Analysis of the Likert-type questions was completed using binary scoring to eliminate any assumption of equal spacing between responses while reflecting the general attitude of the student. For this analysis, we used the binary scoring: (1) positive technology attitudes responses (“YES!” and “yes”) and (0) non-positive responses (“NO!”, “no” and “neither yes or no”). The item scores are inverted for negatively phrased questions: (1) negative technology attitudes responses (“NO!” and “no”) and (0) non-negative responses (“YES!”, “yes” and “neither yes or no”). As an item-wise analysis, we calculated a McNemar test for each Likert-type question, to test the hypothesis: the proportion of students responding positively to the statement in the pre-test was different from the proportion of students responding positively to the statement in the post-test.

Systems Engineering Scale: For each of the 10 multiple-choice questions, we assigned a score of 0 (incorrect) and 1 (correct) for each participant response. Each participant could then be assigned a systems engineering subscore on a scale from 0 to 10 representing the number of items he or she answered correctly. We then tested the hypothesis: the distribution of the student scores was different between the pre-test and post-test. The score distribution had an asymmetrical distribution where the number of students achieving a maximum score on the evaluation prevented a normal distribution. This indicated that the appropriate statistical test for our hypothesis was a Wilcoxon Signed Ranks Test, a non-parametric test for comparing the median score of the distributions.

IV. OUTCOMES

Through the data and analysis described, we identified two primary outcome themes: Technological Fluency and Complementary Non-technical Skills. Technological Fluency covers technical knowledge gains, confidence, and changes in technology stereotypes. Complementary Non-Technical Skills encompasses teamwork, perseverance, and

TABLE II. INTER-RATER RELIABILITIES FOR OPEN-ENDED QUESTIONS

Open-Ended Questions	Coding Agreement	
	Inter-rater reliability % agreement	Number of codes compared
How did this experience change how you think about technology? (post)	91.0%	N=199
Did you enjoy doing this project? Why or why not? (post)	84.4%	N=244
Should other students have this experience? Why or why not? (post)	84.4%	N=237
What was the best thing that you learned during the project? (post)	91.0%	N=210
What parts did Evan use to make the flower? (pre & post)	100.0%	N=193 ^a

^a. Inter-rater reliability was calculated on a subset of 193 responses out of a total of 359 responses.

several other personal skills. All student quotes included below are provided verbatim.

A. Technological Fluency

1) Learning about Robotics

As we hypothesized, students self-reported learning about robotics, technology, computers, programming, specific robotic components used in the class, and engineering design concepts across many different open-ended questions. For the following three open-ended questions, learning about technology was one of the top three most common student responses to each question. When asked “What was the best thing that you learned during the project?”, the majority of students (56.8%, N=139) described a technological learning gain. For example one student said “The best thing was just basically programing the hummingbird. When you tell something to do something and it works it feels amazing,” (8th grade male, academic language arts). When asked “Should other students have this experience?”, 17.7% of students (N=130) said other students should because they would learn about technology. When asked “Did you enjoy doing this project?”, 16.8% of students (N=131) reported that they enjoyed the project because they learned about technology. For example, a student said “YES! I didn’t know much about robotics before this project. I definitely feel more educated about robotics now than I did before this project. It was a GREAT learning experience!” (7th grade male, accelerated language arts). In response to the question “How did this experience change how you think about technology?”, 13.2% of students (N=129) reported that they learned something new about technology. For example, one student reported “i understand it much more now!!!” (7th grade female, accelerated language arts). These self-reported learning gains about specific and more generalized technology knowledge and skills are supportive of the hypothesis “Arts & Bots increases student grounding of technical knowledge and technical skills.”

In addition to self-reported technical learning, an open-ended knowledge question, designed to measure student understanding of robotic systems and components, indicated significant technical learning gains. Students watched a short video of a craft-based robotic flower catching a ball in its petals. After watching the video, they were asked “What parts did Evan use to make the flower?”. Student short answer responses were coded as being: 0) video could not be played, 1) I don’t know, 2) a non-technical answer, 3) a conceptually

correct technical answer but using incorrect terminology, or 4) a correct technical answer. Non-technical answers included craft materials, nonspecific technical parts (i.e. “robot parts”, “knob”), or structural parts not contributing to the robot’s function (i.e. “metal”). Correct technical answers included terms such as “servo motor”, “circuit board”, “gears” and “pressure sensor”. Correct technical answers that were misspelled were coded as correct. Sixty-nine students were unable to play the video on school computers in either the pre- or the post-survey and were excluded from analysis. A McNemar’s Test indicated there was a significant increase in the proportion (47.2% pre-, 95.5% post-) of students who gave a technical response, as shown in Fig. 2, to the question on the post survey, $\chi^2(1) = 41.09$, $n = 89$, $p < .0001$. This result supports the technical knowledge and skills hypothesis as these students demonstrated both increased knowledge of robot components and increased skill in describing a novel technological system.

Another part of the Knowledge Survey, the qualitative Systems Engineering Scale, measured significant learning gains between the pre- and post-surveys as shown in Fig. 3. A Wilcoxon Signed-ranks test indicated that the Systems Engineering knowledge subscore post-test (median = 8) was significantly improved over the Systems Engineering knowledge subscore pre-test (median = 7), $Z = -4.820$, $p < .0001$, $r = .41$, $n = 138$. These increases indicate not only an improved understanding of robotics, but also improvements in student understanding of the systems engineering concepts of inputs, outputs, and processing. This finding of increased technology systems engineering further supports the knowledge and skills hypothesis.

On two attitude Likert-type responses related to learning technical knowledge, there were significant differences found between the pre- and post-surveys. On the statement, “I am curious about how robots work”, McNemar’s Test indicated there was a significant decrease in the proportion of students who agreed with the statement on the post-survey, $\chi^2(1) = 4.84$, $n = 108$, $p = .043$. In addition, a McNemar’s Test indicated there was a significant decrease in the proportion of students on the post survey who agreed with the statement “I would like to learn more about robotics”, $\chi^2(1) = 7.2$, $n = 108$, $p = .012$. At first glance, these decreases in curiosity seemed discouraging; however in combination with the measured and self-reported gains in knowledge with respect to technology, we hypothesize that for some students the project was adequate

Fig. 2. Percent of students giving non-technical and technical responses on the open-ended knowledge question: “What parts did Evan use to make the flower?” (N=89).

in fulfilling their desire for learning about technology. This interpretation indicates that future implementations may be improved by placing more emphasis on the expansive and growing field of robotics and introduce Arts & Bots to students as a fragment of that field in order to seed new curiosity. In addition to this reported satisfaction of learning, we saw corresponding improvements in student confidence, described in more detail below.

2) Improved Confidence

Given the self-reported and measured learning gains in technology and robotics, it is not surprising to see that students had increases in confidence with technology as well. On the Confidence sub-scale Likert-type item, “I am not good at making robots” a McNemar’s Test indicated there was a significant increase in the proportion of students who disagreed with the statement on the post-survey, $\chi^2(1) = 5.7$, $n = 108$, $p = .024$. That is to say that the number of students who took a stand for their own abilities making robots increased. This interpretation is supported by findings from the earlier extracurricular Arts & Bots pilot, which also found an increase in student confidence with respect to robots [4], as well as by short answer responses described below.

Students answering the question, “How did this experience change how you think about technology?”, mentioned that they felt more confidence in their technology skills after the project (5.4% of students, N=129). Some students noted increased confidence in programming, for example, “I always thought technology was far too complex for me to ever have even a basic understanding of programming and how it works. I now know that I will be able to learn basic programming skills if I choose to do so” (7th grade male, technology education). Other students had increased confidence working with the hardware,

Fig. 3. Distribution of student scores on the 10 item Systems Engineering Scale, median score bar indicated. (N=138)

TABLE III. WHAT WAS THE BEST THING THAT YOU LEARNED DURING THE PROJECT? RESPONSE SUMMARY

What was the best thing that you learned during the project?	Percent of Students
	N=139
Technical Learning	56.8%
Teamwork (positive indication)	22.3%
Multidisciplinary Integration	6.5%

^a. Categories representing less than 4.5% of students not shown.

such as, “I think I got a lot better at learning how to hook things up to the humming bird, and it taught me not to be afraid of messing up” (8th grade female, academic language arts). Beyond confidence in specific technical skills, for some students, the experience also resulted in a shift in identity with respect to technology. For example, one student said “it made me feel more connected and confident using the robotic elements it made the technology feel more accessible instead of just something really smart people or nerds do” (8th grade female, accelerated language arts). This finding of increased confidence with technology in part supports the second hypothesis “Arts & Bots increases student motivation and confidence to engage with technology.”

3) Breaking technology stereotypes

One interesting aspect of the Arts & Bots experience is the way it challenged stereotypes students held about technology. When asked “How did this experience change how you think about technology?”, 17.8% of students (N=129) reported that they found that it was harder than they expected. For example, one student reported “This experienced changed how I think about technology because I thought all technology was easy for me. After completing this project I thought this was actually difficult.” (7th grade female, accelerated language arts). This was the highest-scoring sub-code for this question. However, we do not believe this simply meant that students found the project to be too hard. Instead, we believe that students gained a more realistic understanding of the challenges involved in complex, real world engineering design problems. Examining all students in our selected set (7th and 8th grade on their first Arts & Bots experience) with post-survey results, 23 students (17.8%, N=129) said that they discovered that technology was harder than they thought. Of these 23 students, 87.0% reported enjoying the project, 13.0% reported they did not enjoy the project. Stated another way, although students found technology more challenging than they expected, it did not indicate that students didn’t enjoy the project. In contrast, 11.6% of students (N=129) reported that they found that technology was less challenging than they expected. For example, one student said “After this experience, I thought that technology wasn’t as confusing as I thought it would be and that it wasn’t only an amazing learning experience but also a fun project.” (7th grade male, accelerated language arts). Since many students answered the question, “How did this experience change how you think about technology?”, with statements about how technology was either harder or easier than they had expected suggests that first-hand experience helped the students develop a more realistic metric of the complexity of technology development. This realistic metric of complexity is yet further support of the hypothesis “Arts &

TABLE IV. DID YOU ENJOY DOING THIS PROJECT? WHY OR WHY NOT? RESPONSE SUMMARY

Did you enjoy doing this project? Why or why not?	Percent of Students
	N=131
Yes - Technical Learning	16.8%
Yes - Enjoyed Technology	13.0%
Yes - Novelty of Experience	13.0%
Yes - Teamwork (positive indication)	13.0%
Yes – Fun Experience	12.2%
Yes - Enjoyed Building	9.9%
Yes - Vague Learning Gain	8.4%
Yes - Creative	5.3%
No - Teamwork (negative indication)	4.6%

^b. Categories representing less than 4.5% of students not shown.

Bots increases student grounding of technical knowledge and technical skills”.

Students also reported an increased appreciation for technology. The second most common response to “How did this experience change how you think about technology?” was from 17.1% of students (N=129) who reported that it increased their appreciation for technology. Responses coded as increased appreciation could include appreciation for the complexity of technology, understanding of applications of technology in everyday life, or reporting a new perspective on technology. For example, one student said “This experience makes me appreciate the people that do computer programming for a living.” (7th grade female, accelerated language arts), and “This experience changed my thought on technology because I used to think that technology was only cell phones and gadgets like those, but now I know that there is more to technology than meets the eye.” (7th grade female, accelerated language arts). Students mentioned increased appreciation for technology in their responses to other questions as well, though in smaller proportions: “Should other students have this experience?”, 2.3% (N=130); and “What was the best thing you learned during the project?”, 2.2% (N=139). The reported increase in appreciation for technology reflects student statements towards valuing the role technology plays in their lives and the world. Value is a contributing factor for motivation and thus these findings are supportive of the hypothesis on motivation and confidence.

Not surprisingly, given the creative and interdisciplinary nature of Arts & Bots projects, students also reported learning about creative uses of technology. 6.5% of students (N=139) mentioned the multidisciplinary nature of technology in response to “What was the best thing that you learned during the project?”. For example, one student stated “Poetry can be very difficult to understand, but using robotics and creating a visual view of the poem can help you understand it more.” (8th grade female, accelerated language arts). When asked “Did you enjoy doing this project?”, 5.3% of students (N=131) reported that they enjoyed the project because it was creative. For example, a student said “Yes, I like how people can be creative with their minds since [since] there are so many options of

TABLE V. HOW DID THIS EXPERIENCE CHANGE HOW YOU THINK ABOUT TECHNOLOGY? RESPONSE SUMMARY

How did this experience change how you think about technology?	Percent of Students
	N=129
More challenging than I thought	17.8%
Gained appreciation for technology	17.1%
Technical Learning	13.2%
Less challenging than I thought	11.6%
No change reported	8.5%
Increased enjoyment of technology	7.8%
Increased perseverance	5.4%
Increased interest in technology	5.4%
Increased confidence with technology	4.7%
Found technology to be fun	4.7%

^c Categories representing less than 4.5% of students not shown.

materials to choose from.” (8th grade male, accelerated language arts). This recognition of technology as a creative medium is aligned with both the definition of technological fluency as creative application of technology and the Arts & Bots program goal of providing a robotics intervention that is focused on creativity and self-expression.

Finally, students reported that Arts & Bots can influence perspectives on technical careers or that the learning is applicable to students’ futures. When asked “Should other students have this experience?”, 18.5% of students (N=130) said yes, because it would help their future or career. For example, one student said “I think other students should have this experience because it could increase your ability to one day go to college and maybe also have a career in technology.” (7th grade female, accelerated language arts). This was the second highest response category for this question, superseded only by yes because it was fun (33.1%, N=130). This demonstrates that students value the role that technology may play in the future lives and careers of their peers and believe that Arts & Bots contributes positively to this role.

In summary, student responses show that students’ understanding of the complexity of engineering design and technical projects became more grounded in reality, students came to appreciate technology in the larger world around them, students came to see that technology could have creative applications, and they considered the benefits of what they had learned from the project for their lives in the future.

B. Complementary Non-Technical Skills

1) Teamwork

Beyond the primary goal of improving the technology skills, knowledge, and attitudes that comprise student technological fluency, we also saw evidence of students developing non-technical skills. One of the most prominent non-technical skills mentioned by students in the short answer responses was teamwork and working with their peers. The learning of teamwork skills was the second most common code (22.3% of students) surpassed only by learning about

TABLE VI. SHOULD OTHER STUDENTS HAVE THIS EXPERIENCE? WHY OR WHY NOT? RESPONSE SUMMARY

Should other students have this experience? Why or why not?	Percent of Students
	N=130
Yes – Fun Experience	33.1%
Yes – Career/Future Benefits	18.5%
Yes - Technical Learning	17.7%
Yes - Vague Learning Gain	15.4%
Yes – Teamwork (positive indication)	10.0%
Yes – Novelty of Experience	6.2%

^d Categories representing less than 4.5% of students not shown.

technology (56.8%) when asked “What was the best thing that you learned during the project?” (N=139). For example, one student said they learned “Not to blame anyone for their mistakes because [you] will end up making at least one and you would not like to be blamed” (7th grade female, accelerated language arts). Teamwork appeared in the responses to other questions as well. For “Did you enjoy doing this project?”, 13% of students (N=131) reported that they enjoyed the project because they enjoyed the teamwork. When asked “Should other students have this experience?”, 10.0% of students (N=130) said yes because they would practice teamwork. For example, a student replied “yes because it changes your thinking on how you can do projects and work with other students” (7th grade female, accelerated language arts) and “Yes I think there are a lot of people my age that would like this, it brings both tech savy people and people who can work well with their hands together.” (8th grade female, academic language arts). This trend is especially notable because teamwork is not explicitly addressed by either the Attitudes or Knowledge surveys.

In addition to these self-reported teamwork learning gains, we also saw a decrease in the number of students who agreed with the statement “It’s important to me to know more about technology than most people” following Arts & Bots. A McNemar’s Test indicated this was a significant decrease in the proportion of students, $\chi^2(1) = 6.7$, $n = 108$, $p = .014$. At first look, this decrease in the perceived value of technological knowledge seems discouraging; however we believe that the relative value students apply to their knowledge and skills is changed through the teamwork aspects of the Arts & Bots project. This interpretation is supported by some student responses to open ended questions, for example “the best thing i learned in this projected [project] was that everybody did something to help the group so it would be teamwork” (8th male, academic language arts) and “That you need to make sure everyone is working and following along to the best of their ability so you get it done quickly.” (7th grade female, accelerated language arts). Student statements like the ones above directly support the idea that students not only learned the value of communication and teamwork but came to value the contributions of their teammates towards successful completion of a technical project of this scope.

Teamwork was such a large component of student experiences with Arts & Bots, we also see reports from students who had negative teamwork experiences. The highest

negative response code for “Did you enjoy doing this project?” was negative teamwork (4.6% of students, N=131). While most students mentioning teamwork found it enjoyable or beneficial, some students had negative teamwork experiences. Anecdotal reports from teachers suggest that teamwork is a very challenging area for middle school students, thus seeing both positive and negative reactions to teamwork is not surprising.

The prevalence of teamwork in the short response questions can be explained by the integral role that teamwork plays in Arts & Bots projects. The scope of these Arts & Bots projects was such that no single student could complete the project on their own. In addition, the complex, interconnected nature of an engineering design projects requires students to collaborate closely with each other, rather than simply working in parallel. In short, Arts & Bots forces students to practice teamwork.

2) Other Skills

While teamwork was the most prominent non-technical skill reported by students, several other skills also surfaced across the open-ended question responses. Perseverance was the most notable of these with 5.4% of students (N=129) reporting increased perseverance with technology in response to “How did this experience change how you think about technology?”. Responses stating that the project or technology was challenging but rewarding or worthwhile in the end were coded in to this category, for example, “.... The use of the different robot parts was challenging but very rewarding in the end, but not as challenging as expected.” (8th grade male, accelerated language arts). Perseverance surfaced in response to other questions in smaller proportions: “What was the best thing that you learned during the project?”, 2.9% (N=139); “Should other students have this experience?”, 2.3% (N=130); “Did you enjoy doing this project?”, 0.8% (N=131). Time management and problem solving skills were reported by a few students. In response to “What was the best thing that you learned during the project?”, 2.9% of students (N=139) reported time management. In response to “Should other students have this experience?”, one student reported problem solving skills, saying “yes, it helps with team work and problem solving skills.” (8th grade female, accelerated language arts). These skills and dispositions were not explicitly addressed by the hypotheses, the professional development, or the evaluation tools and thus these results suggest an interesting avenue for future work.

V. FUTURE DIRECTIONS

In the future, we plan to continue to: 1) expand upon the outcomes discussed above, as not all outcomes could be reported within the scope of this paper; 2) make improvements to the Arts & Bots system; and 3) explore new areas of evaluation. We plan on expanding upon our findings related to the development of teamwork and other non-technical skills by developing professional development and curriculum materials designed to help Arts & Bots teachers maximize these complementary gains. We will also seek to develop items for measuring these non-technical gains in more detail. We are also interested in the development of evaluations related to the multidisciplinary nature and curricular integration of Arts &

Bots to help assess the impact that Arts & Bots has on student learning of the core discipline, e.g., poetry.

While we have done analysis on the data from the full population of the Arts & Bots students, we would be able to gain more insight by comparing subpopulations. For example, in order to address our program goal and hypothesis of “engaging a broad demographic of participants,” it will be critical to further consider the knowledge and attitudes outcomes from the experience by different genders and by students with different experience levels. It will also be interesting to do further analysis of the differences of outcomes between the different student grade levels in order to help inform teachers in the selection of learning goals that can be achieved with this and similar projects in their particular classes. Longitudinal evaluation of students taking multiple Arts & Bots courses provides another interesting avenue for future work.

VI. CONCLUSIONS

We presented here results from the middle school creative robotics project Arts & Bots. The goal of the Arts & Bots program was to increase the technological fluency of middle school students. Evidence for this goal was found in student self-reported learning and enjoyment of the creative aspects of technology through participation in Arts & Bots.

Our hypotheses for evaluating the Arts & Bots program were:

1. Arts & Bots increases student grounding of technical knowledge and technical skills.
2. Arts & Bots increases student motivation and confidence to engage with technology.
3. Arts & Bots engages a broad demographic of participants, across gender and across prior technological exposure.

The first hypothesis was supported by student self-reported technical learning, significant improvement in technology component identification, significant increases in understanding of systems engineering concepts, and short answer responses demonstrating the grounding of technology concepts through first-hand experience.

The second hypothesis was supported by outcomes of self-reported confidence gains, an increase of students disagreeing with “I am not good at making robots”, and self-reported increases in student appreciation of the real life applications of technology.

The third hypothesis is still being evaluated and as described in the prior section, will be the subject of future work. Outside of the original hypotheses, we also saw strong self-reported outcomes related to teamwork, which warrant further explicit evaluation and augmentation thorough future program development.

ACKNOWLEDGMENT

We would like to thank the teachers whose participation made this work possible; Tom Lauwers of BirdBrain Technologies; Debra Bernstein; and the CREATE Lab members who supported this work especially Beatrice Dias, Clara Phillips, and Dror Yaron.

E-mail: lfx_lfx@bit.edu.cn; ldn@bit.edu.cn; zhengjun_bit@sina.com; zhaosanyuan@bit.edu.cn

Abstract—Introduction to Computing is a public course for the first-year non-major undergraduate students, aiming at training students for the abilities in computer science and technology with computational thinking. However, as new computer technologies emerge continuously and rapidly, it is required for this course to accommodate more and more knowledge. Therefore the teaching contents are growing enormously, which makes it very difficult to cover all of them in limited hours, and therefore sets an obstacle in understanding computing principles and building up a clear and general picture of computing, especially for non-major students. As computer science and technology are becoming more and more essential for various disciplines and majors, it is urgent for the education community to find out an effective and propagable way to solve this problem. In this regard, we employ virtual reality technology to the experiment teaching of this course, and have developed 18 virtual experiments to support the whole teaching process. For example, Turing machine is a basic model for computer science and technology. However, since it is not a real machine, it is not easy for the students to imagine the working process of Turing machine and understand the related concepts. Another example, the execution of an instruction is very important to understand the principles of computer organization. However, as the information flow is invisible, it is difficult and time-consuming for the teachers to explain how an instruction is executed inside a computer. Therefore, 3D modeling and animation techniques are used to demonstrate the invisible micro-structure of computers, and human-machine interaction and visualization techniques are used to present the internal process of information evolution, thus constructing a complete virtual experiment system of this course, including demonstration experiments, verification experiments and interaction experiments. Our virtual experiments have applied software copyrights and served more than 12,000 students from five universities of China since 2013. The evaluation demonstrates that the virtual experiments have produced excellent results in both teaching effectiveness and learning efficiency, relieved the conflicts between limited hours and vast knowledge, and helped students understand and build up the knowledge of computing.

Keywords—virtual experiments, Introduction to Computing, virtual reality.

I. INTRODUCTION

Introduction to Computing is a public course for the first-year non-major undergraduate students, which has been offered in Chinese universities for more than twenty years. Computing technology has become one of the fastest growing domains since the new century. Though computer science is a discipline itself, it can promote the development of other disciplines, and many challenging and frontier research can be conducted using advanced computing technology [1]. Therefore, the development of various disciplines urgently requires computer science and technology to provide deeper and wider support functionalities.

In 1990s when the idea of information era had just swept across China, the goal of this course is to make students familiar with digital media and information tools, which is essentially culture popularization of computer. However, as the role of computer science and technology has become more and more important in various disciplines, the course of Introduction to Computing is now aiming at training students for the abilities of computational thinking [2], which also brings about the reformation and innovation in the goals, contents and means of teaching.

In the rebuilding of this course, some issues have drawn much attention and lead to comprehensive discussion.

On one hand, the concept of computational thinking proposed by Jeannette M. Wing [2] has been accepted in research and education communities in China, and Guoliang Chen further analyzed the connotation and denotation of computational thinking considering the actual situation of Chinese colleges and universities, and proposed the overall goals of the innovation in computing education [3]. However, it is still ambiguous with respect to how to effectively promote the computational thinking oriented reformation of computing education. For example, large amounts of knowledge are not only the reflection of computing discipline, but also a contradiction with the limited course hours. Therefore, it is very difficult to accommodate all these knowledge by using conventional means of teaching, especially when it comes to the invisible, abstract and complex concepts and principles.

On the other hand, experiments are essential for computing education. However, with respect to this course, the

experiments have been keeping the same since 1990s, which are mainly the usage of system software and application software. Therefore, the experiments of this course are not in the line with its teaching contents, and the lack of effective experiments has hindered the goal of computational thinking. Though it is very urgent and important to establish new experiments that match the goal and contents of this course, it is not easy to keep pace with the rapid changing technologies, which brings about obstacles to the new experiment system.

Aiming at the above problems, we design and implement virtual experiments for the course of Introduction to Computing using visualization and simulation technologies. Virtual experiments [4] and virtual laboratories [5] have drawn increasing attention from education and research communities all over the world.

An important advantage of virtual experiments is that students can conduct experiments on unobservable phenomena [4], [6-9]. In this course, the teaching contents severely involve the evolving process of information such as the data transmission on computer networks and the micro-structure of computers such as the execution of an instruction, which are all invisible and therefore cannot be observed by conventional physical means of experiments. Therefore, we use 3D modeling and animation techniques to demonstrate the invisible micro-structure of computers, and use human-machine interaction and visualization techniques to present the internal process of information evolution.

Besides, virtual experiments offer much higher efficiencies over physical experiments because they typically require less setup time and provide results of lengthy investigations instantaneously [10], which enables more efficient and effective understanding on the important and difficult points. This is very important for the course of Introduction of Computing which has very much knowledge and very limited course hours.

II. DESIGN OF VIRTUAL EXPERIMENTS

The development of computing technology has caused enormous impact on education, especially when it comes to the virtual reality technology, which is greatly changing the ideas and methods of education. Based on the virtual reality technology including visualization, human-machine interaction and simulation, we have designed and implemented the experimental system for the course of Introduction of Computing.

In this course, virtual experiments are beneficial in the following three aspects.

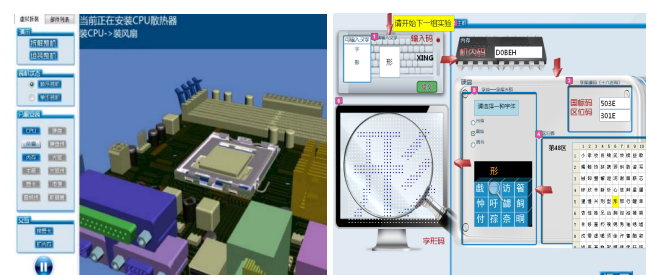

- Describing abstract concepts in the realization of computing.
- Presenting the organization and micro-structure of computers in the working principles of computers.
- Visualization of the unobservable process of the information storage, transmission and processing.

Using the virtual reality technology, 18 virtual experiments including demonstration experiments, verification experiments and interaction experiments are designed and implemented, which are listed in Table I.

TABLE I
LIST OF VIRTUAL EXPERIMENTS

No.	Virtual Experiment	No.	Virtual Experiment
1	Turing machine and virtual assembling of computers	10	Computer animation
2	Representation and calculation of data	11	Word processing
3	Character coding and information processing	12	Data management and data base
4	Execution of a computer instruction	13	Computer based problem solving
5	Process management and virtual machine	14	Execution of an algorithm
6	File management and disc recovery	15	Object oriented approaches
7	Communication in WAN and transmission of emails	16	Simulation and MATLAB
8	Cloud computing and virtual service	17	Computer virus and fire wall
9	Image generation and processing	18	Intelligent optimization

Some examples of the above experiments are shown in Fig. 1. With respect to the invisible process of information evolution, such as the running process of an algorithm, visualization techniques are used to develop verification experiments. With respect to the organization and micro-structure of computers, 3D animation and human-machine interaction techniques are used to develop interaction experiments. With respect to network security such as virus generation, transmission and attack, simulation techniques are used to develop demonstration experiments. Besides, various experiments are also developed to present the concepts and principles in data overflow, file management, process scheduling, network routing, etc., enhancing the understanding of knowledge for the students.

(c) computer virus (d) ant colony optimization

Fig. 1. Some examples of the virtual experiments

III. CASE STUDIES OF VIRTUAL EXPERIMENTS

A. Experiment 1: Turing Machine

The model proposed by Turing presents the essential concept and principle of computing, and is a milestone for computer science. However, because it is not a real machine but an abstract model, physical experiments can hardly be conducted on Turing machine, which brings about difficulties in understanding such important knowledge.

Computer animation is a method to produce the effect of moving objects using a sequence of static images. In this experiment, 3D animation is applied demonstrate the Turing machine and its working process. The computation of 2^x is used as an example, and the rules, states, inputs and outputs are visualized. The experiment includes four 3D models, i.e., the punched tape, the read/write head, the state storage, and the output device. This universal machine model is put onto the screen, and its working process is demonstrated by 42 seconds of animation, which presents the components of the Turing machine, the input of the punch-tape coding, the states of the read/write head, and the output results. Fig. 2 shows the process of the animation, in which (a), (b) and (c) represent the frames at the 32nd, 34th and 36th second, respectively. The concept and principle of the Turing machine is demonstrated in this experiment, which is beneficial for both learning and teaching.

Fig. 2. Working process of the Turing machine

B. Experiment 2: Execution of an Instruction

Even if non-major undergraduate students have the basic idea of 0s and 1s in computers, it is still difficult to perceive the whole process of the capture, transmission, integration, processing, and output of information. This is because the invisibility of the internal micro-structure of computers and the evolution of information. Therefore, interactive experiments are developed to mimic and present the unobservable working

processes.

For example, a computer handles the instructions by repeating instruction fetching, instruction decoding and instruction executing. In order to mimic this process, the interactive experiment, i.e., the execution of an instruction, is designed and implemented, which demonstrates how the components collaborate with each other and how the information flows inside the computer.

The design of this experiment is as follows. Using visualization and human-machine interaction techniques, five stages are incorporated, i.e. interactively specifying the operands, fetching instruction from memory, decoding the instruction, fetching the operands from memory, and executing the instruction. Several important components of the computer, e.g., controller, adder, and storage, are illustrated, and the flow and evolution of the information are visualized. Fig. 3 shows the execution of an instruction, in which decoding and execution of the addition instruction are presented in (a) and (b), respectively.

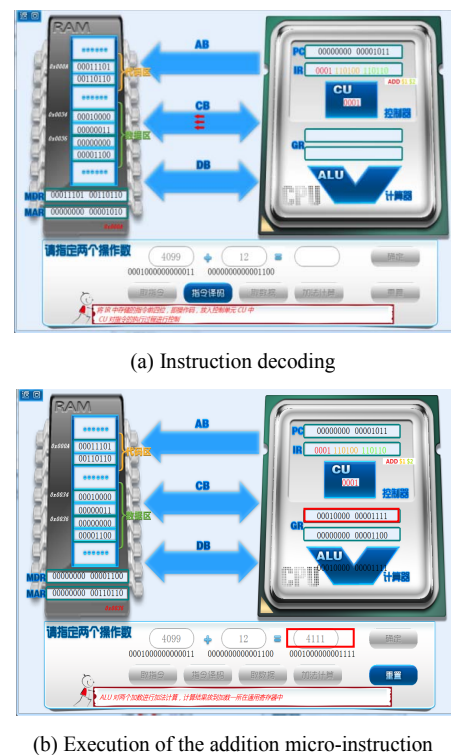

Fig. 3. Emulator for the execution of an instruction

As illustrated by Fig. 3, the interface of the experiment is divided into two main parts. The internal structures of the computer are shown in the upper part, and the human-machine interaction interface is provided in the lower part. The internal structure of the computer mainly includes the RAM and the CPU. Some details such as the sections in the RAM, the ALU and controller of the CPU, are also demonstrated. In addition, the three buses connecting the RAM and the CPU are emphasized, and the information flow can be dynamically displayed during the experiment. For example, Fig. 3(a) shows the decoding stage in the execution of the instruction, when the controlling information flow for instruction decoding is

transmitted on the control bus. Fig. 3(b) shows the status of the ALU and the information flow in the controller when executing the addition instruction.

Since this experiment involves a wide range of information, the experiment report is important for guiding the students to achieve the purpose of this experiment.

The recording sheet of this experiment is shown in Table II.

TABLE II
RECORDING SHEET OF THIS EXPERIMENT

Step 1 Assign two operands	
Question	Result
Operand 1, operand 2	
The address of the instruction in the program counter	
The instruction code at the corresponding instruction address in RAM	
The address of operand 1 in RAM	
The address of operand 2 in RAM	
Step 2: Fetch the instruction	
On which bus does CPU send the memory address to RAM?	
Where is the instruction received from CPU stored in RAM?	
What information is stored in MAR? What is its binary code?	
What is the memory address corresponding to the binary code in MAR? What data is stored at that memory address? Which register is the data stored in?	
What happens to the content in the program counter after it is accessed? Why?	
On which bus does RAM send the data in MDR to CPU?	
Where does CPU store the instruction received from RAM?	
What is the binary code in IR?	
Step 3: Instruction decoding	
What are the memory addresses of the operation code and the two operands in IR, respectively? (Please denote them by six binary numbers and four hexadecimal numbers).	
Where does decoding happen? On which bus does it send the result to RAM?	
Step 4: Fetch operands	
On which bus does CPU send addresses? Where is the address stored in RAM?	
Which register does RAM use to store the first operand? On which bus does RAM send it to CPU?	
Where is the first operand stored in the CPU after it is fetched from the RAM?	
Step 5: Calculate the addition of two operands	
Where does CPU calculate the two operands?	
When the addition is completed, where is the result stored in the CPU?	

IV. APPLICATION RESULTS

We have designed and implemented 18 virtual experiments which have applied software copyrights and served more than 12,000 students from five universities of China since 2013. These students come from more than 60 majors, and the results presented in this section are collected from 1,158 undergraduate students and 40 teachers in Beijing Institute of Technology. Two types of surveys were conducted, one of which was for the students and the other for the teachers.

The feedback from students is shown in Table III. As indicated in Table III, the motivation of study was enormously promoted with the application of virtual experiments, and most students found it easier to learn the knowledge and perform the experiments, and more effective to communicate in the group and with the teachers.

TABLE III
EVALUATION RESULTS FROM STUDENTS

Evaluated Factors	Items in the Factor	Results	Methods
Motivation	Experiment design	87% were interested in the virtual experiments.	Student survey
	Usefulness of experiments	83% found virtual experiments help them understand knowledge.	Student survey
	Grading criteria	75% were satisfied with grading.	Student survey
Knowledge and Experiment Process	Understanding of knowledge	85% found it easier to understand knowledge via virtual experiments.	Student survey
	Performability of experiments	98% completed the virtual experiments.	Student survey
	Setup experiment environments	89% found it easier to setup experiment environments.	Student survey
Collaboration in Teamwork	Teamwork in experiments	83% were satisfied with the shared environments.	Student survey
	Discussion in teamwork	80% found the discussion more effective via virtual experiments.	Student survey
Interaction with Teachers	Effectiveness of interaction	85% found the interaction more effective via virtual experiments.	Student survey

The feedback from teachers is demonstrated in Table IV, which indicated that most teachers found it more efficient and effective in teaching, as compared with the previous semesters without the assist of virtual experiments.

TABLE IV
EVALUATION RESULTS FROM TEACHERS

Evaluated Factors	Items in the Factor	Results	Methods
Efficiency	Knowledge contained	85% included more knowledge in the course.	Teacher survey
	Experiments completed	96% students completed more experiments in unit time.	Checked by teachers
	Preparation of experiments	98% spent less time in preparation of experiments.	Teacher survey
Effectiveness	Explanation of knowledge	85% found it easier to explain knowledge via virtual experiments.	Teacher survey
	Understanding of knowledge	The average scores increased 12%.	Quiz and exams
	Creativity	8% students contributed to the improvements of experiments.	Grading
Interaction with Students	Efficiency of interactions	85% found the interaction more efficient via virtual experiments.	Teacher survey
	Effectiveness of interaction	82% found the interaction more effective via virtual experiments.	Teacher survey

V. CONCLUSION

With the rapid growth of computing technology, various disciplines require computer science and technology to provide more powerful support, resulting in the innovation and reformation of the course of Introduction to Computing. In order to present the unobservable, abstract and complex concepts and principles, virtual experiments were designed and implemented. The application results show that the virtual experiments are beneficial for both learning and teaching.

Abstract—Signal processing algorithms, software, and hardware are being used in several fields including non-engineering areas such as arts and media. Students in these fields and particularly in the new Digital Culture major at Arizona State University (ASU) use signal processing tools in several of their projects and artistic endeavors. Yet the blind use of these DSP tools in other disciplines, without understanding their properties has been a long-standing problem. In fact, the broader issue is the disconnect between engineers that develop tools and artists that use them to design the next generation digital art applications. In that context, ASU has formed the Arts Media and Engineering (AME) School and more recently, the multidisciplinary undergraduate Digital Culture degree granting program. In order to provide formal training in signal processing to students that are non-Electrical Engineering majors, we piloted a new course titled Signal Processing for Digital Culture. This course, which is being offered online, teaches non-majors some of the basics of signal processing and covers several applications. The only prerequisite to the course is general sophomore calculus. This new online course contains several topics and is focused on an approach that teaches concepts by connecting theory to compelling applications. Future plans include introducing this course at Clarkson University as a Knowledge Area course open to students from all majors.

Keywords—signal processing, DSP online, digital culture, arts and media

I. INTRODUCTION

DSP systems are being used in many STEM related areas and non-engineering fields such as multimedia, arts, and digital music. There are several students in these fields, and at Arizona State University (ASU) arts students use signal processing software tools such as those embedded in Max/MSP [1] for innovative artistic and music synthesis demonstrations. Despite the high level knowledge of the tools by artists, there is a knowledge gap in using these tools while understanding their capabilities and limitations. For this reason, many undergraduate programs started developing their own signal processing courses by covering topics that are similar to those covered in entry level DSP courses in engineering.

In general, the blind use of DSP tools in other disciplines without appropriate understanding of their properties often produces errors in measurements and in the analysis of signals. For example, many students confuse the spectrum of

Concentrations offered in partnership with other ASU schools

- 43 hours of Digital Culture Core credits
 - 22 Digital Culture Studies
 - 9 Digital Media
 - 6 Digital Culture related courses
 - 6 Capstone

- 6 hours of theoretical/historical credits
- 41 hours of general studies credits

Fig. 1. ASU Digital Culture Undergraduate program and its degree concentrations with other disciplines.

the continuous Fourier transform with that obtained by the fast Fourier transform or have trouble differentiating frequency responses of analog systems versus those of digital filters. In general there is a disconnect between engineers that develop tools and artists that use them to design the next generation digital art applications. For this reason, ASU established the Arts Media and Engineering (AME) School and in 2012, the multidisciplinary undergraduate Digital Culture degree granting program (Fig. 1). These programs help create a workforce for several application areas such as interactive gaming, smart stages, digital music synthesis, environmental sound rendering and other applications.

The degree is flexible with many elective courses including Signal Processing for digital culture (EEE 394). This course was developed in Electrical Engineering for non-EE majors. This is being offered online and covers the basics of signal processing along with several applications. The only prerequisite to the course is general sophomore calculus. This new online course contains several topics and is focused on an approach that teaches concepts by covering popular applications. For example, we cover Fourier series and Fourier transform concepts by looking at spectra and harmonics in music signals. We cover filtering by looking at how linear systems are used in compression algorithms in cell phones and MP3 players such as iPods. We will develop computing modules for capturing and interpreting sensor data. Several other DSP concepts and applications are covered at the block diagram level with MATLAB software code

examples and object oriented programming simulations running on tablets and laptops.

Future plans include introducing this course as a knowledge area course at Clarkson University. Knowledge area courses are open to students from all majors. This course will be used to introduce digital signal processing concepts to students in non-Electrical Engineering majors.

We will assess the class with concept quizzes, student interviews and course evaluations. In the sections that follow, we present more details on new materials, content and software modules created for the course.

II. THE SIGNAL PROCESSING FOR DIGITAL CULTURE COURSE

In terms of proficiencies, the EEE 394 Signal Processing for digital culture course is described as follows:

Incoming proficiencies include: Basic Freshman Algebra 100, Basic sophomore Calculus, and Basic Sophomore Computational Tools. The above are prerequisites for the Signal processing for digital culture course. Outgoing Proficiencies include: Junior level Calculus, Computational Tools, Sensors and Signals, System Design/Development.

This signal processing class is for students in non-engineering majors. The course involves qualitative and quantitative descriptions of DSP algorithms, software and applications. Applications covered in the class include those in the arts, music, computing, engineering, financials, and biomedical areas. MATLAB and Java simulations are used to support the DSP concepts taught in the class. Code for all applications and examples will be given to all students. Outcomes include the following:

- The course will enable students to understand simple filtering and signal analysis algorithms and their applications; and
- The course provides skill-building experiences in terms of enabling students to express simple algorithms in MATLAB and Java-DSP.

The course includes the following topics:

Introduction to DSP, History and Applications; Sinusoids and Tones, Frequencies and Spectral Representations; Adding Tones and Superposition; Time shift and phase; Magnitude and phase representations of signals; Periodic Signals, Harmonics and their relation to Music and Vibration; Time-Varying Sinusoids and their Applications; Fourier Series Representations and Applications, Sampling and Aliasing; Oversampling, Digital to Analog (D-to-A) Conversion; Applications to Music and Other Signals; Sampling Rate Standards and Conversions; Sampling and Aliasing software demos; Simple Analog Filters and Frequency Responses, Digital Filters, Frequency Response of FIR and IIR filters, Special Filters for Music and other Applications; Audio Effects, Echo, Reverberation, Vocoder, distortion; Filters for Noise Reduction and Enhancement; Filters programmed as

Oscillators for Tone Synthesis; Examples of Filters for Images; Oscillators and Dual Tone Synthesis, Superposition, Linearity and Convolution; z -transform and transfer functions, Poles and zeros, Frequency Response, Stability; Introduction to Quantization; Applications of Filters in Signal Compression and Cell Phones [2]; Applications of Filters in Audio Compression (Algorithms in the iPod); filterbanks and applications to MP3 [3] and AAC; Psychoacoustics; Continuous and Discrete-time Fourier Transforms; the FFT and the frequency spectrum; applications of FFT in Communications (OFDM [4] and Wi-Fi), applications of FFT in music synthesis and transformations, modulation with the Fourier transform and the FFT; 2-D filters and transforms, JPEG, and MPEG; other applications in the medical, military and arts areas including applications of DSP in Stock Forecasting, DNA analysis [5], DSP and Solar Power monitoring [6], Biomedical applications, and sensors and health monitoring.

III. SOFTWARE DEMONSTRATIONS, LABORATORIES AND COMPUTER PROJECTS

The course uses five different platforms for computer exercises and software demonstrations, including mobile devices [1,7-15]. These are: MATLAB, LabVIEW, Java-DSP [11-13], iOS JDSP [10], and Android JDSP [14,15].

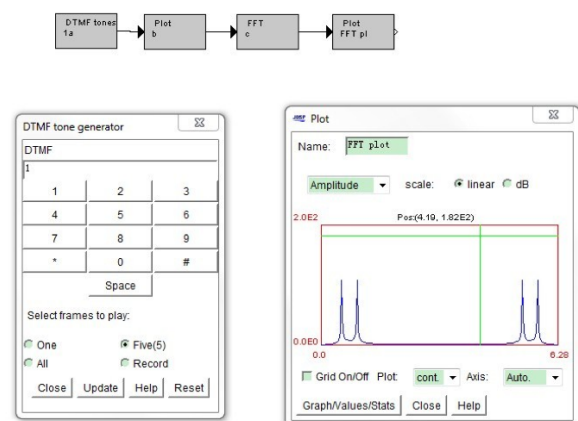

Fig. 2. DTMF demonstration of dual tones and FFT spectrum in Java-DSP (J-DSP).

The course provides several demonstrations in Java-DSP such as the one shown in Fig. 2, where the utility of IIR filters operating as digital oscillators is demonstrated. The simulation also demonstrates the application of the FFT in measuring the frequencies and identifying the digits. This is also assigned as a MATLAB exercise where the students program both the oscillators and the FFT and make measurements.

Another demonstration and homework exercise is developed in MATLAB where students are asked to configure a filter to create an echo effect as shown in Fig. 3.

Students also use the iOS and Android versions of J-DSP to associate MIDI sounds with sine waves and spectra. They are also assigned exercises to synthesize a song using MATLAB. In the class, students learn how to use spectrograms to assess

time-varying spectra of voice and different sounds. Fig. 4 shows the spectrogram of synthesized speech on an iOS device.

$$x(n) + b_2x(n - L) = y(n)$$

```
clc
clear all;
x = wavread('cleanspeech');
L=10; % L=100, 500, 1000, 2000
b=[1,zeros(L,1)',0.8];
y=filter(b,1,x);
sound(y)
```

Fig. 3. FIR filter configured to produce an echo effect with a sound file. MATLAB is used by students to program and evaluate echo effects for different delays.

IV. COMPUTER PROJECTS IN MATLAB

For skill building and programming experiences we provide a more comprehensive MATLAB programming experience where students are asked to program and simulate a music morphing function that makes use of the FFT. Through this exercise, students build theoretical knowledge on sound morphing and vocoding (Fig. 5), and also understand the use of FFT magnitude and phase. Segmentation of sound using windows (Fig. 6 and Fig. 7) in MATLAB, and frame-by-frame processing also helps them understand how sound is processed in DSP systems [16-18]. Issues of non-stationarity of signals also are part of this exercise.

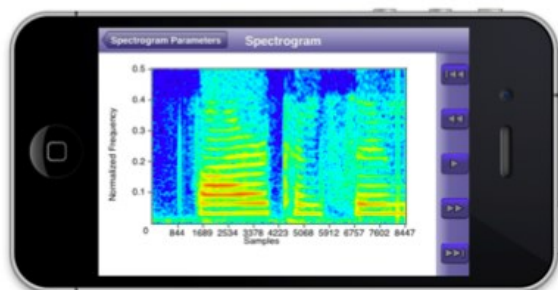

Fig. 4. Time-Frequency Fourier spectra of speech using the spectrogram on the iPhone. The function is also available in J-DSP and MATLAB.

V. PRELIMINARY ASSESSMENT

The class has been received well by students. Some of the students had difficulties in the beginning with understanding the mathematics of signal processing but noted that the block diagram approach of the J-DSP was very helpful. Students also had some difficulties getting comfortable with frame-by-frame programming in MATLAB and manipulating sound files. The online format of the class was also difficult for the students. This semester we are offering the class in a hybrid format where a once a week meeting is required for problem solving and Q&A sessions.

VI. CONCLUDING REMARKS

A signal processing class for digital culture was developed for online delivery. The class is intended for artists but will soon also be offered to non-majors in other disciplines. Some programming and mathematical difficulties emerged in the beginning of the course.

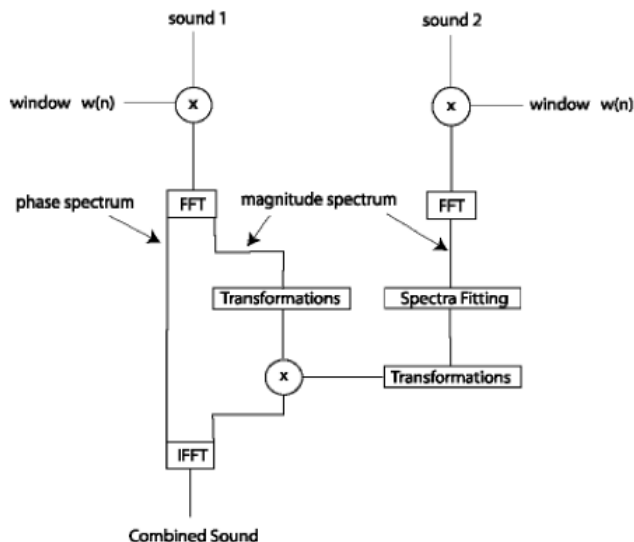

Fig. 5. Sound morphing using the FFT. Students learn how to program frame-by-frame processing and sound synthesis as well as the importance of magnitude and phase in vocoding.

As students became more comfortable with programming, block diagrams, and notations, some of these difficulties were overcome. The course is taught at a high level by connecting theory and applications and using block diagram programming to transfer concepts to students.

An additional problem was the need of a customized textbook for this type of course. Signal Processing First [18] was used, which worked very well for the STEM students in the class.

Fig. 6. Segmentation of speech signals using a rectangular window. Students learn how to develop MATLAB software for frame-by-frame processing and reconstruction. The framing is part of the sound morphing and other projects.

In future semesters, this course will be introduced as a junior-level knowledge area course at Clarkson University. This course will be used to introduce digital signal processing concepts to students in non-Electrical Engineering majors.

Fig. 7. Overlapped frames using triangular windows to combat discontinuities and jitter noise in sound reconstruction. Students are taught how to program overlapping frames and use overlap-and-add to reconstruct sound signals.

ACKNOWLEDGMENT

The authors from ASU are supported in part by the SenSIP Center and the NSF Phase 3 Grant Award 0817596. Paul Curtis was supported by an IAFSE undergraduate TA and an NSF REU award.

An Approach to Improving Student Learning of Civil Engineering Concepts Using Case Studies

Hudson Jackson, Corinna Fleischmann, and Kassim Tarhini

Department of Engineering
United States Coast Guard Academy
New London, Connecticut

Abstract—Engineering educators, professional organizations and practitioner have long recognized the benefits of integrating engineering case studies, especially failures into the civil engineering curriculum. One key benefit is that it provides a pedagogical tool that encourages students to address the complex challenges faced by engineers in the real world. The Civil Engineering Faculty at the United States Coast Guard Academy has successfully integrated case studies in several undergraduate courses to reinforce technical concepts. Case studies provided opportunities for discussion of engineering principles and concepts as well as fostering professional development in ethics and life-long learning. This paper discusses the implementation of case studies and the benefits to student learning especially in identifying problems and developing alternative solutions. Assessment data indicate that the use of case studies enhanced students' learning of engineering principles and improved their understanding of the problem-solving process.

Keywords—Case Study, Assessment, Student Learning, Bloom's Taxonomy

I. INTRODUCTION

A vast amount of published literature emphasizes that learning and retention are enhanced by engaging students in real project activities which simulate the actual work environment. Engineering educators have tried various learning paradigms such as: *case studies, project-based learning, interactive learning, active learning, role playing, flipped classroom and computer simulations*. These activities, complement the traditional classroom lecturing and are used by engineering educators to achieve a higher level of learning based on the six levels of cognitive domain in either the original Bloom's Taxonomy [1] or the Revised Bloom's Taxonomy [2]. The revised levels of learning (lowest to highest) include: (1) remembering (knowledge), (2) understanding (comprehension), (3) applying (application), (4) analyzing (analysis), (5) evaluating (synthesis), and (6) creating (evaluation). Educators have used Bloom's Taxonomy of learning to measure the student's level of understanding, evaluating, and creating engineering solutions.

Several engineering educators have tried to infuse case studies in the civil engineering curriculum or establish standalone case study courses. For example, Akili [3] described the steps taken in planning, developing, and

executing a case study or case history course in geotechnical/foundation engineering at Iowa State University. This course focused on cases that demonstrated the geotechnical practices in the region, pedagogies of engaging students in a collaborative learning environment, and allowing students to develop effective communication skills. Students in this course were required to be an active participant in the group and open class discussions. Cases were normally used to extend the learning experience beyond the traditional classroom activities. The case studies used in this course were related to real world issues that exposed students to the analysis and decisions encountered by practicing engineers.

Delatte, et al. [4] reported the results of various pilot studies that were performed over several semesters to assess the use of failure case studies in the civil engineering curriculum at Cleveland State University (CSU). Student learning through failure case studies was assessed through homework questions, exam questions, surveys, and focus groups. Students commented during the focus groups that the cases helped them make the link between theory and practice. It also helped build engineering identity and it demonstrated the relevance of the technical information presented in engineering courses to the real world. This project extended the work of implementing and assessing case studies at CSU to thirteen other participating universities. A number of educational resources including a website were developed to provide easy access to engineering students, educators, and practicing engineers.

Dai, et al. [5] introduced a case study undergraduate course in the civil engineering program at the Tongji University, China, to enhance learning and make the shift from deductive teaching model to inductive instructional strategies. The course was designed to facilitate the use of laboratory testing equipment as part of the case study investigations. Typical failure cases were obtained from the recent Wenchuan earthquake in China in order to prepare students to assimilate the post-disaster field investigation of failure modes. Students were taught the basic principles of seismic design and the practical engineer's responsibilities to the general public during the lectures. The case studies were used to involve students in seismic design, improve advance knowledge and

comprehension, and promote the professional and ethical responsibilities.

Similar attempts to enhance student learning and understanding of engineering principles are in progress at the United States Coast Guard Academy (USCGA) by integrating case studies into the curriculum. Solutions to real-world engineering problems are more complex and they require engineers to address various issues such as uncertainties, technical and nontechnical constraints, political, cultural, economics, communications, and the consideration of alternatives. One of the objectives of integrating case studies into the curriculum is to simulate these real-world scenarios. This paper is a work-in-progress and focuses on how case studies continue to be incorporated in several civil engineering courses at the USCGA. The emphasis of this paper is on three senior level courses that use case studies to tie together technical aspects, ethical issues, procedural issues, and to engage students at a higher level of thinking and learning.

II. CASE STUDIES IN CIVIL ENGINEERING CURRICULUM AT USCGA

The Civil Engineering Faculty at USCGA has successfully integrated case studies in several upper level undergraduate courses. These cases were used to reinforce technical concepts while providing an opportunity for discussion of engineering principles as well as fostering professional development in ethics and life-long learning. In this approach, case histories that tie together technical aspects, ethical and professional issues are identified and selected. These cases require students to synthesize or evaluate the technical and non-technical issues as compared with the concepts and principles they have learned in their engineering and general education in humanities and science courses.

This paper focuses on the implementation of case studies in two required senior design courses, *Geotechnical Engineering Design* and *Reinforced Concrete Design*, and in an elective course, *Water Resource Engineering*. As part of the ABET requirement of depth and breadth in four civil engineering sub-disciplines, the *Geotechnical Engineering Design* course was introduced into the civil engineering curriculum at USCGA in 2009 as a graduation requirement. The course is purely project-based with open ended problems that require students to make decisions and develop alternatives, similar to what is expected in actual engineering practice. By balancing the need for fundamental engineering instruction with that of cooperative learning, the development of problem-solving skills required for engineering practice is promoted in this course. The case studies used do not only involve design, construction but also legislative disputes to simulate real-life engineering practice.

The *Reinforced Concrete Design* course has been a traditional required course where students learn about the basic analysis and design of beams and columns, floor slab design, serviceability, and shallow foundation design. The course incorporates unique requirements of various team projects that

include: EXCEL programming projects; and the analysis, design, construction, and testing of full-scale reinforced concrete beams. Recently, the course was modified to include case studies and a multi-step design project that require students to analyze and design key components of a multi-story building. The new building design project was developed and coordinated with two other courses in order to simulate real-world projects. The addition of case studies and multistory building project was essential to transition the course to project-based learning and to advance student comprehension of reinforced concrete design. Several case studies have been identified from the published literature and strategically introduced throughout the semester. Case studies are used to either introduce a new topic in the course or highlight critical design and construction practices that should be considered during the design process. The case studies enhanced the classroom environment by engaging students in the discussion of what went wrong and what to do in avoiding similar mistakes when designing key components in a structure.

The *Water Resources Engineering* course was first offered in the Spring of 2014 as an elective course in the civil engineering curriculum. This course offers a basic introduction to the field of Water Resources Engineering. The goal is to expose civil engineers to a broad range of topics relevant to the field of water resources. Course topics include surface and groundwater hydrology, rainfall-runoff analysis, reservoir and river routing, probability and frequency analysis, computer modeling, water excess management/control, and watershed management. Case studies are used in this course to expose students to issues surrounding water resources and to challenge them to realize that engineering decisions are not solely based on hand calculations or computer simulation.

In general, case studies were used in these three upper level courses to enhance the learning experience beyond the traditional classroom activities and expose students to the analysis and decisions encountered by practicing engineers. The case studies provided background for specific topic (module), served as materials for problem formulation and identification, and served as illustrations for examples of engineering concepts and principles covered in these courses. The case studies tie together technical aspects, ethical issues, procedural issues, and help students engage in a higher level of thinking to synthesize and evaluate relevant concepts. The case studies were used strategically throughout the semester to provide students with an opportunity to make the connection between theory and real-life applications, as well as to generate interest in open discussion of engineering problems.

Suitable case studies were extracted from the following widely published resources: archives of the *Association of Engineering Firms Practicing in the Geosciences* [6], Delatte [7], Kaminetzky [8], Watkins [9], Johnson et al. [10], Gleick [11], and Rouge River project [12]. Examples of the case studies students received a week ahead of time in the three courses are summarized in Table 1.

TABLE I. EXAMPLES OF CASE STUDIES

Case Study	Problem Description/Statement	Learning Objective
Geotechnical Engineering Design		
Case 1: University building expansion, NJ	Dewatering and excavation support. Several challenges including underground utilities and limited access.	Addressing construction management issue and selection of suitable equipment.
Case 3: Leaning tower of Pisa, Italy	Inadequate soil investigation, effects of differential settlement, selection of suitable soil improvement & stabilization techniques.	Understanding of soil-structure interaction, importance of thorough site investigation and selection of suitable foundation system.
Case 4: Schoharie Creek Bridge failure, NY	Scour, inadequate bridge inspection and maintenance.	Importance of investigation and proper maintenance of bridges. Importance of understanding hydraulic forces on foundations.
Reinforced Concrete Design		
Cocoa Beach five-story cast-in-place concrete building collapse, FL	Inadequate design, poor construction, and quality control.	Addressing key construction issues including severe cracking and excessive deflection, proper rebar placements, punching shear strength, and lack of formwork design.
Skyline Center at Bailey's Crossroad high rise concrete building, VA	Catastrophic collapse of a high rise building due to quality control and lack of formwork plan.	Importance of proper quality control related to punching shear, formwork (shoring and re-shoring slabs), and ensure proper concrete strength before formwork removal.
Water Resources Engineering		
Flood control reservoir operation during the Great Midwest Flood of 1993	Following the Great Midwest Flood of 1993, concern was voiced that the US Army Corps of Engineers did not operate flood control reservoirs in an optimal manner therefore contributed to the damage.	Understand reservoir operating plans particularly for flood control; evaluate (in hindsight) the effectiveness of reservoir operations during an extreme flood event.
Combined Sewer Outflow (CSO) Case study	In the Rouge River Watershed, MI, water quality was improved through CSO reduction.	Practical understanding of how CSOs are reduced and further explanation of the detrimental effects of CSOs.
Three Gorges Dam China	Case study provides an overview of challenges and decisions that were faced during construction.	Understand the complexity of the decisions that had to be made during the construction of this dam
Watershed Management on Groundwater and Irrigation Potential in India	An increase in population has led to increased water demand for irrigation and agricultural purposes in semi-arid and rural areas of India.	Understand the impact of watershed management on the ground water and irrigation potential of a watershed facing drought like conditions.

Students were required to review each case and address key aspects on a template before class discussions. The grading rubric template provided students with guidelines of the following key aspects that must be considered while reviewing each case study:

1. *Review the case content* – Students were required to provide a 2-4 sentence summary on the case or “bird’s eye view” of the case. Key questions that must be addressed include: What is going on in the case? What are the facts of this case?
2. *Identification of the problem* – Students were required to identify the key issues of the case and develop a problem statement.
3. *Collection of relevant information* – In general, no additional literature review or search for new information is formally required. However, students are expected to make the connection with already acquired knowledge and evaluate if any additional information is required to fully assess the case. In a few of these cases, instructors purposefully withheld key information to get students more engaged in this step.
4. *Development of alternatives* – Students were encouraged to come up with alternative ways of solving the problem. Open classroom discussions facilitate the exchange of

ideas and students are encouraged to question the validity of each proposed solution.

5. *Selection of a course of action* – Having completed the first four steps, students are then encouraged to identify suitable approaches or solutions they think is most appropriate to address the issues based on the available information. Basically students are asked to select or identify the most appropriate course of action to resolve the problem. The cases presented may not have a straight forward solution.
6. *Recommendation of an implementation plan* – If a solution can be identified, students are required to proposed some form of implementation plan that may need to address any constraint defined in the problem statement.

III. ASSESSMENT

The template described above was used in the three courses as a standard grading rubric. Sample performances on case study 1 and 4 (see Table 1) used in the *Geotechnical Engineering* course are shown in Figures 1 and 2. In the figures, “Exceeds,” “Meets” and “Below” represent scores of at least 90%, 70%-89%, and less than 70%, respectively. General guidelines were given at the beginning of the semester with more discussions and emphasis followed based on student performance after submitting their analysis of each case. For example, Figure 1 indicates that most of the students adhered to the template guidelines and showed good understanding of the concepts. Performance was fairly good on most components of the rubric. However, 55% and 67% of students performed poorly on “problem statement” and “alternative solutions”, respectively on the first case study presented in the *Geotechnical Engineering Design* course. Therefore, more emphasis and guidance were provided on the subsequent case studies and this resulted in modest improvement in student performance on case study 4 as shown in Figure 2.

Fig. 1. Student performance geotechnical engineering case study 1

Fig. 2. Student performance geotechnical engineering case study 4

In general, students struggled to adequately identify and develop problem statement and 50% of the students still performed below expectation in case study 4. The faculty is investigating suitable approaches to expose students to more opportunities of developing problem statement to enhance their understanding in this area.

Similar trends in student performance shown in Figures 1 and 2 were also observed in the *Reinforced Concrete Design* and *Water Resource Engineering* courses. Overall student performances in the three courses for the graduating class of 2015 are presented in Figure 3. The figure represents average overall student grades on four case studies in each course. Most students are either meeting or exceed expectations. The *Geotechnical Engineering Design* and *Reinforced Concrete Design* courses are both offered in the fall semester. Both courses are design-focused with a common semester project that further exposes students to high levels of critical thinking. The *Water Resource Engineering* course is offered in the spring semester as an elective. The grading rubric is under continuous review based on the feedback received from students and faculty experience during each semester.

Fig. 3. Average Overall student grades for the Class of 2015

In addition to the graded assignments, student feedback was collected using in-class surveys. The focus of the survey was to have students self-assess their understanding of the principles and provide feedback on the effectiveness of the instructional method in meeting the course objectives. Students commented that project-based learning and the use of case studies improved their learning and comprehension. It also enhanced their ability to make the connection between theory and practical applications. They felt better prepared to complete their capstone design project and ready to work as civil engineers.

IV. CONCLUSIONS

The Civil Engineering Faculty at USCGA has successfully integrated case studies in several undergraduate courses. This paper focused on the implementation of case studies in two required senior level courses, *Geotechnical Engineering Design* and *Reinforced Concrete Design*, and in an elective course, *Water Resources Engineering*. The selected cases were used to reinforce technical concepts while providing an opportunity for discussion of engineering principles as well as fostering professional development in ethics and life-long learning. Using case studies or project-based learning as an active learning methodologies are powerful tools educators can use to engage students in the learning process and help students make the connection between theory and practice. In general, students exposed to case studies and project-based activities achieve a higher level of learning through this exposure to real-world problems. It was also observed at the United States Coast Guard Academy that Students who experienced this process during the fall semester performed better on their capstone projects in the spring semester. It is anticipated that in the future, case studies will also be introduced in some lower level courses. This will enable faculty to monitor any progressive changes in students' learning and professional skills resulting from the use of case studies throughout the Civil Engineering curriculum. With more targeted assessment data, faculty will be able to make continuous improvements to the program. The goal is to progressively infuse case studies and design throughout the four year Civil Engineering curriculum.

A Project Component in a Web Engineering Course

Samuel A. Malachowsky and Daniel E. Krutz
Rochester Institute of Technology
{samvse, dxkvse}@rit.edu

Abstract—Web applications are an extremely important and ubiquitous part of today's world. Students must not only know how to develop them from a technical perspective, but in doing so need to understand how to follow the proper principles of software engineering - delivering the project on time, on budget, and in a high quality manner.

At the Department of Software Engineering at the Rochester Institute of Technology, we offer a Web Engineering course which not only introduces students to a variety of web technologies, but more importantly it shows them how to use them in a collaborative environment while properly utilizing web engineering methodologies. The course includes a significant project component requiring students to use a variety of contemporary technologies and resources to create a robust web application. The main premise of the project is for each group to create a web portal using both custom-built and already existing components. The project takes place over the entire 15 week course term, includes multiple releases, and has students work in teams of 4-5.

This innovative project component has received significant praise from both students and faculty members while fulfilling an emerging area of our curriculum. Students enjoy the real-world nature of the project and the ability to work with contemporary technologies in a format which closely mimics what they will see in industry. This paper outlines the educational objectives, project details, some sample project results of our class offering, as well as student feedback about the project. The goal of this work is to share the project, its importance, and lessons learned for use at other institutions with similar educational goals.

Keywords—Web Engineering, Software Engineering, Computing Education

I. INTRODUCTION

Creating high quality web applications on time and on budget can be in many ways more difficult than traditional application development. Developers must not only master web development technologies, but different methodologies as well. Web-deployed development is likely to have a significantly higher amount of all three types of maintenance (corrective, adaptive, and perfective) by its very nature; evolvability and ease of deployment are a major reason why it is so popular. In addition to focusing on maintainability, developers need to balance the concepts of uptime, security, worldwide availability, and accessibility with a torrent of different browsers, devices, and screen resolutions currently in use and in the development pipeline.

Web engineering is defined as the systematic, disciplined, and quantifiable approach to development, operation, and maintenance of web-based systems and applications [13], [18], [20]. While similar to software engineering, the concept of web engineering differs in several key areas [6]. A higher emphasis is placed on growth and change, compressed

schedules, performance criticality, and small teams working on very short schedules [5]. While many institutions offer classes directed towards developing web applications or software engineering, very few offer courses in web engineering - the successful combination of the two concepts [1], [2]. Because of the critical elements described above, the application of engineering principles to this particular type of development is critical.

At the Department of Software Engineering at the Rochester Institute of Technology (RIT), we offer a Web Engineering course to help meet the demands that students would face when tasked with creating web applications. The purpose of this course is to instruct students in using proper web engineering principles and to allow them to practice doing so with a prominent course project. This project component includes teams of 3-5 students, runs the entire (15 week) semester, and involves creating a web application in multiple iterations using a variety of contemporary technologies and resources.

The goals of the project are to reinforce course concepts, allow students to gain experience creating web applications, and the application of web engineering concepts. Secondary goals include reinforcement of in a team skills and the opportunity to use current technologies. Student teams are expected to fulfill all steps of the software development lifecycle including the successful creation of all necessary requirement, design, test, and deployment artifacts, and development of the product using proper web engineering principles. This project has proven to be invaluable at reinforcing academic concepts discussed in the classroom as well as providing an enjoyable real-world experience for the students.

The rest of the paper is organized as follows: Section III describes the course including learning objectives. Section IV provides an overview of the project detailing requirements, deliverables and evaluation methods. Section V relates a sample project and some student feedback. Section II presents some related works. Section VI describes challenges and future work, and Section VII concludes the paper with a summary.

II. RELATED WORK

While several institutions offer courses in web engineering [1], [2], we are not aware of any which use a project component such as the one we present. Preston [17] discussed the importance of using real-world projects similar to ours in computing courses and found that through practical project applications, classroom principles were significantly solidified for the students. Several other works have discussed their success in using real-world projects in computing engineering courses as well [10], [11], [15].

TABLE I. WEEKLY TOPICS & PROJECT DELIVERABLES

Week	Classroom Topics	Project Deliverables	Project Point Total
1	Course Introduction, Introduction to Web Engineering	Team Formation	0%
2	Introduction to Web Development Technologies		
3	Javascript, JQuery	Requirements Documents	10
4	Web Services		
5	Web Testing	Design Documents, Test Plan	10
6	Exam, Twitter Bootstrap	Beta Release	3
7	R1 Presentations	Release 1 (R1)	20
8	Introduction to Databases	R1 Post Mortem	4
9	HTML5		
10	Security - Abuse & Misuse, Threat Modeling

12	Exam, Usability in Web Applications	R2 Post Mortem	4
13	Analysis of Web Traffic		
14	Emerging Web Technologies		
15	R3 Presentations, Final Exam	Presentation, R3, R3 Post Mortem	5, 20, 4

Van der Duim et al. [22] spoke about the “Free Riders” problem where some students working on teams do not contribute as much as their peers. Students reported several reasons for free riding including lack of project interest, lack of social skills, and overall course workload. Other works have also reporting similar problems for software engineering projects [9], [19].

Deshpande et al. [5] described the concept of web engineering, why it is needed, how the concepts helps improve web application development, and how it should be incorporated into education and training. The work argued that while software engineering was relevant to conventional application development, web engineering was needed for web application development due to the differences in testing, development, and maintenance. Ginige [6] discussed many of the failures in the development of web applications and also argued for more of a web engineering approach when developing web applications. More recent works have begun to extend web engineering into more specific focuses, such as security [3].

III. ABOUT THE COURSE

The Web Engineering course has been offered at RIT for three years, with the primary goal being to instruct students in how to properly apply software engineering principles to the creation of web applications. A 300-level course, and typically taken by upper-division students in sections of 25-30, approximately 130 students have taken the course so far. While this is an engineering and not a programming course, specific technologies such as .NET¹ and jQuery² are discussed and concepts such as web services and security are covered. Students are primarily evaluated on their comprehension of engineering principles and not specific technologies or programming abilities.

The students taking the course are typically upper-level Software Engineering students and have a reasonably high level of development experience. A good portion of the students are very experienced with web development - having gained expertise either through personal projects or internships. Typically one third have extensive experience, one third have some experience, and the remaining third have little or no exposure. Exams and homework are two thirds of the final grade, and the project is one third. Prerequisites include Introduction

to Software Engineering, Personal Software Engineering, and some basic programming courses.

Some of the biggest areas of emphasis include customer elicitation skills, requirements documentation, and acceptance testing within the context of web engineering. The weekly topics, project deliverables, and suggested project point totals of the course are shown in Table I; further details may be found on the course website³. Instructors are encouraged to deviate from our course plan as they see fit and as new technologies and concepts become prominent.

IV. ABOUT THE PROJECT

A group project is an important aspect of the course; research has found projects to be extremely beneficial to student learning [4], [7], [20]. The project lasts the entire term of the course (15 weeks), and has student teams creating deliverables throughout. Team size is targeted to 3-5 students, as this is often the size of groups in industry and has been found to be conducive to student learning in previous research [7], [16]. For simplicity and student support purposes, a web technology platform should be chosen by the instructor. For the last three years, we have chosen the Microsoft .NET framework as the core of the project, although we expect other institutions to select the technology based upon preference and student competency.

The main premise of the project is for each group to create a web portal using both custom-built and already existing components. This is accomplished through web service and Application Programming Interface (API) calls, with possible sources including Google's, FaceBook's, and Yahoo's APIs.

A. Project Requirements

When crafting the course project, several considerations were at hand. First, we wanted it to represent a real-world product, using-real world technologies. This is important since the goal of the project is to emulate what the students would see in their careers after college. Additionally realistic development goals help to further challenge and encourage students [8], [12], [20]–[22]. Second we wanted to foster student interest in the project. Developing a solution using APIs from well-known and respected companies proved exciting to the students. This

¹<http://microsoft.com/net>

²<http://jquery.com/>

³<http://www.se.rit.edu/~swen-344/>

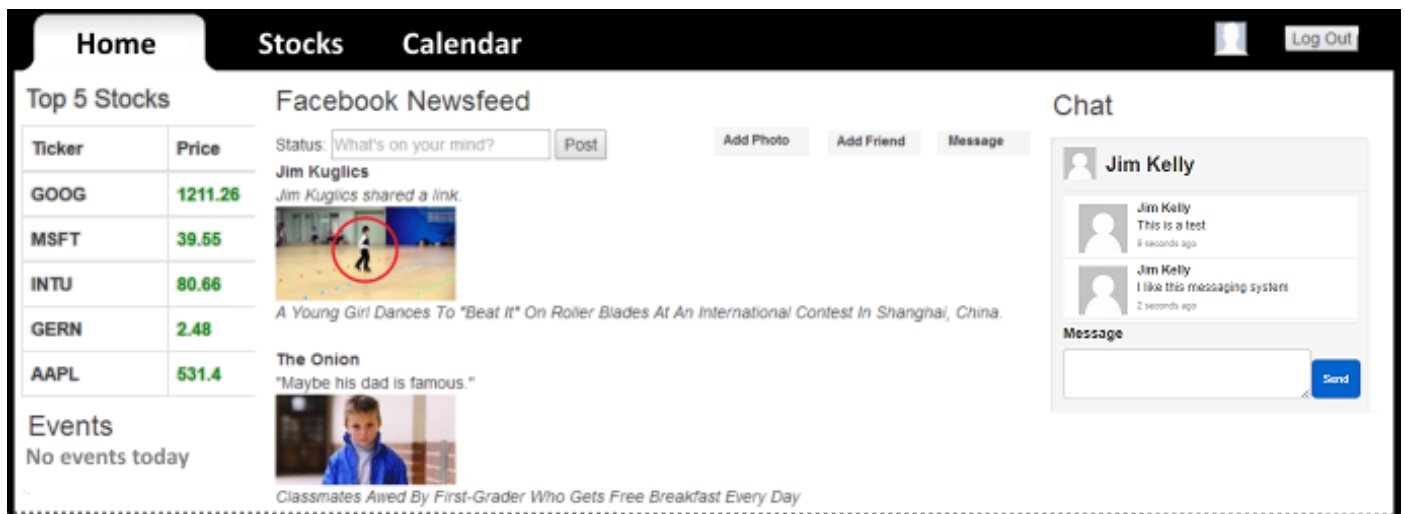

Fig. 1. A Sample Completed Student Project

enthusiasm has helped them to remain focused and drive their desire to learn and apply ingenuity.

The instructor takes on two distinct roles for the project: teacher and customer. The way the customer reacts to student questions significantly differs depending on what role the instructor is currently playing. While representing the role of teacher, the instructor gives project advice and answers technical questions whenever possible. As the customer, an attempt is made to mimic a client in the real world, and students are encouraged to clarify requirements as such. So that students may understand which role the instructor is playing, they are encouraged to ask whenever they are unsure and begin their statements with “As the customer” or “As the teacher.”

The goal of the project is to create a personalized web portal that would be customized for each user. We choose to require that the user be able login with their Facebook account, as Students of the millennial generation have been found to be more engaged with programming projects that have social relevance [14]. Once the user has logged into the application, they are to be exposed to several pieces of personal, customizable information. Perhaps the most significant is an area on the main page which is very similar to the wall in the traditional Facebook application. For this section, students are asked to again tie into the Facebook API to retrieve the necessary data. They are required to modify the appearance of these items and apply aspects of usability covered in the course. Various other Facebook APIs such as photo albums, chatting with friends, and status updates were used in similar ways.

In addition to the relatively simple API interaction, the students are also required to write custom software that has its own functionality and also interacts with external data services or feeds. One example is a simple stock/share price module requiring the user to enter a stock that they have fictitiously purchased along with the purchase price and number of shares. This information is to be stored in a student created MS-SQL database and information such as the current share price is to be retrieved from a third party web service (i.e. Markit

On Demand⁴ or Yahoo⁵). The student’s page is expected to display the current stock price, the day’s high and low price, and the amount of money the investment has made or lost for the user so far. A chart is also to be displayed for the stock, retrieved using an external feed of the group’s choice. Other potential aspects of the application include a weather-based component and a chat feature. The development cycle has a secondary goal of familiarizing students with HTML5, javascript, database design, and the use of libraries such as Twitter Bootstrap⁶ and jQuery. A sample end-result screenshot is shown in Figure 1.

Teams are also expected to write their code in a clean manner while using a version control system of their choice, such as Git⁷. Since teams are to produce multiple releases, each team is provided with a Windows Server virtual machine to deploy their project to, and are expected to produce and adhere to a robust deployment strategy. Finally, teams are required to use proper defensive coding practices to protect against SQL injection and cross-site scripting attacks. Instructors may choose to place more emphasis on specific aspects such as usability, security, testing, etc.

B. Weekly Actions & Deliverables

In order to mimic the iterative nature of typical web application development cycles, we require teams to submit multiple project releases. These submissions also serve to reinforce the importance of maintainability and extensibility in web applications. While we encourage instructors to deviate from this plan as they see fit, we have outlined our deliverables and project releases below, based on a 15 week semester. Suggested timing and point totals are listed in Table I.

⁴<http://dev.markitondemand.com>

⁵<http://finance.yahoo.com/q/hp?s=API>

⁶<http://getbootstrap.com/>

⁷<http://git-scm.com/>

Week 1: Team Formation

Teams are formed using an on-line survey where students are encouraged to indicate who they would and would not like to work with and their level of experience with web development and software engineering. The instructor's goal is to create balanced teams who are likely to work well together.

Each team is required to self-assign several roles including team coordinator, development coordinator, and testing coordinator. In our case, the course is comprised of upper level students making self-appointed roles appropriate; in the case of more novice students, the instructor may want to appoint team roles, possibly choosing to rotate them in order to allow each student to experience each role.

Week 3: Requirements Documents

Students are provided with a requirements document template which they modify based on their conversations with the customer/instructor. As with all project artifacts, teams are expected to keep these documents up to date for with each release throughout the term.

The grading on these initial document deliverables is not aimed at ensuring that the teams have a completely accurate document on their first attempt. The main goal is to have followed the proper guidelines for producing these deliverables and producing an adequate effort in creating them as accurately as possible. During the second half of the class, each team is given the opportunity to meet with the instructor to elicit requirements and to ask general project questions. In this and future interactions, the students are also able to negotiate expectations with the customer. They are encouraged to show prototypes, screenshots, and anything else they deem useful to the customer. The goal is not to limit customer interaction or punish inquisitions as long as they are reasonable, rather the aim is to encourage customer interaction and elicitation.

Week 5: Design Documents & Test Plan

As with the requirements document, teams are provided a template design document and are expected to use the requirements they've been provided and elicited from the customer as input in its enhancement. Some expected document components include UML diagrams (state, sequence, and class), interface design, and basic database design. Teams are also expected to create a test plan for their project. In our course offerings, teams are instructed to create acceptance tests in a simple excel document. Instructors may choose to have teams use a more robust tool should they see fit.

Week 6: Beta Release

The initial project release is intended to be a lightly scrutinized preview of Release 1 (R1). If time allows, Instructors are encouraged to allow teams to conduct a short 5 minute demo of their applications and a basic progress report, eliciting feedback from their classmates. In our case, students have enjoyed seeing the progress of their classmates and gaining this extra feedback before their first major release.

Week 7: Release 1 (R1)

At this time, teams are asked to deliver a partially working

version of their application and a 15 minute presentation. Teams are also expected to submit all updated project artifacts including the requirements document, design document, and test plan. Some key deliverables are basic connections with the external APIs, a deployment strategy, and cursory implementation. We do not evaluate usability or database setup for this initial release.

The Software Engineering Department at RIT places a large emphasis on the student skills of public speaking, presentation, and internal and external communication. With the first release, each group is asked to give a 15 minute presentation highlighting some of the major aspects of their product and some of the technologies they have encountered. Other aspects of discussion are team roles and dynamics, a short demonstration of their application, and plans for the second release. The presentation is oriented as a progress report for the customer.

We ask teams to identify any missing features or requirements not able to be delivered for the initial release. In order to help persuade the students to divulge these undelivered items, they are told they will be penalized much less significantly for any items that they have declared to have missed (as opposed to the instructor/customer finding them). This forces the students to take ownership of their mistakes and be open and honest with their customers, which we feel is an especially important concept once the students graduate to the real world. Hopefully these self-identified problem areas are addressed by the team and defeated in upcoming releases. Assisting in this, students are also required to complete an online, 360° survey rating their teammates and themselves in order to identify problematic areas and team members who are not contributing as much as they should to the project.

Teams may be evaluated upon the quality of their presentation, updated documentation, and created software. Scores may be influenced by team contribution, adherence to process (i.e. using the repository effectively), and metrics such as defect density.

Week 8: R1 Postmortem

Each team creates a self-reflection document containing that went well, what can be improved, and how. Teams are encouraged to think deeply, but to refrain from discussing the overly technical issues they have encountered, as this activity is designed to focus on team, project, and process. Postmortems are evaluated on their thoroughness, identification of strengths and weakness, and plans to overcome these deficiencies. We have seen quality submissions in the 3-5 single spaced page range, but individual instructors may alter this guideline as they see fit.

Week 11: R2

Teams submit their projects, updated documents and conduct a presentation in a similar fashion to their first release. In order to save class time, team presentations may be abbreviated to 5 minutes, or even excluded at the discretion of the instructor. Teams are evaluated on how well they are updating their documentation, adhering to web engineering principles, and the quality of their application. Some expected additional features for R2 include better usability, use of

a database back-end, and a new messaging or chat component.

Week 12: R2 Postmortem

This is similar to the R1 postmortem, but should show more advanced thought and problem resolution.

Week 15: R3 & R3 Postmortem

The final project release is conducted in a similar manner to the first two releases, but with a longer student presentation time. This will allow teams to discuss and reflect not only on R3, but on the entire project as well. Some expected deliverables for this final release include robust security, fully integrated external APIs, a local database, and demonstrations of usability.

The final postmortem should be due a few days after the project, to allow consideration of not only the final release, but the presentation and its preparation as well. Grading should consider all components of the project, including the final product, updated artifacts, postmortems, the presentation, and peer feedback.

V. STUDENT FEEDBACK

A screenshot example of the finished product is shown in Figure 1. Included in this example is Facebook login integration, the top 5 stocks based on user preference, a Facebook news feed with the ability to post to the user's timeline, a daily events display, and a chat plugin which may be used to message anyone also using the application. Other pages not shown include a stock price simulator and a Facebook-integrated calendar feature.

In recent examples, many many teams have decided to use Bootstrap for their UI, a Pusher Chat⁸ widget, and a Yahoo stock API⁹. Because of ease of implementation, a local SQL database has typically been used to store user data. Groups are encouraged to research other APIs, feeds, and sources of information when creating their application, and the API discovery process has been a valuable part of the overall student learning process.

Student feedback has been very positive. At the conclusion of the term, students are asked to fill out an anonymous course evaluation survey. Many students have commented about how much they enjoyed the project, and how much they learned during the 15 week term. Table II shows the student responses to three applicable questions in percentage format.

TABLE II. END OF COURSE SURVEY RESULTS

Survey Question	Agree	Neutral	Disagree
The project was relevant to the course	86%	10%	3%
The amount of project work was appropriate	93%	0%	6%
I learned a lot in the course	85%	11%	4%

VI. CHALLENGES & FUTURE WORK

While the project has seen considerable success since its inception three years ago, there is still work to be done and

areas of improvement. Like with many team based projects, a problem we encountered was how to deal with students who do not contribute to the project. This is a dilemma which is not at all unique to this project and occurs in a wide variety of software engineering student projects [22]. One way which we have dealt with this issue was to ask students to fill out a brief peer review survey after each major project deliverable. The goal has been to identify non-contributing students and address the situations recorded by students as necessary. The use of explicit team roles has also served to alleviate this problem slightly.

Instructors can expect students entering the course to have a diverse range of experiences and skillsets, making it difficult to balance between having the project topics be challenging enough for the more advanced students and being simple enough for the less advanced students to not be left behind. This problem may be mitigated through the use of course prerequisites, but it is a challenge that instructors will need to balance with each course offering.

Web development is comprised of fast moving technologies. This includes new tools, languages, and perpetually changing APIs. This means that the course will need to be constant evolving to include these new technologies which will involve significant diligence by the instructor for lectures, the course project, and in class activities. We've also encountered issue with APIs changing in the middle of term, which proved to be troublesome to many of the teams. This did however teach them a valuable lesson about risk mitigation, reactive designs, and the constantly changing nature of the web. While web technologies change at a tremendously fast rate, and keeping the course up to date is always a challenge, Instructors need to remember that the primary focus of the class is on instructing proper engineering principles; programming is of secondary importance.

VII. SUMMARY

Using proper web engineering principles to create web applications which are on time, on budget, and high quality is an important skill for students to master. We have created a project component within our Web Engineering course in order to reinforce the class's concepts with the goal of resembling a real-world project with components that may be seen by the students soon after graduation.

Over the last few course offerings, we have refined the project to better suit the learning objectives of the course and to keep it relevant with the fast-paced nature of web technologies. We have also seen a significant amount of student interest and enthusiasm about the project, which has carried over into the course as well. Students returning from their first jobs as web engineers have also stated that the project had prepared them well for their job and the situations they faced. Because of the success we have experienced, we encourage others to consider the use of this project in their Web Engineering courses.

Abstract— This paper presents a study to address the use of Web 2.0 tools in education. The study focuses on secondary education and is limited to the region of Madrid (Spain). The main objectives of the study are to determine the involvement of both teachers and students in the use of Web 2.0 tools. Moreover, we will also examine the different parameters associated with the acceptance and application of Web 2.0 resources. Finally, we will describe the different patterns of interaction of both students and teachers with respect to these digital platforms. As a result, we will be in position of assessing the convenience and acceptance of artifacts based on the Web 2.0 paradigms to be used as effective resources to improve the students' learning experience.

Keywords-words: Web 2.0, Media Education, School 2.0, Knowledge Society.

I. INTRODUCTION.

The term Web 2.0 Websites comprises those Websites that facilitate information sharing interoperability, user-centered design and collaboration in the World Wide Web. There are several tools that allow to share information in the Web 2.0 such as blogs, wikis or social networks as well as other sites that share resources like Google Drive for documents, Youtube for videos, or Dropbox for online storage. Among these tools, there are also learning platforms like Moodle or Claroline and virtual classrooms such as Edmodo, Virtual Virtual Teacher or Tutor.

Our aims are to analyze the acceptance of Web 2.0 tools in the classroom and the involvement of teachers in their use. Therefore, the main objectives of the research activities reported in this paper are presented below:

1. To perform a study of the use of Web 2.0 tools in the classroom in the region of Madrid and to assess the implication of teachers in their use.
2. To evaluate the acceptance of Web 2.0 tools by teachers.

3. To determine whether the use of Web 2.0 tools is widely accepted by students (according to teachers' opinion).

4. To identify predictive factors for a lower use of Web 2.0 tools by teachers in the classroom.

The rest of the paper is structured as described in the following. First, we will present the state-of-the-art after reviewing the previous research on the use of Web 2.0 tools by teachers. Then, the methodology used to carry out our study will be described. Finally, our main results and conclusions together with some threads to validity will be exposed.

A Web 2.0 site allows users to interact and collaborate to join efforts in the process of creating contents that will remain available for a given virtual community. This approach radically differs from static websites where users are limited to the passive viewing of content that have been created for them.

The main aspects featuring the Web 2.0 technologies are enumerated in the following [9]:

1. The term Web 2.0 groups different interactive approaches that have in mind the social component of the net. Provided with these new mechanisms, Internet has acquire a more participative dimension, enabling the exchange of information and several forms of contact among users through individual blogs, wikis, social network sites (Second Life, Facebook, etc), image or video sharing sites (Flickr, YouTube, etc.)
2. The Web 2.0 is and attitude and not precisely a technology. It's most relevant aspect is that it makes clear the next evolutionary steps of Internet.

Facebook is an example of typical social networking projects that, in general, has been developed using the figure of social networks as the main support for students' learning process. [11]

Free Software is any software respectful to the freedom of its users and to the social solidarity of their communities. It is common to associate Free Software to software with no cost, but this is a mistake, because there are free software that you have to pay for using it. Not every free software is free. And above all not every no cost software is free software. [7]

To sum up, free software is defined by the four freedoms of software users.

- Freedom 0: The freedom to run the program for any purpose.
- Freedom 1: The freedom to study how the program works, and to change it for any particular purpose.
- Freedom 2: The freedom to redistribute copies.
- Freedom 3: The freedom to improve the program, and release your improvements (and modified versions in general) to the public, so that the whole community benefits.

Also you should have the freedom to make modifications and use them in your work or free time privately, without even have to announce that this modifications exists [8].

We will take as a reference some figures in the education in Europe and in Spain. That will show us how important can be the use of the web 2.0 tools for the classroom. All of this will give us an idea of the current situation about this topic, in Europe and in Spain [10].

II. STATE OF THE ART

The Society of Information has risen as the result of the implementation of information and communication technologies (ICT) in daily life. The greater use of the ICT paradigms has changed, in many senses, the way of developing many of the activities of the modern society.

The Knowledge Society arises in the context of the Society of Information. The main characteristics of the Knowledge Society are the open access to information, the freedom of expression and the linguistic diversity.

Therefore, the fields of study of our research are Education, Communication and Web 2.0 supporting tools. We considered that it was important to investigate these fields due to the importance that the Regional Administration was giving to the introduction of ICT, particularly the Web 2.0 tools, in education. The incorporation of Web 2.0 tools in teaching is having a great impact in education and the use of these tools is expected to increase according to the principles of the Media Education

and School 2.0, which will be explained later in this summary.

In the Society of Information, a change in "what" we teach and "how" we teach is needed. This new Society forces us to rethink the role of teachers, students and taught subjects in education. Therefore, teachers should try to encourage collaborative works in the classroom, which can be supported by mechanisms such as the Web 2.0 tools.

To the best of our knowledge, there are no studies addressing the particular use of Web 2.0 resources in Spanish secondary education. Therefore, our research study covers the lack of information regarding two relevant points: The Media Education and School 2.0.

With respect to the Media Education, it is noteworthy that skills such as the ones related to the use of many languages, to critical thinking, and to the interaction with others in real and/or virtual modes, should be potentiated [1].

Concerning the Education 2.0, it is noteworthy that the advances occurred in education based on the communication model 2.0, i.e., the Web 2.0, is based, inter alia, on the use of social networks. The active interactive joint of teachers and students is also closely related to collaborative learning and authorship for example blogs and wikis.

Education and Education 2.0 are related through the emergence of the communicative model 2.0 in which both teachers and students are active participants in the communicative act, that is, a continuous exchange of roles where both teachers and students can be authors or co-authors of the information and knowledge. According to the authors of et al. [1], The Web 2.0 has changed the rules of the game and allows Internet to contribute collaboratively in the construction of collective knowledge from individual acts of group communication that can occur in cyberspace and real space.

The receiver and the transmitter of the information are transformed into an EMIREC which sends and receives messages [2]. In this model, the role of the students substantially changes. As the learning focuses on the students, they should take an active role building the teaching-learning process. It is expected that the students are able to exercise autonomy, to develop critical thinking, to adopt collaborative attitudes and to use the theoretical knowledge to solve real problems. This model of communication enhances the possibility that the students cast its own messages through different languages, strengthening the educational proposal of personalized education, as well as affective and emotional processes that occur in all educational relationship.

In addition, the digital literacy is a new concept that should be taken into account when considering the training of teachers in the Media School. Literacy is the education

that everyone needs to live in society. A new model of literacy is needed in the digital society: the digital literacy. Furthermore, this new literacy, defined as the basic capacity to understand and to express in different languages and meanings, is constructed collaboratively between teachers and students, as defined in [4]

What we teach and the way we teach it should be changed. Therefore, the role of the teachers, students and contents in learning should be redefined.

Currently, we are part of a networked society, mainly due to the Internet, that has changed the processes, interests, values and social institutions in the way we knew them. Internet has propitiated new ways of relationship, that wouldn't have been possible without the technological advance. As indicated in [5], Internet is the heart of a new paradigm that currently constitutes the base of our lives and of our ways of relationship, work and communication. Internet processes the virtuality and transforms it into our reality, constituting the network society, which is the society where we live.

We cannot forget the importance of TIC in the school. As specified in [6], The implementation of TIC needs several capacities such as cooperation, capacity of initiative and dynamism in the working places, to be able to work in groups, interactive learning between the members of the group, communication, to be able to work with abstract concepts, to identify and solve problems, aptitude to make decisions, being able to seek and to use the information, predisposition for the permanent training and other.

The appearance of these technologies demands to train teachers, as most of them are not familiar with TIC resources and lack the necessary skills to use them.

The immense majority of the administrators, educational managers and teachers are digital immigrants. (...). These professionals rarely use the digital technologies and are very resistant to modify their conception of the world of the work based on the industrial models of ends of the 19th century [1].

III. METHODOLOGY

In the following, we describe the methodology conducted to perform our study.

A. Inclusion of teachers

First of all, this is an observational study in which teachers from secondary schools in the region of Madrid have been electronically surveyed. No exclusion criteria were established.

It is also directly select the teachers and the center in which they operate. 51 were randomly selected centers of the Community of Madrid and went to the centers getting

contact with teachers of Secondary and Vocational Training to ensure that the sample is as random as possible.

We will consider two distinct populations: Teachers of Secondary Education and Training in the specialty of Computer and Teachers of Secondary Education and Vocational Training non-specialty Informatics (Electronics, training and career guidance, etc ..)

B. Data Collection

To achieve the objectives of the study a questionnaire asking about different aspects, such as the professional profile, the opinion on the usefulness of Web 2.0 tools for teaching, the involvement of teachers in the use of Web 2.0 tools and their perception of student interest in the use of these tools, was designed (Table I).

The structure of the questionnaire is as follows: Professor Facts, Facts Institution, Facts Teaching and Evaluation of Web 2.0 Tools (from 1-5).

Teachers from different schools of the Region of Madrid (both, public and private) were invited to fulfill the questionnaire. The questionnaire will consist of an HTML form heading to a PHP page which will register received data received into a MySQL database. Later, every data will be exported to the SPSS statistic package.

The decision to conduct surveys with 20 questions, both secondary teachers (Mathematics, Physics, Chemistry, Biology, Geology, English, etc ...) as teachers of training courses and degree courses which the subject is taken the subject taught are more accustomed to using the Internet in classrooms of Secondary Schools of the Autonomous Community of Madrid with different profiles ages (21 and 35, of 36-50 and 51-65 years) and professional (official and temporary).

This is done in order to make the results more reliable extrapolating the sample to all types of faculty as teachers of vocational training covers both the specialty of Computer Science, as other (Telecommunications, Electronics, Training and Employment Guidance, etc).

These 20 questions will let us know in a general way what is the use given to the Web 2.0 tools in the classroom but in the study to be conducted through the SPSS [12] tool such questions so we can be encoded obtain robust results and allow us to determine exactly what percentage use these tools and if they do regularly or sporadically, how many hours a week they use, that kind of activity used (individual, group, theoretical, practical) whether these tools promote student participation in class, etc.

This differentiation of different age profiles and different professional categories, are made in order to ascertain as accurately as possible, whether age and professional status substantially influences the involvement of teachers in the use of Web tools 2.0 in the classroom.

C. Statistical analysis

For the descriptive analysis of quantitative variables the mean was calculated. Qualitative variables were expressed as percentages. Comparisons between means were performed using Student's T test for independent samples. Qualitative variables were compared using the chi-square (χ^2) test and the Fisher's exact test. Statistical significance was considered at $p < 0.05$ for the all the comparisons.

A binary logistic regression model was used to estimate the effect of the different variables on the use of Web 2.0 tools. All the variables which reached the statistical significance in the univariate analysis were included in the multivariate analysis. Thus, in the multivariate analysis, the dependent variable was the use of Web 2.0 tools.

D. Justification of the questions of the form.

Questions 1 and 2 give us information about the degree of learning of Web 2.0 tools at both learning as if they are a good resource for learning.

Questions 3 and 4 for determining whether Web 2.0 tools enhance communication between students and teachers.

Questions 6 and 7 indicates whether the use of Web 2.0 tools are an advantage (facilitates their work) or undesirable (workload) for teachers.

Question 8 to determine whether the use of Web 2.0 tools in the best interests of the students in the subject studied.

Questions 9 and 10 to determine if Web 2.0 tools contribute or not a good academic and failing to school failure.

Questions 5, 13 and 14 give us information about the degree of knowledge of students and teachers in the field of Web 2.0 tools.

Questions 11,12, 15 and 16 for determining whether Web 2.0 tools enhance participation, collaboration, cooperation, teamwork and level of student creativity in the classroom.

Question 17 and 18 gives us information about the degree of readiness of students and teachers in the use of Web 2.0 tools.

Question 19 lets us know what subjects or subjects Web 2.0 tools are used

Question 20 tells us whether specific training in the use of Web 2.0 tools is adequate.

TABLE I. THE QUESTIONNAIRE FULFILLED BY THE TEACHERS IS SHOWN ABOVE.

Number	Question
1	Do you consider Web 2.0 Tools are an academic resource useful For Teachers?
2	Do you consider using Web 2.0 tools favor learning in students?
3	Do you consider using Web 2.0 tools contribute to a better student-teacher communication?
4	Do you think using Web 2.0 Tools contribute to better communication between the students?
5	Do you consider Web 2.0 tools encourage acquisition of autonomous knowledge and skills by students?
6	Do you think using Web 2.0 Tools facilitate teaching?
7	Do you consider the Web 2.0 Tools assume considerable workload for teachers?
8	Do you consider Web 2.0 Tools promote student's interest for the subject studied?
9	Do you think Web 2.0 Tools have a positively impact on the academic student performance?
10	Do you consider Web 2.0 tools can contribute to avoid academic failure?
11	Do you consider Web 2.0 Tools improve student participation in class?
12	Do you consider Web 2.0 tools encourage partnership and cooperation attitudes among students?
13	Do you consider appropriate the level of knowledge and management of students on Web 2.0 tools?
14	Do you consider appropriate the level of knowledge and management of teachers who knows Web 2.0 tools?
15	Do you consider Web 2.0 tools improve group work of students?
16	Do you consider Web 2.0 Tools improve the level of creativity of the student?
17	How do you rate the initial willingness of students to use Web Tools 2.0 as a part of teaching resources?
18	How do you rate initial willingness of teachers who knows Web 2.0 as a part of teaching resources?
19	Do you consider is indispensable the incorporation of Web 2.0 Tools in the subjects you teach?
20	Would you consider proper dedicate Web 2.0 tools training aimed at students?

IV. RESULTS

The actual sample size calculated is 120 teachers, but Eighty-one teachers have fulfilled the questionnaire so far. The main characteristics of the teachers included are summarized in table II. Seven fifty-five (47,51%) were male.

(84,16 %) over 30 years and 19 (15,84 %) with more than 30 years of experience. The majority of them were officials (70%) and 70,83% worked in public centers. Approximately half of them (54,16%) were teachers of Computing Science.

Although the surveyed teachers (120) declared that the use of Web 2.0 tools reinforces and benefits the students' learning process, only 63% of them acknowledged using these tools frequently. In addition, only 33% of the teachers being using Web 2.0 tools manifested to use them during whole sessions in the classroom. When focusing on teachers that used the aforementioned tools, only 59% of them did it to work in group. Of all teachers, 85 (75,22 %) are the public center.

On the other hand, with respect to the interest shown by the students in the use of Web 2.0 in the classroom, the majority of teachers that used them (79%) considered that students are very enthusiastic about the use of these tools. A small proportion of teachers (6%) answered that the implication in the use of these tools varies widely and it depend on the characteristic of the student. In teachers' opinion, the students that used Web 2.0 tools seemed to do it for both individual and group tasks.

In the multivariate analysis, to be teacher of Computing Science was the only variable independently associated with the use of Web 2.0 tools in the classroom (odds ratio=7.9, confidence interval 95%=2.5-24.5).

Up to 80% of teachers consider that Web 2.0 tools are useful for teaching. 20% do not use these tools probably because they are not accustomed to these technologies, they have no training or because they do not have enough resources.

Only one third of the teachers that use the Web 2.0 tools do it throughout the whole class.

The majority of teachers that use Web 2.0 tools do it for working in group. This result should be underlined as suggests that teachers know the collaborative character of these tools.

Technological elements always seems attractive to the students (mainly at that age) and that should be use to introduce them in the classroom. Many teachers think that the use of these elements contribute to arouse interest of the students. In addition, these tools offer many facilities to promote and participate in group activities although obviously there are ways of interaction requiring presentiality such as debates, exhibitions, etc.

TABLE II. RESUMES THE MAIN CHARACTERISTICS OF THE TEACHERS THAT FULFILLED THE QUESTIONNAIRE.

Feature	Categorí s	% of participants
Gender	Male	57 (47,51 %)
	Female	63 (52,49 %)
Age	Between 21 and 35 years	19 (15,84 %)
	Between 36 and 50 years	61 (50,83%)
	Between 51 and 65 years	40 (33,33 %)
Experience	Over 30 years	101 (84,16,%)
	Under 30 years	19 (15,84 %)
Type	Officials or fixed	84 (70 %)
	Interins	36(30 %)
Centers	Public	34 (70,83 %)
	Private or concerted	14 (29,16 %)
Area	ICT	65 (54,16 %)
	Non-ICT	55 (45,84 %)

The results of the questionnaire it follows that:

1. **The percentage of male gender among ICT subject** was heigher than the frecueny of mala gender among non-ICT subject. Among as teachers from the ICT subjects, 39 (60%) were men while among non-ICT teachrs 33% where men.
2. With respect to the training in ICT use, in public centers the percentage of teachers that received an especific training in ICT was heigher among those from FP than among those from ESP (65 vs. 54 %) while teachers from no-ICT subjects received low training. Among teachers from private centers, FP teachers from ICT subjects were these who received a more intensive training.

3. Among teachers that received training, 39% were from public centers, fifty six teachers were trained, of which the public schools are 84%.
4. With respect to the number of years of teaching experience in public schools, the mean teaching experience was higher in ESO teachers than in FP teachers. A possible explanation for that is that to be a teacher in a public school access is by opposition also FP is a type of education where newly established subjects and many very current training courses. In private-aided schools, as happens in public schools and years of experience is higher among teachers of ESO and FP.
5. Finally, the number of teachers using Web 2.0 tools was 94.16%). In general, FP ICT are teachers who use these tools more (44.24%). In public schools, the ICT FP (33.62%) are the most teachers use these tools, which is logical since their subjects are mainly technological. In private-aided schools, ICT FP (11.50%) are the most teachers use these tools, for the same reason as above.

V. CONCLUSIONS

Our results suggested that although most teachers believe that the use of Web 2.0 tools promotes the students learning, only half of them use these tools for teaching and only one third acknowledge to be implementing actively the use of these tools in the classroom. In general, teachers think that the use of Web 2.0 tools in the classroom is well accepted by the students.

To teach Computing Science was the only factor independently associated with a greater use of these tools in the classroom (8-fold higher than among teachers in other specialties). The age of the teacher (older age) is associated with a lower use of Web 2.0 tools.

This study underscores the need for action to generalize the use of Web 2.0 tools in the classroom, with particular emphasis on the older teachers and among teachers from other specialties from Computing Sciences. Future studies should aim to identify the handicaps for the implementation of these tools in order to adopt strategies (procurement, training courses, etc.) to avoid them.

Abstract—We propose a web based intelligent student advising system using collaborative filtering, a technique commonly used in recommendation systems assuming that users with similar characteristics and behaviors will have similar preferences. With our advising system, students are sorted into groups and given advice based on their similarities to the groups. If a student is determined to be similar to a group students, a course preferred by that group might be recommended to the student.

K-means algorithm has been used to determine the similarity of the students. This is an extremely efficient and simple algorithm for clustering analysis and widely used in data mining. Given a value of K, the algorithm partitions a data set into K clusters.

Seven experiments on the whole data set and ten experiments on the training data set and testing data set were conducted. A descriptive analysis was performed on the experiment results. Based on these results, K=7 was identified as the most informative and effective value for the K-means algorithm used in this system. The high performance, merit performance and low performance student groups were identified with the help of the clusters generated by the K-means algorithm. Future work will make use of a two-phase approach using Cobweb to produce a balanced tree with sub-clusters at the leaves as in [11], and then applying K-means to the resulting sub-clusters. Possible improvements for the student model were identified. Limitation of this research is discussed.

Keywords—K-means; clustering; collaborative filtering; rules; intelligent academic advising system; course.

I. INTRODUCTION

In tertiary institutions, online academic advising systems can provide prompt advice as and when required, and thus enhance student experience and save staff time and other institutional resources. Therefore such systems are gaining popularity. Research into such systems and development of such systems are in progress. In [1], the authors describe a Web-Based Decision Support Tool for Academic Advising. In their study, 90% of users, consisting of 20 undergraduate students and 5 faculty members, found their system effective and efficient. They consider four models of advising: prescriptive, developmental, integrated and engagement. They also discuss the importance of making systems that are more than data repositories and including more intelligence so the systems are able to

provide reliable advice that students do not have to check back with human advisors. In other words, systems that provide reliable advice.

The advice given by academic advising systems will vary, from student to student, depending on a number of factors such as the academic performance of the student concerned and the major area of study and also may be impacted by other factors such as the nationality, age and gender of the students. There are also academic regulations and rules, which can be applied to provide simple answers to basic questions with the assistance of normal SQL queries.

Goals for academic advising include development of suitable educational plans, selection of appropriate courses, interpretation of institutional requirements, enhancement of student awareness about available educational resources, evaluation of student progress toward established goals and development of decision making skills with reinforcement of student self-direction [1]. Others have used such systems to verify their tracks towards their degree program.

We propose a web based intelligent student advising system using collaborative filtering, a technique commonly used in recommendation systems. This technique assumes that users with similar characteristics and behaviors will have similar preferences [3, 4]. With our advising system, students are sorted into groups and given advice taking into account the relevant factors and also considering their similarities to specific groups. A major use of the online advising system we have proposed and prototyped is to help students choose courses from over fifty courses and five interlinked pathways in the Bachelor of Computing (BCS) program. If a student belongs to a particular group, a course that other students in that group have preferred or performed well in, may be recommended to the student.

The system is developed to be integrated into our current student management system, PeopleSoft. Therefore, our students don't need to create a profile to use this system. Real student data with complete records for the last four years (2011 to 2014) of all 743 students enrolled in over 50 courses in the Bachelor of Computing Systems (BCS) was anonymized and used in training and testing the prototype. Data included academic transcripts as well as biographic data.

K-means algorithm is used to cluster the 743 students into a number of clusters. This is an extremely efficient and simple algorithm for cluster analysis, widely used in data mining. Given a value of K, the algorithm partitions a data set into K clusters [5, 6 and 7].

K-means was chosen at this stage, instead of other clustering techniques, due to its ease of use and fitness for purpose. In the next stage of this project, we will have more knowledge on the data. Cobweb will be used to produce a balanced tree with sub-clusters at the leaves as in [11], before applying K-means to the resulting sub-clusters.

A prototype of the proposed system has been developed for concept approval. This prototype is implemented in ASP.NET and MS SQL database server. The system consists of two main components: a simple question and answer (QA) component and an intelligent advising component (IA) [8].

The QA component maintains a list of frequently asked questions (FAQs) of undergraduate students. A number of academic rules have been implemented, so it can answer routine questions like “am I eligible to take course X next semester?” This component is aimed at helping students in the development of suitable educational plans, selection of appropriate courses, interpretation of institutional requirements and increasing students’ awareness of the multitude of educational and other (such as counselling) resources available to students.

The IA component uses records from our current student management system. This allows the two systems to be integrated easily. There is no need for a student to create a new profile; instead, advice will be given taking into relevant, current student data. Academic and biographic information relating to the student concerned, is extracted from the student management system and used to identify which predefined group the student belongs to, and advice given taking into consideration, among other things, the specific characteristics of that group. It attempts to answer questions like “What courses should I take next semester?” This component is aimed at helping students in the selection of appropriate courses and development of decision making skills with reinforcement of student self-direction. K-means algorithm has been used to generate student groups.

A testing and experiment (TE) component is added for data gathering and experiments. The TE component helps to understand the characteristics of the different student groups and to select a suitable K value for K-means algorithm.

743 Bachelor of Computing student records from 2011 to 2014 were used as the data sample. From these records, ethnicity, age, gender, GPA and courses the student had taken were extracted. Based on these data, we gained a general understanding about the characteristics, performance and the interests for different student groups. The system is trained accordingly to provide useful and helpful advice.

In the rest of this paper, the overview of the system is provided first, the experiments related to K means are then discussed, the testing results and future improvements are discussed after that, and a summary is given at last.

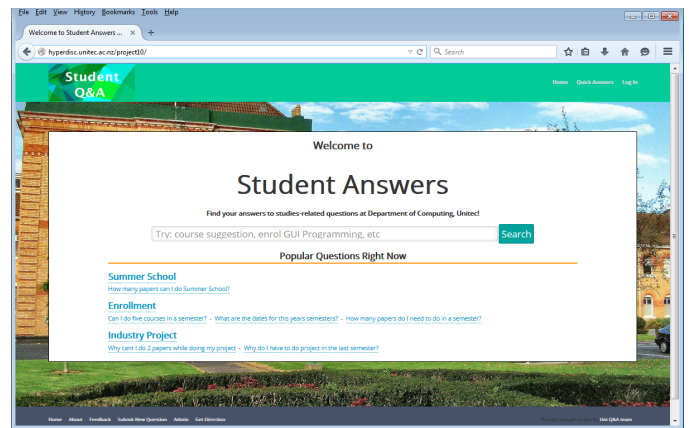

Fig. 1. The home page of the student advising system.

II. THE SYSTEM OVERVIEW

A. The question and answer (QA) component

This component is a basic system that answers questions to common questions students often ask. Examples of questions answered using this feature are:

What are the requirements to do capstone project?

How many papers can I take in Summer School?

In answering simple questions like the above, the system does not access any data specific to the student but a general database of stock questions and answers. Fig. 1 shows the home page of this system.

However, some tiny bit of intelligence is built in, to cater to the changing frequency with which questions are asked at various times during the year. For example, during the period just before Summer School, questions regarding Summer School are listed at top. This also helps the students by making them aware of things they may want to look at while using the system. Fig. 2 shows an example of this type of question and answer system. A number of academic rules has been implemented, so it can answer routine questions like, “Am I eligible to take course X next semester?” with the help of SQL queries.

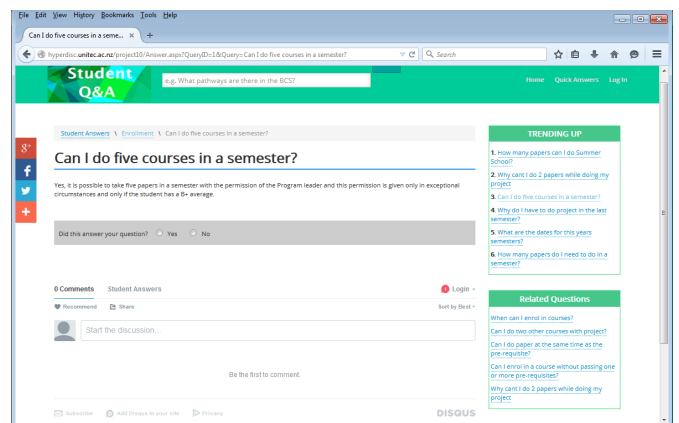

Fig. 2. An example of question and answer.

B. The intelligent advising (IA) component

As the records in our current student management system are used, the information can be extracted from the data is limited, thus the attributes can be used to model a student are limited. The students are modelled by using the existing data as closely as possible. The advising system is expected to help improve the students' performance. Much of existing research around the world use GPA to measure student performance [8]. Research also shows that students' performance depends on many factors such as gender, age, student's competence in English and even nationality and ethnicity. Some other factors that have a significant impact on student performance have been identified as students' communication skills, learning facilities, proper guidance and family commitments related stress [9].

According to [9], students' academic accomplishments and activities, perceptions of their coping strategies and positive attributions, and background characteristics, including family income, parents' level of education, guidance from parents and number of negative situations in the home, were indirectly related to their composite scores, through academic achievement.

According to [9], the student performance should be improved if the administration of the college provides proper learning facilities; the student performance should be improved if the students have good and effective communication skills and have good competence in English; the student should perform well if they are properly guided by their parents and also by their teacher.

Based on the available data, previous research findings and our experience teaching into as well as leading (one of the authors) the program over the past 13 plus years, we loosely related and defined, as a first approximation the following attributes.

- GPA: Relevant to performance.
- Age: Relevant to family stress, e.g. mature students are more likely to have family commitment.
- Ethnicity: Relevant to English competency and family background.
- Gender: Relevant to learning style and how they can cope with the provided learning facilities.

Based on the above attributes, the samples were partitioned using K-means algorithm. Seven experiments were conducted on the 743 records for $k=2, 3, 4, 5, 6, 7$ and 8 . A descriptive analysis on the clusters was done to select a suitable K value and to find the major features for different student groups. The top twelve courses taken by the students in each cluster were also identified. The data was then split into two data sets: training data (372 records) and testing data (371 records), to test the validity and usefulness of the advice given. The experiment results from training data and testing data are compared to evaluate this approach and identify possible improvements.

For a particular student, the similarity between the student record and the predefined clusters from the sample data will be measured by the squared distances from the record to their centroids, the shorter the distance, the higher the similarity. The record will be identified to belong to the cluster with the mi-

This project is supported by Unitec Foci research fund.

nimal distance, and the data in the identified cluster will be used to provide suggestions to the student. The following is an example of such suggestions from the system (Fig. 3).

C. The testing and experiment (TE) component

The K-means is an extremely efficient and simple algorithm; however, it does have shortcomings that were taken into consideration during the development of the system. Most importantly, it assumes that there is prior knowledge of the data set, due to the size of the algorithm (K value) being defined in advance. Another issue is that cluster analysis does not use category labels that tag objects with prior identifiers, i.e., class labels. The absence of category information makes data clustering unsupervised learning [6].

To determine the K value, TE component provides an environment (Fig. 4) which allows the researchers to experiment with seven K values (2, 3, 4, 5, 6, 7 and 8) on the whole sample data set (743 records). The results are displayed in a combination of text and graphic format. For a given K value, the graph visualize the attribute (GPA, age, ethnicity and gender) distribution and the course selection distribution for four majors (Software Development, Networking and Security, Business Intelligence and Other) for each cluster. The text results provide more detailed information. The top 12 most popular courses for each cluster have also been identified (Fig. 5).

Similar experiment environments are provided for both of the training data set (372 records) and testing data set (371 records), which allow the researchers to experiment with ten K values (2, 3, 4, 5, 6, 7, 8, 9, 10 and 15).

III. THE K-MEANS EXPERIMENT

Let

$$X = \{x_i\}, i = 1, \dots, n \quad (1)$$

be the set of n d -dimensional points to be clustered into a set of K clusters,

$$C = \{c_k\}, i = 1, \dots, k \quad (2)$$

Where $d=4$, representing GPA, age, ethnicity and gender.

What papers should I take next semester?

Course recommendations

Based on your previous levels of study, we strongly recommend the following courses:

- ISCG6441: Visual Game Design
- ISCG6422: Multimedia Programming
- ISCG7425: Java Enterprise Programming
- ISCG6425: Data Warehousing

Additionally, below is a list of courses that you might also consider taking in your next semester(s):

- ISCG7410: Information Systems Management
- ISCG7414: Business Systems Analysis
- ISCG5331: Client Operating System Environment
- ISCG5332: Fundamentals of Network Infrastructure
- ISCG6330: Server Operating Systems
- ISCG6332: Configuring Network Infrastructure
- ISCG6400: Hardware Technology
- ISCG6402: Network Administration and Support
- ISCG6413: Testing and Quality Assurance in ICT

Fig. 3. Example of the suggestions from the IA component.

Fig. 4. The experiment environment for the whole sample data set.

Fig. 5. The text experiment output example.

Let $GPA(c_k)$ represent the average GPA of cluster c_k ; $Age(c_k)$ represent the average of cluster c_k . Let m represent the K value for a particular experiment. Let $SDTEV(GPAm)$ represent standard deviation of $\{GPA(c_1), \dots, GPA(c_m)\}$; $SDTEV(AGEm)$ represent standard deviation of $\{Age(c_1), \dots, Age(c_m)\}$. For L experiments, L standard deviation $\{SDTEV(GPA1), \dots, SDTEV(GPAL)\}$ and $\{SDTEV(AGE1), \dots, SDTEV(AGEL)\}$ will be obtained. The larger standard deviation should reflect the larger amount information provided by the clusters in the experiment.

A. The Selection of the K Value

To determine the K value, seven ($L=7$) experiments have been conducted on the whole sample data set, $n=743$, for $K=2, 3, 4, 5, 6, 7$ and 8. Seven standard deviation $\{SDTEV(GPA1), \dots, SDTEV(GPA7)\}$ and $\{SDTEV(AGE1), \dots, SDTEV(AGE7)\}$ have been obtained. These values are depicted in Fig. 6 to identify a suitable K value.

Fig. 6. The standard deviation for GPA average and age average.

It can be clearly observed that when $K=7$, both standard deviation for GPA average and age average are much larger than the other K values. This suggests that the clusters obtained from $K=7$ provide more information than the clusters obtained from other K values. A close look at the individual clusters produced in this experiment, clear characteristics can be identified for each cluster. Cluster 1 consists of all the young female students; cluster 2 consists all the young male students with very high GPA and most of them are of Asian background; cluster 3 consists of all the young male students with very low GPA and most of them are of European background; cluster 4 consists of all the young male students with very high GPA and most of them are of European background; cluster 5 consists of all the male students with low GPA and mixed ethnicities; cluster 6 consists of all the middle aged students with high GPA and of mixed ethnicities; cluster 7 consists all the male students with merit GPA and of mixed ethnicities. Therefore, the clusters generated by the K means algorithm on the whole data set are informative and effective.

B. The Training Data

To verify the value $K=7$ obtained from the above seven ($L=7$) experiments on the whole sample data set, the data was split into two data sets: training data (372 records) and testing data (371 records). Ten ($L=10$) experiments on the training data set ($n=372$) were conducted for $K=2, 3, 4, 5, 6, 7, 8, 9, 10$ and 15 . Ten standard deviation $\{SDTEV(GPA1), \dots, SDTEV(GPA10)\}$ and $\{SDTEV(AGE1), \dots, SDTEV(AGE10)\}$ have been obtained. These values are depicted in Fig. 7 to verify the K value.

Fig. 7. The training data STDEV for GPA, age, ethnicity and their sum.

It can be clearly observed that when $K=5$ and $K=7$, both standard deviation for GPA average and age average are much larger than the other K values. The standard deviation for ethnicity does not make too much difference. This suggests that the clusters obtained from both $K=5$ and $K=7$ provide more information than the clusters obtained from other K values. Which value to take?

C. The Testing Data

As K means is unsupervised learning, there are no predefined labels for the clusters. We would like to check how meaningful it is if we use the course related information obtained from the training data to provide advice for our students.

The training data and the testing data are two data sets randomly and equally split from the whole data set. It is fair to assume that these two data sets should have similar distribution. We classify each testing data record by using the training data clusters, if the resulting testing data course distribution is close to the training data course distribution, then this approach is promising.

Fig. 8 shows the standard deviations of GPA, age, ethnicity and their sum for the clusters generated from the testing result. The standard deviation distribution of the testing result is quite similar to the training data except that there is a slight difference when $K=5$. However, it can be clearly observed that the standard deviation distribution of the testing result is very similar to the whole data set, in particular when $K=7$, both standard deviation for GPA average and age average are much larger than the other K values. The whole data set size is larger than the training data set size; it should be closer to the actual data. So this approach is promising and $K=7$ is the most suitable K value for this system.

D. The comparison of the Training Data and Testing Result

Fig. 9 shows the training data course distribution (percentage) against the clusters and the testing result course distribution against the clusters when $K=7$ for Software Development major, Fig. 10 shows the same data for Network and Security major, Fig. 11 shows the same data for Business Intelligence major, Fig. 12 shows the same data for the other majors.

Fig. 8. The testing result STDEV for GPA, age, ethnicity and their sum.

Fig. 9. The course distribution against the clusters for SD major.

It can be observed that the course distributions in the two cases are quite close for all the majors in general, except for cluster 3; there is a big difference (around 10%) for all the majors. Further investigation is required to find the reason for this and the way to improve this. It is still meaningful to use the training data to predict the preference of the testing data.

Fig. 10. The course distribution against the clusters for NS major.

Fig. 11. The course distribution against the clusters for NS major.

Fig. 12. The course distribution against the clusters for Other major.

E. The procedure to provide recommendations

Given a student record x_i , we could provide the study pathway the student could take or the courses the student could take for next semester. The following is the procedure to follow in providing advices in the IA component.

- 1) Generate clusters $C = \{c_k\}, i = 1, \dots, k$ by using the K means algorithm on the whole data set, where $k=7$.
- 2) Identify which cluster x_i belongs to, say c_m , where $7 \geq m \geq 1$.
- 3) Find out the top 12 most popular courses in c_m , eliminate those x_i has taken, recommend the rest to x_i .
- 4) Calculate all the average marks for all the courses taken by the students in cluster c_m , eliminate those x_i has taken, recommend five courses with the highest average marks.
- 5) Recommend the most popular pathway (major) in cluster c_m to x_i . This is particular useful to new student or for a student who wish to change major.

IV. DISCUSSION

We have a discussion on all the clusters when $K=7$ for the whole data set (Fig. 13).

For $K=7$, if we classify the clusters according to the average GPA, we can have three levels. High performance level, $GPA > 5$, including cluster 2, 4 and 6 (male, European + Maori + Asian, could be mature students); merit performance level, $4 > GPA > 2$, including cluster 1 and 7 (female or male, aged around 25.5, mixed ethnicities); and low performance level, $2 > GPA$, including cluster 3 and 5 (male, aged around 24.2, mixed ethnicities).

An interesting fact is that cluster 3 and 4 have very similar characteristics except that the average GPA for cluster 3 is 1.88 and the average GPA for cluster 4 is 5.81. What could make this difference? By looking at the clustering statistics by major, it is noted that 43.27% courses taken by the students in cluster 3 are network and security courses, only 30.51% courses taken by these students are software development courses. On the other hand, only 34.53% courses taken by the students in cluster 4 are network and security courses, and 39.97% courses taken by these students are software development courses.

Fig. 13. The whole data set clusters for K=7.

The following is a comparison of the top 12 most popular courses for cluster 3 and cluster 4.

Excluding some basic courses such as “Operating System Fundamentals”, “Professional Skills” “Information Systems in Business” and “Project Planning and Control”, we have the following two lists:

Top most popular courses for cluster 3 are:

- Hardware Fundamentals
- Introduction to Databases
- Programming Fundamentals
- Networking Fundamentals
- Hardware Technology
- Multimedia and Web Development
- Network Administration and Support
- Information Gathering

Top most popular courses for cluster 4 are:

- Programming Fundamentals
- Hardware Fundamentals
- Introduction to Databases
- Multimedia and Web Development
- Networking Fundamentals

- Project
- Database Design & Development
- Hardware Technology

From the above two lists we can see that cluster 3 has four network & security courses and three software development courses; cluster 4 has three network & security courses and four software development courses. And also, in cluster 3, the network & security courses have higher priority and in cluster 4, the software courses have higher priority. This suggests that the low performance students prefer network & security courses, while the high performance students prefer software development courses.

Examining all the clusters in the high performance level (cluster 2, 4 and 6), software development courses are much more popular than network and security courses in cluster 2 and 4, cluster 6 is an exception, however the student average age is 46.8 which is also an exception.

Examining all the clusters in the low performance level (cluster 3 and 5), network and security courses are consistently (43.27% and 45.86%) popular while software development courses are consistently less popular (30.51% and 30.83%).

Cluster 5 and 7 are in the similar situation, however, the GPA difference between the two clusters is not that larger, 1.18 and 3.3. Still network courses are more popular in cluster 5 than cluster 7. On the other hand, business intelligence courses are more popular in cluster 7 than cluster 5.

The above also suggests that the low performance students are more likely in network major and high performance stu-

dents are more likely in software major. So in addition to the four attributes used modelling a student in this system, major is another possible attribute.

V. SUMMARY

Based on our experiment data, it was identified that when $K=7$, the clusters generated from the K means algorithm are more informative and effective.

An outline of the procedure to provide recommendations in the IA component was given. These recommendations can only provide a rough guideline to the students for course selection and major selection.

It is meaningful to use the training data to predict the preferences of the testing data; however, there is a big difference (around 10%) in the course distribution for cluster 3 for all the majors. Further investigation is required to find the reason for this and the way to improve this.

The K-means experiment results on the whole data set ($K=7$) suggested that male students aged between 24 and 27 in the software major, mostly of European, Maori and Asian backgrounds, as well as middle aged (around 45) students are more likely to be high performance students. On the other hand, young male students with network major are more likely to be low performance students. Strategies on how to help low performing students to improve their performance and the high performing students to maintain their level of high performance should be developed and integrated into the advice given by this system.

The experiment results also suggested that major is a possible factor that is related to the students' performance. In the next version of the system, in addition to attributes (GPA, age, ethnicity and gender) in the current student model, major should be added as another attribute in the student model.

Existing records in our current student management system are used. While this facilitates the seamless integration between the advising system and the current student management system, the information that can be extracted from the data is limited, and therefore the attributes that can be used to model students are also limited.

Another area to explore is how closely these results based on the 743 student records represent the entire student population.

Further work is planned using a two phase approach similar to the work done by [11] combining the well-known Cobweb

algorithm with K-means. Cobweb will be used to produce a balanced tree with sub-clusters at the leaves as in [11], and then K-means applied to the resulting sub-clusters.

Future work will also involve taking learning styles into account as well as how best to incorporate advice regarding new elective courses in to the system.

ACKNOWLEDGMENT

We would like to thank the "Student Answer" BCS project team for the implementation of the initial prototype.

We would like to thank Thang Nguyen for revising the database, entering all the testing data into the database and implementing the K-means experiment component.

Abstract—A hybrid project and service based learning course has been introduced in the Department of Civil and Environmental Engineering (CEE) at the University of Illinois. The primary objectives of the course are to develop engineering problem solving, professional, and business skills earlier in our CEE undergraduate curriculum by having student teams identify open-ended, ill-defined campus/community problems or opportunities, develop a feasible project scope, and propose sustainable solutions.

The unique features of our course include (1) a blend of service and project learning with faculty instructors partnering with the campus engineering staff to assist with team project mentoring, campus data collection, local field trips, and case studies, (2) formal course assessments through pre and post-class survey and student focus group interviews, and (3) weekly instructor meetings that consist of faculty, teaching assistants, department administrators and engineering staff updating the course during the semester and planning major changes for the next course offering. In this paper, we describe the course organization and its curricular evolution along with evaluation data from student surveys and focus groups as well as the impact of routine instructor community of practice meetings.

Keywords—project based learning, interdisciplinary team projects, case study, field trips, service learning

I. INTRODUCTION

With a new generation of highly motivated engineering student who yearn for hands-on experiences, project and service based learning curricula are a key asset for preparing engineering students for solving 21st century societal challenges as well demonstrating the importance of the university campus experience. Project-based learning (PBL) involve student engagement in open-ended, complex problems and direct student activity towards producing an end product [1]. Student projects are based on challenging problems that parallel similar activities of practicing engineers [2]. Successful exposure to open-ended problems, which present students with conflicting goals, are integral to the development of the ability to apply the principles of engineering while serving within their profession [3]. In addition, students are able to work more autonomously in generating realistic products which allows them to construct and reflect on their own learning. Chinowsky, Brown, Szajnman, and Realph [4] note “by empowering students to learn outside of classroom lectures and developing contextual situations in which they can apply content, universities are much likelier to produce graduates who are able to apply their knowledge in the real world and continue to build upon it in the absence of lectures”.

PBL courses are not new to engineering [5]. One of the motivators in wider adoption of PBL courses within engineering programs has been the industry. Gaps between graduates’ knowledge of principles of engineering and their ability to apply and synthesize these principles were noted [6], as well as a fragmentation of their knowledge [7]. More recently, employers have demanded greater development of students’ non-technical skills such as written

communication, project management, and teamwork [8]. Several studies have found gains in these “in-demand” skills from active participation in both problem and project-based learning [9]. In addition to improvement in non-technical skills, students engaged in PBL score higher on performance assessments, skill-based assessments, and long-term knowledge acquisition as compared to traditional didactic instruction [10-11].

Service learning (SL) courses simultaneously engage students in academic activities and community service experiences, which provide non-structured academic content and develop non-technical skills, such as, communication, and community engagement. [12-13]. SL experiences were also found to improve professional skills such as decision making, ability to make presentations, and improve interpersonal skills [14]. Webb and Burgin [12] found “significant parallels between factors contributing to successful community engagement and effective teaching and learning by students”. SL was also linked to greater retention of students within engineering programs, particularly for students who are members of minority groups [9].

Fully integrating PBL or SL into large, historical engineering departments are challenging because of the inertia in changing the significant quantity of fundamental science and engineering classes as well as campus level minimums for the number of humanity and social science classes. Therefore, Civil and Environmental Engineering (CEE) curricula evolution has generally lagged updates seen in newer departments (e.g., bioengineering, systems engineering).

The University of Illinois’ Department Civil and Environmental (CEE) continues to be a top-ranked program in the U.S. For years, the college of engineering and CEE undergraduate curriculum has provided students with very strong background in the fundamentals of science and engineering but with limited integrated exposures to team projects accept in the senior year as required by ABET. Based on alumni surveys, observations of other institutions engineering curricula, need for greater professional competency, and the literature [15-17], several faculty recognized the gap in our curriculum to provide a team-oriented project or service experience for early-year undergraduate students that could fulfill multiple learning objectives such as developing interdisciplinary problem solving, professional skills (leadership, project management, and entrepreneurial), and business skills (communication, interpersonal, and teamwork). In 2013, a hybrid project and service based learning course was launched to fulfill the aforementioned objectives with four instructional components: (1) self-selected team projects, (2) faculty presented case studies, (3) field trips to local civil infrastructure facilities, and (4) regular assessments through weekly instructor meetings, formal surveys, and student focus groups.

Through an intimate collaboration with the campus facilities and services engineering group, this course is

"intrapreneurial," giving it a unique flavor of service learning mixed with projects that are more constrained in scope. This course provides a unique experience for our early year undergraduate in civil engineering by combining project and service based learning. Through this integration, we hoped to realize gains in both content knowledge and non-technical skills such as writing found in traditional faculty led project courses while also finding gains in interpersonal skills found in traditional service learning courses.

II. COURSE OVERVIEW AND ASSESSMENT

Our hybrid CEE project and service based learning course offers a blend of team-oriented semester projects, discussion-driven case studies, and instructor-led field trips to local infrastructure facilities. Students collaborating in teams of three to four select a campus problem or opportunity of interest. With mentoring from a team of interdisciplinary faculty from Departments of CEE, Agricultural and Biological Engineering, English, and the campus engineering staff, teams define and scope the problem, develop a realistic project management plan, and eventually propose a sustainable solution. Project themes revolve around engineering sustainability, which engages teams in learning opportunities and creates synergy across many disciplines. Table I is an example of several of the projects students accomplished over the past two years. Through team project work, receiving peer-to-peer team project reviews, and instructor feedback, students develop necessary life-long learning, professional, and business skills that are under-emphasized in our current engineering curriculum.

TABLE I. TEAM PROJECTS

2014 Project Tiles	2013 Project Titles
Feasibility of Green Wall Building Retrofit at Krannert Art Center	Evaluation of algae-based bio-binder for asphalt replacement
High efficiency toilet upgrades and water management	Energy production from swine manure
Feasibility of Solar Panel Parking Lot	Evaluation of the possibility of using raw water on campus
Introducing LEED Lab Campus Course	Business Instructional Facility (BIF) energy assessment – LEED Platinum Certified
Grey Water Collection and Use in Campus Buildings	

Formal student surveys and focus group data collected by evaluation professionals in the College of Education, combined with the weekly instructor meetings, and collaboration and mentoring from faculty with engineering education expertise, helped refine the course over a two-year period. A result of these formative evaluation activities and discussions during the weekly meetings led to the conclusion

that students' writing/communication and project management skills need strengthening, and thus the course evolved to formally include these objectives. In addition, significant class time is allotted for students to conduct their team project work and receive guidance and mentoring from course faculty and campus engineering staff, teaching assistants, and other subject matter experts.

III. UNIQUE COURSE FEATURES

This hybrid course combines aspects of project and service based learning experience while encouraging engineering faculty and campus facilities and services engineering staff (i.e., course instructors) to collectively mentor student teams. An instructor's community of practice was established from the initial course development and implementation in order to foster ownership among multiple faculty members so that longevity of the course is assured. Research has demonstrated that regular meetings and broad faculty engagement along with departmental leadership involvement is the most significant factor in maintaining the stability of a course. Course changes are done in conjunction with formal student feedback from surveys and focus groups, as well as feedback from the engineering education on how to adapt evidence-based reforms in the course (e.g., use of active learning with i-clickers and successful practices adopted from other PBL and SL courses). Additionally, the case studies instruct students in the process and skill of solving engineering problems that are required for their team projects. Field trips provide an exciting student experience on the complexity of engineering infrastructure and a connection to their career studies and projects. Finally, the second hour of the weekly class was reserved primarily to establish regular interactions between the student teams and faculty/engineering staff mentors.

IV. COURSE BACKGROUND AND FORMAT

The hybrid PBL and SL course in CEE is two credit hours and meets once per week. The course is designed for sophomore students in CEE but is broadly advertised throughout the campus to include any engineering or non-engineering disciplines. The class is organized with a faculty course director, multiple faculty instructors who present case studies, lead field trips, and provide expert feedback; engineers from the campus facilities and services (F&S) department; and two teaching assistants, who actively participate in weekly classroom activities. Several additional professors and community professionals contribute to several case study lectures throughout the semester. A professional writing instructor from the English department is also now part of the course, providing students with formal feedback on their semester project reports and presenting technical writing tips.

Throughout the semester, seven case study lectures (see Table II) are presented by faculty on contemporary topics covering a particular area in infrastructure engineering and sustainability. The main case study objective is to teach students the process of engineering problem solving by examining real engineering challenges and opportunities. Prior to each case study lecture, students are expected to read background material on the lecture topic and take a ten-

question quiz. Each case study is designed to be interactive with the faculty delivering probing questions via i-clicker technology in order to lead to facilitate faculty-student dialogue and promote additional inquiries.

Several case studies are integrated with field trips to local civil and environmental infrastructure facilities. The four field trips, listed in Table II, combined with the case study lecture, provide students with opportunities to actively participate in a complex engineering problem and solution in the classroom and in the field, experiencing live and the multidisciplinary nature of designing and building civil infrastructure facilities.

Team projects are key to teaching students how to define a problem or opportunity, propose a solution or feasibility study to their problem, identify what component can be solved in a semester time span, execute a plan of action, and communicate the results in various formats (proposal, interim report, presentations/poster, and final report). This team format is intended to acclimate students to working across disciplines at an earlier point in their undergraduate educational experience than what is normally required in our CEE department. One of the course's goal is to transform our more traditional approach of solving problems in early years of CEE education from a compartmentalized and individual approach into multidisciplinary problem solving team with students from different CEE concentration areas and across the campus.

TABLE II. CASE STUDIES AND FIELD TRIPS

Case Study Lectures	Faculty / Expert	Field Trips
Urban Stormwater Management and Green Infrastructure	Professor, Environmental Hydrology and Hydraulic Engineering	Urban stream passing through campus and designed for city stormwater management and visual amenity
Wastewater Treatment and Biofuel Production	Professor, Agricultural & Biological Engineering	Champaign-Urbana wastewater treatment plant
Power Generation and Infrastructure	Director, Campus Facilities and Services	Campus Cogeneration Abbott power plant
Building Information Modeling (BIM) and 4D Visualization for Construction	Professor, Construction Management	Construction project of new student residence hall integrated with BIM
Construction Material Recycling – Resource not Waste	Professor, Transportation and Construction Materials	
Structural Health Monitoring of Railroad Bridges using Wireless Smart Sensors	Professor, Structural Engineering	
Urban Design and Human Health	Professor, Landscape Architecture	

Teams are formed after several weeks of formal and informal project idea exploration. Students take an initial

pre-semester survey on project themes that they are most excited about and then during multiple organized sessions, students communicate with each other and campus experts and instructors to better define project themes. During the next step, students draft a three-page proposal laying out project objectives, scope, tasks, required resources, and project timeline. As the semester progresses the students gather project information and data via the literature, interviews, observations, and interactions with mentoring from the course faculty and experts. An interim project report is required two-thirds into the semester that provides valuable feedback to teams and allow for changes to projects to meet end of the semester goals. At the end of the semester a final project report is submitted summarizing the findings and accomplishments by the teams. The course culminates in a team project poster presentation that is judged by practicing engineers from the campus and local community.

Informal technical feedback is provided weekly by student-instructor interactions and by the teaching assistants during class and office hours. Technical writing comments are first provided by the English instructor for all deliverables, secondly through peer review, and finally during final grade assignments for each deliverable by course faculty. Students have verbal communication opportunities during periodic three-minute presentations given by each team to communicate project objectives, status, and key findings.

V. COURSE ASSESSMENT AND EVOLUTION STRATEGY

Several key components of the course development and reformation actively utilize student assessment and evaluation data along with weekly instructor meetings. To assess the effectiveness of the course in accomplishing its learning objectives and gather formative feedback to inform course improvements, students were asked to complete questionnaires at the beginning and end of the semesters as well as volunteer for an end of the semester focus group discussion. A complementary WIDER grant from the National Science Foundation, focusing on evidence-based active learning reforms for science, technology, engineering, and math courses, was instrumental in providing expertise from an external evaluation team from the College of Education. This team led development of the survey instrument and focus group guide and conducted the data collection and analysis activities with approval by the University of Illinois Institutional Review Board.

The course was designed to include a cooperative teaching environment with weekly meeting of primary instructors (faculty and campus engineering staff), teaching assistants, and teaching pedagogy experts during the semester and monthly meetings off-semester. This enables necessary changes to the course during the semester while also giving time for strategic planning and changes for inclusion in the next course offering. All instructors were invited to participate and provide feedback to the instruction team. The weekly instructor meetings assessed the previous week's case study activities, including the field trip and project progress, and provided mid-course adjustments as

needed. Long-range planning and course refinement occurred primarily in the off-semester course meetings.

A. Student survey

At the beginning and end of the semester, students were asked to anonymously and voluntarily complete an 18-question pre/post-survey, which included both close- and open-ended questions. Survey questions were designed to assess the following: 1) students' perceptions of the helpfulness of course activities and the course overall for their engagement and learning; 2) changes in students' perceived level of engineering, professional, and business skills and perceptions of engineering as a profession; and 3) influence of the course on students' future engineering-related career plans. Additionally, student demographic data was collected including gender, race/ethnicity, international and language status, and academic standing. Pre-post changes in students' responses to select survey items before and after students completed the course helped provide evidence of the effectiveness of various components of the course for developing students' knowledge and skills and perceptions of engineering as a profession. The surveys were completed by 61% of the students. Both survey results were analyzed by course instructors and teaching assistants. Post-survey results were analyzed by the external evaluation team.

B. Student focus group

At the end of the course, all fifteen students were invited to voluntarily participate in a focus group discussion conducted by the external evaluation team who had not previously associated with the students. Two forty-five minute group interviews of 7 (4 male, 3 female) and 6 students (4 female, 2 male) were held during class time. Open ended questions were given to spark feedback and discussion regarding general topics such as the course structure, the students' assessment of what they learned, skills they used, and how this course has influenced their understanding of the engineering profession and their role in it. Interviews were audio-recorded, with permission from all participating students, and anonymous transcripts were analyzed by the external evaluation team and summarized for the course instructors [5].

VI. ASSESSMENT RESULTS

In this section, we provide brief descriptive information regarding students who participated in the 2014 survey, focus group interviews, and changes to the course made based on the evaluation data. We provide the survey mean on a 1 to 4 point scale, where 1 means either poor, not interested or not important and 4 means excellent, very interested or very important. A sample of the some of the key results are summarized next.

A. Course Format

Students reported that all aspects of the course enhanced their learning experience. Students scored the best components of the course to be field trips (3.88), research experience (3.75), project-based learning (3.63), and developing their project-management skills (3.63). Additionally, in both the questionnaire and focus groups,

students reported that interacting with practicing engineers was helpful because these interactions exposed them to different areas of engineering. They also reported that the field trips were helpful because they provided hands-on, experiential learning, and the project proposals were helpful for learning project management skills, e.g., start a project, set a timeline, and technical writing as noted in the student quote below:

I find the opportunity to develop and pursue a project to completion the most helpful. This class exposes underclassmen civil engineering students to the field because they choose a project to tackle and complete the project in a given period of time. Just like they would in the industry. It is a unique class that allows students to develop technical and applied skills rather than the theory that is learned in most other classes. – Student

Students valued having multiple instructors for hearing a diversity of perspectives, especially at the beginning of their projects, and for learning about a variety of engineering subfields as noted in the following quotation.

The four consistent instructors that we had, they each specialized in something different, so if we went to one instructor and asked them for advice, it would be different than what another instructor would say. That's good because it helped us get different views, and we decided which view we wanted to integrate for our own proposal. It was really good to have multiple resources to go to. – Student

B. Learning and Engagement

Students rated the course most helpful for thinking about the material rather than just memorizing it (3.75), understanding what it means to be a professional in this discipline (3.63), building on prior knowledge in this discipline (3.63), taking ownership over what I learn rather than only relying on the teacher (3.63), feeling excited about learning (3.63), and working with peers to solve problems (3.63). Students noted that they developed a variety of important skills related to project development and management including how to write proposals, how to interact with other professionals in the field, communicating data, and working with others. Additionally, several students stated that this course helped them realize the value of doing projects that had a real impact on people and society.

I think starting a project from the beginning, and trying to imagine where it's going to go two months from then was really helpful because that's not something we'd done before, but it's going to really pertinent to our careers. – Student

Survey results taken before and after completing the course, shown in Figure 1, show the change in overall student self-rating of their project, communication, and teamwork skills. Collectively, the students self-assessed an improvement

from mostly fair (2.79/4.0) to (3.52/4.0) good/excellent in their own project, communication, and teamwork skills, most significantly in their written communication. Overall, the student focus group responses had mixed reactions about the writing instructor despite strong self-assessment of the importance of technical writing. International students felt the writing instructor support was helpful and improved their proposals.

Fig. 1. Students' self-rating of project, communication and teamwork skills before and after completing the course in fall 2014

VII. SYNTHESIZING COURSE ASSESSMENT INFORMATION

Results of the student feedback relative to the overall course objectives, fostering improved student-instructor engagement, and implementing a collaborative teaching and feedback environment within a community of practice was largely successful. Multiple instructor involvement with their own particular specializations was an effective method for discussing a wide range of topics and added a layer of confidence that students were receiving exposure to the latest research and trends in many fields. As one student put it “it’s really nice having each topic presented by someone that knows it really well—and specializes in it.” Another student benefit of involving experts to present case studies is that data being presented about real projects familiar to the expert hold students attention and sparks discussion.

The critical mission of campus division of F&S is to support the academic engine of university, and a connection to F&S was a critical component of this course. The partnership with F&S connected students to their projects with data sets and campus F&S engineering professionals. One student said, “One of our ideas could actually be implemented in the university—knowing that, that’s pretty cool.” F&S has been instrumental in refining problem statements, providing data, mentoring students, and presenting a case study and hosting the field trip at power plant and their continued participation in our course is critical.

When students were asked what the most important skill that they learned in the course was, their overall comments expressed how important professional writing is and the

value of good communication skills, which validates keeping a technical writing aspect to the course as well as continued opportunities for student presentation of projects. Field trips were ranked as the most interesting aspect and the most helpful for understanding the roles of engineers. Although arrangement and supervision of field trips are time consuming, clearly students gain tangible experience from them and thus they are an essential part of the class. Case studies provide an early opportunity for many students to learn what engineers do and show students how to frame a problem, which in turn assists them in their team projects and future classes.

VIII. COURSE CHANGES STEMMING FROM STUDENT AND INSTRUCTOR FEEDBACK

The student and instructor feedback led to changes between the first and second year of the course. The main changes included adding a case study on structural health sensing and monitoring as well as adding an English department instructor to provide formal technical writing feedback to students prior to instructors grading the delivered reports. Teaching students how to write clear project objectives, how to define a problem, and how to establish tasks and distribute them among team members during the course's first offering was not overly successful but during the second offering formal training was given and the students responded positively. The course schedule was also altered to give more in-class time during the beginning of the semester for students to develop their project ideas. Finally, time was given at multiple points in the semester for students to orally present their project progress both for their benefit, and so that teams could learn what the other teams were doing.

Modifications to the next offering of the course in the fall 2015 will include refining the project identification process to include assignment for individual students to generate project ideas based on campus needs, presentation of each student's top two project ideas, and delaying team formation and initial project proposal deliverable. Several case studies will be introduced earlier in the course to accommodate more time given to project idea development. A learning management system software (ScholarTM) will be implemented to allow for online collaboration across and within the teams, a semantic writing tool for project reports, pre-class quizzes, peer review, instructor grading, report editing statistics, permanent archiving of the team projects, and scaling the class to larger number of students. The introduction of this course into CEE is currently only an elective but effort is underway to make it a core requirement for sophomores in our undergraduate CEE curriculum. Finally, the pedagogical innovations and lessons learned from this course is already impacting senior design course in our CEE curriculum.

IX. CONCLUSIONS

The development of a hybrid project and service based learning course at the sophomore level for the Department

of Civil and Environmental Engineering at the University of Illinois provides a major shift from the traditional faculty lecture format used in most CEE courses. Additionally, transforming students' traditional way of solving problems from an individual, compartmentalized approach to a multidisciplinary problem solving team approach at earlier years in the undergraduate curriculum will acclimate students to think like an engineer and allow them to work across disciplines more efficiently in the junior and senior years. The primary objectives of this course are to teach students problem solving, professional competency, and business skills as well as to identify as a CEE. The objectives are met through intimate collaboration with the campus engineering staff, discussion-driven case studies led by the course instructors, field trips to local civil infrastructure facilities, and most importantly through student-defined team projects related to a problem or opportunity observed on our campus through hands-on learning experience.

Current successes in the course derive from a strong instructor community of practice that facilitate activities such as weekly meetings during the semester and monthly meetings when the class is not in session, discussions of improvements, and incorporation of research based instructional strategies. Formal course assessments rate student-instructor interactions and subject expert feedback as an important aspect of the course. The course's success is also intimately linked to the expertise provided by campus engineering personnel, evaluation experts, engineering education experts, and English writing expertise. Additionally, the collaborative teaching environment ensures that the course reforms are sustainable over the long term.

ACKNOWLEDGMENTS

The authors would like to express appreciation to the University of Illinois College of Engineering Strategic Instruction Initiative Program (SIIP) grant and Department of Civil and Environmental Engineering resources to develop and reform this course over the past 2 years. Special thanks to University of Illinois Campus Facilities and Services for making available their pertinent facilities, engineering staff, and information to our faculty and student teams. The authors also acknowledge funding support provided by National Science Foundation WIDER grant DUE1347722.

Abstract— According to Federal Council of Engineering, in Brazil the Engineers deficit is estimated at about 20,000 per year on several areas of engineering. Among other factors, one of the causes of this deficit is the high failure rate in the disciplines within the technical area which causes students to take up to twice the time required to complete the course. This phenomenon is also reflected in the Vocational courses of the Engineering area mainly because the students are teenagers that quickly discourage before traditional classes. Therefore there is a failure to achieve the goal of education and considering the specificities of each student deficiencies. One of the issues that has been extensively studied in recent years is how we can improve the teaching of technical subjects in vocational courses and engineering that, in Brazil, have a failure rate that reaches 40% in some cases. In countries with more developed education, such as Finland, Sweden, Korea and others, they are already using more modern methods aimed at excellence in learning, such as "Project Based Learning", "Collaborative Learning", "Learning by Doing", "No Child Left Behind", among others. These methods change the educational philosophy and teaching bases, putting the student as a central element of learning and working their specificities and self-development in a participatory and motivating environment. Thus, this paper presents the use of these modern methodologies applied to technical vocational education in the Federal Institute of Amazonas, in Mechanical Areas, Electronic and Electrical Engineering, in subjects in which failure rate reached 40% when using the traditional teaching used by the Campus. The results of using these methodologies in four groups involving about 120 students demonstrated substantial improvement in the learning of technical subjects, with consequent reduction in the failure rate and increase the motivation and self-esteem of students to give continuity to the studies in this area and join Engineering courses.

Keywords - Project Based Learning; Collaborative Learning; Learning By Doing.

I. INTRODUCTION

In Brazil there is a deficit of professionals from the fields of technology. Particularly in the area of Engineering, this deficit reaches 150,000 professionals as pointed out by the study conducted in 2012 by the National Confederation of Industries - CNI. In addition, the offer of courses in technology is limited; the situation becomes more complicated because of the high rates of dropout and retention of students. Due to failures in technical disciplines, students have no success in completing their courses. Usually, in Brazil, the students feel demotivated in traditional classes which do not catch their attention.

In these traditional classes, more often, the specificities and weaknesses of each student are not considered, and this can be

understood because the philosophy of education in Brazil is more centralized in the teacher and in the contents that have to be shown.

The necessary students' motivations to the conclusion of their studies and ingress in the engineering faculty are a problem in vocational education in Brazil. Some of the students who started a vocational course in engineering area did not continued in the same area; instead they changed to another course/area when they went to the university.

Another problem when the student starts in a vocational course in Brazil is the disabilities originated from basic levels. Consequently, it is necessary the search of new methods, alternative teaching and learning processes to improve this condition that negatively influences the development of technological professional education in the country.

Furthermore, in [1] the author says that the environment of education needs to adapt to the actuality. Currently the changes that came with the digital age and new technologies have made the teacher to reconsider his goals and teaching methods. The first step indeed is to identify what is the key knowledge and skills that students need in a digital age and how the technology is changing everything, including the context in which the contents are taught. Is it effective to use only a blackboard and chalk where the students are accustomed to the interactivity of smartphones and social networks? Therefore it all has to be evaluated and considered.

Granted that in countries where the education has excellent results, such as Finland, Sweden, Korea and others, they have used more modern methods to obtain the excellence in learning, for instance Project Based Learning, Collaborative Learning and Learning by Doing, among others. The Finnish education to illustrate is among the best in the world. One of the factors behind this success is the constant formation and teacher training both in educational area as in operational area, also investment in modern tools and equipment that facilitate learning in the classroom, technical laboratories and computer resources [2].

In Brazil there are more than 500 campuses in the Federal Institutes of Technological Education - IF, that are a net of public college sponsored by Brazilian government, free of charge. These Institutes are nowadays the main place to study vocational courses and also engineering courses.

In the Amazonas state, There is an IF called Federal Institute of Amazonas - IFAM, where it was started a project to improve the teaching and learning processes using modern pedagogical tools applied to technical vocational education. Were chosen two different Campuses and three vocational technical courses divided in four groups involving about 120 students. The first Campus is from Presidente Figueiredo city, in the middle of Amazon rainforest, and the other one is from Manaus city, the capital of the Amazonas state. In both Campuses the results show a substantial improvement in the learning of technical subjects and the increase of student's motivation.

II. MODERN PEDAGOGICAL TOOLS USED IN THIS WORK

In this digital age, several countries started the use of new pedagogical and technological tools, and there are several "innovative" approaches to teaching that actively involve the student in a "student centered learning" perspective.

There are actually a wide variety of approaches to facilitate students learning together (as opposed to learning individually). In this work we used three of this approaches that are described in the next subsections: Collaborative Learning, Learning by Doing and Project Based Learning. These approaches are considered new and modern at IFAM according to our reality; despite they are used in other places since years ago.

A. Collaborative Learning

The most common definition to collaborative learning is the situation in which two or more students learn or try to learn together some content [3]. The learning could occur in a small group, in a class, in a community with thousands of people or in a society with hundreds of thousands of people. Many authors, including [4] and [5], consider the collaborative approach more efficient then individual approach.

Collaborative Learning is an educational philosophy, not just a classroom technique. In all situations where people come together in groups, it suggests a way of dealing with people which respects and highlights individual group members' abilities and contributions. In the collaborative model groups would assume almost total responsibility for answering the question, solve the problem or execute the project.

In Collaborative Learning, the group determines if they had all the elements to realize their job. If not they look for other information sources until they have the necessary knowledge. A basic planning is necessary and the tasks divisions are decided by the group work. Each member contributes with his skills to obtain synergy. Although it is true that work in group is not a trivial task (especially in Brazil) and the natural leaders appear in the group to facilitate this challenge. The group would decide what to do, how to do and how to show their results, but the final product is determined after consultation with the teacher. [6]

The teacher has an important contribution in this process, which is not specify the actions but rather assess the progress of each group and provide suggestions about each group's approach and the results achieved. The teacher would be available for questions and would facilitate the process by asking for progress reports from the groups, facilitating group discussions about group dynamics, helping with conflict resolution; he will act as a coach.

According to Vygotsky [7], the students are capable of performing at higher intellectual levels when asked to work in collaborative situations than when asked to work individually. Group diversity in terms of knowledge and experience contributes positively to the learning process. There are several benefits to apply Collaborative Learning, and in [8] some of them are presented, based in students' feedback after a Collaborative Learning project and the results with main answers were as follow:

- Benefits Focusing on the Process of Collaborative Learning
 - Helped understanding
 - Pooled knowledge and experience
 - Got helpful feedback
 - Stimulated thinking
 - Got new perspectives
- Benefits Focusing on Social and Emotional Aspects
 - More relaxed atmosphere makes problem-solving easy
 - It was fun
 - Greater responsibility- for myself and the group
 - Made new friends
- Negative Aspects of Collaborative Learning
 - Wasted time explaining the material to others

The major challenge in this job to use collaborative learning was the Brazilian culture. Brazilian students are very social and creative but usually they have an aversion to commitments and difficulties to punctuality and deadlines. Because of this, the teachers' action was fundamental to help them to stay focused in their tasks.

B. Learning by Doing

One of the most important problems when we are using traditional teaching methods is that students are not learning skills; these teaching methods are centered in teachers and in transferring contents that can be found in the learning goals defined in school curriculum [9].

In vocational technical courses there are the practical classes but, in some cases, this "practice" is used to confirm or valuate the knowledge. For instance, a student from Mechatronics course needs more than to know about the technological contents, he needs to know how to do a specific task.

The Learning by Doing approach, or experiential learning, can be defined as "the strategic, active engagement of students

in opportunities to learn through doing and reflection on those activities, which empowers them to apply their theoretical knowledge to practical endeavors in a multitude of settings inside and outside the classroom” [1].

The Learning by Doing method disposes the student as the central focus of learning. It makes him able to build cognitive learning through proposed problems that submit him to the motivating situations.

Thus, the student ceases to be passive in the education system and becomes the central object of his own development. The teacher is no longer the only knowledge provider. The lectures with unilateral transmission of knowledge disappear to transform the class in a room for interaction with the construction of knowledge fostered by discussion and research, encouraging the participation of the student inserted in a group.

The choice of this work in using Learning by Doing method is to improve the student's skills to help them climb the pyramid of taxonomy of cognitive domain, as shown in Figure 1, in which the student is leaving the remembering level to achieve levels of applying, analyzing, evaluating and even creating.

Fig. 1. Revised taxonomy of cognitive domain. Image: © Atherton J S (2013) CC-NC-ND [10].

There is a wide range of design models that aim to embed learning within real world contexts, and all of them focus on learners reflecting on their experience of doing something, so as to gain conceptual insight as well as practical expertise. Kolb’s experiential learning model [11] suggests four stages in this process:

- Active experimentation;
- Concrete experience;
- Reflective observation;
- Abstract conceptualization.

The result of Learning by Doing approach is a curious, motivated, challenged, creative and with entrepreneurial spirit student, ready to lead and work as a team. In general, the classes become a discussion workshop on real problems and the teacher becomes a mediator, far beyond a simple transmitter. The student who had been subjected to this methodology in the learning period is able to make practical and harmonious decisions, as experienced unusual situations

in practical applications of simulated problems or even real world problems.

C. Project Based Learning

In recent years Project Based Learning – PBL, one of the most effective tools used in technical subjects and engineering education, has become increasingly accepted as a useful concept in engineering education. PBL is becoming the favored pedagogical model for teaching engineering design to transform methods of teaching to address more complex open-ended real-world problems [12].

In [13] the author makes a Project Based Learning (PBL) review. PBL is a learning model that organizes learning around projects. According to definitions found in books and handbooks on the subject, projects are complex tasks supported in challenging questions or problems involving students in planning, problem solving, decision making, or investigative activities; Gives the opportunity to the student to work with relative autonomy; culminates in realistic products or presentations.

Projects involve students in a constructive research and an investigation is a process directed to a target that involves research, knowledge building and resolution. One question involved in this issue is, "what a project must have to be considered PBL?" There are five criteria [13] for the answer to this question. The five criteria are centrality, guiding question, constructive investigations, autonomy and realism.

In short, in PBL the projects are the central teaching strategy. Students learn the central concepts of the discipline through the project. PBL projects are focused on questions or problems that lead students to find the core concepts and principles of a discipline, besides involving constructive investigations.

An investigation is a process driven by goals that involve research, the construction of knowledge and resolution. But in order to be considered as a PBL project, the central activities of the project should involve transformation and construction of knowledge, new insights, and new skills for the students. All of this combined with the autonomy and realism.

The projects do not take pre-determined paths. PBL incorporates real-life challenges, where the focus is authentic problems or issues (not simulated) where solutions have the potential to be implemented.

Based in [14] we can affirm that project based learning matches some important teaching principles:

- Situation relatedness: Contents are arranged according to concrete current or future situations.
- Action relatedness: Contents offer assistance and orientation for concrete actions.
- Science relatedness: Contents are oriented both by the level of knowledge as well as by the topics and methods of the respective scientific discipline.

- By examples: Contents were selected so that the wealth of knowledge is depicted by a few typical cases (which are representative for similar issues).

Several studies have suggested standard steps for PBL; however the specific local conditions should be guiding these steps because we need to evaluate the availability of time, physical space, laboratories, equipment, and human and financial resources. Considering the nature of the courses involved in this work, we present the following steps for a generic PBL, which can be adapted to other situations.

- Analysis of the learning domain and involved skills
- Division of the class in groups
- Recognition of each participant in his group
- Conception of collaborative activity
- Planning of collaborative activity
- Implementation of collaborative activity
- Partial evaluation of collaborative activity
- Adjustments and corrections in the implementation
- Presentation of the final result
- Overall project evaluation.

Throughout this process, the teacher's role is to guide and advise, rather than to direct and manage, student work. This is crucial because the students that start their courses in Federal Institute of Amazonas are not used to working by project and therefore has difficulty in self organizing, despite the ease of work in group.

III. APPLYING NEW PEDAGOGICAL TOOLS TO IMPROVE LEARNING IN TECHNOLOGICAL CONTENTS

The teaching philosophy of Federal Institute of Amazonas vocational courses is to foster qualified students equipped with integrated knowledge to science and technology with critical thinking and ethics. One way to attend this is improving the learning and teaching methodologies. In this Section we show how we applied the new pedagogical tools discussed in section II.

A. Expected learning outcoming

First of all, before starting the use of modern pedagogical tools, it is important to set what is expected to the student to achieve when he takes part in this kind of methodology. In this case, after completing the projects, the students should be able to do the following:

- Work collaboratively across disciplines (informatics, electronics, microelectronics, etc.).
- Demonstrate proficiency in the use of appropriate knowledge and tools to solve open-ended real-world problems;
- Gain experience in hands-on, problem solving and team interaction.
- Improve academic performance.

- Demonstrate effective oral and written communication skills in the context of collaborative teamwork.
- Communicate with companies and find opportunities or problems to be solved;
- Understand the fundamentals of project management.

B. PBL implementation methodology

The PBL was developed in stages, starting with a presentation to students about the new learning method based on a project, including collaboration and practice. Then, the class was divided into groups of four to five students who, at first, were presented in the group to realize affinities, strengths and weaknesses of each one. After these initial stages, the used methodology can be summarized in the flowchart shown in Figure 2.

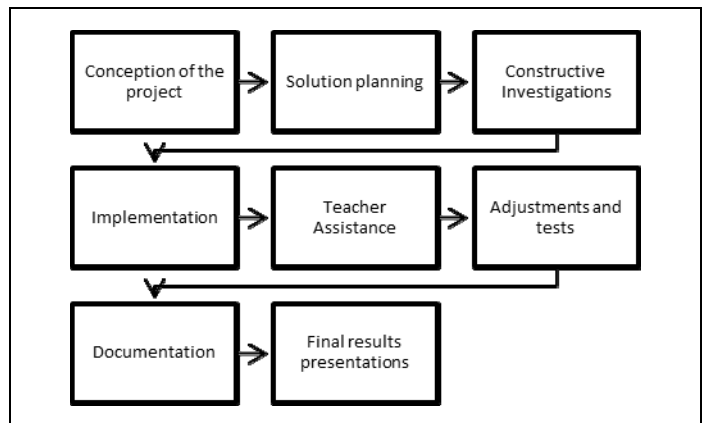

Fig. 2. PBL Methodology used in this work.

The time required for each stage depends on the available time and project complexity. In this work the PBL was developed in a semester and the actions in each stage were:

- *Conception of the project*: The students themselves choose which projects they will work on. They observe community problems that could be solved and have ideas to start their projects.
- *Solution planning*: After students had picked a project, each group, they plan next steps and how to obtain resources needed to support the chosen solution to the problem.
- *Constructive investigations*: Using books, articles, internet and others sources, they make investigations in a collaborative environment that involve research, the construction of knowledge and problem resolution.
- *Implementation*: Students in teams implement their projects in a collaborative and experiential way.
- *Teacher Assistance*: Not only at this moment but especially when the first problems occur, the assistance of one or more teachers is fundamental to help students in their projects administration.

- *Adjustments and tests:* Students make tests and improvements in their projects until the goal is achieved.
- *Documentation:* After all project adjustments, the group writes a technical report about their project, including diagrams, components list, drawings, etc.
- *Final Results Presentation:* The projects are presented to the community and teachers to the assessment of the groups projects. The grading can be based on individual and group performance as well as theoretical learning on project management as it was made here.

IV. APPLYING NEW METHODOLOGIES IN CAMPUS PRESIDENTE FIGUEIREDO

A. Course description

Campus Presidente Figueiredo-CPRF is located in a rural area distant 107Km from the capital of Amazonas state and was founded in 2010. Among others, it offers Mechanics and electrical vocational courses. These courses are offered as full-time and the students take high school along with the vocational course. There was among the students a high failure rate in technical disciplines, difficulty in learning and lack of motivation especially in technical disciplines. Teachers at IFAM apply a variety of teaching and learning methods to support the learning performance of the students. Traditional forms of teaching and knowledge transferring such as the traditional lectures have been being complemented by more self-responsible and activating forms of learning. One of the main reasons is that students do not learn solely through listening but also through facing up and dealing with the learning contents.

In this context we applied modern pedagogical tools, mainly PBL projects, for the students from the last year of these two courses to engage and motivate them to continue in the technological and engineer areas.

B. Project Results

About 60 students of Mechanics and electrical courses of CPRF vocational courses took part in the PBL projects. The Projects have been pooled into twelve teams. The idea or the project itself was suggested by the students themselves.

To obtain success using PBL methodology and allow that students conclude it in a positive perspective, it was important that the projects should fulfill the following:

- be a real problem in their fields and be of direct benefit to the local community;
- include mechanics, electrical, and electronic key components;
- be suitable for 5 students and equivalent to 10 weeks of workload;
- Consider environmental issues and sustainability;
- Include technological innovations.

The steps as shown in Figure 2 were taken to the development of the PBL projects. As a result, follows a list of actual projects developed by IFAM –CPRF students:

- Thermal energy powered engine;
- *Canecatron*: mug liquid mixer;
- Homemade air conditioner;
- Fan;
- low cost irrigation system;
- hydropower generator;
- wind power generator;
- automatic clothesline;
- thermal energy powered car prototype;
- Beetlebot;
- Stirling motor;
- Mousebot.

Specifically one example of the projects is a low cost irrigation system. One student's family has at their place a vegetables plantation. As part of her routine, the student had to wake up very early to water the plantation, and it needs to be watered twice a day. This team implemented an automatic irrigation system using recycled materials that worked as planned and is now being used in the student's plantation (Figure 3).

Fig. 3. Automatic irrigation system being tested - one of the PBL projects implemented at CPRF.

To this end, during the implementation of the projects students had to seek for new knowledge, applying therefore the self-learning methodology in a Collaborative Learning perspective. To consolidate this knowledge the students had to build the actual part of the project, which characterize the Learning by Doing methodology. At every stage of the project the teacher's support was important both motivating and guiding the student's actions.

The students implemented the projects and after all adjustments the projects were presented to the community and the contribution of each student had been graded. The grading was based on individual and group performance as well as theoretical learning on project management.

It can be assumed that almost all students that took part in projects liked the experience. This is a very important fact concerning the question of motivation.

In conclusion, some statistical data are shown in Figure 4 and Table 1. The first one shows a comparison between the approvals rate applying the traditional teaching and the modern pedagogical tools (PBL) approach in the two classes where the projects were taken. It is possible to see that both of them improve the approvals, especially in the mechanics course. The second one shows the class grade point average with and without PBL approach. After applying modern pedagogical tools (PBL) in teaching, students' performance had improved substantially. Where the improvement were 24,8% and 67,8%, and again, the biggest improvement occurs in mechanics course. This confirms the potential of this methodology.

Fig. 4. Comparison between the approvals rate applying the traditional teaching and the modern pedagogical tools (PBL) approach in the two classes where the projects were taken.

TABLE I. CLASS GRADE POINT AVERAGE APLYING PBL APPROACH AND WITHOUT PBL APPROACH.

Class GPA	Mechanics students	Electrical students
Without PBL approach	5,63	7,65
Applying PBL approach	9,50	9,55
Percentage Improvement	68,7%	24,8%

Table 1 – This is a comparative of Class GPA with modern pedagogical tools (PBL) approach and without PBL approach.

Fig. 5. PBL projects and students in the implementation stage. The pictures show diferent groups acting in diferent projects.

The PBL Project exhibition, Figure 5, has become a mandatory item on the development of the activities of teaching, research and extension at CPRF making it a determinant factor in the formation of our students for the labor market and promotes the motivation for continuing in engineering courses.

V. APPLYING NEW METHODOLOGIES IN CAMPUS MANAUS DISTRITO INDUSTRIAL

A. Course description

Campus Manaus Distrito Industrial - CMDI was founded 23 years ago in the city of Manaus, Amazonas state capital, which has about 2 million inhabitants and more than 600 industries of electronics devices and motorcycle. CMDI offers courses in engineering area, acting in engineering and vocational technical education.

Among these courses, there is a vocational technician electronics course integrated to high school, where the student studies full time both in high school and vocational technical course. In this course, as others in the same area, we have observed students' demotivation for the technical contents in the last year of the course.

In this context, the electronics course was chosen for the implementation of PBL with concepts of collaborative learning and learning by doing. The course has two classes divided in 30 students, and the PBL was applied to both classes in the last year of the course (third year), reaching 60 students.

B. Projects Results

The methodology presented in Figure 2 was used. To motivate the projects, it was applied an initial learning process of technical knowledge based in research in media, newspaper and regional real problems that could be solved using electronic systems prototypes developed in classroom. Among these real problems, were presented to students the difficulties of people with disabilities or some kind of disease as an opportunity to propose new ways to help them. Thus encouraging and stimulating the students to use the technology to solve problems like inclusion of people with special needs (Figure 6).

Fig. 6. Visiting a children with special needs school (a) and wheelchair users association (b).

The experience was significantly better when students visited schools for children with special needs and a wheelchair users association. The students could experience the everyday life of these people.

In the next step the class was divided into groups of 3 to 4 students to start the projects. Each group defined the problem to be treated and one possible solution. Many students had deficiency in the previous formation and they did not have the expected knowledge or skill required to students in the last year course. Because of that was essential to identify weaknesses and strengths through reviewing contents and technological tools required for the projects development.

The implementation of prototypes were made in electronics and automation laboratories; which have the necessary tools, machines and measuring equipment to assemble and identify possible errors to make adjustments in the prototype. This stage was very important in the learning process. The groups searched the necessary theoretical knowledge using Collaborative Learning and found the ways to execute their planning with success in developing their prototype, applying the Learning by Doing approach.

As an example, Figure 7 shows a robot prototype controlled by mobile phone via Bluetooth, developed in the laboratory with acrylic parts and low cost electronic embedded system. This project consists in use the robot to navigate in environments with difficult access, without human intervention.

Fig. 7. Robot prototype controlled by mobile phone via Bluetooth.

The main result of the modern pedagogical tools was the student learning improvement, as one of them said: "now I'm really learning to be an electronics technician and began to understand those things that I studied before and did not know why." Concerning to the projects, 70% of the groups conclude the project and 30% did not succeed in completing the project, in most cases because of lack of organization and planning or even for lack of dedication to the project. However, all groups had effectiveness in learning of contents expected for the course.

As a result of the use of the mentioned modern pedagogical methods, it was not possible to quantify gains on issues such as drop out and failure rate, because in the last year course these rates are already low even in traditional teaching. However, were observed important improvements in the following aspects:

- Students perception of the opportunities in the real world and relate this to their training and future career;
- Work in team in a collaborative environment
- More independence in the students own learning
- Work under pressure and have to obtain results with the limited resources, especially time;
- Motivation to learn and complete the project
- Proud to present to teachers, parents and friends the result of their work.

As an additional result, some of the best projects were presented in science and technology fairs, some of them receiving awards and even being chosen to participate in national events. One of these projects was the braille phone, a mobile phone designed to send messages in braille for blind people (Figure 8). This project was presented in the Science and engineering Brazilian fair and gained the first place in engineering area. Nowadays the student is cursing electrical engineering at the university.

Fig. 8. The prototype of the braille phone, a mobile phone for blind people designed to send messages in braille.

VI. FINAL REMARKS

In a digital age where students have easy access to lots of information, most of them confused and disconnected, the professional education in Brazil needs to reformulate its teaching and learning methods, not using only traditional methods but using modern pedagogical methods, which this work demonstrated to be an important way to improve the quality of education, encouraging students to give continuity to their studies in engineering area.

Developing this work in schools where traditional teaching is used by most teachers was not an easy task. The teachers involved with the project had to break some paradigms involving the school, and convincing students and parents about the new method. We observe that the greatest difficulty to apply the new methods was the cultural shifts from passive learning to learning by doing and collaborative work, something unusual for students, although they had enjoyed the experience.

The results show that educational levels increased, the students were more motivated and the involved teachers satisfied to see the good result of their work. The applied modern pedagogical tools reached what we expected and in addition it served as a parameter for other teachers who saw the

results of the projects and felt interested in knowing and applying the same methods.

The next steps are multiply this successful experience and training other teachers to use these and others modern pedagogical tools, with the objective of taking the professional education at IFAM to an excellence level.

ACKNOWLEDGMENT

The authors are grateful to IFAM, Campus Presidente Figueiredo and Campus Manaus Distrito Industrial and the staff of these organizations, without that support the realization of this project would be impossible. We also thank CNPq / Program “Teacher for the Future”, Call CNPq/SETEC/MEC 015/2014.

Evaluation of Student Learning Outcomes in Fourth Year Engineering Mechatronics through Design Based Learning Curriculum

Sivachandran Chandrasekaran, John M. Long, Matthew A. Joordens

School of Engineering

Deakin University

Geelong, Victoria Australia

siva.chandrasekaran@deakin.edu.au, j.long@deakin.edu.au, m.joordens@deakin.edu.au

Abstract—This paper focuses on evaluation of student learning outcomes in fourth year engineering mechatronics through design based learning curriculum. The purpose of all engineering degrees is to provide strong grounding with principles of engineering science and technology. By learning engineering methods and approaches in an academic environment, graduates can enter the world of work and tackle real world problems with innovation and creativity. In many cases, academic staff are responsible for driving and setting high expectations in their classrooms. Sometimes staff are expected to teach subjects outside their expertise. This research paper is concerned with evaluating student learning outcomes through feedback sought from students on design-based learning approach.

Keywords—*Design based learning; Project based learning, Students learning outcomes; Engineering education;*

I. INTRODUCTION

Design-based-learning (DBL) education is a form of project/problem based learning in which students gain knowledge while designing a solution (object or artifact or report) meaningful to the students. It involves collecting information, identifying a problem, suggesting ideas to solve it and evaluating the solutions given. Once students have chosen the problem to focus on, they design a solution to solve it. Finally, the students receive feedback on the effectiveness of their design both from the facilitator and from other participants. Design-based learning is especially used in scientific and engineering disciplines. Students at Deakin University in Australia are given the opportunity to provide feedback on the units they are studying and the teaching staff through the use of a course-experience survey. The course-experience survey collected anonymously from students gathers student evaluations of the quality of the unit, its material and the way it was taught [1]. The course experience survey is collected every semester, which gives an opportunity to compare the student experience of the fourth year engineering unit when it was taught through design based learning curriculum. The project in this unit involves students designing, building, and demonstrating a simple robot. The DBL in this unit was a very effective approach for student learning.

II. DIFFERENT LEARNING PEDOGOGIES

A. Project Based Learning

Project-Based Learning is perceived to be a student-centered approach to learning. It is predominantly task-oriented and facilitators often set the projects. In this scenario, students need to produce a solution to solve the project and are required to produce an outcome in the form of a report guided by the facilitators. Teaching is considered as input directing the learning process. The project is open ended and the focus is on the application and assimilation of previously acquired knowledge.

Engineering students require the opportunity to apply their knowledge to solve problems through project-based learning rather than problem solving activities as those do not provide a real outcome for evaluation [2-4]. One of the greatest criticisms of traditional engineering pedagogy is that it is a theory based science model that does not prepare students for the 'practice of engineering'. Self-directed study is a large part of a student's responsibility in project based learning modules [3, 5-7].

B. Problem-Based Learning

In this type of learning and teaching, students are usually presented with a situation, a case or problem as a starting point. The role of the teacher is to be a supervisor of the learning process. The subject knowledge gained by students is considered to be about the same for problem-based learning as it is for traditional teaching methods, however it does aid in developing creative thinking skills for problem solving. In this approach, students learn how to learn. Using problems or cases from real life in teaching is effective for motivating students and enhancing their learning and development of skills. Students need to learn how to find information when needed as this is an essential skill for professional performance.

Problem solving is a component of the problem-based approach. Problem-based learning (PBL) focuses on problem scenarios rather than discrete subjects and the selection of the problem is essential in PBL [8-10]. The teacher acts to facilitate the learning process rather than to provide knowledge and solving the problem may be part of the process. Here, problem scenarios encourage students to engage in the learning process. The learning process is the central principle, which enhances students' motivation, and is a common element in

problem and project-based learning. PBL is an approach to learning that is characterised by flexibility and diversity, which can be implemented in a variety of ways in different subjects and disciplines. Students work on their own learning requirements and teachers support this learning [11-14].

III. DESIGN BASED LEARNING IN ENIGNEERING

Design based learning (DBL) is one type of project-based learning which involves students engaged in the process of developing, building, and evaluating a product they have designed [15]. In engineering science classrooms, DBL opens new possibilities for learning science. Working and completing design based activities can make students feel proud of their achievements, as well as building up their confidence as thinkers, designers, and that will benefit them through their education and life. Design based learning encourages a thriving learning context for students' active participation and construction of knowledge instead of passively learning about engineering science from textbooks and lectures [16]. Overall, design based learning supports encouraging evidence that this project/problem based learning increases students' science content knowledge and engagement working on the design challenge, enables students to transfer knowledge into another task, learn through collaboration, and develop students' positive attitudes towards engineering design education.

At Deakin University, the engineering program increasingly involves Design-Based Learning, or DBL projects at different levels of course structure. It engages students in real-world assignments. It starts right from the first year of engineering. In the DBL projects students will work in a group of approximately four to six students on absorbing innovative issues. In this way, students will gain an idea of the field of work and students will learn to work in a team and try to solve problems by using technical and psychological knowledge. This is important, because in the future students will often cooperate with people from other disciplines. Students will often be the bridge builder between (technical) specialists, the consumer and society. The Design-Based Learning program is a cutting-edge, inquiry-based curriculum that engages students in simulations and understanding of essential questions. Engineering science and technology are at the core of its challenging multi-disciplinary curriculum.

IV. SENIOR MECHATRONIC DESIGN AT DEAKIN UNIVERSITY

All senior mechatronic-engineering students enroll in SEM433, Mechatronic Design. Running over 12 weeks, the course has been taught both on-campus and via distance education [17]. For over 20 years, Deakin has offered an accredited Bachelor-of-Engineering degree via distance education and online learning [18, 19]. The enrollment numbers are on average 15 on-campus and 6 off-campus per year. The course has five key learning goals. On completing the course, students can:

1. Become experienced in dividing a complex design problem into a set of subsystems and then integrating the separate solutions into a final design;
2. Understand how the various disciplines of their undergraduate course can be combined in a single system design;

3. Comprehend the time, cost and availability constraints that must be faced in engineering practice;
4. Solve open-ended problems in the basic areas of mechatronics;
5. Achieve competence in expressing design concepts in formal reports;
6. Design and make a device capable of fulfilling the given task definition.

A. The basic project

In this course the students must build some kind of robot. Early offerings required the students to build a simple robot that could navigate through a maze, or follow a line around a painted track [20]. The original microprocessor for this course was the eight-bit 68HC11, mounted on a board specifically designed for our students [21]. The project encompasses all the elements of a mechatronic design project:

- Mechanical parts for chassis, transmission, and steering.
- Sensors for detecting the elements of the problem.
- Motors to drive and steer the robot.
- Analog electronics for motor drives.
- Digital electronics in the form of logic devices and the microprocessor.
- Computer programming to give instructions to the robot.
- System design to draw everything together within the required budget.

B. Sumo-robots

In the last few years this robot has been a "sumo robot" [22]. This is a robot that must push another robot out of an arena. The problem is given to the student from the point of view of a company seeking tenders for a job. The task of the sumo robot is to push or lift the opposing robot out of a circular arena. There are three phases to this task:

Phase 1: The sumo robot are placed in the arena facing away from a gray box. It must find the box and push or lift it out of the arena within 3 minutes. The box is 200-mm × 200-mm × 200-mm and weighs 500 g.

Phase 2: The sumo robots are placed in the arena facing a plain gray box. It must evade the box (which will be attacking!) for one minute and stay within the arena.

Phase 3: The sumo robot are placed in competition with the other robots.

The competition is knock-out competition. Each match between two robots consists of up to three games of three minutes each. The first robot to win two games wins the match. In the first round, robots with similar times from the first phase are matched against each other. The winners of the first round play each other. If there is an odd number of robots, the robot with the fastest time from the last round will automatically enter into the next round without having to compete in the

current round. Points are awarded based on how many rounds a robot survives.

C. Robot specifications

There are a number of constraints applied to the students' robots:

1. The robot is to be completely autonomous.
2. The robot must be purpose built, no off-the-shelf robots allowed.
3. The sumo robot itself must fit inside a box that is 200-mm long \times 200-mm wide \times 300-mm high.
4. The robot can weigh no more than one kilogram.
5. The robot must have some status indicators. (Indicating at least attack and evade status.)
6. The surface will be flat.
7. The robot is to be initially placed on the field by the student facing away from the opponent.
8. After placement, it must not be touched by anyone until the task is completed or failed.
9. The arena will be circular with a diameter of 1540mm.
10. The arena will be matt black with a 20-mm wide white line around the edge.
11. The arena will be raised from the surrounding ground by at least 10-mm.
12. If any part that comes off a robot and falls or is pushed outside the arena, then that robot loses that game.
13. The robot that touches outside the arena first is deemed the loser.
14. A robot must start a game in the same pose that it was when placed in the box used to check its dimensions.
15. A robot that damages another robot (apart from damage expected in robots pushing each other) will be disqualified.
16. No weapons! But a lifting mechanism is allowed.
17. The total expenditure on the project must not exceed \$A150 (Note: this sum does not include the cost of the microcontroller but will include one set of batteries).

This specification is given and each student must build a prototype to get the job. As specifications in industry are never complete, the students do not receive a complete one either, but must collectively suggest various ideas to fill the gaps of the specification. The lecturer then adjudicates on the final specification as the client. All this is put forward in relationship to the lecturer's industry experience and it spurs the students to settle on a specification that is to their advantage when designing their own robot. The brains of this robot is the Arduino 16-bit microcontroller that the students interface to the mechanism and into which they program instructions.

D. Assessment and competition

The grading is calculated from a preliminary report (20%), a final written report (30%), demonstration of the finished product (40%) and project construction (10%). To be eligible to obtain a pass in this unit students must achieve at least 50% in both of the project demonstration and construction assignments. On-campus students undertaking this unit take part in three hours of weekly lectures and tutorials for the first six weeks, followed by six more weeks of three-hour lab sessions to work on their project. Off-campus students work on their project at home, guided by content posted to the course website (fig.1), a published study guide [23], and by direct communication with the lecturer. Weekly web-conferencing tutorials are also given to for the off-campus students [24]. Weekly lectures are also recorded and posted to the course website (fig.2).

The major difference between senior engineering students and the engineer in industry is the amount of experience they have. Students are at the stage when they should be able to research a topic for themselves. To this end, each student is given one topic on robotics, such as motors, controllers or batteries, to become an "expert" on. When students ask about an item that is in your topic, it is expected that the expert will answer before the lecturer does. Bonus points are given based on how well the student does. The lecturer is the backup in that case that the expert does not know a particular answer to a question. The report assessments also contain a section for expert topic areas. Expert topics include batteries, motors, gearing, steering, chassis, sonar, light sensors, programming, uP interfacing, and motor control.

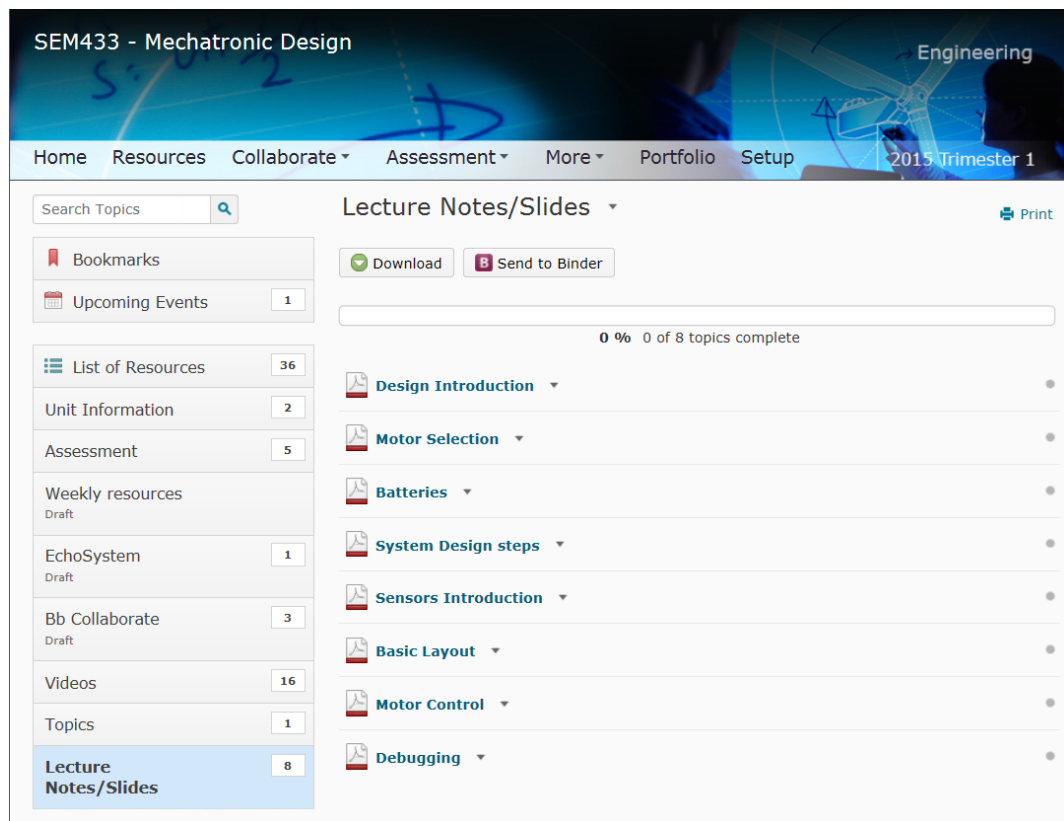

Fig. 1. Sample of the Mechatronic-Design course website.

Fig. 2. Example of a lecture video on servos.

Once the students have built their robots, there is a competition at the end of the semester as their robots battle each other, with some extra credit for the winner (that is the one who wins the “tender”.) This is a day of both frustration and fun. Frustration as the students try to fix last minute problems, and fun as they pit their robots against each other. This includes the off-campus students, who are given the option to send their robots to the lecturer to run in the competition, or to attend the event in person. Most off-campus students elect to attend and in doing so meet the other students

with whom they have been communicating during the semester.

E. Purpose of the reports

The first report is a written project proposal pertaining to the problems presented in the project. The proposal is viewed as a document that sets out and guides the development process of the student’s solutions to these problems, which would be used by a project manager to guide a team. In this case, the student is both the manager and the team. The proposal seeks to answer several key design questions:

- What is the problem?
- What is the proposed solution?
- What is the mechanical part of the solution?
- What is the electrical/motor part of the solution?
- What is the sensor design?
- What is the proposed strategy design?
- Expert topic?

The section with the proposed mechanical solution presents first an outline of the general approach to solving the problem of chassis and mechanical design. It includes computation of speed and torque requirements, motor control/steering strategy, a sketch of the design including details of wheel, motor and battery placement, computation of the minimum turning radius

of the robot, and a description of the number, type and placement of the sensors to be used along with explanations of all decisions made.

The proposed electrical/motor solution presents an outline of the approach to motor selection and control. It includes selection of motor type and performance. If the design is based upon a pre-existing motor then the suitability of the motor must be demonstrated and its torque, current, and power determined. There is also a calculation of electrical current and power and thus details of the battery requirement. Students must also estimate of the run-time it would take for the robot to cover a distance of 50 m and the remaining power in the motor battery at the end of such a run. And the students give a description of the electronic motor-control interface.

The sensor design includes a description of the number, type and placement of the sensors to be used along with explanations of all decisions made, a description of the sensor/controller interface with any debugging aids that may be required, what sensors will be used and why, and how the sensors will be connected and powered. Finally the proposal presents an outline of the approach to artificial intelligence and control, including a summary of the strategy to be used by the robot in the execution of the task, including the system response to all possible sensor conditions. Students construct a workflow chart as a timetable for completing the project, including a list of design, implementation and evaluation tasks to be completed.

The final report contains a project update, comments on the robots functionality, possible improvements, cost of the project (including bill of materials) and the listing of the final software code.

V. RESULTS AND DISCUSSION

Fig. 3 shows a typical student's robot in the competition circle. The robot is seeking its opponent before the two try to push each other out of the arena. An example design and a brief showcase of the robots and the resulting competition have been posted to YouTube:

- <https://www.youtube.com/watch?v=Hp6gX0PB33U>
- <https://www.youtube.com/watch?v=dnP8bsA-nyY>

Fig. 4 shows typical grades for this course. Four years are shown. Many of the resulting projects are of excellent quality and this trend has existed for several years. Off-campus grades were comparable with on-campus grades.

At the end of each semester, students are asked to evaluate the course by replying to a survey [1]. Students respond to statements on the course material, website, feedback on assignments, and quality of the lecturing. They use a five-point Likert [25] scale (5 = strongly agree, 1 = strongly disagree, 3 = neutral) to indicate what they think about a number of statements.

Fig. 3. Student sumo robots in the arena.

Fig. 4. Typical average grades (percent) in senior mechatronic design. The minimum passing grade is 50%.

One statement concerns the students' satisfaction with the lecturer, and another concerns the students' overall satisfaction with the course. Students are also invited to make comments on the quality of the course. Sample evaluation scores over the period 2009-2013 are shown in fig. 5. In general, the student satisfaction with this course is quite high, among the highest in the Deakin School of Engineering. We note that although on-campus and off-campus satisfaction with the teaching are nearly the same, the off-campus satisfaction is slightly less than the on-campus satisfaction with the course overall. This difference disappears when one considers the spread of responses. When asked what the best aspects of the course were, students replied with the typical comments in table 1. Student comments tend to be very positive.

Fig. 5. Scores of student satisfaction with the teaching (left) and the overall course (right), off-campus and on-campus. Perfect satisfaction is a score of five.

TABLE I. STUDENT COMMENTS ON THE BEST ASPECTS OF THE COURSE

I learned a heap. Will help with my major project.
Being able to use the knowledge from the degree to put together a full project to create a sumobot.
That we were able to build an actual robot, instead of just do the theory about one.
The challenge of bring all the parts together. Especially being taught how to use the milling machine not only to do circuits but more importantly how to use Solidworks files.
It truly is the definition of engineering - the practical application of knowledge. Best aspects: - Video lectures. I can't stress enough how important it is for those of us off campus.
The building, hands-on experience.
The more positive aspects of this unit are essentially those which it sets out to achieve namely the practical problem solving of an open ended task. I found this project puts a lot of emphasis on the detail of a design as it is not a theoretical exercise and nothing will look after itself.
Provided materials were succinct and helpful.
Awesome (recorded lectures) were very helpful during the design phase.
I can honestly say that I have learnt more in this unit than any other so far - and because I've applied this knowledge I will actually retain it.

We often find that students who have completed this unit and go on PhD studies, will help the lecturers with this unit in following years, even building a new robot to enter the competition again. When this happens the lecturers can use their experience as further inspiration for the students. We also found that the practice of having individual student experts on specific aspects of building a robot very beneficial to student learning [26].

This course has been offered both on-campus and off-campus for many years. In spite of the significant differences between the two cohorts [27], our experience with this course shows that at least in mechatronics, a successful distance-

education undergraduate engineering program can be provided, affirming the claim that universities should be able to provide engineering education “anytime, anywhere” [28].

This course has been built on the design-based learning model of education, and in the context of a senior project course it has proven to be highly successful. Other courses in our School have experimented with design-based learning in on-campus and off-campus modes [29, 30]. Current work is focusing on obtaining specific student perspectives and opinions on increasing the DBL content across all engineering majors, and extending DBL further in off-campus teaching [31-33].

VI. CONCLUSION

The purpose of an engineering degree program is for the student to gain a strong foundation on fundamental applied science, using that knowledge to design and make solutions to real-world problems. Deakin University in Australia teaches a design course for senior mechatronics students whereby they design and build a small “sumo robot.” The course is an excellent example of design-based learning in engineering education. In addition to being delivered to on-campus students, off-campus students (who do not attend on-campus classes) have also successfully taken this course for many years. The percentage of students who pass this course has been quite high over the years, and it receives a great deal of positive feedback from its students. Our School is now investigating how design-based learning can be incorporated into other courses in its engineering programs.

Abstract—This work aims to implement business intelligence strategies in an educational institution based on the distance education, particularly in the online tutoring process. In this paper we propose to use the business intelligence paradigm to analyze the online tutoring process, based on the data collected on the interactions of students and teachers in a virtual learning environment, and the results recorded in the institutional academic system of evaluations. This analysis should answer the following questions: 1) Can we define a model of online tutoring that can adapt to each student profile? 2) Can we predict the success of an online tutoring process for a course and a student given? To this purpose, this paper presents three aspects: characterize and determine the key elements in an online tutoring process, build a descriptive model of the online tutoring process, and build a predictive model of the success of the online tutoring process. The models to be defined will be based on data mining techniques, and will be obtained from the current data stored in transactional databases of the University. This data is preprocessed with ETL techniques to build a multidimensional model, and the key elements are obtained through operations OLAP.

Keywords—Business Intelligence Systems, Data Warehouses, Learning Analytics, Online Tutoring

I. INTRODUCTION

Business Intelligence (BI) has a high range of use based on the information and knowledge hidden in an organization, to reach its strategic and tactical objectives [1, 3, 9]. But this paradigm must be used correctly following the objectives, processes and situations in the organization, to allow the good decision-making about tendencies, opportunities, etc. in the organization. Some key concepts for BI are the determination of the current and target situations, and the definition of the correct indicators to be used for strategic analysis.

BI encompasses data, information and knowledge management, modeling of processes and policies of the organization, with a previous data processing procedure to guarantee a high quality of the data to be used. That is, this data must be integrated, cleaned, inconsistency must be eliminated, etc. But the main points to generate knowledge are the tasks of data mining or *OLAP* (On-Line Analytical Processing). They allow specific analysis of the different subject previously defined like strategic or tactical goals for the organization.

In the last decade has had a great development of technologies (tools, environments, etc.) for BI [3, 9]. Nowadays, it is necessary to define strategies about how to use properly BI in specific domains. Each domain needs analyze their data in their own terms, according to its goals, based on their organizational processes, etc. There is a gap between the organizations and the BI paradigm that must be solved.

In this paper we propose a first intent to bridge this gap on the domain of education, by introducing the notion of *Learning Analytics* (LA) like the specific aspect to be exploited for a BI project in the education context. LA is defined as the use of data of an educational organization (of the students, of the learning process, etc.) to build models, etc., in order to improve the learning process [2].

The LA in the domain of *Business Intelligence Systems* (BIS) requires historical data and/or data collected from various sources of an educative environment. LA needs data warehouses and a careful process of extraction, transformation, load and store data of the educational organization. In this paper, we'll present some of the aspects of the BI systems' linked at the domain of LA, such as: methodology, lifecycle, modeling techniques and finally, some indicators for a study case.

Particularly, we analyze an online tutoring in order to define the LA procedure to be carried out in this context. An online tutoring is the process of tutoring in a virtual environment like the *Virtual Learning Environments* (VLE), where teachers and learners can be in different places and moments.

This paper focuses on study this specific model of education (online tutoring), in order to define three key concepts: target situations, indicators, and how they are analyzed from a LA process based on BI. The main contributions of the paper are: i) the definition of the target situations and indicators in the context of an educational BI project, ii) the design of a process to capture the strategic business goals, the situations that influence these goals, and the indicators to measure their fulfillment in an educational organization, and iii) the demonstration of the procedure in a real-study case to analyze the strategic goals in an organization

For the implementation phase we used different BI

techniques, like data warehousing, OLAP, data mining, etc. The system gathers data from different functional systems such as: the system of students register, VLE, etc.

The rest of the paper is organized as follows. Section 2 introduces key aspect about BIS, LA, and online tutoring concepts. Section 3 presents the target situations and the indicators to make LA using BIS in an online tutoring. Section 4 presents a complete example, and Section 5 discusses and analyzes our results.

II. THE THEORETICAL ASPECTS

This section introduces the three key concepts in our work.

A. The concept of Business Intelligence System

During strategic planning, SWOT (Strengths (internal, favorable), Weaknesses (internal, unfavorable), Opportunities (external, favorable), and Threats (external, unfavorable)) analysis [2, 3] is often used to identify the internal and external factors that are favorable and unfavorable for fulfilling certain goals. An objective of a business defined during strategic planning, basically: i) may be refined into subgoals; ii) may be satisfied in more than one way; and iii) its satisfaction may be affected by other objectives.

We propose to model the SWOT for each business objective like a target situation. Intuitively, a target situation defines a partial state of the world in terms of things, their properties, and interrelations among them. The target situations are the organizational state that we like to reach.

A BIS permits analyze business information in order to support and improve management decision making across a broad range of business activities, and in particular it gives knowledge to help in the decision. BIS leverages the large data infrastructure investment, for example, in ERP systems, where substantial business aspect like its knowledge is not exploited. Investment in BI systems is very interesting to produce this knowledge, but there is a complete absence of a specific and rigorous method to measure the realized business value. BIS have the potential to maximize the use of information and knowledge to create a smart platform of organizational analysis [1, 3, 9].

Normally, BI uses collected data during the daily operational processes, and transforms the data into information and knowledge [3, 9]. The main characteristics of BIS are: the capability of providing representative information to the high-level management of an organization, to support strategic activities (goal setting, forecasting, planning, etc.), and also tracking performance (gather, analyze, and integrate internal and external data in indicators). BIS can access both historical and real-time data to define views of the information and summarize it into indicators for the different members of an organization.

Normally, a BIS provides the information that executives need for strategic and tactical decision, that often requires

the combination of data from ERP and non-ERP applications (integration), in unusual reports different from daily transactions, to take real time decisions based on them. The main differences between ERP and BIS are:

- ERP systems are transaction-processing and BIS is based on the extraction, analyze, and visualize information from ERP and standalone systems (for that, it uses components like data warehousing, tools capable of collecting, processing, storing and retrieving data from different sources, friendly graphical user interfaces, OLAP, data mining, etc.).
- BIS is oriented towards business opportunities rather than transactional needs, for strategic decisions.

In [1] describes detailed the components and architectures of a BIS. In general, a BIS lifecycle follows traditional development of a software project: initial study, project planning, analysis, design, construction, and implementation. A main point are the data, which can be exploited in different BI studies if they are extracted, processed and stored correctly, and are improved in successive versions.

B. Learning analytics

LA can be defined as the utilization of data produced by the students in order to build models, knowledge, etc. and analyze them to improve the learning process by predicting and advising to the students, discovering of knowledge and information necessary during their learning, etc.[2, 14]. The interests to use LA can be [2, 14]:

- For educational organizations, to improve current courses or develop new curriculum offerings;
- For administrators of educational institutions, to take decisions about matters such as marketing, recruitment, performance problems, etc.
- For students, to improve their learning processes, patterns of learning, achievements, with tailored assessment materials, learning pathways, etc.;
- For the professors, to identify 'risk' students, in terms of drop out or course failure, to predict the students requiring extra support and attention, etc.

LA is different of the field of educational data mining (EDM). In general, EDM is based on the intelligent tutoring paradigms, and LA focuses on Learning Content Management Systems (LCMS). For some authors, EDM encompasses LA [2, 14], which combines institutional data, models (predictive, descriptive, etc.) and statistical analysis, to create knowledge for the students, professors, or administrators, in order to improve academic behavior. Some aspects that increase the interests in LA are:

- The important number of components of the online educational platforms: VLEs, LCMSs, the student records, etc.
- The important quantity of data from these components about student background, learning process (for

example, from VLEs), interesting to apply BI techniques to these educational data.

- The necessity to have evidences about the progress of the pedagogical process, etc., in real time.
- The desire of an educational organization to improve its online education in order to give a high quality education.

Some important domains for LA are [2, 14]: BI, Data Mining, Web analytics, Social Network Analysis, Artificial intelligence, and Statistics. Some examples of LA software tools are:

- SNAPP: a learning analytics tool that visualizes the network of interactions resulting from discussion forum.
- Student Success System: It provides indicators to understand why a student has problem, predict student performance and identify students into risk.
- LOCO-Analyst: a context-aware learning tool for analytics of learning processes taking place in a web-based learning environment.
- BEESTAR INSIGHT: a real-time system that automatically collects student engagement and attendance, and provides analytics tools and dashboards for students, professors and administrators.

Some problem opens are the ethics of the data collection, of the analyses, etc. (see [2, 14] for more details).

C. Online tutoring

Online Tutoring (OT) is the process of tutoring in a virtual environment where teachers and students can be in different spaces and time [4, 5, 6, 7, 10, 12, 13]. Online tutoring has different approaches; it is addressed to different users, and has different interfaces and online learning methodologies. The online virtual environments usually imply Learning Management Systems (LMS), VLE as Moodle, etc.

The tutoring can be a group of students simultaneously logged (many-to-one tutoring), or a student independent learning, with tools for self-reflection, knowledge construction, collaborative or group-based learning, etc. (e-moderation) [13]. The online tutoring can be asynchronous, which is tutoring where the student submits a question and the tutor responds at a later time, or synchronous online tutoring where is shared an interface, such that both the tutor and the students are online at the same time. Generally, a tutor is a professor who has responsibility for teaching in a program in a university. Two necessary assumptions about online tutors are that they possess sufficient academic qualifications and have specific training to develop online communication. Online tutoring requires three components [4, 5, 6, 7, 10, 12]:

- A educational method (pedagogy), with instructional support;
- One online tutoring management to coordinate and

organizes the service;

- A usable user interface and technical support to maintain both the hardware and the software operational.

OT supposes a self-motivated and independent student, based on constructivist principles, focuses on achieving goals of learning, student autonomy, self-reflection, collaborative learning, and communities of learning.

The similarities between online and face-to-face tutoring are the needs for roles in the group and to encourage in-group interaction, and the differences are the needs of a computational structure and the definition of online activities. In general, the online activities are known as e-activities, with the following characteristics [4, 5, 6, 7]:

- They define relevant learning activities;
- They are based on key topics to provide engagement and motivation.

There are tools for e-activities like worksheets, online bulletin boards, etc. The typical stages for learning in online tutoring are four [4, 5, 6, 7]: i) Access and motivation, ii) Online socialization, iii) Information exchange, iv) Knowledge construction.

III. OUR BUSINESS INTELLIGENCE SYSTEMS' METHODOLOGY

In this section we propose a methodology for educational BI projects. Our methodology defines the main steps in all BI project, and allows reuse the specific methodologies, tools, etc. from other domains inside of its steps. For example, data mining methodologies, data preprocessing techniques, among others. Our methodology starts from the main aspects to be considered in a BI project: define the target situations, define the indicators to find out if these are reached, and identify the data/semantic mining tasks to calculate these indicators. Based on these ideas, we propose a methodology to develop BIS projects compose by the next steps [1, 3, 9]:

A. Stage 1: Definition of the target situations

In this case, we define the strategic questions that the BI project must respond. Normally, the target situations are the strategic questions that the organization must respond. These target situations justify the BI project, and define the business needs and opportunities identified. The target situations describe specific organizational states that are important to improve their performances. These situations have a high influence on the business of the organization, and normally, with the current operational data, it is impossible to obtain the response to reach them. They require strategic information that must be extracted from the operational data. That is, they require the extraction of the knowledge hidden on the operational data of the organization, using data/semantic mining tasks.

The target situations define the indicators to be obtained. A successful organization analyzes these strategic situations defining indicators, in order to help the organization to make the correct decisions to reach these situations. Generally, these indicators quantify various aspects of the organizational activities, for this it is necessary to monitor the organization. The indicators in a BIS normally are obtained from data/semantic mining tasks or from OLAP operations. It can be composed of other indicators, and normally is a complex computation because it represents the generation of knowledge.

The first main point in this step is to define the target situations. These situations describe different types of states in an organization: strengths, weaknesses, opportunities and threats. To analyze these states, and in particular to know if the organization is close to it, normally are defined indicators. More specifically, we identify indicators what can be observable.

The second main point in this step is to define the indicators. The indicator definitions are based on the organization's mission, and require discovering strategic knowledge to achieve the goals. Therefore, analyzing those indicators are important tasks in any strategic planning process. During the strategic planning process, the indicators allow making decisions at the decision points. At each point, one option is chosen from a pool of available options using the information and knowledge provide by the indicators. In some cases the indicators exist, or must be calculated from various sources and ERP systems of an organization from its different functional areas, for example financial, inventory, purchase, order management, production, etc.

B. Stage 2. Data Model of the BI project

Now, we need to determine the source of data to be used to calculate the indicators, that is, to carry out the analysis around the question. Normally, during this stage is designed the data warehouse which contains both historical and current data, and its optimizations, for fast query and analysis. Data warehouses are based on multi-dimensional databases design, in order to consider the main data required to respond to the target situations. Traditional relational database systems can handle these situations, but using multiple queries (in many cases, the queries are so complex that are difficult to maintain). Data warehouses require the extraction, transformation and processing of data for a high-level integration and analysis, for these reasons, in this stage are defined these tasks. The data warehouse is very important for the BIS, because it prepares the data to be used on the BI project (clean, correct, normalize, etc.). Some of the steps in this stage are:

- Analyze the operational data of the organization, that is, in this step are identified the data sources, with its ER diagrams, attributes and references between data.
- Design the Multi-dimensional database, which defines the logical and physical model. The data model is used to define the data warehouse
- Design the ETL process (extract / transform / load),

which depends on quality of data sources.

The multidimensional models represent an extension of the relational model and normally are based on a star schema. They consist in the relationship between some dimensions and facts or measures, to define an n-dimensional cube based models that use a multidimensional view over an individual data. In BIS, the multidimensional model must allow to respond to the business requests. We need a business vision over data structure, so the star schema or the n-cube based models must incorporate business aspects or demands, not only the facts or the relationship between data. The performance indicators are calculated from these data.

C. Stage 3. Extraction of knowledge (indicators) based on the target situations of the BI project

In this stage are defined different types of models or metrics for statistic interpretation, and analysis of the target situations, using the respective indicators. At this level are used technologies like OLAP, data mining, etc. The OLAP engine is a query generator to explore and analyze summary and detailed information from multi-dimensional databases. Typical OLAP operations are "slice and dice" data by various dimensions, "drill down" into the source data, or "roll-up" to aggregate levels (for more details about these operations see [1, 3]). OLAP provide tools for "what-if" analysis, to find the trends and patterns within the data, but it will not discover hidden relationships or patterns. For these tasks are required more powerful tools like semantic/data mining techniques. These techniques make it possible to discover hidden trends or rules that are implicit in the data. Patterns or models discovered by them are validated and then to become operational tools to be used in decision processes. OLAM (on-line analytical data mining) systems are OLAP systems used for data mining in multidimensional-data.

The definition of the OLAP operations is very complex because it must give new knowledge or information hide in the data warehouse according to the indicators. Must be analyzed what data must be slicing and dicing, or data that must be rotated, and drill down or roll up over hierarchical levels. So, it is necessary a multidimensional model in which these operations can be made easily, in real time; OLAP operations that define relationship between dimensions, facts and hierarchies to calculate strategic indicators.

Regarding to the data mining or semantic mining tasks, they are very complex. There are specific methodologies for this step. The main aspect to consider is that the data/semantic mining tasks must be very well defined, and for each one there is a very important step of preparation of the data composed by two aspects: the definition of the conceptual view of the data (the different attributes to be considered to build the predictive or descriptive models), and the construction of the operational view of the data (that is, the extraction of the data to build the models and test

them). If these views are wrong, the results of the data mining or semantic mining tasks are wrong too.

IV. STUDY CASE

In order to show our methodology, we propose here a study case.

A. Description of the BI Project

A problem of BI systems is measuring success. In deploying a BIS there are many risks involved: system design, data quality, and technology obsolescence. Decisions based on business process BIS should not be viewed only as a data repository or a large set of data. Instead, system's implementation should concern on conceptualizing new data models, processes, and indicators that form the content of BIS.

Particularly, our goal is to test LA like a result of a BI project on the domain of OT. We have tested our approach in an Ecuadorian university where one of the main activities is the distant education. Particularly, the Universidad Técnica Particular de Loja (UTPL) has a distance campus based on a competency-based teaching model. In this model, the student is the central actor in the educational process, and the process is mediated by a teaching team, tutorials, resources learning and new technologies [10, 12]. For online tutoring, UTPL uses: a Virtual Learning Environment (VLE) which is based on MOODLE platform, a Video Conference System, e-mail, phone tutoring, etc. The students in distance modality through the forums, chats and video conferencing in the VLE, can get points for their subjects [10, 12]. Therefore, the teacher must meet certain activities that enable the communication and evaluation of teaching-learning process. Among the activities that the teachers should develop are:

- Propose at least a forum, a chat and videoconferencing every two months.
- Post an ad per week throughout the academic year.
- Answer the question of the students through the email
- Upload educational resources.
- Define questionnaires for the students

For the UTPL, describe information and knowledge of the organization is very important, in order to analysis the OT process at the university: the performance of the students, the model used of distance education, etc. Here, we use our BI approach for LA of OT.

B. Our Business Intelligence Systems' Methodology applied to the study case

Stage 1: Definition of the target situations

For the UTPL, the target situations to be detected in order to make strategic decisions about the future of this type of studies are:

- Is it possible to define a model of online tutoring for the computer career, to increase student participation? (descriptive model)

- Can it predict the success of the online tutoring for a given year and a specific student? (predictive model)

These target situations describe specific organizational states of the UTPL, very important to improve its performance; the main states are: What is the quality of the online tutoring model of the UTPL? And What is the performance of the students?

Based on these target situations, was defined a set of general indicators that allow describe these states: rate of success of the student, behavior of the students and professors on the OT platform (messages, chats, etc.), among others. Now, with these target situations and indicators we describe the rest of stages in order to determine/analyze them.

Stage 2. Data Model of the BI project

The start schema of the multidimensional model defined in this BI project for the study case is the shown in the Fig 1. The main aspect here is to specify the key indicators to build the models that allow analyzing the target situations. In the case of UTPL platform for the OT process, the key indicators that can be obtained are:

- Number of students (numEst)
- Rate of success (Taprob)
- Num Ressources load
- NumTaksDefined
- NumCommentsProfessorStudent
- NumREAS
- NumMessReceived
- NumMessRead
- NumMessRep
- NumChatDefined
- NumParticChat
- NumForumsDefined
- Prediction (indicador) (pred_aprob)

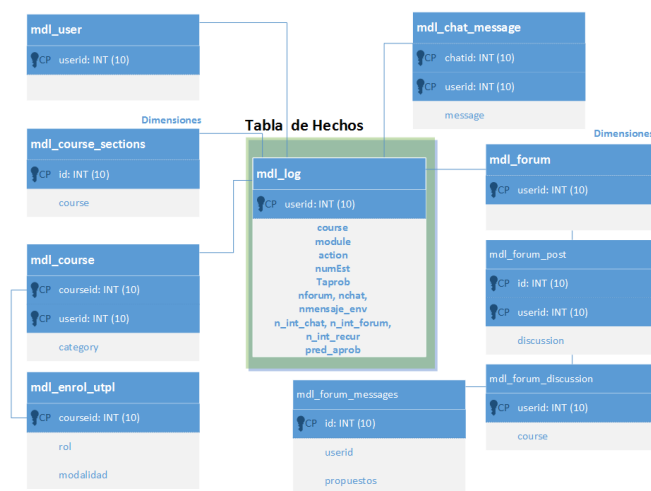

Fig. 1. Multidimensional model

These variables describe specific aspects that represent elements to characterize the OT on the UTPL according to its computational platform (VLE and academic system). The multidimensional model is defined using these indicators as base (see Fig. 1). The fact table is composed by these indicators, among other variables. Additionally, there is a dimension to describe the courses, and the rest of dimensions describe the different activities during a course (chat, message, forums, etc.) in the OT platform. This information is extracted from the UTPL platform using ETL operations. The details of the ETL operations are given in [15].

The indicators are going to define the descriptive and predictive models. Some of these indicators are calculated using OLAP operations from the multidimensional model presented on Fig. 1. In Fig. 2 we show the schema of the VLE platform of the UTPL, and Fig. 3 gives an example of an OLAP operation to determine one of the indicators: NumForumsDefined.

Stage 3. Extraction of knowledge based on the target situations of the BI project

In this step are built the descriptive and predictive models. That is a typical data mining task. Due to the importance of this task, in the next section is described the procedure. The indicators of the previous phase are the conceptual view used during the data mining tasks.

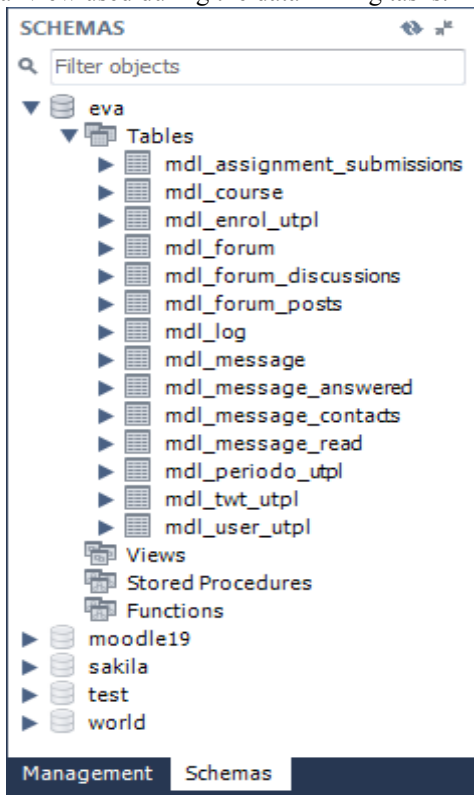

Fig. 2. Schema of the VLE platform of the UTPL

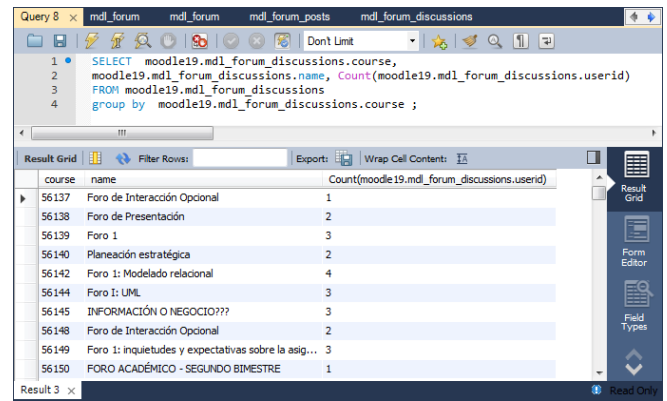

Fig.3. OLAP operation for the NumForumsDefined indicator.

V. DATA MINING TASK FOR LA OF AN OT

In this study the data mining techniques play an important role to uncovering information about the students and the interactions that are generated in the VLE, in order to better understand the OT process and optimize the use of resources used in this environment. For this, classification algorithms are considered to predict the performance rate of students in the courses where the OT process were developed. We also consider association rules in order to determine a descriptive model that characterizes the use of the tools on the platform during the OT process. The building of the descriptive and predictive models need several steps:

A. Descriptive model of the OT for the computer career

To obtain the descriptive model of the first target situation, the data was first preprocessed and then three experiments were performed with association rules, in order to obtain the model with the best results. The association rule allows discovering interesting relations between the indicators about the OT process (in [11] there is a good description of this technique). It identifies rules about the relationship among our indicators using the information on the multidimensional model and different measures of interest. The R tool was used (its "arules" library) [16].

In this way, in this paper are used associative rules to discover relationship among the indicators (descriptive model), based on three experiments:

- First Experiment: 10 attributes are used. In general, not very significant rules were obtained.
- Second Experiment: 9 attributes are used, and are deleted the attributes where the possible values of their instances are little.
- Third experiment: 8 attributes are used, and the best results are obtained, with meaningful and interesting rules. For this case are used the next attributes: Ads (NumCommentsProfessorStudent), Learning Resources (Num Ressources load), Forums (NumForumsDefined), Tasks (NumTaksDefined), REAS (NumREAS), Chats (NumChatDefined), NumMssEnv (NumMessRep), NumParticipantesChat (NumParticChat).

For this third experiment were obtained rules 24, which are shown in the Fig 4.

According to the results of the Fig. 4, the first 6 rules are considered very obvious, or of little interest, which is reflected in the measures of support and interest. In the case of rules 4, 5 and 6, they represent an interest of 68% approximately. In particular, the rules 12, 20 and 21 are the more significant.

They describe very well the relationship between the attributes involved. We observe a significant level of support and confidence in these rules, that highlights the dependence between four variables mainly: Ads, Forums, Chat and REAs we can see the percentage of correctly classified instances is of 91.7736% and incorrectly classified is 8.2264%. This can be corroborated with the Fig. 5 that determines the attributes with more relationship.

Based on these results we respond to the first target situation: Is it possible to define a model of online tutoring for the computer career, to increase student participation? We can conclude that it is possible to define a model of OT process to optimize the utilization of the VLE platform, that is, the quality of the OT model of the UTPL.

Fig. 4. Best rules obtained.

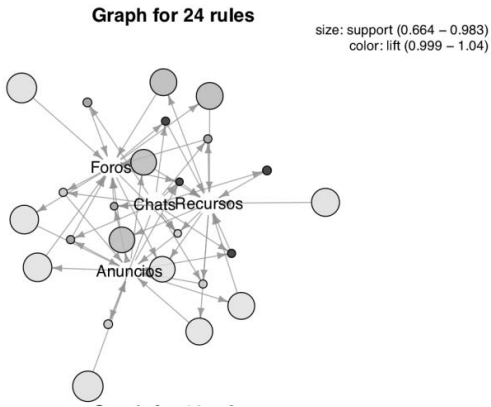

Fig. 5. Relationship between the attributes

For example, we can identify the student participation in the tools of the platform, and determine which are being less utilized, that could contribute to the learning process of students.

B. Predictive model of the success of an online tutoring for a given year and student

For the second target situation, the next experiments are proposed in order to predict the rate of performance of the students in a given course. Particularly, a predictive model is constructed using Bayesian networks. A Bayesian network is a probabilistic graphical model that represents a set of variables and their conditional dependencies (see [8] for more details about this technique). In our case, we define a probabilistic graphical model to predict the rate of performance of the students, using the indicators of the multidimensional model.

The dataset used refers to demographic and academic data of students corresponding to several semesters. The experiment was conducted in Weka with a dataset of 67825 instances. For training is considered 66% of this dataset and the rest 34% to the test. Attributes considered for this experiment are shown in Table I.

TABLE I. ATTRIBUTES USED IN THE MODEL

ATTRIBUTE	DESCRIPTION
ECV_ID	Certification ID
COE_ID	Educational component identifier
ETR_CODIGO	Promotion Code
GCR_CODIGO	Credit code
DISCAPACIDAD	Disabilities
ESTADO_CIVIL	Marital Status
GENERO	Gender
CENTRO MATRICULA	Place of registration

Classes to predict were Promotion Code, which has the value: approved, reprobates, and others. The confusion matrix obtained is shown in Table II.

TABLE II. CONFUSION MATRIX

a	b	c	<-- classified as
9915	19	634	approved
130	8758	130	reprobate
918	0	2566	other

As we can see the percentage of correctly classified instances is of 91.77 % and incorrectly classified is 8.23%. Based on this matrix, we proceed to calculate the precision and recall metrics to measure the model performance.

- Precision: 90%, that means 90% approval predictions are correct.
- Recall: 93%. That means, the 93% of the students who will pass the courses are included in predicting.

Consequently, for the proposed objective the results obtained are considered acceptable, since the model allows to project approval rate that subsequent semesters could have.

In response to the second target situation: Can it predict the success of the online tutoring for a given year and a specific student? The model obtained can predict the rate of performance of a new student in a given course.

VI. CONCLUSIONS

BIS has a powerful impact on strategic decisions to reduce the time and to improve the quality for making decisions. BIS improves the quality of management in organization through new types of technologies and techniques for extracting, transforming, processing and presenting data, in order to provide strategic information. One of the major risks in the process of developing a BIS is the system design that stem from poor conceptualization of an enterprise. A solution for covering this risk is characterizing each domain and defining the specific elements to be considered during a BI project.

In this way, in this paper we specify an approach to develop BI project in an educational organization, based on LA. We propose a methodology based on target situations, and the indicators to be considered to study each one of these situations. Our methodological approach focuses on applying BI in OT process in a University.

Thus, the LA were specified for OT process, where particular target situations are required to be analyzed in order to study the performance of an OT process using the BI paradigm. Unlike other works, in this study various data mining techniques considering aspects of BI in the context of LA for OT process are combined. The results are very

interesting, and next works need to think in procedures to define indicators automatically for BI project in an educational organization based on LA, in order to exploit the advantage of these paradigms.

Design and Impact of a Classroom Intervention to Support Teaming Metacognition

Lee Rynearson, Morgan Hynes
School of Engineering Education
Purdue University
West Lafayette, USA

Abstract— Exercises to bolster student metacognition relating to teaming performance and thereby teaming performance itself were designed and deployed alongside an existing teaming performance instrument and a survey investigating the frequency of teaming-centric metacognitive events. The results suggest that the exercises were successful in raising students' metacognitive awareness of aspects of their teaming performance but did not achieve a corresponding rise in teaming performance itself. Additional learning tasks helping students translate metacognitive awareness into higher performance may be required. Overall teaming performance rose by a small amount in both the experimental and control cohorts and did not appear to be influenced by the metacognitive development exercises.

Keywords—*metacognition; teaming skills; team project*

I. INTRODUCTION

The overall efficacy of active learning techniques in improving undergraduate course learning outcomes is well documented [1-4], and more recent work in engineering education has moved towards building a deeper understanding of what specific elements of learning environments and learning tasks are most effective and how best to implement them [5, 6]. Research into collaborative learning also contributes to understanding effective active learning principles and practice for multi-student activities, including such areas as designing or selecting team-appropriate tasks [7, 8] and preparing students to work together to solve them [9, 10]. Based on the growing body of research supporting learning task design at a granular level along with discipline- and topic-specific investigations into pedagogical efficacy, educators increasingly have the ability to design and deploy research-based classroom interventions instead of relying on experience or best-practices alone.

One popular active learning technique that could potentially benefit from such research-based learning task design efforts is team engineering projects. Team projects sharply gained popularity in engineering following the finalization of new ABET standards in the year 2001, which included new “professional skills” required of engineering graduates, including teaming skills [11]. Active learning methods including team projects were quickly identified as a pedagogical method that could support student acquisition of professional and technical skills simultaneously [12, 13], while also receiving the aforementioned benefits of active learning.

Team projects are also seen as a means to prepare students to solve problems situated in societal contexts [14, 15] similar to those found in industry [16]. Given these facts, there exists a strong need in engineering to guide students in the acquisition of effective teaming skills. While a wealth of literature on team formation, support, and performance already exists for the undergraduate academic environment, vigorous research continues in this area and substantial room exists for innovations in teaming skills instructional design.

This paper presents the initial efforts and results from an active learning task design drawing upon research in active learning, teaming, and metacognition to target improvement in students' teaming skills performance in two discrete areas – team interaction and regulating team working processes. Performance in these areas is plausibly mediated by metacognition. While some interventions have been proposed in these areas in engineering contexts [17, 18], including interventions explicitly incorporating aspects of metacognition [19-21], exploration of the intersection of active learning and metacognition in engineering instruction remains limited. For this study, exercises intended to bolster student metacognition in the teaming contexts of interest were designed and deployed alongside an existing teaming performance instrument. The results suggest that the exercises were successful in raising students' metacognitive awareness of aspects of their teaming performance, but without a corresponding rise in teaming performance. Additional learning tasks helping students translate metacognitive awareness into higher performance may be required. Substantial future works are outlined to address limitations in theory and methodology identified through the implementation of this study.

II. METHODS

A. Background

The assessment of aspects of metacognition has been attempted by numerous means, including “questionnaires, interviews, the analysis of think-aloud protocols, observations, simulated recall, on-line computer-logfile, and eye-movement registration” [22, pp. 8]. While different methods clearly afford the ability to work with different sample sizes and present more or less of an obstacle to collecting detailed data, other benefits or pitfalls of metacognition assessment methods may be less clear. Veenman identifies an ongoing “need...to

determine far more precisely what metacognitive knowledge or skill component can be assessed successfully by which method [22, pp. 9].” One key distinction between methods that has been identified is whether the data-collection method is “on-line” or concurrent with the metacognitive activity being assessed, or “offline” and data is collected before or after the metacognitive activity being assessed. It is recommended that both on-line and offline data be collected until metacognitive measurement is better understood [22].

This study’s assessment efforts in metacognition were supported by the availability of Tarricone’s comprehensive Taxonomy of Metacognition [23]. This work exhaustively synthesizes previous research to provide a broad, inclusive overall structure of human metacognition. This structure can be employed by pedagogical researchers to delineate the facets of metacognition targeted for intervention or measurement. While the overall structure of metacognition provided by Tarricone is too complex to discuss in detail in this work, specific elements of it targeted by this study can be listed. First, growth in knowledge about metacognition in general and metacognitive knowledge of teaming skills tied to interactions between team members in particular (both varieties of declarative metacognitive knowledge) were targeted during the intervention through assigned readings and in-class discussions. Second, procedural metacognitive knowledge of task was targeted by giving students practice with some basic procedures cultivating and benefitting from metacognition in a teaming context. Third, successful practice required students to increase their awareness of metacognitive feelings, essentially taking a higher degree of notice of specific team-related thoughts related to teaming performance. Finally, increased fluency of metacognitive skills and executive function in the teaming domain was also sought as an outcome of the learning tasks, whereby students would regulate their teaming behavior based upon the previously listed metacognitive knowledge and awareness, improving their teaming performance. The details of the experimental procedure and sample will be discussed next.

B. Overview & Sample

The experiment was undertaken on a convenience sample of students from two sections of a first-year engineering course, with one section selected to receive the experimental intervention (120 students) and the second section to act as a control (114 students). The sections were served by different instructors at different times of day. International students comprised approximately 25% of the sample from each section. Both sections performed four peer assessments of teaming performance spread across the term, and both sections completed two administrations of an online survey into the frequency of specific metacognitive behaviors. The experimental section also received an intervention composed of a short reading assignment and lecture relating specific aspects of teaming with specific metacognitive actions, followed by a class-length (110 minute) exercise overlaying metacognitive awareness cues onto an unstructured team project working period. This exercise included logging occurrences of specific teaming-relevant metacognitive events (see Fig. 1) and each student’s worksheet was collected for analysis.

C. Data Collection

The four peer assessments were administered at regularly spaced intervals across the semester with the well-known and robustly validated CATME [24] peer assessment system. Evaluations of self and peer performance across the five dimensions of the instrument (Contributing to the team’s work, Interacting with teammates, Keeping the team on track, and Having relevant knowledge, skills, and abilities) were gathered. The initial CATME evaluation was used to assess the comparability of the experimental and control cohorts. While the overall average teaming performance between the two sections was comparable (difference in mean overall performance <1.5%), the control section’s standard deviation for Keeping the team on track was found to be more than 20% higher than that of the experimental section, suggesting that the match between the two cohorts is not ideal for statistical comparison. This is believed to be due to the fact that the control section was at a time of day favored by a minority of students, leading the class cohort to be comprised of either very dedicated students or relatively less organized and accomplished students, with relatively fewer students with moderate performance. The relatively weak statistical control provided by the control section did not greatly detract from the interpretability of the results. As peer evaluations have been repeatedly demonstrated to correspond well to actual student performance [25, 26] the third and fourth sets of CATME results for ‘Interacting with teammates’ and ‘Keeping the team on track’ were also used as measures of teaming performance before and after the experimental intervention.

The online survey (see Table 1) asked students ten Likert-scale multiple choice questions and presented two open-response text prompts. The multiple choice questions asked students to rate the frequency that they experienced specific metacognitive events in three areas derived from CATME’s teaming performance behavioral anchors. CATME uses sets of several actions, performed at various levels, to behaviorally anchor student evaluation of self and peer teaming performance for each of its five dimensions. For example, when measuring performance in the ‘Interacting with Teammates’ dimension, students are asked to determine whether the team member being evaluated more closely matches “Listens to teammates and respects their contributions” or “Asks for and shows and interest in teammates’ ideas and contributions” [24, pp. 626] among other options. In contrast, the survey simply asked students how often they would agree with the statement “I notice that I ask for and show an interest in teammate’s ideas and contributions” while working with their team on a scale including never, rarely, sometimes, often, and ‘all the time’ as potential responses. Without behavioral anchors, there is little reason to believe that a response of ‘sometimes’ from one student is comparable to the ‘sometimes’ of another student, but a desire to create a short survey that could be administered in class with a high completion rate and the intention to use pre-post changes rather than absolute measurements of metacognitive event frequency for analysis decided the issue. The open-response questions asked students to describe a recent notable event in their team and to describe their approach to managing their team’s workflow. Time was provided in class for both

TABLE I. ONLINE SURVEY PROMPTS

Question Number	Question Prompt (select from never, rarely, sometimes, often, all the time): When working with my teammates on class work...
1	I consider how best to present information to the team or an individual team member so that they are most likely to respond constructively to it
2	I notice instances where something I said seemed not to have been understood, and either confirm that it was understood or clarify my statement(s)
3	I notice when I think there may have been a mistake and consciously act to understand
4	I notice that I monitor the progress my team overall is making and try to change things if the progress is not adequate
5	I notice that I monitor the progress an individual team member is making on a given task
6	I notice that I give teammates timely, specific, and constructive feedback
7	I notice that ask for and show an interest in teammate's ideas and contributions
8	I notice that make sure that teammates stay informed and understand each other
9	I notice that provide encouragement or enthusiasm to the team
10	I notice that I ask for or respectfully received feedback from a teammate
11	Please consider a notable team-related event or occurrence in your team in the last few weeks. This event could be positive or negative but it should be important enough that you can remember it clearly. As if you were seeing your team from the outside, how would you describe what occurred? Please include what you think each member of your team was or might have been thinking before, during, and after the event.
12	Please write a few sentences describing how you approach the task of keeping your team's efforts on track and productive

the pre- and post- administrations of this survey for both the experimental and control sections.

The experimental section was asked to complete a reading prior to arriving in class on the day of the in-class metacognition exercise. The reading was written for the purpose of this study and was approximately 500 words in length. Students were briefly reminded of the importance of teaming skills to engineers, introduced to the idea of being consciously aware of teaming performance and using this awareness to improve teaming outcomes. The reading also briefly introduced the exercise to be performed and asked students to consider what examples of specific actions might look like in their team, such as a team member checking on the team's progress on a task, or a teammate confirming understanding of a recent communication. These prompts were intended to increase the probability of metacognitive feelings being consciously noted when the actions were later exhibited by teammates or themselves. The word 'metacognition' was avoided and language was chosen to communicate the concepts with a minimum of new vocabulary and with an emphasis on simplicity, to permit all students (especially ESL students) to

understand the reading. A short lecture and discussion was given in the class before the exercise was begun, reiterating the points in the reading and again asking students to contemplate specific examples relating to themselves. The lecture and discussion occupied approximately ten minutes.

The in-class worksheet (see Fig. 1) asked students in the experimental section to mark down the number of times they engaged in one of seven specific metacognitive activities in five-minute intervals using checkmarks. Students made a checkmark each time they noted that they had engaged in a listed metacognitive activity. The seven activities were further shortened versions of the three CATME-derived 'Keeping the team on track' and the four 'Interacting with teammates' prompts employed in the online survey. The prompts were further shortened for the worksheet to allow for fast reference by students as they noted metacognitive events in passing. The majority of students' time and attention during this activity was to be directed towards working with their teams on an ongoing class design project, and the ability to quickly identify the correct column to mark the occurrence of a particular metacognitive event in was seen as key to allowing the design project work to continue naturally. Setting the teaming metacognition exercise as an overlay on top of regular working time was seen as more likely to allow the transfer of metacognitive awareness and constructive teaming responses based upon it to additional in-class and out-of-class team working times. The instructor periodically reminded students to engage with the worksheet as they worked on the project. The earlier distinction between on-line and offline measurement of metacognitive events is blurry with this measurement technique on a per-student basis because some students filled out their worksheet regularly throughout the working time as metacognitive events occurred (online) but others assessed their metacognition only when directed to by the instructor, filling in their sheets retroactively (offline). At the end of the class period, the worksheets were collected for analysis. The control section engaged in the team working time without any directed metacognitive exercises.

III. RESULTS

CATME peer evaluation data was available for 100% of students who completed the course in both the experimental (n=120) and control sections (n=114). It should be noted that CATME performance data is the product of both self and peer evaluation. While some students did not contribute to some CATME evaluations, as long as their peers did, some assessment for each student remained available. Therefore, not all measurements from CATME of student performance have an equal amount of observation behind them. It was found that teaming performance in the target areas increased for students in both the experimental and control sections by relatively small amounts between the initial and final CATME surveys. In the control section, the average performance on a five-point scale rose from 3.98 to 4.13 in Interacting with Teammates (a gain of 3.1%) and from 3.94 to 4.12 in Keeping the Team on Track (a gain of 3.5%). In the experimental section the average performance on a five-point scale rose from 4.06 to 4.12 in Interacting with Teammates (a gain of

Fig. 1: Sample of Blank Worksheet

1.1%) and from 3.89 to 4.10 in Keeping the Team on Track (a gain of 4.2%).

As the practical significance of these results is limited and as previously mentioned the experimental and control sections are not ideally matched, the statistical significance of the teaming performance difference between the experimental and control sections was not assessed.

The pre-post set of metacognition-focused online reflections was completed by 79 of 114 students in the control section (69% response rate) and 113 out of 120 students in the experimental section (94% response rate). In the control section, the average performance on a five-point scale across all ten multiple choice questions rose from 3.68 to 3.88 (a gain of 5.6%) and from 3.71 to 3.87, a gain of 4.4%. Thus, higher gains were observed in the control section. Details of student responses to the survey appear in Table 2.

The in-class worksheets completed by the students in the experimental section were analyzed for potential relationships with responses to the CATME instrument and the metacognitive awareness survey. Worksheets were available for 112 students for whom CATME self and/or peer evaluation scores were available and who had completed the pre and post metacognitive awareness surveys. No significant correlations were observed between the number of instances of metacognitive awareness reported on the worksheet and teaming performance as measured by CATME, either holistically or between questions derived from specific dimensions on the worksheet and the corresponding area of CATME performance. However, a Pearson correlation coefficient of -0.19 was found for the relationship between the number of instances of metacognitive awareness reported on the worksheet and the change in scores between the pre and post metacognitive awareness surveys, at a P-value of 0.045. It should be noted that the linear relationship between factors implied by the use of the Pearson correlation coefficient represents an exploratory conception of the phenomenon; there is not yet enough evidence to support assertions about the form

of any such relationship. However, as an exploratory analysis, this finding has implications which are discussed later.

Finally, text from the open-text-responses questions was examined. Analysis of this data was largely informal, using Wordle (<http://www.wordle.com>) to look for macro-scale differences. Responses to the first open-text-response prompt, asking students to relate an account of a recent notable teaming event, did not appear to differ between the pre and post surveys or between the experimental and control groups. Responses to the second question (asking students to relate their approach for managing their team's work) seemed largely unchanged between surveys for the experimental group, but the control group showed a substantial rise in the use of certain words such as 'track', 'time', 'task', 'sure', and 'keep'.

IV. DISCUSSION

CATME teaming performance scores and scores on the metacognitive awareness survey rose, for both the experimental and control sections. However, in most cases the growth reported was not large. Some individual prompts, such as #9 on the metacognitive awareness survey ("I notice that I provide encouragement or enthusiasm to the team") did show growth greater than 7%, suggesting that growth in metacognitive awareness may not be evenly distributed across the performance areas. Overall, the fact that some growth was reported on average for both sections and both instruments suggests that existing class procedures supports some level of metacognitive awareness in the teaming context and some teaming performance growth. However, the low levels of growth reported align with the continued need to develop and deploy more effective pedagogies for teaming skills.

The fact that performance was found to increase by larger amounts for the control section is not interpreted to mean that the intervention was counterproductive. It can be noted that the control section's starting metacognitive awareness scores were substantially lower for prompts where the control section gains were sharply higher than those of the experimental

TABLE II. ONLINE METACOGNITION SURVEY RESULTS

Prompt	Experimental Section				Control Section			
	<i>Pre-Test</i>	<i>Post-Test</i>	<i>Change</i>	<i>Change %</i>	<i>Pre-Test</i>	<i>Post-Test</i>	<i>Change</i>	<i>Change %</i>
1	3.95	4.04	0.09	1.8%	3.94	4.03	0.09	1.8%
2	3.65	3.84	0.19	3.7%	3.64	3.81	0.18	3.5%
3	3.75	3.95	0.19	3.9%	3.85	3.99	0.14	2.7%
4	3.66	3.84	0.18	3.5%	3.74	3.89	0.15	3.0%
5	3.35	3.44	0.09	1.8%	3.31	3.44	0.13	2.5%
6	3.60	3.70	0.10	1.9%	3.46	3.81	0.35	7.0%
7	4.01	4.16	0.15	3.0%	4.00	4.11	0.11	2.3%
8	3.77	4.00	0.23	4.6%	3.63	3.96	0.34	6.8%
9	3.54	3.92	0.38	7.6%	3.61	3.99	0.38	7.5%
10	3.78	3.81	0.04	0.7%	3.63	3.81	0.19	3.8%

section. This suggests that the control section may have had more room for skills growth. The text-mining results also suggest that the control section showed more changes in how they discussed teaming activities.

Another reason to doubt the intervention was counterproductive is that students may confuse metacognitive awareness of performance with performance itself. Students were prompted to respond to questions that are about noticing whether they take a specific action, not whether they do take a specific action. However, this is an offline measurement of metacognitive activity and presents students with an opportunity to conflate their performance in noticing ongoing actions with their performance in actually performing the related action. For instance, students could perform the teaming action without having consciously noticed the opportunity to do so or students could improve their noticing of opportunities to take specific actions (which would be an improvement in metacognitive awareness) without actually implementing the related teaming action, then mark themselves poorly by focusing on the action element of the prompt rather than the 'noticing' element.

One indication that this may have occurred is the statistically significant ($P = 0.045$) negative correlation between engagement with the in-class metacognition logging worksheet and scores on the metacognitive awareness survey. The fact that students who engaged more extensively with the worksheet tended to report a lower level of metacognitive awareness on the post-intervention survey suggests that the instrument may be measuring something other than it was intended to. It seems likely that students who engaged more deeply with the worksheet raised their internal expectations of their performance in teaming metacognition and then gave themselves lower scores on the survey. This is similar to models of self-efficacy ("a person's estimate of his or her capacity to orchestrate performance on a specific task," [27, pp. 183]) where increased knowledge of a domain may in fact change individuals' perceptions of success and in fact lower their self-efficacy within that domain. For example, in a study

of teacher professional development on engineering group of middle school teachers were reported as having lower self-efficacy for teaching computer programming after learning a new programming language [28]. The fact that a difference was measured suggests that the intervention may have an impact and may hold some promise for later, more precisely implemented and better supported interventions. For example, as no correlation was detected between the rise in metacognitive awareness survey scores and teaming performance, students may require more support in translating awareness of teaming actions or opportunities for them into constructive responses leading to higher teaming skills performance.

V. FUTURE WORKS

While the increases in teaming performance and metacognition in the targeted areas observed in both the experimental and control sections is positive, and the probable rise in student metacognition suggested by the experimental results is heartening, the goal of this ongoing project is to design and implement an intervention that not only increases student metacognition in targeted team-related areas but translates that increased awareness into actual and constructive actions taken by the students in their teams. As discussed, this was not observed in the results from the initial intervention. Therefore, future works are planned to restructure the intervention and its assessments, working towards the goal of measurably improving student teaming performance.

It is anticipated that future iterations of this intervention will scale up the quantity and frequency of time spent in class explicitly dealing with teaming metacognition, employ varied interventions starting earlier in the course, increase the sample size, take additional steps to promote consistency in class practices between the experimental and control groups, and give additional training and emphasis on translating awareness of teaming issues into constructive actions.

Increased support for and emphasis on accurate peer ratings through the CATME system will also be implemented. The

relatively high initial scores, relatively static scores over time, and relatively high number of students whose ratings decline noticeably over the term suggest that some students may not have engaged deeply with the CATME rater training materials or rating process. Increasing student rating capability and motivation may yield more reliable measurement.

The limitations of the reflective survey of metacognitive frequency used in this study suggest that improved, additional, or alternative assessment methods may be appropriate. While the future assessments to be employed have not yet been selected, one potential avenue is to infer the use of metacognition through team actions while engaged with a problem, similar to Schoenfeld's work with metacognition in mathematics [29] or the NOME coding for naturalistic engineering settings developed by McCord [30]. As it is hypothesized that social anxiety may be one mediating factor between metacognitive teaming awareness and concrete teaming action, assessment of this and other potential mediating factors may be considered in future research works.

Abstract—The main contribution of this work in progress is an open source architecture for seamless integration of open access educational resources located in heterogeneous learning management systems (LMS) distributed across the network. One of the main advantages of the proposal is the simplicity in creating, managing and making available new content that builds on the existing material in different repositories. Some previous works addressed similar issues but either in simpler environments, i.e., when the distributed systems were homogeneous, or they require extensive knowledge to take advantages of the integration, from the point of view of both the content creator and the manager of each learning system. Our solution exploits the possibilities offered by the Content Management Interoperability Services (CMIS) interface typically present in many content repository platforms allowing users to browse and interact with contents stored in several heterogeneous places. Some preliminary results show that it is possible to efficiently combine engineering learning material taken from our technical university with other online resources made available from different educational institutions. Moreover, two extensions, currently in development, aim at providing seamless videoconferencing integrations between the teacher and the learners as well as at supporting remote laboratory sessions by means of controlling programmable objects in remote laboratories with real-time video feedbacks for the students.

Keywords—Electronic learning, Courseware, Content management

I. INTRODUCTION

In the latest years the wide availability of digital technologies and communication networks that allow access to plenty of material led to the production of a huge amount of didactic materials. These documents in electronic format, often called Learning Objects (LOs), comes in widely different types. Hence, the educators can often use them even beyond the environments for which they were originally made.

To store and properly index learning objects a considerable amount of software solutions have been developed in various forms. These systems are named *Learning Management Systems*, e.g., Moodle [1] and Chamilo [2]: they provide content repository features so that users, typically teachers, can upload and store their materials with the final aim of organizing them into self-contained courses. Other systems, the so called *Enterprise Content Management* systems such as Alfresco [3] and Nuxeo [4], provide the users with only general repository functions including indexing and basic search and share functionalities.

However, the number of platforms and repositories available for e-learning purposes is increasing rapidly [5]. The

direct consequence of this rapid expansion is the production of a vast number of LOs which can be used to create entire on-line courses. However, the drawback of the situation is the increasing amount of heterogeneity among *Learning Object Repositories*. Moreover, different institutions (e.g., universities) typically perform different choices in terms of chosen LMS and their configurations. Therefore, LOs are useful only if they are used within the scope of the organization for which they have been developed.

From the point of view of reusing LOs, one of the main issues is that typically LOs do not contain information about what is possible to do with them. In particular, each LO repository typically specifies a set of rights which is, in general, different from the one of the others, making it very difficult for a user to freely use the LOs without carefully dealing with the specific constraints of each object. However, even when freely usable LOs are found, the LMS employed by the educational institutions may pose obstacles to such use, for instance due to the difficulty in using the content or the complexity of the interfaces offered by the tools. To avoid this situation, the recent trend is to develop tools that allow accessing, in an easy way, the content of the repositories and directly perform actions through the use of simple web interfaces [6]. Our proposal is following this trend but, in addition, it aims at integrating together the repositories of many different institutions that can be based on different software and technologies.

Concerning this aspect, the so called Unified E-learning Repositories (UER) [7] are moving towards this direction. In particular, they offer the possibility to connect, from a centralized point, to a variety of repositories. However, since the repositories involved are typically homogeneous, this causes difficulties in the implementation phase, for instance when different institutions that do not use the same system are connected or merged together.

Nearly all the mentioned approaches attempted to deal with the situation by offering new instruments, oriented at both content creation and handling. To overcome these issues, in this work we present an innovative approach that, instead of proposing and developing yet another complete set of products as done by most of the works in literature, reuses most of the tools that have already been deployed trying to exploit their full potentials as much as possible. The key idea is to exploit the features provided by the so-called CMIS (Content Management Interoperability Services) API [8]. By means of this API it is possible to access, from a centralized web platform, a number of distributed repositories which can be

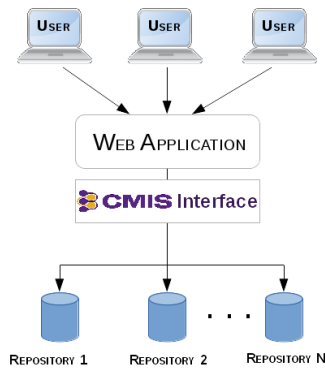

Fig. 1. Block diagram of the proposed architecture.

of different type and be physically located in different places, i.e., directly the repositories located at different institutions.

The main features of the proposed platform are the easy-to-use interface and the possibility to rapidly compose and share learning objects with a few clicks, without the need to download anything for local processing. Since one of the main targets of the proposed platform is engineering education (EE) we believe it is necessary to guarantee, to all users, the basic freedoms to read, edit and redistribute content as well as the system itself. The former aspect is addressed by selecting, as default, the Creative Commons BY-SA license [9] for the contents, whereas the latter is guaranteed by means of licensing all the developed software under the GNU GPL v3 [10] license. In this way the students will be free to learn even by investigating the source code of the learning architecture itself. Moreover, this solution also suits the requirements of the Italian government that strongly encourages the use of open standards for interoperability. Therefore, the approach is suitable for being selected as one of the official platforms to be used in the context of electronic education. In fact, it has recently been submitted for evaluation in a government call seeking national-level solutions for e-learning.

Note that the platform is a work in progress as it is currently being extended in two important directions to provide an improved and more integrated learning experience. First, a videoconference system is being integrated, since we believe that it is necessary to address the increasingly common case in which not only the teaching material is available online, but also lectures are given entirely by means of the Internet. Through the integration of a videoconferencing tool there will be the possibility not only to prepare the course contents for a frontal lecture but also to directly use the platform as the primary way for teaching. The second direction is particularly aimed at practical subjects such as engineering, where it is absolutely important to learn by doing. We are extending the tool to support remote laboratory sessions in addition to the more traditional remote lectures. Some preliminary experiments are currently being conducted, experimenting with interactive remote robot piloting sessions in which students develop code that is then run on the robots, which are in turn observed remotely through video streaming.

II. SYSTEM DESCRIPTION

A. Motivation

The general aim of this novel architecture is to provide access to a number of heterogeneous repositories of LOs through a unified web interface which is the reference for all the activity performed by both the teachers and the learners. To this aim we provide a set of pre-configured tools to perform the most important operations such as searching, querying, downloading, sharing and merging of LOs to create new ones. The platform is designed in an extensible way so that new tools can be integrated. As it will be explained later, we are currently working towards including functionalities such as remote lecturing and remote laboratory interaction.

B. Technical Specifications

The block diagram of the proposed architecture is shown in Fig. 1. To achieve modularity and extensibility, during the design phase a number of frameworks have been analyzed. Drupal [11] has been selected to build the first prototype since it boasts a modular design which is well suited for our aims. Wherever necessary the front end has been designed using the Bootstrap [12] framework. In addition, many modules are already available under open source licenses which allowed the Drupal active community of developers to extensively test them. We relied on a LAMP (GNU/Linux OS, Apache web server, MySQL database and PHP) web stack to host the platform since it is one of the most common configurations that can be typically very easily deployed on most servers running open source software. Moreover, LAMP stacks can be easily set up on any platform and plenty of tutorials and resources are available in the network to guide in this process.

To test the platform with different repositories, we initially selected the Alfresco Community Edition and Nuxeo, which are the platforms adopted by the two universities in our city. However, the platform is ready to interact with any CMIS-compliant solution.

C. Web Interface and Typical Usage

All users (students and teachers) access the platform by means of a web interface, through any recent web browser. The landing page immediately presents all the most important actions, i.e., search and download. Learning objects are retrieved through simple web downloads, therefore almost no technical knowledge is required. They can be downloaded in their native format (e.g., PDF for documents or AVI files for video) or exported in the form of a ZIP file with an embedded HTML5 presentation. In other words, the ZIP includes an HTML file that, when clicked, plays back all the content in the form of an HTML5 presentation.

The basic actions that all users can do include:

- search for a content by formulating a query;
- check the description of the results and select the desired ones (a screenshot of the developed user interface is shown in Fig. 2);
- export the content in several formats, including a user- and device-friendly HTML5 presentation.

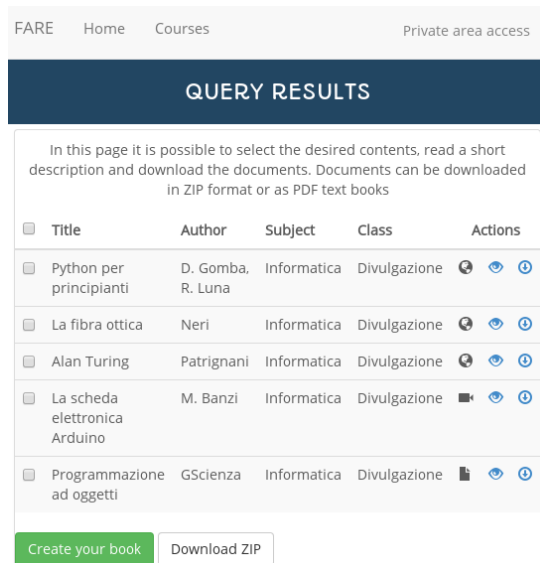

Fig. 2. A sample screenshot of the user interface.

The latter possibility has been particularly appreciated by both the student and the teachers as it allows to present the content of the LO, in the form of an automatically generated slideshow, by simply using a recent web browser that supports HTML5. Moreover, such an approach is able to deal with the variety of devices that students may use to watch the content, i.e., the standard PC screens, tablets, and smartphones.

Other functionalities are available after authentication. For instance, students can save their searches. Teachers, instead, are presented with a larger set of functions. For instance, they can also upload content through the browser, as well as extract contents from LOs and merge them automatically in new virtual objects that can then be shared and made available to the students as if they were regular LOs. Moreover, the teachers can also export the content in formats particularly suitable for teaching, e.g., with large navigation buttons and media formats suitable for presentation on electronic interactive whiteboards.

D. Improvements vs Previous Systems

The proposed platform improves over existing ones especially in the activities where it is needed to rapidly compose and share learning objects with a few clicks. Other systems typically require to familiarize with sometimes complex editing environments or require to download content for local processing. In our system nothing needs to be downloaded locally for processing since during the design phase this has been deemed too complex, error prone, and unintuitive especially for less skilled teachers. Note that, while our initial tests addressed the EE field, we aim to build a system for any discipline and school level.

Moreover, one of the key functionalities is that access to and search of learning objects are completely transparent regardless of the heterogeneity of repositories in which they are hosted: the platform automatically manages transfer, merges, creation of new content, and it also provides permanent links to the newly defined content.

Finally, videoconferencing tools are being integrated with a dual purpose: traditional remote lectures as well as interaction with remote laboratories. In the latter case the functionality

will be used to remotely observe real objects (e.g., remotely programmed robots) in action as if students were actually in the lab. We believe that this feature is currently unique for this system.

III. TRIALS AND USAGE

A. Current Testing

The platform has already been tested by including some EE content taken from the e-learning repository of our university. Moreover, some teachers added self-produced content in the form of booklets or short essays about computer-related topics. We are currently linking the electronic repository of the other university in our city so that additional material coming from the Computer Science course of study can be added.

To evaluate the effectiveness of the proposed system we asked the participants to fill up a questionnaire about their user experience with the system, from both the technical point of view (e.g., response times, appropriateness of the results, etc.) and the user friendliness (e.g., intuitiveness of the interface, navigability, difficulties in finding features, etc.). Moreover, users could also provide free comments.

Summarizing the preliminary feedback obtained by means of the questionnaire, the teachers involved in the tests confirmed the user friendliness of the interface also for the most complex tasks that required to interact with different LOs to create new ones that can be made immediately available for the students. The HTML5-based presentation feature was particularly appreciated in the free comments section, primarily because it is a very easy way to preview and experience the contents.

B. Future Directions

As mentioned in the Introduction, the platform is a work in progress. In fact, it is currently being extended, on the basis of the users' feedback, along two important directions to provide an improved and more integrated learning experience.

First, a videoconference system is being integrated in the platform, since it is necessary to address the increasingly common case in which not only the teaching material must be available online, but also lectures should be given and available entirely by means of the Internet. The videoconferencing module is being developed integrating the Big Blue Button [13] communication suite. The new web application landing page will feature an additional area that include the possibility for the educator to rapidly start a remote lecture and invite the students to join it. The students will see all the currently available lectures and they can immediately join them if desired. The teachers can benefit from an *interactive board* in which they can load presentations. The contents saved in the private area are directly inserted inside the interactive board component of the system. In this way whether a teacher is physically in class or is delivering an on-line lesson, the contents of the repository are seamlessly and immediately available for fruition.

A second promising direction is aimed at educational areas such as engineering, where the practical part plays an important role. In other words, for these subjects it is absolutely important to learn by doing. We are currently

extending the platform to support remote laboratory sessions in addition to the more traditional remote lectures. To start the development activities we are focusing on a *robotics* course that we are trying to incorporate in our platform. For this particular teaching activity the robots include both software and hardware components, the former being developed by the students. It is clear that, in such a situation, a satisfactory experience can be difficult to achieve if it is not carried out in a real laboratory. Furthermore, the difficulties of handling the hardware can represent a huge obstacle especially when students with limited experience are involved. Moreover, the cost of the hardware components, i.e., robots, may be non-negligible therefore they cannot be acquired in large quantities.

To address this situation a virtual solution could be used, where the real robot is substituted by a virtual avatar. This approach would allow the students to create the algorithm and then test it on the virtual simulator. Though this is certainly an option that has also been explored in the past [14], dealing with actual devices is sometimes preferable from the point of view of the students since the activity is perceived as more real.

Therefore, our approach focus on the so-called *hybrid laboratory*. This approach needs a physical lab where the robots are set up, as well as a web platform to interact with the robots. In this case the students are able to program the robot and then send the source code to the platform that will check it and compile the code. In case the results are suitable for running on the actual hardware, the executable code will be loaded inside one of the robots in the laboratory and the software will be executed to animate the robot. The students will be able to check the behavior of the robot by controlling the real-time video stream from the laboratory thanks to a streaming tool integrated in the platform, which could also be a special session created by means of the previously discussed Big Blue Button software suite. Although at the current stage we still need the human operator to load the software into the robot, we are planning to automate this task by means of wireless connections between the robot and some dedicated servers in the lab, so that there could be just one human operator performing only supervision and maintenance tasks. We are currently experimenting with the robotic toys series *Lego Mindstorm* [15].

C. Eliciting Additional Participation

The most difficult part of deploying an effective system is to ensure that participation is sufficiently high and make sure that most of the users are active. We are planning to increase the participation by means of agreements with locally-funded projects about improving high-school teaching. In particular, the system will be part of the “School 2.0” activities (starting September 2015) of the “Fondazione per la scuola” [16], an initiative of the “Compagnia di San Paolo” foundation, funded by banks, regional and local government institutions and higher-education institutions. The “School 2.0” will involve students and teachers in nearly all high schools in the Torino area, therefore the amount of users involved is expected to increase considerably. This will be an ideal experimentation in light of a possible adoption of the system at the national level, if the submission to the government call seeking national-level solutions for e-learning will be successful.

IV. CONCLUSIONS

This paper described an open source architecture for seamless integration of open access educational resources located in heterogeneous learning management systems (LMS) distributed across the network and managed by different institutions.

A key advantage of the proposed architecture is the simplicity in creating, managing and making available new content which can be either uploaded or directly created by means of the web-based interface from parts of objects already available even in different repositories, without the need to download them for local processing. Our solution exploits the possibilities offered by the Content Management Interoperability Services (CMIS) interface present in many content repository platforms so that the users are presented a uniform and repository-independent interface for all the contents in all connected repositories, even in the case of heterogeneous repositories.

Preliminary tests with some teachers and students showed great interests from both categories. Moreover, the tests allowed to check the functionality of the system by combining engineering learning material taken from our technical university with other online resources made available from different educational institutions.

On the basis of the users’ feedback, two extensions of the platform are currently being developed. One aims at providing seamless videoconferencing integrations between the teacher and the learners. The second aims at creating the infrastructure necessary to remotely manage and control physical objects (such as robots) in remote laboratories allowing the students to perform practical experimental activity as if they were in the laboratory itself by means of a live video feedback.

m.aldmour@ju.edu.jo

Abstract—MUREE project aims at the development of courses for training specialists about renewable energy production by combining face-to-face learning with on-line attendance. In this sense, remote laboratories are nowadays essential for distance education, even more within MUREE project, since Jordan students are not able to use face-to-face traditional laboratories due to their different physical location. These remote laboratories can be employed by instructors within their virtual classrooms, so that students can carry out their on-line experiments from anywhere and at anytime. For MUREE project, remote laboratories are seen as pedagogical elements that must be fully-integrated into a the learning/teaching process. Therefore, this work focuses its attentions toward the integration of remote laboratories into Learning Management Systems (LMSs) and, additionally, discusses the advantages and disadvantages of this approach.

Index Terms—Distance Education, Remote Laboratories, On-line Experiments, Learning Management Systems (LMSs).

I. INTRODUCTION

Within the field of Engineering Education making practical experiments is essential, as an accompaniment to magisterial classes, in order to enforce theoretical and practical concepts. This task is much more complicated in distance education, since students attend mainly to virtual classes. Therefore, the use of remote laboratories can help them to minimize this inconvenient. In addition to this, online evaluation experiments will help instructors to prepare suitable evaluation on-line experiments, in similar conditions as students are in the same physical location as the real laboratory.

According to this, the main objective of the MUREE project [1], which supports this work, is the development, integration, accreditation, and evaluation of renewable energy courses in the context of Engineering degrees from several universities in Jordan. This project follows the guidelines proposed by the Bologna process, and considers the previous experimentation with renewable energy equipment, in order to allow us to study the best approximation of remote laboratories.

Institutions can desire to share their laboratories by means of the integration of laboratories into shared courses among different universities, avoiding the need to reproduce the same deployment in each institution. The sharing of laboratories, not only cost, but also allows students to have a wider offer of laboratories. So, this is a key element for choosing a particular integration methodology for this project. From the MUREE project perspective, the integration of the remote laboratories into a Learning Management System (LMS) satisfies the need of pedagogical support for experimentation. There are different methodologies to perform this task in the literature which will be explored in this work, thus finding out the most suitable for our purposes.

In this work we pay attention to the main three ways of integration of remote laboratories into LMSs. The first approach is based on the use of middleware that expands the capabilities of the remote laboratories. This middleware is known as Remote Laboratories Management Systems (RLMSs). The second analysed approach is the extension of learning content standards to include the remote laboratories. Finally, the most suitable approach from the perspective of this project is the use of the extension mechanism provided by LMSs themselves. The main advantages and disadvantages of three approaches are explained in the following sections. Finally, the main benefits of the chosen approach are detailed.

The rest of this paper is organized as follows. In Section II, the most popular laboratories are described. Section III analyzes how to perform the integration of remote laboratories into learning environments. The discussion about the main benefits of integrating remote laboratories into LMSs is detailed in Section IV. Finally, Section V highlights our final remarks and suggests guidelines for future work.

II. REMOTE LABORATORIES

A *remote laboratory* is a software and hardware equipment that allows students to remotely access real devices located at a particular institution. Users access this equipment as if

they were in a traditional hands-on-lab session, but through the Internet or a network. According to this, there are many examples and classifications in the literature [2]–[4].

Renewable energy is not new for remote laboratories. For instance, remote laboratory experiences to perform activities related to the quality of the generation of energy can be found in [5] and [6]. Similarly, several renewable energy laboratories can be found in the literature. In [7], authors propose a laboratory used to analyze the creation data of the eolian energy. In particular, it consists of a real eolian turbine monitored by a set of sensors, deployed in conjunction with a meteorological station. Data are stored in a shared database, so that students can create their own client applications. As for remote laboratories focused on the solar energy, there are several examples, such as [8], [9], and [10]. In this project, two remote laboratories, a solar panel laboratory and a wind turbine laboratory, are developed as prototypes for testing the integration process. More details of this are given in [11], where the technical implementation details, the designed experiments and the gathering of experiment data are detailed.

However, despite the widespread use of remote laboratories, they have several design and construction issues that have not received much attention. On this topic, we can mention [12], where the impact of the selected technologies for the development of remote laboratories is analyzed. But most of the published literature focuses only on the objective of a certain application within a conducted course showing their functional and operational aspects [13]. In previously mentioned work [3], a study of 42 different remote laboratories concluded that they use different software architectures without being reused or shared among universities.

The lack of common standards in lab definition and connectivity specifications is one of the major impediment to the adoption and wide-scale networking of labs for teaching and training purposes. It is clear that an standard access interface can help in this direction. There are several projects oriented towards the creation of repositories of remote laboratories, classification ontologies and metadata standards for remote laboratories such as Lab2go [14] and *Laboratory Description Language* (LDL) [15].

III. ANALYSIS OF THE INTEGRATION OF REMOTE LABORATORIES INTO LMSs

A Learning Management System (LMS) is a software application that eases the provision of theoretical online classrooms by means of integrated features and tools such as administrative tools, synchronous and asynchronous communication tools, assessment and tracking tools, multimedia sharing tools, and standard compatibility. The goal is to make use of all the services provided by open-source LMSs, such as Moodle [16] or Sakai [17], and apply them in the remote practical laboratory sessions. Thus, several initiatives have been launched to integrate remote laboratories into LMSs. This section tries to summarize these projects.

A. Remote Laboratory Management Systems

In case an institution desires to share a remote laboratory among other institutions, they need some additional resources. Another component to take into account is that remote laboratories are in many cases expensive equipment and are confined to the private usage of their owner university due to the complexity of their inter-operation. Additionally, in order to solve the problem of providing practical skills to students despite the lack of equipment and funds in educational institutions, technology enhanced learning based on the sharing of equipment between institutions is suggested for wide-scale implementation across countries. This was a breeding ground for new researchers to attempt to establish a seamless, interoperable, and shareable integrated architecture that encompasses several remote laboratories from several universities in order to span their dissemination and interinstitutional operation. Under this concept appears a new type of middleware called *Remote Laboratory Management Systems* (RLMSs), such as MIT iLabs [18], WebLab-Deusto [19], Labshare Sahara [20]), or RELATED [21]. These RLMSs provide development toolkits to incorporate remote laboratories, as well as management tools and common services. A summary of the principal characteristics of these platforms is represented at Table I. A further and more detailed review on the integration and interoperability of remote laboratories nowadays can be found at [22] and [23].

The main drawback of this approach is that the integration of remote laboratories into LMSs requires additional layers, adding complexity to labs in terms of performance. On the other hand, RLMSs do not provide by themselves all the convenient resources for distance teaching/learning of students with all the implications that this methodology involves. Specifically, students must carry out their practical activities in an autonomous way and, therefore, additional Web-based resources to the remote labs should be included into the course. For this reason, the RLMSs should not only present a description of the phenomena under study and its didactic context for remote experimentation, but also the scaffolding tasks student must follow to achieve his/her goals.

B. Extending Learning Contents Standards

A different approach to the integration of remote laboratories into learning process is based on the extension of well-known learning contents standards such as SCORM and IMS. A first approach in this direction is Library of Labs (LiLa) project [24], which has created a repository portal that includes online laboratories from distinct universities. LiLa objectives are closer to Lab2go but they offer access to the remote laboratories. Experiments are represented by SCORM packages, that can be easily integrated into Learning Management Systems. LiLa provides access control and booking systems as an inherent part of shareable content objects (SCOs) to have the same effect if the SCO is deployed out of the LiLa portal (in an LMS). The access to the experiment, either in the LiLa portal or in the LMS, is provided by a URL.

Table I: Summary of RMLS found in the literature

	Labshare	iLab	WebLab-Deusto	Related
Developed by	UTS (Sidney, Australia) [20]	MIT (Boston, USA) [18]	Deusto University (Spain) [19]	UNED (Spain) [21]
Platform	Cross-platform	Windows server	Cross-platform	Cross-platform
Authentication	Username and password and interface to federate australian universities	Username and password	Username and password, LDAP, OpenID, Oauth 2.0	Username and password, OAuth, OpenID
Authorization	Yes	Yes	Yes	Yes
Booking system	Scheduling and queue	Scheduling and queue	Queue	Scheduling and queue
Federation of laboratories	Yes	Yes	Yes	No
User monitor	Yes	Yes	Yes	Yes
Types of experiments supported	Batch and interactive (controlled and uncontrolled)	Batch and interactive	Batch and interactive (controlled and uncontrolled)	Batch and Interactive
Integration of a remote laboratory	Complex	Easy	Easy	Easy
Other characteristics			Mobile access and integration in Moodle	Mobile access and Augmented Reality

Very similar to LiLa project is Open Collaborative Environment for the Leverage of Online Instrumentation (OCELOT) [25] project. OCELOT is a open-source, collaborative online framework and middleware. In this case remote laboratories are packaged into IMS Content Packages. And a relevant feature is that it combines Web Semantic and ontologies to define the collaborative interactions.

The main drawback of this approach is that the SCORM and IMS content packages are standards oriented to package static contents. This approach must extend the existing standards to include the needed features for the management of remote laboratories. So, the LMS must be aware of the standard extension and offer support to then.

C. Integration by Using LMS Extensions

Many LMSs offers their own extension mechanism. So, a different option to integrate remote laboratories into LMSs is the creation of an extension of the corresponding LMS. This approach has been chosen by this project. The main benefits are detailed in the next section.

As an example, the MARVEL project [26] has created a booking module for the most popular open source LMS, Moodle, which is based on hour slots. Although it had been modified to facilitate the integration of remote laboratories, this approach is oriented to a fixed scheduling schema and remote laboratories only built with LabVIEW control panels. This fixed scheduling scheme does not allow different types of experiments take place. As the session slot is fixed maybe this session duration can not adapt to the students' needs. Other disadvantage of Labview control panels is the need of a web plugin in order to execute the laboratory interface.

Another Moodle approach can be found at [27] where a Moodle plugin and a dotLRN plugins are proposed to integrate remote laboratories into Learning Management System. In this work, they do not present a clear integration strategy for general laboratories which are integrated ad-hoc. On the other hand, they present a useful extension for WebLab Deusto

platform for its integration into Moodle. So, the scheduling schema is delegated to the underline middleware. The integration of a remote laboratory in this case is complex: first integrate it into WebLab Deusto, afterwards, install and configure the corresponding plugin. Our approach is a more straight forward step.

EJSapp [28] proposed a set of Moodle plugins for the integration of virtual and remote laboratories. The remote laboratories are represented by EJS applets. They offer a scheduling schema, collaborative tools for shared sessions, and a manager for the experiment resulting files. The main drawback of this approach is that two different activities can be developed on the same laboratory or equipment, and the plugin threat them as different and concurrent activities. To solve this situation, a middleware is needed.

It is also remarkable that most of the integration proposals do not pay much attention to the monitoring of the student during the performance of the experiments. This is also a key element in the development of a new proposal.

IV. DISCUSSION

The integration of remote laboratories into LMSs have several benefits. First, this integration allows the versatile use of on-demand learning laboratories as learning resources. A remote laboratory does not provide by itself all the convenient resources for distance teaching/learning of students with all the implications that this methodology involves. Specifically, students must carry out their practical activities in an autonomous way and, therefore, with complementary Web based resources to the remote labs should be included. For this reason, all the remote laboratories in this framework should not only present a description of the phenomena under study or the didactic context of the experiment for remote experimentation, but also the scaffolding process that students must follow in order to achieve the proposed goals.

Second, when integrating laboratories into LMSs, a set of experiments can be deployed depending on a particular

learning/teaching process. Therefore, it is important to define specific activities, for instance, which consists in understanding the transformation of the solar and aeolian energy sources into electric energy. Thus, a key aspect to be addressed is the development of a personal learning context into the LMS that offers to students a work-space and supports their learning process with the appropriate learning resources, including the services that the remote laboratories provides, in this case, the solar and aeolian prototypes developed in this project. The aeolian laboratory focuses on helping students to understand how wind is directly related to the generation of energy, and the solar laboratory is focused on how the solar motherboard and the angle of incidence of the solar light are correlated. According to this, students are asked to handle the obtained data in order to generate their own plots as homework, and to make some conversions of unit measurements, such as Watts and Joules.

Third, the integrated learning environment must organize the access of users to available experimentation modules and simplify the organization of user groups. It should also be able to integrate other educational services such as notification services by email, news, forums..., allowing users (students and instructors) their interaction and the collaboration among the learning community. In order to support this, some management services (like control access or current status) have been added to the renewable energy laboratories [11]. Furthermore, a remote laboratory must report instructors students' tracking including the data collected during the simulated and real.

To sum up, this type of integration makes feasible to have a scalable architecture, which provides a real and flexible interaction environment for laboratory users (students and instructors). Much functionality is added automatically by the LMS, so the laboratory's developer only has to focus on the laboratory itself.

V. CONCLUSIONS AND FURTHER WORK

The integration of remote laboratories into LMSs is of real of interest, because of the fact that instructors will be able to specify courses by using remote laboratories as an additional activity. This is even more noticeable in distance education and, what is more, it may enhance the scientific skills of students. For these reasons, this work presents the state of the art in this topic and analyses the best way to perform this task, and discusses the main benefits of this integration.

As a future work, it is planned to perform a fully-functional integration of our remote laboratories into one of the most popular LMSs, as Moodle is. Evaluations from the users' points of view (both instructors and students) will be also conducted in order to analyze their satisfaction. In addition, a study of the recolected data from the experimental sessions will be analyzed in conjunction with the students satisfaction.

ACKNOWLEDGMENT

Authors would like to acknowledge the support of the following European Union project: MUREE (530332-TEMPUS-1-2012-1-JO-TEMPUS-JPCR); and a Local Project (2014-

027-UNED-PROY) from the Spanish University for Distance Education. Furthermore, we thank the Region of Madrid for the support of E-Madrid Network of Excellence (S2013-ICE2715).

Abstract— An education collaboration between the University of APEC (UNAPEC) in the Dominican Republic and the College of Engineering at the University of Puerto Rico-Mayagüez (UPRM) yielded a novel Masters Program completed by fifteen Dominican engineers using sustainable energy as focus. The authors proposed and executed this distance learning program with collaboration from Engineering and Social Sciences professors. The program addressed the Dominican energy problem from a technical perspective, but also considered and integrated social aspects of the problem. This education paradigm provided an integrated perspective of the local and regional energy dilemma needed to advance a sustainable energy future in countries with scarce traditional energy sources. After the courses were completed, each student presented a Masters project proposal. The proposals were reviewed by UPRM, UNAPEC faculty and in some instances by the supervisors of the students at the transmission company. All projects addressed a technical need existing in the Dominican power system. Each student defended the work before a panel composed of three to four UNAPEC faculty, and two to three UPRM faculty (using videoconference). Assessment results for the program reveal that program objectives were successfully attained.

Keywords— *Electrical engineering education, sustainable development, distance learning, graduate education.*

I. INTRODUCTION

Sustainability has been a key global issue since “Our Common Future” was published in 1987. Even though there was previous work on sustainability, the most widely-known definition remains the one proposed in 1987: “the use resources today in a way that does not compromise the ability of future generations to meet their needs” or some variation [1]. In the last ten years, a significant number of graduate and undergraduate initiatives have used sustainability either as a central theme or a key area of emphasis. For example a project-based approach is used in [2] to expose undergraduate and graduate students to interdisciplinary experiences in sustainable energy. Also a renewed power and energy program initiative has been developed with an inter-disciplinary focus including sustainability to provide a comprehensive approach to energy and the environment [3]. Another example is a PhD

program in Sustainability that includes convergence between specific disciplines and sustainability [4].

This paper presents a sustainability-based distance education program, developed at the University of Puerto Rico-Mayagüez (UPRM) and delivered through videoconference to the University of APEC (UNAPEC) in the Dominican Republic. UPRM and UNAPEC have had academic collaborations since 1994. In the early 2000’s these universities began a joint degree in Electrical Engineering, which graduated eleven Dominican engineering students with Masters degrees in the areas of communications and electronics. A second cohort of students began a Masters program in electric power engineering, with focus on sustainable energy on 2007. After visits to the Dominican Republic and meetings with university and electric industry officials, the authors proposed and executed the program with collaboration from Engineering and Social Sciences professors. The program was structured to meet the needs of the power industry, in traditional areas of power generation, and distribution as well as alternative areas related to sustainable energy. Using the definition of sustainability from “Our Common Future”, a sustainable energy framework was used to structure the program. Most courses were delivered through distance learning using videoconferencing systems, except a handful of courses that were in person. A strong component of the program was the integration of an assessment component across the curriculum to measure the effectiveness of the content delivery, educational practices, technology, and student satisfaction. This paper describes the latter part of the program, the Masters projects the students developed and the program assessment.

II. PROGRAM CURRICULUM

Since sustainability was used as a framework for the program, a sustainable energy cluster of courses was included in the curriculum: renewable energy, biomass conversion and a course on energy and society. The interdisciplinary nature of sustainable energy was presented to students not only through the topics of the curriculum, but also through the professors. Colleagues from Chemical Engineering and Social Sciences taught two of the courses in the sustainable energy cluster. The

curriculum also included the deregulated perspective in energy markets and power system economics (the Dominican power sector is deregulated on the generation level and partially in the distribution level). Finally, more traditional courses were included in the Generation and Transmission cluster: Power system operation and control, stability and reactive power. Table I shows the order and period in which the courses were taught, identifying the area for each course. All courses were worth three credits, except for a six credit introductory course that served as a refresher course.

All students worked for the state-owned transmission company, thus the program was offered at night, one course per period. All courses were delivered by faculty from UPRM to UNAPEC via videoconference, except a few courses that were offered during the summer. There was an instructor at UNAPEC to help with coordination at the Dominican side. For further description of the development and initial phases of the program, the reader is referred to [5].

TABLE I. A SUSTAINABILITY-FOCUSED ELECTRIC POWER ENGINEERING MASTERS PROGRAM

Area	Program Curriculum	
	Course	Period
Intro	Computational Tools (6 credits)	May-Aug 2007

Final	Research Project	Sep-Dec 2010 Jan-Apr 2011

(E: Economy, D: Distribution, GT: Generation & Transmission, SE: Sustainability)

A. Course Assessment

The graduate program was supported by an assessment system for continuous improvement. The assessment system was developed to quantify the effectiveness of the videoconference modality in student learning and satisfaction. Students were involved from the beginning in the assessment and evaluation of the program and they were aware of the importance of their participation and support to improve the program. A student evaluation questionnaire was developed to understand the effectiveness of the course, validated through expert assessment and then deployed as a pilot in the first course of the program. Student responses were analyzed to

identify needs and areas of opportunity to improve the questionnaire. Expert validation and pilot testing were used to evaluate the questionnaire structure, concepts assessed and the corresponding questions. As a result of the assessment process a system of “best practices” was developed to share insights and lessons learned with the program professors.

In this particular program the assessment system, as described in Fig. 1 helped to maintain the program quality and provide opportunities for student development.

Research shows that there are several factors that impact student satisfaction in distance learning courses. We studied the student needs and preferences, and obtained student feedback about the learning environment to successfully support the design and implementation of the program [6]. Several techniques such as content validity analysis, focus group and midterm evaluations were used to analyze whereas the findings from the literature review and the questionnaire validity evaluation were aligned with the program, learning process and student needs. A novel midterm evaluation, in the form of a focus group through video conference was implemented in the program. By this time students were familiar with the equipment, technology and course dynamics. The focus group was used to gain student insights on: (1) teaching process, (2) program experiences and expectations, (3) communication strategies between students and instructors, (4) information exchange experiences, (5) faculty performance (i.e., environment, expression, dynamism and motivation). Table II presents the relevant findings collected from the focus group discussion.

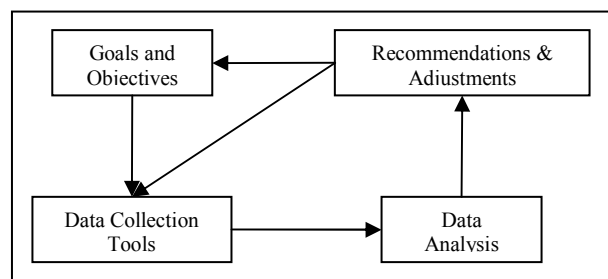

Fig. 1. Assessment process followed in the program

The results from the focus group aligned well with findings in the literature. Most of the concepts identified in the distance learning literature were part of the issues students presented in the focus group. Student insights were related to: (1) appearance and structure, (2) technical problems, (3) procedures and expectations, (4) content delivery, (5) communication and instructor presence and (6) instructor performance. The only issue that literature highlights that was not mentioned by students was knowledge and application. Table II summarizes the findings related to student insights and comments aligned with the concepts studied. The findings were used to correct problems and improve the learning experience for students in the remaining courses of the program.

TABLE II. ASSESSMENT RESULTS FROM FOCUS GROUP WITH STUDENTS IN THE MASTERS PROGRAM

Concepts	Findings
Appearance and Structure	Good use of internet page to share content and information
Technical problems	Distortion in the PowerPoint presentation when the professor moves in the camera field. The problem was avoided through the use of a laser pointer, a ruler or the computer mouse to point to items in the presentation Great quality of the sound between sites.
Procedures and expectations	Student had challenges connecting to internet during class. Some courses lacked syllabus, and appeared lack of organization with the content. There is not enough time to cover the material in some courses. There needs to be more collaboration to have books available in the library as well as journal articles discussed in class.
Content delivery	Provide an alternate system to view the professor and the course content separately during transmission. Suggestions to use multiple screens in the transmission to view the professor and course content in separate screens. Provide students with computers during class and allow students with personal computers to access internet during class to download material. Record CD's of courses during live transmission.
Communication and Instructor presence	Faculty is easy to access to answer questions. Professors are available through multiple means such as the course website, email, office phone and personal phone.
Instructor performance	Reasonable time to complete class work and activities.

Table III shows results from the course "Power System Operation & Control". Students were given the opportunity to assess all courses using the same instrument.

In the assessment process students openly expressed their concerns and ideas, and they were incorporated to improve the program. This had a positive impact in the course evaluations as well as the program final evaluation. In one of the assessment activities one student stated "thanks for allowing us an opportunity to share our suggestions and being open to use our feedback". For the most part evaluations had scores above 4 in a 5 point scale. The greatest challenge in the program was the quality of the video conference communication during classes. There were frequent problems with video delays, and audio problems that the instructor in his classroom was not able to detect on time. Constant and swift technical assistance

is thus a requirement at both ends of a distance learning program using videoconference.

TABLE III. SAMPLE ASSESSMENT RESULTS FOR ONE COURSE

Item	Average	Std. Dev.
I contact the professor and receive an answer promptly	4.7	0.47
Homework complement class material	4.5	0.52
Class material helped me attain new knowledge useful for innovative, fast and practical problem solving	4.7	0.47
The medium to receive, read and download class documents is effective	4.2	0.41
Announcements, documents and professor's notes are easily obtained	4.5	0.52
The professor creates an appropriate learning environment that encourages students to ask questions	4.9	0.30
At the beginning of class I had enough time to get familiar with relevant terminology and technical language about concepts I know that are called differently.	4.5	0.52
The Professor's teaching methods are aligned to my learning style.	4.5	0.52

III. MASTERS PROJECTS

From the initial program cohort of 27 students, 17 completed the courses with the required grades. The next program phase was the submission of a Masters project proposal for evaluation and approval. From the 17 students that completed the curriculum, 16 presented pre-proposals for Masters projects. UPRM faculty helped the students in narrowing or broadening the scope of their proposals as needed. After that, students presented the formal written proposal. The proposals were reviewed by UPRM, UNAPEC faculty and in some instances by the supervisors of the students at the transmission company. All project proposals addressed a technical need existing in the Dominican power system. Proposals included a timeline of work that usually spanned several months. Table IV summarizes the topics chosen by the 15 students who successfully completed the Masters project.

Students received guidance from faculty in Puerto Rico and the Dominican Republic during their projects. Once students had made substantial progress in their work, they registered for the course "Research Project" at UNAPEC. The course entailed three progress reports over a three-month period. After each progress report, UPRM faculty gave students feedback on what areas needed improvement. Towards the end of the course, students were informed whether they were ready or not to defend their Masters project.

The first group of students presented their projects on December 2010. Each student had to defend their work before a panel composed of three to four UNAPEC faculty, and two to

three UPRM faculty (the latter connected through videoconference). A second group of students defended their work on April 2011. The last student to present the Masters project did so in July 2011. Students received a traditional letter grade for their Masters project, based both on their oral presentation as well as on their written reports. However, a rubric was used by the authors to assess the degree of attainment of important learning objectives for the program. Table V shows the results from applying the rubric to all projects. Fig. 2 shows these results graphically, providing further evidence of the success of the program. All items assessed had a score over 70%. The lowest score (2.93 or 73%) was the inclusion of sustainable energy topics in the Masters projects. Student proposals included diverse topics, not all of them related directly to sustainable energy. Even though the program's framework was sustainability, it was not a requirement to include sustainability in their projects. Faculty did not want to force students but rather allow students to freely select if they wanted to pursue sustainable energy topics in their work. Nevertheless, even those that did not include sustainability explicitly, they did so partially through consideration of social or environmental issues in their projects. The overall goal of the program, to give students a more holistic perspective of their role as engineers, was thus met.

TABLE IV. MASTERS PROJECTS SUCCESSFULLY PRESENTED

Project	Topic
1	High Voltage Line Stability
2	High Performance Conductors to Improve Performance of High Voltage Lines
3	Economic Analysis of the Power Generation Units connected to the Dominican Power System
4	Underground transmission line design
5	Evaluation of Static VAR Compensator in a critical Bus of the Dominican Power System
6	Restoration Criteria for the Dominican Power System
7	Aggregate Value of Distribution System Services
8	Estimation and Characterization of Hazardous Waste
9	High Voltage Fuel Cells
10	Integration of Wind Parks to the Dominican Power System
11	Reactive Power supply from the Hydroelectric Power Plant at the Northern region of the Dominican Republic
12	Feasibility of Establishing the Bio-Refinery approach in the Dominican Republic
13	Interconnection Analysis for Wind Parks in the Northern region of the Dominican Republic
14	Feasibility Analysis of an Interconnection between the Dominican Republic and Haiti
15	Protection Schemes

TABLE V. RUBRIC USED TO ASSESS MASTERS PROJECTS AND AVERAGE RESULTS FOR EACH ITEM

Item	Score (1 to 4)
Significance of the project for the local electric power industry	3.80
Innovative solution for the local electric power industry	3.27
The project includes sustainable energy topics	2.93
The project considers social and environmental implications	3.40
The project includes economic analysis	3.00
The student demonstrates current knowledge and skills about the electric power industry	3.60
Application of engineering tools to solve electric energy problems	3.53

Fig. 2. Assessment results from students' Masters projects

Only one eligible student did not submit a final Masters project. Fifteen (15) Dominican engineers graduated with a Masters degree from this distance learning program. The degree was signed by the Chancellors of both UNAPEC and UPRM, as evidence of the collaboration between the institutions to provide this service to the Dominican Republic.

IV. PROGRAM ASSESSMENT

After all students defended and submitted their Masters project, and all grades were posted, they were asked to assess their experience in the program. Table VI shows the results of this program assessment. The authors knew the program was successful because of the course evaluations, the results from the oral defense of each project, and the results from the Masters project rubric. However, student perceptions of the program further evidenced success, especially the first item on Table VI, where students unanimously agreed that the program provided them an "integrated vision" that will allow them to work on "the energy challenges of the 21st century". All items were above 90%, except for "gained responsibilities as leaders or decision makers in the electric power grid" that received an 80% affirmative response, which is still high considering that this item requires an action from the employer.

TABLE VI. ASSESSMENT RESULTS FOR THE PROGRAM

Item	Average	Std. Dev.
This program helped me build an integrated vision of Power Engineering that will allow me to design innovative solutions for industry and the service sector that address the energy challenges of the 21st century.	5.00	0.00
I am prepared, with current knowledge, to respond in a practical, fast, innovative, competitive and coherent way to the challenges of unregulated electrical markets.	4.64	0.50
Through this program I was able to acquire knowledge to apply science and techniques to problems related to electrical engineering.	4.91	0.30
The program helped me deepen my knowledge in problems related to the generation, transmission and distribution of electric energy.	4.73	0.47
The program helped me build an integrated vision of the power system that will allow me adapt and face diverse.	4.73	0.47
Through this program I was able to study alternatives and possible innovative solutions for the Dominican power industry.	4.82	0.40
Through this program I was able to study alternatives and possible solutions considering social and environmental implications.	4.45	0.52
Through this program I was able to study alternatives and possible solutions considering economic implications.	4.64	0.50
The program helped me identify applied and technological innovation processes in the electric power sector.	4.82	0.40
The program helped me obtained new knowledge in the electric energy field.	4.73	0.47
The program helped me broaden my philosophical and theoretical frameworks in sustainable energy.	4.64	0.50
I look forward to carry out, in the future, responsibilities associated with direction, analysis or decision making in power system.	4.82	0.40
After completing the program I have assumed leadership or decision making positions in the electric energy system.	4.09	0.83
I have contributed solutions to specific problems that relate to the scientific, technical and economic development of my country.	4.55	0.52

As part of the final program assessment, students had an opportunity to reflect about their future professional goals. Student responses to this question show student convictions about “having the tools and skills to make better decisions in their daily work; the framework for technical discussions with higher analytical power; desire to continue pursuing scientific research to support their country”. The final project incorporating a real world problem was viewed by students as essential. Even some students reported that they want to continue developing knowledge in the area as well as feeling empowered to share what they learned with others. In particular one student was motivated to “start his career as academic faculty and in the long term, achieve a leadership position in the electric sector”.

The assessment process showed that the program strength relied on faculty knowledge; contents quality and ethical standards; the use of technology in the program; and the final project which provided an opportunity to do research and make a real contribution to their society. The comments from the participants indicated that the program helped them become better professionals through the use of different educational methods and activities as well as faculty “ethical values, commitment and quality in the execution”. Also the assessment process highlighted several areas of opportunity to strengthen the program in the future. These areas of improvement include: (1) support in research methodology as well as more mentoring during the process of the project, (2) inclusion of elective courses, (3) provide more feedback to students during the program, (4) provide online tests and practice activities to support learning using the program website, and (5) have the opportunity to select the final project topic earlier in the program.

V. CONCLUSIONS

A novel, international, distance learning graduate program was successfully completed by fifteen Dominican engineers. The program addressed the Dominican energy problem from a technical perspective, but also considered and integrated the social and environmental aspects of the problem using a sustainability framework. This education paradigm yielded an integrated vision of the local and regional energy dilemma needed to advance a sustainable energy future in countries with scarce traditional energy sources. The students unanimously agreed that the program provided them this integrated vision that will allow them to work on the energy challenges of the Dominican Republic. The assessment results for the program revealed that the program was successful in attaining its objectives.

This collaborative program between UNAPEC and UPRM also had a positive impact at UPRM. The work enriched the courses taught at UPRM in the traditional way through improved teaching materials and methods, as well as the professional development of the professors. Finally, the approach used in the conceptualization and execution of this program could be replicated elsewhere. In customized programs such as the one described in this paper, it is of paramount importance to align the needs of society (in this case the electric sector in the Dominican Republic) to the

program's academic requirements while keeping the core knowledge that needs to be mastered by the participants. A thorough assessment process is needed to ensure that this societal alignment and contents requirements are maintained throughout the program, and that the program achieves its goals.

Abstract – Nationwide, only 17% of community college students go on to complete a bachelor's degree within six years of enrolling at a community college and even a fewer number in the STEM fields. Community college students are more likely to be non-traditional, who are coincidentally comprised mostly of members of underrepresented groups. In this work, we examined the academic development of a cohort of non-traditional students as they transferred to an elite four-year institution from local community colleges. Drawing from educational and psychological research, we evaluated student motivation, resilience, and self-regulated learning habits throughout the first year of their transfer. The broader goal of this project is to better understand the self-regulated learning skills and motivation of non-traditional students from the point of transfer to degree completion. This in turn will foster the development of pedagogical techniques and support systems that are better suited for non-traditional students, with the ultimate goal of on-time degree completion and entrance into the STEM workforce.

Keywords – Non-traditional students; self-regulation; goal orientation, cohort models.

I. INTRODUCTION

Increasing the number of students who major in and graduate from the fields of Science, Technology, Engineering and Mathematics (STEM) has been a common discussion topic among academic and professional stakeholders. [1-2]. In recent years, there has been a sense of urgency to reform undergraduate instruction to improve STEM degree interest, retention, and graduation [3]. Meanwhile, it is estimated that about 40% of students who start off in a physical science or engineering major switch to a non-STEM field before graduation [4-5]. Lack of persistence and dropout rates are even higher for students who start their education at community colleges, many of whom also come from underrepresented groups [6]. More than other college students, these groups face hurdles entering and remaining in a STEM curriculum. Some of the major hurdles faced by these students are economic burdens and academic unpreparedness. The socioeconomic status of a student usually determines the level and rigor of

the education that the student receives at the public school system. In less affluent neighborhoods, where many non-traditional and community college students reside, the academic programs are often less rigorous. Fewer advanced science and mathematics classes are available and students have a harder time preparing for the demanding curriculum required of most STEM majors. Despite these hurdles, this population represents a potential talent pool from which to draw a more diverse and inclusive workforce in the STEM fields [7].

In Fall 2013, approximately 7.1 million students attended two-year community colleges, representing 40% of all undergraduate students in the United States [8]. However, on average, only 17% of students who start at two-year institutions finish their studies at a four-year institution within six years [9]. Many community college students are from underrepresented populations including minorities, first generation college attendees and students from low resource families. In addition, a large percentage of community college students are considered non-traditional, a demographic that includes adult-learners, low-income financially independent students of college-age, young mothers, and working professionals who never completed their post-secondary education. Recent works in the STEM education field have indicated that cohort programs, peer-based community building activities, hands-on experiences and active engagement can contribute to higher success and retention rates of non-traditional students [10-14].

In this paper we examined the development and progress of non-traditional students who transferred and enrolled at The George Washington University (GW) in Fall 2014. This work followed students who transferred from local community colleges into the cohort-based Integrated Information Science and Technology (IIST) program at GW. This two-year interdisciplinary degree completion program is specifically designed for community college graduates to finish their bachelor's degree in two academic years at GW. More details about the program and the curriculum can be found in a previous FIE conference paper [15].

This project is supported by NSF grant #: DUE-1356400

Using educational and psychological research, we measured and evaluated student motivation, resilience, and self-regulated learning habits to determine how these relate to past work experiences, age, demographics, and academic performance. Additionally, we looked at the pre-existing beliefs and goals of the incoming transfer students and evaluated their academic progress, changes in behavior, and performance throughout the first year of their studies in our program. Specifically, academic performance was tracked in a sequence of Python programming courses over the 2014-2015 academic year. Special attention was given to motivation orientation, short-term/long-term goals and computer efficacy and e-learning capabilities.

II. METHODOLOGY

This work was guided by research and theory in education and psychology; specifically, self-regulation theory. Research in this area has clearly established the intimate connection between affective (i.e., emotional) and cognitive states and resulting academic performance, with emotions such as frustration often driving behavioral decisions [16-17]. For example, there is typically a decline in student motivation over the course of the semester and a corresponding drop in key self-regulatory cognitive strategies tied to achievement [18]. Ongoing research on this issue has pointed to the need to go beyond traditional achievement/cognitive factors for predicting success and designing interventions [19]. Over the past 25 years, self-regulation theory has become the dominant approach in educational and applied psychology to understanding learner motivation [20]. The process of self-regulated learning (SRL) involves cognitive, affective, and behavioral components, and describes the continuous process of achievement striving, monitoring, and evaluation that successful learners engage in over time. SRL has proven to be a useful framework for understanding the mental processes involved in learning. With regard to college STEM education, research has demonstrated that self-regulation predicts higher grades and is associated with different facets of goals, beliefs, and emotional reactions [21]. Furthermore, students' self-regulation is associated with retention in their degree path [21-22].

In this study, we examined our student population and tried to better understand their motivation, aptitude and attitude towards STEM fields and careers. This was accomplished by analyzing the data provided in application packages, by conducting surveys to measure motivation levels and identify obstacles, and by tracking success trajectory and academic performance over the first year of studies at GW after transfer. The data collection included the following:

- *Admissions materials:* The information that was provided by the students on their application packages

was examined. This included demographic information (gender, age), past academic performance (GPA, computer and math literacy) and professional experience (number of years working). This information was used as a baseline to understand initial motivations for entering the program.

- *Surveys:* Surveys were administrated twice during the academic year (end of Fall 2014 & Spring 2015 terms) to better understand students' goal orientation, motivation, self-directed learning and short-term/long-term goals. Three different classes of goal orientation theory (learning, prove performance and avoid performance) were used to characterize our non-traditional students' intention to master challenging situations and their desire to validate competency through positive or negative judgement [23-24]. Short-term goal measurements were categorized as goals related to achievement (i.e., studying to get better grades and attain a higher GPA), learning oriented goals (studying for the sake of learning and mastering concepts), or a mix of achievement and learning oriented goals. Long-term goals were measured according to future STEM and non-STEM related academic and career endeavours.
- *Academic performance:* This was analyzed through overall GPA and performance in a sequence of CS1-CS2 type Python programming courses.

III. RESULTS

Fig. 1 provides an overview of some of the characteristics of students that were part of this study. We had an initial sample pool of 26 students during the Fall 2014 term. The average age, employment status and number of professional work experience exemplify the non-traditional aspects of our students. This graph is based on the data for all 26 students, and the first survey that was administrated during the end of Fall 2014 term.

Fig. 1 Characteristics of students who entered the IIST program in the Fall 2014 term.

The data shown in Fig. 1 can be summarized as follows:

- The average age of the student sample was 31, with an average of 12 years of work experience and a 42% to 58% female-male ratio.
- Most of our students exhibited high learning goal orientation ($M = 4.46$), medium prove performance goal orientation ($M = 3.08$), and low avoid performance motivation ($M = 2.13$). Data was measured on the Likert scale of 1-5, with 1 being the strongly disagree and 5 being the strongly agree option on the survey and M representing the mean calculated value. This indicates that the dominant motivation factor for our students was the desire to learn, and that our students were more likely to take risks and try a challenging task. This result is not surprising as adult learners tend to be more self-regulated and motivated, and they are more conscious about education cost. In addition, coming back to school and entering the program is already indicative of this group's willingness to take on challenging situations, affirming their high prove performance goal orientation.
- Men showed higher level of computer self-efficacy than women, who consistently showed lower skills though not significantly lower. A follow-up survey conducted during the spring term indicated that women increased in both computer self-efficacy and performance. Men also reported a significantly higher level of prove performance orientation in the second semester.

IV. ANALYSIS

To further investigate the learning characteristics of our student population, a more in-depth analysis was conducted using the demographic information presented above, the result of both fall and spring surveys, and the academic performance of students over the course of the academic year. Subgroup analyses were conducted for three groups of interest: gender, age, and employment status. Past research has suggested that these variables are relevant to the experience of barriers to academic achievement and graduation. The result is summarized in Table 1 and is described below - note that the information provided in Table 1 is based on the 21 students who continued in the program after the first term. 5 students dropped out of the program after the end of the fall term.

A. Women vs. Men

The data collected in this study revealed a number of interesting differences related to gender, with both men and women displaying different sources of motivation and changes over time in learner characteristics. Men showed significantly higher overall academic performance compared to women as indicated by cumulative GPA.

However, women as a whole improved more over time than men, most notably in their improvement in course performance between the fall and spring terms, which was equivalent to over half a letter grade.

These differences may be tied to motivation as several indicators demonstrated the differences in the motivation or sources of motivation for men and women. Women's motivation appeared to be tied more to goal-orientation and their focus on learning as stated in their academic goals. For instance, when asked about their short-term goals, 70% of women stated goals related to learning compared to 9% for men. Additionally, for learner characteristics that were measured during each semester, learning goal orientation significantly predicted course grade in the spring for women, but not for men. For prove performance goal-orientation, men increased between the two semesters while women showed a slight decrease, resulting in a significantly higher level for men.

Women also became more confident in their abilities to use computers over time, increasing in computer self-efficacy on the second survey. Men reported higher levels than women for both surveys. Computer self-efficacy is likely an important characteristic critical to success in STEM coursework that focuses heavily on computer use, such as the Python programming courses completed by participants in this study.

	Gender		Age		Employed	
	M	W	< 30	> 30	No	Yes

TABLE 1. SUBGROUP ANALYSIS OF 2015 SPRING CLASS BASED ON GENDER, AGE AND EMPLOYMENT STATUS.

B. Younger than 30 years old vs. Older than 30 years old

Overall, learners across both age groups were similar on measures of motivation and learner characteristics. Surprisingly, the older-learners (30 and over) in this sample had higher computer self-efficacy than those who were under 30. However, at the time of the second survey those under 30 reported higher levels of computer self-efficacy and similar to older-learners. They were also higher in self-regulated learning, which is somewhat expected. There were no differences between the older and younger learners for goal orientation, though interestingly both groups decreased significantly in learning goal orientation over two semesters.

Older learners stated more of a range of academic goals with about a third stating goals related to achievement. Those below 30 were much more likely to state goals related to learning and achievement than those who were 30 and over. Finally, a small percentage of those under 30 stated that long-term career goals were not part of their plans as they seemed too distant, or because of a desire to focus on finishing their degree. All participants 30 and over stated long-term career goals. In expressing the barriers to their goals, those over 30 stated barriers related to time-constraints from work and family much more than those under 30. In terms of performance, both groups were similar on a range of measures such as assignment grades, exams, and GPA.

C. Employed vs. Non-employed

Those who are currently employed were higher in age, self-directed learning, avoid performance goal orientation, and showed a greater range of academic goals compared to those who were not employed. Those not working primarily stated goals related to learning or learning and achievement. Both groups performed relatively similar in terms of course performance but those who were not employed showed a greater improvement over the course of their studies.

D. Dropouts

19% of the sample dropped out after one semester (5 out of 26). Of these 5, 4 were men who were also over the age of 30. 50% of men who dropped out were between 30-49 years of age and 2 were over 50 years of age. 1 person who dropped out was female and less than 25 years of age. Only two participants who dropped out completed the survey in the fall. However, they were much higher in prove performance goal orientation (3.25 vs. 2.99 average per item) and avoid performance orientation (4.63 vs. 2.06 average per item). Reasons for dropping out tended to revolve around extenuating factors, non-traditional backgrounds, and long delays between prior coursework and enrollment in the program, leading to a more difficult adjustment. Class performance was also much lower for

those who dropped out compared to those who are still currently enrolled in the program.

V. DISCUSSION AND CONCLUSION

Throughout this preliminary study, we have found that non-traditional students have unique characteristics, goal orientations and motivation levels that should be taken into consideration. Overall, the students were characterized by high levels of motivation and academic success. However, noteworthy differences were found between men and women. Specifically, women entered the program with more learning-oriented goals, and had lower levels of academic achievement. Women also showed greater improvement between the fall and spring terms. Age did not appear to have a strong effect on motivation or performance; however older students were more likely to have STEM-related career goals.

One of the more interesting aspects of this study is in the changes over time that was observed in the performance and learner characteristics of the student sample. Students in each of these subgroups entered the program with varying levels of goal orientation, computer self-efficacy and self-directed learning, but over the course of two semesters became more similar in these measures and in course performance. These findings may also be a result of the effectiveness of the cohort model. Surprisingly, employment status also had few effects on motivation or performance, with both employed and unemployed students performing at the same level. This is noteworthy given that many students reported that employment-related barriers (e.g., lack of time) interfered with their ability to devote time to schoolwork and the success trajectory in the program over the two years.

In the follow up study, we plan to continue to observe this group of students as they enroll in their second year of studies at GW and as they continue their transfer journey in our program. We also plan to explore ways to support high-risk students who are in danger of dropping out. A better understanding of their background and motivation goals might allow us to identify indicators that could allow us to approach such situations early on. By providing just-in time support and additional resources we might be able to help such students remain in the program. A further analysis of barriers and obstacles that students face could also be taken into consideration to better serve the students.

A more general goal of this study and subsequent work is to better gauge self-regulation, goal orientation and motivation levels of non-traditional students from the point of transfer to degree completion. The end result would be a framework and pedagogical techniques that can better equip educators to support this population and to provide a supporting environment to foster the growth of these students, with the ultimate goal of on-time degree completion and entrance into the STEM workforce.

Abstract—This work in progress paper describes a mixed methods study designed to investigate transfer student pathways as a means to increase engineering degree production and broaden participation in engineering careers. The study explores the framework of transfer student capital and its relevance for engineering transfer students. In this paper, we provide an overview of a survey instrument developed to collect data from more than 6,000 students who successfully transferred to one of four 4-year institutions in Texas as new engineering students between 2007 and 2014. Our study expands the small body of literature on engineering transfer students and sheds light on specific policies and practices that impact transfer.

Keywords—*broadening participation; engineering; transfer; pathways; persistence; transfer student capital; social capital*

I. BACKGROUND

In 2015, President Obama introduced *America's College Promise*, a new proposal to make “two years of community college free for anyone who is willing to work for it” [1]. The plan to remove cost as a barrier and make higher education accessible to all Americans would require a significant investment from both federal and state governments. Current estimates indicate that the program would cost the federal government \$60 billion over the course of ten years and an

additional \$20 billion contribution from state governments. To maximize results from such a substantial investment, it is important to address and resolve existing challenges related to degree completion and upward transfer for community college students within engineering. In this paper we provide an overview of our current NSF study focused on transfer students in Texas that is aiming to meet that objective.

II. STUDY ON TRANSFER STUDENT PATHWAYS TO ENGINEERING DEGREES – WORK IN PROGRESS

A. Motivation

For more than a decade, the National Research Council (NRC) and National Academy of Engineering (NAE) have emphasized the important role that community colleges play in broadening participation and expanding pathways to engineering degrees [2, 3]. However, leaders in higher education have acknowledged that the transfer student pathway within engineering is not operating at full potential [2].

The existing body of literature on engineering transfer students is slim and fragmented [4]. Most of what we know is based on the community college literature more generally, which is limited in its application to engineering transfer students. Current literature suggests that common barriers to transfer student success in STEM includes: 1) inaccurate and/or passive transfer advising; 2) weak transfer/articulation policies; 3) lack of course transferability; 4) the sudden shift from a supportive environment to one with competitive

This material is based upon work supported by the National Science Foundation under Grant No. 1428502. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation.

classroom pedagogies; 5) unfamiliarity with academic rigor and expectations at 4-year institutions; 6) feelings of isolation; and 7) poor experiences with financial aid [5-8]. While these studies identify key challenges, Dowd [5] argues that “the body of literature focusing specifically on transfer in STEM is not robust enough to substantiate conclusions about the unique programmatic features that are necessary to design effective STEM transfer pathways” (p. 112).

New research suggests that creating transfer pathways into 4-year public/private colleges can broaden participation in engineering specifically for Hispanic students [9]. Given that more ethnic/racial minorities begin their pursuit of higher education at schools other than 4-year public/private colleges, it is critical that we create pathways into engineering from 2-year public colleges. According to the National Center for Education Statistics, 56% of Hispanic students and 48% of African American students in undergraduate education during Fall 2012 were enrolled in 2-year public colleges [10].

B. Purpose and Research Questions

The purpose of this mixed methods research is to develop a clearer understanding of transfer student pathways as a means to increase engineering degree production and broaden participation in engineering careers. The study sites for this research are 4 of the top 10 producers of U.S. Hispanic engineers, and all are based in Texas: The University of Texas at El Paso, Texas A&M University, The University of Texas at Austin, and The University of Texas-Pan American [11].

Our study expands the small body of literature on engineering transfer students and sheds light on specific policies and practices that impact transfer. Specifically, our investigation addresses the following research questions:

1. How does transfer student capital relate to academic achievement and degree attainment for transfer engineering students at 4-year institutions?
2. How do Hispanic and non-Hispanic transfer students compare on measures of transfer student capital and its relation to academic achievement and degree attainment?
3. How do students decide to transfer into engineering at a 4-year institution?

4. What institutional policies facilitate success and enable transfer pathways into engineering at 4-year universities for transfer students?
5. How do institutions hinder transfer students in their transitions to engineering at 4-year universities?

Findings from this study can inform decisions on how to allocate limited resources (i.e. financial and human) to diversify pathways and increase the number of students who transfer into and succeed in engineering at 4-year institutions. In addition, this research will help policy makers and higher education administrators (i.e., deans, department chairs, and admissions officers) understand the barriers and perceptions that prevent more students from transferring into engineering at 4-year institutions so that they can make data-informed adjustments to their existing institutional practices.

C. Theoretical Framework - Transfer Student Capital

The framework for transfer student capital serves as a guide to organize this study on engineering transfer students [12, 13]. Transfer student capital is the accumulation of knowledge about higher education that develops in a student as he or she interacts with faculty, receives academic advising/counseling, studies for coursework, navigates through university transfer policies to fulfill academic requirements, and proceeds through the transfer process from a community college to a 4-year institution [13]. This theory suggests that the students who possess larger accumulations of transfer student capital are more apt to successfully transfer from a community college to a 4-year institution [14]. Our study explores the framework of transfer student capital and its relevance for engineering transfer students.

D. Methodology

The methodology guiding this study is an explanatory sequential mixed method design; a qualitative strategy will be used to extend findings from a quantitative analysis. Data sources for each research question are summarized in Table 1. The quantitative phase consists of a cross-sectional survey-based approach that also draws on data from institutional student records to address research questions 1 and 2. The qualitative phase is an embedded case study that will include semi-structured interview data to address research question 3.

TABLE I. RESEARCH QUESTIONS, PHENOMENA, AND DATA SOURCES

Research Question and Phase	Population	Data Collection	Phenomena of Interest
RQ 1 & RQ 2 quantitative survey	6,100 students who transferred into engineering for the first time between 2007 and 2014	Cross-sectional data from an adaption of the L-TSQ survey and student academic data	Transfer Student Capital
RQ 3 qualitative embedded case study	Institutional stakeholders and students who transferred into engineering for the first time between 2007 and 2014	Semi-structured interviews with purposeful sample of stakeholders and students selected based on survey findings	Academic Adjustment
RQ 4 & RQ 5 quantitative survey & qualitative embedded case study	Combined population from RQ 1, 2, & 3	Combined data collection from RQ 1, 2, & 3	

We will use findings from the quantitative phase to form interview protocols and identify a purposeful sample of “stakeholders” at the four institutions for the interviews in the qualitative phase. Information from both the quantitative and qualitative phase will be used to address research questions 4 and 5.

III. DEVELOPING THE ENGINEERING TRANSFER STUDENT SURVEY

A. Alternate Survey Instruments

The survey for our study is an adaptation of the Laanan-transfer students' questionnaire (L-TSQ) [13-15] plus a compilation of survey items extracted from the following multi-institutional research studies that investigated transfer student experiences in STEM: Prototype to Production: P2P [16] and Measuring Constructs of STEM Student Success Literacy: Community College Students' Self-Efficacy, Social Capital, and Transfer Knowledge [17, 18]. To address validity, our survey was developed using input and feedback from content experts on the project advisory board and representatives from the participating 4-year institutions and their partner local community colleges. Representatives included a combination of administrators, faculty, and staff from 8 institutions with working knowledge of policies and practices in Texas that impact students who transfer to 4-year institutions as new engineering students.

B. Content

The final survey instrument is comprised of six sections that include a mix of multiple choice and open-ended questions. At this time, we estimate that students will need 15-20 minutes to complete the 45 question survey. Multiple survey items are embedded in 16 of the 45 questions. A high level summary for each section of the survey is provided as follows:

1) *Personal Information (19 questions)*. Part 1 of the survey captures participant background information, including: gender, race/ethnicity, citizenship, age, education attainment, future degree aspirations, parent/guardian education attainment, mode of admission at receiving institution, identification of primary sending institution, and expected/actual time to degree completion.

2) *Transfer Pathway (2 questions)*. Part 2 captures students' reasons for starting their education at a different institution and factors that influenced their decision to transfer to the receiving institution.

3) *Experience with the Transfer Process (8 questions)*. Part 3 captures students' perceptions of the transfer process and usefulness of information sources on how to transfer. This section also captures data on student experiences prior to transfer, including: experiences with academic advising at both sending and receiving institutions, and use of student resources at the receiving institution.

4) *Experience at Sending Institution (1 question)*. Part 4 captures students' perceptions of preparation received at the sending institution with respect to learning and study skills.

5) *Comparing Experiences at Each Institution (8 questions)*. Part 5 captures data that allow us to compare student experiences at the sending and receiving institutions before and after transfer, respectively. In this section, questions focus on student experiences with faculty, coursework, and time management at each institution.

6) *Experience at Receiving Institution (7 questions)*. Part 6 captures students' perspectives on transfer challenges and general perceptions of the receiving institution. This section also captures students' perceptions of the adjustment process and social support available at the receiving institution.

C. Need for Local Customization

In working with the full project team, we quickly recognized the need for local customization during our effort to develop the Engineering Transfer Student Survey because of varying terminology and practices (which is a finding in and of itself). During survey development, we defined key terms to increase clarity for study participants and stakeholders and dedicated careful attention to appropriate use of terminology. The final versions of the instrument have been customized to accommodate the following:

1) *Alternative Transfer Pathways*. The sample population in this study includes students coming from transfer pathways that may be classified as upward (e.g. from community college to 4-year institution), lateral (e.g. from one 4-year institution to another), swirl (e.g. return to original institution), or double-dipping (e.g. dual enrollment at both community college and 4-year institution) [19]. To capture unique and diverse perspectives, survey questions were further customized to address students who pursued alternative transfer pathways to engineering, such as students admitted into formal co-enrollment programs as well as students who are concurrently enrolled in two institutions.

2) *Local and Sensitive Terminology*. During our working meetings across 2-year and 4-year institutions, we identified terms that are mistakenly used interchangeably, but carry unique meaning from an institutional perspective. For example:

- *Dual enrollment* is a term used to describe high school students who are enrolled in dual credit/early college high schools; where *concurrent enrollment* is used to describe post-secondary students enrolled in multiple institutions of higher education at the same time.
- *Co-enrolled* is a term used to describe student participants in formal co-enrollment programs such as the Texas A&M Engineering Academy. Students admitted into this academy have applied to Texas A&M University and receive a coordinated admissions offer to co-enroll in both Texas A&M University and Blinn College. Unlike co-enrolled students, *concurrently enrolled* students have separate admission offers from multiple institutions.
- The terms *counselor* and *academic advisor* are used interchangeably at 2-year institutions to refer to professional staff hired to advise and assist students with

their academic plans. At four-year institutions, the more common term is *academic advisor*.

- The terms *previous institution* and *receiving institution* are used in our survey to capture and compare student experiences. For cases where students attend more than one institution prior to transferring, we define *previous institution* as the college/university where the student spent most of their time. Based on this working definition, the students is invited to identify his or her previous institution; we do not use “most recent university attended prior to transfer” as the default.

3) Unfamiliarity with Upward Transfer Policy Jargon.

Administrators on the project team agreed that engineering transfer students would not be familiar with jargon used at the state-level to advance upward transfer policies, such as *2+2 programs*, *course or program articulation agreements*, and the *Texas Voluntary Transfer Compact Program* (a finding worthy of future investigation in our study). Based on this feedback, we minimized references to *articulation agreements* and excluded the terms *2+2 program* and *Texas Voluntary Transfer Compact Program* from the final surveys. Whenever possible, we replaced the upward transfer policy jargon with local terminology (i.e. EPCC-UTEP Degree Agreements, Texas A&M Engineering Academy, Texas A&M University System Program for System Admission, UT System Coordinated Admission Program) to increase relevance for study participants.

IV. FUTURE WORK

In this paper we provide an overview of our current NSF study focused on transfer students in Texas. The purpose of the study is to develop a clearer understanding of transfer student pathways as a means to increase engineering degree production and broaden participation in engineering careers.

We launched the two year research project in October 2014 with a collective effort to develop a survey customized for transfer students in engineering. We are collecting and analyzing survey data through Fall 2015. At that time, we will launch the qualitative phase of the study to extend our findings from the quantitative phase.

We envision that our research findings on what helps and hinders transfer can be used to: 1) make improvements and revisions to existing policy; and 2) serve as a guide for states and institutions seeking to adopt new policies that promote upward transfer in engineering.

ACKNOWLEDGMENT

The authors would like to thank the following Advisory Board members and university administrators for providing insightful feedback during the development and customization of the Engineering Transfer Student Survey for this study: Dean Tonie Badillo, El Paso Community College; Dr. Monica Cortez, Texas A&M University; Dr. Eli Esmaeili, South Texas College; Dr. Ben Flores, UTEP; Assistant Dean Patricia A. Gore, UT Austin; Dr. Julie Martin, Clemson University; Dr. Sylvia McMullen, Blinn College; Dr. MaryJane McReynolds,

Austin Community College; Ms. Jackie Perez, Texas A&M University; Dr. Soko S. Starobin, Iowa State University; Dr. Cristina Villalobos, UT-Pan American.

Influence of Professional Demographics on Faculty Feedback in Asynchronous, Video-Annotated Peer Review (VAPR)

James J. Pembridge, Yosef Allam, Lisa K. Davids
Engineering Fundamentals
Embry-Riddle Aeronautical University
Daytona Beach, FL

Abstract— The use of an asynchronous video-annotated peer review system (VAPR) presents the opportunity to enhance teaching and diffuse pedagogical practice in higher education. The process involves the video recording of classroom teaching by each faculty member, which is then reviewed and annotated in real-time by faculty peers to identify specific instances of good practices, opportunities for improvement, and opportunities to incorporate research-based teaching approaches. The purpose of this study is to analyze the nature of faculty peer comments generated throughout the peer feedback process. Each peer-generated video annotation text file was coded to characterize the type of feedback given, encompassing characterizations such as: good practice, suggestions; types of teacher knowledge; and general attributes of teaching. The demographics of the peer authors, for corresponding annotations, are also classified based on highest degree, familiarity with the course as an instructor, and familiarity as a student. Findings indicate that a majority of the comments are related to the direct instruction of the course, rather than the content of the instruction. While not statistically significant, familiarity with the course as instructor is positively correlated to the number of comments pertaining to pedagogical content knowledge. These findings support the need for peer-review by faculty familiar with the course to offer context specific suggestions as well as those peers unfamiliar with the course to offer opportunities to diffuse instructional strategies from other contexts.

Keywords— *faculty peer review, professional development,*

I. INTRODUCTION

Faculty peer review has long been implemented in higher education as a form of formative feedback to support the refinement of instructional practice [1]. However, structural barriers limited the time and access required to implement this approach broadly. An alternative to the traditional form of peer review was developed to limit these issues using an asynchronous video-annotated peer review (VAPR).

This approach allows for faculty to review each other's classes in a systematic process that supports faculty reflection and shared vision to support the change and diffusion of pedagogical practices through social reflexivity [2]. While the process is systematic, the formation of the peer review pairings is less understood; commonly a pairing of convenience rather than optimally structured to encourage a deeper reflection that

will facilitate faculty change. As a first step to this optimization, this study seeks to characterize the type of comments faculty make in peer review based on professional demographics that may affect the type of feedback provided.

II. PEER REVIEW OF FACULTY TEACHING

In her review of peer review via teaching observation in higher education, Blackmore [1] summarizes the application of peer review as a tool for change that provides a method of assessing performances in order to help faculty peers improve so that good practice can be identified and shared [1, 3, 4]. Peer review is increasingly used within organizations to measure, evaluate and improve job performance by providing feedback to the individual on performance [4].

In their report of collaborative peer review for improving college teaching, Keig and Waggoner [5] note that faculty should play a role in instructional improvement through peer review because they are especially well qualified to identify events specific to the classroom [7]. These events include factors affecting the instruction, classroom procedures, and use of language to engage students, and components related to the discipline and curriculum in general. In addition, faculty possess insight into vital components of teaching that cannot be adequately assessed by students and administrators [6, 8-12].

In their review of literature, Keig and Waggoner also note that problems can persist from pairings due to too congratulatory and inaccurate assessments [1, 13]. There is often a fear of being too critical in the review of peers, however Cole [13] identified that a "culture of criticism is essential to the reviewing of ideas that can lead to improvements in the quality of a product. Because of this potential to be too congratulatory or critical, it was noted that checks and balances are needed [13].

Blackmore [1] notes that peer review has strength in its ease of establishment, being more inclusive for all faculty, and opportunity for greater dissemination. The selection of the reviewers is dependent on the purpose of the observation, expectations for the process, and which aspects of teaching are in need of improvement [6]. When the focus is on course content and level of complexity, adequate peer review may require input from reviewers with a considerable amount of expertise in that field of study. However if the focus is on more

general pedagogical techniques including presentation skills, instructor enthusiasm, and organization, familiarity may not be required.

Nonetheless, there may be less of a focus on subject and discipline as a result of pairings that include self-selected pairs, pairing with coordination, and groups with external input [1]. Peer reviewers do not have to be from the same subject disciplines. Good practice can be shared among the various subject specialists. Involving reviewers from other non-related fields can provide an advantage to the peer review [1, 15-17]. The use of non-familiar users may also limit “the perpetuation of conformity of teaching” noted by Cox and Ingleby [17], and may also reduce conflicts of interest [6]. In addition, periodic change in pairing ensures that more experienced teachers are paired with less experienced [19].

While there has been substantial insight into the process of peer review, there is less insight into the specifics of those reviews, including what events that might be observed by the reviewers [6].

Peer Review Comments

In examining faculty peer review of teaching implementation, Bernstein, Jonson, and Smith [19] make suggestions based on observations of an American Association for Higher Education derivation of a peer review system. Pairs of faculty interacted on three topics of discourse: course intellectual content and goals, teaching practice, and student learning (p. 74). Participating faculty cited beneficial, high-quality discussions and were “extraordinarily positive” (p. 79) about the experience. Faculty also altered class practices, generally by reducing lecture-based, passive instruction and replacing it with more active methods.

Peer review commentary on observations made by fellow faculty in the classroom of the observed should lead to teaching reflection and change [20]. Arreola’s [21] form-driven faculty peer review feedback system calls for establishing teaching role parameters including content knowledge, curriculum, and instructional practices, each with an assigned weight and rating. However, these are not just sourced from observations, but conferences and course material.

Ratings from reviewers of those faculty being observed in the classroom should be reliable and valid, despite the fact that they, “...are not as well established as they are for student ratings” [22]. Nonetheless, Paulsen found several studies showing reliability in peer review of teaching. Again, Paulsen’s review of the literature found unanimously that reviews should be comprised of content knowledge, teaching effectiveness feedback, with Cashin [23] adding curriculum and course design. There should be consistency in required peer review contents to encourage reliability across faculty peer review portfolios. Effective formative evaluation should identify areas for improvement and pathways to success. Teaching should be more similar in its subjection to the rigor of review as research traditionally is.

Gosling [24] calls for a peer review model in which both parties, the observed and observer, benefit and learn from the

peer review process. The mutually beneficial aspect of this preferred peer review model is coupled with shared responsibility; there is a “collective responsibility for teaching” (p. 3). Teaching observation should include observation and interplay of student evaluation, assessment, outcomes, and curricula.

Yin’s [25] case study on the implementation of a formative, developmental peer review process was summarized [26], with leadership championing the process as a necessary professional development component. The observations involved annual events that included pre-observation conferences, classroom observation with standardized forms retained by the observed faculty, and a private post-observation discussion regarding the observation and relevant institutional criteria. Again, the observation activities are intended to be mutually beneficial. Summaries are collected by the coordinating personnel and integrated good practices are circulated, supporting diffusion. Confidentiality is maintained. The university overall improved significantly and faculty participant feedback was positive.

Chism [27] calls for the use of standard checklists and worksheets based on the teaching entity’s protocol concerning the peer review process, its purpose, and its goals, with observations reviewed by those both familiar and unfamiliar with content. The classroom observation form provided by Felder and Brent [28] provides for ten ratings to be given by two reviewers to allow for reconciliation and reliability in the areas of instructor preparedness, content knowledge, enthusiasm, clarity of speech, use of examples, visual aids, questions posed, attention of class, student involvement, and respect to students. There is also space provided for providing open-ended descriptions of strengths and areas of improvement. Berk [29] generally provides for similar areas for scaled ratings.

Peer review participants should gain experience and apply an observation and reflection conceptual framework resulting in a video portfolio that includes classroom teaching videos accompanied by instructor-provided self-assessments and context [30]. Video portfolios must feature content that stimulates reflection and faculty discourse on teaching practice per situated cognition and social constructivism theories. The authors recommend use of “functional criteria” that cite evidence from the videos to support teaching evaluation such as student responses or behaviors in the classroom resulting from the instruction, environment, and so forth. Both the reviewer and the observed benefit from scoring and being scored while citing functional criteria in videos as both parties reflect on practice.

Video portfolio commentary featured callouts of practice deemed noteworthy by research assistants that had corresponding times in footage, which were later rated 1 (basic) through 5 (masterful) [30]. Each callout was categorized in a hierarchical model the investigators developed. Top-level criteria were: pedagogy, climate, mathematical thinking, and classroom management. At the next level, 18 aspects of teaching fell under these criteria, listed in the Appendix (pp. 291-293). Pairing of scorers was used for consistency in ratings. In analysis for consistency among scorers, “...scorers may have been applying a theoretical

standard of ‘best practice’ to the observed actions of the teacher, rather than evaluating how functions of teaching are being accomplished within the class as a whole”. There was a significant difference in scorers’ scores in the criteria when examining scorer professional demographics as educational research-oriented individuals versus teachers. An important caveat is that the demographics of individuals categorized as educational researchers were graduate researchers, thus may not have the combination of research AND teaching practice that full-time academic faculty may have. Think-aloud monitoring of scorers showed some deviation from the intended approach to scoring for which scorers had been trained, collecting and recording data supporting each criterion then assessing based on collection. Participation in assessment of practice via video taping showed increases in teaching reflection and awareness of changes in practice in their classrooms. Results also showed that reliability in scoring and consistency in language of practice can be maintained through social moderation.

Kavas and Ozdener [31] used an online version of a teaching practice assessment form to gauge pre-service teachers on the criteria of content knowledge, teaching, assessment and communication skills. Wu and Kao [32] used asynchronous, video-annotated streaming video review of teaching for pre-service teachers in Taiwan, featuring ratings in 10 areas (objectives, contents, examples, inspiring learning, organization, provoking thinking, awareness of students, wording, incident handling, and time management) and accompanying comments. The observed were required to reply to peer comments to promote reflection on practice. Pre-service teachers’ attitudes were overwhelmingly positive about the feedback system. Reviews averaged 7.6 comments each per teacher, with two-thirds commenting with a timestamp pertaining to a particular event in the video. The greatest number of comments (35%) pertained to interactions with students. Miyata’s [33] approach to streaming on-demand video also encouraged self-reflection. Pre-service teachers rate themselves on similar aspects as literature already discussed, then have conferences with mentors to evaluate and stimulate their self-reflection.

III. VAPR PROCESS

The video-annotated peer review (VAPR) process was developed to support the diffusion of research-based instructional practices and create a formative feedback process that will serve to enhance faculty development and teaching improvement. The process was crafted using the guidelines specified by Chism [34] for peer review and video-based cases for faculty development by Marx, Blumenfeld, Krajcik, and Soloway [35]. This process of peer review was determined to enhance diffusion of research-based practices given the shared classroom experience of the reviewers and instructors and the shared critical evaluation of those experiences [36].

The VAPR process requires faculty to select which of their class sessions to record for peer review. The videos are then reviewed using software capable of video annotation. The video annotation software reads and displays the video file and stores any comments or tags created by the reviewer in the annotation file at specific time-stamps.

The sessions are first recorded using a high definition digital recorder. After the class session is recorded, the instructor is given the video file and is asked to reflect and summarize the perceived execution of the course. The instructor creates the annotation file, linked to the video file, and uploads the pre-observation summary and pre-reflection as the first comment (associated to timestamp 00:00). This initiation of video-annotated commentary by the observed faculty allows the instructor to consider the course goals and learning objectives while situating the reviewer in the context of the class. The pre-observation summary also provides the reviewers an opportunity to familiarize themselves with the course outcomes, concerns, and rationale for pedagogical techniques.

The instructor then shares the files with a representative from the local Center for Teaching and Learning Excellence and two other faculty to review the video. The reviewers may pause the video and insert their comments at the appropriate timestamp. This comment-video timestamp association alleviates decontextualized statements. The review of the video by two faculty provides an opportunity for the sharing of practices and the reviews thereof to engage in social reflexivity that will support the reflection of their own instructional practice [2].

To aid in the review process, the reviewers are provided a table of attributes that was defined to comprise effective teaching by a university committee. This table provides several examples for each main attribute, of which there are five (Table I). The simplicity of the form is similar to the evaluation form suggested by Felder and Brent [28]; it also reflects many common attributes that have been deemed important and shown to have direct impact on student learning [34].

The table of attributes, adapted from the model described by Bergquist and Phillips [37] illustrated by Keig and Waggoner [5], guides the reviewers to provide feedback on the instructor’s organization, knowledge of subject matter, clarity and pace, atmosphere of the classroom, and professionalism. It is void of numerical ratings and lacks an emphasis on summative evaluations to encourage participants to share an open and honest exchange of thoughts and feedback, without fear of a potentially negative impact on their promotion and tenure [38].

Finally, the subject of the review watches their own video and annotated comments provided by the reviewers at the specified timestamps, and is asked to create a post-observation reflection summary that provides them the opportunity to reflect on the intent of the class and how their peers perceived the class session and use of pedagogical techniques. The process is then repeated with different faculty reviewers, with the intention of changing and sharing practice.

TABLE I. PEER REVIEW ATTRIBUTES GUIDE

Instructor's Organization (<i>The instructor...</i>) <ul style="list-style-type: none"> presented the material in an effective, organized manner. presented the material at an appropriate level for the course and students. provided clear, concise examples and visual aids to clarify the material. used technology, to improve course delivery or facilitate activities.
Instructor's Knowledge of Subject Matter (<i>The instructor...</i>) <ul style="list-style-type: none"> illustrated command of the subject matter. presented material that was important and current.
Clarity and Pace of Instruction (<i>The instructor...</i>) <ul style="list-style-type: none"> defined new terms or concepts. elaborated or repeated complex information. made explicit statements drawing student attention to certain ideas. spoke in a voice in an audible voice with clear enunciation. avoided distracting mannerisms. spoke at a pace that allowed students to take notes, if applicable (PowerPoint or notes may be available) paused during explanations and after asking questions. provided explicit directions for assignments.
Instructional Atmosphere (<i>The instructor...</i>) <ul style="list-style-type: none"> conveyed enthusiasm for the subject and appeared engaged in the instruction. conducted the class so that students felt comfortable to ask questions. varied the tone and pitch of voice for emphasis and interest.
Instructor's Professionalism (<i>The instructor...</i>) <ul style="list-style-type: none"> arrived to class on time. answered questions respectfully, avoiding condescension, treating students with respect. dressed in a professional manner commensurate with the subject matter profession. appeared confident, demonstrated command of the classroom

IV. PROBLEM STATEMENT & RESEARCH QUESTIONS

The purpose of this study is to examine the trends of faculty peer comments generated throughout VAPR with respect to characteristic attributes of teaching and Shulman's types of teacher knowledge. Specifically, this study seeks to explore the following research questions:

- 1) *How does familiarity with course content, context, and purpose being reviewed relate to the comments made throughout the video feedback?*
- 2) *How does educational and professional background relate to the comments made throughout the video feedback?*
- 3) *What are the prominent faculty professional and educational demographics that relate to the type of feedback provided?*

V. METHODOLOGY

This study employs an exploratory quantitative analysis to classify the peer-review comments annotated during the first implementation of a peer review process. The review followed the standard implementation of the VAPR process in the Spring 2014 semester with observation, selection, and recording a class session, providing a pre-observation

reflection, review by the institution's Center for Teaching and Learning Excellence, review by two consecutive faculty, followed by completion of a post-observation analysis.

A. Participants

Nine faculty, within the same engineering department, all participated in VAPR for the first time acting as both observed on one session and reviewing participants on two of the other eight observations. The course covered first-year through junior level course work including: introduction to engineering design, introduction to programming, graphical communications, fluids, and advanced modeling. These courses varied in time from a one to two hour duration for the observation commitment. The participants classified these courses as being representative of a typical class session without any anomalies, quizzes, or tests.

Participants were comprised of both tenure-track and non-tenure track faculty at academic ranks ranging from instructor to associate professor. Non-tenure track faculty are primarily responsible for teaching 12-15 credits per semester while tenured and tenure-track faculty are to teach 8-9 credits per semester while also being involved in research, which includes engineering education research. Participants' full time teaching experience ranged from 3 to 14 years with an average of 9 years.

B. Data Collection

Following the review process, each of the nine observations included a peer-generated video annotation text file that was imported into Excel. Each entry was categorized for the type of feedback given, encompassing characterizations such as: suggestions or identification of good practices, attributes of the instruction from Table I (instructor's organization, knowledge of subject matter, clarity and pace, atmosphere of the classroom, and professionalism), and Shulman's seven types of teacher knowledge.

Shulman's categories of teacher knowledge include subject matter knowledge, pedagogical knowledge, pedagogical content knowledge, curricular knowledge, knowledge of the learners, knowledge of educational context, and knowledge of educational ends, purposes, and values [11]. Subject matter knowledge, also referred to as content knowledge, is related to the depth and breadth of knowledge that a faculty member has with respect to the topic that faculty member is teaching. Pedagogical knowledge pertains to basic principles of class management and organization of materials, often learned through propositions and case knowledge [11, 39]. Pedagogical content knowledge combines the subject matter knowledge with appropriate pedagogical knowledge to advance understanding in that area. Pedagogical content knowledge reflects what experts know about how subjects can be taught effectively, what misconceptions are likely to arise, and how to help students achieve the specific learning goals of the domain [11]. Knowledge of the educational context define the teacher's understanding of the classroom and the physical limitations and accessibility of the classroom, whereas knowledge of the curriculum represents the broader understanding of the course outcomes, assignments, and access to books and other resources. Knowledge of the learner reflects the faculty's

conceptions of the students' cognitive and affective characteristics that include prior requisite knowledge and motivation. Knowledge of educational ends, purposes, and values refers to the degree to which teachers align with the purpose of their course and how it fits into the overall curriculum.

The peer authors' backgrounds of corresponding annotations are also classified as familiarity (having taught the course in the past or not) and experience (taken a similar course as a student or not, tenure or non-tenure track, years of academic career experience, and highest degree attained).

TABLE II. CHI-SQUARE ANALYSIS CATEGORIES

Categories	Groups
Attributes	Familiarity
Instructor's Organization (<i>IO</i>)	(Yes, No)
Knowledge of Subject Matter (<i>KoSM</i>)	Course Taken
Clarity and Pace (<i>C&P</i>)	(Yes, No)
Classroom Atmosphere (<i>CA</i>)	Highest Degree
Professionalism (<i>P</i>)	(MS, PhD)
	Years Experience
	(Low, Mid, High)
Teacher Knowledge	
Subject Matter Knowledge (<i>SMK</i>)	
Pedagogical Knowledge (<i>PK</i>)	
Pedagogical Content Knowledge (<i>PCK</i>)	
Curricular Knowledge (<i>CK</i>)	
Knowledge of the Learners (<i>KoL</i>)	
Knowledge of Educational Context (<i>KoC</i>)	
Knowledge of Educational Ends, Purposes, and Values (<i>KoEPIV</i>)	

C. Data Analysis

The data were primarily analyzed through descriptive statistics to determine the frequency of types of comments made and the relative percentage of comments that fit into each category based on the faculty demographics.

A Pearson chi-squared analysis was also conducted to determine if there is a statistically significant association between the types of peer review comments and faculty demographics. The chi-square test was run for each comparison of categories and groups listed in Table II.

VI. FINDINGS

Through a comparison of relative percentages of comments (Table III), when categorizing for attributes of the instruction 52% of the comments were related to clarity and pace with 35% focusing on the classroom atmosphere. When looking at these comments, it appears that clarity and pace were identified as separate categories. Those commenting on clarity frequently identified good practices or suggestions with respect to making sure that the students understood the content of the course. They often made suggestions for alternative forms of instruction that included on-line videos and physical demonstrations of the problems that related the intent of the

course back to real-world applications. In comparison, comments addressing pace were focused on maintaining involvement in the class and ensuring that students were keeping up with the structure of the class. This included, but was not limited to, providing time for students to think about a problem when asked before requesting an answer and providing them additional time to work out in-class problems. These types of comments were aligned with notes when the same student was answering the questions. In classes with a computer lab format, several comments drew attention to keeping the students at the same step as the instructor.

TABLE III. FREQUENCY OF COMMENT TYPES FOR INSTRUCTIONAL ATTRIBUTES

Attribute of Teaching	
Instructor's Organization	6%
Subject Matter	0%
Clarity & Pace	52%
Classroom Atmosphere	35%
Professionalism	7%
Teacher Knowledge	
Subject Matter Knowledge (<i>SMK</i>)	8%
Pedagogical Knowledge (<i>PK</i>)	43%
Pedagogical Content Knowledge (<i>PCK</i>)	21%
Curricular Knowledge (<i>CK</i>)	0%
Knowledge of the Learners (<i>KoL</i>)	6%
Knowledge of Educational Context (<i>KoC</i>)	16%
Knowledge of Educational Ends, Purposes, Value (<i>KoEPV</i>)	6%

Comments pertaining to instructional atmosphere were directly related to ensuring an optimal learning environment with high participation. Comments of this category included providing suggestions for where to stand during the lecture, encouraging faculty to move away from the podium, and phrasing of statements that may deter or decrease student self-efficacy. For example:

"Be careful about 'so that's easy'. Yes, it should be easy, but if somebody is struggling to understand what you did (and as quick as that was, it could be many students), you don't want to turn them off to the rest of the material because you said 'well this is easy'."

When examining the distribution of comments categorized by type of teacher knowledge, the highest was focused on pedagogical knowledge at 43% of annotations, followed by 21% for pedagogical content knowledge, and 16% for knowledge of the educational context. Pedagogical knowledge comments were represented in the form of what Shulman [39] classifies as principles, maxims, and norms. Principles typically derive from empirical research about practices. In these instances, one common principle that was referenced by several participants addressed the use of peer instruction through polling students in class. A maxim provides practical

claims, such as involving humor in class, offering insight into when questions should be asked, and the structure of the classroom. One example of this involves a recommendation about encouraging student participation:

“What about making students who are working on specific problems sit near each other. This way if they have common questions they can all listen in. This will also incorporate a small level of cooperative learning.”

“You might consider taking a break or giving students something to work on or answer every 15-30 minutes.”

Fewer pedagogical knowledge comments were focused on norms, which express a philosophy or value with respect to teaching. Several of these comments addressed the role of the student in higher education and that the instruction should make the student ask and answer why, rather than blindly receiving the knowledge.

Pedagogical content knowledge comments pertained to the specific instruction techniques related to the topic being addressed. Many of these pedagogical content knowledge comments offered suggestions to the practice, rather than identification of good practices, by adding specific examples to the demonstrations of the phenomenon or practice as seen below:

“Mixture of lecture and questions posed to students on section views, general purpose, different types, and nuances between 6 common types of sections views and their construction -- could spend a bit more time on applications unless covered later (why one type vs. another type could apply) and also infuse some real world everyday examples (apples, engine cutaways at a science and technology museum for children, swiss cheese - what part of slice you hatch vs. don't hatch, etc.).”

Other pedagogical content knowledge comments addressed the ordering of topics to offer clarifications to student understanding. Without an in-depth understanding of the subject matter and an understanding of the students many of these comments would not have been possible.

As noted by Bingham and Ottewill [12] and Cole [13] there exists the potential for reviewers to be either too congratulatory or too critical, either of which have the potential to decrease the effectiveness of the peer review. In this single case 29% of the comments offered suggestions, 66% identified a good practice, and the remaining 5% of comments identified a good practice, but then built on the practice by providing an additional suggestion on the pedagogical implementation.

A. Comparison of Faculty Demographics and Peer Review Comments

The chi-square analysis of dependence identified that there was no statistically significant identification that the number of comments made was related to the groupings identified in Table III. The only values close to significance was familiarity teaching the course and experience as a student in the course.

Since the chi-square failed to identify any statistical significance between the categories and dependency on the grouping, descriptive statistics have been used to explore

general trends between the two groups for both the frequency of teaching attribute comments and teacher knowledge comments (Tables IV and V). The largest variance in frequency of comments among the teaching attributes occurred with the respect to the differences in highest degree and tenure status, where a higher percentage (9%) of comments on clarity and pace came from faculty with a Master's degree and non-tenure track. In comparison there was a variation of 8% between the same groups when looking at classroom atmosphere. In this category of comments, 8-9% more comments came from faculty holding a PhD and those that were tenure track.

TABLE IV. PERCENTAGE OF TEACHER ATTRIBUTE COMMENTS BY GROUP

	Teaching Attribute				
	IO	KoSM	C&P	CA	P
Familiarity					
<i>Taught</i>	7%	1%	51%	36%	6%
<i>Not Taught</i>	5%	0%	57%	32%	7%
Experience					
Student	6%	1%	54%	35%	5%
Not Student	8%	0%	50%	35%	8%
Highest Degree					
<i>MS</i>	7%	0%	58%	29%	6%
<i>PhD</i>	6%	1%	49%	38%	7%

When examining the descriptive differences between groups with respect to the teacher knowledge comments, there is a larger difference for familiarity with respect to the frequency of pedagogical knowledge comments and pedagogical content knowledge comments. In comparison all other grouping and categories had an absolute difference of 7% or less with an average difference of 2.5%. In this scenario, faculty who taught the course previously offered 12% more pedagogical content knowledge comments than those who never taught the course. In comparison, those who had never taught the course made 15% more pedagogical knowledge comments.

TABLE V. PERCENTAGE OF TEACHER KNOWLEDGE COMMENTS BY GROUP

	Teacher Knowledge						
	SMK	PK	PCK	CK	KoC	KoL	KoEPV
Familiarity							
<i>Taught</i>	9%	39%	25%	0%	5%	17%	5%
<i>Not Taught</i>	7%	54%	13%	0%	3%	15%	8%
Experience							
Student	9%	42%	22%	0%	5%	18%	5%
Not Student	8%	46%	19%	0%	4%	13%	10%
Degree							
<i>MS</i>	6%	48%	21%	0%	3%	15%	7%
<i>PhD</i>	9%	40%	21%	0%	7%	17%	5%

VII. CONCLUSIONS AND DISCUSSION

The approach to evaluating peer review comments discussed here represents a cursory examination of general comments made in one implementation of the review. It comes

as no surprise that a majority of comments were related to the direct instruction occurring in the class. Due to the limitations of the peer-review system, faculty are significantly removed from the immediate atmosphere of the classroom creating the potential for unfamiliarity with the course context. The guiding parameters of the peer-review, in this study the prescribed Table of Attributes, may also provide a significant impact on the characterization of comments being made. Therefore, adoption of peer-review can be tailored to the community of practice to yield the desired results of pedagogical change.

The findings from this study begin to provide insight into the design of the faculty community involved in the peer-review process. Since familiarity with the course has more of a relationship to the types of comments made rather than any of the other groupings explored, faculty have the opportunity to diffuse more content-specific instructional techniques. However, the inclusion of reviewers unfamiliar with a course being reviewed has the potential to diffuse general pedagogical techniques from other disciplines and course contexts. This illustrates the need for a mixed-approach when formulating faculty groups to engage in the peer-review.

While this study observed a high percentage of positive comments in comparison to suggestions for instructional improvement, this is not a result of self-congratulatory practice among the participants. Upon closer examination of the comments, it appears that the positive comments reflect an affirmation of cultural norms to teaching practices utilized by the community of practice. An excessive amount of negative comments and suggestions has the potential to disengage participants in the community to change their practice, while the positive comments can reinforce practices valued by the community involved in the peer-review. Therefore VAPR has the potential to establish cultural norms of teaching within a community thus enhancing the inclusion of innovative and evidence-based instructional techniques provided they are valued by the community. Additional work will explore this cultural norm of teaching approaches within a community of practice and how categorizations of peer-review comments change over time.

ACKNOWLEDGMENT

The authors would like to gratefully acknowledge the National Science Foundation for their support of this work under the TUES I program (NSF # 1244852). Abstract—Research on nontraditional students in engineering is sparse. We use longitudinal data from eleven public, research universities in the United States to investigate nontraditional (NTS) and traditional (TRS) students who ever declared engineering as a major. Nontraditional students could help fill the national call for more science, technology, engineering, and mathematics (STEM) degrees in the United States. The researchers focus specifically on engineering students because it has been found that they are different from the other disciplines under the STEM umbrella. The research questions addressed in this paper were: Is the peer socioeconomic status different for nontraditional students compared to traditional students? What choices are nontraditional students making for their major, and are these different from or the same as those made by traditional students? Is the pathway different for nontraditional students compared to traditional students? This paper shows that socioeconomic status of nontraditional students in engineering is lower than traditional students in engineering. We show some different choices that nontraditional students make for their engineering major. This research also shows that nontraditional students who start in engineering are less likely to switch to and graduate in other majors than traditional students—non-traditional outcomes are more binary, resulting in either graduation in engineering or leaving the university without a degree, so non-traditional students lead traditional students in both of those outcomes.

Keywords—nontraditional; socioeconomic status; pathway

I. INTRODUCTION

This study focused on pathway, choice of major and socioeconomic status of nontraditional students compared to traditional students in undergraduate engineering majors. There are misperceptions about what engineering is within the United States that is preventing students from majoring in it. Many institutions are having a hard time recruiting and graduating enough engineers to meet the demand. Nontraditional students could be an avenue to fill this unmet demand.

Higher education has the challenge of educating students, controlling costs, and maintaining equity. The issues of equal access, retention, and degree completion have not gone away partly due to the escalating costs in higher education. Higher education has shifted their financial aid policies towards self-

help aid from gift aid, regardless of students' financial need. This change in policy makes it harder for low socioeconomic students to attend college.

This paper was focused on understanding nontraditional students' pathways for degree completion, what choices are they making for a degree, and whether their socioeconomic status plays a role in their decision to stay. We used quantitative data in this study to see large overarching patterns in many different institutions.

There is not much data on nontraditional students in engineering. This study explored pathways, choice in major and socioeconomic status to gain a better understanding of nontraditional students in engineering.

A. Defining a “nontraditional” student

There are numerous ways to define a student as “nontraditional” because a “traditional” student definition is defined by attending a 4-year university in the fall preceding high school graduation. They are not married nor have any dependents, attending part-time, working a full-time job while enrolled, and are not financially independent [1]. Some researchers have defined commuter students as nontraditional because they do not live on campus and therefore have a different college experience because they are living off campus [2, 3]. A nontraditional student is one who follows a path that is different in one or more ways from the traditional path.

The National Center for Educational Statistics (NCES) has shown that public, four-year institutions have 43% of their students are traditional, and the other 57% have at least one or more characteristics that would define them as nontraditional [1]. MIDFIELD is comprised of public, four year institutions from which the data for this study comes from. These institutions have 20% of their students with one nontraditional characteristic, 23% have between two and three, 14% have at least four [1]. It has been shown that the more nontraditional characteristics then the more likely chance of the student leaving higher education institutions [1]. It is common for researchers to use age as a determining factor for nontraditional students, specifically being over the age of 24 [1, 4, 5, 6, 7, 8, 9, 10]. The researchers in this study use being over the age of 24 as the determining characteristic for being nontraditional.

This material is based upon work supported by the National Science Foundation (NSF) under Grant 1361058.

MIDFIELD does not have access to other data to be able to use other nontraditional characteristics to analyze. We are currently working on expanding the database to be able to look at different aspects of nontraditional students.

B. Why Peer Economic Status?

The NCES has shown that if students have more nontraditional attributes, then they are less likely to graduate [1]. For students that are already considered nontraditional by age, does their socioeconomic status set them apart even more? Other research has shown that lower socioeconomic status can be an even bigger factor for student attrition in higher education [11].

Higher education costs are escalating every year, and many institutions are raising the cost of tuition to help manage their school's budget [12]. It was found that students with the highest departure rates within science, engineering, or mathematics (SEM) majors had financial need or were underrepresented minorities [12]. One-third of students with financial need leave the institution after one year of college. This study also showed that male students in SEM received a larger proportion of gift aid than non-SEM majors and all females [12].

Tones, Fraser, Elder, and White researched the support services for low socioeconomic mature-aged students in Australia. They found that mature-aged students had additional barriers in higher education including disabilities, commuting issues, and family and friends did not value educational goals [13]. It was reported that low socioeconomic mature-age students had limited resources of financial assets, health, study skills, and a home computer. They used the financial assistance department more often, and used the counseling services less often than middle and higher socioeconomic students.

MIDFIELD researchers have Peer Economic Status (PES) which uses high school free lunch eligibility as a proxy for the economic conditions of the high school a student attended before enrolling in the university [11]. PES is defined as 100 percent less the free-lunch percentage of a student's high school so that a school with a higher PES has a lower fraction of students eligible for free lunch and likely better resources. Orr, Ramirez, Ohland, and Lundy-Wagner researched the variables in MIDFIELD for students' free lunch participation in their high schools prior to attendance at the university and found that school level variable is a better predictor than district-level variables for six-year degree completion [14]. Engineering degrees have hope for lower socioeconomic status students to have steady income and stable job prospects, and this research informs the community of how well or not-so-well, this information is reaching lower socioeconomic students and whether they are choosing engineering degrees.

Privacy laws make it nearly impossible to find out individual's financial information. Thus, researchers are using other means, such as first-generation status, parent education level, parent occupation, parent income level, or Federal Pell grant eligibility [14]. Unfortunately, MIDFIELD does not have any of those variables, which is why there was the creation of the PES variable. PES does not measure an individual's level of poverty, but the abundance of poverty at high schools.

School-level poverty is correlated with individual-level poverty, academic achievement, postsecondary matriculation, and school resources [14].

Understanding the socioeconomic background of nontraditional students that pursue engineering degrees will help all the stakeholders have more relevant understanding for increasing nontraditional enrollment in engineering degree programs.

II. METHODS

A. The MIDFIELD Database and its Characteristics

This research utilizes Multiple-Institution Database for Investigating Engineering Longitudinal Development (MIDFIELD), which consists of a dataset with 1,014,984 students, whereas 210,736 of those students ever declared engineering as a major, at eleven U.S. institutions with nine of these in the Southeastern U.S [15]. One-tenth of the engineering degrees awarded in the United States were by MIDFIELD institutions. MIDFIELD includes seven of the 50 largest U.S. engineering institutions by engineering enrollment (institutions in which over 20 percent of students major in engineering, versus the nine percent national average) [16]. MIDFIELD was designed to have engineering students overrepresented. Results from this research are anticipated to generalize to the same type of institutions, which are large public universities with above average enrollment of engineering students, and therefore are relevant to institutions producing most engineering graduates nationally. Since this dataset includes whole population data, statistical inference is unnecessary—all reported differences are true differences for the institutions and subpopulations studied for the time period.

B. The Population Studied in This Work

Of the total MIDFIELD population, this work focuses on the 141,125 students who ever declared engineering as a major and have sufficient data in MIDFIELD to calculate six-year graduation rates. Nontraditional students (NTS) make up 3.2% (4,500) of the group studied. In this paper, nontraditional students are defined as students who have surpassed their 24th birthday at first matriculation to the institution. Traditional students (TRS) are defined as being younger than 24 at first matriculation. In this paper, graduation is defined as having graduated by the sixth year from matriculation, following a standard of reporting by the Integrated Postsecondary Education Data System (IPEDS) [17].

III. RESULTS AND DISCUSSION

Table I shows the terms and definitions that are used throughout the rest of the paper. These definitions separate the majors that are offered at the institutions that were used in this study. The researchers generalized the majors into groups of majors because there were too many different majors to be able to get any useful results when looking at each major from each university.

This study compared each grouping of majors of traditional and nontraditional students.

TABLE I: DEFINITIONS OF TERMS USED IN ANALYSES

Term	Definition
A&H	Arts and Humanities
AGR	Agriculture
BUS	Business; Economics, Management, Marketing and Related Support
CON	Continuing (enrolled, but not graduated at the sixth year)
ENG	Engineering
HSI	Health Sciences
ITD	Interdisciplinary
ONS	Other Non-Science
S&M	Science and Mathematics
SOC	Social Sciences
TEC	Technology
TOLEDO	Trajectory of Leaving Education, Destination Obscure. Used to describe a student who no longer appears in the database, but never received a degree.

A. Where are nontraditional students after six years?

Table II shows the sixth-year destination for nontraditional and traditional students. All of these students had engineering as their major at one point during their undergraduate experience. Nontraditional students are more likely to graduate in engineering, but they are also more likely to leave the institution (TOLEDO) than traditional students. Thus, nontraditional students were less likely to switch to non-engineering majors and they were less likely to still be enrolled at the sixth year (CON). The higher incidence of TOLEDO as a destination for nontraditional students may indicate that they have stopped out of education for a while, transferred to another school, or dropped out of higher education for good—the MIDFIELD dataset cannot distinguish among these pathways. While this finding generates hypotheses, further research is needed to explain why nontraditional students are less likely to switch to non-engineering majors.

Students that choose engineering as a major at some point in their college career have good chance to graduate with an engineering degree, NTS had 43.5 percent and TRS had 41.8 percent graduation in six years. This means that nontraditional (NTS) students have a higher rate of graduating with an engineering degree within 6 years than traditional students. Both NTS and TRS have the same overall pattern of choice of major, as shown in Table II, where neither group chooses interdisciplinary or health sciences at a high rate, but both groups have a higher rate in science and mathematics degrees. NTS did not go into mathematics or science, business, technology, or social sciences degrees as often as TRS. NTS do not see these other degrees as alternatives to an engineering degree as much as TRS. NTS chooses other non-science degrees, agriculture, interdisciplinary, or health sciences almost never.

TABLE II. SIX-YEAR OUTCOME FOR NONTRADITIONAL AND TRADITIONAL STUDENTS STARTING IN ENGINEERING.

Major	Six-year Outcomes		
	NTS	TRS	Total
ENG	43.5%	41.8%	41.8%
S&M	3.6%	4.9%	4.8%
BUS	0.6%	3.4%	3.3%
TEC	0.2%	1.6%	1.5%
SOC	0.4%	1.1%	1.1%
A&H	0.6%	0.8%	0.8%
ONS	0.2%	0.8%	0.7%
AGR	0.2%	0.6%	0.6%
ITD	0.0%	0.4%	0.4%
HSI	0.0%	0.2%	0.2%
CON	9.1%	10.7%	10.7%
TOLEDO	41.6%	33.8%	34.2%

We broke down the choice in major into specific engineering majors in Table III. Table III shows that NTS are choosing different engineering majors compared to TRS. Nontraditional students are not choosing BIE, EOE, ISE, TXE by over half compared to traditional students choosing that same major.

TABLE III: NONTRADITIONAL AND TRADITIONAL STUDENTS' CHOICES OF ENGINEERING MAJORS THAT GRADUATED.

Graduate Group		Engineering Choices	
		NTS	TRS
MCE	Mechanical	21.3%	20.0%
ELE	Electrical	28.5%	17.1%
CVE	Civil	16.7%	13.6%
ISE	Industrial/Systems	4.2%	10.6%
CHE	Chemical	7.6%	9.7%
CPE	Computer	8.5%	8.5%
ASE	Aerospace	3.5%	6.7%
EGE	General	2.6%	3.3%
MTE	Materials	1.5%	2.3%
BIE	Bioengineering / Biomedical	0.7%	2.0%
EOE	Other Engineering	0.7%	2.0%
TXE	Textile	0.6%	1.4%
ARE	Architectural	1.2%	1.0%
ESE	Engineering Science and Mechanics	0.3%	0.6%
NCE	Nuclear	0.5%	0.5%

Nontraditional students are choosing CVE, ELE, MCE more than traditional students, although they are the top choices for both groups, TRS students are choosing other engineering majors at a higher rate than NTS. The majors that nontraditional students are choosing are more widely known as traditional engineering than the other more nontraditional engineering majors. It may be that the nontraditional students are choosing ‘safe’ degrees that they have heard of and know other people with those degrees. They may feel that they cannot risk getting an engineering degree that is not as well known or may have more trouble getting a job.

B. Nontraditional student PES

First, we looked at nontraditional and traditional students by gender. The larger difference is between nontraditional and traditional students. Both female and male nontraditional students have lower PES than traditional students, but the effect size is not large, as shown in Table IV.

Nontraditional males have the lowest PES at 84.91, and traditional males have the highest at 88.7. Females are not the highest and lowest but have a spread of 2.83 PES percentage points.

In Table V, we show that the average PES of traditional and nontraditional students by institution. MIDFIELD institutions are comprised of large, public research institutions mostly in the southeastern U.S. but there is a variety of different average PES values for traditional and nontraditional students. Table V shows that traditional students have a higher PES across all institutions except nontraditional females at institution F. TRS males have the highest PES scores at each institution. Traditional female students consistently have a slightly lower PES than traditional male students, but higher than both male and female NTS. There are two institutions, C and D, where NTS females have the lowest PES value, but all the other institutions lowest PES values with NTS males.

Students that come from high schools with fewer resources are bringing in more diversity than their nontraditional status. These students are consistently showing a lower PES than traditional students. Nontraditional students are, on average, from a lower socioeconomic background, and have more barriers to graduating associated with low socioeconomic status.

Table VI shows the PES for students with various sixth-year outcomes. There is some evidence that economic factors play a role in students leaving the institution, since students at TOLEDO have a lower average PES. TOL (TOLEDO) PES for nontraditional and traditional students is 84.46 and 87.46. Among those students who switch majors, PES does not seem to be a factor, since engineering has an average PES of the disciplines shown, and students switch into majors with both lower and higher PES averages.

TABLE IV: AVERAGE PES FOR NONTRADITIONAL AND TRADITIONAL STUDENTS BY GENDER.

Type of Student	Average PES	
	Female	Male
NTS	84.95	84.91
TRS	87.78	88.7

TABLE V: AVERAGE PES BY INSTITUTION AND GENDER

Institution	TRS		NTS	
	Female	Male	Female	Male
A	89.77	90.46	86.65	85.38
B	91.56	91.73	87.18	86.21
C	86.74	87.79	85.06	86.57
D	90.51	90.99	86.24	88.02
E	86.41	86.64	83.65	83.46
F	87.31	87.89	96.61	85.65
G	81.49	82.08	XX	72.37

TABLE VI: PES OF NONTRADITIONAL AND TRADITIONAL STUDENTS WITH VARIOUS SIXTH-YEAR OUTCOMES.

Major	Average PES	
	NTS	TRS
HSI	96.14	87.18
ONS	90.61	90.37
TEC	88.82	90.33
BUS	88.68	89.44
S&M	87.73	90.59
ENG	85.74	89.91
AGR	84.52	87.63
TOL	84.46	87.46
CON	82.07	86.53
SOC	80.2	88.84
A&H	76.75	88.92
ITD	XX	90.85

In Table VI, HSI for nontraditional students had the highest PES overall. ONS was the only other major that nontraditional students have a higher PES than traditional students and this was the major where the students were the most similar. A&H was the lowest PES for nontraditional students. The lowest PES for traditional students was CON at 86.53. Traditional students have a higher PES in ENG than nontraditional students, 89.91 vs. 85.74. Nontraditional students have a high graduation rate that suggests that they

have more circumstances that they overcome, although the effect size is not large, which they may make up for with maturity and determination.

IV. CONCLUSIONS

This research focused on nontraditional students pathways, choice of major, and peer economic status because these all matter in the success of nontraditional students graduating with engineering degrees. The results from this work show that nontraditional students enrolling in engineering are more likely than traditional students to graduate in engineering, but are also more likely to leave the institution without a degree. Both might be explained by a higher level of commitment to the engineering degree—empowering a higher graduation rate, but leaving those students blind to other options where they might change majors and graduate. It may also be that if nontraditional students cannot complete the engineering degree, they do not have the resources (financial, time, etc.) to change majors and continue. There is some support for the latter conclusion in studying economic indicators from the PES values at high schools that students attended.

Nontraditional students are more likely to choose and graduate in mainstream engineering majors such as civil, electrical, and mechanical while avoiding more specialized engineering majors. This may be because they are less likely to have heard of those majors and are concerned about getting a job.

More research is needed to investigate how nontraditional students choose a major, their motivation to persist, their lack of interest in switching to non-engineering majors, and the impact of high school economic background on their educational experience. This work reveals some fundamental findings and generates valuable hypotheses for future research.

Culturally Situated Survey of Engineering Identity for Latina/o Undergraduates

Renata A. Revelo

Education Policy, Organization, and Leadership
University of Illinois at Urbana-Champaign
Urbana, IL
revelo@illinois.edu

Abstract—Measures of engineering identity have been designed for an aggregate group of engineering students leaving the ways that students of color develop their engineering identities unexplored. This work in progress paper presents a culturally situated survey of engineering identity for Latina/o undergraduates. The survey was built using data from 20 interviews and observations with engineering Latina/o students. This study took an asset-based approach through the use of the Community Cultural Wealth framework. The survey was administered to 75 students. Using the survey responses of 33 engineering identity items, exploratory factor analysis was performed to examine the structural validity of the survey.

Keywords—*engineering identity; Latinas/os; retention; underrepresentation*

I. INTRODUCTION

One way to address retention of undergraduates in engineering is through a study of engineering identity development. Research has shown that college students who identify as engineers are more likely to persist in engineering than those who do not identify as engineers [1], [2]. Current measures of engineering identity have been designed for an aggregate group of engineers [3], [4], [5] leaving the experiences of engineering students of color unexplored. Moreover, because these measures were not designed for students of color, they may not be culturally situated in the experiences of these students.

This study presents a culturally situated understanding of the way students of color develop an engineering identity in order to affirm, incorporate, and acknowledge students' cultures and cultural values. A study of engineering identity development for Latinas/os is warranted not only because such study has not been previously studied, but also because studies of identity development specific to students of color can help schools of engineering address retention in engineering. The purpose of this paper is to present the construction and validation of the survey of engineering identity development.

II. RESEARCH METHODS

The research question posed in this study was in what ways and to what extent does membership in the Society of Hispanic Professional Engineers (SHPE) influence the

engineering identity development of Latina/o students? This research question was answered using a two-phase mixed methods design. The mixed methods study was designed with a developmental purpose [6] – that is, with the goal of using the results from the first phase to develop the second phase. The first phase of the study [7] was composed of 20 semi-structured interviews with Latina/o undergraduates and observations. In the second phase of the study, I created and piloted a web survey of engineering identity using results from the first phase. Using the pilot survey data, I ran exploratory factor analysis to examine the structural validity of the survey. This paper focuses on the second phase of the study.

III. THEORETICAL FRAMEWORK

This study was guided by Yosso's Community Cultural Wealth (CCW) theoretical framework [8]. The CCW framework was created to study and acknowledge the wealth in the lived experience of students of color. This framework posits six forms of capital: aspirational, linguistic, familial, social, navigational, and resistant. Aspirational capital "refers to the ability to maintain hopes and dreams" even in the face of barriers. Linguistic capital "includes the intellectual and social skills attained through communication experiences in more than one language and/or style." Familial capital "refers to those cultural knowledges nurtured among *familia* (kin) that carry a sense of community history, memory and cultural intuition." Familial capital also "engages a commitment to community well being." Social capital refers to the "networks of people and community of resources." Navigational capital "refers to skills of maneuvering through social institutions." Resistant capital "refers those knowledges and skills fostered through oppositional behavior that challenges inequality." This framework enables researchers to identify and document wealth "to transform education and empower People of Color to utilize assets already abundant in their communities" (p. 89).

Through the use of the CCW framework, I investigated the Latina/o engineering student experience by focusing on the knowledges these students bring to their engineering programs and schools rather than focusing on deficiencies. Additionally, the use of CCW allowed me to explore the students' experiences and engineering identity development

from an asset-based framework.

IV. SURVEY DEVELOPMENT

Interviews with 20 Latina/o student members of SHPE and observation of events at a SHPE chapter and at the 2014 national SHPE conference revealed three new dimensions of engineering identity development [8]. These new dimensions were engineering role modeling, having a commitment to the community, and being part of an engineering *familia*. The results from the first phase of the larger study also confirmed the following, previously found dimensions of engineering identity: intrinsic and psychological motivation to pursue engineering [9], professional skills development [3], [9], [10], and leadership skills development [3], [10].

Using primarily the results from the first phase of this study, I constructed a survey that was situated in the experiences of Latina/o engineering undergraduates. The survey consisted of 48 questions including 33 items of engineering identity.

A. Survey Constructs

The survey constructs, developed using results from the first phase, were **commitment to community**, **developing as a professional**, **developing as a leader**, **engineering role modeling**, and **having an engineering familia**. **Commitment to community** referred to the students' ties to the local (university) and home community via outreach and service. **Developing as a professional** referred to students' gaining non-technical professional skills through local, regional, and national SHPE workshops. Similarly, **developing as a leader** referred to students' gaining leadership skills through local, regional, and national SHPE workshops and by serving in SHPE committees and SHPE executive boards. **Engineering role modeling** referred to having a Latina/o engineering role model and being an engineering role model to other Latina/o students. Finally, **having an engineering familia** referred to the family-like support that students provided and received within SHPE. In addition to these five survey constructs, the already-developed construct of intrinsic and psychological motivation [9] to study engineering was added to the survey. Though the interview protocol did not directly address motivation for studying engineering, aspects of intrinsic motivation to study engineering were present in the ways students talked about their engineering journeys in their interviews.

B. Survey Items

In total, there were 33 engineering identity items for the six survey constructs. For the motivation construct, I used 5 previously developed survey items to measure intrinsic and psychological motivation to pursue engineering [9].

For the remaining five survey constructs, I used the interview and observation data to develop items. For the **commitment to community** construct, there were 4 items including involvement in the community and STEM outreach. For the **developing as a professional** construct, there were 5 items including gains of non-technical professional skills, and participation in workshops to address professional skills. For

the **developing as a leader** construct, there were 5 items including ability to take on leadership roles and participation in workshops to address leadership skills. For the **engineering role modeling** construct, there were 8 items including the importance of being and having engineering role models and Latina/o engineering role models. Finally, for the **having an engineering familia** construct, there were 6 items including importance of having peer support from other Latina/o engineering students.

Guided by the goal of creating a culturally situated survey of engineering identity development for Latina and Latino students, I used participant language and specific experiences to create survey items. As examples of participant language, I used the terms *familia* and SHPE *familia*, instead of only asking about peers or support, to honor the terminology that students used in the interviews. As an example of specific experiences, to explore the construct of commitment to community, I asked about involvement with *noche de ciencias* ("science night" – an outreach science program for kids and parents) as a specific experiential example of commitment to community.

C. Survey Standards

After the survey items were constructed, I followed content, cognitive, and usability survey standards to minimize measurement error [11].

To address content standards, whether the survey items were asking what they were intended to ask, I sought feedback on the survey items from content area experts. Experts included two scholars in the fields of higher education and engineering education and potential survey takers. These experts were familiar with the content of the survey. Through this review process, I ensured that the survey items mapped to the constructs and that they were aligned with the overall research question.

To address usability and cognitive standards, I consulted with a survey expert to ensure the survey items were appropriate in wording, structure, and formatting. After the survey expert consultation, I made the following changes to the survey. First, I changed leading questions to balanced questions. Leading questions, such as some yes or no questions, are unbalanced and could lead to acquiescence bias [12]. Instead of asking the survey respondents, "Do you consider yourself an engineer?" with yes or no answer options, I asked them, "Which of these statements best describes you?" and provided item-specific response options. Second, instead of presenting a matrix of questions in one page, I opted for one question per page. When each page has only one question, survey respondents concentrate on each question at a time. Conversely, a matrix or grid of questions can overwhelm the survey respondent and cause survey breakoffs, item missing data, and respondent dissatisfaction [13]. Another reason for presenting one survey question at a time is that questions that are positioned higher up on the screen are rated more favorably than questions that are positioned at a lower location on the screen [13]. Third, I reworded and restructured agree/disagree questions. Agree/disagree scales have been shown to have more acquiescence bias from survey takers

because survey takers more often agree with the statement regardless of the question [14], [15], [16]. Finally, I used a unipolar scale (with four to five items) for maximum validity and reliability [17].

To address cognitive and content standards, I conducted two separate cognitive interviews with content area experts. These interviews helped to address the understanding of each survey item. The content area experts were undergraduate engineering students who were members of SHPE at the time of the cognitive interview. During the interview, I asked the content area experts to take the survey as if they had received it via email. After they took the survey, I asked the content area experts to do retrospective think-alouds [11] for every item. In a retrospective think-aloud, the respondent is asked a series of questions about how they answered the survey items. These questions probe about the cognitive process of answering a survey item. Through feedback from the retrospective think-aloud, a researcher can also optimize wording and formatting of the survey items. The content area experts provided wording and format changes to the survey. After the changes were made, I pilot tested the web survey with three more content area experts; they had minimal formatting changes.

D. Procedure and Participants

The final web survey consisted of 48 questions, which included the 33 engineering identity items, and demographic questions. On average, the survey took about 13 minutes to complete. The final survey was distributed using SurveyMonkey® to SHPE undergraduates who intended to graduate in 2015. A link to the survey was sent to 1,629 students via email. After two weeks, 105 people responded to the survey. After data cleaning, there were 75 cases that were used for exploratory factor analysis.

The gender breakdown for survey participants was 47% female, 52% male, and 1% who did not respond. About 77% of the participants were fourth or fifth year undergraduates. The majority of participants were non-transfer students (64%). They represented a range of engineering majors; the top five majors were mechanical engineering, civil engineering, aerospace engineering, chemical engineering, and industrial engineering. Almost all participants identified as Latina/o, Chicana/o, or Hispanic (92%), 8% of the participants identified as Latina/o, Chicano/o, or Hispanic sometimes, and one participant was unsure. With regard to ethnicity, the top four ethnic backgrounds that participants identified with were Mexican, Puerto Rican, Ecuadorian, and Colombian. Nineteen participants had family members, other than their parents or siblings, who were engineers. Eight of the participants knew engineers through their high school teachers. With regard to the highest level of a parent's education, 19% of the participants responded that the highest level of education for a parent was a High School Diploma or GED followed by a 16% for Bachelor's degree. With regard to SHPE, about 41% of the participants were involved with SHPE for 3-4 years. The majority (56%) were executive board members.

V. RESULTS AND DISCUSSION

A. Exploratory Factor Analysis

I ran Exploratory Factor Analysis (EFA) using R Studio with five factors retained. I chose Principal Axis Factoring (PAF) in order to maximize the variance extracted by the factors [18]. Practically, PAF was also chosen in order to examine the shared variance among variables in the dataset through a small number of factors [19]. Oblique rotation was chosen to rotate the factors for two reasons. First, inspection of the factor correlation matrix revealed that two factors were highly correlated (.76). Second, oblique rotation is recommended for social science research where factors are more likely to be correlated in practice [20]. I chose oblimin rotation to simplify the factor structure by minimizing cross products of loadings [18].

The final simple factor structure (shown in Table I) consisted of five factors and twenty-six items. The final five factors explained 57% of the variance in the data. Factor 1, motivation, consisted of five items and had a Cronbach's alpha reliability coefficient of $\alpha = 0.74$. Factor 2, community, consisted of five items and $\alpha = 0.77$. Factor 3, professional and leadership, consisted of nine items and $\alpha = 0.94$. Factor 4, role modeling, consisted of three items and $\alpha = 0.75$. Factor 5, engineering *familia*, consisted of four items and $\alpha = 0.85$. The final simple factor structure had a Cronbach's alpha reliability coefficient of $\alpha = 0.91$.

B. Item Reliability Analysis

All of the factors had acceptable reliability coefficients of 0.74 and above as shown in Table II.

TABLE II
DESCRIPTIVE STATISTICS FOR FACTORS

Factor	No. of items	Mean (SD)	Skew	Kurtosis	Alpha
Motivation	5	4.40 (0.46)	-0.50	-0.36	0.74
Community	5	4.42 (0.51)	-0.59	0.40	0.77
Professional & Leadership	9	3.89 (0.88)	-0.92	0.55	0.94
Role Modeling	3	4.31 (0.64)	-0.92	0.85	0.75
Engineering <i>Familia</i>	4	4.28 (0.72)	-0.75	-0.44	0.85

VI. IMPLICATIONS

This study proposed three new dimensions of engineering identity; namely, community, role modeling, and engineering *familia*. These dimensions encapsulate ways that Latina/o student members of SHPE identified and developed as engineers. The results from this study have at least three implications for schools of engineering. First, engineering courses can incorporate in the curriculum ways to foster and nurture these dimensions of engineering identity. For example, to foster the community dimension, students could have the option of working with a community organization on an engineering design project that meets a need for the organization. Second, engineering administrators can incorporate these dimensions in their programmatic retention efforts. For example, role modeling could be incorporated

organically into already-existing student development programs, such as first-year programs that have an engineering introductory course for student success. Third, one of the ways that schools of engineering could adapt these dimensions is by using the survey for evaluation and assessment of identity development of students. Using these results, schools of engineering can assess academic opportunities that may be available for students to develop as engineers.

VII. FUTURE WORK

We plan to build on this survey in at least three ways. First, to further address construct validity, future work will compare the measures of engineering identity examined in this survey with other measures of engineering identity. Second, we plan to distribute to a national sample of SHPE undergraduates. Using those results, we will investigate the relationships between identity development and student and university characteristics and context. For example, we will look at within group differences with regards to race, ethnic background, gender, type of institution, and first generation status. Finally, we plan on expanding on this survey to make it applicable to non-SHPE, Latina/o students.

ACKNOWLEDGMENTS

I would like to thank Dr. Michael Loui and Dr. Lorenzo Baber for their insights in developing this survey. Thank you Sowmya Anand and the Survey Research Laboratory at the University of Illinois at Urbana-Champaign who consulted with me on the survey format and structure.

TABLE I
ITEM AND FACTOR LOADINGS FOR FINAL FACTOR STRUCTURE

Survey Items	Factor 1 (Motivation)	Factor 2 (Community)	Factor 3 (Professional & Leadership)	Factor 4 (Role Modeling)	Factor 5 (Engineering <i>Familia</i>)
How good do you feel when you are doing engineering?	0.66				
How fun do you think engineering is?	0.71				
How interesting do you think engineering is?	0.71				
To what extent do you like to build stuff?	0.43				
To what extent do you like to figure out how things work?	0.35				
As an engineer, how important is giving back to the community through outreach such as Noche de Ciencias (Science Night)?		0.79			
How important are STEM outreach programs for kids?		0.38			
As an engineer, how important is being involved in your community to you?		0.71			
As an engineer, how committed are you to the well being of your community?		0.64			
In your journey as an engineer, how important is being an engineering role model to middle school and high school students?		0.36			
To what extent has your participation in SHPE helped you develop as a professional?			0.75		
To what extent have you acquired nontechnical, professional skills from SHPE that you need to become an engineer?			0.72		
To what extent have you attended SHPE workshops to learn about nontechnical, professional skills that you need to become an engineer?			0.74		
To what extent have you developed your nontechnical, professional skills through your SHPE involvement?			0.93		
To what extent has your participation in SHPE helped you develop communication skills to network with other professionals?			0.84		
To what extent has your participation in SHPE helped you develop as a leader?			0.91		
To what extent has your participation in SHPE helped you acquire leadership skills that you need to be an engineer?			0.86		
To what extent have you attended SHPE workshops to learn about leadership skills that you need to be an engineer?			0.76		
To what extent have you been able to take on leadership roles in SHPE that you need to be an engineer?			0.58		
In your journey as an engineer, how important is finding engineering role models within SHPE?				0.34	
In your journey as an engineer, how important is being able to find engineering role models?				0.77	
In your journey as an engineer, how important is having an engineer role model?				0.75	
How important is to have a SHPE <i>familia</i> (family) of engineers to you?					0.56
How important is having support from other Latina/o engineers to you?					0.99
To what extent do you feel like you are part of a <i>familia</i> (family) when you are around Latina and Latino engineers?					0.45
To what extent does seeing other Latina/o engineers succeed make you feel like you can succeed in engineering?				0.32	0.63

Note: loadings < 0.32 are suppressed

Summary— Online learning tools have allowed professors to carry out their classes in an interactive way, synchronic as well as asynchronic, giving them the opportunity to explore from different points of view specific themes or concepts, achieving greater dynamism in their classes through the active participation of students. This article presents the results of the implementation of a software tool for massive use designed with the objective of allowing Engineering students to strengthen their basic mathematical knowledge as well as to improve their results in courses such as Calculus I and Mathematics I. These courses are part of the first semesters of the syllabus for all undergraduate programs of the School of Engineering, and are basic courses in the formation of an engineer at Universidad EAFIT (Medellín, Colombia).

This software tool for massive use allows students to self-diagnose, to solve exercises with different levels of complexity and difficulty, to visualize academic contents such as video classes and virtual resources, and to know their evolution in the understanding of basic concepts in calculus. On one hand, this facilitates the beginning of their studies at the university. On the other, it gives the professor an initial diagnose of the level students have to start the course so that continuous analytics can be performed based on the learning process of the student.

Furthermore, this article shows the results of a comparative analysis done to two groups of students, a Control group and an Experimental group, that took Calculus I as part of their undergraduate studies. The experiment lasted two months with testing done at the beginning and at the end of the course. The objective was to register the level of knowledge acquired by the students and compare the differences between the two groups, control and experimental. The testing also allowed the progress of the student between tests to be measured, taking into account that the experimental group had the opportunity to explore the platform during this two-month period. Therefore, the analysis performed served to gather information useful for evaluating the effectiveness of the proposed system in the learning process of the students at the University.

Keywords— Calculus, e-Learning, Practice, Evaluation, Calculus Teaching, Tools

INTRODUCTION

The Calculus course offered as part of the curriculum for undergraduate students at Universidad EAFIT's School of Engineering is considered one of the courses with the highest dropout ratio in all programs in the University. Faced with this issue, the University conceived an educational innovation project with the goal of developing a Software Tool to determine the starting level of competency in calculus for each student attending the Calculus I course, and provide an effective leveling tool for the concepts that are prerequisite to obtain a good performance in that course.

In the next sections we will (a) describe the fundamentals that served as framework for the development of the Software Tool for massive use that allows students to self-diagnose and level their knowledge of pre-calculus before the commencement of their studies at the University; (b) the process carried out for the development of the tool; and (c) the results of the first pilot test with students.

I. THE LEARNING OF CALCULUS AND THE DIGITAL SOLUTIONS FOR LEARNING

It is of the outmost importance for students the acquisition of a good mathematical ability in the first stages of schooling [1]. Likewise, “the difficulties in the understanding of numerical concepts and problems in calculus during the first years may interfere with the acquisition of mathematical abilities in the future” [2] as well as in the formation of engineers.

It is required, for the understanding of Calculus, that students have an adequate mental attitude so that

they are willing to complete every single one of the activities suggested by the professor or by the textbook to reinforce the theory of the course. At the same time, it is fundamental to practice and link concepts with real life situations because. This way, students can acquire a better understanding that allows them to apply, justify, support, and defend their solutions and solving processes in front of their classmates.

Traditionally, professors help students understand what prerequisites are needed for Calculus as part of the course. This allows students to exercise their reasoning capacity, and allows new students to identify which concepts they have as baseline to approach the course and what concepts they can't grasp and why.

Another technique used in the Calculus course is the interaction between students to create questions and to answers them. This technique, called collaborative construction, enables the understanding of the concepts. Additionally, professors use strategies that allow them to catch the attention of students by highlighting important concepts making them easier to identify and understand. This way, for example, the student can go over his/her notes without any problem to identify concepts and procedures.

Nowadays, learning environments must take into account the framework of constructivism. [3] This approach sustains that the process of teaching and learning can be understood better if the observer is able to see the professor as the facilitator and students as the main characters responsible for building their own knowledge through their own experiences or those proposed by the professor, their own reflections, readings, and the sharing of ideas with their classmates and professors. These theories are also seen in the approaches presented by Vico, Kant, Mark, and Darwin. [4] Thus, the goal is for students to enjoy learning and to be committed to learn for the rest of their life.

Applying this approach to teaching and learning in Basic Sciences, such as Math and Calculus, poses challenges that have been identified by several authors. For example, Vrancken, Gregorini, Engler [5] pose that "teaching Calculus is one of the

biggest challenges of modern education because its learning has numerous difficulties related to high level thinking, where processes such as abstraction, analysis, and demonstration are implicated. [6]

During the past couple of years, some successful experiences have been reported in the implementation of online mathematical courses platforms. Some examples are: ALEKS [7], from McGraw-Hill publishers, offers courses in diverse topics categorized for all levels of education; the IXL web platform [8], through interactive interfaces, supports the learning of many topics such as pre-calculus; and the Khan Academy¹ platform, a repository of short videos that teach complex mathematical concepts in a very simple way.

Subsequently, the evolution of Technological Tools for learning have made possible that today we can configure learning solutions that support formal, collaborative, and experiential processes. Some solutions are: the so called MOOC² (Massive Online Open Course); immediate answering systems that activate student participation in the classroom by allowing students to answer to quiz, surveys, and discussions through their smartphones; tools that allow the creation of animated and interactive web content; eLearning platforms that allow the user to learn in a fun way by gaming; and tools that allow the automatic creation of dynamic and interactive presentations and allow the user to save them in standard formats recognized by Learning Management Systems (LMS).

All these elements inspired the creation of the Software Tool for the teaching of Calculus. This tool integrates multiple different solutions for learning while allowing the collection of data needed for using analytic tools to inquire about the learning process of students.

¹ Khan Academy: A non-profit organization with the mission of providing free world class education to anyone, anywhere in the world. <https://es.khanacademy.org/>

² MOOC: (Massive Online Open Course) Is a distance learning course found online to which anyone can register, doesn't have a limit of participants, and students work at their own pace.

II. DEVELOPMENT PROCESS OF THE ONLINE COURSE

After researching and exploring existent tools, the development process of the pre-Calculus course –which houses the Software Tool- started with the instructional design using the ADDIE (Analysis, Design, Development, Implementation, Evaluation) methodology [9]. The result of the analysis was the specification of competencies, methodologies, activities, contents, rubrics, and evaluations needed in the tool.

Based on the learning objectives of the course and the pedagogical structure of the contents proposed in the analysis and design stage, the resources for the course were developed. This was achieved by carefully completing digitalization, graphic design, proofreading, audiovisual production, and integration processes through IMS [10] standards such as VDEX [11], LTI, QTI2 and SCORM [12], as well as other formats that allow the export and import of contents such as MBZ for courses, and GIFT and AIKEN for workshops. Likewise, eLearning standards to guarantee the durability, interoperability, accessibility, and reusability of all learning resources were incorporated.

The content development included the creation of digital audiovisual resources that were dynamic and interactive and the generation of workshops through algorithms in Java to obtain multiple versions of the same document. Figure 1 shows the content architecture of one of the eleven modules of the course.

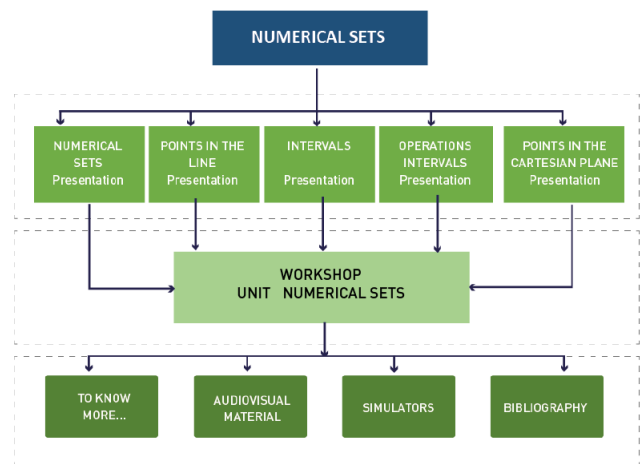

Figure 1. Navigation Map

The interaction model for tracking the learning process was designed under principles that could guarantee a good user experience. This experience relates to the whole range of activities that can make a student to learn, [13] as some people process concepts through practical experience, reflective observation, which leads them to be able to solve a problem.

Figure 2 shows the cycle for tracking learning processes.

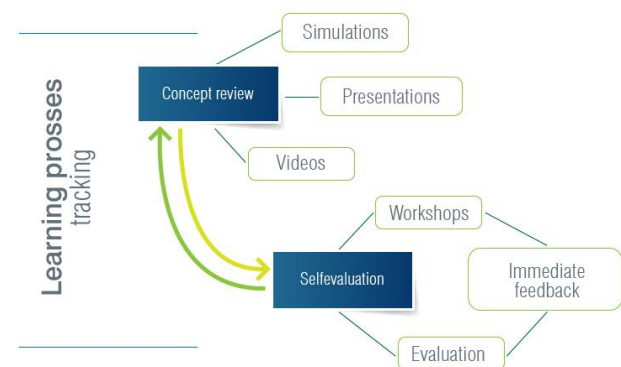

Figure 2. Interaction model for the internal organization of contents

For the implementation of the course, a framework Figure 3 capable of supporting the required services was designed. It integrated different systems to manage learning activities, course material, evaluation/assessment, and LaTeX language [14] for the treatment of the mathematical content.

Figure 3. Tools for the development of the contents of the course

The technological architecture used in the project is shown in figure 4. This architecture includes a server where the Moodle platform runs along with a database (where all data and interactions of students is saved). All contents from the course are also stored in that server. This entire infrastructure is hosted in the Cloud so professors and students can access the platform in a safe way from anywhere as long as they have their usernames and passwords.

Figure 4. Technological Architecture

The Pre-Calculus course used, as the base for its module of training and evaluation, the system developed by the project “Evaluation System for the Statistics Course”. This project proposed the use of a system integrated with the LMS that generates automatic questions [15]. All the work structure for question generation is integrated with the LMS

using Java programming language and using IMS academic standards [16] based on XML [17] such as QTI1 [18], QTI2, and XML-MOODLE [19]. The results are questions in different formats like multiple-choice, true or false, and pairing.

Different examples of questions used in unit workshops are presented in figures 5, 6 and 7.

Figure 5. Example question in the unit for “Operations with Intervals”

Figure 6. Example question in the unit for “Algebraic Fractions”

Figure 7. Example question in the unit for “Exponentiation”

Once the course was fully developed, different tests and necessary modifications were done before running a pilot test.

III. PILOT TEST

Description of the Pilot Test

The approach applied to measure the effectiveness of the Tool in terms of students' results, was the comparison of two groups coursing Calculus I. The first group was denominated Control, and the second group was denominated Experimental. Both groups were evaluated the same way. Each group executed two short tests in printed format (a diagnostic test and a final test). The only difference between both groups was that the first group, the Control group, didn't have access to the Tool and the other did. The tests were carried out during the first and last day of the two-month period designated for this pilot.

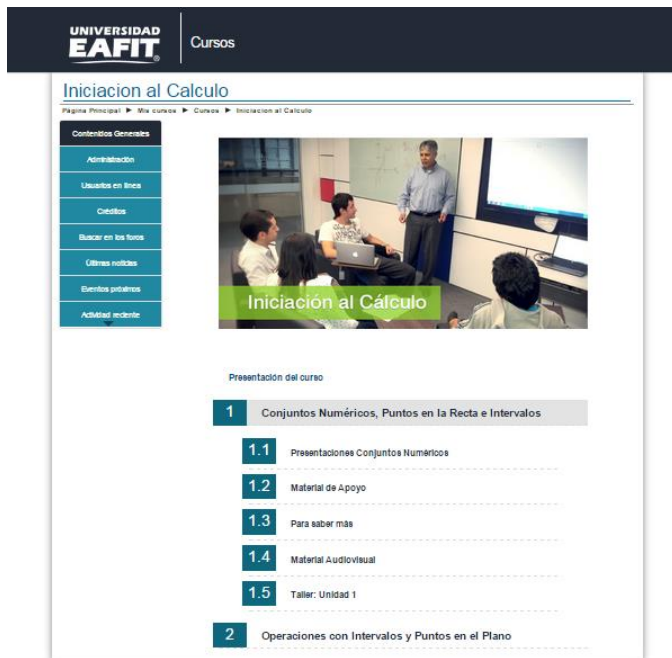

Figure 8. Snapshot of the Pre-Calculus Course

The first test was carried out in printed format at the beginning of the course for both the control group (26 students) and the experimental group (25 students). The test included three topics: numerical sets, intervals, and regions in a plane; for a total of 13 questions. Both groups had a very high percentage of first time students (close to 90%) and a remaining 10% of recurring students. Regarding the duration of the test, 90 minutes were set as the time limit. This test was done in order to have an

initial diagnose and register the mathematical concepts that the student is clear on the point of Calculus I course.

Once the initial testing was complete, both groups continued with their classes. The experimental group had access to the course module on the Software Tool, giving students access to different materials and academic resources among which they could find workshops and audiovisual content. The access was enabled for a period of two months so students could explore the platform to its fullest, identify their mistakes, and improve their mastery of the course's concepts.

The second test was carried out at the end of the two-month trial period for both the control group (26 students) and the experimental group (25 students). This one tried to resemble the conditions of the first test as much as possible. The objective was to obtain a register of the variation of the acquired knowledge of the students to compare it with the results of the first test on themselves (to look for signs of improvement) and between the two groups to see the effects of the platform on the results of the experimental group (that had access to the Tool for two months) against the results of the control group.

IV. EVALUATION OF RESULTS

A. Analysis of the Results Achieved in the Control Group

Figure 9 shows the results in the two tests carried out in the control group. The table shows the topic evaluated, the level of difficulty in a scale from 1 to 5, the specific competence, and the average score that students achieved in the topic.

Topic	Difficulty level (1-5)	Competences	Control Group 26 Students Test 1	Control Group 26 Students Test 2
Numeric al sets	1	Locate decimal numbers on the real line and converts decimal values to fractions	57%	79%
	2	Solve simple problems with a fraction applied to a context		
	3	Performs complex operations with fractional applied to a context		
	3	Locate decimal numbers on the real line and converts decimal values to fractions		
intervals	2	Recognize the conventions used in the representation of intervals	71%	77%
	3	Operations with intervals (Union)		
	3	Operations with intervals (Intersection)		
	3	Operations with intervals (Difference)		
Points and Regions	3	Locate points in the Cartesian plane	94%	77%
	2	Distinguish between quadrants of a Cartesian plane		
	4	Operates between points on a Cartesian plane		
Average Rating %			71,89%	77,51%
Average Rating 0-5			3,59	3,88

Figure 9. Control Group's Results

The results of the first test show that students in the control group have a good level of understanding of the topics evaluated. According to the results of the second test, there was increase in the average grade, which went from 3.59 (on a 0 to 5 scale) to 3.88. This can be interpreted as an improvement in the level of understanding of the students of the topics evaluated in the tests.

It is important to say that this group decreased their results in the last part of the second test, this could be because the questions varied between both tests, for example, in the first test the students had to calculate the distance between two points and in the second test they have to calculate slope of a line segment, despite that this questions are part of the same section, they could have different difficulty level for the students.

On the first test of the subject of points and regions they obtained a 94% yield, while in the second was 77%, this can be explained by the fact that the observation period the students did not entered to the Software Tool, as well as in regular classes the professor did not carried out reinforced understanding activities of these concepts.

B. Analysis of the Results Achieved in the Experimental Group

Figure 10 shows the results in the two tests carried out in the experimental group. The table shows the topic evaluated, the level of difficulty in a scale from 1 to 5, the specific competence, and the average score that students achieved in the topic. The results of the first test show that the students in the experimental group have a lower initial level of understanding than students in the control group (3.28 compared to 3.59 on a 0 to 5 scale).

Topic	Difficulty level (1-5)	Competences	Experimental Group 25 Students Test 1	Experimental Group 25 Students Test 2
Numeric al sets	1	Locate decimal numbers on the real line and converts decimal values to fractions	61%	69%
	2	Solve simple problems with a fraction applied to a context		
	3	Performs complex operations with fractional applied to a context		
	3	Locate decimal numbers on the real line and converts decimal values to fractions		
intervals	2	Recognize the conventions used in the representation of intervals	65%	78%
	3	Operations with intervals (Union)		
	3	Operations with intervals (Intersection)		
	3	Operations with intervals (Difference)		
Points and Regions	3	Locate points in the Cartesian plane	72%	81%
	2	Distinguish between quadrants of a Cartesian plane		
	4	Operates between points on a Cartesian plane		
Average Rating %			65,54%	76,07%
Average Rating 0-5			3,28%	3,80

Figure 10. Experimental Group's Results

According to the results of the second test, there was increase in the average grade, which went from 3.28 (on a 0 to 5 scale) to 3.80. This can be interpreted as an improvement in the level of understanding of the students of the topics evaluated in the tests.

C. Percentage Improvement from Test 1 to Test 2

Figures 11 and 12 show how much students in the control and the experimental groups, respectively, improved from the first test to the second. The net improvement was 5.6% for the control group whilst the experimental group improved by 10.5%. It is

important to point out that both groups had traditional classes with their respective professors.

Figure 11. Improvement from test 1 to test 2 for the Control Group (in %)

Figure 12. Improvement from test 1 to test 2 for the Experimental Group (in %)

This analysis highlights that, although the difference is not significant between the average score in the second test for both groups, the experimental group achieved the highest percentage change (10.5% vs. 5.6%) of both groups from test 1 to test 2. A priori, the increment could be attributed to the use of the platform by students in the experimental group, but further research and new tests must be completed to support this hypothesis.

V. CONCLUSIONS AND FUTURE WORK

- The Software Tool achieved the integration of different solutions in an ecosystem dedicated to learn Calculus. This allowed, along with practice processes, to complement the learning process with videos, digital resources, evaluations, and learning analytics.

- The architecture designed can be replicated for other courses that require leveling out the learning of basic concepts such as concepts to improve processes of reading and writing.
- Integrating the Software Tool with other solutions that can be adapted to the students' learning styles can enrich it.
- The online Pre-Calculus program has had very good results during its course. Today it has 11 modules that cover: numerical sets, points in a straight line and intervals, operations with intervals, points in a plane, exponentiation, factorization, algebraic and arithmetic fractions, radicals, rationalization, trigonometry, problem solution, straight lines, and circumferences. This allows students to strengthen their learning process.
- To stimulate active participation from students, it is important to offer stimuli or incentives to them. For example, awarding bonus points to students that affect the grade of the first midterm exam of the course.
- The Software Tool proved to be a resource that facilitates the leveling out in the learning of basic Calculus and mathematical concepts. After this study, the University institutionalized in 2015 the use of this tool with all freshmen.
- In the analysis of results obtained in the different tests, we observed that students have frequent difficulties with topics such as numerical sets and intervals when they first start their undergraduate program. More specifically in competencies such as locating decimal numbers or fractions in a real straight line, converting decimal values into fractions, and completing operations with intervals. The good news is that their level of understanding of the subject increases exponentially once it is reviewed in the Software Tool.

- From 2014 to 2015 more than 2000 students were registered in the platform for the leveling out previous to the Calculus I course.
- Since 2015, a new experimental pilot is being completed with middle school students of different public schools in the city of Itagüí, Colombia with the objective of measuring the effectiveness of the tool and converting it into a MOOC.

Construct Peer Assessment Instrument Using Existing E-learning Tools

Xiaosong Li

Department of computing and information system
Unitec institute of technology
Auckland, New Zealand
xli@unitec.ac.nz

Abstract—Work in Progress: This paper reports the study on how peer review instruments based on existing e-learning tools can affect the quality of peer review process and how this type of tools can benefit the reviewers. The study starts from a pilot study on constructing peer assessment instruments for an assignment in a Master course by using PeerMark and Moodle workshop. A comparison of these two tools has been given. Moodle workshop is more robotic, provide more options, but not very easy to use. Turnitin PeerMark is easy to use, more effective, but provides less options. Moodle workshop seems to have the potentials to facilitate guidance to the reviewers, feedback to the reviewers, peer interaction and knowledge construction better. A combination of the features of both tools should make a better peer assessment tool. Further investigation is required on how these tools can be improved or combined to organize a complex peer assessment marking criteria properly and to benefit the reviewers better. A plan for the next step research has been given, including further evaluation, software implementation and formal evaluation framework development.

Keywords—Work in Progress; peer assessment; e-learning; Turnitin PeerMark; peer review; peer review tools; Moodle Workshop.

I. INTRODUCTION

Peer assessment has been widely used in tertiary education due to that it facilitates student involvement, student engagement and student centered learning, thus enhance student learning, and it also allows students practice their professional skills and social skills [1].

A latest research [2] indicated that the prior research on the peer assessment has primarily examined the learning benefits that result from the receipt of peer reviews, with few studies specifically exploring the merits of producing feedback reviews or the learning mechanisms. Most of the researches are focusing on the peer review process, rather than the quality and the necessary functions of a peer assessment instrument.

In order to support peer assessment in large classes, computer support can be regarded as a necessity to manage the whole process of assignment submission and grading [3]. To make the peer review process efficient and effective, a number of commercial or free software have

been used. These include Turnitin PeerMark and Moodle Workshop and Moodle Forum.

PeerMark is a built-in peer review tool of Turnitin which is a web based e-learning system particularly good at plagiarism-prevention. Moodle is a free, open-source PHP web application for producing modular internet-based courses. It is a popular e-learning system. Moodle workshop is the peer assessment module of Moodle.

Turnitin has been widely used and the experiences of using Turnitin PeerMark have been reported in research publications [2, 3 and 4]. However the marking criteria used in these practices are usually simple and short in the range of 4 to 10 items, it's hard to find a report on using PeerMark for complex marking criteria. This raises questions, if a software tool like Turnitin PeerMark or Moodle workshop is suitable for a peer review assessment with complex marking criteria? What are the necessary features of these software tools? The focus of the peer assessment is usually on the collaborative learning and the opportunity to practice professional skills and social skills. The effectiveness of the peer assessment tool was not given sufficient attention.

This research takes the two widely used peer assessment tools, Turnitin PeerMark and Moodle workshop, as the starting point to explore how the peer review instruments can affect the quality of the peer review process and how this type of tools can benefit the reviewers.

There are many aspects related to the quality of the peer review process. According to reference [5], peer evaluation reliability and validity are concerned by both of the instructor and the students, in particularly, the students have very low confidence in their peers. One of the reasons is that peer reviewers are novices in their disciplines, to overcome this drawback, various functions such as calculating individual reviewer's review accuracy and authors' back-evaluations about the helpfulness of reviewer feedback would be helpful [6]. If peer review instruments can facilitate guidance to the reviewers and facilitate feedback to the reviewers, it would improve the reviewers' skills and thus improve the quality of the peer assessment.

Vague feedback and misinterpretation of writers' intentions on the reviewers' part have been found to be two major reasons why most of the reviewers' comments are not effective. Four characteristics of comments were identified to facilitate student's revisions: clarifying writers' intentions, identifying problems, explaining the nature of problems, and making specific suggestions [7]. This also confirms that if guidelines like the four characteristics can be implemented in the peer review instrument, it would improve the quality of the peer review and benefit the reviewers.

A web based peer review system can play multiple roles: an information distribution channel and management center; a forum for peer interaction and knowledge construction; and storage for knowledge construction procedures [8]. The most effective individual appears to be the strategic adapter who effectively constructs a project, adjusts to peers' comments, and serves as a critical reviewer as well. This suggests that if a peer review system can facilitate peer interaction and knowledge construction, it would make the participants more effective.

This paper reports the study on how peer review instruments based on existing e-learning tools can affect the quality of peer review process and how this type of tools can benefit the reviewers. The study starts from a pilot study on constructing peer assessment instruments for a summative assignment in one of our Master courses by using PeerMark and Moodle workshop. The tools are then compared and discussed based on the experiments.

In addition to the general factors such as fairness, effectiveness and reliability, the discussion also includes the following issues related to the benefits of the reviewers for a peer assessment tool:

- Guidance to the reviewers.
- Feedback to the reviewers.
- Peer interaction.
- Knowledge construction.

The experiments from the pilot study provide better understanding of the features and capability of these peer assessment tools. To have a complete understanding on these tools, more experiments are required. It is expected to develop a formal evaluation framework for this type of e-learning peer assessment tools.

In the following sections, the pilot study is discussed first, and then a comparison of PeerMark and Moodle workshop is given, finally a summary.

II. THE PILOT STUDY

The pilot study includes the experiments on constructing peer assessment instruments for a Master course assignment by using PeerMark and Moodle workshop. The assignment is a study report on an existing web based system. Accumulative grading has been used in the marking criteria. The marking criteria consist of four categories: technique part (consists of 10 items),

architecture part (consists of 8 items), industry policies (consists of 6 items) and overview of the report (consists of 7 items). To facilitate guidance to the reviewer, five dimensions, **Description**, **Investigation**, **Analysis**, **Critique** and **Literature**, were defined for the items. These dimensions are electively linked to each item. Table I shows a simplified version of the marking criteria to demonstrate the pattern required when constructing the assessment instruments, where D=Description, I=Investigation, A=Analysis, C=Critique, L=Literature and M=Marks. A dimension is checked if it should be considered for that particular item.

Two experiments had been conducted on PeerMark: three students and each reviewed two assignments; four students and each reviewed two assignments.

For the review options, PeerMark supports anonymous review and non-anonymous review. For anonymous review, it allows single blind review and double blind review. Double blind review was used in the experiment for fairness. The condition for this option is no student name on the report. For the reviewer assigning, it supports system randomly distribution, teacher pairing students up and self-assessment. The students' reviews will be assessed by the teacher. The system randomly distribution was used in the two experiments. In the experiment for three students, each student was allocated two papers, and each paper received two reviews, it was fair and balanced. In the experiment for four students, each student still was allocated two papers, so the student work load was balanced; however, one paper only received one review and another paper received three reviews, this was not fair. This should be adjusted by the teacher pairing students up option.

As a result, the proposed marking criteria in Table I can be implemented in the PeerMark and the assignment can be marked. However, it seems difficult to create categories in the marking criteria, so it could not be organized properly. And also, there seems no space to attach the selected dimensions to each item. This leaves less guidance to the reviewers.

TABLE I. ASSESSMENT CRITERIA PATTERN

Categories	Items	Dimensions					M
		D	I	A	C	L	
Technique	Purpose	X		X			2
	History	X	X	X			2
	Domain	X	X				2
	Popularity	X	X	X	X	X	3
Architecture	Design	X	X	X	X	X	3
	Database	X	X	X			3
	Roles	X	X	X		X	2
	Software	X	X	X		X	2
Industry	Brief	X					5
	Security	X	X	X	X	X	5
Overview	Consistency						4
	Presentation						4

The similar experiments had been done on Moodle workshop, where five students had been involved. A few things need to be highlighted for these experiments.

For the reviewer assigning, scheduled random allocation, manual controlled random allocation and manual allocation are supported. The manual controlled random allocation was used in the experiments. Two options are supported by Moodle in this case: the first option is two reviewer per submission; the second option is two reviews per reviewer. Both options were used in the experiments.

For the first option, two reviewers were allocated to each submission, as a result, each of the five students received two reviews. This was fair and balanced. For the second option, two reviews were allocated to each reviewer, this was done twice. For the first time, each submission received two reviewers and it was fair and balanced. For the second time, one submission received one reviewer, one submission received three reviewers, and all the other submissions received two reviewers. This was easily adjusted by switching to the manual allocation model.

Moodle work shop provides four grading strategies: **Rubric**, **Accumulative grading**, **Comments** and **Number of errors**. Among these, **Rubric** matches the marking criteria pattern in Table I most closely. It allows categorizing the items and allows attachment of the selected dimensions for each item. However, it does not allow partial credit for each item, only allows overall comments and not for each item. **Accumulative grading** allows partial credit and item comments, but it does not allow categorizing the items. **Number of errors** provides YES/NO options and comments for each item. This could be used to provide feedback to the reviewers.

Both PeerMark and Moodle workshop can implement the marking criteria pattern in Table I, however, none of them can implement it perfectly. Moodle workshop seems to facilitate the guidance and feedback to the reviewers better.

III. COMPARING TURNITIN PEERMARK AND MOODLE

To gain a deeper understanding, Turnitin PeerMark and Moodle workshop are compared in the following aspects:

- **Comment** – PeerMark supports a comment tool which allows students comment on the paper they are reviewing. A comment is equivalent to the notes that a student may write in the margins of a paper. A comment might be: "I like this idea. Think you could develop it further in this paragraph." A comment may be up to one thousand characters in length. PeerMark also supports text boxes for entering comments. On the other hand, Moodle workshop only supports text boxes.
- **Configuration workflow** – When create a new peer assessment, both PeerMark and Moodle workshop support a wizard style configuration workflow which is easy to flow. In Moodle workshop, it seems easy to

switch backward and forward between the workflow phases. This may provide more opportunities for the reviewers to revise their comments according to the feedbacks of their peers and the instructor, thus facilitate peer interaction and knowledge construction.

- **Marking criteria** – PeerMark support marking criteria library which allows marking criteria reuse; Moodle workshop supports assessment form which allows editing the marking criteria for one assessment. Both PeerMark and Moodle workshop are not perfect for complex marking criteria. When the marking criteria are getting longer, they cannot be organized properly. However, Moodle workshop provides four grading strategies, one of them allows categorizing the items, these make Moodle workshop to facilitate marking items organization, the guidance and feedback to the reviewers better.
- **Grading schema** – In Moodle work shop, the grade for one assessment consists of two portions: grade for submission, this sets the maximum grade a student can attain from a teacher for a given submission; grade for assessment, sets the maximum grade a student can receive for assessing other students' work. The grade can be calculated automatically. In PeerMark, some manual processes seem to be involved. This definitely facilitates feedback to the reviewers.
- **Pre-event learning** – Moodle workshop allows a teacher upload an example assessment for practice, this certainly facilitates knowledge construction; PeerMark seems does not support this.
- **Review allocation** – Both PeerMark and Moodle workshop support random allocation, manual allocation and self-assessment. Moodle workshop provided two options for random allocation, this could improve the fairness of the workload.
- **User Interface (UI)** – PeerMark UI is simple and easy to use. Moodle workshop provides more options and not easy to follow. How it does provide many instructions to help the users.

From the above, we can see that the two tools share common features such as configuration workflow, review allocation and feedback to the reviewer. The two tools share shortcomings as well, such as marking criteria management. Turnitin PeerMark owns some effective features such as the comment tool and the criteria library. Moodle workshop owns some robotic feature such as grade intelligent calculation. Moodle works seems to have the potentials to facilitate guidance to the reviewers, feedback to the reviewers, peer interaction and knowledge construction better. A combination of the features of both tools should make a better peer assessment tool.

IV. SUMMARY AND FUTURE WORK

In summary, Moodle workshop is more robotic, provide more options, but not very easy to use. Turnitin PeerMark is easy to use, more effective, but provides less options.

Moodle works seems to have the potentials to facilitate guidance to the reviewers, feedback to the reviewers, peer interaction and knowledge construction better. A combination of the features of both tools should make a better peer assessment tool. Further investigation is required on how these tools can be improved or combined to organize a complex peer assessment marking criteria properly and to benefit the reviewers better.

Further experiments and studies are required to get deeper understanding of these tools.

The plan for next step research includes:

- Split the students in the Master course used for experiments into two groups: one group will use Turnitin PeerMark, another will use Moodle workshop for peer review. Then we will evaluate the fairness, effectiveness, reliability and the benefits to the reviewers for both cases. Students' opinion regarding these aspects will be solicited.
- Repeat the above process for another course by making possible improvements identified from the first process.
- Consider other existing e-learning peer assessment tools.
- Identify the useful features for all the tools studied. Identify the features should be improved for all the tools. Identify the necessary features should be added to these tools. Implement an improved peer assessment tool on Moodle.
- Develop a formal evaluation framework for e-learning peer assessment tools.

Abstract— This paper presents the realization of Fuzzy Logic Controller concepts using operational amplifiers as a tool to teach students about design and modeling. Design of a FLC is performed because this path provides a good background for the student to experience a complete process approach that goes from verbal description of a problem throughout the final practical implementation, passing through the process of mathematical modeling and the understanding of what a realization of a function means. All the basic blocks consist of operational amplifier circuits that are taught in a first circuit course, just pushing the application a little beyond but still within the reach of the already acquired background.

Keywords—practical implementation; fuzzy logic; operational amplifiers; membership function; teaching circuits and control.

I. INTRODUCTION

In educational technology related areas, students are motivated with the validation of theories with practical implementations [1], because then the functionality of what is learned in the classroom takes real form in a tangible form [2].

In our department, in addition to regular classes, mentoring students for later work in design or research is done regularly on this context, teaching skills must include hands on experience that could help them integrate knowledge from different courses. This paper offers a tool that has been used by the authors to help students understand some concepts and relationship that many don't see until senior courses, or even after graduating.

In particular, students find it difficult to associate mathematical functions and algorithms to physical realizations. For many, the closest they get to this relationship is using the computer to realize mathematical algorithms. But very few consider this an experience of realizing a mathematical algorithm with an electronic physical system.

Starting with an idea previously developed with similar purposes [3], this work presents the construction of a Fuzzy Logic Controller (FLC) with simpler circuits so practically a first course in circuits with additional skills learned in precalculus, and enhanced with some help, is enough to provide students valuable help to overcome the above mentioned mental barrier. Although FLC are usually realized

with IC's [4] the implementation presented here uses discrete Operational Amplifiers (OA) and resistors. Students also learn the importance of interpreting results with this experience, since the circuits used are the same that appear in courses for quite different applications.

II. WHY A FUZZY LOGIC CONTROLLER?

FLC provides a tool to develop skills covering different “abstract” stages in the physical realization of a project. In short, the proposed experience has provided students with a complete experience as an example of the chain:

Language Description → Mathematical Model → Physical Realization

The process goes through the following stages:

- It starts with a set of rules provided by an expert using “plain” human language [4, 5].
- These rules are then modeled using Fuzzy methods.
- Students can go through the mathematical work of validating the model; software tools such as MATLAB® can be used at this stage to facilitate these tasks.
- Students “realize” physically with circuits the mathematical functions needed.
- Validation follows through simulation and experimental activities, measuring responses for example in oscilloscopes.
- The system is finally assembled and validated connecting the different blocks.

Once the FLC has been built, it can be further used in different applications.

III. FUNDAMENTAL CONCEPTS OF FUZZY LOGIC

A. FL Principles

The basic principles of FL can be introduced early to students and are simple enough to use almost immediately. For

this reason, it can be fast used by undergraduates in projects, and is also easy to understand the applications.

FL is in short a mathematical model for human reasoning where expressions are not totally true nor completely false, and applies logic rules such as modus ponens or modus tollens using such expressions. Examples abound to illustrate how humans make decisions with this type of reasoning.

Also, FL is used to model systems which are difficult to deal with mathematically, some of which do not have mathematical model available [5].

To model the human reasoning, FL utilizes definitions such as membership functions (MF) to provide a “truth value” to expressions, and mathematical operations such as minimum, maximum, weighted sum and others, to deal with the reasoning rules [5, 6].

B. Typical Membership Functions (MF) Used in FL

Fig. 1 shows common membership functions: “S”, “Z”, “Trapezoidal” and “Triangular”. Using only these functions it is possible to model almost all problems.

Fig. 1. Membership Function Types

The OA is the most popular electronic low cost device available and used in applications. The fundamentals are included in basic circuit texts [7] and OA's are included in early laboratory courses. Thus, it is a candidate to use for different projects and applications in early courses.

C. Membership Functions

Looking at Fig. 1, we should focus on OA circuits that allow a) positive or negative slope, and b) Saturation. Fig. 2 shows a circuit which happens to be the backbone of the configurations used to introduce OA to students: the inverting and non-inverting amplifiers [7]. The first one is obtained by connecting V_n to ground, while the second one grounding V_m .

Here, we use it to generate the membership functions by controlling the slope and position of the function, as well as pushing the OA into saturation region.

The slope sign and position depend on which voltage V_m or V_n is used as *INPUT* to receive data, and which one as *OFFSET* to position the curve. The slope, measured in the Output-Input plane, is obtained with the OA working in linear operation, that is, when V_{out} falls in the range $(0, +V_s)$.

Otherwise, the OA is saturated, yielding the desired slope in the “S” and “Z” functions.

Unlike many basic circuits, where dual power supply is used, we work here connecting the $-V_s$ terminal to ground, i.e. $-V_s = 0V$. This has the additional advantage of using only one power supply.

D. Analysis of the Circuit

Fig. 2. Non-Inverting Amplifier Mode Fundamental block

If we define $K = R2/R1$ and assume that the OA would never saturate, then applying the usual analysis for ideal OA [7], we arrive at

$$V_{out} = (K + 1)V_m - KV_n \quad (1)$$

The result (1), however, is valid if and only if the condition $0 \leq V_{out} \leq +V_s$ is fulfilled. We use these considerations for generating the slope in “S” and “Z” functions. Outside this range we go to the saturation regions of the functions.

E. Generating the “S” Function

From Fig. 1, the “S” function requires a positive slope. From (1), we see that V_m should be used as input, and V_n used for offset. Taking into consideration the conditions for V_{out} , we can obtain (2).

$$V_{out} = \begin{cases} 0 & \text{if } V_{in} \leq V_a \\ (1 + K)V_{in} - KV_{offset} & \text{if } V_a \leq V_{in} \leq V_b \\ +V_s & \text{if } V_{in} \geq V_b \end{cases} \quad (2)$$

Here, $V_a = K V_{offset}/(K+1)$ and $V_b = V_a + V_s/(K+1)$.

Fig. 3 shows the behavior of the output voltage with respect to the input voltage for different changes in slope described by the dotted lines.

Fig. 3. Generation of “S” Function ($K_1 > K_2 > K_3$)

F. Generation of “Z” Function

For the “Z” function, we exchange the input and offset roles. That is, now V_m is used as offset and V_n as input. In the linear region, equation (3) applies.

$$V_{out} = V_{offset}(1 + K) - V_{in}(K) \quad (3)$$

The condition $0 \leq V_{out} \leq +V_s$ determines the V_{in} constraints. Fig. 4. Shows the results for different values of K .

Fig. 4. Response for “Z” Function ($-K_1 < -K_2 < -K_3$)

G. Generating the Trapezoidal Function

We obtain a “Trapezoidal” or “Triangular” MF by subtracting “S” functions as illustrated in Fig. 6, the subtractor of Fig. 7. An analysis of this circuit yields (4). The block symbol in Fig. 7 is introduced for easier explanation later.

$$V_{out} = \begin{cases} 0 & \text{if } (V_2 - V_1) \leq 0 \\ \frac{R_b}{R_a}(V_2 - V_1) & \text{if } 0 \leq \frac{R_b}{R_a}(V_2 - V_1) \leq +V_s \\ +V_s & \text{if otherwise} \end{cases} \quad (4)$$

Fig. 5. Two “S” Functions with Different Slope and Offset

Fig. 6. “Trapezoidal” or “Triangular” MF Subtracting two “S” Functions

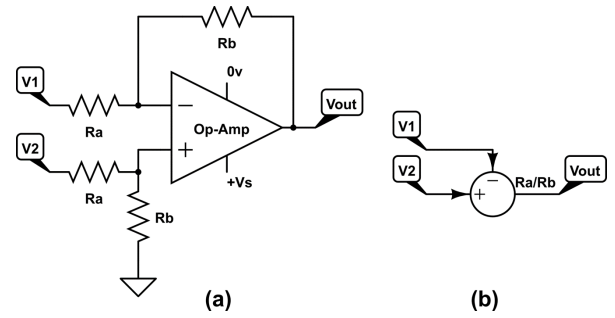

Fig. 7. Subtractor (a) Circuit; (b) Functional Block Representation

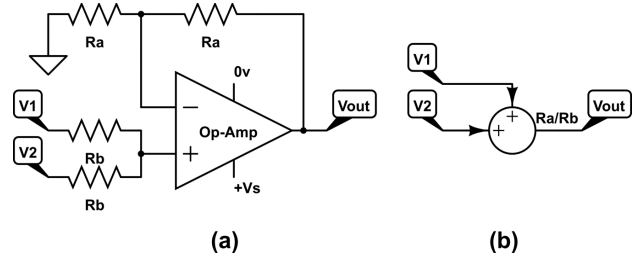

Fig. 8. Adder (a) Circuit; (b) Functional Block Representation

H. Minimum and Maximum functions

For classical logic, the operations of disjunction (*OR*), conjunction (*AND*) and negation (*NOT*) on propositions, are defined as the union, the intersection and complement [8]. Popular definitions in FL are (5).

$$\begin{aligned} X \text{ AND } Y &= \min(X, Y) \\ X \text{ OR } Y &= \max(X, Y) \\ \text{NOT } X &= 1 - X \end{aligned} \quad (5)$$

Here, “1” is physically understood as the saturation voltage. The minimum operation is realized combining the subtractor of Fig. 7 together with an adder of Fig. 8. The block diagram for a minimum realization is shown in Fig. 9.

Fig. 9. Realization for a Minimum Function

Here, if $X \geq Y$ then $A = (X - Y)$ and $C = Y/2$. Also, Because of (4), $B = 0$, so $D = Y/2$. These are added, and the output is Y . Similar reasoning applies if $Y \geq X$, producing X as output.

Adders and subtractors can also be used to produce the maximum function. One last stage is defuzzification, which can be realized using a weighted sum or the maximum circuit.

I. Experimental Verifications

The above theoretical analyses were first validated through simulations. Fig. 10 shows curves obtained at this stage.

Fig. 10. Responses on the Simulator Oscilloscope

Having verified that simulation performed as expected, electronic circuits were built so results could be verified experimentally. Fig. 11 shows the oscilloscope printout of membership “Z” and “Trapezoidal” functions.

Fig. 11. Printout with Inputs MF for a Ramp Function Entry

Fig. 12, on the other hand shows the minimum output response after the two memberships of Fig. 11 are used as inputs.

Fig. 12. Printout with Minimum Rule Response

IV. FL SYSTEM SIMULATION AND CONSTRUCTION

To culminate the process, we need to use the designed blocks setting up a FLC. With this in mind, we start by the mathematical description of a system. MATLAB® Fuzzy Logic Tool provides us with a user friendly package to do this [9]. Fig. 13 shows the first screenshot to configure the system consisting of two inputs and one output. The student did the complete mathematical analysis and hardware simulation before proceeding to construct the system, which worked as expected.

Fig. 13. FL System with Subway Train MATLAB® Example

V. CONCLUSIONS AND WORK EXTENSIONS

Although it may be argued that building nowadays a fuzzy system with operational amplifiers is not convenient, there are many practical consequences of this exercise. Among them, we can mention

- Construction as a proof of concept for analog designed systems. Do not forget that analog offers advantages in many practical situations over digital realizations, or else that it can be used as a subsystem in a mixed signal system.
- Help in learning FL Concepts and the electronics associated to it.

On the other hand, this experience has provided an excellent tool to introduce EE students at early stages to the process of system design through a practical hands-on exercise where the complete cycle:

Language Description → Mathematical Model → Physical Realization

For this experiment, only first circuit course knowledge using operational amplifiers is needed. Furthermore, it provides student with the unique experience of looking at one circuit from different points of view. This is essential for a good engineering practice, where similar, or even the same, physical systems are applied to very different fields. All depends on practical interpretation.

This work needs to be extended with a full application to a control systems problem. This is left for future work.

Using Audio Amplifier Distortion Characteristics as a Pedagogical Tool to Explain Signal Processing Theory

Paul Crilly, Richard Hartnett

Department of Engineering, Electrical Engineering,
U.S. Coast Guard Academy, New London, CT

Paul.B.Crilly@uscga.edu

Abstract—This paper will describe how audio amplifiers specifications can be used as a pedagogical tool to help explain distortion concepts in signal processing theory. Audio entertainment systems are an ideal and practical vehicle for this subject since these are ubiquitous among students, and audio quality or lack thereof is readily perceived. We will consider various distortion types including amplitude, phase, and nonlinear. In the nonlinear distortion category we present harmonic, and intermodulation. Also discussed are distortions due to limits of dynamic range, and quantization errors. We then present how distortion concepts can be integrated into a signals and systems course.

Keywords—distortion; fidelity; signal processing; audio engineering

I. INTRODUCTION

The topic of signals and systems is a major component of electrical engineering (EE) curricula. However, this area tends to be mathematical, and thus for some students, may be perceived as being somewhat abstract as compared to other EE topics. Many EEs ask how the content in their signal processing course relates to what is encountered in their everyday world – which often consists of devices such as audio entertainment systems. An important segment of a signal processing course is system distortion – specifically, to what degree is the output a facsimile of the input. These distortion types include, amplitude, phase and nonlinear. While the standard signal processing course covers theory of distortion, many undergraduate electrical engineering students often cannot relate this theory to real world phenomena. For example, an electrical engineer should be able to understand and articulate why a CD player, even though quantization noise is added during the recording process, is inherently superior to reproducing a concert as compared to analog magnetic (cassette) tape.

II. SIGNAL DISTORTION

A. Distortionless Systems

The assumed goal for an audio amplifier is that it accurately replicates the original input*. In other words, it has *high fidelity* or is *distortionless*. More formally a *distortionless system* is where the output is a scaled and delayed version of the input. This is expressed as $y(t) = Kx(t - t_d)$ with $x(t)$ and $y(t)$ the input and output, respectively, K is a constant gain factor, and t_d is a constant time delay. The system function would therefore be $H(j\omega) = Ke^{-j\omega t_d}$, where ωt_d is the system's phase term. Because K is constant, we say the system has a *flat* response over all frequencies. The types of distortion typically encountered are amplitude, phase, and nonlinear. System distortion will affect the shape of the output signal; in addition, nonlinearity can also add artifacts to the output and/or affect the relative amplitudes of the various input components.

B. Amplitude Distortion

Amplitude distortion occurs when the K term varies with frequency. The degree of amplitude distortion is often called *magnitude response*. Thus a high quality system will have a “flat response.” For example, it is desirable for an audio amplifier to have a response that is constant from 20 Hz to 20 kHz, the range of the human ear. In practice, flat means the response can vary as much as 3 dB. An example of amplitude distortion would be the telephone system where the frequency range is 300 to 3000 Hz; adequate for voice, but not music. An extreme example is a system where the input is a square wave, “rich” in harmonics, and the output is a single sinusoid. System bandwidth is a measure of amplitude distortion.

C. Phase or delay distortion

Phase or delay distortion occurs when the phase term, ωt_d is not a linear function of frequency. However, most human ears, with the exception of a musician, or the mastering engineer, are relatively insensitive to phase distortion. Therefore, phase distortion is usually not of significant concern in music systems.

* To be sure, some desire a system where distortion and/or other artifacts are intentionally added into the output. The vacuum tube amplifier is one example where the unintended distortion is pleasant to the ear.

We present a brief example of phase distortion. Consider a system with flat frequency response and linear phase with an input of $x(t) = 10 \cos \frac{\pi}{2}(t-2) + 2 \cos \frac{\pi}{6}(t-2)$ and transfer function of $H(j\omega) = 5e^{-j3\omega}$, yields an output of $y(t) = 50 \cos \frac{\pi}{2}(t-5) + 10 \cos \frac{\pi}{6}(t-5)$. Note the two components have equal time delays and thus meets our non-distortion criteria. The same input to a system with nonlinear phase where $H(j\omega) = 5e^{-j\omega^2}$, yields $y(t) = 50 \cos \frac{\pi}{2}(t-5.61) + 10 \cos \frac{\pi}{6}(t-1.32)$.

Note there is no amplitude distortion, but the uneven relative time delays indicate phase distortion. An example of a system whose input is a square wave and whose output response has minimal amplitude distortion, but phase distortion is shown in Fig. 1. References [1]-[4] contain additional information on amplitude and phase distortion.

Fig. 1. Output waveform from a system with negligible amplitude distortion, but nonlinear phase distortion. The system's input is a square wave.

D. Nonlinear distortion

A *linear* system is one where proportional changes in the input result in the same proportional changes in the output. Consider the classic operational amplifier circuit where the voltage gain is $A_v = 10$, and power supply $V_{ss} = \pm 12$ V. The circuit will operate linearly if the input voltage, $|v_{in}| \leq 1.2$ volts, otherwise the output flattops to the power supply rails and hence the amplifier is no longer linear. In fact, when the input is large enough such that the amplifier exceeds its linear dynamic range; it becomes *overloaded* causing the output to have additional frequency components or artifacts. Thus the system is *nonlinear* and thus exhibits nonlinear distortion. Not only can a nonlinear system cause these spurious outputs, but in the case of multiple inputs, the weaker input may be drowned out by the stronger one. As we will see later, the range of input magnitude such that the amplifier does not overload is referred to as *dynamic range*.

Nonlinear distortion can be modeled in the following manner: $y(t) = a_1x(t) + a_2x^2(t) + a_3x^3(t) + \dots$ [1] where one or more coefficients are significant relative to a_1 . This nonlinear system may produce spurious output artifacts. Harmonic and

intermodulation are two types of nonlinear distortion and are described below.

Harmonic distortion is where a single tone sinusoidal input generates harmonics. Consider a system with $y(t) = x(t) + 0.1x^2(t)$ and input $x(t) = \cos 2\pi f_m t$. The resulting output is $y(t) = \cos 2\pi f_m t + 0.05 + 0.05 \cos 4\pi f_m t$. Neglecting the DC term, the output spectral magnitude, $|Y(f)|$, is shown in Fig. 2. Note the spurious harmonic at $2f_m$.

Fig. 2. Harmonic distortion example for a system with a single tone input.

Intermodulation distortion is the result when the nonlinear elements in the system cause the multiplication or modulation of the input components to generate additional, but spurious output terms. Recall that the product of two cosines results in two new cosine functions whose angles are the sum and difference of the original functions. Consider the above nonlinear system, except that instead of a single input, we have two inputs at different frequencies. If the input were $x(t) = \cos 2\pi f_1 t + \cos 2\pi f_2 t$, the output becomes $y(t) = (\cos 2\pi f_1 t + \cos 2\pi f_2 t) + 0.1(\cos 2\pi f_1 t + \cos 2\pi f_2 t)^2$. If we carry out the math, we observe four additional and spurious sinusoidal outputs at frequencies $2f_1$, $2f_2$, $(f_1 + f_2)$, and $(f_1 - f_2)$. If $f_1 = 2$ kHz, and $f_2 = 5$ kHz, then in addition to an output of 2 and 5 kHz signals, the output would also yield tones at 4, 10, 7 and 3 kHz. This is illustrated in Fig. 3. Going beyond this simple example, imagine the level of intermodulation distortion if the input was music with its many harmonics. Initially it may appear that a level of 0.1 in the squared term of x doesn't seem significant, but 0.1 is only -20 db. The human ear can perceive sounds that are 30 dB down from the average signal level.

Fig. 3. Intermodulation distortion example with 2 tone input.

In published specifications of some commercial audio systems, all distortion products are lumped together and constitute *total harmonic distortion* (THD). THD can vary from -38 to -137 dB (0.013% to 0.000013%. Cabot [5]

provides an excellent discussion on the theory and measurement of these types of distortion.

E. Dynamic Range

Dynamic range is the difference (for dB) between the loudest and weakest sounds, an example being an orchestra's brass versus woodwind sections. Dynamic range is a limitation on a system's linearity. The ability of an audio amplifier to preserve the relative powers of these sections is a measure of its dynamic range. Dynamic range is defined as $DR_{db} = 20 \log_{10} (V_{max} / V_{min})$ with an orchestra having a DR of 120 dB. It should be noted that DR may be limited by the recording system. For example, a cassette tape's DR is 70 dB, whereas a CD ROM's DR is 96 dB [1]. Thus for digital plus analog systems, the DR is dictated by the number of quantization levels, the media, and the analog electronics. This is illustrated in Figure 4. In observing Figure 4, consider the following example. Let's say we are interested in recording an orchestra with the full range of instruments. In order to "fit" the orchestra's range of 120 dB inside the CD's 96 dB dynamic range we have to limit the amplitude of the brass section and/or slightly increase the amplitude of the woodwind section. Therefore, in systems where the recording and/or sound system has less dynamic range than the original input, we must employ some type of amplitude compression (e.g. logarithmic compressor) so the recorded sound will fit inside the amplitude limits. In another example, to tape record a live performance, we have to compress the 120 dB input so it will fit inside the tape's 70 dB range. Note that this amplitude compression introduces a different sort of nonlinear distortion whereby we sacrifice output signal shape fidelity in order to minimize overload and spurious output components. A manifestation of the increased dynamic range is in the transition from tape to CD players inside automobiles, where there is an increased tendency for users to adjust the sound volume.

Fig. 4. Graph to illustrate dynamic ranges for various music sources.

F. Desirable distortion

To give the devil his due, we conclude this section with a brief commentary of vacuum tube amplifiers. The vacuum tube, like a transistor is an amplifying device. The vacuum tube inherently has a relatively wide dynamic range as compared to the bipolar transistor. When a tube amplifier is overdriven so the output is clipped, the clipping is less abrupt than its transistor counterpart, hence more pleasant to the ear (i.e. a softer manifestation of nonlinearity). However, since the 70s, the vacuum tube amplifier has been obsolete since with today's technology, a solid state amplifier will meet any realistic

fidelity specification. Power wise the tube amp is much less efficient than its solid state counterpart, and many tube amplifiers have some residual 60 Hz background hum. These and other practicalities, suggest there are no technical reasons to use vacuum tubes in audio systems. On the other hand, many audiophiles prefer the sound from vacuum tube amplifiers since they observe that the tube amplifier *introduces a degree of warmth to the listening experience*, and as previously stated, clipping with tube systems is less obnoxious than solid state systems. Finally, many believe the sound quality of the tube-speaker combination is superior to that of its transistor-speaker counterpart.

III. PEDAGOGY

The use of audio systems as a pedagogical tool to enhance learning in the signals and systems area began several years ago when an invited speaker at an IEEE student branch meeting made a presentation on audio amplifier quality. The talk, while mostly qualitative, piqued the students' interest in signals and system theory and gave them an appreciation that abstract signals and system theory can readily explain real world phenomenon. We initially incorporated audio amplifier specification examples into the lecture material of an existing signals and systems course. In the future, it is envisioned that new laboratory projects will be developed where students can audibly experience the various types of distortions as well as observe these on an oscilloscope and dynamic signal analyzer (DSA). Examples would include the effects of overdriving an amplifier, reducing the number of quantization levels when digitizing a signal, and observing and measuring the outputs of various audio amplifiers that have various degrees of total harmonic distortion. While we could offer a separate course on audio distortion, our intent is to integrate this topic into an existing signals and systems course.

Distortion and signal overload is extremely relevant to communications systems and thus was also incorporated into our communication systems course. For example, the *near-far problem* whereby the receiver front end is required to have wide dynamic range in order to be able to simultaneously capture and process both weak and strong signals; a design challenge in any receiver technology, but particularly in today's CDMA wireless phones where multiple signals are all at the same frequency.

A learning objective is that engineering students will better understand the specifications of an audio system and thus be able to make meaningful comparisons between competing systems and go beyond many of the existing electronics and signals and systems courses that assume linearity and primarily focus on maximizing bandwidth. Another objective is that by incorporating audio applications into the signals and systems courses, students are forced to confront the non-ideal behavior of real systems, and understand how this type of behavior affects the listening experience. In any case, audio systems present an interesting case study and thus are an alternative to the usual academic and theoretical black box systems encountered in the undergraduate signals and systems curriculum.

IV. CONCLUSIONS

This paper has presented a perspective on system response that goes beyond the traditional pedagogical undergraduate electrical engineering topics of amplitude distortion, step response, and even phase distortion. Using the audio amplifier example, we have introduced another set of system specifications that characterize system fidelity and

performance. We have also shown that nonlinear distortion affects response by either introducing new artifacts in the output, or because of dynamic range limitations requires the input signals fall within certain signal strengths so as prevent additional output artifacts from being introduced.

Abstract—In this paper, we present an innovative mixed pedagogical method to improve teaching and learning in undergraduate courses related to computer area. The method proposes learning multi-criteria assessments and pedagogical strategies, such as problem-based learning, that should be carried out during the activities. This research was performed in a three-year case study in courses undertaken at the Federal University of Ceará (UFC), Brazil. The main contribution of this work is the mixed pedagogical method that uses the combination of important pedagogical strategies, with promising results. There was observed an improvement in student results and professor evaluations in four of the five cases. In these four courses, researchers used the method with all requirements being met.

Keywords— *pedagogical practices, innovation, teaching undergraduate, professor's evaluation*

I. INTRODUCTION

Professors face difficulties related to teaching and learning activities results in Brazilian computing area undergraduate courses, such as low student motivation, difficulty to link the subjects to labor market, only theoretical focus, among others [1, 2]. These problems are still increasing, because there are difficulties when the students execute text-reading activities, and there is a low turnout of student presence in the classroom during the courses.

There are difficulties inherent to the pedagogical vision of being a professor and analysis of teaching and learning activities results in computing area undergraduate courses. It is important to know what professors that have been successful in the classroom use in terms of pedagogical practices, to mitigate these difficulties.

We proceeded with a survey and subsequently identified some of the difficulties faced by Brazilian professors when teaching in computing area undergraduate courses:

- Difficulties in motivating students in complementary courses when facing competition from other technical courses;
- Bad initial results that decrease the student motivation at the beginning of the courses;

- Difficulty encountered by students in linking the knowledge and skills acquired in courses with their future professional work;
- Theoretical traditional focus related to some courses in computer undergraduate;
- Deficient basic formation of some students in relation to the course requirements;
- Difficult relationships between professors and students.

These problems are increased with the difficulties of students when involved in text reading activities and the low turnout of student presence in the classroom during the courses.

We proceeded with an empirical observation and analysis of courses results in computing area undergraduate during the period 2007 to 2013. This was coupled with the researchers' experience as professors (undergraduate and postgraduate) in the computing and education areas. Our first research results were presented in [13].

In this work, we presented and evaluated from a student prospective view, our classroom practice. We evaluated five courses within two programs at the Federal University of Ceará (UFC), Brazil. The main objective was to experience a mixed innovative pedagogical method, trying to get better student learning results and minimize the presented difficulties when teaching undergraduate in courses within the computing area. We observed the reduction of disaffection in classes, improving the relationship between professor and students, and also the establishment of a link between the acquired knowledge of the course and the market. The planning activities were considered very well in the students' assessment. The students preferred the proposed practice in relation to traditional practices experienced by them so far in the courses. The multi-criteria evaluation was cited by students as being fairer and more motivating than just simply tests and theoretical work.

II. LITERATURE REVIEW AND RELATED WORKS

At a high conceptual level, this work deals with education evaluation and performance, and as such, it derives ideas from several other researchers working in pedagogical innovative practices to improve professor and student performance.

The efficiency of instructional strategies in the student learning has been presented by [3, 8], in the courses of science, engineering and mathematics.

The process of developing an instrument to assess a professor's teaching practice in Brazilian university education was shown in [16], where the work result analysis revealed the existence of important factors that influence professor performance, such as "teacher-student relationship" and "teaching practice". The presented instrument has proven to be a promising element to improve teaching quality in the classroom. Our method uses the professor's teaching practice evaluation by students as an instrument to improve teaching performance in a continual monitoring cycle.

The difficulties inherent to the pedagogical training vision of being a professor and analysis of teaching activities among others, were presented in [4], whereby the authors proceeded with a study evaluating Brazilian professors in the communication area. Thus, the key attributes and practices of accounting for professors that have been successful in the classroom, from the standpoint of students in Brazilian public and private universities, were presented in [5].

The school and classroom contexts with pedagogical innovations employing technology were successfully sustained as presented in Owston [14]. The author cited that the essential conditions for the sustainability of classroom innovation were professor and student support of the innovation, the perceived value of the innovation by professors, professor professional development, and principal approval.

There was a project-oriented framework proposal for engineering schools in [18], which combined pedagogical methods, such as: project-based learning, active pedagogy and traditional teaching paradigms. The authors cited that although comparisons between various pedagogical methods are difficult and sensitive, numerous internal signals confirm the validity of several aspects of their mixed pedagogical proposal.

To meet the needs of engineering graduates who can function comfortably in an increasingly distributed team context, which crosses country and cultural boundaries, the work shown in Daniels et al. [7] evaluated an Open Ended Group Project Framework (OEGP) as a pedagogical strategy, whereby using collaboration.

The feedback concerning the pedagogical practices of graduate teaching assistants was proposed in [6]. The evaluation tool called G-RATE allowed various stakeholders, such as: classroom observers, administrators, graduate teaching assistants, undergraduates, and students, to provide feedback about their pedagogical practices within a laboratory session.

Constructivism has lately been the more theoretical approach when used to guide teaching materials development, especially for multimedia learning environments [17]. The fact that the constructivist approach is predominant means not only a trend reflected in textbooks, because even the idea of constructing knowledge is present in the work of various authors, and depending on which one is the elected benchmark, sets up a pedagogical practice somewhat differently.

There are fundamental common elements, despite the differences between the theoretical concepts of constructivism research. The consideration of the individual as an active agent of his own knowledge displaces concern from the education process (traditional view) to the learning process. In the constructivist view, the students build representations through their interaction with reality, which will constitute their knowledge, an irreplaceable process, and incompatible with the idea that knowledge can be acquired or transmitted. Taking these assumptions means changing some core aspects of the teaching-learning process in relation to the traditional view [17]. Table 1 shows a comparison between traditional and constructivist approaches.

The Problem-based learning (PBL) is a well-referenced method in literature. In PBL, students work in small collaborative groups and learn what they deem necessary to solve a problem. The professor acts as a facilitator to guide the student through the learning cycle [13].

In the PBL learning cycle (see Figure 1), also known as the PBL tutorial process, students are introduced to the problem scenario. The problem is formulated and analyzed through the identification of scenario relevant facts, helping students to represent the problem [10]. To the extent that, students best understand the problem, the possible solution hypotheses are generated. An important point in the cycle is to identify the knowledge gaps in relation to the problem of learning issues that will be studied during their self-directed learning (SDL). Students then use their newly gained knowledge by assessing their hypotheses based upon what was learned. At the end of each solved problem, students reflect on the acquired knowledge. The professor helps students learn the cognitive profile needed for problem solving and collaboration. One of the cited limitations for this method used, is the amount of people necessary to facilitate learning in large classes [10, 13].

TABLE I. TRADITIONAL AND CONSTRUCTIVIST LEARNING APPROACHES

Traditional Approach	Constructivist Approach
Focus on professor	Focus on student
Focus on course programme	Focus on individual significance construction
Student mind is a blank paper	Learning is construction upon previous knowledge
Student is a passive knowledge receptor	Student controls the learning process
Memorization of knowledge	Skills and knowledge will be developed in the context where they will be used

The use of PBL to improve the curriculum of an undergraduate mechanical engineering course was addressed in [9]. The authors stated that a new course was proposed, which was based more upon troubleshooting than topics. Problems were solved by small groups of students with the facilitators help. The paper describes the impressions and experiences of the students in the course, and how the final problem was solved. Our work differs from this prior work, because the use of PBL was just one component of our mixed pedagogical method. The effectiveness of using a management simulation as the PBL "problem" in a strategic planning course was presented in [21]. Strand *et. al.* [22] proposed a course based in the guiding principles of trauma theory and problem-based learning. The article described the course objectives, structure,

and format and reports on an evaluation based on 7 (total) offerings of the course by 4 different schools of social work.

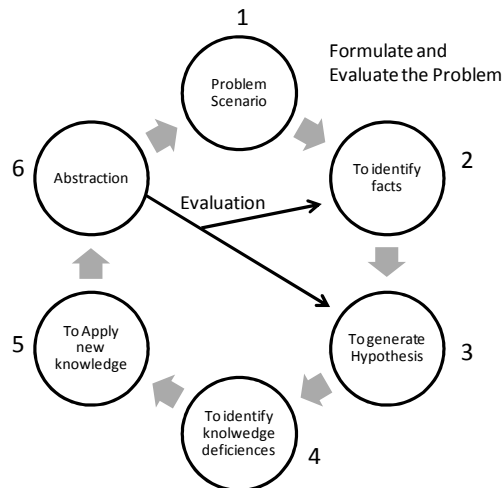

Figure 1. Problem-based learning cycle [13]

It is important to know the problems faced by professors when teaching in their daily lives, when addressing the need for new pedagogical practices. University professors in the communication area said that they faced the pedagogical problems as soon as they appeared. Table 2 illustrates the identified main problems and pedagogical solutions encountered by professors [4].

TABLE II. PEDAGOGICAL PROBLEMS AND SOLUTIONS ENCOUNTERED BY PROFESSORS

Pedagogical problems faced by professors	Solutions encountered by professors
Student unmotivated and listless to continue the course. When the student starts the course he/she will already be getting discouraged. They are such a quick gratification generation.	We're professors, we need to be there giving them motivation to continue. I talk about their future profession, and show some texts about it.
Disinterest, academic failures.	I try to motivate students through case studies and practical projects.
Very heterogeneous student profiles in the classroom. Lack of student motivation. Lack of integration with other courses in undergraduate.	-
Relatively rapid and radical change of the students profile and interests, perhaps due to the ongoing technological transition.	I try to confront the issue by talking with students and avoiding hasty conclusions, whilst maintaining a commitment to ethics and critique education.
Students' disinterested in reading area texts and papers.	Each semester I seek creative ways to attract the interest of students.
Keep relationships with students as subjects and not as teaching objects.	Read specialized books and talk with others professors.
Lack of time to hone skills and implement educational updates.	Read books, search internet and talk with others professors.
Pedagogical issues are not discussed in the course coordination meetings of the professors.	I make my own self-assessments with students, including the issue of course.

In the same work, when asked about the activities development by professors, students in the two evaluated universities answered in the manner as summarized in Table 3. From presented information, we found that some professors searched for innovative classroom teaching practices, but this

activity is not usual. The authors observed that there is often a difference between what was planned and what is implemented in practice by professors. During the evaluated lesson study, the following observations were made: purely expository presentations, indifference, inattention, lack of interaction between professors and students, and sometimes the difference between what was presented and the real world.

TABLE III. STUDENT ANSWERS ABOUT PROFESSOR'S CLASSROOM ACTIVITIES

How the activities should be executed by professors	How the activities are executed by professors
Knowing how to align the market with academics. Respecting the student. Following the course content.	They make presentations using powerpoint. He has pleasure with the execution of activities. He motivates the students. He brings the market to students.
Being more relaxed. Being dynamic. Promoting debates.	We feel like we're at home. We invent products. He does not use alternative strategies. We have to read a text and discuss it in the classroom. He asks the question and tells us what we need to research. However, the lesson is always the same subject.

Research on learning with computing has been a major focus in the learning sciences. In our method execution, students should use computers during the classes. A pedagogical training strategy has been evaluated into the student's undergraduate experience in biology, with good results [19]. A course-based computing approach was tested in Magana et al. [15] and the work results indicated that students performed proficiently in applying computing methods, procedures, and concepts to the solution of well-structured engineering problems. The student self-perceptions of their overall computing abilities and their abilities to specifically solve engineering problems shifted from low to high confidence. The authors' philosophy was based in two premises: computational thinking is best realized in domain-specific, personally relevant contexts; the transfer of learning is better promoted when emphasizing understanding rather than memorization and providing learners with enough time to develop patterns of recognition, and providing students deliberate practice in authentic contexts in which feedback is provided [15]. In a related way, our proposed method includes problems solution as a strategy to be used by professors when planning the courses. Professors should plan the courses to prioritize the transfer of learning between the actors.

Concept mapping is an effective knowledge construction tool for helping learners organize important concepts related to a core issue. An integrated concept mapping and web-based problem-solving environment was developed in [11]. The researchers conducted an experiment to evaluate the effectiveness of the approach on students learning performance, learning satisfaction and cognitive load in an elementary school social studies course. Their results showed that the concept map-integrated approach could enhance the students' web-based problem-solving performance, although the students showed lower degrees of technology acceptance and learning satisfaction in comparison with the conventional web-based problem-solving approach. Using our pedagogical method, the professor can use a concept mapping strategy to plan some classes in a course.

Implementing optional hands-on practice (HOP) activities could prepare the students for the actual hardware manipulation in an introduction to computer science (ICS) course and also to enhance their performance in the future advanced practice courses [20]. The research results showed that HOP participants not only had higher academic scores, but were also less stressed toward the ICS course than the non-participants.

Augmented Reality (AR) is a technology with great potential to impact affective and cognitive learning outcomes. The research presented in [12] assessed to which extent an AR learning application affects learners, level of enjoyment and learning effectiveness. The results indicated that augmented reality can be exploited as an effective learning environment for learning the basic principles of electromagnetism at high school provided that learning designers strike a careful balance between AR support and task difficulty. We consider that depending on the course topics, AR is a possible technology that can be used by professors when planning classes in the courses, using our pedagogical method. Artificial information about the environment and its objects can be overlaid on the real world.

III. PROPOSED METHOD

As basic requirements for the method application, the professor should have an available classroom with Internet access or computer laboratory for use in all planned activities of a course.

The amount and distribution of activities for each course must be balanced between those presented in the proposed method description, grouped and distributed in the lessons, according to the content specificities of the course.

Figure 2 illustrates our proposed method overview, where the professor should plan which resources will be used and in what classes during the planning phase of the course.

The initial course content plan shall be presented and discussed with students, thus enabling the sharing of ideas and possible changes. From the implementation of classes, the teacher will place in sequence, the planned class types according to the content to be followed, always looking to boost its formatting and use of teaching resources, such as: videos, pictures, texts, internet access, among others.

Learning multi-criteria assessments should be carried out during the activities, whereby seeking to generate feedback and discussion results with the students whenever possible. The professor evaluation process by students should be seen as an everyday life tool, whereby the professors will receive online feedback, allowing changes in content planning, both during the course and for the next subjects.

Our mixed pedagogical method consists of the set of activities described as follows:

i. Identification of knowledge and skills that need to be developed by the students

The information concerning the knowledge and skills that will be developed during the course is the guiding elements for all method actions, so it should be identified during the course content planning.

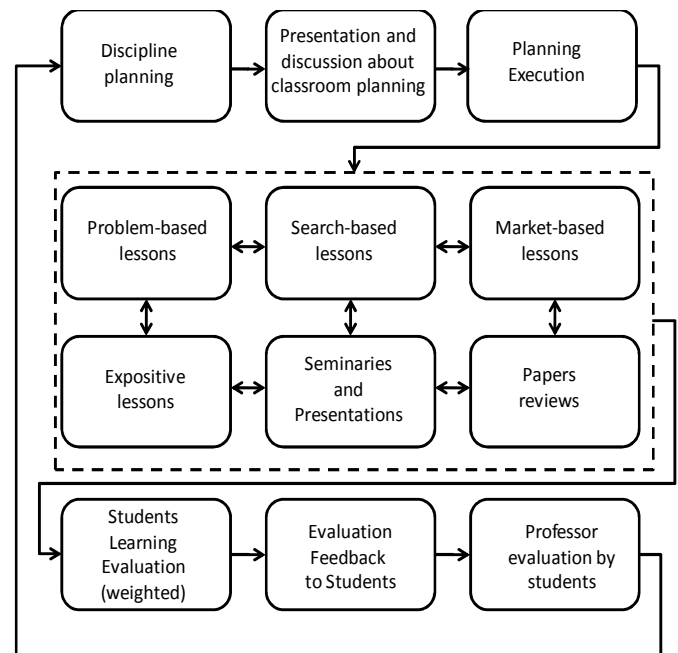

Figure 2. Proposed method overview

ii. Selection of academic papers related to the content of the courses for review

The professor should select a group of journals and conferences in the course area, which may be revised by the students in activities, both in the classroom and at home during the course.

iii. Selection of problems to be solved using problem-based learning strategies in the classroom

Select from books, public tenders tests, certification exams or other events that may arouse greater student interest in relation to the course, a group of problems that can be solved by student groups for specific PBL classes. The problems should have a limited scope, in order to be solved, preferably by up to three classes. Sometimes, depending on course scope, students can use computers and software to help them in activities.

iv. Research and identify market related topics to the subject content practical application

The taught content market applicability in a course is one of highly valued factors by students and can be used as a motivating factor for their participation in course activities.

Professors should seek to identify ways to use the acquired knowledge during courses in business activities, preparing lessons to show this specific purpose. If by chance these applied topics do not exist, they must then move to the next step. It is possible that the professor adopts a set of activities based upon Internet research or other research sources for classroom work. Students can use computers and some software in this activity, depending on course planning.

v. Present and discuss course planning

The information concerning the course's content and lesson plan should be shared with students as early as possible. Professors should discuss the lesson plan with students, adapting it when there are relevant suggestions. Thus, with the active participation of students in project execution, professors can get a greater student commitment.

vi. Adopting a weighted assessment practice

Good students were found to be dissatisfied with unfair evaluation practices [17]. The basis of the proposed method consists in defining a multi-criteria evaluation for courses. The professor can use the following evaluation criteria (objective and subjective):

- Presence in classroom activities (percentage of presence);
- Participation and interest in the process of knowledge collective construction (subjective grade in accordance with the observations during classrooms);
- Development of work/activities in the classroom that can include tests resolution, problem simulations and other activities. Individually and/or in groups (professors must obtain an average grade of executed activities);
- Preparation of paper summaries or other issues at home (to obtain an average grade of completed work);
- Troubleshooting classrooms (Problem-based learning) (professors must seek an average grade for problem solutions executed during the course);
- Students' participate as an author and/or lecturer, developing a paper on a relevant topic of the course. The activity should be planned for the end of the course period (professors must average the grades of the written and presentation work);
- Set the weights of each evaluation criteria (total of weights should equal 1);
- Provide feedback on each activity evaluation carried out by students.

The final result of the course (E_w) should be calculated as the weighted average of all evaluation criteria M_i averages, as shown:

$$E_w = \frac{\sum_{i=1}^n (M_i \cdot w_i)}{\sum_{i=1}^n (w_i)} \quad (1)$$

IV. METHODOLOGY

The research was conducted during the years of 2011, 2012 and 2013. This case study involved five courses in the Information Systems Program and Computer Networks Program at the Federal University of Ceará, Brazil. The case study involved the following steps:

1. Problem validation through interviews with professors and Information Technology professionals;
2. Literature review;
3. Development of the pedagogical proposal;

4. Implementation and evaluation of the proposal in one undergraduate course;
5. Refinement and organization of the method;
6. Implementation and evaluation of the proposal in four undergraduate courses;
7. Tabulation and result analysis;
8. Results publishing.

A. Instrument

Professors are periodically evaluated by students in undergraduate programs at UFC, Ceará, Brazil. We used an institutional assessment system, currently under test at the institution, called SAVI. We applied a questionnaire with 29 items designed to assess a professor in four dimensions: management of teaching activities, development of teaching activities, communication and interaction with students, use of results from students learning evaluation.

The 29 questions answered by students to evaluate the professor in their relative course are shown in Table 4. Professors can view results of their evaluations by students at the end of an evaluation process, either generally or tabulated by course. The system also allows partial assessments that can be made during the course, allowing the teacher to identify problems during the planning execution, and to correct them as required.

TABLE IV. QUESTIONS ANSWERED BY STUDENTS IN PROFESSOR EVALUATION AT UFC

Q1) Professor presented the course-teaching plan upon commencement of course?
Q2) Professor discussed the course-teaching plan upon commencement of course?
Q3) Professor clarified the meaning and importance of course for the program?
Q4) Does the course teaching plan show the content planning?
Q5) Does the course teaching plan contain the general and specific objectives?
Q6) Does the course teaching plan contain a description of the contents / units?
Q7) Does the course teaching plan contain the teaching methodology?
Q8) Does the course teaching plan contain the forms and rules of learning assessment?
Q9) Does the course teaching plan contain the basic and complementary bibliography?
Q10) Professor demonstrates organization and logical sequence to teach the course content.
Q11) Professor uses plain language to improve content understanding by students.
Q12) Professor utilizes appropriate didactic procedures to meet the course objectives.
Q13) Professor streamlines the classroom, promoting activities that encourage student participation.
Q14) Professor clearly guides the requested work solution.
Q15) Professor establishes the relationship between theory and practice, respecting the specific course.
Q16) Professor encourages student's critical thinking.
Q17) Professor knows the course content components area.
Q18) Professor highlights crosscutting issues (social, environmental, cultural, ethical, scientific, etc.), related to course content.
Q19) Professor maintained adequate ethical and professional attitude in the classroom.
Q20) Professor encourages students to obtain high performances.
Q21) Professor respects any student's limitations or failures.
Q22) Professor arrives punctually in class.
Q23) Professor is assiduous.
Q24) Professor maintains good relationship with students.
Q25) Professor establishes clearly, the criteria for assessment of student learning.

Q26) Professor uses assessment practices that value reflection and problem solving issues.
 Q27) Professor uses evaluation forms compatible with the goals and teaching content.
 Q28) Professor uses evaluation forms that capture effectively, the actual student learning.
 Q29) Professor uses evaluation results for feedback and consolidates student learning.

Besides the use of the evaluation questionnaire in the system, the researchers still proceeded with semi-structured interviews with all of the students enrolled in the course, in order to know their preference concerning the adopted practice in relation to traditional practices experienced so far in the undergraduate courses, aiming to identify the strengths and weaknesses of the teaching method and their learning results.

B. Population and Sample

The target population included the professors and students enrolled in each course ($N_1 = 15$, $N_2 = 51$, $N_3 = 18$, $N_4 = 23$, $N_5 = 19$). Thus, the student sample was formed by 107 students enrolled in the evaluated courses during the two years of study, whereby they responded to the questionnaire for evaluating their professors, and also participated in an interview about the specific impact of pedagogical practice adopted on their results in each course.

V. CASE STUDY AND RESULT ANALYSIS

There was the evaluation of five undergraduate courses: Information Systems Advanced Topics, IT governance, Entrepreneurship, Information Systems Management, all within the Information Systems Program, and the Information and Communication Technology Management course within the Computer Networks Program.

We used a PBL-based strategy [10] in some specific classes for this purpose in all evaluated courses. The PBL classes were performed and programmed to follow the course's content. The problems were proposed and solved by small groups of students with teacher facilitation. The students had access to the Internet during the PBL sessions.

In addition to classes using PBL, the proposed method allows the professor to schedule classes where the student will carry out research aimed at solving real cases as applied or even mentioned in books or papers. There were dynamic classes to improve student participation and involvement. Whenever possible, there was a market topic insertion related to what was being presented. In a complementary manner, some works were executed in the classroom and others at home. These studies consisted of: studies on important topics, presentation of summary papers, resolution of public tender tests, and study of best guidance practices adapted for each course topic, whereby trying to consider the current industry standards.

With these integrated actions, researchers established a link between the courses and the market, whereby there was a large increase in student interest. The research strategy in the classroom proposes linking teaching with the research faculty, thus becoming student partners in the search for knowledge, combining theory and practice as partners in the educational process. Aiming to meet the research goal in the course, professors developed research on the identification and

assessment of the course's related problems, which took place during classes and as an external activity.

It is important to emphasize that students evaluated these points in a positive manner, as can be seen from some reports by students obtained during the interview taken after a course lesson:

- "The professor was able to associate course content with topics of the market";
- "Troubleshooting evidence procurement motivated me to deepen my knowledge [...]";
- "Each class had a goal and a different motivation for the course";
- "I am motivated and also thinking about a new business";
- "I want to get a management certificate."

Complementary works were carried out in the classroom and at home, including studies on important topics, presentation of articles summaries, proofs resolution, as well as monitoring of industry standards and the state of the art related to each course.

The proposed method consists of a major advantage, whereby it allows the professor to use creativity in order to plan classroom and home activities, which can improve aspects related to the courses.

A. Some Results

The first case study involved the evaluation of the proposed pedagogical practice in the *Information Systems Advanced Topics* course (*Information Systems Program*). This case was presented in our previous work [13]. The course had fifteen students, which facilitated the implementation of our strategy. This is because we didn't have facilitators involved in the experience (to minimize limitations of many students in class). The university lecturer's function does not exist in Brazilian universities. Importantly, the UFC campus at Quixadá has multimedia features in sufficient quantity for all courses, thus enabling the planning of lessons based on the use of software tools with additional Internet access in the classroom. Our objective was to improve student motivation in relation to course, to create an effective link between the course and the computing profession, and to acquire knowledge of collective construction. The pedagogical course planning was presented and discussed with students throughout the rest of the course, adapting it as necessary. We listened to students' suggestions and adapted the class planning during the whole experience.

The innovative teaching methodology was also one of the strengths indicated in interviews related to this course. The professor implemented oriented works, PBL-based lessons, research presentations, reading books and journal reviews. To improve final results in the course, the professor established a workshop that was totally organized and presented by the students. The course studies consisted of: studies on advanced topics, presentation of summary papers, resolution of public tender tests, and study of best IT governance guidance practices (ITIL and COBIT), which are considered to be the current industry standards.

The professor evaluation by students in this course is shown in Figure 3. Positive indicators were verified in all evaluation dimensions, with percentages greater than or equal to 90% on all questions (evaluation performed by 53.33% of the students in the course). We observed that students issued

and shared information about IT governance importance through means of social networks (i.e. Facebook). Final course results and our innovative strategy were announced in a positive manner among students, which in turn, generated a demand by a new offer for this specific course in other undergraduate programs. An empirical result that strengthens the researchers argument is the fact that our strategy improved the student evaluation mean (8.9 in course), which indicates a very good result. Student evaluation mean in previous courses during last two years was around 7.6.

We continued our study and the proposed method was applied in the year 2012 in two courses. We worked with two scenarios: One course with as few as 18 enrolled Information and Communication Technology Management students and the other course consisting of 51 enrolled Information Systems Management students.

There was a need to evaluate this phase of the study because a vast amount of enrolled students would hinder the process of applying the method, a fact that was expected by the researchers. The context of each course in program and the impact of using the results of the method at the end of each course were evaluated. In some activities during two course evaluation (2012-2013), the professor used as a communication channel for all students, the blog called Simplifying IT Governance. This blog was created based on students' suggestion, after the first evaluated course in 2011.

It was observed that the profile of the students enrolled in the two courses was very heterogeneous, whereby the *Information and Communication Technology Management* course had been formed by mature students with a tendency to be more engaged, they had providing and executing activities in the classroom. Heterogeneous students, some of which were in the second year of their program and others in their first year in program, also formed the other evaluated course.

A large number of the 51 enrolled students in the Information Systems Management course class had great difficulty in achieving interaction between themselves, the professor and the planned activities implementation. The researchers identified a certain lack of student motivation, especially among the students undergoing their first year in program.

These identified aspects and difficulties had a negative impact on the method application and on the overall result of professor evaluation by students in this course. Figure 5 shows the course evaluation scatter highlighted in red. 44% of students enrolled in the course evaluated the professor. There was a downward trend in the average of professor evaluation. The poor final results of these students in the course may have had an impact on professor evaluation by students of this group and may have influenced the overall result.

We refined the method to the following two courses, which were evaluated in 2013, discarding the worst grade in each group of classroom activities; in order to minimize the impact of students justified absences on the student's final grades. We obtained promising professor evaluation results in the most evaluated courses during this study. Figure 4 shows the

professor evaluation by students during IT Governance course in 2013.

Figure 3. System general results of professor evaluation by students in first evaluated case [13]

Professors executed some classroom activities in these courses during our study, following our method guidance. The research strategy in the classroom proposes linking teaching with the research faculty, becoming student partners in the search for knowledge, whereby combining theory and practice as partners in the educational process. Aiming to meet the research goal in the IT governance course, we developed research on the identification and assessment of managing IT service problems, taking place during classes and as an external activity.

Figure 4. System general results of professor evaluation by students in IT governance course - 2013

Interviews results indicated that the most students liked our method activities, executed during the five evaluated courses (87%).

B. Discussion

The overall results of the proposed method were promising, as can be seen in Figure 5 and Figure 6, whereby only one evaluated course obtained a poor professor result. This happened because the student's profile, high level of classroom absence, too many enrolled students, among many other identified reasons.

The results average (Figure 6) for each professor evaluation question was good and researchers could observe that the method interested the majority of the students. The only course where researchers didn't obtain similar results was Information Systems Management (2012). As showed, we identified the reasons that caused this result.

Figure 5. Course's professor evaluation results scatter graph

Figure 6. Professor evaluation average results by questions in all courses

TABLE V. AVERAGE INCREASE OF STUDENTS' GRADES

Course	Increase Percentage
Advanced Topics in Information Systems	17%
Information and Communication Technology Management	20%
Information Systems Management	5%
Entrepreneurship	28%
IT Governance	23%

Is there evidence that students have learned the subject being taught? In interviews, 87% of the students answered yes. Some students enrolled in *Information Systems Management* course related some learning problems, because they had missed several classes, and thus no longer participated in many activities. Table 5 shows the increase percent of the average students grades in the five evaluated courses. Researchers used the previous student average grades in the same courses to calculate these percent. The student's results in four courses were promising, indicating that the proposed method can increase the students' performance, at least in the evaluated cases.

VI. CONCLUSION AND FUTURE WORKS

This paper presented a mixed pedagogical method in the classroom, which was applied in two undergraduate programs held at a Brazilian university.

The researchers obtained important results that can be used by professors in similar experiences. The strategy generated positive results in terms of increasing student motivation in evaluated courses, with an improvement of final student results and a disclosure of the importance of courses between the other students.

Our mixed pedagogical method used the combination of important pedagogical strategies, with promising results. The professor evaluation by students was promising, whereby the researchers observed the reduction of disaffection in classes, improvement in the relationship between professor and students, and also the establishment of a link between the acquired knowledge of the course with the market. The planning activities were considered very good in the students' assessment, whereby classroom planning presentation and discussion clarified the course importance, content information, objectives and bibliography. The students preferred the proposed practice in relation to traditional practices experienced by them so far in the courses.

The multi-criteria evaluation based upon student participation during the courses in various activities, both theoretical and practical, at home and in the classroom, was cited by students as being fairer and more motivating than just simply tests and theoretical work. There was observed an improvement in student results and professor evaluations in four of the five cases. In these four courses, researchers used the method with all requirements being met. The proposed method needs a scenario to a favorable application. In a single course assessment, where the results were not promising, the professor tried to apply the method presented in a course with 51 enrolled students, without the help of facilitators, whilst still facing other restrictive factors already presented in the results analysis.

Professors need to customize assessment activities, according to each course nature in the proposed method. There is a difficulty in applying the method in classes with large numbers of students, where it is essential that the professor require the assistance of a facilitator, in order to implement the method, especially during the PBL activities in the classroom. Researchers suggest the help of a facilitator for each group of 18 students in a class. Classes with low attendance of students can hinder the method application. There was a great difficulty with the evaluation of students who had missed several classes, and thus no longer participated in many activities. Excluding some notes related to these activities was a possible solution to this problem.

Results showed that a differentiation innovative method in the classroom could improve course results. The overall results of the professor evaluation by students were solid and reliable.

In future work, professors can use some facilitators in order to help them in courses. The use of different learning strategies proposed in literature is a possible way to improve our method results in further studies. Other possible work would be to evaluate these practices in other knowledge areas and undergraduate courses.

ACKNOWLEDGMENTS

The authors would like to thank professors and students at Federal University of Ceará, campus Quixadá. This research has been partially supported by Fundação Cearense de Pesquisa e Cultura (FCPC) and CNPQ.

Modeling Student Perceived Costs and Benefits to Cooperative Education Programs (Co-ops) and Pathways to Participation

Beata Strubel, Joyce Main, Nichole Ramirez, Jake Davis, Matthew Ohland

Engineering Education

Purdue University

West Lafayette, IN USA

bstrubel@purdue.edu, jmain@purdue.edu, nramire@purdue.edu, davis455@purdue.edu, ohland@purdue.edu

Abstract— Cooperative education programs alternate education and practice, resulting in increased grade point averages, greater confidence in choice of career, and relatively higher post-graduation salaries. This study examines perceived benefits and barriers for students who choose not to participate in co-ops. Since students who participate in co-ops are more likely to persist in STEM fields, and there are differences in participation rates by race/ethnicity (i.e. Black and Hispanic students participate at lower rates), it is critical to understand the reasons for non-participation. Co-op and non-co-op students from a large Midwestern U.S. research university were surveyed and the responses are disaggregated by gender and race/ethnicity. Choice Theory provides a theoretical framework to model perceived benefits and costs of co-op participation. Decision tree modeling is used to describe the different pathways to co-op participation and examine relationships between student backgrounds and pathways. Constant comparative analysis is used to study open-response questions. Future work will include follow up interviews with students from this survey to gain a more nuanced understanding. Findings have implications for the diversification for the engineering labor force.

Keywords— cooperative education, pathways to participation, Choice Theory, cost benefit analysis, barriers to participation

I. INTRODUCTION

Co-op students gain industry experience before graduation, developing relevant job skills through application of classroom learning. These experiences may enhance students' self-efficacy and increase their confidence in choice of major [1]. Furthermore, co-op students often receive job offers from their employers, and studies show they receive higher starting salaries as well [2]. Additional benefits of co-op are well established in existing literature. However, reasons that some students do not participate in co-op is not well understood. This work will contribute to the body of knowledge by examining perceived costs and benefits of co-op participation for co-op and non-co-op students.

Different pathways exist for students to pursue or not pursue co-op opportunities. This study identifies critical points that students choose to exit or proceed along the pathway to co-op participation. Identification of these critical points will help stakeholders improve policies and communication with students to increase interest and participation in co-op. The

pathways analysis identifies common pathways to co-op participation, and highlights critical points where students choose not to participate in co-op. Stakeholders can use these findings in conjunction with findings about perceived costs and benefits to strategically reach students and address barriers to co-op participation. This study provides key findings about different pathways to co-op participation and increases knowledge about how students perceive co-op costs and benefits.

II. BACKGROUND

A. Benefits to Co-op Participation

Benefits of co-op participation have been well explored in literature. Cooperative education provides work experience prior to graduation as students alternate semesters between work and school, usually completing three or five school/work rotations. Reference [3] found that co-op participation provides experiential learning opportunities that increase student engagement and enhance student learning. Evidence indicates that students involved in these "educationally meaningful activities," such as co-op, demonstrate higher levels of persistence and higher rates of completion in education. Additionally, reference [4] found that co-op students earn higher cumulative grade point averages (GPA) than non-coop students in engineering majors. Beyond graduation co-op students have higher starting salaries, in agreement with research by reference [2]. Reference [2] also found that co-op students are more likely to be employed after graduation. Reference [5] confirmed that co-op students have increased job market prospects, providing strong evidence that co-op participation rate for low ability students increases dramatically in times of low average wage growth.

Furthermore, co-op students exhibit greater certainty about career choice [6]. These students were more likely to have first jobs related to their major and overall career plans. Reference [6] noted that co-op students showed enhanced self-efficacy, which is beneficial in sustaining academic performance and persistence to graduation. Reference [7] also explored student perceptions of learning in the classroom and experiential learning in industry. Benefits of experiential learning include increased ability to view career expectations realistically, increased network of professional contacts, and increased

leadership skills. These experiences provide greater career clarity for co-op students [8].

B. Co-op Program Challenges

Few studies research why some students do not participate in co-op. Reference [9] explored challenges facing cooperative education in the twenty-first century since its launch in 1906 at University of Cincinnati. Reference [9] noted that the term co-op is used to describe various types of work-based learning, suggesting that defining features of co-op include exposure to professional workplaces, socialization in the workplace, development of professional identity, and integration of knowledge into on-campus learning. Reference [9] identified integration between work and school as a fundamental component of co-op and an area that could be improved. Reference [10] also researched experiences of co-op students and noted that participants found their co-op experience worthwhile overall, but individual work experiences had some disadvantages, such as quantity of work during terms, range of work term choices, and support from employers. Understanding students' reasons for not participating in co-ops will help programs improve policies and the co-op experience, and increase interest in co-op participation.

C. Theoretical Framework: Choice Theory in Educational Decision Making

Researchers have used Choice Theory as a theoretical framework to model educational decision making. For example, reference [11] used Choice Theory as a theoretical framework to model educational decisions made by students and their families. Reference [11] explained model choices as decisions made by evaluating costs and benefits of different educational options. This model explained how gender differentials in levels of education have decreased, while class differentials in educational attainment persist. The model was based on secondary effects, defined as choices made by the individuals, rather than primary effects, which encompass levels of ability. Reference [11] aimed to explain differences in educational attainment through differences in choices made by individuals, assuming that choices are influenced by students' expectations about likelihood of succeeding in respective options.

Researchers can apply this framework to analyze survey data. Reference [12] analyzed how European researchers apply rational choice theory in research using survey data. Key concepts of this theory include available alternatives, expectations, and costs and benefits. Rational choice theory assumes that individuals consider the costs and benefits of available options when making a decision and form expectations about the consequences of these actions. For example, a student considering cooperative education would evaluate the costs and benefits of participating in co-op and also consider possible results of participation compared to possible results of participation in alternative activities. Reference [12] explained that researchers can evaluate choices in two ways – 1) directly, by surveying individuals about expectations and perceived costs and benefits, or 2) indirectly, by measuring individuals' actions. Continuing the above example, a researcher could ask a student about perceived costs and benefits of co-op or could record the student's decision to

co-op or not to co-op. Reference [12] advocated applying both strategies in research.

Reference [13] furthered research on social class and educational decision-making of students through rational choice theory. Reference [13] analyzed decision-making within French schools in choosing secondary school tracks, suggesting that students and families evaluate the costs and benefits of an educational track and the likelihood of succeeding in completing that track. Reference [13] postulated that students analyze benefits of each track in the context of maintaining social class position, in line with the model of "relative risk aversion" described by [11]. Reference [13] used bivariate analysis to explore potential association between social class and selected variables related to decision-making. We use the above methods to understand how students perceive costs and benefits of co-op participation in this research.

III. METHODS

The study includes a large Midwestern research university with a voluntary co-op program that offers 3-session and 5-session plans. Co-op students alternate session of academic study with sessions of work with a qualified employer and are expected to stay with the same company throughout the program. Formally initiated in 1954, the program now serves over 1,100 students and more than 300 active employers from private industry and government agencies. While the program serves students in eight different colleges across the university, the College of Engineering has the largest enrollment.

We developed the survey based on input from co-op program coordinators and pilot interviews from Spring 2014 [14]. Co-op program coordinators identified several different ways in which students can enter the program and the pilot interviews informed the questions regarding perceptions. We also collected demographic information such as gender, race/ethnicity, citizenship, and major. Using Qualtrics, we created one survey with several logic steps that categorized students into three groups:

1. Current co-op participants
2. Students who are interested in the program, but not participating
3. Students are not interested in co-op

We used both a quantitative and qualitative approach to analyze survey results. The survey contained both closed- and open-ended response questions about perceptions of co-op, experiences in the process of obtaining co-op placement, and demographic information.

We emailed the survey, developed with input from co-op program coordinators, to 1,938 students who completed the second course of the foundational engineering sequence. Of these students, 286 students responded to the survey for a response rate of 14.8%, which is consistent with the expected response rate for an electronic survey [15]. 136 of these students are co-op participants, and 1,802 students are non-participants. These students were eligible to apply for co-op in Spring 2014. The sample consisted of 69.4% male, 30.6%

female; 72.3% White, 20.2% Asian, 4.5% Hispanic, 0.4% Black, 2.5% other; 86.3% domestic, 13.7% international.

We analyzed responses using descriptive and bivariate statistics of survey questions. Additionally, open-ended responses were coded to analyze perceived costs and benefits of the co-op program. We analyzed open ended responses with constant comparative analysis [16].

IV. RESULTS

We identified students in three categories – 1) current co-op participants, 2) students who are interested in co-op, but not participants, and 3) students who are not interested in co-op. Table I shows the proportion of students in each category. Composition of respondents when disaggregated by gender, US citizenship, and race/ethnicity is comparable to the overall undergraduate engineering population at this large Midwestern research university.

TABLE I. FREQUENCIES OF STUDENTS IN CO-OP INTEREST LEVEL CATEGORIES

<i>Category</i>	<i>Frequency</i>	<i>Percentage of Total (n=286)</i>
Not Interested	143	50.0
Interested, but non-participant	59	20.6
Current co-op participant	59	20.6

^a. Total is not 100%, because the remainder of students did not know about the program or preferred not to answer

A. Pathways to Co-op Participation

Survey results indicate multiple pathways to co-op participation and non-participation. From the survey, five critical points were identified in the path analysis – 1) interest, 2) information, 3) application, 4) interview, and 5) participation. Not all respondents were aware of the program. In fact, about 8.7% of all respondents were unfamiliar with co-op programs. Of the students who knew about co-ops, approximately half indicated they were not interested in co-ops (see Table I). Of non-participants, only 29.2% indicated they were interested in the program (see Table II). Critical points along the pathway to co-op are summarized in Table II. The percentages are calculated within each group of students, co-op and non-co-op.

TABLE II. CRITICAL POINTS ALONG PATHWAY TO CO-OP AWARENESS AND PARTICIPATION

<i>Pathway to Co-op</i>	<i>% of Co-op Students</i>	<i>% of Non-Co-op Students</i>
Aware of Co-op	100.0	89.0
Heard About Co-op from Family	23.7	13.7
Heard About Co-op from Class	40.7	61.7
Heard About Co-op from Promotion	64.4	51.5
Interested in Co-op	100.0	29.2
Applied through Co-op Program	78.0	10.5
Interviewed through Co-op Program	27.1	8.4

A potentially influential piece of awareness and interest in the co-op program is how students learn about the co-op program. We asked students how they heard about the co-op program – from class/professor, from friend, from family, from promotional material, or other. Students could select more than one option. A greater proportion of co-op students indicated they heard about co-op from family (23.7%) compared to their non-co-op peers (13.7%). A greater portion of non-co-op students heard about the program in class (61.7%) compared to co-op students (40.7%). However, a greater proportion of co-op students indicated they heard about the program from promotional materials (64.4%) compared to non-co-op students (51.5%). Follow up interviews with students will explore the influence of each of these information sources on students' decision to choose co-op or not.

Interested students have the opportunity to attend an informational session about co-op to learn more about the program. In the aggregate, including co-ops and non-co-ops, 71.2% of all students interested in co-ops attended an information session about co-op, and 53.6% of these students who attended the information session ultimately participated in co-op. Of the interested students who did not attend the information session, 41.2% participated in co-op. The results suggest that informational sessions are a critical point in which students decide to participate in co-op.

Students who complete an application through the co-op program may then interview through the co-op program. Table II shows that 78.0% of co-op students indicate that they completed an application through the co-op program. Of those students who completed an application, 58.0% of them indicated they interviewed with companies through the co-op program, while 37.7% indicate they interviewed either through a career fair or directly with a company. Of the students who indicated they interviewed through the co-op program, 50.0% participated in co-op. Overall, 33.9% of co-op participants indicate that they obtained their co-op placement by interviewing through the co-op program. Alternative paths include interviewing through a career fair or interviewing directly with a company.

We asked students to rate their experiences with the co-op program on a scale of very satisfied to very dissatisfied in four areas – application process, interview process, company matching, and responsiveness to questions/concerns. On average, co-op students indicate they are satisfied to very satisfied in all four areas. Non-co-op students are, on average, slightly satisfied with the application process, interview process, and question response. However, non-co-op students are, on average, slightly dissatisfied with the company matching. These are students who may have completed the application, but did not continue the process after being dissatisfied with the company match.

Co-op students may participate in a three-session or five-session co-op. The majority (63%) of co-op students in this survey are participating in a five-session co-op. About 43% of these five-session co-op students obtained their placement by an application through the co-op program. In contrast, 4.8% of three-session co-op students obtained their placement by an application through the co-op program. The remaining co-op

students obtained their placement through a career fair or through direct interview with a company.

B. Co-op Students' Perceived Benefits of Co-op

Using Choice Theory as a framework to understand student's decision making processes, we asked students directly about perceived costs and benefits of the program. Co-op students' perceptions of the program's benefits are comparable to the existing literature. While these students list advantages of co-op similar to those found in literature, they speak about these benefits in different ways. Table III lists perceived advantages in ranking order (1 being the most common). 80.0% of co-op students list work experience as a benefit of co-op, and 28.8% of these students list having a competitive edge in the job market as a benefit. Students respond that participating in co-op provides a competitive edge before their first job, leading to "easy placement" and increased job prospects. Co-op students say that they build their resume and will be able to advance in their career more quickly. Furthermore, 49.2% of students list money as a benefit to the co-op program. Students indicate that they "become financially stable" since the salary is better than that of a campus job and that participating in co-op helps pay off loans.

TABLE III. PERCEIVED BENEFITS BY CO-OP STUDENTS

Co-op Participants	1.	Work Experience
	2.	Money
	3.	Competitive edge in job market
	4.	Job training
	5.	Networking
	6.	Career exploration

Co-op students emphasize the career benefits to participating in co-op. They are either less interested or not aware of additional benefits surrounding improved academic performance and confidence in major choice. Some students do refer to gaining "practical knowledge in the field," increasing "awareness of tools and practices in the related industries for my major," and "applying things learned in the classroom." 25.4% of co-op students list job training as a benefit of co-op, while 5.1% view application of classroom learning as a benefit.

C. Perceived Disadvantages of Co-op Participation

Perceived costs of co-op participation differ for co-op students and non-co-op students. Table IV compares perceived cost by both groups of students listed by ranking order (1 being the most common). Co-op students most often list disconnect with peers on campus as a disadvantage to co-op, whereas non-co-op students list increased time to graduation and preference of internships over co-op. 33.9% of co-op students list disconnect with peers on campus as a cost of co-op. Co-op students describe "falling behind friends in classes," "becoming disconnected with friends established in first two years of school," being "difficult to build relationships with people not co-oping," and having "personal disadvantages like difficulty holding relationships and friendships with people at [school]."

TABLE IV. PERCEIVED DISADVANTAGES BY CO-OP AND NON-PARTICIPANTS

Co-op Participants	1.	Disconnect with peers on campus
	2.	Time to Graduation
	3.	Missed Opportunities on Campus
	4.	Off schedule in classes
Non-co-op Students	1.	Time to graduation
	2.	Prefer Internship over Co-op
	3.	Missed Opportunities on Campus
	4.	Commitment to 1 company/industry

In contrast to academic benefits cited in literature to co-op participation, co-op students describe costs of co-op participation surrounding their academic studies, including "making planning for future academic endeavors quite difficult," "significant gaps between challenging coursework," "spending so much time away from school makes it more difficult," and "getting off track with your major."

Non-co-op students list concerns about extending time to graduation and missing opportunities on campus. These students mention desires to participate in other programs, such as study abroad, graduate school, and leadership opportunities within campus organizations. They believe that internships will better fill their needs by "not putting off my graduation date," "not missing any semesters of school," having "the ability to change companies," not "being limited to one company for all terms," and "gaining experience at several different companies (large and small)."

V. DISCUSSION

Both co-op students and non-co-op students list time to graduation and missed opportunities on campus as disadvantages of co-op. That perceived inflexibility of the program has been mentioned by co-op and non-co-op students as a reason for pursuing other experiences than co-op. Literature cites academic advantages of co-op, yet co-op students list being off schedule in classes as a disadvantage of co-op. As reference [9] suggested, co-op programs could improve in integration between school and work. Increased integration could also assist in lessening the perceived disadvantage of disconnect with peers on campus and inability to enjoy other aspects of college for co-op students.

Understanding the decision processes for not pursuing co-ops and the different pathways to co-op participation is useful because co-op programs and employers can use this information to understand how students utilize their programs. Knowing the pathways various students enter the program, schools have the ability to better market their programs and services to students. Employers can also use this information to help them create environments that are more likely to draw in students wanting a co-op. Further, to the extent that barriers to minority participation can be addressed, co-op program staff can recruit a more diverse group of participants.

Based on our analysis of the pathways, we identified several critical points that have implications for potential changes and improvements for different stakeholders interested in increasing and diversifying co-op participation. For example, at the awareness stage, we found co-op participants are more likely to have learned about co-op through family and

promotional materials. This leads to the importance of everyone having correct information. If parents or peers are misinformed early, they may pass on incorrect, discouraging information to potential co-op students. Also, providing more information for students whose parents/peers have not encouraged them to participate may help improve awareness of the benefits of co-op participation to those that did not have family or peer influence. At the interest stage, presentation of co-op benefits can be improved by addressing perceived disadvantages listed by non-co-op students. Co-op administrators, educators, and employers can explain to students how the co-op program provides opportunities for career exploration and professional development. Stakeholders can also provide more information about how co-op students can transition smoothly between school and work. Additionally, at the application stage, non-co-op students indicate they are least satisfied with company matching. Increased communication and clarity around this process could improve students' satisfaction and interest in co-op participation. Additionally, the discrepancy between five-session and three-session application pathways identifies a need for further investigation of co-op program policies.

Non-co-op students express preference for internships over co-op positions. Future research will clarify reasons for this preference. Clarification of what a co-op entails and its flexibility may address this perceived disadvantage and also alleviate concerns about committing to one company/industry. It is interesting to note the difference in perception between co-op students and non-co-op students about the commitment of co-op. Non-co-op students express concern about committing to one company/industry, while co-op students embrace commitment to a company in which they are interested to gain a competitive edge. Co-op students view career exploration as a benefit to co-op, while non-co-op students fear that co-op will limit their opportunities for career exploration by committing to one company/industry. These non-co-op students say that internships will better fill this desire.

VI. IMPLICATIONS AND FUTURE WORK

Future work includes conducting interviews with survey respondents to gain a more nuanced understanding of perceived costs and benefits. Additional insight can be gained by understanding if and how co-op students' perceptions change when they begin the program. Interviews will also increase understanding of non-co-op students' reasons for being less satisfied with the company matching process and why they chose not to participate.

Understanding of critical points in the path to co-op participation will help both co-op programs and employers present the benefits of co-op and possibly increase interest and participation in co-op while lessening concerns some may have about the program. Knowledge of student perceptions of costs and benefits to co-op participation will help co-op programs and institutions convey benefits of co-op participation to students to increase awareness and interest. These programs should consider the influence of family and promotional materials when communicating information about the co-op program. Employers can also gain insight about the interview process and how to convey information about their co-op

programs. For instance, they can focus on highlighting the flexibility of co-ops and opportunities for career exploration. Additionally, they can emphasize opportunities for career development and gaining practical knowledge for the workplace.

This work will also help to further the engineering education field as a whole. Understanding the costs and benefits students consider when making decisions regarding their professional training will help schools develop programs to fit those needs. Students will then be able to choose from programs more suited to fit their needs and desires allowing engineering students to graduate with the knowledge and experience needed to excel in an area they know will be of interest to them.

ACKNOWLEDGMENT

The authors thank the National Science Foundation for support of this research (Award 1329283: Access to Cooperative Education Programs and the Academic and Employment Returns by Race, Gender, and Discipline), as well as Eckhard Groll, Stephen Wanders, Tina Alsup and the SPHERE Lab for their helpful feedback and assistance. Mapping Career Success Competencies to Engineering Leadership Capabilities

Robyn Paul & Dr. Lynne Cowe Falls
Schulich School of Engineering
University of Calgary
Calgary, Canada

Abstract—Societal expectations of twenty-first century engineers have dramatically changed over the past few decades. There is a need to educate engineers not just in technical subjects, but also in many non-technical areas including globalization, communication, and leadership. There has been a growth of engineering leadership education programs offered by postsecondary engineering institutions. The effectiveness of these programs is often measured by the student's acquisition of skills, without considering the benefit of these skills on the students' careers. Using the career success competencies model, this paper seeks to determine if engineering leadership education impacts career success. The theoretical mapping analysis indicated a positive relationship between engineering leadership education and career success. The most significant competencies related to an engineer's career success were career insight, proactive personality, openness to experience, and lifelong learning.

Keywords—boundaryless career; career success; engineering leadership; engineering leadership education

I. INTRODUCTION

Engineering education has had an increasing focus on outcomes-based education. National organizations, such as ABET and CEAB (Canadian Engineering Accreditation Board) now mandate the attributes that students graduating from engineering institutions will have achieved. These attributes are designed to be the skills required for engineers to succeed in today's society, including essential technical knowledge and skills, as well as nontechnical skills, attitudes and character traits.

Over the past decade, there has been a growth of teaching and learning activities focused on the professional skills in engineering. Often to measure the success of these activities, students are assessed before and after. If the appropriate skills are gained, the activities are concluded to be successful in producing a more competent engineer. However, a key element missing in this assessment process is the measurement of whether or not possessing these professional skills is beneficial to an engineer's career.

This paper will focus specifically on the skill of engineering leadership. Leadership education programs have recently had a high rate of growth and development in post-secondary engineering institutions. A 2009 summary of engineering leadership education found that the majority of the 70 programs reviewed were less than 5 years old [1]. The

question then follows, does engineering leadership education have an impact on career success?

To analyze the relationship between engineering leadership and career success, first there must be a clear method of how to measure career success in engineering. General career success measurement instruments have been researched for decades [2], and a widely accepted model of career success will be presented. The model will be analyzed for inclusion of specific requirements of career success within the engineering industry. Then, the model of career success competencies will be mapped to engineering leadership capabilities. This mapping will provide a basic foundation for the link between career success and engineering leadership.

II. CAREER SUCCESS COMPETENCIES

A. Boundaryless Career

At the end of the 20th century, traditional assumptions about employment had changed, and people were able to obtain sequences of experiences across both organizations and employers [3]. It was apparent that employees were no longer restricted to a single organization throughout their career.

The term boundaryless career was introduced in 1993 [4]. Boundaryless careers are simply defined as "sequences of job opportunities that go beyond the boundaries of single employment settings" [5]. Hierarchical relationships are broken down, and there is increased an ability to move across occupational careers and employers [4].

B. Measurement of Career Success

There are two types of career success typically discussed in literature: objective and subjective. Objective career success includes extrinsic measures such as salary, upward mobility, and managerial level [3]. Subjective career success includes intrinsic measures, where individuals are able to evaluate their own career success through "self-defined aspirations, values, needs, standards and career stages" [6].

In the past, career success was commonly associated with extrinsic measures such as increased salary and upwards progression within an organizational hierarchy. However, modern boundaryless careers often have lateral movement within organizations, and these extrinsic measures of career success are no longer valid measurements.

Subjective career success represents a judgement on career accomplishments and a sense of progress towards career goals [3]. These intrinsic measures are more suitable for the boundaryless career. Common examples of intrinsic measures include career satisfaction surveys [7], career commitment [8], wage satisfaction [3], and marketability [9].

C. Career Competencies Model

To cope with the complexity and change of a boundaryless career, three required career competencies were identified by DeFillippi and Arthur in 1994: knowing-why, knowing-whom and knowing-how [5]. Career literature has focused considerable effort on defining, verifying, and conceptually explaining these competencies [10]. The extensive research and verification available is the reason these three career competencies were chosen for the analysis in this paper.

Firstly, the knowing-why competency focuses on the individual's career motivation, personal meaning and identification [5]. It considers the individual's willingness to explore different possibilities, and ability to adapt to change in one's work environment [9]. This competency is associated with awareness of one's needs, abilities, interests, and aspirations related to work-experiences, as well as one's self-concept and self-identity [10].

Next, knowing-whom refers to an individual's career-related connections, both within and outside the organization. It is characterized not only by development of relationships, but also in how these relationships are utilized [10]. An extensive network is beneficial to the individual as a resource, a new source of learning, and an attained reputation [5].

The final career competency, knowing-how, emphasizes an individual's broad and flexible knowledge. This includes the portfolio of career skills and job skills that are useful across organizational boundaries. Knowing-how also includes the aptitudes of continuous learning and opportunity development, which can be defined as one's career identity [9].

Eby, Butts, and Lockwood used these three competencies as the basis for developing a model to measure career success [9]. In their model, each career competency is associated with two or three intrinsic variables for career success. Table 1 provides a summary of the instruments used to measure each variable. Many of these instruments were developed by others. The original source of each instrument and the number of items used in the model is also indicated in Table 1.

This model uses different instruments that have been verified and validated. It provides an excellent overview of the variables required to measure subjective career success and will be used for the analysis in this paper. However, it is widely accepted that subjective career success is a multi-dimensional construct, and the instruments used in Eby, Butts, and Lockwood's model are all single-dimensional [11]. Although this is a recognized limitation of the model, multidimensional career success criteria has only recently been developed, and there is not yet a well validated model.

TABLE I. SUMMARY OF INSTRUMENTS USED BY EBY ET AL. [9] TO MEASURE VARIABLES OF CAREER SUCCESS.

Career Success (CS) Variable	Original Source (as cited in [11])	No. of Items
CS1. Knowing-Why		
- Career Insight	[12]	3
- Proactive Personality	[13]	10
- Openness to Experience	[14]	8
CS2. Knowing-Whom		
- Mentorship	[9]	1
- Internal Networks	[9]	3
- External Networks	[9]	4
CS3. Knowing-How		
- Career / Job Skills	[9]	5
- Career Identity	[15]	4
Perception of Career Success	[7]	5

III. ENGINEERING CAREER SUCCESS

An individual's own importance level of the career satisfaction elements can be influenced by their occupational context. It has been shown that people from diverse occupational backgrounds will interpret the measures of career success differently [16]. It is therefore important to consider career success within an engineering context. Limited literature exists in the field of measuring engineering career success. However, three contextual aspects of engineering career success were determined based on the available resources.

Firstly, lifelong learning is fundamental for success in the 21st century engineering career [17]. Staying abreast with the most recent technological advancements is essential for being innovative and creative. In the career competency model, lifelong learning is included in the variable "career identity".

Secondly, a study in the engineering construction industry found the most critical aspect to fostering a successful career path was developing a professional network [18]. This includes networking, mentorship, training, and constructive feedback, and is covered in the knowing-whom competency.

The same study found that young engineers were aware that they were primarily responsible for their own career development and self-improvement [18]. Further studies have shown that students desire to participate in their learning process and to be proactive players in improving their learning [19]. This third aspect of engineering career success relates to the model's "proactive personality" variable.

All three of these aspects are included in the model, thus the career competency model recommended in Table 1 is appropriate for measuring engineering career success. However, the relative importance of these three aspects may be different in an engineering context and should therefore be given special consideration.

Overall, there is a dearth of literature on measurement of career success in an engineering context. Further research in this area would be beneficial for a more concrete understanding of engineering career success.

IV. ENGINEERING LEADERSHIP CAPABILITIES

Engineering leadership has been highlighted as an important skill for engineers to be able to succeed in their 21st century careers by many, including in the National Academy of Engineering's publication *The Engineer of 2020* [20] and in the recent CDIO syllabus update [21].

It is important to note that leadership skills are beneficial to all engineers, regardless if they plan to pursue leadership roles. Professional skills such as communication, time management and self-reflection are valuable across every engineering discipline. All engineers must be prepared to work in a team environment when solving technical problems [22].

The Gordon-MIT Leadership Program (GLP) was launched in 2007 and aims to develop the next generation of technical leaders [23]. GLP customized a model for engineering leadership, which contains six central capabilities of effective engineering leaders, as shown in Table 2 [24]. The full list of individual skills is provided later in Fig. 1, and full descriptions can be found on the GLP program website [23].

The GLP model was chosen for the mapping analysis. This model was initially designed based on the definition of leadership from the MIT Sloan School of Management. Over the years, the GLP model has been continuously refined and updated. It is highly reputable within the field of engineering leadership, and was used as reference for the extension to the CDIO syllabus, *Leading Engineering Endeavors* [21].

V. MAPPING CAREER SUCCESS COMPETENCIES TO ENGINEERING LEADERSHIP CAPABILITIES

The analysis seeks to map the career success competencies (Table 1) to the capabilities of effective engineering leaders (Table 2). The scope of this paper will discuss only the one-way mapping procedure, and will not address the relationship in the opposite sense. Although each individual engineering leadership capability is important to be an effective engineering leader, each capability may not be required for a successful career. The paper seeks to understand which variables of career success are taught in engineering leadership programs, and this can be achieved through the one-way mapping analysis.

Each career competency variable definition was compared with the individual leadership capabilities to determine if there was a link. Links were classified as "Strong", "Medium", or "Weak". A strong link showed a high level of similarity, often with synonymous words and phrases being used. Medium links had similar concepts that were being applied in a different context. A weak link showed little similarity in the meaning, even though the broad topic may have been the same.

The classification process was done following a constant comparative method. After each variable was classified, it was compared with the other variables classified at that level to ensure consistency. At the end, each variable was compared with the variables that had been classified at different levels. This ensured the difference between strong, medium, and weak links was clear and consistent.

TABLE II. SUMMARY OF CAPABILITIES OF EFFECTIVE ENGINEERING LEADERS DETERMINED BY [24].

Engineering Leadership (EL) Capability	Description
<i>EL1. Attitudes of Leadership</i>	Reflection on beliefs and attitudes; sense of responsibility; foundational leadership skills
<i>EL2. Relating</i>	Develop relationships; listen to others; understand diverse viewpoints; advocate for your position
<i>EL3. Making Sense of Context</i>	Understand the context of leadership; comprehend and explain complex environment simply to others
<i>EL4. Visioning</i>	Create purposeful images of the future; identify what could and should be
<i>EL5. Delivering on the Vision</i>	Move from abstraction to innovation, invention, and implementation
<i>EL6. Technical Knowledge and Reasoning</i>	Deep working knowledge of discipline; understand, decompose, and recombine elements of technical problems

A summary of the mapping is shown in Fig. 1, and the remainder of this section details the reasoning for each link and classification of strength.

A. Knowing-Why (CS1)

The three variables associated with knowing-why were career insight, proactive personality and openness to experience. Each of these mapped to skills in EL1, "attitudes of leadership".

1) *Career Insight*: Career insight is defined as having realistic career expectations, and an understanding of one's strengths and weaknesses [9]. An individual skill included in EL1 is "self-awareness and self-improvement". This includes awareness of one's own personal, interpersonal, and professional skills [24], strongly linking with the definition provided previously of career insight.

2) *Proactive Personality*: The tendencies to identify opportunities, to take action, to demonstrate initiative and to persevere are elements of a proactive personality. An individual skill listed in EL1 is "initiative". This skill is described as the willingness to create a vision and take action, and teaching students the importance of being proactive, which shows a strong link to a proactive personality.

3) *Openness to Experience*: This is defined as individuals who are "imaginative, curious, broadminded and active" [9]. In EL1, the skill "resourcefulness, flexibility and change" includes the ability to be adaptable, and willingness to take alternative courses of action. Both of these skill definitions show an openness to experience and have a strong link.

B. Knowing-Who (CS2)

The three variables associated with knowing-who were mentorship, internal networks and external networks. These variables each had a medium link to skills in EL2, "relating".

1) *Mentorship*: Developing a mentoring relationship was described in CL2 as important for developmental experiences, visibility and exposure, as well as a valuable source of learning [9]. One of the individual skills in EL2 is

“interpersonal skills”, which includes “coaching and teaching, and providing and receiving evaluation and feedback” [24]. A medium link is shown, as mentorship is not directly mentioned, however similar elements are emphasized as those in the provided career competency definition.

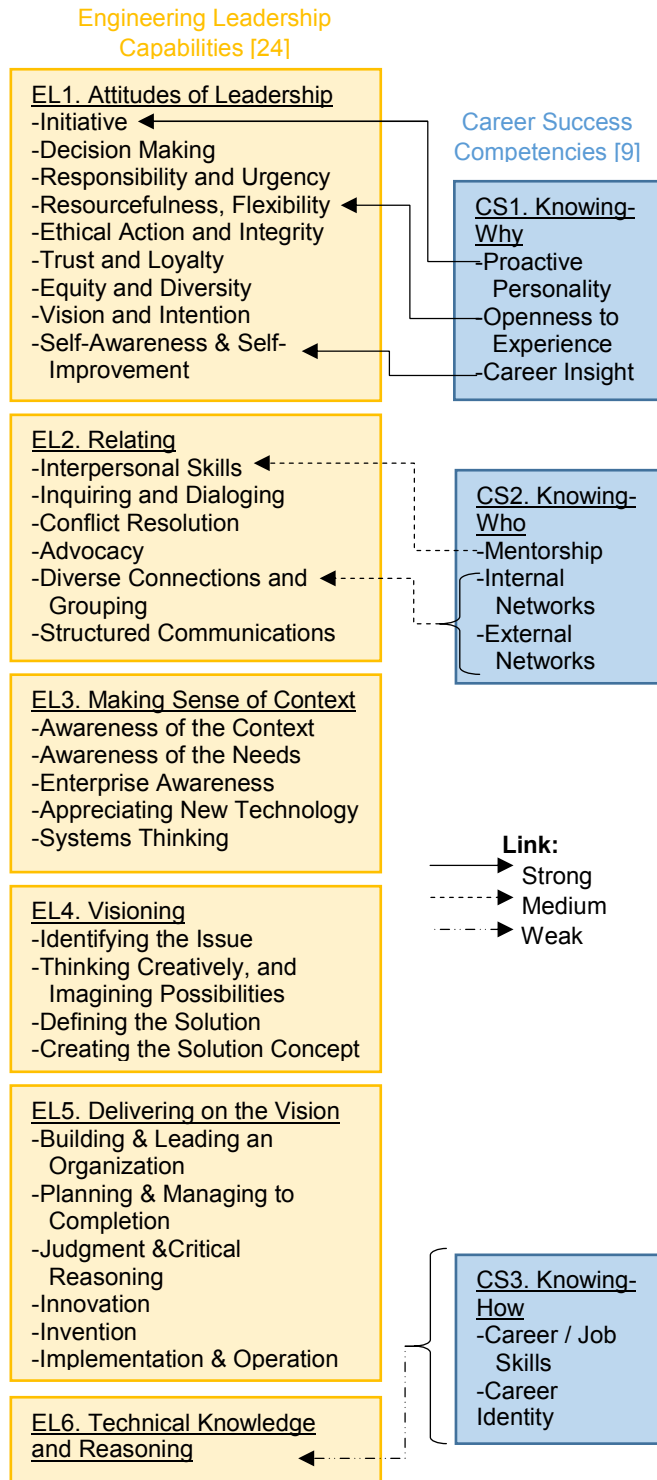

Fig. 1. Mapping between career success competencies [9] and engineering leadership capabilities [24].

2) *Internal and External Networks*: These two CS2 variables were defined as individuals being well connected for support and development within their company, as well as outside of the company. They do not map to separate skills of EL2, but rather to one individual skill called “Diverse Connections and Grouping”. This skill emphasizes connecting with diverse groups of people who have different backgrounds, skills and experiences to “help achieve the goals and technical solutions” [24]. The slightly different meaning of the two definitions shows a medium link.

C. Knowing-How (CS3)

The two variables associated with knowing-how were career / job skills and career identity. This career success competency had the weakest link to engineering leadership capabilities, however it mapped to skills mostly within EL6, “technical knowledge and reasoning”.

1) *Career / Job Skills*: The emphasis of this competency is on the transferability and flexibility of one’s career skills, rather than just the career-related skills themselves. EL6 only discusses the importance of discipline specific technical engineering skills, without mentioning that the skills should be portable. However, EL5 discusses the need for leaders to be able to manage change, which could be interpreted indirectly as a need for flexible skills. Although these engineering leadership skills have some similarity, the link is weak.

2) *Career Identity*: Career identity also has a slight link to EL6, “technical knowledge and reasoning”, however career identity was defined as continuous improvement and opportunity development. Continuous improvement is mentioned in the leadership capability EL1, where it discusses proactive planning for continuing education and future careers. Opportunity development is included in EL5, “develop approaches to incorporating competence outside of one’s enterprise” [24]. Overall, only a weak link is observed.

VI. DISCUSSIONS

All of the career competencies mapped to engineering leadership capabilities, with varied levels of strength. The career competency with the highest link strength was knowing-why, which mapped strongly to EL1, “attitudes of leadership”. Additionally, it has been shown that knowing-why is the greatest predictor of career success [10]. Therefore, if engineering leadership education programs are able to foster “attitudes of leadership” in their students, this is a good indication that there would be an improved level of career success.

Knowing-how has been shown to be the second most influential career competency on career success [10]. A skill included in knowing-how, lifelong learning, was also emphasized as a critically important skills in the engineering literature [17]. However, knowing-how was the competency with the weakest link to engineering leadership capabilities.

Lifelong learning is also not mentioned in the definitions of leadership provided by the CDIO Syllabus extension “Leading Engineering Endeavours” [21] and the National Academy of Engineering [20]. Although both organizations include lifelong

learning skills in their general engineering attributes, they are not specifically mentioned in the skills of engineering leaders. This skills is essential for all engineers to succeed in the fast paced technological innovation of the 21st century, particularly those interested in leadership activities [17]. To improve the success of graduating engineering leaders, it would be beneficial to include lifelong learning in leadership programs.

There is a common maxim, “it’s not what you know, it’s who you know,” and this often is the case. The engineering career success literature supported this where professional networks were determined to be an important aspect of an engineer’s career success [18].

However, in the general literature, networking has been shown to have little impact on career success [10], [25]. This contradiction could be due to the style of networking. Supervisor-focussed networking (i.e. championing) can increase career success, whereas self-promotion can tend to decrease career success [26]. The type of career success being measured (objective vs. subjective) may also effect the correlation observed with networking. Regardless, networking, mentorship and building relationships is important for students for many reasons other than career success (e.g. visibility, exposure, improved learning experiences, and guidance) and should continue to be a part of engineering leadership education programs.

The importance that different elements of leadership have on success in the engineering industry should also be considered. One study showed socio-emotional intelligence (including verbal expression through assertion, emotive availability, and inspiration) had the strongest correlation to successful leadership compared to personality and mathematical-logical intelligence [27]. It is notable that again, this emphasizes the importance of knowing-why (emotional intelligence), over knowing-who (personality) and knowing-how (math-logic intelligence).

It is also important to consider how engineers perceive themselves as leaders. As stated by Rottman, Sacks and Reeve, “engineering leadership depends on engineers recognizing themselves as leaders” [28]. One of the largest barriers to engineering leadership at postsecondary institutions is that leadership activities supported by engineering faculties are primarily through optional extracurricular involvement. Students may view these experiences as exterior to their essential learning experiences, and thus decide not to participate. However, the results from this analysis show that participation in engineering leadership education programs could improve a student’s career success.

Lastly, postsecondary institutions are often expected to produce an extremely well-rounded graduate with a wide variety of skills and abilities. The divide between academia’s responsibility and industry’s responsibility is not well defined. Are there variables within the career competency model that should be the responsibility of industry to develop and foster within their employees? For example, perhaps lifelong learning should be considered a skill that is expected to be taught outside the context of engineering education.

VII. CONCLUSION

Based on the theoretical analysis, all of the career success competencies mapped to engineering leadership capabilities. The skills with the strongest link were those that mapped to the knowing-why competency. The most significant variables related to an engineer’s career success were career insight, proactive personality, openness to experience, and lifelong learning.

Overall, the theoretical results suggest that teaching engineering students skills in leadership would have a positive impact on their career success. These results are valuable to all engineering students, not just those who plan to pursue a career path in leadership.

The analysis performed for this paper was entirely theoretical and the conclusions should be taken with care. Further verification and validation is required to fully understand the relationship between engineering leadership education and career success. Also, the classification procedure was based on the author’s interpretations of the competencies, capabilities, and the strength of their relationship. The potential bias should be taken into consideration.

VIII. FUTURE RESEARCH

Literature on engineering career success is very minimal. This area requires further exploration to provide insight on the contextual importance of the career success competencies in engineering [16]. Investigation of the bias of an individual’s perspective in engineering could also help to gain a more clear view of the field.

The career success model recommended in this paper could be used as a measure for engineering institutions doing curricular development. Using the model would allow institutions to determine the influence their efforts are having on students’ career success. Concrete data such as this would improve the validity of the conclusions made from the theoretical analysis.

Future research could conduct a similar analysis, instead comparing the career competency model to the graduate attributes provided by national accreditation bodies, such as ABET or CEAB. This would provide theoretical insight to the engineering attributes that most enhance career success.

Abstract—This paper introduces the Professional Engineering Pathways Study (PEPS), a three-year study aimed at developing new understandings of early career engineering career preparedness and decision-making. The project takes a national perspective, drawing on data from six partner institutions across the U.S., and focuses specifically on engineering students' experiences, perceptions, and plans as they look toward their initial career steps. The project involves two critical elements. The research element uses a longitudinal, mixed-method approach to examine how engineering students explore, select, and prepare for their chosen careers. The community of practice element focuses on bridging research-to-practice by engaging administrators, faculty, and staff at the six partner institutions in data interpretation and dissemination activities. This research will help drive continuous improvement in engineering programs and universities. Preliminary results of the study will be presented at the conference.

Keywords—college-career transition; preparedness; decision-making; expectancy value theory; cognitive information processing theory; longitudinal; mixed-methods; community of practice

I. INTRODUCTION

U.S. economy needs a diverse and highly qualified engineering workforce, and yet the engineering profession still struggles to attract and retain talent. Fewer than 10 percent of incoming college students in the U.S. pursue engineering as a major [1], and according to data from the National Science Foundation [2], less than half of graduates with engineering as their highest degree pursue careers related to engineering. Concerns about a future shortage of engineers have led to many calls to increase engineering retention, e.g., [3-4]. Yet, these calls often focus on retention in the major or among experienced workers and fail to consider the 30 percent of men and 40 percent of women who leave the field almost immediately after earning undergraduate engineering degrees [5]. To increase retention during the college-career transition, we must learn more about the factors contributing to early

career engineering attrition [6], and particularly, “problematic attrition”. Margolis & Kotys-Schwartz [7] define attrition as problematic if an individual is “pushed away” from engineering by negative experiences and beliefs as opposed to being “pulled away” by other interests or circumstances.

Although literature on the college-career transition of engineers is limited, we can draw on existing literature to inform our inquiry. Several studies have focused on undergraduate students' plans to pursue engineering or non-engineering career options after graduation. For example, Margolis & Kotys-Schwartz [7] explored the decisions of mechanical engineering seniors at a western U.S. institution to pursue engineering careers at graduation and in the future. Ro [8] investigated the plans of engineering sophomores, juniors, and seniors at 31 institutions to pursue six different engineering and non-engineering career options within three years of graduation. Amelink & Creamer [9] identified correlates of long-term engineering career interest among engineering undergraduates at nine institutions. This collective body of research identifies groups of education-related variables that seem to differentiate engineering focused plans from non-engineering plans. These variables include participation in curricular and extracurricular activities such as senior capstone design, co-op/internships, and student organizations for underrepresented groups [7,8], exposure to active/collaborative learning and professional and core engineering skills [8], and positive interactions with engineering instructors, faculty members, and other students [7,9]. Drawing on these findings, we can directly examine how these activities inform students' career decision-making processes.

Our inquiry is also informed by the results of two NSF-funded research studies: the Academic Pathways Study (APS) and the Engineering Pathways Study (EPS). APS was sponsored by the NSF Center for the Advancement of Engineering Education (NSF-ESI-0227558) from 2003 to 2008 for the purposes of studying the undergraduate engineering learning experience. APS was a longitudinal study that

This research is funded by the National Science Foundation (NSF) as a collaborative research grant (NSF-EEC-1360665, 1360956, and 1360958).

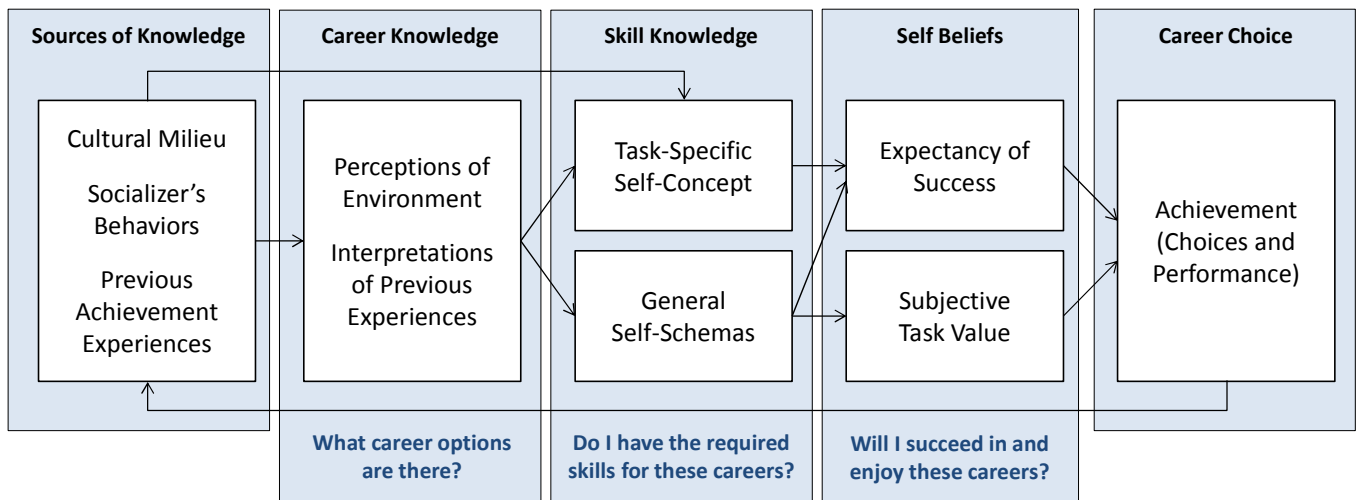

Fig. 1: Professional Pathways Model: Cognitive Information Processing (CIP) Theory [22] as a Lens for Expectancy Value Theory (EVT) [23]

followed cohorts of students across their undergraduate years using qualitative and quantitative data collection [10-11]. EPS was then a continuation study (NSF-DUE-1020678, 1021893, 1022024, 1022090, and 1022644) that examined a sub-set of some of these same participants 4-5 years into their careers [12-14]. Surveys of engineering students and alumni were also conducted as a part of APS and EPS, respectively, for broader sampling [15-16]. Results from EPS showed that 80 percent of early career engineering graduates reported first positions in engineering work [17]. However, results from APS indicate that less than 30 percent of engineering juniors and seniors plan to stay exclusively within engineering fields long-term [18-19]. Within APS and EPS, participation in an engineering co-op/internship and majoring in certain fields differentiated engineering and non-engineering first positions and engineering and non-engineering student plans [17-19]. We also learned through EPS that family, the economy, and other non-school factors can contribute heavily to post-college career plans [20-21].

The APS and EPS studies allowed us to examine experiences broadly across the college-career trajectory. At the same time, we found that a closer look at the college-career transition (college to first job or graduate school) was needed as participants had made significant decisions and changes in careers between college and 4-5 years post-college. Our study follows students directly from college into the postgraduate world enabling us to study how students' first career decisions unfold and which factors become more or less salient to their career decision-making over time. Our study focuses on the three-year period from students' junior year to 1-2 years after earning their bachelor's degrees, as this enables us to explore what happens before and after they graduate. The study takes on a national perspective, drawing on data from six partner institutions across the U.S., and has a specific objective of bridging research findings to practice. To achieve this goal, we designed a two-tiered, mixed-method study with the following sub-goals:

- To investigate how engineering students develop beliefs about their career options and abilities, and how these

beliefs influence their career plans and preparation over time, and

- To engage university administrators, faculty, and staff in using insights into early career decision pathways to improve undergraduate engineering programs and career services.

Anticipated outcomes of our study include a qualitatively rich and quantitatively broad data set on the engineering college-career transition, communities of practice dedicated to improving educational practice at each partner school, and a model for using longitudinal data to inform continuous improvement within engineering schools.

II. THEORETICAL FRAMEWORKS

While several school-related factors (e.g., choice of institution, choice of major, participation in on-campus and off-campus activities) have been linked to engineering students' plans, how these and other factors actively work to influence plans remains largely understudied. Using the Professional Pathways Model (see Figure 1), our goal is to explain how engineering students' experiences and beliefs serve to shape their career goals and actions.

We created the Professional Pathways Model by adapting cognitive information processing (CIP) theory [22] as a lens for expectancy value theory (EVT) [23]. CIP theory describes categories of knowledge that individuals need to make career choices, such as knowledge about what career options exist and what skills these careers require. EVT illustrates how this knowledge is formed (e.g., from cultural representations such as the media, family members and friends, past experiences, etc.) and how it influences individuals' career decision-making (i.e., through expectancies and values). Both theories have shown good results when applied to engineering students, e.g., [24-26].

In parallel with our research effort, we purposefully utilize a community of practice framework [27] to navigate the research-to-practice cycle and disseminate our findings. We will characterize the career "ecosystem" at each of our partner

sites, and then leverage these existing infrastructures to build communities both locally and across schools.

III. STUDY DESIGN

The overall study design is illustrated in Figure 2. The project involves two critical and inter-connected elements, the research element and the community of practice element, each of which are driven by a separate set of questions.

Research Element—For the first time, longitudinal data connecting engineering students’ experiences, beliefs, and career choices will be collected. Through annual surveys and in-depth interviews, we will follow engineering students at six

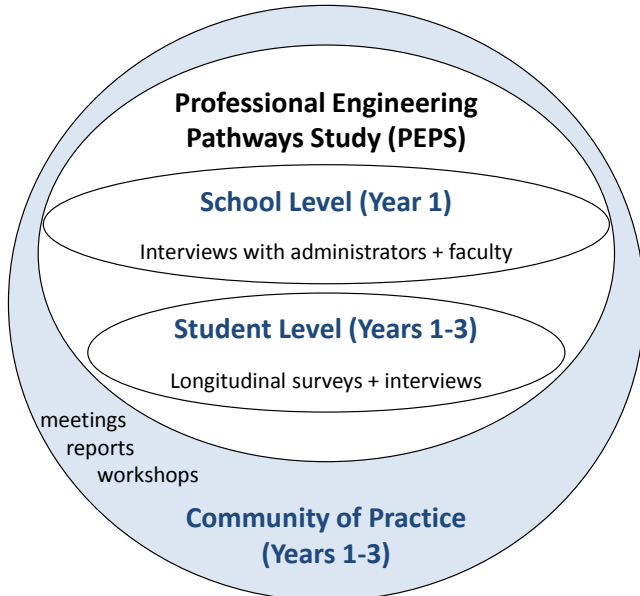

Fig. 2: PEPS Study Design

partner schools, from their junior year to their first 1-2 years post-graduation. These surveys and interviews will be grounded in the Professional Pathways Model and will answer these research questions:

- Career Knowledge: What career options are available to engineering students? How do students develop knowledge of these options?
- Skills Knowledge: What skills and abilities do engineering students need to prepare for, choose, and succeed in their careers? How do students develop knowledge and proficiency in these skills and abilities?
- Career Decision Making: What career goals, values, and expectancies do engineering students have? How do these develop and change over time? What career choices do engineering students make after graduation, and how does their career and skills knowledge affect their decisions?

Data collection at the school level will focus on developing a more complete picture of the career “ecosystems” in which our longitudinal student participants are embedded. This will help us to understand not only what career resources and opportunities are available to students at each partner school,

but also the greater institutional and regional culture in which students are making their career choices. In the first year of the study, we will collect interviews with career services related staff and faculty at each partner institution. These interviews will be supplemented by content analyses of each school’s career services and advising websites.

Community of Practice Element—Findings from the research element of the study will feed directly into the community of practice element. Project results and recommendations will be disseminated back to the partner institutions through annual reports and meetings with our school liaisons, and we will regularly solicit their feedback to support future directions of the project. Working with our partner institutions, we will also determine best practices for broader dissemination and community-building. Using Wenger et al.’s [27] community of practice model as a guide, we will answer the question:

- Educational Impact: How can findings gathered from the research element be used to strengthen the career advising and preparation of engineering students?

Partner Schools—A major aim of our study is to explicate both the personal and the contextual factors which influence engineering students’ career decision-making. The six partner schools in our study were therefore selected for their geographic, institutional, and student diversity. We have two schools each from three different regions in the U.S. (the east coast, the Midwest, and the west coast). We have a mix of public and private schools, as well as predominantly white institutions (PWIs) and schools that serve historically underrepresented groups.

Participants—Table 1 lists the cohorts of participants that will make up PEPS. Also shown are the descriptions, anticipated numbers of participants, and data to be collected for each cohort.

TABLE 1: PEPS STUDY COHORTS

Level	Cohort	Description	Estimated # participants	Data collection
Student	1	Engineering class of 2016	800	longitudinal surveys
	2	Subset of Cohort 1	90	longitudinal interviews
School	3	Career services staff and faculty	18	interviews

In 2014, our six partner schools awarded approximately four thousand undergraduate engineering degrees [28]. Based on this number and our retention rates in the APS and EPS studies, we expect at least 800 engineering students to participate in our survey, from their junior year to 1-2 years post-graduation.

We will also choose 15 students from each school to participate in a longitudinal semi-structured interview. These students will be chosen based on their demographic information and baseline survey responses. We are particularly interested in capturing the stories of underrepresented individuals (e.g., underrepresented racial/ethnic minorities, women, transfer students), for which our institutional sample is particularly well-suited. In addition, we are targeting three

different engineering majors to allow for direct comparability between disciplines: mechanical engineering (ME), electrical engineering (EE), and bio-X (i.e., biological, biomedical) engineering. These majors were selected because students in these majors tend, on average, to pursue different career paths, with ME and EE students among the most likely to pursue engineering focused careers after college and bio-X engineering students among the least likely to [17-19].

Lastly, our third cohort will consist of at least three administrators, faculty, and staff from each partner institution, for a total of 18 across the six schools. These participants will come from university career services, engineering career services, or one of the three majors that we are targeting for this study (i.e., ME, EE, or bio-X engineering). We will interview this cohort as a part of our school-level data collection efforts in Year 1 of the study. We will also invite them to participate in data interpretation and dissemination activities later in the project as part of our community of practice element.

IV. CURRENT STATUS

Interviews of career services related staff and faculty across all six participating schools are in progress. The selection and recruitment of participants were guided by both our web content analyses and recommendations from our school liaisons. All interviews are being audio recorded and transcribed. Transcript analysis will use common qualitative analysis approaches [29-30] to identify pertinent themes by school, by role (e.g., head of career services, faculty, etc.), and by level (e.g., at the institution level, in the major, etc.). These results will be shared with our partner institutions later this year. Design of longitudinal student surveys and interviews will also be underway later this year, aiming for deployment at the six schools in early 2016.

V. PRELIMINARY FINDINGS

Our preliminary findings are based on interviews with faculty and administrators at two of our partner sites. We found that the focus of the career services and advising offered to students can vary across institutions which has necessitated having a nimble and reactive data collection protocol. For example, one site uses high student contact means (e.g., seminars, career fairs, and one-on-one meetings) to support student career search goals at an institutional-level, while career services at another site consists mainly of individual departments directing students to resources if and when students request help. Preliminary findings support our intended plan of using six institutions of various types and sizes so that we can compare and contrast across cases.

ACKNOWLEDGMENT

The authors acknowledge the PEPS research team including Helen Chen, Amy Engelman, Shannon Gilmartin, Gary Lichtenstein, and George Teye. We also thank our study participants and partner school liaisons.

Abstract—The electrical and electronics engineering technology (EEET) associate degree program at Hafr Al-Batin Community College (HBCC) located in the Kingdom of Saudi Arabia (KSA) got accredited recently by the engineering technology accreditation commission (ETAC) of ABET. In this paper, we have described in detail our experiences of using the faculty course assessment report (FCAR) methodology for the direct and indirect assessment of both course learning outcomes (CLO's) and ABET student outcomes (SO's) supported by the cooperative (co-op) training (EEET 290) course in the EEET unit at HBCC. Furthermore, the paper demonstrates how the student's evaluation by his supervisor is also taken into account while assessing both the EEET 290 CLO's and its respective ABET SO's using the FCAR tool. In addition, we have also analyzed the student's self-evaluation of his co-op training experience. Moreover, we have also compared the co-op training given to our students by Saudi Aramco, Saudi Electricity Company (SEC), and Saudi Telecom Company (STC). In this comparison, we have highlighted some strengths and weaknesses of the co-op training offered by these companies. Finally, the results of our analysis are used to propose actions for the continuous improvement of co-op training course in the EEET program at HBCC.

Keywords—ABET accreditation, assessment, cooperative (co-op) training, course learning outcomes (CLO's), engineering technology program, faculty course assessment report (FCAR), student outcomes (SO's).

I. INTRODUCTION

The faculty course assessment report (FCAR) [1]–[3] is a streamlined assessment methodology that allows course instructors to write assessment reports in a concise and standardized format conducive for use in both ABET General Criteria 3 & 4 for accrediting engineering technology programs [4]. The electrical and electronics engineering technology (EEET) associate degree program at Hafr Al-Batin Community College (HBCC) passed the ABET accreditation process [5] by adopting the FCAR as the primary tool for the assessment of both course learning outcomes (CLO's) and ABET student outcomes (SO's). Implementation of the FCAR tool in the

EEET unit at HBCC has served as an effective way for the continuous improvement of all the courses offered by the unit.

The cooperative (co-op) training course is an integral part of the EEET program at HBCC and has the highest number of credit hours as compared to other courses in the EEET program. The co-op training course contributes to 6 credit hours and is coded as EEET 290. The current requirement for enrollment in the co-op training course is that students must have completed at least 48 credit hours and must have maintained a cumulative major grade point average (GPA) of at least 2 [6]. The EEET students at HBCC undergo their co-op training in companies such as Saudi Electricity Company (SEC), Saudi Telecom Company (STC), Saudi Aramco, Saudi Basic Industries Corporation (SABIC), Ma'aden, Schlumberger, Halliburton, etc. Co-op students get trained for a period of one semester (15 weeks) in the industry working in any of the fields of electrical and electronics. The students are required to submit progress reports, final report, and make a presentation at the end of their co-op training.

In our previous paper [7], we had discussed the usage of the FCAR tool for the assessment of both CLO's and ABET SO's supported by the microcontroller applications (EEET 209) course. We had also demonstrated “closing the loop” process for the EEET 209 course using the FCAR tool. In this paper, we discuss how the FCAR tool was customized to analyze the sample data of 3 co-op students from the EEET unit during the spring semester of the academic year 2013–2014 at HBCC. We have also analyzed supervisors' evaluations of co-op students during their training period. This paper also presents a comparison of the co-op training given to our students by Saudi Aramco, SEC, and STC.

The rest of this paper is organized as follows. The CLO's of the EEET 290 course and their assessment methods are discussed in Section II. The grade distribution for the EEET 290 course is presented in Section III. The direct and indirect assessment of both the EEET 290 CLO's and its respective ABET SO's are described in Sections IV & V, respectively. Modifications made to the EEET 290 course and proposed

actions for the EEET 290 course improvement are discussed in Sections VI & VII, respectively. A comparison of co-op training programs of 3 companies is presented in Section VIII. Finally, we conclude our paper in Section IX.

II. EEET 290 CLO'S AND THEIR ASSESSMENT METHODS

We have analyzed the assessments of 3 co-op students for the EEET 290 course during the spring semester (Semester 132) of the academic year 2013–2014 at HBCC. Students 1 & 2 underwent their co-op training at SEC branch in Hafr Al-Batin city under the same supervisor, while student 3 underwent his co-op training at STC branch in Hafr Al-Batin city. All 3 students were assigned different faculty advisors. The co-op students received an orientation session from their respective faculty advisors before the commencement of their training period. During the orientation session, co-op students were advised to spend 40 hours per week (8 hours per day for 5 working days) during their training period. The students were also informed about the due dates to turn in their progress reports, final report, etc. Moreover, the students were also provided with sample copies of all the assessment activities, formatting guidelines, etc. The faculty advisors were also encouraged by the college to arrange company visits. These visits enabled the faculty advisors to check the progress of their students and also meet with their respective supervisors. Furthermore, the co-op students data for different assessment activities such as progress reports, final report, and PowerPoint presentation was collected and graded by their respective faculty advisors. This data together with supervisors' evaluations was then used for the direct assessment of both the EEET 290 CLO's and its respective ABET SO's as described in Section IV.

The CLO's of the co-op training course are listed in Table I. As can be seen from this table, the EEET 290 CLO's focus on the communication, presentation, surveying, technical, and writing skills acquired by the co-op students. CLO's focusing on other skills can be added in the future as a part of the continuous improvement process.

TABLE I. EEET 290 CLO's.

CLO #	Course Learning Outcome
CLO 1	Survey the literature related to your co-op training program.
CLO 2	Develop an ability to communicate clearly and effectively.
CLO 3	Prepare your co-op reports clearly and concisely.
CLO 4	Prepare and explain your co-op PowerPoint presentation.

The mapping of EEET 290 CLO's to ABET SO's is shown in Table II. As can be seen from this table, the EEET 290 CLO's have been mapped to two ABET SO's, namely, (d) & (f). We notice that a majority of the EEET 290 CLO's assess ABET SO (f). ABET SO's (d) & (f) are defined in [4].

TABLE II. MAPPING OF THE EEET 290 CLO's To ABET SO's.

CLO #	a	b	c	d	e	f	g	h	i
CLO 1						✓			
CLO 2				✓					
CLO 3						✓			
CLO 4						✓			

Tables III & IV show the distribution of marks for supervisors' evaluations of co-op students during the first and second

halves of their training periods, respectively. These marks are kept confidential from the students by their respective supervisors and are mailed directly to the co-op coordinator at the college. The co-op coordinator hands over the supervisors' evaluations to the respective faculty advisors. As can be seen from these tables, the supervisors evaluate their respective co-op students based on a list of 10 professional traits. These professional traits are selected by the faculty advisors. It is likely that these supervisors' evaluations may not be reliable and may be affected by a leniency bias [8].

TABLE III. DISTRIBUTION OF MARKS FOR SUPERVISORS' EVALUATIONS OF CO-OP STUDENTS DURING THE FIRST HALF OF THEIR TRAINING PERIOD (SE 1).

Trait	Student 1	Student 2	Student 3
Attendance and Punctuality	1	0.5	1
Attitude	1	1	1
Communication Skills	1	0.5	1
Dedicated	1	1	1
Dependable	1	1	1
Diligent	1	1	1
Motivated	1	1	1
Reliable	1	1	1
Responsible	1	1	1
Self-Disciplined	1	1	1
Total Marks Scored	10	9	10

TABLE IV. DISTRIBUTION OF MARKS FOR SUPERVISORS' EVALUATIONS OF CO-OP STUDENTS DURING THE SECOND HALF OF THEIR TRAINING PERIOD (SE 2).

Trait	Student 1	Student 2	Student 3
Attendance and Punctuality	0.5	0.5	1
Attitude	1	1	1
Communication Skills	1	0.5	1
Dedicated	0.5	1	1
Dependable	1	1	1
Diligent	1	1	1
Motivated	1	1	1
Reliable	1	1	1
Responsible	1	1	1
Self-Disciplined	1	1	1
Total Marks Scored	9	9	10

The abbreviations used in Tables III–XIV are as follows: PR 1 is progress report 1, SE 1 is supervisor evaluation 1, max. is maximum, avg. is average, intro. is introduction, concl. is conclusion, FR is final report, Q&A is questions and answers, and PPT is PowerPoint presentation. In Tables V–VIII, the EAMU is a performance vector with the following four categories [3], [9]: E is for exemplary with a point value of 3, A is for adequate with a point value of 2, M is for minimal with a point value of 1, and U is for unsatisfactory with a point value of 0. Based on the feedback received from the previous FCAR's and depending on the quality of co-op students in the EEET unit, we have set a uniform metric goal of 2 for all the CLO's of the EEET 290 course. In other words, during Semester 132, we were aiming to achieve an adequate level of performance by the co-op students in each of the CLO's of the EEET 290 course.

Table V shows the marks obtained by each of the 3 co-op students in the progress reports and supervisors' evaluations. Tables VI & VII show the marks obtained by each of the 3 co-op students in the final report and PowerPoint presentation, respectively. The maximum marks row vector in Tables V–VII and Table X contains the maximum marks for the corresponding item in the respective column. For example, in Table V,

PR 1 & 2 in the maximum marks row vector are for 10 marks each, while PR Total in the maximum marks row vector shows the combined maximum marks for both the progress reports.

TABLE V. DISTRIBUTION OF MARKS FOR PROGRESS REPORTS AND SUPERVISORS' EVALUATIONS.

Student #	PR 1	PR 2	SE 1	SE 2	PR Total	SE Total
Student 1	7	9	10	9	16	19
Student 2	6	7.5	9	9	13.5	18
Student 3	6	8	10	10	14	20
Max. Marks	10	10	10	10	20	20
E	0	0	2	1	0	2
A	0	2	1	2	1	1
M	3	1	0	0	2	0
U	0	0	0	0	0	0
Avg.	1	1.67	2.67	2.33	1.33	2.67

TABLE VI. DISTRIBUTION OF MARKS FOR FINAL REPORT.

Student #	Intro.	Relevancy	Format	Concl.	FR Total
Student 1	10	8.5	8.5	8	35
Student 2	9	8	10	7	34
Student 3	10	10	8	9	37
Max. Marks	10	10	10	10	40
E	2	1	1	0	1
A	1	2	2	2	2
M	0	0	0	1	0
U	0	0	0	0	0
Avg.	2.67	2.33	2.33	1.67	2.33

TABLE VII. DISTRIBUTION OF MARKS FOR POWERPOINT PRESENTATION.

Student #	Intro.	Clarity	Depth	Concl.	Q&A	PPT Total
Student 1	5	4	3	4	4	20
Student 2	4	4	3.5	4	3.5	19
Student 3	5	5	4.5	3.5	4	22
Max. Marks	5	5	5	5	5	25
E	2	1	0	0	0	0
A	1	2	1	2	2	3
M	0	0	2	1	1	0
U	0	0	0	0	0	0
Avg.	2.67	2.33	1.33	1.67	1.67	2

In Table VIII, the EAMU vector ranges are shown for progress reports, supervisors' evaluations, final report, and PowerPoint presentation. The EAMU vector ranges are decided by the faculty advisors. In Table VIII, range 1 is for the different components of PowerPoint presentation like intro., clarity, etc., range 2 is for PR 1 & 2, SE 1 & 2, and the different components of final report like intro., relevancy, etc., range 3 is for PR Total and SE Total, range 4 is for PPT Total, and range 5 is for FR Total. The EAMU vectors in Tables V–VII are determined by counting the number of students whose assessment marks fall in the respective range category shown in Table VIII. For example, in PR 1 column (see Table V) the marks scored by all 3 students fall in the range we have set for M (see range 2 column in Table VIII). Therefore, the EAMU vector for PR 1 is (0, 0, 3, 0), respectively. Now, the average of the EAMU vector for PR 1 is calculated as shown below:

$$\text{Average} = \frac{0 * 3 + 0 * 2 + 3 * 1 + 0 * 0}{\text{Total number of students}} = 1, \quad (1)$$

where 3, 2, 1, & 0 are the point values of E, A, M, & U, respectively.

III. EEET 290 COURSE GRADE DISTRIBUTION

In this section, we discuss the distribution of grades and the calculation of GPA for the EEET 290 course. The weightage

TABLE VIII. EAMU VECTOR RANGES FOR THE EEET 290 COURSE ASSESSMENTS.

Vector	Range 1	Range 2	Range 3	Range 4	Range 5
E	4.6 to 5	9.1 to 10	18.6 to 20	22.6 to 25	35.1 to 40
A	3.6 to 4.5	7.6 to 9	15.1 to 18.5	17.6 to 22.5	27.6 to 35
M	2.6 to 3.5	5.1 to 7.5	10.1 to 15	12.6 to 17.5	20.1 to 27.5
U	0 to 2.5	0 to 5	0 to 10	0 to 12.5	0 to 20

assigned to each assessment of the EEET 290 course, as shown in Table IX, is decided by all the faculty advisors and is subjected to revision on a timely basis. The lower and upper ranges for each letter grade are the same for all the EEET courses and are shown in Table XIV in [7].

TABLE IX. ASSESSMENT POLICY FOR THE EEET 290 COURSE.

Assessment	Weightage
PR 1	10%
PR 2	10%
SE 1	7.5%
SE 2	7.5%
FR	40%
PPT	25%
Total	100%

The weighted total marks in Table X are obtained by calculating the total marks scored by each student in different assessment activities such as progress reports, supervisors' evaluations, etc., and then scaling down by their respective weightages as shown in Table IX. Note that the maximum marks for SE 1 & 2 in Table V are not the same as those in Table X. This is not a discrepancy. The maximum marks for SE 1 & 2 in Table X are the actual maximum marks assigned by the faculty advisors for supervisors' evaluations as shown in Table IX. Marks obtained by the students for SE 1 & 2 in Table V have been scaled down to 7.5 and then entered in Table X for determining their respective letter grades.

TABLE X. WEIGHTED TOTAL MARKS FOR EACH ASSESSMENT OF THE EEET 290 COURSE.

Student #	PR 1	PR 2	SE 1	SE 2	FR	PPT	Total
Student 1	7	9	7.5	6.75	35	20	85.25
Student 2	6	7.5	6.75	6.75	34	19	80
Student 3	6	8	7.5	7.5	37	22	88
Max. Marks	10	10	7.5	7.5	40	25	100

The distribution of grades for the EEET 290 course is shown in Table XI. As can be seen from Tables X–XI & Table XIV in [7], students 1 & 3 got B+, and student 2 got B. Finally, the GPA for the EEET 290 course is calculated as shown below:

$$\text{GPA} = \frac{Q}{N} = \frac{10}{3} = 3.33, \quad (2)$$

where Q denotes the quality points as defined in [7] and N is the total number of students in Table XI.

IV. DIRECT ASSESSMENT OF BOTH THE EEET 290 CLO'S AND ITS RESPECTIVE ABET SO'S

In this section, we describe how the average EAMU scores obtained from Tables V–VII in Section II were utilized for the direct assessment of both the EEET 290 CLO's and its respective ABET SO's.

TABLE XI. DISTRIBUTION OF GRADES FOR THE EEET 290 COURSE.

Grade	Number of Students
A+	0
A	0
B+	2
B	1
C+	0
C	0
D+	0
D	0
F	0
Total (N)	3

Table XII shows the mapping of EEET 290 CLO's to ABET SO's using the average EAMU scores obtained from Tables V–VII in Section II. For the sake of simplicity, we have used any one assessment for each CLO except CLO 2, wherein, we have considered both the evaluations by the supervisor as can be seen from Table XII. For example, we have selected SE Total, which is found to assess CLO 2. The average EAMU score for SE Total (2.67) obtained from Table V is entered for CLO 2 in Table XII.

TABLE XII. MAPPING OF THE EEET 290 CLO's TO ABET SO's USING AVERAGE EAMU SCORES (DIRECT ASSESSMENT).

CLO #	a	b	c	d	e	f	g	h	i
CLO 1						PR 1: 1			
CLO 2				SE Total: 2.67					
CLO 3						FR Total: 2.33			
CLO 4						PPT Total: 2			
Avg. EPAN	0	0	0	2.67	0	1.78	0	0	0

In Tables XII & XIV, the EPAN is a performance vector with the following four categories [3], [9]: E is for excellent with a point value of 3, P is for proficient with a point value of 2, A is for apprentice with a point value of 1, and N is for novice with a point value of 0. Based on the feedback received from the previous FCAR's and depending on the quality of co-op students in the EEET unit, we have set a uniform metric goal of 2 for all the ABET SO's supported by the EEET 290 course. In other words, during Semester 132, we were aiming to achieve a proficient level of performance by the co-op students in each of the ABET SO's supported by the EEET 290 course. The average EPAN scores in Table XII are calculated by taking the average of all EAMU scores in the respective columns.

Figures 1–4 illustrate the direct assessment of both the EEET 290 CLO's and its respective ABET SO's. Figure 1 shows a plot of the average EAMU scores obtained from Table XII with respect to the EEET 290 CLO's. As can be seen from Figure 1, we have achieved an adequate level of performance by the co-op students in all the EEET 290 CLO's except CLO 1. Figures 2 & 3 show the plots of the average EAMU scores obtained from Table XII with respect to the EEET 290 CLO's supporting ABET SO's (d) & (f), respectively. Figure 4 shows a plot of the average EPAN scores obtained from Table XII with respect to the ABET SO's supported by the EEET 290 course. As can be seen from Figure 4, we have achieved a proficient level of performance by the co-op students in only ABET SO (d) supported by the EEET 290 course.

Fig. 1. Average EAMU Scores For All The CLO's Of The EEET 290 Course Obtained From Direct Assessment.

Fig. 2. Average EAMU Scores For The EEET 290 CLO's Mapped To ABET SO (d) Obtained From Direct Assessment.

V. INDIRECT ASSESSMENT OF BOTH THE EEET 290 CLO'S AND ITS RESPECTIVE ABET SO's

In this section, we describe how the data obtained from the co-op students self-evaluations of the EEET 290 CLO's as shown in Table XIII was utilized for the indirect assessment of both the EEET 290 CLO's and its respective ABET SO's.

The co-op students self-evaluations of the EEET 290 CLO's as shown in Table XIII was conducted at the end of their co-op training by their respective faculty advisors. A self-evaluation of the EEET 290 CLO's provides an opportunity for the co-op students to evaluate their level of accomplishment of CLO's. In Table XIII,

- 4 is strongly agree,
- 3 is agree,
- 2 is neutral,
- 1 is disagree, and
- 0 is strongly disagree.

The scaled averages in Table XIII are calculated as described in

Fig. 3. Average EAMU Scores For The EEET 290 CLO's Mapped To ABET SO (f) Obtained From Direct Assessment.

Fig. 4. Average EPAN Scores For The ABET SO's Supported By The EEET 290 Course Obtained From Direct Assessment.

[7]. As expected, the indirect assessment of both the EEET 290 CLO's and its respective ABET SO's is not reliable because all students tend to either agree or strongly agree that they have accomplished the CLO's, as can be seen from Table XIII.

TABLE XIII. CO-OP STUDENTS SELF-EVALUATIONS OF THE EEET 290 CLO's.

CLO #	4	3	2	1	0	Scaled Avg.
CLO 1	1	2	0	0	0	2.49
CLO 2	2	1	0	0	0	2.75
CLO 3	3	0	0	0	0	3.00
CLO 4	2	1	0	0	0	2.75

Table XIV shows the mapping of the EEET 290 CLO's to ABET SO's using the scaled averages obtained from Table XIII. Figure 5 shows a plot of the average EPAN scores obtained from Table XIV with respect to the ABET SO's supported by the EEET 290 course. As can be seen from Figure 5, we have achieved a proficient level of performance by the co-op students in both the ABET SO's supported by the EEET 290 course. As can be seen from Figures 4 & 5, the average

EPAN scores for ABET SO (f) do not match.

TABLE XIV. MAPPING OF THE EEET 290 CLO's TO ABET SO's USING SCALED AVERAGES OBTAINED FROM TABLE XIII (INDIRECT ASSESSMENT).

CLO #	a	b	c	d	e	f	g	h	i
CLO 1						2.49			
CLO 2				2.75					
CLO 3						3.00			
CLO 4						2.75			
Avg. EPAN	0	0	0	2.75	0	2.74	0	0	0

Fig. 5. Average EPAN Scores For The ABET SO's Supported By The EEET 290 Course Obtained From Indirect Assessment.

Finally, the co-op students evaluations of academic preparation, faculty advisors, supervisors, co-op trainings, and co-op organizations are shown in Table XV and Figure 6. From Figure 6, it is easy to determine the ratings for academic preparation, faculty advisors, etc., for each student. This determination of rating for each item of each student was not possible from Table XV.

Fig. 6. Co-op Students Evaluations Of Academic Preparation, Faculty Advisors, Supervisors, Co-op Trainings, And Co-op Organizations.

TABLE XV. CO-OP STUDENTS EVALUATIONS OF ACADEMIC PREPARATION, FACULTY ADVISORS, SUPERVISORS, CO-OP TRAININGS, AND CO-OP ORGANIZATIONS.

Sl. #	Item	4	3	2	1	0
1.	The academic preparation for my co-op training was adequate.	2	1	0	0	0
2.	I received adequate communication from my co-op faculty advisor.	1	2	0	0	0
3.	My supervisor adequately explained my responsibilities.	1	2	0	0	0
4.	My supervisor was always available when I needed assistance.	0	2	1	0	0
5.	My co-op training was closely related to my career interests.	2	1	0	0	0
6.	I would like to recommend this organization for future co-op students.	2	1	0	0	0

VI. MODIFICATIONS MADE TO THE EEET 290 COURSE

The below modifications were made to the EEET 290 course during the spring semester of the academic year 2013–2014 after reviewing the proposed actions section of its FCAR from the fall semester of the same academic year. This demonstrates “closing the loop” process for the EEET 290 course.

- CLO 1 focusing on the surveying skills acquired by the co-op students was introduced and assessed.
- The weightages assigned for the final report and PowerPoint presentation assessments were swapped.
- Indirect assessment of both the EEET 290 CLO's and its respective ABET SO's was done by utilizing the data obtained from the co-op students self-evaluations of the EEET 290 CLO's.

VII. PROPOSED ACTIONS FOR THE EEET 290 COURSE IMPROVEMENT

First, it is proposed to reduce the number of credit hours of the EEET 290 course from 6 to 3. This proposal is made because the number of credit hours for the co-op training course in five other similar ABET accredited programs in the Kingdom's colleges is 3. For the remaining 3 credit hours, the EEET unit at HBCC can consider introducing a project work course, thus keeping the same number of total credit hours required for the EEET associate degree program.

Second, it is proposed to conduct only one evaluation by the supervisor with a weightage of 7.5% for the entire co-op training period. This proposal is made because the supervisors' evaluations may not be reliable.

Third, it is proposed that the students turn in weekly reports for all 15 weeks of their training period. In these weekly reports, the students will be advised to briefly list all of the co-op training related activities carried out by them during their training weeks. Also, all the weekly reports must be reviewed, signed, and stamped by their respective supervisors. The students will be advised to e-mail their given weekly report during the subsequent week to their respective faculty advisors. These weekly reports will be assigned a weightage of 7.5% in the assessment policy for the EEET 290 course.

Fourth, it is proposed to share the co-op students evaluations of academic preparation, faculty advisors, supervisors, co-op trainings, and co-op organizations from Table XV and Figure 6 with their respective supervisors. This will help the supervisors to continuously improve themselves.

Finally, it is proposed to organize an orientation seminar focusing on CLO 1 for the next batch of co-op students. This

proposal is made as we did not achieve an adequate level of performance in CLO 1 by the co-op students we have analyzed in this paper.

VIII. COMPARISON OF CO-OP TRAINING PROGRAMS

In this section, we present a comparison of the co-op training given to our students by Saudi Aramco, SEC, and STC. Note that no HBCC EEET students underwent their co-op trainings at Saudi Aramco during the spring semester of the academic year 2013–2014. However, the co-op training program of Saudi Aramco is compared with that of SEC and STC based on our prior experiences.

A. Saudi Aramco

1) Strengths:

- The co-op training program is well planned and organized.
- The co-op training program matches well with the academic preparation.
- The co-op students are under close supervision throughout their training period.

2) Weaknesses:

- There are no case studies included in the co-op training program for associate degree EEET students.
- There are not many employment opportunities available for HBCC EEET graduates.

B. SEC

1) Strengths:

- There is an excellent match between the co-op training program and academic preparation.
- Employment opportunities are available for HBCC EEET graduates.

2) Weaknesses:

- The co-op training program is not well planned and organized.
- The co-op students are not under close supervision throughout their training period.
- There are no case studies included in the co-op training program for associate degree EEET students.

C. STC

1) Strengths:

- Employment opportunities are available for HBCC EEET graduates.

2) Weaknesses:

- The co-op training program is not well planned and organized.
- The co-op training program does not match well with the academic preparation.
- The co-op students are not under close supervision throughout their training period.
- There are no case studies included in the co-op training program for associate degree EEET students.

IX. CONCLUSIONS

As a result of this study, the following conclusions can be drawn:

- In the direct assessment of the EEET 290 CLO's we observed that the co-op students performed at an adequate level in all the EEET 290 CLO's except CLO 1.
- In the direct assessment of the ABET SO's supported by the EEET 290 course we observed that the co-op students performed at the proficient level in only ABET SO (d).
- As expected, the indirect assessment of both the EEET 290 CLO's and its respective ABET SO's is not reliable.
- Proposed actions from the FCAR of the fall semester of the academic year 2013–2014 were implemented during the spring semester of the same academic year, thus demonstrating “closing the loop” process for the EEET 290 course.
- It is recommended that the companies operating in Saudi Arabia design their co-op training programs in consultation with the respective faculty advisors in the Saudi universities and colleges.
- It is recommended that the co-op supervisors in companies operating in Saudi Arabia undergo training on co-op supervision.
- It is recommended that at least one case study is included in the co-op training program for each associate degree EEET student.
- Finally, we propose not to send our future students for co-op training at STC because of a mismatch between their co-op training program and EEET associate degree program at HBCC.

ACKNOWLEDGMENT

The authors gratefully acknowledge the support provided by the University of Hafr Al Batin.

Is this thing on? Determining Comfort Level with Communication Skills in a Technical Discipline

Adrienne Decker, Christopher A. Egert

Rochester Institute of Technology

Rochester, NY - USA

adrienne.decker@rit.edu, caeics@rit.edu

Abstract— Students with a technology focus often express and demonstrate that they find it difficult to communicate their ideas and designs. Students in the Rochester Institute of Technology's School of Interactive Games and Media are further challenged in that in order to be successful in their pursuit of a career in game design and development, they need to effectively convey their game ideas and design specifications while expressing the passion for the ideas that will convince others to climb on board and work on their projects. In this paper, we discuss the way we help our students develop these skills within a course structure. Through several course offerings, the faculty and students anecdotally noted that the students communication skills improved and their comfort in communication improved as well. In order to more accurately determine if this observed improvement was measurable, a survey of comfort with communication skills was created. The paper will present the results of an exploratory study using the instrument, which involved administering the survey to the students in the course as well as students in another course without a focus in development of these skills. The results from both sets of students were analyzed to determine if there was an increase in comfort with communication skills and to begin a process of validating this new instrument.

Keywords— *communication skills; professional skills; game production*

I. INTRODUCTION

Today's students in technical fields must navigate several challenges to be successful within the workplace. Along with a command of technical skills and the ability to be adaptable as technology changes, students of the technical discipline must also be adept at skills such as verbal and written communication. Although this statement is not revolutionary, technical disciplines are becoming increasingly reliant upon collaboration and teamwork. In the past, employees with extreme technical skill could sometimes be considered "exempt" from interacting with their colleagues. Today's reality is that most employers can no longer tolerate a mindset of isolated productivity. Employees must be able to present their ideas in a convincing manner, and must be skilled in the arts of presentation, persuasion, critique, and mediation.

Although this has been a pervasive problem, educators are still challenged in the classroom to provide learning experiences that focus upon communication skills in a convincing context. However, we often make such exercises

peripheral to the technical content, often separating the technical creation and the essential communication tasks such as ideation, presentation, and documentation. Such tasks are only a minor component of technical assignments, with the occasional course requiring a culminating communications-based project, such as an end-of-term report or a final presentation. Even in such cases, these tasks are a portion of the assessment and often have a marginal impact on the overall assignment assessment.

Today's challenge addresses the question of how to we actually create authentic technical and educational processes and practices that allow faculty to explore successful and even unsuccessful communication and interaction patterns with students. Furthermore, how do we move beyond treating communication skills as an extra and separate component to the technical work?

To help frame this exploration, there are two basic levels: finding means to determine levels of communication comfort in learners and finding means to link technical and communication educational outcomes in course design. This paper addresses our initial results in exploring the first task – comfort level with communication skills in a technical discipline.

II. BACKGROUND

Communication skills in general have been recognized as important for some time. ABET gives specific focus for such skills in applied science, computing and engineering programs as a desired course and program outcome [1][2][3]. Given the importance, there are several approaches to including these skills in the curriculum. Institutions readily recognize the importance and have developed approaches that best work for them and their curriculum and students.

A. Integrating Communication throughout the Curriculum

The PITCH program [4] aimed to integrate communication skills for engineering and computer science undergraduate students throughout the entire curriculum. This program focused on multiple aspects of communication that include written documents, poster presentations, oral presentations, and design reports. The students were given various types of assignments throughout their four years. The faculty focused on making rubrics and samples available to the students ahead

of time as a means of instruction on proper communication techniques.

At SUNY Oswego, communication skills were integrated in the curriculum by adding a required technical writing course and adding elements to other courses (e.g. reports, presentations) as well as adding a multi-disciplinary team aspect to some team projects [5].

In Australia, Falkner and Falkner also touted the advantages of integration across the curriculum and actually propose a methodology by which others can design communication skills curricula [6].

B. Taking outside courses

Although not as popular, some institutions require one or more additional outside courses for their students. For the Information Technology department at University of Cincinnati, the students are required to complete specific communication courses. The senior design capstone for these students is viewed as a culminating experience where they bring the communication pieces and their IT curricula together [7].

C. Communications Course within Curriculum

Still another approach is to create a stand-alone communications course inside the technical curriculum. University of Toronto did this with their "Communication Skills for Computer Scientists" course [8]. This course focused on writing, speaking, and interpersonal communication. Students were asked to deliver a number of speeches throughout the term ranging in duration from 60 seconds to 5 minutes. Within these assignments, they were asked to describe information from a graph or chart, participate in a mock interview, and to present a topic of interest. They were coached through this process; videos of the speeches were posted online for comment and critique by instructor and student alike.

In [9], we see another instance of a course within the department created for introducing communication skills that focused on writing and oral skills through the use of lab sessions. At the end of his paper, Lawrence argues that one course is simply not enough and that integration of communication skills throughout the curriculum is better.

D. Specific component within a course

Some institutions have yet to find ways to integrate communication skills fully throughout their curriculum. Instead, they find success integrating one or two aspects into an already existing course, rather than creating an entire course devoted to the topic.

At Andrews University, technical writing and oral communication practice are integrated in the entire first year of engineering courses. Tasks include the writing of reports and giving of multiple presentations with feedback [10].

At Denison University, computer science and mathematics students focus on communication skills in their sophomore year. While enrolled in specific courses within their major, the

two groups are brought together once a week for a lab. During the course of the term in this lab session, students presented three talks on topics in math or computer science which are peer reviewed by other students. They are also asked to self-critique their presentations and to critique talks outside the course (departmental talks or campus-wide talks). Survey results indicated that they are now more at ease presenting math or computer science material in front of an audience and have increased willingness to present their talks at the department, regional, or national level [11].

At Roger Williams University, they focused on enhancing oral communication skills by asking students to extemporaneously talk about a random topic for three minutes once a week. The talk stops at the end of three minutes or when the presenter uses a distractor ('um', 'ah', or long pauses without speech). Though these talks are not formally assessed, it is noted that there is improvement in student performance in presentations within other courses [12].

A multi-institutional effort was described in [13] for integrating communication skills into a data structures and algorithms class. This course was typically taught in the second year of the curriculum. Writing, speaking, reading, listening, and teaming were focused on through various assignments. Students were asked before and after to rate their ability in reading, writing, speaking, and teaming. Students rated themselves more positively at the end than at the beginning, but the authors do not indicate whether those increases are of statistical significance.

Bennett and Urness describe a CS1 course that used daily student presentations as a way to address communication skills at the introductory level [14]. Students select topics for these presentations, which allowed for greater coverage of breadth of computing topics than a typically programming-focused CS1 course. The presentations were only a few minutes in length and generally students provided interesting presentations. The authors studied student change in attitude toward computing, but not communication skills. Anecdotally, the instructors indicate that they see improvement in student's skills.

For a junior-level course in object-oriented programming at King's College, peer evaluated oral presentations have been added [15]. Michael observed that the student participation (in the peer evaluation process) made them more invested in the presentations as a whole. He notes, however, the interesting range of opinions (across the spectrum of positive and negative feedback) about certain presentations that were collected from the peer evaluation forms.

In [16], we see the use of a student-centered model with problem-based learning and peer assessment to tackle the problem of developing communication skills. The students developed writing skills through the use of wikis and oral presentation skills via poster presentations. The authors of the study report that students enjoyed the wiki assignments. The authors believe this is because they were not traditional writing assignments (e.g. reports). For the poster presentations, the authors discuss how they provided feedback and allowed students to improve by asking them to present multiple times, iterating on their ideas each time.

E. Assessment of communication skills

In [17], a focus group study was employed to look at engineering students' beliefs about their learning of communication skills. While the focus group asked about communication in general, the participants focused on writing as the main form of communication in their responses. The participants in this study indicated that they learned communication skills better when they received more examples of good communication on which to model. They also indicated that they wanted examples grounded in the real world as to how communication would fit into their future.

III. OUR COURSE

In the School of Interactive Games and Media at Rochester Institute of Technology, all of the graduate students are required to enroll in the Game Development Processes course. This course has been focusing on aspects of communication as it directly relates to the art of game concept pitch process [18]. Development of communication skills is not a direct learning outcome of the course, but rather of our graduate program as a whole.

At first, we explored many of the approaches outlined in the previous section as a means to enhance communication skills throughout the course. However, we quickly noted that these techniques did not map well with the needs of the course. The pitch process is more than just communication, but instead lends itself more into the format of limited dialogue with an audience under constraints of time and succinct information presentation, all while adjusting to the needs of the audience. As such, prior discussed methods do not focus upon the richness of such a dialogue and do not address the nuances and adjustments needed as part of the practice of this format.

This course and its content lend itself to the inclusion of assignments that can potentially help to increase student comfort and ability with communication skills, but it is not the only place these skills are integrated. So our model for integrating communication skills maps most closely onto the models that integrate different aspects of communication skills within various courses.

While more details about the course can be found in [18], we will recap the structure of the course as it relates to communication and pitch and detail how the latest version of the course (Fall 2014) changed from the previous structure mentioned. The communication skills that this course is focused on increasing are oral communication skills (presentation, ideation, pitch, critique). In Fall 2014, the class met three times a week for fifty minutes each class period. Within the class, there were various group activities employed. The instructor for the course assigned the students to groups ensuring that through the semester, the students were required to work with as many of the other students as possible with minimal overlap.

A. Ice-Breaking and First Assignment

Within the first three weeks of the course, we provide the students with an overview of many aspects of the game industry through interactive experiences. In the third class of

the semester, we discuss aspects of the industry as seen in the Entertainment Software Association's 2014 Industry Report [19]. To do this, we use a variation of the game Wits & Wagers [20] in which the students are divided into four teams that compete against each other. In the next class, we use a variant of Pictionary [21] to get students to describe to their classmates, through drawings on the board, the various roles one could have in the games industry. For class 7, the students are challenged to a competition using three unique games, a synonym-based word puzzle game (a "word rebus" where instead of pictures standing in for words, words stood in for other words), Taboo [22], and Charades [23]. These three are used to illustrate the various types of communication that are useful in a team setting: written, verbal, and non-verbal.

For each of these games, someone in the class is required to give clues or present in some fashion to the class. Then, the rest of the class must participate in some way if they want to get the answer and/or earn points for their team. From observations in the last several course offerings, including the Fall 2014 offering, the students were very eager to interact and the atmosphere in the room was light and fun. The students seemingly had a good time playing the games and interacting with their classmates.

Within the first two weeks, the first assignment for the course requires the students to complete a deliverable is assigned and collected. This assignment asks the students to forecast the future by looking at current trends in the field and putting together a presentation (a set of slides) about the trends that they find the most interesting, appealing, and/or promising. The slides are submitted to the faculty, but there is no presentation of the assignment. The grading for the assignment, however, is based on how well they expressed the trend through visual storytelling and minimal textual explanation. Slides that are "walls of text" are not sufficient for the exercise, and are not accepted as a deliverable.

At the beginning of class 6, the start of the third week of classes, several examples are pulled from the submitted assignments and critiqued as a group for aesthetics, ability to convey information, and ability to hold interest. Both strong and weak examples from student submissions are critiqued. At this stage in the course, the submissions are critiqued anonymously. We discuss as a group and through critique how the information was effectively or not effectively conveyed. We discuss ideas of how to convey information visually. As part of the critique process, the students are also taught techniques for critique. They learn how to separate out their personal biases from subjective analysis and learn how to present feedback in constructive ways.

B. Ideation and Presentation of Ideas

Starting in the fourth week of class, we move into the topic of ideation. Coming up with good ideas is not an easy task and if we want our students to succeed in a fast-paced industry, we need to make sure they have some techniques for rapid generation, exploration, and evaluation of novel ideas. We introduce them to three techniques during weeks four and five that will give them some tools for ideating in the future, blue sky [24], brainstorming [25], and mind mapping [26].

Each technique is given approximately two class periods broken up with the following structure: present the technique, students work in small groups and perform the technique, students informally present the ideas generated. For each of these techniques, it is helpful to “seed” the session with a theme or idea as well as a goal. We have had the instructor give a theme (thought about before class). We used the game Name 5 [27] to generate lists of “things” and choose from those lists to ideate around, and we have also used the Grow a Game website [28]. The goal is for the students to come up with a game idea.

After the students have been given the “seed” and performed the technique for a short time (10-25 minutes depending on the technique), the teams are instructed to focus on the best of the ideas generated and flesh out their group’s game idea for 5 more minutes. After that time, one person tells the entire class what the game idea was and how the technique got them to that idea. During these informal presentations, we tell the other groups that questions are appropriate, positive comments are welcome, negative comments are not, and constructive suggestions are actually the best.

C. Pitch

After an idea is hatched, we need to form a cohesive game concept around it and present that concept to the stakeholders that will eventually decide if it will be moved into production as a game. This pitch process is one that we spend significant effort on during the class. The students are led through a series of discussions and lectures about what the important parts of a pitch are and what makes a good pitch [18]. Then, we ask them to perform the task of pitching, many times.

For the Fall 2014 semester, the students were first asked to pitch their ideas for their semester-long project to the course instructor. This was done during class 11. This pitch needed to be done early to facilitate the progress of the project and make sure students were on the right track early or risk an unsuccessful project by the end. These pitches were limited to 10 minutes in length. After the teams presented their pitch, there was a short time for questions from the audience. Feedback was then given to each team by the instructor about their project as well as their pitch.

In what would become a theme for the semester, they were told they were going to do it again for class 17. This time for only 8 minutes and that they would need to ensure all group members spoke, and that they would be presenting their ideas to another instructor who had not heard the first pitches. Therefore, they could not rely on previous knowledge of the audience. At least one person would have never heard about their game before, and that was the person that was ultimately grading them and giving them feedback on their second attempt.

A few weeks later (in class 24), the students were surprised with an in-class exercise in which they were asked to pitch another group’s semester-long project. In what we call “minute-pitch swap” the groups were allowed 5 minutes to introduce the other group to the games and then 8 minutes to prepare a maximum 2-minute pitch about the other team’s game. The purpose of the exercise is two-fold; first, it gets the

original team talking about their project again, and second, it allows the other team to put their spin on the project and present it in a different way than the project’s “owner”. In some cases, this caused the groups to re-think or enhance certain aspects of their project based on what the other group found important and/or focused on for these short presentations.

On class 30, the groups were told that they would have to prepare another pitch for class 34 (in a little over a week). They were assigned groups and given 8 minutes to pitch a new game idea picking at least two elements from the following list of themes: gangsters, gardening, fire, turtles, an attic, and airplanes. After the pitches from class 34 were complete, the groups were instructed to go back and do the same pitch again for class 36 focusing on polish of the pitch.

The last pitch of the semester was in the form of the final project presentations. While not a pitch, per say, the students were instructed to treat it more like a longer, product pitch. The product was done, they were now selling it to their target audience and related stakeholders. Basically, we did not want them to perceive the final presentation like a presentation, but to keep the lessons learned from pitch as they described to us their final product.

D. Other Presentations

There were other presentations required of the students throughout the semester. Some presentations were more traditional. The semester-long project ended with a postmortem presentation in which the members of the group reflected back on what worked and what did not for their project and within their group structure and work patterns. The final for the course was a presentation on business and legal concerns as they relate to starting an independent game studio.

In the middle of the semester, groups were formed to present to the class about various software design methodologies (e.g. Scrum, Agile, Waterfall, etc.). For this presentation, the groups were tasked with creating an interactive exercise for the students as part of their presentation. This exercise was to be designed to illustrate the methodology that they were presenting to the class.

As you can see, we utilize a number of different techniques to encourage our students to communicate with each other in teams and to the class as a whole that are both formal and structured as well as casual and semi-structured. Throughout the semester, in conjunction with these activities, the students are asked questions by their peers and by their instructors. In other words, they participate in and are subject to critique of their ideas and presentations. As described in [18], the instructors feel that these exercises have a positive benefit to the students and their communication abilities. A question that remained unclear is whether or not the students felt any difference in their communication skills and abilities.

IV. METHODOLOGY

Due to the amount of focus on oral communication skills and the observation of the course instructors that by the end of

the course that students seemed to be better at communicating, we wondered whether or not the students perceived a difference in their comfort with their communication skills by the end of the semester. Our main research question was: For students enrolled in the Processes class, would there be an increase in comfort level with communication skills at the end of the semester when compared to the beginning of the semester?

In order to determine whether or not this was the case, we created a study that used a quantitative methodology that followed a quasi-experimental design approach [29]. The Comfort with Communication and Critique survey was created (Appendix). This 5-point Likert-scale survey, (1=Strongly Disagree, 2=Disagree, 3=Neutral, 4=Agree, 5=Strongly Agree), consisted of 23 statements. Within the survey, participants were asked their level of agreement with statements about their oral communication skills and ability to give and receive critique.

The survey was created with a mix of positively worded and negatively worded statements to avoid the problem of a student simply picking “5” for all statements. The same score for all statements does not make sense given the nature of the statements and therefore, any data with the same answer for all statements would be removed from the analysis.

This survey was administered at the beginning (during class 3) and at the end (at the final exam) of the Game Development Processes Course. It was delivered as a “quiz” through the university’s learning management system. The quiz format was chosen because it provides a way to track the responses back to an individual student. The students were told that even though this survey was under the “Quiz” tab for the course, it was not a quiz, and was not a graded component for the course. Therefore, participation was voluntary.

In order to provide a contrast to the results from the Processes class, the same survey was administered during week 1 (class 3) and the final week of the semester to a class called Production Studio. The purpose of production studio is to allow upper-division undergraduate students a chance to work on projects of their choosing under the direction of a faculty member. In this course, there is not an emphasis on ideation, pitch, or process, and students were not exposed to the range of presentation and critique activities as they were in the Processes class. In fact, the students were expected to receive instruction in production processes in prior coursework, with the focus of the course being a simulation of the Kickstarter process. Presentations and communications were critiqued by the instructor and by the class, and although there were recommendations for improvement, there is no learning outcome for this course for exploring process models directly.

As a secondary research question, we wanted to see that there was no difference in comfort level with communication skills in the Production Studio group.

After the two surveys were administered, the data was exported from the learning management system by the individual course instructors and the participant’s survey from the beginning of the semester was paired with their survey from the end of the semester. Following the pairing,

information about which student completed which survey was removed. The data was saved in Microsoft Excel format and Analyse-It was used to analyze the results of both groups.

V. RESULTS

There were 15 students enrolled in the Game Development Processes course for the Fall 2014 semester. Of those 15, 14 completed both administrations of the survey, giving a response rate of 93%. For the remainder of this section, this group will be referred to as the experimental group.

There were 19 students enrolled in the Production Studio course in the Fall 2014 semester. All of the 19 students completed both administrations of the survey, giving a response rate of 100%. For the remainder of this section, this group will be referred to as the control group.

We will call the survey given at the beginning of the semester the pre-survey and the survey given at the end of the semester the post-survey. The mean for each statement for both the pre-survey and the post-survey is shown in Table 1, and is categorized by each statement. Results are shown for pre- and post- results by the control and experimental groups. A mapping of statement identifiers to the actual statement text is shown in the Appendix of this paper.

TABLE I. SURVEY AVERAGES PER STATEMENT
(* INDICATES SIGNIFICANCE, $p < 0.05$)

	Survey Average			
	Control Group (n=19)		Experimental Group (n=14)	
	Pre-Survey	Post-Survey	Pre-Survey	Post-Survey
S01	4.53	4.21	4.43	4.43

S23	3.16	3.37	2.79	3.14

A. Comparisons between pre-survey and post-survey results in experimental group

Our main research question was concerned with a difference in pre-survey to post-survey scores in the experimental group. We performed a pair-wise analysis of results by statement. Due to the low number of samples, we used the Wilcoxon rank-sum test for non-parametric analysis. For the experimental group, we did not find significant differences from pre-survey to post-survey responses.

B. Comparisons between pre-survey and post-survey results in the control group

Our second research question asked whether there was a difference in pre-survey to post-survey scores within the control group. Due to the same constraints as the first analysis, we used the Wilcoxon rank-sum test for non-parametric analysis.

For the control group, some of the statements revealed significant differences from pre-survey to post-survey results in statements related to speaking, critique, and mediation.

The first category where we notice some significant difference in score is in statements related to oral communication. Statement 2, "I feel unsure of myself when I speak to a person of authority (e.g. Professor, Boss)" demonstrated a significant difference between pre-survey and post-survey results ($W(7) = 0.0, p < .05$). Furthermore, statement 6, "I become less confident if someone asks a question during my formal presentation" showed significant difference between the surveys ($W(6) = 0.0, p < .05$).

For critique, statement 19 asked, "I feel confident in my ability to give useful critique of other's ideas". This statement also showed a significant difference between pre-survey and post-survey as well ($W(6) = 0.0, p < .05$).

Finally, for the category of mediation, statement 21, "I feel that through my writing, I can mediate problems or differences between team members" presented a significant difference in score ($W(7) = 0.0, p < .05$). The remainder of the statements did not demonstrate any significant difference.

VI. DISCUSSION

The results from the survey for our main research question were disappointing. There was not a statistically significant change in the responses of the students from the beginning to the end of the semester.

One possible explanation for this is the fact that the students were already fairly comfortable with their communication skills when they entered the course. The course is made up of graduate students. It is possible that they were exposed to activities before coming into the graduate program either in an undergraduate program or a professional setting that prepared them for communicated and they felt comfortable doing it.

Although we did not find statistically significant differences in responses, we did notice some trends that point to areas of further investigation, based upon confidence interval differences in individual statements between the pre- and post- survey [30, 31].

The statement where answers changed in the less desirable direction was statement 9, "I am confident in my ability to convey ideas orally", pre-survey mean was 4.0 and post survey mean was 3.93 showing a decrease in agreement of 0.07. While also not significant, it did cause us to ponder another question that would require further observation. We question as to whether prior to coming into the class, students may have been over-confident in their abilities in oral presentation and throughout the various activities, they realized that they were not as prepared as they had thought and it changed their views by the end of the semester.

A. Control Group

The results from the control group were surprising. We hypothesized that there would not be a change in the comfort level for the control group due to the lack of interventions and lack of focus on communication skills within their course. However, we did find statistically significant differences for some of their responses.

They became more confident in their ability to give critique (statement 19) and mediate problems or differences between team members in writing (statement 21). They became less confident in their ability to speak to a person of authority (statement 2) and in their ability to remain confident if someone asks a question during a formal presentation (statement 6).

We do not know why this is the case. As with the Processes class, the perspective of the instructor is that the students improved in their communication skills over the course of the semester. The fact that they had such a positive jump in their perceived ability to give critique and mediate differences through writing could be a side effect of the nature of the course which was project based and involved teams.

Their decreased confidence with regards to speaking to authority and being asked questions during a presentation is puzzling and there does not seem to be a reason given the course structure as to why this would be the case.

Looking at the non-statistically significant responses for this group, we see that for statements where the students should disagree more (4 and 18), they in fact, agree more. For statement 4 "I am not very confident when I perform in front of a large group of people", the pre-survey mean was 3.26 and the post-survey mean was 3.37, showing an increased agreement with this statement and a difference of 0.11. For statement 18,

"I cannot take criticism from others well", the pre-survey mean was 2.37 and the post-survey mean was 2.63, showing an increased agreement and a difference of 0.26.

We see the same "opposite" results for three of the statements where the students should agree. In statements 1, 8, and 10, their mean score for agreement dropped by the end of the semester. For statement 1 "I am confident when I speak one-on-one with a fellow classmate", the pre-survey mean was 4.53 and the post-survey mean was 4.21 showing a decrease in agreement by 0.32. For statement 8 "I am confident in my beliefs as I present my viewpoint", the pre-survey mean was 4.16 and the post-survey mean was 3.89 showing a decrease in agreement by 0.27. For statement 10 "I am confident in my ability to convey ideas in a written form", the pre-survey mean was 4.37 and the post-survey mean was 4.16 showing a decrease in agreement by 0.21.

Overall, it seems that this group became less confident of their communication abilities as the semester came to a close, but we don't have any explanations as to why this may have occurred.

VII. LIMITATIONS AND FUTURE WORK

Even though we tried to design this study with as much rigor as possible, we viewed this strictly as a first step and exploratory in nature. We wanted to more systematically investigate the impact the various interventions in the Processes course were having on the students comfort with communication. To that end, we created a new instrument that was administered to two groups of students. We are limited by the fact that the instrument is in fact new and had not been used before. We are also limited by the number of participants we had in the study. Further, the control group was not a complete control as there were aspects of the course that required them to use communication skills.

For the instrument, we need to work to ensure reliability and validity. This can only be done by administering the survey to more participants and we are actively working on ways in which this can be done both within the Processes course and outside.

For our Processes course, we did not receive the intended results we wanted from the study. We did not see a statistically significant increase in the student's comfort level with their communication skills. However, we have noted previously and again with the Fall 2014 semester offering, the instructor observation that the students' communication and presentation skills did improve throughout the semester. Therefore, our next step is to determine if our observations are flawed about the increased ability in communication skills, if our belief that this is partially caused by an increase in comfort with those skills is flawed, or if our instrument needs to be adjusted to better detect comfort with communication skills.

The surprising results came from what we considered our control group. For this group, it appears that their confidence in their communication abilities actually decreased during the semester. Nothing that was in the course or its expectations gives us an idea as to why this may have occurred. In order to

determine why this may be occurring in this course, further investigations are needed.

APPENDIX

COMFORT WITH COMMUNICATION AND CRITIQUE SURVEY

1. I am confident when I speak one-on-one with a fellow classmate.
2. I feel unsure of myself when I speak to a person of authority (e.g. Professor, Boss).
3. I am confident when I speak to a casual gathering of friends (e.g. telling about my weekend plans).
4. I am not very confident when I perform in front of a large group of people (e.g. talent show, play, musical performance).
5. I am confident when I have to give a formal presentation to a group.
6. I become less confident if someone asks a question during my formal presentation.
7. I am confident I can express a given viewpoint that is not my own in a formal presentation.
8. I am confident in my beliefs as I present my viewpoint.
9. I am confident in my ability to convey ideas orally.
10. I am confident in my ability to convey ideas in a written form.
11. I am confident in my ability to convey ideas in an email.
12. I am confident in my ability to convey ideas in a formal document, design document, or written report.
13. I am confident in my ability to create an effective presentation (e.g. Powerpoint).
14. I am confident in my ability to create an engaging presentation (e.g. keep the audience interested).
15. I feel more comfortable telling someone my thoughts face to face.
16. I feel more comfortable telling someone my thoughts in written form (email, text, etc.).
17. I understand how to critique others.
18. I cannot take criticism from others well.
19. I feel confident in my ability to give useful critique of other's ideas.
20. I feel that I am able to mediate differences between different viewpoints.
21. I feel that through my writing, I can mediate problems or differences between team members.
22. I feel that I am capable of making a convincing presentation that can change someone's mind.
23. As people critique my presentation, I find myself swayed to their viewpoint.

Abstract— We are exploring whether and how “Digital-Storytelling” can be used to a) attract and engage student apprentices otherwise estranged from STEM-linked career or education pathways b) help student apprentices address the complexities of ill-formed or “wicked” design problems typical of sustainable engineering. Building on preliminary evidence from a pilot 2014 study we hypothesize that apprentices who engage in digital storytelling can gain proficiency in key reasoning skills related to scientific argumentation including: 1. formulating and articulating problem statements 2. anticipating and understanding tradeoffs, limitations and contingencies of proposed solutions and 3. justifying solutions relative to requirements/specifications articulated in the problem statement. Our continuing work is in the development and validation of evaluation and assessment instruments appropriate for evaluating these skills among apprentices focused on digital storytelling and for drawing comparisons against apprentices engaged in “hands-on” sustainable design projects. Our overarching objective is to offer evidence validating digital storytelling as an alternative pedagogy for introducing and teaching STEM reasoning skills to newcomers or “outsiders”.

Keywords—*apprenticeship learning; scientific argumentation, problem-solving, digital media; media-rich learning environments, systems engineering; sustainability engineering.*

I. INTRODUCTION

This work is motivated by our interest in developing and refining pedagogic models that can be used to improve and encourage broader participation in engineering education focused on sustainable development. More specifically, we are interested in learning whether and how *digital storytelling* can be leveraged to draw learners from diverse backgrounds and disciplines into STEM-linked problem-solving activities and coursework and then to enrich and sustain their involvement. Another goal is to counterbalance those occasions when newcomers to STEM education must passively “internalize” new and unfamiliar material by providing more occasions for learners to “externalize” their emerging understanding.

Theories of “situated cognition” [1] in the learning sciences emphasize that learning is a fundamentally social

endeavor [2] that cannot be separated from the context in which it takes place [3] [4]. Theories of situated cognition posit that skills and knowledge develop interdependently through increased degrees of “intent participation” [5] in different learning communities [6], and are reinforced through responsive facilitation [7] or devices that function as learning scaffolds [8] [9] [10]. We see digital storytelling as not only a powerful way to create inclusive learning communities [11] focused on STEM topics but, perhaps more importantly, as a means of providing learners with critical opportunities to participate in *active* knowledge-building as they work to develop creative representation(s) of their *own* emerging understanding of sophisticated STEM topics and practices.

Additionally, in social psychology, “Self Determination Theory” [12] explains why learners benefit when teachers support self-directed learning or learners’ sense of autonomy. Research in this area began thirty years ago with empirical experiments looking at the effects of extrinsic rewards on intrinsic motivation but has evolved to emphasize self-regulation through internalization and integration [13]. Despite widespread and growing respect among engineering educators for pedagogical approaches that support student autonomy such as Inquiry-based Learning, Active Learning, Project-based Learning, Problem-based Learning, Critical Thinking, Academic Service Learning, etc., educational researchers exploring the “disconnect” between rich empirical evidence for the success of “student-centered” pedagogies and the actual characteristics typical of engineering classroom environments found that many faculty continue to fall back to their usual routines of traditional instructional methods. One study found that faculty who were well-informed and motivated to teach classes aligned with a learner-centered pedagogy still required more access to feasible models and need support in finding/implementing specific strategies they can use to re-design their courses [14]. We believe that many of the proven pedagogical strategies developed to support other forms of “hands-on” apprenticeship learning [15] [16]

can be adapted to structure learning environments that successfully use digital media to promote self-directed learning and thereby greater understanding of STEM knowledge and practices among newcomers.

As a *design-experiment* [17] [18] **Apprenticeships in Sustainability Science and Engineering Design (ASCEND)** iteratively implements, investigates, evaluates and refines a pedagogic model of apprenticeship learning (also called problem-based learning) in sustainability engineering through digital storytelling. Through our own preliminary research, we have seen how digital media can help to engage newcomers to STEM with content, processes, and technology involved in sustainable engineering projects. This is especially applicable to youth already immersed in the increasing ubiquity of our now digital age. Digital storytelling can help newcomers express or “externalize” their emerging understanding of sophisticated STEM content and/or practice by engaging students’ creativity and personalities in ways that writing about science might not. Digital storytelling can also afford participants a sense of “ownership” or “self-determination” to an equal or greater degree than some laboratory-based activities or other models of “hands-on” or “experiential” learning [19]. Digital storytelling may also prove instrumental in supporting and promoting active “learning communities” that provide context for STEM-learners connecting real-world problems to knowledge and skills prioritized in the formal learning context of higher education. Finally, as we will argue throughout the remainder of this paper, digital storytelling can be used to engage newcomers and experts alike in the specialized practice of *scientific argumentation*. Assessments of learners participating in this model can be compared to learning among participants engaged in “hands-on” aspects of sustainable engineering projects.

A. Innovative Practice

As access to digital media, digital production and editing tools increases, educators are increasingly turning to digital media as a way to empower and motivate learners to explore and engage with a range of topics. However a review of the literature [20] shows that attempts to revitalize STEM education through digital media largely rely on digital content supplied or created by *experts* and then conveyed to learners through media rich environments. These approaches should be distinguished from any that employ digital media as a means of fostering *learner-generated* content.

Digital storytelling differs notably from documentary filmmaking [21] as it is a highly reflexive activity that leads participants through powerful forms of self-discovery in relation to the topic, their place in society and their intellectual and creative abilities, allowing them to engage in rigorous meaning-making [22] [23]. Hughes [24] observes that the multimodal design of digital storytelling offers multiple entry points of creativity providing greater potential for storytellers to claim ownership of their story without fundamentally changing the content. Building on this premise, digital storytelling has been proposed as a “multimodal” pedagogical tool that can “create new forms of signification” to connect

personal history, voice and identity with the broader public issues faced by concerned communities and science [25]. Researchers in the the learning sciences have demonstrated a number of educational benefits for students who engage in this increasingly popular practice: for example, learners who do not identify with dominant socio-cultural groups [26] can employ multiple modes of representation to “push back” against powerful “master narratives” [27]. However, while educators working outside of STEM are increasingly using digital storytelling as a means to support students’ identities yet foster motivation to learn, autonomy and self-efficacy this potential is not being fully realized by engineering educators or others working in formal and informal STEM education contexts.

B. Research Focus and Hypothesis

Our research focuses on how digital storytelling can be employed to help newcomers to STEM gain proficiency in engineering-specific reasoning skills. For example, one essential skill for engineers is the ability to formulate and articulate well-defined problem statements that entail specifications/requirements for a desired solution [27]. This can prove especially difficult in learning contexts focused on engineering for sustainable development due to the nature of the problems under examination. As two researchers from Chalmers University of Technology recently emphasized: “Environmental and sustainability problems are not purely technical problems. Many of the most pressing issues, such as climate change, resource scarcity, and pollution, require holistic approaches that go beyond technical systems analysis and optimization. Such problems have been called *wicked sustainability problems* (WSPs) because they are highly complex, contested, and lack definite solutions” [28].

Preliminary results from our own pilot study with teenage apprentices at an alternative education vocational training center indicate that apprentices focused on digital storytelling were able to articulate more sophisticated problem statements than their counterparts – apprentices who were focused on more traditional “hands-on” or “design-and-build” tasks. Specifically, when asked about the issues motivating the construction of a rainwater catchment and smart irrigation system, digital storytelling apprentices were able to articulate statements that connected multiple issues including energy, pollution /storm water runoff, and water conservation while the apprentices working on building and installing the system itself were more likely to provide statements that focused only on one issue: water conservation [29]. Our continuing work is to develop and validate methods to assess how well learners are able to formulate and articulate problem statements, anticipate tradeoffs, limitations and contingencies on solutions and justify solutions relative to specifications in problem statements.

B. Expected Significance

Our assumption is not that learners engaged in digital storytelling will gain the same skills and knowledge as learners engaged in other “active learning” approaches. Rather, we recognize that there will be tradeoffs when the learning outcomes associated with any one approach are compared to any other. Neither do we assume that assessment of any particular set of skills or knowledge should be used to make claims about overall efficacy of any teaching model. We do

assume that the ability to formulate and articulate valid problem statements is an engineering process skill of sufficient importance (and more so when sustainable development agendas are implicated) as to warrant investigations of pedagogy designed to support this particular learning outcome. We also argue that evidence of improvement among digital storytellers in their ability to engage in scientific argumentation - to an equal or greater degree than apprentices focused on design-and-build tasks - can be used to validate digital storytelling as an appropriate pedagogical strategy for engineering education. Especially when the larger goal is to introduce and teach STEM process skills to newcomers or outsiders or to work with collaborators from other disciplines.

The **significance** of ASCEND is that, if successful, it will demonstrate a new pedagogical model that can be used to expand and diversify participation in STEM by providing incentives to non-STEM students, in particular, to engage with STEM-linked knowledge, research and activities. We expect that ASCEND's storytelling approach will attract those women and underserved minorities whom may otherwise be reluctant to pursue STEM-related fields in higher education or in the workplace. The model can also be used to introduce and promote development of STEM content knowledge and process skills.

II. METHODOLOGY

A. Scientific Argumentation: Engineering vs. Science

The majority of the literature on scientific argumentation as a formal practice (e.g. [30] [31]) traces its heritage back to a seminal article [32] that maps out an idealized microstructure for legitimate (i.e. scientific) explanation. A major caveat however, is that this literature focuses on arguments that use evidence resulting from scientific investigations to make claims that answer questions, while we are focused now on a type of argument that is slightly different (if no less "scientific"). Arguments that use evidence to justify working solutions with respect to the requirements and constraints laid out in an initial problem statement are characteristic of engineering. While "problem definition" is widely recognized as a critical step in any engineering design process, and repeatedly identified as a target learning outcome for engineering educators, literature that includes specific criteria for evaluating the quality or validity of a particular problem statement (a.k.a. the Toulmin model for evaluating scientific explanations) is scant. One exception is the recent dissertation work by Arnberg [33] which included a study of undergraduate interns engaged with design problems for their research with the Akamai Workforce Initiative (AWI). AWI partners with high-tech industry, astronomical observatories, cutting-edge research, and inventive education to meet needs in astronomy, remote sensing, and other technology industries in Hawai'i. This study found articulating measurable solution-requirements was a more challenging aspect of articulating a problem statement than identifying constraints.

B. Engineering Design Problems

Stojcevski [34] distinguishes "design problems" from other problem solving such as "story problems" (identifying patterns or breaks in patterns), "troubleshooting" (identifying

faults in a functional system or domain) or "case/system analysis" (stating attributes of ill-structured or complex problems rather than on hypotheses for generating actual solutions). Design problems are "more than just story problems", and they are not "restricted to troubleshooting". Rather design problems "incorporate new designs [while remaining practical and achievable in a way that many case studies are not]". Problem-design statements must specify and meet the needs and desires of people, function within defined constraints, and define minimum requirements for anticipated solutions. The problems encountered by apprentices in our study fit Stojcevski's description of design problems in so far as all projects elected for the ASCEND apprenticeship program are defined in consultation with sponsors/clients expecting highly tangible deliverables.

C. Evaluating Problem Statements for Sustainable Designs

In order to determine the degree to which apprentices can demonstrate their ability to formulate/articulate valid problem statements for the sustainable engineering projects they get involved with, we need to establish scoring criteria to evaluate their statements. This is no small undertaking and there are several considerations that must first be addressed:

1. **Wicked Design Problems:** Sustainable design projects are multifaceted and multimodal [35] and so dubbed "wicked problems" because they involve complex systems and must tackle added challenges like emergent behavior (a system behaves differently than the sum of its parts). To avoid reductionism, systems engineering requires decision-making that other brands of engineering can avoid [36]. For example, in systems engineering making strides in one direction (e.g. energy conservation) can result in setbacks in other directions (e.g. pollution). Overall, the challenge is to formulate statements that maintain technical accuracy on specifics while also accounting for the emergent properties of system relations.
2. **Multi-media:** Participants in our research will use multiple different kinds of media on different occasions to express their evolving understanding of the problems/issues motivating the wicked design project they are most involved with. Our challenge will be to decide which media should be prioritized for our formal evaluations or alternatively how to balance out or account for the differences we expect to see in the way problems are framed across media.
3. **Addressing Multiple Audiences:** Digital storytelling apprentices will be trained to pay attention to the needs and context of their viewing audiences during production. Creating media that is palpable and relevant to the everyday lives of non-expert viewing audiences will impact the way a problem is explained and therefore conceived. Assessment efforts will need to account for the ways in which these influences play into participants' thinking about a problem definition.
4. **Change Over Time:** Our interest is in tracking and understanding how an apprentice's understanding of the problem and ability to formulate/articulate problem

statements is changing over time. Unlike creating an “answer key” for a final exam where learner responses are benchmarked against a “correct” or “best” response, we need to create flexible scoring criteria sensitive to, and representative of incremental changes.

Despite the challenges identified above, we maintain that some basic elements of problem statements for (sustainable) design problems can be readily identified and presumed as necessary to support achievable solutions.

- *(why) Needs assessment:* Describes why a solution is needed based on current, predicted or unforeseen conditions. Includes data on baseline conditions.
- *(what) Functional Specifications:* Identifies tradeoffs across domains and boundary conditions for what a solution must minimally accomplish in multiple domains.
- *(how) Design Constraints:* Specifies procedural constraints that govern system commitments, design, construction, and implementation. May include criteria for decision making among multiple constraints. For example, to what degree do time constraints trump other considerations?
- *(who) Stakeholder Interests:* Who will use and (directly or indirectly) benefit or be impacted by the resolution of this problem, on what terms and to what degree? Identifies implications for the design process.

D. Strategy and Scoring Mechanism.

We expect that as an apprentice becomes more deeply involved with a project (whether through digital storytelling or design-and-build activities), the ways in which an individual comes to understand the issues or problem underpinning that project will evolve. We are committed to evaluation strategies that prove sensitive to changes over time in participants’ thinking rather than work as summative evaluations of one-time statements. In order to document these changes it is imperative to schedule sequential data collection sessions. On a weekly basis, a moderator will prompt participants to respond to questions about the problem their project is meant to solve and record their responses as “audio diary” entries using Sound Cloud freeware. Over time the moderator’s role should become less crucial as participants learn how to record audio diary entries. A challenge will be to make sure that participants do not repeat themselves from one week to the next, but articulate subtle changes in their perspective and understanding.

For this initial study we will be working with a population of 18 digital storytelling apprentices and 12 design-build apprentices over a 10 week period March 23, 2015 – May 29, 2015. Initially we expect to collect only 10-12 entries per week in the first 1-4 weeks, but anticipate closer to 20 entries per week by the final 12-15 weeks. Overall we hope to collect a minimum of 120 entries averaging 4 entries per participant.

We will analyze each audio diary entry for evidence of the basic elements of a problem statement described earlier. The following scores will be marked for each element:

N/A – Not Applicable

0 – Missing altogether but needed

1 – Available but barely evident

2 – Available but minimal, unclear or inappropriate

3 – Available and appropriate but could be stronger/clearer

4 – Available, clear and appropriate

5 – Exemplary, robust and comprehensive

We expect to find evidence of these different elements distributed across multiple audio diary entries. For example, in one session a participant might speak intelligently about design constraints and in another session focus more on the implications of different stakeholder interests. A score of 3 or more for each element would be considered evidence of proficiency, however it would not be necessary to score 3 or higher for *each* element on *each* occasion. Proficiency will be acknowledged as long as a score of 3 or higher is recorded on at least one occasion for each element.

It will be interesting to compare scores for audio diary entries completed by apprentices involved in digital storytelling with the way the problem is represented in the final digital production they submit for public screening. This comparison could help us understand to what degree and how a participant’s anticipation of the reception by a viewing audience can impact their own understanding of the problem.

E. Inter-rater agreement

The data will be reviewed and scored by the lead ASCEND evaluator as well as an assistant. Distinct from inter-rater reliability, inter-rater agreement is a measurement of the consistency between the absolute value of evaluators’ ratings. It represents the number of times each rating (e.g. 1, 2, ... 5) is assigned by each rater divided by the total number of ratings. After scoring the sample independently the lead evaluator and assistant will reconvene to discuss any discrepancies. A new sample set of data will be recorded after these discussions. A joint probability of agreement of 85% will be established before independent scoring continues.

III. RESULTS AND TIMELINE

Data collection will be completed in late May, 2015 and all data will be compiled and archived. Analysis will begin in June 2015 and completed in August, 2015. Given this timeline, the results of this study will not be available in time to be included in this WIP paper but will be available for presentation at the FIE conference October 21-24.

ACKNOWLEDGMENT

Funding from the National Science Foundation has supported this work. Funds awarded through the Center for Advancing Informal STEM Learning are managed by UC Santa Cruz under award No. DRL-1323804. We also acknowledge the unremitting commitment from our dedicated videography instructors: Chris Refer and Ricardo Velasco. Finally this work would not be possible without the contributions and extensive cooperation from Bradley King – teacher and acting principal at the Green Careers Vocational Training Center where this study is being conducted.

Is Information Technology General Education Effective for Non-Engineering Major Students?

An Exploratory Study on Ethnically Chinese Classrooms

Abstract— The role of computer and information literacy in the contemporary digital society is as important as language proficiency. This is widely exemplified in the graduate requirements in many tertiary institutions: students must pass the compulsory IT subject(s), often as a mandatory General Education (GE) course, before graduation irrespective of majors. Challenges arise to the computer science faculty as students are from different academic backgrounds with diversified level of IT background, and are often less motivated than taking a course in the major program. In this paper, we attempt to explore the reasons fostering students to devote efforts (i.e., persistence) in the GE IT course in tradition confucian examination-orientated educational settings. Student behavior and perceptions in two major groups of ethnically Chinese students (Mainland China and Hong Kong) are analyzed, revealing that mastery is the main reason leading to persistence in the mandatory IT course. Theoretically, we address the paucity on GE IT related research on ethnically Chinese students through validation and comparison of findings from the literature, leading to new directions of research. Practically, we generalize our experience from practitioner's view and propose different suggestions to effectively deliver GE IT courses under the confucian culture.

Keywords—General Education, Confucian Culture, Ethnically Chinese Student, Computer and Information Literacy, Persistence

I. INTRODUCTION

While computer and information literacy becomes the necessity to survive in the 21st century, scholars have been stressing the importance of including computer literacy in the syllabus e.g., Molnar [1]. This is exemplified in a variety of reformation in the educational system across different disciplines, e.g., the integration of computer and information literacy into K-12 teacher education [2]; the extensive use of computer technology in medical education [3]; and the integration of information technology syllabus in nursing education [4].

Computer and information literacy syllabus is now integrated across different disciplines and often included in the curriculum as credit-bearing courses in the tertiary institutions, with equal importance as language training in the curriculum. In many institutions, at least one fundamental information and communication technology subject is included in the syllabus

across all undergraduate majors, often in the form of a mandatory semester-wide credit-bearing course in the General Education (GE) domain for the Year 1 students. This ascertains that all graduates are in possession of sufficient computer literacy, so that they will have the knowledge and computer operation skills to use the digital educational resources e.g., the open education resources [5] and well equipped for lifelong education.

Successful delivery of the mandatory IT GE course to junior undergraduate students, however, is often challenging to the teachers. Kinnunen and Malmi [6] highlight an institutional “culture” issue that can demotivate students from devoting efforts in the mandatory IT GE course: a belief that failing in the mandatory IT GE course would not affect the performance in the major courses. False perception on the “disconnection” between major subjects and the mandatory IT GE course further discourages students to take up an active learning attitude in the mandatory IT GE course. Thus, increasing university students’ motivation the mandatory IT GE courses becomes one of the concerns of the front line faculty members.

Traditionally, research on computer education tends to focus on the junior computer science students on year-1 foundation subjects, e.g., the effective teaching and learning of entry level programming courses. Until recently efforts have been made to promote “kids programming”, i.e., to develop the logical thinking and problem solving ability of young children [7][8]. There is paucity in research on effective teaching and learning of compulsory foundation IT courses to non-IT major students. Our research questions are: 1) What factors, i.e., persistence, can motivate students to actively participate in a mandatory IT course for non-engineering majors? 2) How do students view the relationship between the major subjects and the mandatory IT subject? and 3) How does the curriculum arrangements affect students’ attitude on a mandatory GE IT course?

Addressing the research gap in the effective delivery of mandatory IT GE course to junior undergraduate students, this paper reports an exploratory study on year 1 students’ perceptions with respect to mandatory IT GE courses in two ethnically Chinese university classrooms at the Hong Kong Special Administrative Region and the Guangdong Province of

China. With the ethnically Chinese student population, our research also provides an insight on how Chinese students perceive the value of mandatory courses outside the major of studies.

Next section presents the related works on the research of undergraduate IT courses for non-engineering major students.

II. RELATED WORKS

A. Values and Expectations of Mandatory GE IT Course

Computer and information literacy has a great impact on interdisciplinary learning in the contemporary world. More than a decade ago, Rockman [9] has already stressed that solid information literacy foundation as the basis for “connection” between courses by enabling students to achieve the learning outcomes through problem-based learning activities that require extensive information searching. Some years later, Laird and Kuh [10] confirm that use of information technology for educational purposes would have a positive effect on student engagement especially in active and collaborative learning. Recent work by Benson & Filippaios [11] further explore the difference in workplace productivity between generations who have higher and lower computer and information literacy levels, asserting that the younger IT savvy generation is more advantageous in identifying new business opportunities than the elder generation.

Educators have well acknowledged the impact of computer and information literacy in academic and workplace productivity. Wong and Cheung [12] present an extensive discussion on a mandatory IT course delivered at the Hong Kong Baptist University, emphasizing that the course is a joint effort between the Computer Science Department, Library and the Office of the Information Technology. The 8 intended learning outcomes cover different aspects of computer and information literacy (p.59):

- Describe the importance of information technology and information literacy;
- Describe and explain fundamental concepts of different areas of information technology;
- Describe and explain the fundamental concepts of information management cycle;
- Use IT tools to search, store, organize, process and maintain information;
- Evaluate sources of information;
- Communicate and present information effectively in electronic formats;
- Describe and explain the issues of legality and ethics in searching, sharing and using information;
- Describe the major trends in and social impacts of information technology

Next section extends the discussion with an outline of the research and evaluation on students’ perceptions of the mandatory IT GE courses.

B. Research and Evaluation on Mandatory IT GE Courses

A variety of domains are evaluated on students’ perception on mandatory IT GE courses. Wong and Cheung [12] adopted an institutional-wide teaching and learning questionnaire to solicit feedback from students enrolled in the mandatory IT GE course. Items in the survey include six aspects: 1) Improvement of other courses; 2) Usefulness of the IT GE course; 3) Intellectual stimulation; 4) Course experience; 5) Student satisfaction; and 6) Course workload. A 7-point likert scale was adopted in the survey: 1 represents strongly disagree; 4 represents neutral and 7 represents strongly agree. Average scores of the six items ranges from 3.21 to 5.13, indicating students generally have a slightly positive (meaning from “somewhat disagree” to “somewhat agree”) perception on the items.

Further interpretation of the results reveals that delivery of the mandatory IT GE course as challenging to the faculty and support staff in terms of student motivation and infrastructural support. Gasiewski et al. [13] report similar findings on introductory science, technology, engineering, and mathematics (STEM) courses in junior undergraduate students, asserting that student engagement is the most important issue in student retention in the compulsory STEM foundation courses. Learning will only be effectively when students are motivated, resourceful, and engaged.

C. Design of Computer and Information Literacy Courses

Information literacy has become an important topic in the Library Science discipline. While computer literacy provides the necessity foundations to operate effectively for information retrieval and analysis, it should be integrated into interdisciplinary domains [2]. The computer and information literacy course should have a mission to diminish the gap of IT knowledge between different student groups, e.g., male and female students [14]. While the computer literacy, i.e., skills for operating a computer, remains the primary focus of the course, properly designed mandatory IT GE course can also improve creativity and collaborative skills of the learners [15].

Stephens and O’hara [16] identify five main areas of mandatory IT courses in 84 business school programmes: 1) fundamentals of IT infrastructure; 2) systems development process; 3) types of business information systems; 4) strategic applications of IT; and 5) managing the information age organization (p.184). While the first topic is the foundation of IT development emphasizing more on the technical aspects, the remaining four themes are more focused on the management aspects. In other words, the application of information technology (systems) in the business context is considered more important than the technical operational skills in the business schools. Acknowledging the requirements of the intended learners and teachers (i.e., outside the computer science department) would be necessary to design “servicing” courses that are targeted at the non-engineering (computing) majors.

D. Summary of Lesson Learnt from the Related Works

The above related works provide useful clues in the design and evaluation of mandatory IT GE courses for non-

engineering major junior undergraduate students. Table 1 summarizes the findings from the related works that form the basis of our exploratory research.

TABLE I. BASIC CONCEPTS OF EXPLORATORY RESEARCH

Domain	Description	Reference
Student engagement	Most important factor for student retention in mandatory course	[13]
Connection to the real world activities	Course only perceived as useful when it help to improve the productivity in the workplace/ major area of studies	[2], [12], [16]
Mastery	Leaners can master the materials in the course irrespective of the IT knowledge gap prior to course enrollment	[14]
Personal Best (PB) Goals	Influent to student engagement and satisfaction	[12], [13]

E. Research Gaps and Directions

In the engineering education research domain, emphasis has traditionally been put on the teaching and learning of technical subjects by engineering students. Until recently, researchers and practitioners advocate the importance of a new pedagogical solution for technology education that can pay attention to the diversity e.g., individual differences and capabilities; gender; social, economic, cultural or political differences; and even differences among countries [17]. There is a paucity of research looking from non-engineering major students' perceptions towards the mandatory IT GE course, especially how students perceive the value of the IT course and how to make the IT course "connected" to the real life experience. Moreover, cultural differences are rarely addressed in the related research findings.

Our exploratory work attempts to fill in the above research gaps on non-IT students' views on a mandatory IT course, as well as comparing ethnically Chinese students' perceptions with the findings in the literature. Next section follows with the research approach and methodology, outlining the research design and data collection methods.

III. RESEARCH APPROACH

To evaluate students' perceptions on the mandatory GE IT courses, self-administered survey was administered during the semester (i.e., before the end of the teaching weeks) to students who were taking the mandatory GE IT courses. Data were collected from two groups of junior undergraduate students: one group is from the Guangdong Province of China (the mainland China) majoring in business and the other group is from Hong Kong majoring in education, representing two different groups of ethnical Chinese students with different cultural backgrounds.

The self-administered questionnaire contains 16 multiple choice questions with 7-point Likert Scale covering the

domains as identified in Table 1. Instruments used in the survey are adopted from the existing literature:

A. Student Engagement [10]

- [ENGAGEMENT1] I discussed ideas from my readings or classes with the subject teacher outside of class
- [ENGAGEMENT2] I discussed grades or assignments with the subject teachers
- [ENGAGEMENT3] I asked questions in class or contributed to class discussions, either online or face to face.

B. Connection to the Real World Activities [18]

- [REAL1] I found the content of the IT course reflects the activities I have done at school, work or home.
- [REAL2] The practice in the tutorial/ lab sessions are related to the activities I have done at school, work or home.
- [REAL3] My performance in this course accurately reflects my ability to solve problems using computers and the Internet

C. Mastery [19]

- [MASTERY1] I want to learn as much as possible in this class
- [MASTERY2] I desire to completely master the material presented in this class.
- [MASTERY3] I hope to have gained a broader and deeper knowledge when I am done with this class.

D. PB Goals [19]

- [PB1] It is important to me to do better than the other students in the IT Course
- [PB2] I am motivated by the thought of outperforming my peers.
- [PB3] It is important to me to do well compare to others in the class.
- [PB4] I am striving to demonstrate my ability relative to others in this class.

After soliciting students' behavior and perceptions in the mandatory IT GE course, evaluating the persistence of students in the IT GE course, although mandatory, would provide some insights to researchers and practitioners on designing better "servicing" IT courses. Therefore, an extra construct, persistence, is added to the survey.

E. Persistence [20]

- [PERS1] If I can't understand my schoolwork at first, I keep going over it until I understand it

- [PERS2] If I can't complete my tutorial/ laboratory exercise at first, I keep going over it until I can complete it
- [PERS3] Overall speaking, I keep trying to work out an answer to the problem in this subject.

IV. RESULTS AND ANALYSIS

Anonymous survey was administered to two cohorts of students taking the mandatory IT GE courses in the Mainland and Hong Kong. Online survey was set up in the Moodle sites of the courses respectively, and was announced to the students through email broadcast and face to face during the lecture time. Response rate from mainland is 43.53%, while that from Hong Kong is 42.37%. Table 2 shows the descriptive statistics from the two groups of students.

TABLE II. DESCRIPTIVE STATISTICS

Item	Mean values			Difference
	Mainland (N=37)	Hong Kong (N=25)	Overall (N=62)	
ENGAGEMENT1	4.92	4.60	4.79	0.32

“Difference” refers to the absolute value of difference between the means of Mainland and Hong Kong students. * denotes the 3 most significant differences in the mean value between Mainland and Hong Kong students.

The internal consistency (reliability) of the constructs is assessed with Cronbach's Alpha, ascertaining that all instruments are reliable in this exploratory study. Table 3 shows the Cronbach's Alpha values of the constructs. All values are above the 0.7 level which indicates that the survey items are reliable.

TABLE III. CRONBACH'S ALPHA

Construct	Cronbach's Alpha
Engagement in the subject	0.705
Connection to the real world activities	0.805
Mastery	0.863
Personal Best Goals	0.894
Persistence	0.797

Partial Least Square (PLS) modelling [21] is adopted to assess the relationship between different constructs and persistence, i.e., the dependent variable in our proposed model. R^2 of our model is 0.329, indicating that the model explains 32.9% of persistence behavior of the students taking the mandatory IT GE course. Figure 1 shows the path analysis of the research model (*: $p < 0.05$; **: $p < 0.01$; ***: $p < 0.001$).

Fig. 1. Path analysis of the research model

V. DISCUSSIONS

This is one of the early exploratory works to study the perceptions of non-engineering undergraduate students' views towards a mandatory IT GE course. Findings in our research model provide some insights for researchers and educational practitioners (e.g., teachers and instructional designers) on designing the teaching and learning activities for better student retention. Next presents our further elaborations on the findings.

A. Student Engagement and Persistence

Although student engagement is believed to be a predictive indicator of persistence (i.e., retention to the course), our study shows that student engagement only exhibits a weak relationship ($p=0.173$) with persistence. This can possibly be explained with the syllabus and graduation requirements.

In the context under our study, the IT course is one of the mandatory graduation requirements. Generally speaking, students do not have any alternative options, e.g., an elective course, to replace or substitute the mandatory IT GE course to fulfill the graduation requirements. Whether the learning experience is engaging or not does rarely have any impacts on students' attitude on this course: students must pass this course in order to graduate. Graduation can be considered as the strongest extrinsic motivation factor leading to persistence in the mandatory IT GE course.

It is worth exploring the relationship between student engagement and persistence because it shows somewhat a weak relationship. Further investigation into the research model with a data driven approach provides some clues on the weak relationship by including a mediator between the two

constructs. Figure 2 shows the mediating relationship between student engagement, mastery and persistence (*: $p<0.05$; **: $p<0.01$; ***: $p<0.001$).

Fig. 2. Path analysis of the mediating relationship

PLS analysis reveals that student engagement indirectly influence persistence on the IT GE course through the mediating effect of mastery. Further investigation into this observation warrants attention from researchers as it may explain whether the same behavioral factors can explain students' behavior in mandatory or elective courses.

B. Connection to the Real World Activities and Persistence

The relationship between the connection to the real world activities and persistence cannot be supported statistically ($p=0.995$). Further analysis of the descriptive statistics would be able to explain the findings.

The greatest difference between the mean values by Mainland and Hong Kong groups of students in this survey is recorded on [REAL3] (My performance in this course accurately reflects my ability to solve problems using computers and the Internet.) Mainland students tend to agree more in this statement while Hong Kong students have a much lower level of agreement.

A possible explanation is the pedagogical model adopted in the Mainland and Hong Kong. The Outcome Based Teaching and Learning (OBTL) approach [22] has been widely adopted in Hong Kong, emphasizing that the Course Intended Learning Outcomes, Teaching and Learning Activities, and the Assessment Tasks should be constructively aligned. Assessment Tasks, however, still tend to focus on written examinations at the end of the semester that may not be able to assess the problem solving skills with computers and the Internet. Consequently, Hong Kong students expressed disagreement with [REAL3]. On the other side, OBTL is not widely practiced in the Mainland, which means that the teaching and learning activities could be examination-driven. It is natural that students perceive the examination results could reflect the computer and information literacy due to the practice for examination without extensive exposure outside the classroom.

C. Mastery and Persistence

Our path analysis shows that mastery has a strong and direct relationship with persistence ($p<0.01$). Generally speaking ethnically Chinese students tend to be afraid of making mistakes (also known as "loss of face") [23]. It is definitely not a pleasant learning experience if a student was asked by someone (either teacher or student peers) but could not give the "right" answer.

In such Chinese Confucian cultural background, mastery becomes the intrinsic motivation to drive persistence. Chinese students tend to be very diligent to understand the subject

matter discussed in the class in order not to "lose the face". This is not due to any penalties given by the teachers in the classroom but is mostly due to the unpleasant feeling when feeling a "failure". From our descriptive statistics, the influence of mastery on Mainland students is much stronger than that of Hong Kong students.

D. Personal Best Goals and Persistence

Statistically personal best goals do not have a significant relationship with persistence ($p=0.809$). Personal best goals are driven by competition between student peers so that one aims to outperform the others.

In China, competition among peers would be the norm to secure limited educational resources (e.g., admission to university, award of scholarship etc.). Often, examination results (summative assessment) determine the access to the limited resources, this exerting a pressure for students to outperform the others.

Adopting a data driven approach, we similarly explore the mediating effects between Personal Best Goals and Persistence. Surprisingly, mastery plays a very strong mediating effect between personal best goals and persistence. Figure 3 shows the mediating relationship between personal best goals, mastery and persistence (*: $p<0.05$; **: $p<0.01$; ***: $p<0.001$).

Fig. 3. Path analysis of the strong mediating relationship

PLS analysis shows that personal best influence persistence on the IT GE course through the mediating effect of mastery, with an exceptionally strong relationship between personal best goals and mastery ($p=0.000$). A promising research direction would be looking at the additional mediating and moderating effects between personal best goals and persistence.

VI. LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

We admit that this exploratory study has some limitations that may affect the generalizability of the results. First, the small sample size ($N=62$) and low response rate (around 40%) would not be sufficient to claim a generalized conclusion. However, this limitation can be justified by the nature of the research settings. While most of the students consider the mandatory IT GE course as less important than the major courses, it is unavoidable that they do not put the tasks of IT course as the first priority. As this self-administered survey is anonymous and was conducted outside the classroom, it is natural that many students did not respond to the survey. Secondly, the path modelling is mainly data driven at this exploratory stage. An extensive interdisciplinary review on related works would be helpful in building a more extensive model in the next steps.

Next steps of this research include an extensive review of the path model by incorporating suitable constructs as the mediators or moderators on the path model. As we have

already observed differences in students' perceptions between the Mainland and Hong Kong ethnically Chinese student groups, future research may also compare perceptions from other ethnically Chinese student populations, e.g., Singapore and Taiwan student groups. This would be practically useful of International educators to identify and address the behavior and needs of the increasing number of ethnically Chinese students who are studying abroad.

VII. CONCLUSIONS

With the needs to provide computer and information literacy education to serve the non-engineering major undergraduate students, this exploratory research attempts to evaluate non-engineering students' perceptions on mandatory IT GE courses. Specific research questions are: 1) What factors, i.e., persistence, can motivate students to actively participate in a mandatory IT course for non-engineering majors? 2) How do students view the relationship between the major subjects and the mandatory IT subject? and 3) How does the curriculum arrangements affect students' attitude on a mandatory GE IT course?. A survey was conducted to two groups of ethnically Chinese students from the Mainland China and Hong Kong. Our findings indicate that 1) Mastery is the factor that directly leads to persistence in the mandatory IT courses, while personal best goals and student engagement influence persistence through the mediating effect of mastery. 2) Although connection to real world activities was believed to be directly related to persistence but statistically does not show a strong relationship in our study. Instead, the personal belief that one must master all course contents has a more dominant impact on students' persistence in the IT GE course. 3) The compulsory nature of our IT course that students have no choice but to pass the IT course for graduation, thus often the learning remains at the surface level to complete the course requirements. Whether the course is engaging or not does not have a direct relationship for persistence.

The findings from this exploratory study provide insights to educators on designing mandatory GE IT courses for ethnically Chinese students. Notably, giving students a sense of mastery in the subject matter would lead to high level of persistence. Next steps of the research would be interdisciplinary review of the research model, as well as to extend the study across groups of ethnically Chinese students.

Abstract—We are experimentally conducting a fine-grain comparative analysis of two different methods of producing pre-recorded lectures versus a traditional live lecture. The two different pre-recorded lecture production methods do not require assistance from university staff members and therefore represent a low-cost approach. The first method is generating narrated slides using PowerPoint during a live lecture and the second method is the recording of a live lecture from the instructor's point of view using a head mounted camera such as Google's Glass. We present some of our preliminary results of this comparative analysis, which indicate that little interactions exist overall between the implemented modus of presenting instructional materials and the observed student learning gains within the study configuration. Thus, as a preliminary indicator within our study confines, instructors are enabled to select the most convenient fashion of lecture presentation. We are presently expanding our set of experiments (different cohorts, different specific subject matter, etc.) to obtain broader conclusions.

Index Terms—Educational technology; instructional media; content generation; multimedia

I. INTRODUCTION

The production of pre-recorded lecture materials is poised to become part of the standard practice of teaching. The increasing use of pre-recorded lecture materials for instruction is being driven by two factors: (i) the expansion of access to course materials for students via online courses, and (ii) the utilization of classroom time for non-lecture activities (i.e., flipping the classroom [1]). Recording classroom lectures can become a high-cost endeavor involving several video recorders and one or two staff members to oversee the recording process. Is it possible to use a low-cost production method that only involves the instructor that can be nearly as effective as the original live lecture? Answering this question is the primary objective of the study we are conducting.

We are conducting a study of production methods that produce pre-recorded lecture materials while an instructor is conducting a live lecture. These production methods are low-cost in that they require minimal equipment and leverage the time an instructor has already spent to produce a segment of a live lecture. Initially we are experimenting with two low-cost production methods: narrated slides and instructor point-of-view (POV) video. Our focus is on short segments of live lectures that cover a single concept in undergraduate computer

science and engineering courses. We compare the learning outcomes of these low-cost pre-recorded lecture production methods to the learning outcomes of a live lecture covering the same material.

A. Related Work

In [2] the authors compared tablet-drawing style (i.e., Khan academy style) pre-recorded lecture materials to narrated PowerPoint slides. This comparison found a balanced set of strengths and weaknesses to both approaches: viewers found Khan-style handwriting more engaging because it was personal but found the narrated PowerPoint slides more effective because they were clear and legible. These findings prompted the authors to create a hybrid method called TypeRighting. With TypeRighting, text is written by hand but then fades into a particular typeface soon afterwards.

In [3] the authors compare live lecture recording (videos of an instructor using a blackboard), recording of Khan-style tablet drawing, and self-guided book reading. The study focused on mathematics instruction for high school students. The authors found that the live lecture recording of the instructor using a Blackboard resulted in the best learning outcomes followed by the Khan-style tablet drawing. The self-guided book reading resulted in the worst learning outcomes.

In [4] the authors present the results of a large scale Massive Open Online Course (MOOC) study of various pre-recorded lecture production methods. The focus of this study was on student engagement as measured by the time students spent watching pre-recorded lecture materials. The MOOC was administered by three top-tier universities in the United States: MIT, Harvard, and UC Berkeley. The authors' primary findings were that shorter videos, Khan-style tutorials, instructors that spoke fast and with enthusiasm, were the most engaging.

The study we are conducting complements the existing work by focusing on undergraduate university level material on computing at universities with significant populations of first-generation college students. A significant number of first-generation college students may result in large inherent variances of student performance. With a broad group of students that includes significant numbers of first-generation students

we may better understand the differences in the pre-recorded lecture production methods on student performance.

B. Outline

The remainder of this paper is structured as follows. In Section II we describe the setup of our initial experiments. Specifically, we discuss the two low-cost pre-recorded lecture production methods in detail, how we deliver those pre-recorded lecture materials, and how we evaluated the learning outcomes of the students. We continue in Section III with a presentation and evaluation of the results before we conclude this paper in Section IV.

II. EXPERIMENTAL SETUP

Our initial experiments were conducted for a lecture on a brief introduction to computer processes. As part of the experiment, students were presented with a pre-test, instruction, and post-test sequence as part of their course activities in two different settings. The live lecture evaluation was performed at a major public higher education institution in the Southwest with students that have a closely related major. The two pre-recorded lectures were delivered to students in a foundational class open for students across campus (i.e., a general education credit course) at a major public institution in the upper Midwest. In both experimental configurations, students had some degree of prior exposure to the overall computing concepts as part of their curricular and course progressions. An additional limitation of this pilot study is that we did not capture prior online learning exposures by students.

A. Lecture Presentation Formats

The underlying educational content for all three lecture presentation formats was identical and complete in a self-contained fashion. The differences inherent to our evaluation were introduced by the manner in which the content was presented to students: live, narrated slides, or instructor POV video.

1) *Live Lecture*: During a live lecture the instructor presented and discussed a set of slides that:

- introduced the concept of processes (units of computational work distinguished from a program)
- identified and discussed the sections of memory associated with each process
- identified and discussed the states that processes transition through during their lifetimes
- identified and discussed the data that an operating system maintains for each process (in the process control block)

2) *Narrated Slides*: Students were presented with pre-recorded narrated slides covering the same material presented during the live lecture. The narrated slides were produced using the “record slide show” feature of Microsoft’s PowerPoint.

3) *Instructor POV Video*: Students were presented with pre-recorded instructor perspective video of a lecture-style narration of the content, which places this approach in between viewing a live lecture and narrated slides. The video was recorded using Google Glass, which is a monocular head-mounted augmented reality display featuring a front-facing camera. Minimal post-processing was performed to concatenate segments of recorded instructor POV video.

B. Evaluation

To evaluate the impact that the different lecture presentation formats have on the academic achievement, in this contribution we focus on the near transfer of content immediately after learners experienced the different formats. The employed questions were selected to determine in a comprehensive fashion yet short duration if the student learners were able to grasp the main conceptual facets of processes and comprised of several different types, such as true-false (T/F), ordering of elements (Order), matching of elements (Match), and multiple possible selections (M/S). We provide an overview of the questions we employed in the pre- and post-test that surrounded the instructional content delivery in Table I.

To evaluate the subject matter understanding, different types of questions were utilized to evaluate several underlying concepts. The different questions were presented in-classroom as part of the traditional lecture as paper-based tests, with the same configuration on pre- and post-test. The narrated slide and instructor view configurations were delivered using an online learning management system and questions on pre- and post-tests were randomized for each student and attempt.

III. EXPERIMENTAL RESULTS

The gathered results were scored as achievement in each question (and in total) and were afterwards homogenized on a percentage scale to allow for overall comparisons. A total of $N = 48$ students participated in the study, with 19 students in the traditional lecture format, 21 students in the narrated slides format, and 9 students in the instructor view format groups. We compare the differences between the post- and pre-test as learning gain for each student learner’s pairwise attempt per question and overall by subtraction.

A. Overview

Initially, we evaluate the score attained for the pre- and post-tests separately. Interestingly, the evaluation of statistically significant interaction of presentation mode and difference between pre-test and post-test using a one-way ANalysis Of VAriance (ANOVA) did not result in any broadly observable trend. We provide the scores for each question as a relative a percentage in Table II. Comparing the individual questions, we note that on average, students exhibited an average passing level (considering a typical 60 % requirement for passing grades) in the pre-test. The only exception here is question 1 ($M = 0.35, SD = 0.48$), which a portion of students had apparent problems with, as indicated by the low average and high standard deviation. The remaining questions

TABLE I

PRE-TEST AND POST-TEST QUESTIONS PRESENTED TO PARTICIPATING STUDENTS IN ALL LOCATIONS AND FOR ALL EDUCATIONAL CONTENT DELIVERY MODES. QUESTIONS WERE PARTIALLY RANDOMIZED FOR ONLINE INTERACTIONS.

No.	Question	Type
1	A process control block contains compiled program code.	T/F
2	Multiple processes can be created from the same program.	T/F
3	Please correct the order of process states (if necessary): (i) Ready, (ii) Waiting, (iii) New, (iv) Running, (v) Terminated	Order
4	Write the letter of the most appropriate word for each description. (i) A set of instructions that describe a course of action the computer should take (Program). (ii) A sequence of instructions that are executed and memory utilized by the computer for a particular course of action (Process). (iii) A section of memory to store data associated with function calls (Stack). (iv) A section of memory containing data that is dynamically allocated (Heap).	Match
5	Please select all items that would be found in a process control block. (i) Process identifier, (ii) Process state, (iii) Program code, (iv) Process memory allocation information, (v) CPU register values	M/S
6	Please select all the reasons why a process might be in the waiting state. (i) Waiting for an I/O transaction to complete. (ii) Waiting for its time quantum to expire. (iii) Waiting for an event to occur. (iv) Simply waiting for its turn to execute.	M/S

TABLE II

PRE-TEST AND POST-TEST SCORES FOR ALL STUDENTS BY QUESTION AND OVERALL.

Quest.	Pre-test		Post-test	
	M	SD	M	SD
Q1	0.35	0.48	0.51	0.51
Q2	0.84	0.37	0.92	0.28
Q3	0.69	0.27	0.85	0.26
Q4	0.68	0.33	0.70	0.34
Q5	0.72	0.24	0.85	0.25
Q6	0.72	0.27	0.79	0.29
Total	4.00	0.87	4.61	1.16

TABLE III

DIFFERENCES BETWEEN PRE-TEST AND POST-TEST BY QUESTION AND INSTRUCTIONAL CONTENT PRESENTATION MODE.

Quest.	Instr. POV (N=9)		Narr. Slides (N=21)		Live Lecture (N=19)		Total (N=49)	
	M	SD	M	SD	M	SD	M	SD
Q1	0.11	0.31	0.19	0.39	0.16	0.37	0.16	0.37
Q2	0.00	0.00	0.10	0.30	0.11	0.30	0.08	0.27
Q3	0.11	0.18	0.10	0.27	0.24	0.26	0.16	0.26
Q4	0.00	0.56	-0.08	0.49	0.13	0.33	0.02	0.45
Q5	0.31	0.39	0.00	0.31	0.18	0.25	0.13	0.32
Q6	0.17	0.50	0.02	0.40	0.07	0.22	0.07	0.36
Tot.	0.70	1.30	0.33	1.55	0.89	0.82	0.61	1.26

scored about twice as high on average with lower differences amongst learners. This accumulates to a total average of $M = 4$ out of 6 attainable points, with a standard deviation of approximately 20 % ($SD = 0.87$). Shifting the view to the post-test, we observe that the overall trend remained, with question 1 receiving the lowest attained student performance with the highest variability ($M = 0.51$, $SD = 0.51$). Overall, the variability per individual question remained at the same level, but increased for the slightly higher average total score per student learner ($M = 4.61$, $SD = 1.16$).

Thus, students on average totaled better post-test scores, but the differences between their performance increased. Specifically, we note that the higher level of variability indicates that a large portion of students performed similar or slightly worse on the post-test when compared to the pre-test.

B. Impact on Learning

We now evaluate the impact that the different instructional presentation formats have on the learning gain. We present this gain in answering the different questions (as well as total test scores) as direct comparison between the post-test and the pre-test in Table III.

Initially, we focus on the entire student population, for which averaged learning gains between 2 and 16 percent are observed. Most misperceptions or not generally available prior knowledge can be determined for questions 1 ($M =$

0.16, $SD = 0.37$) and 3 ($M = 0.16$, $SD = 0.26$), whereby question 1 also exhibits a high variability across learners. Similarly, the total score increased by about 15 % on average, but with an increased level of variability ($M = 0.61$, $SD = 1.26$), as discussed earlier. As a portion of students did not showcase an increased performance on the post-test, with some students performing worse, we note that this observation could be indicative of ceiling effects that were encountered [5].

Next, we compare the results obtained by presentation mode. Here, we note that students performed best for question 1 when they viewed the narrated slides version of the content. Question 2 exhibits similar levels of increase for narrated slides and lecture presentation, but no average learning gain for students experiencing the instructor's view ($M = 0.0$, $SD = 0.0$).

Questions 3 and 4 required a more detailed retention of content from the participating subjects, as ordering and matching are more complex than true/false questions. We note that for these questions, the lecture was the most beneficial to students. Specifically, for question 3 students increased performance by 24 % in the lecture group and about 10 % in the other two groups. The matching question 4 posed a challenge, as students in the narrated slides group even experienced a question-specific reversal effect.

The last two questions interestingly scored highest for the

Fig. 1. Interaction by presentation mode for question 5 with significant interaction between the presentation employing narrated slides and recorded instructor views.

learners that went through the instructor's view presentation of content, with higher levels of gains ($M = 0.31, SD = 0.39$ and $M = 0.17, SD = 0.5$, respectively) than observed for the lecture presentation ($M = 0.18, SD = 0.25$ and $M = 0.07, SD = 0.22$, respectively). The main difference that was revealed by ANOVA was for the difference of question 5, with $F(2,46) = 3.781, p = .030$. A Tukey post-hoc test revealed that the difference between the instructor view and narrated slides for this question exhibited a significant interaction ($p = .014$), illustrated in Figure 1. Specifically, we note that the level of increase in correct answers for this question as highest for the students that were watching the instructor's view recording. However, only the difference to the narrated slides was high enough to be considered statistically significant.

Comparing the total score gain learners achieved between their pre- and post-tests, we note that the highest increase in performance is attained by students that attended a regular lecture ($M = 0.89, SD = 0.82$), followed by those that used distance education-friendly means of watching an instructor's first person view version of a lecture ($M = 0.70, SD = 1.30$), trailed by the narrated slides version ($M = 0.33, SD = 1.55$). The overall differences could stem from the cohorts of the sampled student populations across institutions or the individual students' prior exposure to online learning environments, both of which were not captured in the present study.

IV. DISCUSSION AND CONCLUSION

We are conducting a study of production methods that produce pre-recorded lecture materials while an instructor is conducting a live lecture. Our study, specifically, seeks to uncover whether low-cost (money and time) pre-recorded lecture production methods can provide similar learning outcomes to a traditional live lecture.

In this paper we presented our findings from initial experiments we have conducted comparing two low-cost production methods: narrated slides and instructor point-of-view (POV) video for presenting lecture material on computer processes. We found that overall, no statistically significant differences were exhibited for the different modes of instructional content presentation and student learning gains within the confounds of this pilot study. For practitioners, this yields the potential implication that the generation of content to support online instruction could be performed with very little additional efforts. When choosing to perform recording the instructor POV as part of regular lecture activities, the generation of content becomes almost transparent and might only require a very limited amount of effort, such as generally required for minor post-processing and content provisioning through online learning management systems.

We cautiously note, that this initial study only covers one specific subject matter in combination with near-transfer performance evaluations shortly after the described intervention with a limited set of questions. With an increase in learner numbers and the presentation mix across institutions paired with a more robust evaluation and recognition of prior online learning exposures and student progression through the provided materials, additional insights could arise.

The evaluation of student performances were tailored to a question format that can be readily administered using learning management systems, making them suitable for large hybrid/online settings as well, which will be part of our future works. This study, in turn, is ongoing and our plan is to expand our experiments along different dimensions while addressing the limitations of this pilot study:

- Expand the lecture subject materials to span a larger fraction of undergraduate material in both institutions
- Expand the number of low-cost pre-recorded lecture production methods studied with finer granularity of interaction and exposure
- Evaluate long-term impacts on learning gains within the presentation format mix for both institutions

These future endeavors will be inclusive of research covering examination approaches and far-transfer implications.

Zip-code 69077-000 – Manaus-Brazil.

Abstract—Manaus, the capital city of the state of Amazonas and the sixth Brazilian largest gross domestic product, demands highly qualified hardware and software developers for consumer electronics and telecommunication sectors of its free trading zone. However, what can be viewed as an opportunity for the youth alumni of local institutions of higher education contrasts with the low level of qualification provided by such institutions. As a consequence, most positions either remain opened or are occupied by professionals from other Brazilian regions. Moreover, the issue relies more on soft skills than on hard skills, as the local institutions are aligned with International standard academic curriculum and cover modern technologies. Soft skill is the enter barrier to the job market. English proficiency, communication skill, writing (in both Portuguese and English) skill, among others, are top listed failure reasons in the hiring processes. As one project manager highlighted: “it is much cheaper and quicker for the company to fill in some specific technological gaps, than to leverage a poor English proficiency”. This paper presents a proposal of an involving activity aiming to address several soft skills at the same time, with minimal disturbance in the student daily routine. The concept is based on the impact of immersing the student in a systematic project development experience. Clear communicated project goal, where the students have specific roles, with assigned accountable peers, everything under the umbrella of an Agile-like software development process (derived from SCRUM) are in the core of the activity. This paper details the incremental implementation methodology of the program among four research areas, and 23 projects or project activities, involving 34 students. The results of the two years running program will also be described, including the increase of progress visibility by advisors, the improvement of students communication and writing skills and the qualification on SCRUM software development process tools and documentation. The authors mapped important success factors in achieving relevant improvement on students' profile, and presented a list of recommendations for the next phase of the program, including some obvious one, as the importance of the active participation of advisors, and some less obvious one, like the resistance to the Internet online tool due to daily meeting coinciding with the peak of Internet usage in the University.

I. INTRODUCTION

Manaus, the capital city of the state of Amazonas in northern Brazil, hosts a free trading zone with up to 720 industries, concentrated in sectors such as consumer electronics, informatics, telecommunication, and two-wheels (motorcycles and bicycles). Given the technology driven aspects of such

industries, there is a high demand for qualified hardware and software developers to support R&D activities of product and manufacturing processes. However, what could be viewed as an opportunity for the youth alumni of the few local institutions of higher education contrasts with the low level of qualification provided by such institutions.

In short, specialized human resource in Manaus is an issue in quantity and quality. As a consequence, most positions either remain opened or are occupied by professionals from other Brazilian regions. Moreover, the issue relies more on soft skills than on hard skills, as the local institutions are aligned with International standard academic curriculum and cover modern technologies. English proficiency, communication skill, writing (in Portuguese and English) skill, among others, are top listed failure reasons in the hiring processes when the candidates show they are qualified in the required technology. As one project manager highlighted, “it is much cheaper and quicker for the company to fill in specific technological gaps, than to leverage a poor English proficiency”.

The present paper proposes an involving learning activity [1] aiming to address several soft skills at the same time, with minimal disturbance in the student daily routine. The concept is based on the impact of immersing the student in a systematic project development experience. Clear communicated project goal, where the students have specific roles, with assigned accountable peers, everything under the umbrella of an Agile-like software development process (derived from SCRUM) are in the core of the activity. This activity is in the context of a broader program denominated PROMOBILE (Large Scale Qualification **PRO**gram on **MOBILE** Technologies), and follows the learning vortices methodology [2], extending the involving activity principles to an interconnected approach. The principle behind a vortex is that any educational action is more effective when the enrolled student can see from the beginning the whole educational path, being constantly challenged to get the next step towards his career opportunity.

The implementation methodology of the program engaged four research areas, and 23 projects or project activities, involving 34 students. We also describe the results of the two years running program, including the increase of progress visibility by advisors, the improvement of students commu-

nication and writing skills, and the qualification on SCRUM software development process tools and documentation. The authors mapped important success factors in achieving relevant improvement on students' profile, and presented a list of recommendations for the next phase of the program, including some obvious one, as the importance of the active participation of advisors, and some less obvious one, like the resistance to the Internet online tool due to daily meeting coinciding with the peak of Internet usage in the University.

The most important contribution of this paper is a methodology to leverage soft-skills toward the needs of the global organizations. The methodology can be easily reproduced in any institution of higher education.

The remainder of this paper is organized as follows: Section II presents the context around the problem and the fundamental principles of this proposal; Section III details the solution applied to develop the needed soft skills; Section IV we present the results, and in Section V we conclude the paper with a few important remarks.

II. PROGRAM CONTEXT AND PRINCIPLES

The three (Federal, State and Municipal) spheres of Brazilian government defined a series of tax reduction policies in Manaus to promote the establishment of R&D activities by the companies with facilities in its free trading zone. The driven law, nicknamed as *Informatics Law* for Manaus free trading zone [3], has the explicit intention to deepening the product value chain in the region, with local added-value.

In an urge to fulfill the increasing demand for highly qualified professionals, government and private companies created new or improved existing local courses of higher education on a diversity of Science, Technology, Engineering, and Mathematics (STEM) related areas. Despite the improvement of the ranking of universities and colleges nearby, Manaus is located in the Northern region of Brazil, where the education facts and figures are worse countrywide. As a consequence, the efforts to increase the number of tech courses contrasts with the poor background of undergraduate candidates, leading to a dropout rate as high as 80%. Furthermore, the remaining 20% alumni struggle with lack of most basic skills such as Portuguese (native language) writing, or oral presentation. For the most qualified ones, the lack of English skills prevent them to access the best positions.

One may suggest the trivial solution to relocate qualified people from other places to Manaus. In the end we live in an global market, global companies have a long term experience with moving outsiders from here to there, and Amazon rain forest has its appeal, one may argue. However, life is not so easy for any HR department when the topic is to hire highly qualified personnel for positions in Manaus. The city is isolated from the rest of the country, surrounded by the jungle, with road connection to very few cities (see Figure 1), and flight ticket costs more expensive than average. As many Brazilian big cities, Manaus has profound infrastructure problems, including education and medical services. One may add to it: poor public transportation, high urban violence

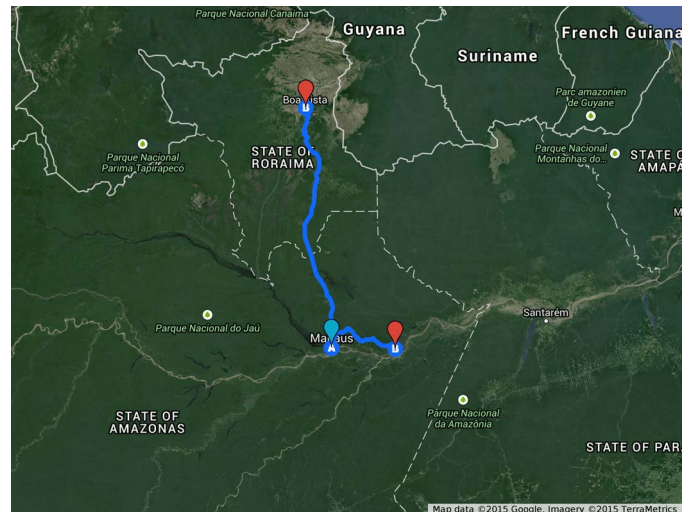

Fig. 1. Manaus (Green Mark), in the middle of the Amazon Rain Forest is located in the north margin of the Black River, the largest tributary of the Amazon River. Red Marks point to the two largest cities with road connection (in blue) to Manaus: Itacoatiara and Boa Vista.

records, high living cost, all-year hot and humid weather typical of the Amazon rain forest. Finally, one would then realize the big picture: relying on relocating professionals to Manaus is unrealistic.

A. Main Program: The Vortex Approach

In an attempt to deal with the situation, a group of researchers and company professionals met at the Institute of Computing (ICOMP) [4] of the Federal University of Amazonas to find a sound strategy to develop local human resources with adequate profile. The resulting program, named PROMOBILE, was conceived in the basis of the Student Involvement Theory[1]. However, we extend the concept of involving activities by grouping and interconnecting them under the same background. The activities have a common and well defined goal: building a professional profile out of students that are, with few exceptions, unmotivated, under-skilled, and immature [2].

The involving activity, a gear in the main Program, is called a *Learning Vortex*. The Learning Vortex is formally defined as “an activity occurring in one or more cycles, with a self-contained subject, and connected to another Vortex in such a way to contribute either in depth of knowledge or in number of persons to the whole Program” [2]. Table I lists the Learning Vortices defined by the Promobile program.

TABLE I
PROMOBILE LEARNING VORTICES.

#	Vortex	Quality	Quantity	cycle
1	Optional Subjects	medium	medium	semester
2	Talent Devel. Progr.	high	medium	year
3	Short-term events	low	high	semester
4	Advanced Training	high	low	year

The Vortex 2, the New talents development program, is defined as a participation in different projects where the students will receive scholarships, with clear granting and maintenance requirements. The candidates enroll in cycles of off-class project activities with different degree of challenges in different aspects. This is the chosen Vortex to host the strategy to develop soft skills, as the project environment naturally promotes communication and writing skills.

Targeting to better benefit from the potential of the activity, we tailored an well known Agile Software development process (SCRUM) to fit to our context, and to uniformly induce the learning actions. Native language writing and oral skills, leadership, English, besides the SCRUM itself, are just a few of the exercised soft skills. Highly productive students will receive leadership coaching. They also coordinate a small group of colleagues, and will receive a differentiated scholarship, promoting values, like meritocracy, punctuality, and self-starter attitude.

We describe the tailoring of SCRUM in the next sections. The details and how it is adopted by the several research groups inside Promobile are outlined as follows.

III. ADAPTATION AND ADOPTION OF SCRUM AT PROMOBILE

Over the past decades, several product development methodologies have been created. Among of them, there are the agile or light methods [5]. The agile methods propose to split the work in short cycles or iterations of a few weeks long aiming to achieve fast and adaptive product development process. The agile methods are adaptable and flexible and are indicated for rapid shifting demands in which results must be delivered in short periods of time. SCRUM is one of the agile methods [6].

While traditional product development strategies focus on processes and tools, the agile methods value individuals and interactions. In the same way, agile methods value customer collaboration over contract negotiation, responding to change over following a plan, and working software over comprehensive documentation [7].

A. SCRUM principles

SCRUM, as an agile method, is a framework in which people can deal and solve complex and adaptive problems, while delivering high value associated products in a productive and creative manner. SCRUM states the good practices to develop and manage products, so people can improve them [8].

The SCRUM framework associates roles, events, artifacts, and rules. Each component in the SCRUM framework has a specific purpose and is essential for the success of SCRUM. The roles associated with SCRUM compose the SCRUM team. The roles are: Product Owner, Development Team, and SCRUM Master. The events in SCRUM are: Sprint, Sprint Planning Meeting, Daily Meeting, Sprint Review Meeting, and Retrospective Meeting. The artifacts in SCRUM are: Product Backlog, Sprint Backlog, and Burndown chart.

A product owner has a complete view of the business and typically understands better the customer needs. The product owner represents an internal or external customer. The product owner determines demands and ranks each of them by importance and priority. Priorities are defined based on how valuable is the activity. Decisions are typically made based on customer priorities and on return on investment.

The Development Team is responsible for delivering usable products based on the inputs from the Product Owner. Development Teams are structured and empowered by the organization to conduct and manage their own work. Development teams are self-organizing and cross-functional.

The SCRUM Master has the role of keeping everyone aligned with the SCRUM principle. The SCRUM Master helps the Product Owner to produce a clear Product Backlog. The SCRUM master works together with the Development Team to keep focus on the chosen work items.

A Sprint is a time frame typically of two to four weeks. During the Sprint, the Development Team works to deliver parts of the product in a usable and shippable state. In the Sprint Planning meeting, together with the SCRUM Master and the Product Owner, the Development Team defines what will be developed in the coming Sprint. The work selected in the Sprint Planning Meeting to be done during the Sprint is known as the Sprint Backlog.

Daily, the Development Team meets for 15 minutes in the Daily meeting, or stand up meeting. The team checks the progress of each person by answering the following questions:

- What did I work from the last meeting until now?
- What am I going to work until the next meeting?
- What are the impediments blocking the progress of my work?

In the end of the Sprint, the Development Team demonstrates the work produced during the Sprint. The Product Owner judges if the produced items are acceptable or not, based on what has been defined in the Sprint Planning Meeting. Figure 2 illustrates a typical SCRUM workflow.

The work is organized as User Stories. All user stories are documented in a Product Backlog. The product backlog is maintained by the Product Owner, who is responsible to keep the priorities of each user stories based on their perceived added value. A subset of the product backlog is selected by the Development Team to be produced in every Sprint Planning Meeting. The set of user stories of each Sprint is the Sprint Backlog.

B. SCRUM in the academic context

SCRUM is being adopted as a structural framework by the industry to manage and develop complex products since the beginning of the 1990 decade. However, in the academic sphere, the reports of its usage are scarce.

There are experiments reported in specialized literature using students to compose the SCRUM teams [9], [10]. Also, there are literature reviews [11], [12] and systematic literature reviews [13], [14]. But most works focus on reporting case studies [15], [16], [17], [18], [19], [20].

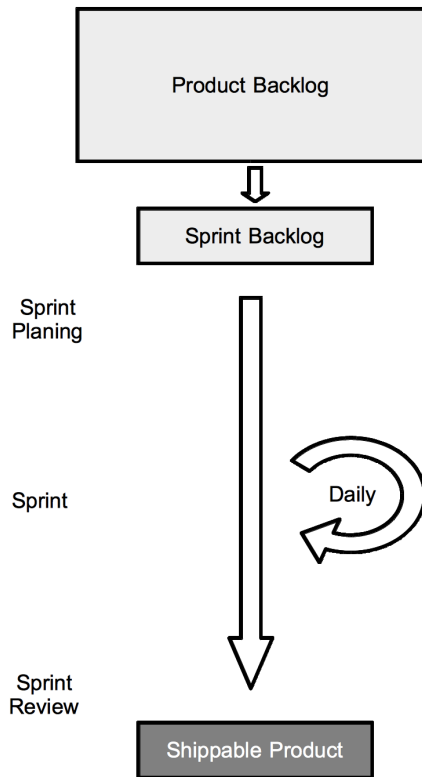

Fig. 2. SCRUM basic work flow. Part of the Product Backlog is selected to be developed during the sprint. During the Sprint, the Development Team meets daily in a 15 min stand up meeting. The Development Team delivers parts of the product in shippable state at the end of each Sprint.

To the best of the authors knowledge, this is the first work to report a case study with dozens of students as participants. This is also the first work to report the usage of SCRUM as the framework to conduct research projects within academic context.

C. The existing research group work flow

The existing advising process in the research groups involves periodic meetings in which a Senior researcher, the advisor, shares his/her vision about the research work ahead. A typical research group has a bi-weekly advising meeting. In some cases, the advising meeting happens once per week. The advising meeting is usually a one to one meeting, in which the advisor reserves one to two hours to discuss with one student his/her research project. Sometimes, the senior researcher aggregates students in groups of two or three, when their research topics are enough related to each other. A researcher group has from five to 20 students.

The challenges in this approach appear for both roles, students and senior researcher. On the researcher side, managing multiple projects is the key bottleneck. A common struggle heard from senior researcher is finding the right frequency for advising meetings so that the project would succeed. A

too frequent, such as every week, advising meetings may overwhelm the researcher and long periods without meeting the students may cause the students to work on unwanted items. In this context, students struggle to coordinate research project activities with their regular activities. Also, understanding correctly the activities to be developed combined with lack of specific technical knowledge are also recurring problems.

D. Similarities of SCRUM and the existing working flow

The adoption of SCRUM is made because its provision fits the needs of the current way of work flow of the involved research groups. We have noticed some similarities between the SCRUM framework and the existing working flow of the research groups. For example, at some extent, the existing working flow continuously and periodically reassess the project progress by means of advising meetings. Also, the Senior Researcher is the person who has best knowledge about the expect results of a research projects, sharing similar responsibilities and perspectives as a product owner with respect to a final product.

Table II illustrates the mapping between SCRUM roles, events, and artifacts with the way the research group activities were done before the SCRUM implementation. However, as the Table II shows, the mapping between some of the SCRUM entities are missing in the existing peculiar environment found in academic sphere. For example, the role of a SCRUM master is missing in the existing working flow of research groups. Also, the only official event present in the existing work flow prior to SCRUM is the advising meeting.

TABLE II
SIMILARITIES BETWEEN SCRUM COMPONENTS AND RESEARCH GROUPS EXISTING COMPONENTS. THE RESEARCH GROUP ENTITIES BEFORE THE SCRUM IMPLEMENTATION IS ON THE RIGHT COLUMN. THE SCRUM COMPONENTS ARE IN THE COLUMN SCRUM. N/E MEANS NON-EXISTING.

Type	SCRUM	Existing
Roles	Product Owner	Advisor (Senior Researcher)
	Development Team	undergrad and graduate students
	SCRUM Master	N/E
Events	Sprint	One/Two Weeks Time frame
	Sprint Planing Meeting	Advising Meeting
	Daily Meeting	
	Sprint Review Meeting	
	Retrospective Meeting	
Artifacts	Product Backlog	Research Objectives
	Sprint Backlog	N/E
	Burndown Chart	N/E

E. Implementing SCRUM

The process of implementing SCRUM for each research group was divided into three phases. Phase 01, training and coaching, is the most demanding and time consuming for all involved parts. Phase 02, monitoring, is the one in which

the involved parts understand the underlying process. Phase 03, self-improvement, the participants reach maturity with the process and start to improve it. Figure 3 shows each phase.

Fig. 3. The implementation of SCRUM in the academic environment took three phases. In the first phase, the team is trained and coached. The second phase the team becomes independent. The third phase the team starts to improve the process by themselves.

Phase 01 has two parts. In the first part, the students and the senior researcher participate in a series of training sessions. The training sessions are required to expose the SCRUM material to the involved people. In most cases, the undergrad students have already heard about SCRUM, but have never used it in practice. Graduate students tend to have real world experience with SCRUM. Sometimes, past experience may be problematic given that people may have used SCRUM differently or have bended its rules in several ways. Convincing all involved parts to follow the rules as strict as possible, at least for the first two sprints, is essential during the training sessions. The outcomes of the first part are: trained personnel in SCRUM practices, SCRUM roles definition within the research group, creation of the first version of product backlog for the research projects.

The second part of Phase 01 is composed by the first two sprints of the research group. The second part demanded strict coaching from a SCRUM experienced person, acting as a SCRUM master. During the first sprint, the newly defined development team and the product owner may have several

doubts and questions related to what to do and how to deal with the SCRUM practices. In the second sprint, the involved parts start to understand the process. During Phase 01, it is crucial to get full engagement from the senior researcher, who has the best knowledge about the research goals, the group deliverable, the project details, and the team best grouping combinations.

The team get independent enough to require minimal monitoring only after a couple of sprints. In Phase 02, the coaching required is reduced as the team has understanding of the implemented practices and each individual already knows what needs to be done. During Phase 02, the doubts about SCRUM are replaced by suggestions on how to improve the implemented practices.

Phase 03, the research group is fully independent and can be self managed. In Phase 03, the research group becomes self manageable and self improvable. Therefore, representatives from each research group, the nominated SCRUM masters, have periodic meetings to discuss improvements on the implemented practices and to share experience on how to solve problems in common related to the agile method.

IV. RESULTS

In this section we present the results obtained during the process of implementing SCRUM in a academic environment involving research groups.

A. Description of the SCRUM teams

The SCRUM implementation took place in four different research groups. The research groups are in Embedded Systems, Computer Vision and Robotics, Intelligent Systems, and Mobile Computing. The SCRUM teams are composed by a senior researcher, graduate students, and undergrad students. Graduate students participate in researches developed by the research groups. Undergrad students are part of Computer Science, Computer Engineering, and Information Technology courses.

The senior researcher takes the role of product owner. The scrum master is usually the most experienced student in the research group, typically a graduate student. The scrum master acts as such for the entire research group. The development teams have usually only one single participant. However, the SCRUM events are conducted with all members of the research group. Therefore, even though they are part of different SCRUM development teams, all members of the research group participate in the same sprint planing, sprint review, daily, and retrospective meetings.

Table III illustrates the new mapping between SCRUM components and the research group activities and roles after implementing SCRUM. As shown in Table III, we followed the SCRUM framework as much as possible. Some items of the SCRUM framework had to be adapted due to the peculiarities of the academic environment. The differences are detailed in Sections IV-C and IV-D.

In this process, four research groups participated. The first group has seven projects. The second and the third groups

TABLE III

SCRUM COMPONENTS IN THE NEW ENVIRONMENT. THE RESEARCH GROUP ENTITIES AFTER THE SCRUM IMPLEMENTATION IS ON THE RIGHT COLUMN. THE SCRUM COMPONENTS ARE IN THE COLUMN SCRUM.

Type	SCRUM	Research Group
Roles	Product Owner	Advisor (Senior Researcher)
	Development Team	undergrad and graduate students
	SCRUM Master	Experienced student
Events	Sprint	Four Weeks
	Sprint Planning Meeting	Sprint Planning Meeting
	Daily Meeting	Daily Meeting
	Sprint Review Meeting	Sprint Review Meeting
	Retrospective Meeting	Retrospective Meeting
Artifacts	Product Backlog	Research Objectives
	Sprint Backlog	Sprint Backlog
	Burndown Chart	Burndown Chart

have five projects. The fourth group has six projects. Most projects, sixteen out of twenty three, are composed by only one person in the development team. While four projects have two participants, only two projects have three participants in the development team. The largest development team, composed by four members, is part of the first research group. The second research group is composed by undergrad students only.

The initial scope of the product of each SCRUM team was software developed in the PROMOBILE training program. Some of the initial SCRUM projects became part of research projects. Therefore, research activities and results were incorporated into their backlog. Therefore, we realized that extending the scope to other research projects was possible. Thus, the scope currently covers also research results out of PhD or Master's theses of graduate students. Undergraduate students are involved in research initiation programs, which are also structured as a SCRUM team.

B. Characteristics of a Product Backlog of a research project

The Product Backlog of a research project in the PROMOBILE program is constructed following the recommendation of SCRUM. We followed the rules strictly. However, some characteristics of research projects make the user stories unique. Research projects include cyclic iterations and refinements that are typically not present in a software development project.

Research projects, in general, have investigation elements, experimentation phases, and reporting. Depending on the results of experimentation, new hypotheses may be created and may require to be retested. Therefore, recurring user stories and tasks may appear in the Product Backlog of a research project.

Another common user story is the reporting of results by means of papers. Writing papers is also a process that require constant refinements and recurring iterations and reviews with

senior researcher. Specially when the text is produced by students.

Recurring user stories and tasks are usually not well solved with SCRUM. The way they have been dealt in this context is to consider versions. Therefore, although one user story may be accepted, but after evaluating the experiment results new hypotheses appear, the cycle may be repeated, but now considering different conditions. Thus, new versions, or different results or parts of the research are developed in the new user stories.

C. Peculiarities of the academic world

We identified items specific to the academic environment that required us to change some of the SCRUM rules. The peculiarities of the academic world that conflict to SCRUM rules are:

- *Students do not engage a full working day.* The main objective of an undergrad or graduate student is his/her major course. The situation is even more peculiar for undergrad students, who engage in research project as secondary or complementary activity. They have to reserve a good part of their day to attend classes, for instance. Graduate students may engage in full day of research activities, however, they still have to attend classes.
- *Students have a busy schedule.* Because students participating in a SCRUM team are attending to different classes, sometimes in different phases of their courses, they usually have conflicting schedules.
- *Research projects developed by students tend to be done by an army of one man.* Undergrad and graduate courses require students to write dissertations or thesis on a research subject. This type of work is expected to be done by only one student. Therefore, most SCRUM projects will have a development team of one single person.

D. Changes in SCRUM

SCRUM had to be adapted to fit the peculiarities of the academic world. Here we list the changes we had to implement to adjust the framework to the applied environment:

- *Development team size.* SCRUM recommends having development teams of five to ten members. Because most projects are developed by one single person in this context, we had to overlook this rule to allow projects with one member.
- *SCRUM masters may be part of the development team.* In this SCRUM implementation, each research group had one SCRUM master. The SCRUM master, apart from acting as such for all projects in the research group, also had its own research project, in which he/she would participate as part of the development team.
- *Daily meeting frequencies.* Due to the tight schedule of students, daily meetings happened only three times per week. Some research groups also tried performing reports using virtual tools, such as instant messaging, or email.

E. Improvement of soft-skills by means of SCRUM practices

We have observed in SCRUM framework several opportunities for students exercise their soft-skills. During a regular Sprint, for instance, the implemented SCRUM offers three opportunities of 15 minutes per week of oral communication skill exercise to express objective and structured project progress by means of the daily meetings. Apart from oral communication skills, during daily meetings, students also exercise their leadership and decision making skills.

Sprint planning meetings, which occur once every four weeks, exercise oral communication skills. But during the sprint planning meetings, students also collaborate on project planning, in which they need to describe clearly their ideas in written form of user stories. During sprint planning meetings, students also exercise their ability to commit to the amount of activities they are capable to deliver in the coming four weeks.

The sprint review meetings are opportunities for oral presentation and demonstration of their results. The push to demonstrate something working motivates students to be well prepared to the meeting and show case their results. Presenting a working piece of their research project brings extra motivation for students. Even when they fail to deliver what they have promised, we have noticed that after a couple of sprints, students learned to confidently report their failure and use it to improve next sprints. Because a failure is the result of only four weeks, students feel confident to share the results and use them to help their decisions in the next sprint planning meeting.

In summary, we observed clear improvements in the following skills:

- **Writing:** Writing skills are exercised during the elaboration of reports, sprints reviews, and planning meetings. We observed that besides grammar, the ability to condense ideas and information is also exercised. The results of a questionnaire show that 70.4 % of the students report an improvement in their writing skills.
- **Oral presentation:** These skills are mostly exercised during the daily meetings. However, the sprint review and planning are the most intense moments, where not only the capacity to speak clearly is exercised, but also to communicate ideas under pressure. The results of a questionnaire show that 70.4 % of the students report an improvement in their oral skills.
- **Punctuality:** As most agile process, SCRUM is driven by a well defined and marked pace. All participants have to keep the schedule, daily meetings, follow that realization of features, and to be part of sprint reviews and planning meetings. Contrary to a regular classroom attendance, if one student delays 10 minutes he will be noticed by his peers. Stealing-time-of-others is a characteristic easily communicated to everyone. The results of a questionnaire show that 100.0 % of the students report an improvement in their capability of organizing their project activities and 100.0 % of the students also reported improvement in participating in group activities.
- **Leadership:** Leadership is specially developed by those

students assigned as SCRUM master. They have to organize meeting, call the participants and to drive them towards the completion of their sprints, even though they are peers with no clear hierarchy assigned. In this sense, leadership is also exercised among the other students, as they know that they have to support the SCRUM master. The questionnaire showed that 66.7 % of the students believe that they improved their leadership skills.

- **Transparency:** This is something that we observed during the sprint review and planning meetings. Students are encouraged to be open and to be very honest about the realization of their sprint, and to be realistic when deciding what new feature will be included in the next one. In the first sprint, some students tried to argue that their feature was satisfactorily deployed. However, after some interactions they also had the initiative to reevaluate an incomplete feature. The questionnaire showed that 88.9 % of the students have improved their decision making skills.
- **SCRUM:** Although the knowledge of SCRUM can not be seen as a soft skill, it is worth to mention the students also learn how to work under a development process. Moreover, most of R&D based in Manaus adopt SCRUM in their software development activities.

F. Report of improvements

We collected the most recurring improvement reports from the retrospective meetings of all research groups. The details of each improved item are as follows.

- **Organization.** Organization is the improvement most reported during the Retrospective meetings on all research groups. Students report that having guidelines and structured roles and events help to keep the motivation in the research project.
- **Communication.** The communication between the researcher and the students improved due to the structured and transparent way of writing user stories. The standard way of defining parts of the research project as user stories works as a protocol between the researcher and the students.
- **Pace.** The events implemented and suggested by the SCRUM framework serve as self motivation for the participants of the research project. Students report that they force themselves to be well prepared for daily meetings and sprint review meetings. Senior researchers report that the established pace help them to better organize their schedule.

G. Lessons learned during the Process

Here are the major difficulties found during the process of implementing SCRUM for the PROMOBILE program:

- **Daily meetings.** Daily meetings were the piece of SCRUM that most students reported difficulties to follow. The main reason for this problem is the conflicting schedules between the participants. We reduced the frequency

of this meeting to three times per week to mitigate this problem.

- Advisors engagement. We noticed that the engagement employed by the Senior Researcher is crucial for the success of SCRUM in this context. Specially during the training of Phase 01, students feel more confident and tend to reflect the engagement of their Advisor.
- Recurring impediment reports due to Internet connection. In order to enable virtual daily meetings, we adopted an online tool to track the SCRUM activities. However, this decision in some cases generated resistance to the Internet online tool due to daily meeting coinciding with the peak of Internet usage. At least one group reported they moved from the online tool to a spreadsheet based tool.

H. Recommendations for improvements

Targeting a better implementation and to reduce the reported difficulties, we recommend:

- Forming SCRUM teams with students that share similar schedule. In this way, the development team may be able to properly meet for daily meetings.
- Using physical boards to track the Sprint progress. Using online tools has advantages and disadvantages. In this context, for tracking the sprint progress, using a physical board may avoid problems accessing the online tool during daily meetings.

ACKNOWLEDGMENT

Part of the results presented in this paper was obtained through R&D activities of *PROMOBILE*, project sponsored by Samsung Eletrônica da Amazônia Ltda. under the terms of Brazilian federal law No. 8.248/91; and FA-PEAM through projects 1135/2011 (PRONEX) and 582/2014 (PROTI-PESQUISA).

V. CONCLUSION

We presented in this paper a novel methodology to develop students' soft-skills applied in the peculiar environment of the capital city of the state of Amazonas of Brazil. The methodology was tailored to fill in the identified gaps in the job market of Manaus based on reports of hiring managers, human resources professionals, and the youth alumni. The common understanding is that professionals graduated in local institutions of higher education lack soft skills, such as English proficiency, oral, and writing communication. In this text, we described a SCRUM based methodology, the process of implementing it in the *PROMOBILE* program, and the its impact on students' soft-skills.

The key differential of our approach is its applicability to any institution of higher education. The present work uses SCRUM as the framework to conduct research projects within academic context. Also, to the best of the authors knowledge, this is the first report of a case study with dozens of students as participants of four different research groups and 23 SCRUM teams.

After implementing the SCRUM based methodology, we observed noticeable improvements of the participants soft-skills. The SCRUM framework offers several opportunities for students exercise different skills by means of well structured events, roles, and artifacts. Writing, Oral presentation, Leadership, Transparency, Organization, and Pace are the improvements most reported by the involved people. Besides, SCRUM itself is a desired know-how, given that most R&D based in Manaus adopt SCRUM as their primary software development process. Even when they do not adopt SCRUM, the principles behind a systematic development process are still a good skill set to be carried by students as professionals.

As future work, we will follow up the research groups and their evolution as entities using SCRUM. We are going to replicate the methodology in other research groups and implement the suggested lesson learned. We are also interested in validating the outcome and the impact of this intervention in the hiring process of the students who participated in this study.

Nanotechnology: Simulation and Design

James E. Morris
Department of Electrical & Computer Engineering,
Portland State University,
PO Box 751, Portland, OR 97207-0751, USA
j.e.morris@ieee.org or jmorris@pdx.edu

Abstract— A faculty team from Electrical and Computer Engineering, Biology and Physics have developed three 300-level general education lecture courses in nanotechnology and a 400/500-level supporting laboratory with NSF support. This paper focuses on one of these courses:

ECE/SCI 383U Nanotechnology: Simulation and Design.

The course is open to science/engineering majors and students from non-technical fields alike, with minimal pre-requisites, and qualifies as a general education course for most of these. It includes four components:

- A qualitative lecture course in nanoelectronics
- A lab course in nanoelectronics simulation with LTspice
- A reading and discussion course in nanotechnology generally, but focused on nanoelectronics, and
- A technical writing course using laboratory reports as exercises.

The paper reports on the background and structure, and experiences to date.

Keywords—nanotechnology; nanoelectronics; simulation; LTspice.

I. INTRODUCTION

The prediction is that a nanotechnology workforce of 6 million will be needed by 2020 to feed a \$3 trillion/year industry [1], and the challenge to educators is to meet this demand with inherently multidisciplinary programs [2]. Not all of these workers will be scientists or engineers and for students of other disciplines the need is for exposure to the technical aspects of nanotechnology at a level which can be integrated into their own disciplinary framework as general education.

A “sequence” of three 4-credit 300-level General Education (GE) lecture courses in nanotechnology, has been developed in the Departments of Physics, Biology, and Electrical & Computer Engineering (ECE). These are available as for elective credit in students’ majors, but are primarily designed for non-majors for GE credit [3, 4]. These courses are scheduled through the academic year as a sequence beginning with PH 382U *Introduction to Nanoscience and Nanotechnology* in fall, followed by BI 372U *Nanotechnology, Society and Sustainability* in winter, and ECE 383U *Nanotechnology: Simulation & Design* in spring, but in fact each course is actually stand-alone. The “U” suffixes stand for University Studies (UNST) which indicates GE eligibility.

GE at Portland State University (PSU) includes thematic “clusters” of junior courses. Students must choose three courses from one of these clusters which must be outside the student’s major. The three new courses are all taught by active learning principles and are included in the junior *Science & Liberal Arts* cluster as SCI 382U, SCI 372U and SCI 383U, and in the *Design Thinking/Innovation/Entrepreneurship* cluster in the School of Business Administration under their PH/BI/ECE identifiers. Every graduate must complete the entire GE sequence [5], which consists of:

- A freshman sequence of three quarters in a single elective cross-disciplinary topic
- Three elective sophomore courses which then serve as prerequisites to three of the many junior GE clusters
- Three elective junior courses from a single cluster which includes courses from multiple departments, grouped around a single theme.
- An integrating two-quarter senior capstone experience, including some form of community service.

A future goal is the introduction of nanotechnology capstone projects which will integrate STE and non-STE “graduates” of the nanotechnology courses alike into industrial nanotechnology projects as practiced in ECE Senior Design.

Every course at PSU which is approved for the GE (UNST) program has goals defined in terms of

- Inquiry and Critical Thinking
- Communication
- The Diversity of Human Experience, and
- Ethics and Social Responsibility

These goals are regularly assessed for all GE courses and actually provide a good match to the non-technical sections of the Accreditation Board for Engineering & Technology (ABET) accreditation criterion 3 f, 3g, 3h and 3j [6, 7]. For many engineering students, the linkage of the GE/UNST component of the degree structure to their technical studies will provide relevance and a more meaningful context [8].

The nanotechnology cluster courses are tailored to support interaction between STE (science, technology and engineering) and non-STE students, who take them together. There are no course-specific college-level prerequisites for any of them, which means more specifically that there can be no calculus expectations.

These courses have previously been reported on elsewhere [9-11]. A follow-on 2-credit ECE 410/510 *Nanotechnology Laboratory* course has also been developed and will be described separately elsewhere [12].

II. NANOTECHNOLOGY PROGRAM

Technically advanced nanotechnology courses are now relatively common, especially in active research departments, and many with an interdisciplinary flavor [13]. This program, however, addresses the recognized difficulties in developing technical awareness in the general population [14-17] by bringing STE and non-STE students together in the same classroom in courses with both technical and social contents. The overall program goals are to:

- Address the need for greater technical awareness in the general student population
- Extend the breadth of nanotechnology education for science and engineering majors, and
- Expose both student groups to the social, economic, and ethical issues of nanotechnologies.

and the program objectives are stated as:

- To expand the educational opportunities in Nanoscale Science and Engineering (NSE) for STE majors, and especially to open up a greater level of awareness of the roles of the other disciplines.
- To increase awareness of the potential applications of NSE technologies, based on a qualitative understanding of their underlying scientific and engineering principles, amongst the general non-STE student body.
- To develop an understanding in both student groups of the social, economic, and ethical issues which are posed by the development and adoption of NSE technologies.
- To provide hands-on NSE laboratory experiences for both STE and non-STE students, and
- To promote both broad and specialized NSE skills to enhance nanotechnology-related employment opportunities for STE and non-STE students alike.

These objectives have been achieved within the constraints of existing degree regulations and crowded curricula by using the existing campus junior GE elective structure. Each course is tailored to support interaction between the STE and non-STE. There are no college-level prerequisites for any of the courses which means no calculus!

The STE majors in the cluster courses outside the major (i.e. for GE credit) benefit in several ways:

- By seeing nanotechnologies from a different disciplinary perspective, supplementing their advanced nanotechnology studies within the major,
- By gaining an understanding of the social, economic, and ethical issues which surround their chosen area of specialization, and
- By satisfying their GE requirements with courses directly relevant to their major, providing context and greater interest.

For STE majors, the remaining GE requirements provide sufficient flexibility to complete the PSU institutional humanities and social science distribution requirements for STE degrees.

Examples from nanotechnology provide non-STE majors with an understanding of the role of technology in society and how scientists and engineers function, as they explore the same social, economic, and ethical issues. This awareness has a ripple effect, propagating into the general community through discussions and social interactions with their non-STE peers.

The university itself will also benefit from the program as a model for increased relevance of the GE sequence to students' majors in all specializations. The program enables STE students to improve communication on technical issues with non-STE students and simultaneously provides non-STE students with an appreciation for both the benefits and the potential pitfalls inherent in developing these (or any other) new technologies.

As the importance of nanotechnologies grows for local industry, it will benefit by the increased availability of both more broadly educated specialists and more technically aware non-specialists, and from the R & D efforts (including social impact studies) of the capstone teams.

The courses are of special interest for high school science teachers and the faculty team is currently planning a one-day workshop at the Oregon Science Teachers' Association's annual conference to discuss how the materials that have been developed might be used in high school (and middle school) classrooms. The course materials will also be made available to the academic community at large, e.g. on NanoHUB.

For STE majors who take the courses for technical elective credit, the engineering or scientific content must be sufficiently different from the core curriculum and other electives to augment that curriculum and maintain their interest in the technical side. At the same time, the equally important objective is to engage them in the broader social issues to be raised and discussed. For non-STE majors, the complementary challenge is to present technical material in an understandable way to students without the traditional technical background, so that the social issues can still be interpreted within a technical context. For some, those social issues provide the base from which they can interpret the technical aspects of the classes. Both groups need to appreciate the difficulty of predicting social consequences of nanotechnology. As

examples, while self-assembly manufacturing techniques may lead to reduced costs and promote wider use of new products, the escalating use of silver nanoparticles in health, electronics, and the home may be affecting the aqueous environment and food chain [18]. Nano-composite materials can provide increased strength and stain resistant coatings, but the toxicity of nanoparticles is poorly understood and differs from that of the corresponding bulk materials. Such examples further the goal of creating a better informed and more engaged citizenry.

III. ECE/SCI 383U NANOTECHNOLOGY: SIMULATION AND DESIGN

A. Course Objectives

Engineers rely heavily on commercial modeling and simulation software for both design and analysis. This course provides insight into the engineering design process for non-STE students and an expanded experience for ECE majors to modelling techniques beyond those used in the core curriculum. These are used to model nanotechnology phenomena, materials, structures, and devices, and to design applications in LT-SPICE. The software is free and is the ECE Department staple, being installed on all laboratory PCs and available for students to download should they choose to run their simulations on their own laptops or at home. Eventually, students develop and run their own models. The lab runs in an active learning mode with STE and non-STE majors working in pairs. Most of the non-STE students have never taken calculus, which is therefore not used. The course also draws upon the resources of the NSF- supported Purdue website repository "NanoHUB,"

The Course Outcomes are stated to be:

- Understanding of the basic concepts of nanotechnology
- Understanding of the role of computer simulation in engineering design
- Competence in the application of one simulation software
- Understanding of the physical operation of selected nanodevices
- Understanding of environmental, health and social issues of nanotechnology
- Ability to write competently and appropriately to the context

The challenge is to provide material accessible to students with no calculus or physics background, while offering appropriate challenges to ECE and physics majors. The technical content is focused on LT-SPICE modelling of nanoelectronic devices and circuits, presented as an example of how engineers employ modelling and simulation. A very brief introduction of the electrical concepts that will be needed, (but no others,) is followed by a familiarization exercise in graphical LT-SPICE modelling of simple resistive and RC circuits and a diode characteristic. From there on, the LT-SPICE simulations are selected to demonstrate selected

nanoelectronic examples in a studio/lab environment. Ideally the student groups are balanced, so each pair consists of one STE and one non-STE student, and effective bilateral learning here should be based on the STE/non-STE student interaction. The STE students are challenged to be able to explain technical concepts without benefit of mathematics, which colleagues who have previously taught similar crossover courses advocate as a truly educational experience. The course also presents challenges for ECE students, nanoelectronic examples requiring LT-SPICE capabilities that are not used elsewhere in the curriculum and a need to develop their own models.

Electron tunneling is the continuing theme of the lab simulations, with all but one based on this effect, albeit indirectly. The course also provides non-technical majors with some more general appreciation of how device principles can be employed in circuit and sensor applications. The most successful GE courses are usually those that incorporate the instructor's research interests or viewpoints which would not normally be included in core curricula. Hence, the course uses nano-devices such as TDs, RTDs, SETs, etc., and an emphasis on graphical techniques and graphics-based simulations. *Ad hoc* guest lecturers have also presented research related material, e.g. nano-laboratory safety issues, etc.

B. Course Structure

Catalog description: Introduction to basic electrical concepts, nanotechnology, and the principles of modelling and simulation. Modelling and simulation are used to examine environmental and health hazards and the applications of nanotechnology in environmental and biomedical sensing and in current and future nanoelectronic technologies. Course is designed for both STE and non-STE majors.

"This course will provide insight into the engineering design process for non-engineers and an introduction to the applications of nanotechnology in micro/nanoelectronics, environmental nanosensors, biomedical devices, etc. Understanding of these applications will be achieved by the combination of qualitative explanations of device operation with quantitative simulations of performance."

The course plan for spring 2015 is shown in Table 1. There is also a weekly discussion session based on the textbook [19] and to a lesser degree on a variety of specified references [20-25]. The simulation labs are based on publications in the research literature [26-38].

The course runs as:

- One 75-minute lecture (streamed on-line)
- One 75-minute discussion period
- One 170-minute lab period

These times meet the normal campus distributions for a 3+1 credit course. In addition, a block of time is scheduled for individual meetings with the WIC tutor.

Evaluation is based entirely on eight weekly lab project reports on the computer simulation exercises, a final individual discussion paper on a topic TBD, and on participation in the class discussions.

The complete grading scheme is shown below. There are no formal exams.

- Eight simulation assignment reports: 80%
 - Technical accomplishment (8x5.0%)
 - Technical report content (8x2.5%)
 - Writing (8x2.5%)
- Final topic paper: 20%
 - Content 15%
 - Writing 5%
- [Class participation bonus 10%]

Lectures	Simulation Labs
Syllabus & Introduction to EE concepts	Introduction to EE concepts (cont'd)
Introduction to EE concepts (cont'd); LT-SPICE	1. Introduction to LT-SPICE
Nanoparticles	2. Single electron box
Electron tunneling	2. Quantum Cellular Automata (QCA)
Carbon Nanotubes (CNTs)	4. CNT composites
Resonant Tunnel Diode (RTD)	5. RTD & circuits
Single Electron Transistor (SET)	6. SET & circuits
Memristors & Nanosensors	7. Nanosensors;
No lecture	8. Memristor & circuits
Guest lecture: Environment & Nanotoxicology	Lab visits: Nanotechnology & TEM/SEM labs

Table 1. Fall 2015 ECE/SCI 383U course outline

The course is a designated Writing Intensive Course (WIC), so 25% of the grade is specifically allocated to the writing, (format, spelling, grammar, style, etc.) with the emphasis always on writing to the target audience (e.g. peers, supervisors, lay readers, etc.) For ECE majors (only) the course may be substituted for the BSEE/BSCpE WR327 Technical Writing requirement, which is reflected in the writing assignment formats (e.g. technical report, executive summary, journal/conference paper, newspaper article, position paper, e-mail, Powerpoint™, poster paper, etc.) as specified in the lab notes. First drafts of the lab reports are due by e-mail on Friday after the lab on Wednesday. The WIC tutor provides feedback on the drafts (in person if the student attends the voluntary Friday WIC workshop) which are e-mailed back by 5pm on the following Monday, with the final version submitted the following Wednesday. This schedule provides a one-week two-step lab reporting cycle. Final WIC grading is completed by the end of the week and the instructor completes the technical grading for return at the Monday lecture. The WIC tutors are English graduate students who have completed a course in teaching writing.

The BSEE and BSCpE curricula are very full and students have a very limited choice of ECE electives which must be selected from a limited list for each specialization. The program's concept is based on a balance of STE and non-STE

students and the challenge is to attract enough ECE students to provide a STE core. The WIC designation and departmental acceptance as a replacement for the traditional Technical Writing class is intended to accomplish that, but given that half of the ECE juniors are community college transfers who satisfy their writing requirements prior to transfer, and assuming that the remainder take their writing course uniformly distributed across three quarters, it needs almost all of the eligible ECE majors to take the nanotechnology course to fill the STE slots and balance the non-STE students.

Instead of a graduate teaching assistant, the course employs an undergraduate "alum" as a mentor. Although undoubtedly dependent on the individual chosen, this has proved to be a key component to the success of the course.

IV. CONCLUSIONS

The course is running for the second time at the time of writing (spring 2015.) The external evaluation team runs on-line pre- and post-course surveys, student interviews, and classroom observations, but none of these were performed for the first offering. Consequently, the changes that were made for the second run had to be based on the internal campus student course evaluations and conversations with students during the course itself. As a result of these, the course was totally restructured.

The main point was that while students in BI/SCI 372U expressed a desire for more technical content, the reverse was true for ECE/SCI 383U, where the delivery of technical content was much too fast for the non-STE students, even with no calculus employed. In addition, while students expressed appreciation for the required textbook [19] and the prescribed reading schedule, the subsequent discussion promised in the syllabus generally gave way to the "need" to get through more theory to support the labs. Furthermore, the "lab" session was originally only expected to provide a start on the lab exercises which were to be completed at home. That worked for some, but in general it was clear that more lab time is needed to move others further along.

But the biggest changes required were modifications to the LT-SPICE labs themselves. The design of the experiments leant heavily on the research literature, and frankly some of the models could not possibly have worked as published. These are being reworked during the second offering of the course, and are working better. Nevertheless, more work is needed on the labs before the course runs again, and the undergraduate mentor is working with one of the students to identify ambiguities in the lab instructions and where more clarification is needed. In addition, new experiments are proposed, e.g. nanoCMOS, CNFETs, a more physically based tunneling model, etc.

Although the course title includes the word "design," there has been negligible design component to the course. It is intended that this be rectified by the addition of a small simple design component to each lab exercise.

One aspect of the course which did work extremely well was the interaction between the STE and non-STE students, primarily in the generous commitment of STE time to assist the non-STE students with the lab exercises. The limited discussion of social issues provided less need than expected for non-STE viewpoints. Also, there was no evidence of any disparity in the writing abilities of the STE and non-STE students.

The current class includes physics, chemistry, biology, pre-med, mechanical engineering and general science majors, but only a few qualifying as genuine non-STE. The STE/non-STE balance is a target that has clearly been missed, despite targeted recruiting.

Another missed target, although perhaps the same one, is the ECE student enrollment which was to have been encouraged by the technical writing provision. It turns out that the standard technical writing course is run totally on-line every term, including summer, and that almost all ECE students take it that way over summer. None of the other students (whether STE or non-STE) need the WIC qualification, there apparently being more than enough to meet campus requirements, so it is proposed to abandon the WIC component in future.

Interestingly, just on half the students currently enrolled have previously taken both the physics and biology courses and are very positive about the sequence, with one (non-STE) contemplating a change of major. These students qualify for an informal certificate of completion which seems to have been a motivating force, much to the faculty's surprise.

At the end of the spring 2015 course, (the second offering,) student comments on the course evaluations included: "A lot of work for a GE course," and "A difficult course but I learned a lot."

ACKNOWLEDGMENT

These courses are being developed with the support of NSF Grant EEC-1242197 under the Nanotechnology Undergraduate Education program and will all be externally evaluated for quality feedback.

Incorporating Parallelism and High Performance Computing into Computer Science Courses

David R. Monismith Jr.

Department of Mathematics, Computer Science and Information Systems
Northwest Missouri State University
Maryville, MO
monismi@nwmissouri.edu

Abstract— This work describes research, efforts, and outcomes for several Computer Science courses after incorporating XSEDE High Performance Computing (HPC) Resources and recommended and required curriculum additions from the ACM 2013 Computer Science Curricula and IEEE Technical Committee on Parallel Processing Curriculum Guidelines. The work herein describes the courses affected by this work, including Computer Organization (44-345), Operating Systems (44-550), Software Engineering I and II (44-561/2), and Parallel Programming (44-599) - undergraduate and cross-listed courses at Northwest Missouri State University. Guidance for novel content in these courses was drawn from the ACM/IEEE CS 2013 Curricula and from recent research on HPC education. As recommended by the curricula guidelines, topics in parallelism were incorporated into many required Computer Science courses. Therefore, an analysis of contact hours devoted to parallelism in required CS courses at Northwest is also included. Results, based upon student surveys from the Operating Systems (OS) course and course reviews, indicate student interest and success in students having learned key topics in parallelism. Particular emphasis was placed on incorporating parallel computing topics into the OS course.

Keywords— *High Performance Computing; Novel Course Curricula; Parallel Programming.*

I. INTRODUCTION

Innovative course modules play an important part in students' university education. They allow educators to introduce material from research and stimulate students' interest. For example, advances in operating systems (OS) courses have come in many forms. These include the development of simulated operating systems for instruction (e.g. Nachos and Pintos) [1,2], kernel development modules [3], use of mobile operating systems [4], and many others. Course focus may vary widely, as well. Course assignments, particularly those related to parallelism may provide an application, simulation, or engineering-oriented focus or may emphasize other aspects depending upon students' interests.

Regardless of the focus of assignments and the audience, fundamental computer science courses such as Computer Organization and Operating Systems must provide coverage of basic principles. For example, introductory OS courses should include topics such as history, concurrency, synchronization, deadlock, scheduling and dispatch, memory management, security, and file systems. Elective OS topics might expand

upon core topics, consisting of modules on networking, kernel development, virtual machines, device management, file systems, real-time and embedded systems, fault tolerance, or system performance evaluation [1-15]. Similarly, Organization courses should include coverage of assembly, basic CPU architecture, fetch-decode-execute, etc [16,17]. Many existing OS and Organization courses provide coverage of multi-core and superscalar architectures, GPUs, and related operating system utilities. For example, the Calvin College OS course included coverage of multi-core scheduling in 2009 [18]. At Lewis and Clark College, the Organization course covers cache architecture and coherence through GPGPU programming [19]. Special topics in such courses are often related to parallel programming, multi-core architectures, and distributed computing [1-19]. To describe coverage of parallelism, a significant portion of this paper provides an experience report of the use of high performance computing (HPC) and parallel programming throughout the CS curriculum.

There are several compelling reasons to use HPC and parallel programming in instruction. First, adding HPC and parallel programming provides multiple learning opportunities and outlets to make the learning process more exciting. Students are able to access hardware that is generally only available to graduate students and faculty researchers such as NSF XSEDE supercomputing resources – TACC Stampede, TACC Ranger, and Purdue Steele [20]. Similar tools such as LittleFe Cluster computers provide an easy on-ramp to HPC tools [21,22]. This may provide a sense of ownership and pride over the class. It may also increase students' level of interest by making the course exciting and fun. Next, HPC utilities provide a platform for students to learn about UNIX/Linux, batch scripts, batch operating systems, C programming, and the message passing interface (MPI). Teaching about all of these tools gives students an opportunity to learn many details of multi-threaded and multi-process programming.

Coverage of topics in lecture and through assignments play a strong role in teaching and reinforcing concepts. These are covered in detail for courses applicable to this work. For example, Computer Organization students experienced lectures introducing multi-core processors, SIMD Instructions, Flynn's Taxonomy, superscalar and pipelined architectures. Assignments included questions on topics including GPGPU processing and supercomputing to increase awareness of parallelism. In Software Engineering I, coverage of testing topics such as parallel design, deadlock, and live-lock

increased student awareness of parallel processing issues. In Software Engineering II, students engaged in a semester-long project, requiring a database or another complex tool, which presented opportunities for experience with topics related to parallelism. Furthermore, OS class assignments using C, MPI, and POSIX threads (PThreads) included hands-on applications of threaded and process-based techniques such as semaphores, barriers, blocking and non-blocking message passing, thread scheduling, etc. Weekly lab assignments were included to ensure students were engaged with hands-on experience. Lectures covered POSIX and MPI Programming assignments, and homework emphasized use of parallelism. These started with threaded and MPI-based matrix multiplication to teach load balancing and scaling. Further assignments covered the producer-consumer problem using a gather pattern, deadlock through a cell phone tower simulation, and multi-core round robin scheduling. Final assignments included file I/O benchmarking using the Lustre parallel file system and a tutorial on the Xeon Phi coprocessor.

This work provides a description of the use of both HPC and Parallelism in several courses. These include in an application-oriented undergraduate OS course, Computer Organization, Software Engineering I/II, and Parallel Programming. First, background on curriculum standards, existing courses, HPC and parallel programming utilities, and hardware resources are provided. Course goals are described, including basic course components, topic coverage, and HW/SW coverage. Discussion of lectures and projects is also provided. Additional content covered includes research and information related to development of parallel curricula with emphasis on HPC technologies for the Computer Organization, Operating Systems, and Software Engineering courses. Thereafter, an analysis of the CS contact hours related to parallelism is presented as they relate to the ACM/IEEE CS 2013 Curricula [23]. Finally, survey results from the OS course are presented, and conclusions are drawn about the efficacy of the content presented.

II. BACKGROUND

Background coverage necessary for this document spans several areas. There are many existing courses from which Parallel Programming content and examples may be drawn. For example, an OS course could include coverage of the Linux and Android kernels [3,4], simulated or pedagogical operating systems [1,2], or even theoretical topics to introduce parallel, multi-threaded, or multi-core concepts. Guidelines for course content related to parallelism and HPC were drawn from textbooks and ACM/IEEE curriculum standards [23]. Software and hardware resources are discussed. Student background and interests were also considered. Background is provided on each of these issues in this section.

A. Survey of Existing Courses

A survey of several courses provides some insight into what is currently taught in Computer Organization, OS, and Parallel Programming. Many, introductory OS courses provide an overview of processes, threads, scheduling, synchronization, deadlock, memory management, security, and various advanced topics [1-15]. Computer Organization courses cover

topics including performance, assembly, digital logic, etc., as shown in [16], [24], and [25]. Finally, parallel programming courses cover libraries such as OpenMP and MPI and provide coverage of topics such as load balancing, message passing, parallel algorithms, parallel complexity, and more [26,27]. Discussion of Data Structures and Software Engineering courses is omitted in this section as ideas were drawn predominantly from curriculum standards. In this section, a brief survey of existing Computer Organization, Operating Systems, and Parallel Programming courses with emphasis on topics in parallelism is provided.

In Computer Organization and similar Systems courses, attempts to incorporate parallelism may be found at several colleges. For example, [24] and [25] include coverage of instruction level parallelism, superscalar pipelines, and even OpenMP. Reference [19] even includes coverage of CUDA to provide students a better understanding of the importance of cache. This is accomplished through control and comparison of CUDA local variables, shared memory, and global memory. These CUDA memory structures represent GPU registers, cache, and RAM [19]. Ideas from these courses and from the ACM 2013 Curriculum Standards were incorporated into 44-345 at Northwest and are discussed in the next section.

Numerous Parallel Programming course sites are available; however, ideas for 44-599 were drawn from a few major sources. These include [26], [28], and [29]. Content in such courses includes basic parallel programming concepts such as processes and threads, and often includes parallel primitives and communication tools such as map, reduce, scan, histogram, scatter, gather, and various all-to-all communications. Topics covered often include sorting, searching, linear algebra, FFT, image processing, and related topics.

Significant variety exists in topics covered in OS courses. At Berkeley, students study databases, networking, security, and privacy [15]. Calvin College faculty added multi-core scheduling and a comparison of POSIX and OpenMP threads to their OS and Networking course [18]. Some graduate level OS courses emphasize HPC. TAMUCC has a course in advanced operating systems using MPI for projects. It covers distributed variants of mutual exclusion, scheduling and process management, shared memory and file systems, recovery and fault tolerance [12]. Ideas for the 44-550 OS course at Northwest were drawn from the TAMUCC course as well as several distributed systems courses. These included use of MPI, threads, multi-core scheduling, and networked file systems. Additional content was drawn from a distributed systems course at the Australian National University [30], from the past OS instructors at Northwest [13], course materials from Tulane [5], the SC12 Advanced MPI tutorial (for MPI-IO) [31], and numerous discussions with HPC educators at various HPC conferences.

Some OS courses place emphasis on kernel engineering in assignments [3,4,9,11]. Reference [3] uses a standard Linux kernel, and [4] uses the Android kernel (likely the first OS course to use it). Such courses are quite interesting and allow students to learn about device drivers, disk IO, etc., directly. Another approach that many schools use is a pedagogical operating system such as Pintos or Nachos. In these courses,

students complete portions of a model OS without needing to understand system utilities [1,2]. Other courses use an application-oriented approach; wherein, assignments involve simulation of OS utilities and programming with existing OS tools [8,10,13]. Variations in approaches are often based on instructor preference and student skills. The approach used in 44-550 was both application and simulation oriented. Provided core competencies are met, such variation in course content provides different strengths to new computer scientists entering the workforce. Students at Northwest have strong experience in Java, and little experience with the command line and C programming. So, an application-oriented approach was chosen by the author.

B. Hardware and Software Resources

In this section, both hardware and software resources essential to the inclusion of parallelism and HPC in coursework are discussed. First, hardware resources such as desktops, laptops, and compute clusters are examined. Thereafter, various operating systems and software resources for parallel computing are investigated.

HPC resources or their equivalent are often readily available for educators. Many computer science and engineering departments have multiple rack unit servers available where a batch scheduler may be installed. Schools without access to such resources, can make use of a LittleFe cluster – a low-cost (>\$2000), 6-node, open-air cluster [21,22], the Extreme Science and Engineering Discovery Environment (XSEDE) [20], and Amazon's EC2. These and other free or low cost options can provide computing resources for educators. Access to XSEDE and EC2 resources do require the educator provide a CV and summarize planned work [20].

Since HPC resources (e.g. XSEDE) are often highly utilized, a batch queue is used to allow for sharing of resources. Resources must be requested using a batch script, and such systems are often built as a cluster with a linux variant for an operating system [20]. Such systems are often built from multiple nodes (e.g. multiple rack servers), and users often require free OS and software options. Therefore, distributed computing resources are often Linux-based. OS options studied by the author for parallel programming and/or distributed system use include Linux variants such as CentOS, BCCD (the Bootable Cluster CD), Ubuntu, and Cygwin (a Linux shell for MS Windows). These options are freely available and either include or have tools to easily install parallel computing tools. Many such tools provide for desktop/laptop users to easily and freely install parallel programming tools [10,20-22].

A wide variety of tools exist for parallel programming. These include C libraries such as Pthreads, OpenMP, and MPI [26,27]. Additional tools such as Java Threads, Python, and novel parallel programming languages like Chapel also exist. The message passing interface (MPI) library is used for HPC interprocess communication in C and Fortran and is available with limited support for Python and Java. Other such libraries are available, but MPI is perhaps the most commonly used HPC library for message passing. MPI is a library of functions that provides process creation, parallel file IO, point-to-point, process-to-process communication, and many other features. It

provides functionality for parallel and distributed computing across both homogeneous and heterogeneous compute nodes [31-33]. MPI can also be installed on a laptop and can provide added functionality, including the ability to oversubscribe or schedule more processes than processors available on a compute node. Additionally, MPI, when combined with a batch scheduling system and appropriate OS utilities, provides the ability to send messages back and forth between processes without concern for particular architecture or topology [31-33].

When teaching MPI, it is not necessary to present all the functions included within the standard. Basic functionality is more important [34]. For OS and Parallel Programming, functions to start and end MPI, to obtain basic environment data, and to send and receive messages are of particular importance. These allow students to learn Parallelism and OS fundamentals like concurrency, interprocess communication, race conditions, and deadlock [10,12]. A set of basic functions recommended to introduce students to MPI is provided below.

- `MPI_Init` – Initialize the Message Passing Interface
- `MPI_Finalize` – Close the Message Passing Interface
- `MPI_Comm_rank` – determine a process's identifier
- `MPI_Comm_size` – determine the number of processes
- `MPI_Send` – Send a message (blocking)
- `MPI_Recv` – Receive a message (blocking)
- `MPI_Irecv` – Receive a message (non-blocking)
- `MPI_Isend` – Send a message (non-blocking)
- `MPI_Test` – Determine message receipt (non-blocking)
- `MPI_Wait` – Wait for a non-blocking message
- `MPI_Barrier` – Wait for all processes to call barrier
- `MPI_File...` – Provides parallel file IO.

Teaching these functions and explaining their purpose gives students an introduction to many Parallel Programming and OS topics. Since the MPI environment creates multiple processes that execute all the code contained between the initialization and finalization steps, these provide a starting point for discussion of multiprogramming. `MPI_Comm_rank` and `MPI_Comm_size` functions provide environment information including the number of processes running and each process's identifier (i.e. its rank). Again, these are core issues in an OS course and reinforce process control block (PCB) content and understanding of the process table. The send and receive functions allow for discussion of interprocess communication with and without shared data. These functions also allow for early introduction of concepts such as waiting and deadlock without the need to review synchronization tools. Additional MPI functions that provide functionality for scatter, gather, broadcast, and all-to-all message passing can be covered in detail for Parallel Programming courses but are not necessary for OS. Finally, MPI file I/O tools allow for introduction to networked file systems [10,12].

C. ACM 2013 Curriculum Guidelines

ACM 2013 Curriculum Guidelines (CS2013) call for increased inclusion of topics related to parallel computing in numerous "Knowledge Units" (KU). Areas related to parallelism include Architecture and Organization, Information Assurance and Security, Operating Systems,

Parallel and Distributed Computing, and Systems Fundamentals. Each KU has a minimum number of contact hours that institutions with Computer Science degrees *should* cover [23]. The author has estimated the minimum number of CS2013 contact hours related to parallelism by KU that an instructor should cover in the list below.

- 3.5 of 16 Architecture and Organization (AR) Hours
- 0.5 of 9 Information Assurance and Security (IAS) Hours
- 9 of 15 Operating Systems (OS) Hours
- 15 of 15 Parallel and Distributed (PD) Hours
- 11 of 27 Systems Fundamentals (SF) Hours

This minimal estimate was computed as the number of topics within a Knowledge Unit (KU) including parallelism, divided by the total KU topics, and then multiplied by KU contact hours. Thus, computer science students should experience at least 39 contact hours (e.g. one full course) related to parallelism during their undergraduate careers. An estimate of these items is provided in Figure 1.

III. COURSE GOALS AND METHODOLOGY

Within this section course goals and methods are presented for the Data Structures, Computer Organization, OS, and SW Engineering courses. Several generalized goals were set by the author for this work. These included meeting and exceeding CS2013 [23] requirements, improving student job prospects, making coursework more interesting and relevant to “real world” standards. Furthermore, the author desired to help students to become competent to assisting with research and/or jobs requiring HPC resources. This provided students with a thorough understanding of both parallel programming and parallel hardware.

A. Software and Hardware Resources

All students at the author’s university are provided with university issued laptops. Since 2013, installation of parallel programming tools such as OpenMP, Pthreads, and MPI have been straightforward. Such tools are supported through Cygwin and are also available on multi-node Linux clusters. Prior to 2013, the author provided all students with a bootable live

DVD of Knoppix that was remastered with OpenMPI [33,35]. Currently, students are able to install software such as OpenMPI in Cygwin, install a Linux virtual machine with BCCD, or to use a Linux cluster such as LittleFe or Stampede [20-22]. Thus, all students are provided with access to the necessary software. These tools provide students with the capability to compile, debug, and run programs locally and allowed them to experience a Linux operating system. Furthermore, at Northwest, OS and Parallel Programming students have access to HPC resources via XSEDE through educational allocations of 10,000 or more Service Units (SUs) where 1 SU = 1 CPU-core hour [20]. Students are instructed in the use of ssh/sftp and on using batch scripts to submit and run jobs on various clusters within two weeks of entering the OS or Parallel Programming courses.

B. Data Structures (44-242)

The Spring 2014 Data Structures course, taught by Dr. Phillip Heeler, included lectures consisting of approximately 6 contact hours on parallelism through a two week module. This module included an introduction to Java Threads including the start, run, and join methods. Examples including race conditions and semaphores were provided to students. Several lab assignments were completed or started by students in class and covered Linux and parallel programming on a LittleFe cluster. Additionally students completed an assignment involving computing binomial coefficients with multiple threads that required students to use the join method to synchronize their results [36].

C. Computer Organization (44-345)

Within the Computer Organization course, approximately 7.5 contact hours were devoted to topics related to parallelism [23]. Topics related to parallelism in this course have been refined over three iterations of the course (Spring 13, 14, and 15). In particular, contact time involved several lectures related to parallel hardware/software, and hands-on activities.

Lectures included discussion and interaction with cluster components from a LittleFe system including compute nodes, networking hardware (switches and cabling), and networked storage [16,21,22]. Such interaction involved logging onto the system in class, writing, compiling, and running a program [16,37]. Furthermore, in class activities included description and execution of the N-Body problem through the GalaxSee LittleFe learning module [21,22]. Several lectures were also devoted to benchmarking—multi- vs. single core, Amdahl’s Law and Speedup. Further lectures included coverage of multi-core CPU components including cache and vector registers. Finally, lectures were provided on Flynn’s Taxonomy; SIMD vs. MIMD instructions; shared, associative, and direct caching methods; and cache layouts with respect to UMA, NUMA, and ccNUMA architectures [16-19].

Students were provided with ten homework assignments and several projects. Several homework assignments were started in class and were partially or completely devoted to parallel topics. These included problems related to benchmarking, Amdahl’s law, and speedup. Additional problems included a research question asking students to compare of Xeon Phi and CUDA cores. Furthermore, students were asked to complete a Linux lab on a LittleFe

cluster; to compile, run, time, and compare several OpenMP threaded loops; and to run several snippets of Intel assembly code to gain a better understanding of Flynn's Taxonomy. The assignment related to Flynn's taxonomy included explaining assembly instructions and C code for SISD, SIMD, and MIMD such as AVX and SSE instructions and their differences with serial and threaded code [16].

D. Software Engineering I/II (44-561/2)

Software Engineering I was taught by the author in Fall 12 and 13, and it included approximately 3.6 Contact Hours on parallelism. This coverage included discussion of Java Threads and Sockets using instant messenger code from [38]. Additionally, students engaged in research papers over self-selected topics. Students were provided with potential topics and references and were asked to clear their choice of topic with the instructor. Such students wrote a 6-8 page paper and performed a 5-7 minute presentation in class. Excellent papers were submitted to a local contest sponsored by KCP&L, and 3 of 4 finalists were from 44-561. Students' topic choices were influenced by placing paper references related to parallelism on the assignment specification. Suggested topics included distributed databases (3 papers were written on HBase, Riak, Cassandra, and other NoSQL databases), accelerators – comparing CUDA programming, OpenACC and OpenCL; Concurrency, Parallelism, and Performance; OpenMP, MPI, and POSIX Threads; Cluster Computing; Evolutionary Algorithms; Reinforcement Learning; Supervised vs. Unsupervised Learning; Pattern Recognition; and Classification and Segmentation. Students were given the option to select their own topics and several chose Professional Certification, Introductory Programming Languages, and Mobile Programming Platforms.

In Software Engineering II approximately 3.75 contact hours were devoted to parallelism in the Spring 13 and 14 semesters. Lectures related to parallelism included discussion of defensive programming (e.g. live-lock) and peak loads [23]. A significant portion of class time was devoted to semester-long projects wherein students completed a complex application involving web services, a database, and another complex tool. These student projects were completed in teams of 4 to 5 students and included a massive online multiplayer game built from scratch that used sockets, threads, and UDP game connections [39]; Kritik – a speech presentation grading tool that involved a client (an oral communications professor), iOS, CoreData, CSV conversion, and the Dropbox API [40]; and an online Audio Manager that made use of Python, Jinja2, SQLAlchemy, MusicBrainz API, AudioDB API, FanArt API, and the LastFM API [41]. Project evaluation was accomplished with weekly in-class meetings, four in-class presentations/milestones, and weekly mini-milestones. This allowed for students to experience much of the software lifecycle and many aspects of the Agile Development process.

E. Operating Systems (44-550)

In the OS course approximately 29.8 contact hours were devoted to topics related to parallelism [10,23]. This included lectures, lab assignments, homework assignments, and projects of significant size. Lecture topics included coverage of PThreads and MPI related to CS2013 KUs and were

focused on hands-on, application-oriented coverage of KUs, and a significant portion of class time was devoted to labs. Lectures also included an emphasis on Scheduling, Memory Management, Load Balancing, Communication Primitives, Threads, Processes, File Systems, and Security [14].

Lectures were divided into modules spanning two to three week segments. As many students had little experience with UNIX/Linux command line utilities and C programming, a module providing a brief introduction covering command line compilation, syntax, control structures, and functions was provided. During these first two to three weeks, OS history and functionality was also introduced. Students were also provided with accounts on an XSEDE allocation (11,000 Service Units in Fall 2014) and LittleFe. Topics covered also included processes, threads, PCBs, thread descriptors, POSIX threads, MPI_Send, MPI_Recv, C memory allocation, and commands such as `fork` and `exec` [7,10,14,26,42].

The next three weeks of lecture included an introduction to Pthreads and MPI processes with heavy discussion of the ready, run, and blocked states; race conditions; an introduction to deadlock; interprocess communication; and discussion of tags (message identifiers) in MPI. Lecture also covered semaphores, the producer-consumer problem, race conditions, and the reader-writer problem. Finally, in preparation for the projects, it was necessary to cover non-blocking I/O including `MPI_Wait_some`, `MPI_Irecv`, `MPI_Get_count`, `MPI_Wait`, and `MPI_Irecv`. Lectures also included coverage of monitors, discussion of MPI types, and further review of XSEDE systems [7,10,14,20,26].

Weeks 6 through 9 included full discussion of deadlock including mutual exclusion, deadlock principles, prevention, detection and recovery, avoidance, the Banker's Algorithm, and resource allocation graphs. Further lectures included atomic transactions, dining philosophers program, an introduction to scheduling, and further discussion of deadlock in MPI and non-blocking I/O for a project that involved simulating cell phone tower switching [7,10,12,14].

In weeks 10 through 12, the author covered standard scheduling techniques including First-Come-First-Served (FCFS), Shortest Job First (SJF), Shortest Remaining Time Next (SRTN), and Round Robin (RR). Additionally, lectures included coverage of performance, Gantt Charts, and turnaround time. Continued coverage of parallel and HPC topics included multi-processor scheduling and review for a scheduling exercise that required semaphores to implement FCFS and RR schedulers. Additional lecture was devoted to real-time and dynamic scheduling algorithms [7,10,12].

Weeks 13 through 15 included coverage of file I/O, file and IO systems, and memory management. This included coverage of files, pipes, and redirection, and preparation for the fifth project on File I/O in C and MPI. Next, topics related to file management were covered including fragmentation (external/internal), bitmapping, file structures, MPI file data types, and partitions. File systems were also discussed and included FAT, FAT32, NTFS, Ext4, Lustre, and Virtual File Systems. Students were also provided with a discussion of disk mounting/unmounting, shared/unshared file pointers,

parallel file I/O, DMA, and disk drive variants. In the last week of class, lectures covered memory management and included process address space, binding, paging, segments, and discussion of the TLB. Finally, a project was introduced that required students to implement a threaded, paged memory manager [7,10,12,31,32,43].

F. OS (44-550) Assignments

Students were asked to complete several assignments on both LittleFe and TACC Stampede systems in Fall 13 and 14 and used TACC Ranger/Purdue Steele in Fall 12. Such assignments were graded for both compilation and correctness. Students in the most recent iteration of the course were subject to a 25% penalty for failure to complete assignments on Stampede. The most recent group of OS students completed 12 lab assignments, 5 homework assignments, and 5 projects. Brief descriptions of these assignments are provided herein [10,20-22].

Lab assignments were short assignments, often started in class, and were completed by most students with little help. Labs were similar to worksheets and provided significant instruction to complete specific tasks. The first three labs were straightforward introductions to Linux, C, command line compilation, PThreads, MPI, LittleFe, and XSEDE [10,20-22,32]. All students that attempted these labs completed them successfully, and students often referred back to such labs as reference material. Thereafter several labs on threads and MPI were provided with a significant amount of boilerplate code. These included a simple load-balancing example using square matrix addition, an MPI Pi Calculator using the Mersenne Twister pseudorandom number generator, and a threaded producer-consumer lab [10,26]. Further labs covered the dining philosophers problem using MPI, condition variables and scheduling with PThreads, and file I/O with MPI [7,14]. The final three labs included coverage cache using MPI matrix multiplication by row and column, study of Xeon Phi accelerators, and implementation of bash shell scripts [10,20,26,37]. Homework assignments covered straightforward mathematical, graphing, and practice programming problems typical of an OS course. Both homework and lab assignments were graded for correctness with a significant amount of leeway given for compilation.

Programming assignments in the OS course were two to three week assignments covering many of the lecture and lab topics. For most assignments, students were required to provide both a threaded and process-based solution. The first of these was a standard C assignment that involved control structures, functions, and multiple C files – e.g. storing books in a library [10,42]. The second of these was a simple load-balancing problem that required students to apply a blurring operator to a 2D matrix, using convolution. Since this operation is embarrassingly parallel, students were asked to implement the problem using both PThreads and MPI. Further assignments are discussed in detail, as they required significantly more effort on the part of students [10,26].

The third assignment for the Fall 2014 group was a Monte Carlo numerical optimization program that was to be implemented in both a threaded and MPI fashion. This required students to find the minimum of a mathematical

function using a pseudorandom number generator. Each of many worker threads or processes was to search for a minimum and report that result back to a master thread/process to allow for determination of a global minimum. Students were to ensure both programs were effectively load-balanced and compare runtimes [10,26,30].

For the fourth program students simulated a number of vehicles traveling in a circle. Within this simulation students assumed that one person per vehicle was talking on a cell phone. The goal was to create an effective system for switching calls between cell phone towers. To make this simulation easier, students were allowed to assume that cars would always move in one direction (that is, either a clockwise or counterclockwise direction). It was also assumed that towers had a circular transmit radius, towers were located almost directly on the road, and tower transmit radii overlapped. The transmit radius of every tower was also assumed to be the same. Each tower was represented as a process and distance covered by a vehicle per unit time was assumed to be constant. Students were to provide as input to the simulation: the cell tower spacing in degrees, the cell tower transmit factor, the radius of the driving track in miles, the number of time steps in the simulation in minutes, and the speed of the car in miles per hour. This simulation provided students a similar experience to the dining philosophers problem in a different format.

For the final project, students wrote a threaded, paged memory manager that provided paged management to worker threads that each performed either decryption, a dot product, or matrix multiplication. Input data for each thread was provided through the memory manager thread via file input. Additionally, as input, students provided memory size, number of frames per page, frame size, number of worker threads, and matrix filenames for each worker thread. Students were to assume each thread could cache one row and one column of the matrix and the sizes of the matrices belonging to it. Prior to performing computations threads were required to acquire data from the memory manager. To obtain data, threads were required to call to the memory manager and request data one element at a time by passing the appropriate row and column and matrix identifier to the memory manager. Next, the memory manager simulated the page table by finding the appropriate frame number in the page table, and using the frame number to access a simulated physical memory (an array). When encountering page faults, students were to swap matrix data out of memory and replace it with the data needed to continue processing. Students assumed all threads were processed at the same time in a first-come first-served manner. If there was not enough memory for a thread to perform its processing, that thread waited until memory was available. Provided available memory, the memory manager allocated space for an entire row and column for each active worker thread. Students provided as output, the average worker thread runtime in milliseconds, the average number of frames used per worker thread, the average number of page faults per worker thread, the total runtime, the total number of frames used, and the total number of pages used [7,10,14,21,22].

These assignments provided students with a thorough and extensive OS and HPC experience. They covered the required

CS 2013 OS topics and provided for extensive hands-on experience with parallel programming techniques. Such experience also covered many required topics from the IEEE TCPP recommendations [23].

G. Assessment

To assess student learning outcomes, the author conducted surveys of the Fall 2014 Operating Systems cohort. This group of students was surveyed at both the beginning and end of the semester and was asked the following set of questions. The results of these questions are presented in the next section.

1. Have you used a Linux operating system?
2. Have you used a Windows operating system?
3. Have you used a Mac operating system?
4. Have you used the command line?
5. If yes, check situations in which you have used the command line.
6. What is your opinion of the utility of the command line interface?
7. When do you think more than one computer is required for parallel programming?
8. Prior to this class have you ever used threads?
9. If yes, please mark the type of threading that you have used.
10. Have you ever used multi-process programming?
11. If yes, check the operating systems and/or frameworks in which you have used multi-process programming.
12. Prior to this class have you ever used any synchronization tools? Please indicate the tools that you have used and indicate your experience level.
13. In what manner have used synchronization tools prior to this class, please indicate your experience level with such tools?
14. If you have used scheduling tools prior to this class, please indicate your experience level with such tools.
15. Have you had experience with OS level memory management? Please indicate your experience level.
16. Have you had experience with cache or cache management?
17. Please indicate your experience with the following memory access models, especially as they relate to cache.
18. Have you had experience with CPU Pinning? Please indicate your experience level.
19. Have you had experience with any parallel programming primitives?
20. XSEDE Resources were _____ in this course.
21. I find the use of XSEDE resources _____ in this course.

IV. OPERATING SYSTEMS RESULTS

Teaching OS with MPI is not an easy task. It requires prior knowledge of students' skill sets and course content may require several rounds of refinement. Course reviews for the first and second iterations of the author's OS course were mixed. This was expected because the course content was new, and many students at Northwest had little experience with C programming. Moreover, many OS students had little experience with Linux programming or shell environments. Supplemental materials and lectures on C programming were provided to assist OS students in learning the CLI and C [10]. Starting with the second cohort (Fall 2013) of OS students, all students were required to use C for the entirety of the course. This improved course reviews from 3.0/4.0 in 2012 to 3.85/4.0 in 2014 and allowed for additional time to be spent on parallel programming concepts while maintaining adequate coverage of OS concepts. This is further evidenced by results from selected questions from the pre- and post-surveys, which are

provided in following tables. Pre-survey results are shown within parentheses, and post-survey results are shown without parentheses. Results were self-reported by students through two voluntary surveys. Students received a small number of bonus points for completing the surveys.

	Yes	No	Response Count
1. Have you used a Linux operating system?	86.4% (75.0%)	13.6% (25.0%)	22 (20)
2. Have you used a Windows operating system?	100% (100%)	0% (0%)	22 (20)
4. Have you used the command line?	100% (75.0%)	0% (25.0%)	22 (20)
8. Have you used threads?	100% (55.0%)	0% (45.0%)	22 (20)
10. Have you ever used multi-process programming?	86.4% (15.0%)	13.6% (85.0%)	22 (20)
16. Have you had experience with cache or cache management?	54.5% (25.0%)	45.5% (75.0%)	22 (20)

Table 1: Pre and Post Course Results (pre-course results shown in parentheses)

Table 1 indicates a significant increase in the number of students that gained exposure to the command line, threaded programming, and multi-threaded programming after completing the OS course. Students were also asked several questions to gauge student opinion, interest, and expertise.

6. What is your opinion of the utility of the command line interface?					
Not at all useful	Slightly Useful	Useful	Very Useful	Rating Average	Response Count
0 (0)	0 (7)	11 (8)	10 (5)	3.48 (2.90)	21 (20)

Table 2: CLI Opinion Question

12. Have you ever used any synchronization tools? Please indicate the tools that you have used and indicate your experience level:					
Answer Options	No Exp.	Little Exp.	Moderate Exp.	Expert	Response Count
MPI Send/Recv	1 (17)	10 (1)	10 (0)	1 (0)	22 (18)
Android Messages/Intents	9 (10)	2 (4)	8 (4)	2 (1)	21 (19)
Semaphores	1 (17)	10 (0)	10 (1)	1 (0)	22 (18)
Broadcast	11 (14)	9 (2)	2 (2)	0 (0)	22 (18)
Wait	3 (13)	13 (3)	4 (2)	1 (0)	21 (18)
Mutex Locks	2 (17)	11 (0)	8 (1)	1 (0)	22 (18)
Condition Variables	1 (15)	13 (1)	6 (1)	2 (1)	22 (18)
Atomic operations/variables	5 (16)	13 (1)	2 (1)	1 (0)	21 (18)

Table 3: Synchronization Tools Experience Question

In tables 2, 3, and 4, students were asked about their opinion of the command line and about their experience with synchronization tools. Notice the drastic change in students' opinions of the CLI after they completed the OS course, which had heavy focus on Linux, Processes, Threads, and the CLI. Post-course, all students believed this tool to be either useful or very useful. With respect to synchronization tools and usage, students' experience level with tools such as semaphores and MPI send/recv primitives showed a significant shift from "no

experience” to either “little” or “moderate” experience, indicating that students did indeed gain familiarity with such tools in both multi-threaded and multi-process applications.

13. In what manner have used synchronization tools, please indicate your experience level with such tools?					
Answer Options	No Exp.	Little Exp.	Moderate Exp.	Expert	Response Count
MPI	1 (17)	11 (1)	9 (0)	1 (0)	22 (18)
Android	9 (10)	5 (5)	7 (3)	0 (1)	21 (19)
Multi-threaded	0 (12)	10 (5)	11 (1)	1 (0)	22 (18)
Multi-process	1 (15)	14 (2)	6 (1)	1 (0)	22 (18)
Distributed across multiple systems	7 (17)	13 (1)	1 (0)	0 (0)	21 (18)
To prevent Deadlock	2 (14)	11 (2)	7 (1)	1 (1)	21 (18)
To prevent Livelock	16 (18)	4 (0)	1 (0)	0 (0)	21 (18)

Table 4: Synchronization Usage Experience Question

14. If you have used scheduling tools, please indicate your experience level with such tools.					
Answer Options	No Exp.	Little Exp.	Moderate Exp.	Expert	Response Count
First-come, first-served	2 (12)	12 (5)	7 (1)	1 (1)	22 (19)
Round Robin	2 (15)	11 (2)	8 (0)	1 (1)	22 (18)
Shortest Job First	2 (16)	15 (1)	4 (0)	1 (1)	22 (18)
Shortest Remaining Time First	2 (17)	15 (1)	4 (0)	1 (0)	22 (18)

Table 5: Scheduling Experience Question

15. Have you had experience with OS level memory management? Please indicate your experience level:					
No Exp.	Little Exp.	Moderate Exp.	Expert	Rating Average	Response Count
5 (18)	14 (2)	3 (0)	0 (0)	1.91 (1.10)	22 (20)

Table 6: Memory Management Experience Question

In tables 5 and 6, results are presented from questions asked to gauge students’ perceived experience levels with scheduling and memory management. Similar to the results in tables 3 and 4, these results also indicate that students did indeed gain familiarity with standard OS topics.

20. XSEDE Resources were in this course.					
Not at all useful	Slightly Useful	Useful	Very Useful	Rating Average	Response Count
3 (1)	2 (6)	13 (10)	4 (1)	2.82 (2.61)	22 (18)

Table 7: XSEDE Experience Question

21. I find the use of XSEDE resources in this course.					
Not Interesting	Somewhat Interesting	Inter-esting	Very Inter-esting	Rating Avg.	Response Count
1 (4)	7 (6)	9 (6)	5 (2)	2.82 (2.33)	22 (18)

Table 8: XSEDE Interest Question

Tables 7 and 8 provide results from questions that gauged student interest in HPC resources, particularly those from XSEDE. These results do show increased student interest in HPC resources, but the results may include slight bias.

Students in Fall 14 OS and Spring 15 Parallel Programming courses were required to use XSEDE resources in all programming assignments and were informed that a 25% penalty would be invoked on each assignment where they did not use such resources. As a result, student XSEDE usage dramatically increased from 2012 and 2013 usages (approximately 20x CPU-hour use increase), but interest was not high enough to encourage most undergraduate students to take the Spring 15 Parallel Programming course. In fact, only one undergraduate student chose to take Parallel Programming as an elective.

Thus, OS students gained familiarity and experience with HPC resources, multiprocess programming, multithreading, and standard OS topics including concurrency, synchronization, deadlock, scheduling, etc. Results indicate that the OS course was successful in educating students about both OS topics and HPC. Based on the author’s experiences and student comments from the Fall 12 OS course, it is reasonable to conclude that using a single language such as C to teach all assignments is more effective than using both C and Java. Moreover, hands-on activities to ensure students are able to log into XSEDE resources were key to the success of the course. Experiences in the Fall 12, 13, and 14 OS courses when attempting to login to Ranger, Steele, and Stampede showed that a full class period devoted to logging in and system experience is necessary to ensure students do not experience difficulty in completing assignments with XSEDE.

V. CONCLUSION

Several undergraduate and graduate courses involving high performance computing were discussed. Implementation of such courses is possible at a regional university using free and low cost resources, but such courses require effort to maintain. Doing so makes HPC accessible to undergraduates. Inclusion of frequent lab components is especially beneficial to ensure adequate coverage of HPC topics and to stimulate student interest. Students did experience some difficulty in adapting to the command line, in using CLI text editors, in working with pointers, and in conversions between matrix dimensionality (e.g. 1D to 2D). They were, however, successful in learning both required content, parallelism and HPC topics.

Abstract— Computer Science has evolved towards a discipline with different branches. Software is designed, produced and linked taking into account different viewpoints. This process typically involves multidisciplinary teams: Front End Developers, (OO)Programmers, Database Engineers. Software developers, who were educated in different computing disciplines, meet on the shop floor, where they link together software that was designed from different viewpoints. In this paper, the emphasis is on human characteristics, rather than on the formal properties of programming and modeling languages. Do the involved computing practitioners refer to the same concepts when they use the same words? A preliminary version of this study [1] addressed the assessment of differences in mental representations of abstract entities involved in programming and modeling. In this extended version we report the results of an experiment, designed to compare mental representations of abstract concepts with mental models described in the literature. We point at differences between groups of students, enrolled in different computing curricula, and explore possible explanations.

Keywords: computer science education, engineering education research, human factors

I. INTRODUCTION

In the past couple of decades, Computer Science has developed different branches, each with its own body of knowledge and its own problem area. Different computing curricula have their *raison d'être* in different approaches to the digitalization of information. What happens when the paradigms meet, when engineers link together software that was designed from different points of view? This area is characterized by persistent problems, such as the Object/Relational impedance mismatch.

Many attempts have been made to solve these problems by developing new software, such as Object Relational Mappings. This is problematic, though. The problem with these solutions is their validation. Multidisciplinary teams that work on tangible artifacts can discuss advantages and disadvantages of machine control software, plant engineering software or computer graphics software, knowing that they refer to the same tangible or visible artifacts. But many computing professionals work exclusively on abstract entities. Technical

solutions of the Object Relational Impedance Mismatch can only be evaluated if practitioners perceive a common field of application, if they work with the same abstract entities.

The new ACM/IEEE guidelines for the undergraduate program in Software Engineering (SE) [2] acknowledge the problem of working with abstract entities and the challenges it involves for “knowledge exchange during the process of [software] design” (pg. 11). Although we acclaim the attention for this phenomenon, we regret the location of the problem inside the SE discipline. We suspect practitioners from other branches than SE to conceptualize abstract entities differently than SE. More generally, we suspect different computing disciplines to operate from different conceptualizations.

We will focus on the cognitive backgrounds of the issue, rather than its pedagogical perspective, although we will touch on educational implications. This paper describes an experiment to assess differences in mental representations of abstract entities, involved in programming and modeling. We recruited students of comparable age and level of education, enrolled in different computing curricula, and asked them to help us understand the way they conceptualize abstract concepts. In a preliminary (work-in-progress) version of this study [1], we reported incompatible ways to characterize the abstract notion of “object”. We also found indications for group preferences: significant discrepancies between participants, enrolled in different curricula.

This extended paper focuses on the explanation of the differences we have identified. We compare the participants’ mental representations with mental models described in the literature. We provide an overview of the research on cognitive aspects of programming and database interaction and explore the notion of individual preferences in mathematical problem solving [3].

In section II we explore the notion of a mental model. In section III we give an overview of research on cognitive aspects of programming and database interaction, followed by discussion in section IV. In section V we design an experiment to assess possible differences in mental models between senior students, enrolled in different computing curricula. Results are

given in section VI, followed by a reflection in section VII, conclusions in section VIII and relevance in section IX.

II. BACKGROUNDS

A. Mental models

According to Craik, the mind constructs “small-scale models” of reality and uses them to anticipate events [4] [5]. Johnson-Laird [4] formulated a theory of mental models, meant to explain human thinking and reasoning. People, states Johnson-Laird, do not only apply inference rules while reasoning; they also consider the semantic content of the problems they are solving. Norman [6] is more specifically concerned with mental models in Human-Computer Interaction. Users, states Norman, construct mental models of computer systems incrementally, while interacting with systems. The resulting models are constrained by the users’ prior knowledge, needs and context. These models are often incomplete. They are limited by the human information processing system, by experience and by needs that can be contrasting: the need to focus and the need to retain important details. They are parsimonious in order to reduce mental complexity. User mental models are unscientific and unstable. They evolve over time: people learn, people forget. People use metaphors to simplify their models. Nevertheless, mental models are functional to support tasks such as planning, execution, assessment of results and understanding of unexpected events.

There is little agreement on the exact definition of the term “mental model”. Does the term refer to temporary structures in Working Memory (WM) or knowledge structures in Long Term Memory (LTM)? Cañas and Antolí [7] introduce this definition: a mental model is “*the dynamic representation that is formed in WM combining the information stored in LTM and the extracted information from the environment*”.

Knowledge, in particular knowledge concerning computing paradigms, is acquired by education and experience and stored in LTM as knowledge chunks that evolve in time. According to Norman, evolution is not necessarily positive: improvement is possible, deterioration also. These knowledge chunks can only be used if they are retrieved and instantiated in WM, in what we will call a mental model from now on, following Cañas’ and Antolí’s definition.

Human WM is limited. People take these limitations into account and adopt strategies to keep mental models manageable in WM. The question here is: can we assume mental models of practitioners with different backgrounds to be compatible with each other?

B. Individual preferences

Schwank [3] studies the way people select mental models to represent mathematical knowledge. Schwank distinguishes a *predicative* and a *functional* approach to mathematic thinking. Predicative thinking is “static grasping”, thinking in terms of judgments and relations; functional thinking is “dynamic grasping”, thinking in terms of actions, processes and their effects. Schwank adopts this metaphor: predicative thinking is like solving puzzles, where one looks for (static) patterns. Functional thinking is mechanical thinking, like using gear: the

focus is on what happens next. Most mathematical problems can be solved either way; this also applies to many problems in computer science.

Schwank used Raven’s progressive matrices to assess problem solving preferences (Raven, cited by Schwank [9]). 3x3 matrices lacking the lower right symbol were presented to the participants, which were asked to *construct* the last symbol to complete the sequence (instead of *choosing* the last symbol as is requested in Raven’s intelligence test). The participants were asked to argue why they draw that particular symbol. Schwank found support for the thesis that the preference for a predicative or functional mode in problem solving is a stable individual characteristic.

C. Assessing mental models: the teach-back protocol

Mental models can not be observed directly. Many authors draw conclusions about respondent’s mental models based on their behavior [11]. Van der Veer adopts a different strategy: he asks the participants. Van der Veer [12] extends an hermeneutic method designed by G. Pask, intended to elicit information about mental models (the Teach-Back method), and adopts it to detect differences in mental representations of users interacting with computers.

A situation is simulated where the respondent has to interact with a computer. He/she is asked to explain the computer’s functioning to an imaginary counterpart, a colleague or a student, who has similar experience with the situation. The questions are designed to activate both declarative and procedural knowledge structures, to obtain an overall picture of the participants’ mental models. Questions are presented on white sheets of paper, and the participants are instructed to express themselves in whatever way they consider most adequate: text, drawings, keywords, diagrams etc. In this manner, the participants are encouraged to externalize the mental model they made of the situation. Next, the protocols are scored “blind”, along pre-defined scoring categories in order to map the respondent’s mental representations. Rating implies (1) reading the protocol in its entirety and trying to understand fully what it says; (2) trying to formulate how the participant understands the space of the teach-back question and (3) classify the responses into relevant categories for the purpose of the study. Rating the answers is a complex task: the rater has to interpret the participant’s intention and classify it by means of scoring rules. This task requires considerable training. In order to safeguard reliability, two or more persons score the answers independently.

III. LITERATURE REVIEW

A. Objects

One of the basic notions of software development is the “object”. According to Booch, Rumbaugh and Jacobson [13] an object is “A concrete manifestation of an abstraction; an entity with a well-defined boundary and identity that encapsulates state and behavior; an instance of a class”. Objects are software constructs that can refer to real-world entities, entities that are also called objects (although some authors use the term domain objects [14]). A class describes a set of objects [13]. Equivalent objects can coexist during program running: instantiation generates bags of objects.

Nevertheless, the term instance is seen as synonym with object [13].

Handling these different natures of objects requires switching between mental models. In the next sections, we will review the literature on understanding of programming constructs.

B. Cognitive aspects of (OO) programming

Robins, Rountree and Rountree [15] provide us with an extensive literature review of research concerning learning and teaching programming between 1970-2003. In a survey study, D tienne [16] reviews empirical research on OO design and assesses claims about the cognitive benefits of the OO paradigm.

Robins, Rountree and Rountree mention different kinds of mental models involved in learning programming: mental models of the “task, problem or specification” that has to be solved by the program, mental model of the programming language, and mental models of the behavior of the running program. Many studies have noted a central role played by a model (or abstraction) of the computer. Du Boulay et al. [17] call this the “notional machine”, an idealized, conceptual computer that is defined with respect to the language. Novices should develop an appropriate notional machine to master a programming language: the notional machine underlying Pascal is very different from the machine underlying PROLOG. A study by Mayer [18] confirms that students supplied with a notional machine model perform better while solving some problems than students who are not given the model.

A model of program comprehension was provided by Pennington [19]. Comprehension occurs in the context of a problem domain. The program’s text is re-organized in mental representations with help of available knowledge structures. Pennington studies expert FORTRAN and COBOL programmers, and finds significant differences in their performances of comprehension tasks.

The OO approach has claimed to make modeling the problem domain easier for programmers. D tienne investigated this claim. She found that novice programmers have difficulties in class creation. According to D tienne, novices need to start with a procedural representation of the situation. This seems to indicate that knowledge is organized in terms of procedures, not in terms of objects and relations. But for expert OO designers, the claims find support. Experts do analyze problems in terms of objects and their relationships. Also the claim that OO designers design solutions that are closer to the problem domain is supported. Expert OO designers seem to shift between object view and procedure view.

D tienne comments on the oddity of the situation: if OO design is driven by domain knowledge, then the biggest benefit should be observed in novices; but this is not the case.

C. Cognitive aspects of user-database interaction

Today, the Relational Model is the leading model in database theory. There is no need to know how data are stored in a Relational Database in order to write a query: knowledge of the (abstract) data model of the database is sufficient.

Cognitive aspects of query languages were studied at the same time as cognitive aspects of programming (Reisner,[20]). One of the issues was the procedurality of the query language. Some query languages specify more step-by-step methods to obtain results than others. SQL, today’s standard, is a set-oriented language, and was been labeled “less procedural” or even non-procedural in the debate.

Chan, Wei and Siau [21] focused on cognitive processes of abstraction in the user-database interface. They distinguished three levels of abstraction: a conceptual level (a description of the user’s world), a logical level (describing the database world in in set-theoretical terms) and a physical level (describing states in computer memory). The authors concluded that naive users’ understanding of how to write queries was best supported by a model of the conceptual level.

De Haan and Koppelaars [22] explicitly address database professionals. Professionals need to control the RDBMS, which is why professional database engineers should master the logical level, and the database world’s description in terms of set theory. Database professionals work with “objects” in the database world, a mathematical construct, based on set theory. No studies on the cognitive aspects of this kind of user-database interaction are known to us.

IV. A NEED FOR EMPIRICAL STUDY

The question here is how programmers, designers and professionals characterize the abstract software structures they work with. We observe that this characterization can change over time. Novice OO programmers mainly adopt a procedural strategy and start with a procedural representation of the topic they are considering (Detienne,[16]) Expert OO designers are able to switch between object view, emphasizing relations in the problem domain, and procedure view, emphasizing the execution of the program.

We are interested in mental models, instantiated in WM by computing professionals while communicating with each other. WM has limited capacity. Experts seem to be able to switch between object view and procedure view. This does however not mean that they can use the two views simultaneously, or that they are able to switch while communicating with colleagues.

We found multiple references to mental models in the literature concerning cognitive aspects of (OO) programming and user-database interaction. These are: (1) the notional machine, simulating an idealized computer, (2) the object view, where the individuation of (problem domain) objects guides the design activity, emphasizing static aspects of the solution, (3) the procedure-centered view, emphasizing the dynamics of a program and (4) a set-theoretical model, describing the problem domain in abstract terms and thus defining the database world. The notional machine and a procedure-centred view correspond to Schwank’s functional thinking; set theory and the object-view correspond to predicative thinking.

We found references to discrepancies between professional groups. Pennington reports of expert COBOL and FORTRAN programmers performing differently on program comprehension tasks.

We also found unsolved issues, in particular the oddity reported by D tienne. If OO design is driven by domain knowledge, why do novice designers experience difficulties in class creation? This could match Schwank’s observation of functional thinkers: they are able to learn to accomplish “predicative” task successfully, but might need more time or perform worse than predicative thinkers.

We hypothesize differences between professional groups in the instantiated mental models used to handle a concept that is fundamental to most computing disciplines: the “object”.

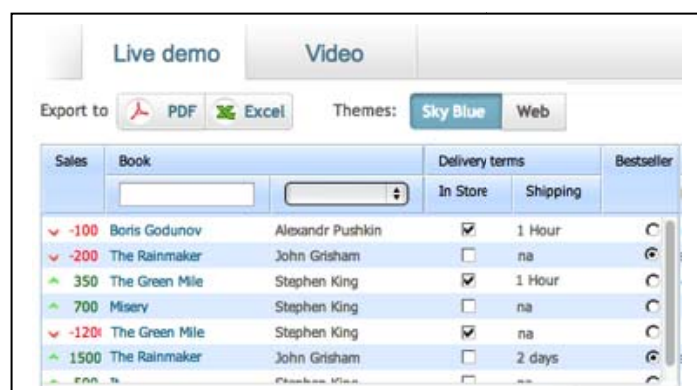

V. EXPERIMENT DESIGN

Do future computer professionals perceive sets of objects or bags of objects (instances)? Do they locate “objects” in the problem domain or in the programming domain? Do they think of software in terms of processes in the notional machine (sequences of events, communication between objects) or in terms of structures (attribute values, relationships, queries)?

We designed a Teach-Back protocol to elicit this information, and enquired students enrolled in different computing curricula. The participants’ answers were scored along categories, derived from the four types of mental models mentioned in section IV. Four raters were involved in this experiment. Three have been lecturing Computer Science in Dutch higher education for over 20 years; one is senior designer of documentation for scientific software. All the raters have a background in Computer Science and hold a Master’s degree or equivalent.

A. Context

The protocol is introduced by a brief case description, an online Bookstore (see Figure 1). It states that only information about books is relevant for our purposes, and that, therefore, the rest of the data is skipped. This results in a dataset with repeating rows having the same state. Participants are asked to describe the “Book-objects” they distinguish. No indications are provided for the choice of a theoretical context.

Sales	Book	Delivery terms	Bestseller
-100	Boris Godunov	Alexandr Pushkin	<input checked="" type="checkbox"/> 1 Hour
-200	The Rainmaker	John Grisham	<input type="checkbox"/> na
350	The Green Mile	Stephen King	<input checked="" type="checkbox"/> 1 Hour
700	Misery	Stephen King	<input type="checkbox"/> na
-120	The Green Mile	Stephen King	<input checked="" type="checkbox"/> na
1500	The Rainmaker	John Grisham	<input type="checkbox"/> 2 days

Fig. 1. Online Bookstore.

The situation is, in fact, ambiguous: the question can be answered by describing: (1) Book-objects in the problem domain (books in the bookstore’s assortment), (2) Book-objects in the programming domain (Book-objects in permanent storage), (3) Book-objects in the programming domain (instances of Book-objects), (4) objects in the programming domain (elements of the HTML-document).

B. Questionnaire

We asked the participants, how many different Book-objects they saw in the table in Figure 1. To answer the question, a mental model had to be instantiated.

Participants were presented with white sheets of paper and were instructed to explain in writing to an imaginary fellow student:

1. How many different Book-objects they saw and what these objects were,
2. What would happen if the system was asked to produce additional information about one of the books.

These questions activate declarative and procedural knowledge structures (section II-C). A last question aims to obtain an indication of the respondent’s preference for predicative or functional thinking. Following Schwank’s method, we used a matrix from Raven’s test (Figure 2) as explained in section II-B. We asked participants:

3. to add the missing symbol and to explain how they had constructed the solution.

Fig. 2. The matrix used to match individual problem solving preferences.

C. Research questions and scoring categories

This experiment was designed to answer the following research questions.

- a) Are there differences across the disciplines in the amounts of objects counted by participants?

The aim of research question a) is to identify possible communication problems between computing professionals. Scoring was based on the participants’ answers to the first part of question 1 of the questionnaire (how many different objects do you see?).

Although differences in amounts of objects can indicate differences in mental models, their occurrence is not sufficient to draw conclusions. Research question b) focuses on the participants’ mental model.

- b) Are there differences across the disciplines in the mental models, instantiated by participants?

Scores concerning questions b were based on the interpretation of the participant’s answers to both questions 1 and 2 of the questionnaire. To determine the mathematical structure envisioned by participants (Set or Bag, see sections III-A and III-C) and the participants’ approach to software

(object view or procedure view, see section III-B), we defined the following sub-questions:

- b1. *Does the participant envision a set of Book-objects or a bag of Book-objects (instances)?*
- b2. *Does the participant make assumptions about the software implementation?*
- b3. *If the participant describes the programming domain, on which aspects does s/he focus?*

Different problem solving preferences might reflect on the approach to software, resulting in different mental models. We investigated the participants' problem solving preference, as defined by Schwank (see section II-B).

- c) *Which problem solving strategy adopts the participant to construct the solution of question 3?*

For each research question and sub-question, scoring categories were defined.

- a) To analyze discrepancies between the numbers of Book-objects counted by the participants, we scored:
 - 4 objects (or 5, if the participant counts the last row, which is only partially visible),
 - 6 objects (or 7, if the participant counts the last row),
 - A: a number that is not traceable to Book-objects,
 - N: no number mentioned,
 - Both: both answers "4 objects" and "6 objects" are mentioned and explained
- b) To determine the participants' mental models, we analyzed the answers to research questions b1..b3.
 - b1. Does the participant envision a Set of Book-objects or a Bag of Book-objects?:
 - S: a set of objects
 - B: a bag of objects (instances)
 - N: none of the above answers are supported by the participant's description
 - BS: participant sees both possibilities, a Bag of objects and a Set of objects

Rating the dominant aspect of software description (b3) is only possible if the participant describes the software. Many participants did not. We rated the granularity of software description (b2), and – if the software was described in some detail – the dominant aspect.

- b2. To determine the granularity of software description, we scored:
 - Macro: the participant describes the system in terms of its macro-structure, or as a black box. No details about the software's implementation are added.
 - Detail: the participant adds detailed hypotheses about (part of) the software's implementation.

- b3. To determine the dominant aspect in the description of software, we adopted the following categories:

- S: Participant focuses on static aspects of software (Détienne's object view)
- P: Processes are also described (Détienne's procedure view)
- M: Unclear. Participant provides mixed information

- c) To determine the participant's problem solving strategy, we used Schwank's categories,:

- P: Predicative thinking. Participants refers to the location of symbols to justify the solution he proposes
- F: Functional thinking. Participant perceives symbols as entities that can move, and performs motion analysis to justify the solution he proposes
- N: No choice could be made

D. Reliability

Scoring was done by two raters at the time. The raters interpreted the participant's answers and scored them along the categories we discussed in section V-C. The raters had been trained by scoring 6-10 questionnaires, followed by more sessions where interpretations issues were discussed. Still, discrepancies between raters do occur where interpretation is involved. The degree of agreement (inter-rater reliability) is expressed by Cohen's Kappa coefficient [23]. Generally, a coefficient above 0.75 is considered very good; between 0.6 and 0.75 as good and between 0.4 and 0.6 as fair ([23], page 280). Reliability was calculated on the questionnaires that had not been used for training purposes.

After scoring the categories and measuring the reliability, the discrepancies were discussed between the raters. If agreement was possible, the discrepancies were solved. In the other case, the answer was scored as "N" (research questions a, b1 and c) or "M" (research question b3). All issues concerning research question b2 could be solved.

E. Participants

The teach-back questions were answered by five groups of male Bachelor students, enrolled in professional curricula:

- 35 attending 1st year classes of Business IT and Management. Most of them enrolled in a professional curriculum in a computing discipline in 2013, 2 in 2010. They were not included in our samples.
- 19 attending 3rd year Business IT and Management, enrolled in a professional curriculum in a computing discipline in 2011. The exceptions: 1 enrolled in 2010, 1 in 2008.
- 18 attending 3rd year of Computer Science, field of study Information Engineering. Most enrolled in 2011. The exception: 6 enrolled in 2010, 1 in 2009, 1 in 2002.
- 29 attending 3rd year of Computer Science, field of study Software Engineering. Most enrolled in 2011. 4 enrolled in 2010.

- 4 enrolled in other computing curricula. They were not included in our sample.

All groups had attended at least one course “Relational Databases” and one course “Introduction to Programming in Java”. The Business IT and Management curriculum emphasizes modelling. The Computer Science curriculum concerns software development. Computer Science has two fields of study: Software Engineering puts the emphasis is on programming, Information Engineering on the construction of business solutions [24][25].

F. Hypotheses

Different computing disciplines seem to allow, or even to promote, fundamentally different conceptualizations of the “object”. These differences between disciplines can be systematic. Systematic differences would lead both to different conceptualizations and to different amount of objects detected, therefore to systematically divergent frequencies of the answers to the questions in section V-B. We cannot formulate expectancies about the magnitude of this effect.

To test the effect, we will investigate if we can reject the following null hypotheses in favour of plausible alternative hypotheses. We will reject the null-hypotheses if the probability p of finding our results less is than 0,05. In that case, we will conclude that the deviation from the null hypothesis is significant. We will state that we have found significant differences if the deviation is conform our expectation.

We will test the following null hypotheses:

Ha: “there is no difference between the amount of different “objects” reported by members of the following groups: 3rd year students Business & IT Management, 3rd year students Information Engineering and 3rd year students Software Engineering”.

Hb: “there is no difference between the conceptualization of the notion of “object” reported by the members of the following groups: 3rd year students Business & IT Management, 3rd year students Information Engineering and 3rd year students Software Engineering”

Hypothesis Hb can be divided in

Hb1: “there is no difference between the structures (set or bag) envisioned by the members of the groups mentioned above.”

Hb2: “there is no difference in granularity of description of the software between the members of the groups mentioned above.”

Hb3: “there is no difference in the aspects, emerging from the software descriptions of members of the groups mentioned above.”

Hc: “there is no difference between the problem solving preferences of the members of the following groups: 3rd year students Business & IT Management, 3rd year students Information Engineering and 3rd year students Software Engineering”.

VI. RESULTS

A. Ha: amounts of different objects reported

From the answers to question 1 of the questionnaire: “How many different Book-objects does the participant count?”, the following categories were scored:

- 4: 27 participants. Many of them explain their choice (“There are 6 Book-objects, but two of them occur twice, hence 4 different Book objects”, “there are 4 Book objects, since some are double”).
- 6: 19 participants.. Explanations vary from “n rows, n Book-objects” to “6 Book-objects. Some occur twice, but they are still different objects” and technological explanations (“I am thinking OO-Java”).
- A: 8 participants mention an amount of objects that is not traceable to Book-objects: they count 1,2,3,4,12,14 or 16 objects. They describe: classes, attributes, User Interface objects (e.g. search-fields) or attribute values.
- N: 12 participants do not answer the question. 4 out of these 12 give elaborate answers, incidentally illustrated with diagrams, without counting the objects (e.g. “7 books, described with title and author. 2 of them occur twice”).
- B: 0 participants. The answer: “We see 6 instances of 4 Book-objects” is never given. One student counts “6 instances of 4 Books”. He is one of the participants that were not included in our sample (see section V-E).

TABLE I. NUMBER OF BOOK-OBJECTS , SAMPLED BY CURRICULUM

	Number of objects			
	4	6	O	n
3 rd BIM	7	2	10	19
3 rd IE	5	10	3	18
3 rd SE	15	7	7	29

Discrepancies between raters were very limited (Cohen’s Kappa = 0,795). Agreement on 1 answer was not possible; it was scored “N”, as indicated in section V-D.

The scores of question a) are shown in Table I. Column “O” (“Other”) summarizes the categories “A” (a number, not referring to Book-objects) and N (not a number). Category “B” was not scored in our samples.

We found significant differences between the samples in Table I (chi sqr = 13,1 ; $p < 0,05$) and reject Ha. Students Software Engineering seem to count more often 4 objects. Students Information Engineering seem to prefer counting 6 objects. Student Business IT and Managements seem to elude the question.

B. Hb: mental models across the disciplines

To determine differences in mental model, the participants’ answers to the questions about the system (questions 1 and 2 of the questionnaire) were read in totality and interpreted. This could only be done if the participant had answered at least one

of these. This was not the case for two participants; one of them was included in our sample. Questions b1..b3 were scored for 17 students, enrolled in the Information Engineering curriculum, instead of 18.

The following categories were scored for research question b1 (“Does the participant envision a set of objects or a bag of objects?”):

- Set: 26 participants. (“There are 4 Book objects, because some of them are double”, “6 records representing 4 Book objects”).
- Bag: 25 participants (“6 instances”, “12 different objects, Books and Authors”)
- N: 14 participants. this category was scored if question 1 was not answered, if no useful answer was provided (e.g. “2 Book-objects”) or if the answer was contradictory (“Book objects are identified by their attributes: ID, title, author. I see 4 Book-objects with different ID’s”)
- BS: this category was not scored.

Some discrepancies between raters occurred (Cohen’s Kappa = 0.597). Agreement was not possible on 2 answers in this sample. They were scored ‘N’.

The meaning of the term “different” is ambiguous in OO-programming. Equivalent instances can refer to the same object. We found 3 answers reflecting this dilemma: “6 Book-objects, but two of them occur twice, hence 4 different Book objects”. They were scored as “Bag”.

TABLE II. SET OR BAG, SAMPLED BY CURRICULUM

	Set or Bag			n
	Set	Bag	N	
3 rd BIM	5	7	7	19
3 rd IE	6	11	0	17
3 rd SE	15	7	7	29

The answers to research question b1 are shown in Table II. We found significant differences between the samples in Table II (Fisher’s exact test, $p=0,0101279$) [27] and reject Hb1. Students Software Engineering seem to show a preference for the structure “Set”, where students Information Engineering appear to work with “Bag”s of objects. Students Business IT and Management are random divided between the options.

The case provides minor structural information about Book objects, in Figure 1. While scoring b2 and b3, the raters focused on information that was added by the participants, information that could not be traced back to the case or the questions.

Discrepancies between raters occurred (Cohen’s Kappa = 0.576). Agreement was not possible on the scores on question b3 for the answers of 5 participants. They were scored “M”.

The following categories were scored for research question b2 (assumptions about the software implementation):

- Macro: 18 participants roughly described the software they had envisioned without adding structural or process information. (“the name of the book is looked up in the database”, “If the user points at the row, the system displays information”).
- Detail: 48 participants provided more detailed information (list of attributes, class diagram, code, activity diagram, query)

TABLE III. GRANULARITY OF DESCRIPTION OF SOFTWARE, SAMPLED BY CURRICULUM

	Granularity of software description		
	Macro	Detail	n
3 rd BIM	9	10	19
3 rd IE	5	12	17
3 rd SE	3	26	29

The scores of question b2 are summarized in table III. Approximately 90% of the Software Engineering students provided implementation information, against ca. 70% of the Information Engineering group and 50% of the Business IT and Management group. The differences are significant ($\chi^2 = 8,21$, $df=2$, $p < 0,05$). We reject Hb2.

The following categories were scored for research question b3 (“dominant aspects in the description of software”):

- S: 28 participants mainly added structural information (attributes or relationships, class diagram, query)
- P: 14 participants mainly added information about procedures (activity diagram, sequences of events, communication between software components)
- M: 6 participants added both kinds of information

The scores of question b3 are summarized in Table IV. We found no significant differences between the samples in table IV. (Fisher’s exact test, $p=0,12682945$) [27]

TABLE IV. DOMINANT ASPECTS IN SOFTWARE DESCRIPTION, SAMPLED BY CURRICULUM

	Dominant aspects in software description			n
	S	P	M	
3 rd BIM	9	1	0	10
3 rd IE	5	6	1	12
3 rd SE	14	7	5	26

We found significant differences in mental models of students enrolled in different curricula, and reject HB. Apparently, there are differences in the way future professionals conceptualize software.

Some of the participants appear to be in doubt (it depends on the interpretation of the figure, on the relationship between title and author, etc.), but seem not to be able to give expression to their doubts.

C. Hc: problem solving preferences

For research question c, the following categories were scored:

- P: Predicative. (“the circle’s position is the same in every row, the dot’s position is the same in every column”, or: “I choose the missing symbol”)
- F: Functional (“In each row, the dot moves counterclockwise while the circle stays at the same place”)
- N: No choice could be made

Discrepancies between raters were limited (Cohen’s Kappa = 0.742). Agreement could not be reached on 2 answers; they were scored “N”.

The scores of question c are summarized in table V. We found no significant differences between the samples in table V. (Fisher’s exact test, $p=0,25695717$) [27]

TABLE V. PROBLEM SOLVING PREFERENCES, SAMPLED BY CURRICULUM

	Problem solving preference			n
	P	F	N	
3 rd BIM	6	7	6	19
3 rd IE	5	11	2	18
3 rd SE	14	11	4	29

VII. LESSONS LEARNED

Our initial ambition was to classify mental representations of “objects”, in problem domain objects, stored objects or instances. We partially succeeded. We were able to underpin some observations about the participants’ mental models. We determined the mathematical settings participants refer to while working with objects (set or bag), and assessed in which terms they envision software while communicating with colleagues (macro or detail). No conclusions could be drawn about the location of the objects in problem domain or programming domain. This might be due to different causes. One applies to the casus. Students know bookstore-cases from their courses on Databases. The choice for a bookstore might have appealed to previous knowledge, pointing towards a possible interpretation for the term “object”. Also, the formulation of question 2 of the questionnaire (“What happens if the system is asked to produce additional information about one of the books?”) might have suggested a macro approach to the system, reinforcing that interpretation. We will take this experience into account for the new version of the questionnaire.

Interpreting student mental models has proven to be challenging, even for experienced assessors of students’ work. The raters are puzzled by the measure in which their interpretations can differ. One example is: although “set” and “bag” are well-defined mathematical concepts, some of the participants’ answers gave cause for discussion. One student explained how he counted: “Objects are different versions. E.g. [if we have]: 1,2,1. 1 and 1 are the same: 2 different objects”. The raters (one has an engineering background, one is a former

database professional) scored respectively “Bag” (different objects: 1 and 1), and “Set” (different objects: 1 and 2). Both understood the other’s point of view, but agreement could not be reached. Rating in teams of mixed expertise appears to be crucial in this experiment. Structured interviews with participants may be necessary in the future to fully understand some of the answers.

VIII. CONCLUSIONS

Our investigation showed at least two ways to characterize the abstract notion of “object” that are currently used by professionals. Both characterizations are correct, but they are not compatible: they lead to different judgments on the number of “objects”. Some participants identified 4 Book-objects, others identified 6 Book-objects. The preference for 4 or 6 objects was not distributed at random. Apparently, Software Engineers are more likely to see 4 objects, in contrast with most Information Engineers, who show a preference for detecting 6 objects.

One third of the participants could not provide information about the amount of objects. Although some of them expressed doubts about the question, only one of them was able to point in the direction of possible ambiguity of the notion of “object”.

We found indications for the instantiation of different mental models across the disciplines. SE, IE and BIM students in our study seem to differ in their perception of the appropriate structure for objects (set or bag). More in general, they appear to differ in the measure in which they envision a possible implementation while discussing software. Further research is needed to better describe computing professionals’ mental models, and investigate differences across the disciplines.

We did not find significant differences in the way different groups approach software (object view or procedure view). No significant differences between individual problem solving preferences were found across the groups either. This might indicate that the differences we describe are acquired, hence a responsibility of designers of computing curricula.

IX. OUR MESSAGE FOR EDUCATION

The immediate relevance of our work is in curriculum design. We recommend all computing curricula to explicitly cultivate awareness for different approaches to computing concepts. Based on this study, we also recommend educators and practitioners to establish and use a refined terminology for the notion of “object”. A refined terminology will improve recognition of different mental models. Whether it will support computing professionals sufficiently in handling different mental models, is an issue that needs to be researched.

The lack of agreement about the definition of one of the basic notions of the computing discipline, we have found between students enrolled in different curricula, is worrisome, just as the apparent difficulties to recognize this issue and to discuss it properly.

ACKNOWLEDGMENT

We thank raters Jikke van Wijnen and Brigit van Loggem. We thank the students and lecturers of the HU University of Applied Sciences Utrecht for their cooperation.

Abstract—Project management is an essential activity across several areas, including Software Engineering. Through good management it is possible to achieve deadlines, budgets goals and mainly delivering a product that meets customer expectations. Project management activity encompasses: measurement and metrics; estimation; risk analysis; schedules; tracking and control. Considering the importance of managing projects, it is necessary that courses related to Information Technology and Computer Science present to students concepts, techniques and methodology necessary to cover all project management activities. Software project management courses aim at preparing students to apply management techniques required to plan, organize, monitor and control software projects. In a nutshell, software project management focuses on process, problem and people. In this paper we proposed an approach to teaching and learning of software project management using practical activities. The intention of this work is to provide the experience of applying theoretical concepts in practical activities. The teaching and learning approach, applied since 2006 in a Computer Science course, is based on teamwork. Each team is divided into groups assuming different roles of software process development. We have set four groups, each one assuming a different role (manager; software quality assurance; analyst and designer; programmer). The team must be conducted across the software process by its manager. We use four projects, each group is in charge of managing a different project. In this paper we present the proposed approach (based on hands on activities for project management); we summarize the lessons learned by applying the approach since 2006; we present a qualitative analysis from data collect along the application.

Keywords—*Learning Project Management; Practical Activities; Teaching Methodology; Teamwork.*

I. INTRODUCTION

Software Engineering is a discipline to software production. Besides the technical issues, like process, methods and programming languages, there are people involved in. Concerning technical aspects, it is usual for teachers to use systems as cases your studies perform analysis, design, coding and testing, for example. However, teaching software engineering has challenged professors especially concerning software project management. Teaching software project management is usually a theoretical course, practical tasks are usually focusing on theory application using tools to simulate scenarios. Those tools are used to simulate what-if hypothetical scenarios, like [refs to simulations].

Most of the focus in the teaching project management

is based on theoretical approach. The practical part comes second, and in many cases not even addressed. Thus, students do not experience practicing. To tackle this problem, it is found in literature the use of system software simulating software development teams. However, such approach based on simulation do not allow students to deal with people: as manager, s/he must be trained to organize technical people into effective teams and coordinate them to achieve effective communication and results. Such issues are no addressed by simulators.

We consider important to students not only the opportunity to apply theoretical information into scenarios, but also the opportunity to handle situations with people as similar as possible to real projects. In this paper we present our experience on a practical approach to software project management teaching and learning. In this paper we also present the requirements for the application of practical approach proposed, as well as the lessons learned. We have used this approach since 2006 in a Computer Science undergraduate course. We considered the first year as a pilot study. After 2007, we have applied SPARTA using the organization presented in this paper, adapted year by year according to the lessons learned.

The remainder of this paper reports the teaching project and its results. In Section II is presented the context required and the processes to software development. Section III provides details about SPARTA approach and constraints to hands on software project management. Section IV presents the results and the discussion. Related works are briefly presented in Section VI. Finally, Section VII presents conclusions and further work.

II. THE CONTEXT: SOFTWARE PROJECT MANAGEMENT

Software development process is concerned primarily with software development. Methods, languages and tools [1]–[5] to support development tasks are usually focused on Software Engineering courses aimed to technical issues. The Technical Processes are used to define the requirements for a system, to transform the requirements into an effective product, to permit consistent reproduction of the product where necessary, to use the product, to provide the required services, to sustain the provision of those services and to dispose of the product when it is retired from service [6].

The *Technical Processes* define the activities that enable organizational and project functions to optimize the benefits and reduce the risks that arise from technical decisions and actions [6]. Therefore, such content must be presented to student before the management content, during previous course. For that, the curriculum of a Computer Science course must be organized in order to provide technical skills, before expose students to management content. Technical Processes are, for example, *System Requirements Analysis*, *System Architectural Design*, *Implementation Process*, *System Integration Process* and *System Qualification Testing Process*. They are out of scope of this paper, but considered as background to management and, consequently, essential to manager.

In addition, *Software Support Processes* provide a specific focused set of activities. A supporting process assists the *Software Implementation Process* as an integral part with a distinct purpose, contributing to the success and quality of the software project. *Software Documentation Management Process*, *Software Configuration Management Process* and *Software Quality Assurance Process* are examples of support process. They are also considered as background to management and, consequently, essential to manager since a manager has to decide about them [7], [8].

Concerning software management, there are several processes [6] involved, such as *Organizational Project-Enabling Processes* – they are: Life Cycle Model Management Process; Infrastructure Management Process; Project Portfolio Management Process; Human Resource Management Process; and Quality Management Process. Finally, the **Project Management Processes** are used to establish and evolve project plans, to assess actual achievement and progress against the plans and to control execution of the project through to fulfillment. The Project Management Processes – *Project Planning Process* and *Project Assessment and Control Process* – are applied with a level of rigor that depends on the risk and complexity of the project.

Individual *Project Management Processes* may be invoked at any time in the life cycle, as required by project plans or unforeseen events. Such dynamical characteristic requires from manager to attend different situations along software development. Frequent casual communications between developers and end-users, and between project managers and clients, are necessary to keep the project relevant, useful and effective for the end-users, and within the bounds of what can be completed. It is important to note that we do not have a real client, but we have *roles* presented in next section, one of them is the *client role*. Effective interpersonal communication and conflict management and resolution are important to software project management. While end-user participation, effective communication and teamwork are not sufficient, they are necessary to ensure a good outcome, and their absence will almost surely lead to a bad outcome. In SPARTA approach we encourage the students to establish and use their communication canal using tools to keep record (logs) used to student assessment (discussed in Section V).

Risk management is an important issue on *Software Project Management*. It consists in measuring or assessing risk and, then, establishing strategies to manage the risk. In general, the strategies employed include transferring the risk to another phase, avoiding the risk, reducing the negative effect of the

risk, and accepting some or all of the consequences of a particular risk. However, considering the context of SPARTA approach – a practical activity in a course – it is not fair to expose the student to real projects with real risks, what would result in students fail the course. Therefore, we create a controlled environment that avoid some risks, such as risks related to technological aspects, equipments and market, which includes a cost-benefit analysis as well as a list of fallback options for project failure, called a contingency plan. The avoided risks are presented in theoretical ways, but not considered in practices. During the practical project, the students have to deal with risks like human resource availability.

Requirements management is the process of identifying, eliciting, documenting, analyzing, tracing, prioritizing and agreeing on requirements and then controlling change and communicating to relevant stakeholders. Also, considering the context of SPARTA approach we must establish a controlled environment regarding requirements, using a set of requirement suitable to time (course length) and avoiding modifications along the development. Change impact analysis of altered scope, which includes requirements analysis at the change level, is an important part of the software engineering process – whereby business analysts or software developers identify the altered needs and, then, they are then in a position to re-design or modify a solution. Theoretically, each change can impact the schedule and the budget of a software project. Regarding project management, changes must consider risk-benefit analysis before approval. However, change impact is not handled during the course, and it is out of scape of SPARTA.

III. PRACTICING PROJECT MANAGEMENT: THE SPARTA APPROACH

The main idea is to allow students the experience on software project management, but who manage, manage other people activities and tasks. For that, we proposed an approach based on *roles*. In general, the *roles* are chosen to address management and non-management tasks. Non management tasks are chosen among *Software Support Processes* and *Technical Processes*.

For that, the class is divided into *groups*, and their members will play different *roles* for a given *project*. For a given project, one is the *manager* and others play different roles in charge of different tasks from *Technical Processes* and *Software Support Processes*. Other projects must be assigned to the group, choosing another one as *manager*, in a rotating assignment – consequently, the manager of the first project will assume a different role on the second project. The number of projects assigned to a group depends on the number of roles defined. SPARTA organization is shown in Table I. Considering the project *P1*, the team *11* is the *manager*, and the teams 12, 13 and 14 assume different roles. And teams 12, 13 and 14 are managers of other projects. As mentioned in Section II, the projects must be chosen in order to avoid risks, especially time constraints.

To chose the roles it is necessary to balance the number of students and time to development. Also, it is necessary to take into account subjects from students background, deciding which subject should be prioritized. In order to emphasize

development and quality assurance skills, we have used four roles: **Manager, Analyst & Designer, Programmer** and **Software Quality Assurance (SQA)**. Thus, we used four projects, as shown in Table I: for instance, the Group 1 is composed by teams 11, 12, 13 and 14, and a Project P1, *Team 11* is responsible to manage the software development activities, planning tasks and controlling their results; *Team 12* is responsible by Software Quality Assurance (SQA) activities; *Team 13* is responsible for project analysis and design; finally, *Team 14* must implementing the project. Each roles is discussed in the following subsections.

A. Manager Role

The main focus is the **manager** role. The manager must define the plan to software development and control the evolution. The purpose of project planning is to identify the scope of the project, estimate the work involved, and create a project schedule. Project planning begins with requirements that define the software to be developed. The project plan is then developed to describe the tasks that will lead to completion. The purpose of project monitoring and control is to keep the team and management up to date on the project's progress. If the project deviates from the plan, then the project manager can take action to correct the problem. Project monitoring and control involves status meetings to gather status from the team.

The first task for managers is "hire" their teams, what is done during the first class. For the students, the *hiring* consists in choosing their partners. Considering the rotating assignment, note that a manager hires and is hired at same time.

Secondly, a project is assigned to a manager by the teacher (a software requirement document is provided). To emphasize manager responsibilities and leadership, the teacher communicate only with the manager about the project. The manager, has, then, sets objectives (the manager must set goals for his/her team, and decides what work needs to be done to meet those goals), organizes their teams (the manager divides the work into manageable activities, and selects people to accomplish the tasks that need to be done) and define measures for planing and controlling tasks (the manager establishes appropriate targets and yardsticks, and analyzes, appraises and interprets performance).

For that, the manager must use the requirement document to obtain estimation about size, effort and time to develop. We have used empirical models, such as Constructive Cost Model (COCOMO) and Walston and Felix model [9]. After estimations, the manager must choose a methodology for software development and breakdown into tasks – see discussion on next subsection. In addition, the manager must define the schedule assigning tasks and deadlines to each team. We have used PERT/CPM charts to analyze critical paths, and Gantt charts. The manager have used MicroSoft Project [10] as tool to create schedules (Gantt charts).

The processes (and methods) used to complete the work defined in the project plan to accomplish the project's requirements are executed – other teams must follow the planning executing what was assigned to them. Manager are also in charge of monitoring and controlling the execution, to observe project execution so that potential problems can be identified

in a timely manner and corrective action can be taken, when necessary, to control the execution of the project. Manager must chose an approach (task or time based control) to observe and measure regularly the evolution to identify variances from the project management plan.

Regarding Monitoring and controlling tasks, they consist in: Measuring the ongoing project activities; Monitoring the project variables (cost, effort and scope) against the project management plan and the project performance baseline; Identify corrective actions to address issues and risks properly. As mentioned, SPARTA approach assume a controlled environment to constraint risks, so that manager are required to monitor effort and time.

B. Analyst-Designer Role

The Analyst-Designer role is in charge of developing the software, following the plan defined by the *manager*. We have encouraged our students to use the method described in [11] because it is iterative and evolutionary. Therefore, the *manager* must create the plan using the phases Plan and Elaborate, Build and Deploy, as depicted in Figure 1.

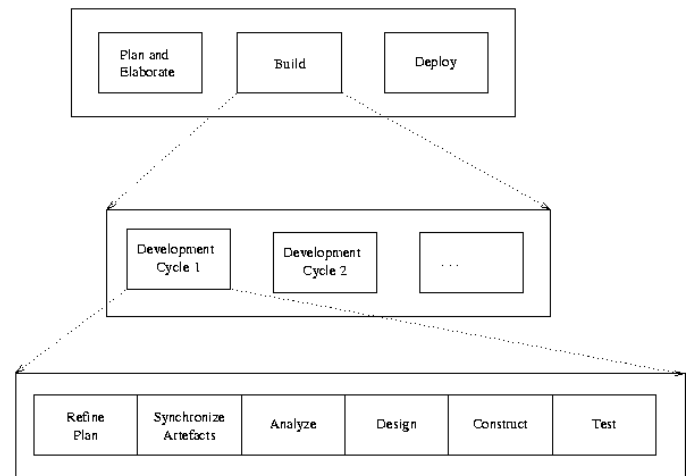

Figure 1. Iterative Development Cycles [11].

An iterative life-cycle is based on successive enlargement and refinement of a system through multiple development cycles of analysis, design, implementation and testing, which demand the continuous monitoring by managers. In addition, it helps the *manager* to distribute the tasks along the project timeline avoiding concentrating long tasks to human resources.

We do not specify any tool to support Analysis and Design tasks, but most of students have used *Astah UML*, is a modeling tool that supports Unified Modeling Language¹.

C. Software Quality Assurance Role

The Software Quality Assurance role is in charge of review software artifacts in order to create a software in good standard of quality design. The main goal is to apply techniques to validate software artifacts, especially to create and execute test cases. The Software Quality Assurance role must follow

¹The tools is available from <http://astah.net/>

TABLE I. SPARTA ORGANIZATION USING FOUR ROLES

Groups	Teams	ID	Projects			
			P1	P2	P3	P4
1	1	11	Manager	SQA	Analyst/Designer	Programmer
	2	12	Programmer	Manager	SQA	Analyst/Designer
	3	13	Analyst/Designer	Programmer	Manager	SQA
	4	14	SQA	Analyst/Designer	Programmer	Manager

the plan defined by the *manager*, using the artifacts created by *Analyst-Designer* and *Programmer* roles as input. One might observe in Figure 1 that software quality assurance tasks crosscut the method suggested, facilitating the *manager* task to reduce risks.

We have used different SQA method depending on the artifact to be verified/validated. To document requirement, we have used Perspective Based Reading [12], [13]. To program validation, we have used JUNIT test cases.

D. Programmer Role

The Programmer role is in charge of implementing the software design, following the plan defined by the *manager* and the design specification created by *Analyst-Designer*. We have encouraged our students to use JAVA language.

E. The Teacher

During SPARTA execution, the teacher has two different roles basically. Initially, the teacher plays the client role, defining the requirements to the *manager*. As an instructor, during the development, the teacher might provide support to managers as an external consultant, in order to inquire manager into decision leading them to think about alternative ways to software development under construction.

F. The Projects

We have used four projects, briefly described here. The first system, identified as *P1*, aims to provide support to the activities involved in management courses, as record curricula, distribution of lessons, didactic and pedagogical planning, monitoring of teaching activities, among others. Since it is a support system (sub-system), it must be able to exchange data with other systems available through text files. There are 25 requirements, 3 of them considered medium and 22 considered low level of difficulty.

The second system proposed, identified as *P2*, aims to provide support to the activities involved in the management of bank accounts, whether they are current accounts, savings or credit card accounts. The system must be able to exchange data with other systems available through text files, especially files containing your banking, obtained over the Internet. There are 20 requirements, 6 of them considered medium and 14 considered low level of difficulty.

The third system, identified as *P3*, aims to provide support to the activities involved in the management of resources that can be shared by multiple users, should be established time-lines or reservations for effective use. The resources managed by the system can be, for instance, classroom, laboratories, and computers. Therefore, the system must be able to deal

with different types of resources and suggest similar resources available during reservation. There are 21 requirements, 6 of them considered medium and 15 considered low level of difficulty.

The forth system, identified as *P4*, aims to keep a music library, with musical productions, authors, performers, etc. The system should also play a particular song, or playlist, chosen by the user. There are 26 requirements, 3 of them considered medium and 23 considered low level of difficulty.

An important issue about the system chosen is: all of them were defined considering their length, not only in requirements and technical similarities, but also the Function Points estimation [14] – both systems result in similar points. Also, some requirement were intentionally chosen to have a vague specification, in order to introduce variations across multiple implementation, allowing different technical decisions along the project development.

IV. RESULTS AND DISCUSSION

The results were collected after students had answered a survey about the project. This survey was applied at the end of the Software Engineering Course. The first question is about the organization of teams, it was asked if the organization with defined roles was useful for practice and activities learning. Answer are shown in Figure 2, the great majority of students rated as beneficial the division of the team as pairs with defined rules. According to students the division helped the development process of the project that they managed.

Figure 2. Question 1: team organization.

The second question is about the proposed practical activities, students answered if these activities helped to sedimentary acquired technical knowledge, as shown in Figure 3. Students justified their answers saying that with the Software Engineering subjects were easier to be consolidated, highlighting

the importance of defined roles. Besides, it was a excellent opportunity to learn from mistakes which emerged with the implementation of activities.

Figure 3. Question 2: practical activities.

In third question students discussed the importance of managing a software project. The answers were categorized into three assessment standards: great, good and regular, as shown in Figure 4. Evaluating the results in these it was concluded that most students agreed that the experience of managing a project was valid.

The students said that it was essential for learning and gaining experience in the application of Software Engineering knowledge in real projects of companies or organizations. Also it was a great way to understand and be able to apply knowledge in activities involving teamwork, deadlines and organized work. Students that had their answers as regular said that they already had some knowledge, so it was a opportunity to review some concepts.

Figure 4. Question 3: importance of managing a software project.

In Question 4 it was asked about if it was possible to apply theoretical concepts learned in classroom in a project management. Almost the totality of students agreed that they were able to apply the concepts in practical activities, as shown in Figure 5. During the management they applied the most important and essential concepts learned in the classroom, as the use of some design patterns, the conduction of Technical Reviews [12], [13], metrics and estimation software tasks, the methodology to development [11]. The activities of manage

demed a caution. Also, it was important to ensure that the schedule was running as planned, i.e., if the control points verification.

Figure 5. Question 4: applying theoretical concepts

In Question 5 students answered about their difficulties on managing a project. The difficulties can be categorized into human resource management and planning and control of the project, as indicated in Figure 6. In all years, except for 2012, the biggest difficulty has been dealing with the human factor, since the vast majority had no experience in managing people before. Project managers were unable to deal with delays and non-compliance with some tasks. On the other hand, the lack of experience was appointed as the reason for the difficulty in planning a schedule and most important, follow it.

Figure 6. Question 5: difficulties on managing a project

The last question was about the team performance, students were asked if they as manager/owner condition, would hire their employees based on their performances. The hiring rate is shown in Figure 7, which was an opportunity for students to individually evaluate each team element of the project development.

Although human resource management be pointed as the major difficulty in the project management, in most cases managers would hire their staff. Factors such as theoretical knowledge, practical skills and mostly, a good capacity of teamwork were crucial for the evaluation. On the other hand, delays and lack of commitment to the project were identified as the main reason for not hiring.

Figure 7. Question 6: hiring rates

Finally, it was asked to each student whether s/he approved SPARTA approach and we summarize the results in Table II – more than 90% approved SPARTA approach as a way to practice software project management.

TABLE II. POSITIVE FEEDBACK FROM STUDENTS PER YEAR AND ITS PERCENTAGE

Year	Enrolled Students	Positive Evaluation	
		Students	Percentage
2007	24	22	91,67%
2008	43	36	83,72%
2009	42	39	92,86%
2010	34	30	88,24%
2011	39	39	100,00%
2012	34	31	91,38%
2013	51	44	86,27%
Total	267	241	90,26%

V. LESSONS LEARNED AND OBSERVATIONS

We have applied SPARTA since 2006. We considered the first year as a pilot study. After 2007, we have applied SPARTA using the organization presented in this paper. Year by year we have improved details considering the feedback provided by students.

Initially (2006 and 2007), the teacher had no role specific: the teacher only provided the requirement documents to students and monitors them as *managers*. After 2007, some requisites were modified and defects (such as, ambiguity and inconsistency) were introduced demanding SQA activities and corrections. Also, the teacher assumed the *client* role, supporting the managers to clarify requirements and receiving the final product at deploying phase. We introduced client role after have observed problems in communication – both on interpreting requirements and interpersonal communication. Also, some groups reported excessive delay in project plan and conflicts among members.

By introducing *client* role we reduced the conflict and, consequently, we facilitate its management and resolution. Software developers, users, project managers, customers and project sponsors need to communicate regularly and frequently. The information gained from discussions allows the project team to analyze threats and to act in order to minimize

threats. For example, casual conversation with users, team members, and other stakeholders may often surface potential problems sooner than formal meetings. However, the *client* must be contacted by students independently of role – in other words, the *client* has no proactive attitude, but students are encouraged to be proactive. The communication must focus on whether the team has understood the project and whether the team is making progress towards that goal.

Another lesson learned is regarding the evaluation criteria and schema. Each manager should evaluate their team members, individually. Considering the crossing assignment, one might assign unearned grades to colleagues aiming at receive back unearned grades. For that, we considered the crossing evaluation but introducing the teacher in order to avoid collegiality in grade assignment. The rationale is: whether a manager gives high grades to their employees, but present poor results, it is possible to infer that s/he is a poor manager. Consequently, the teacher should apply penalty, decreasing the grade to the manager.

Risk management is a weakness in SPARTA approach. The controlled environment, especially regarding requirements, does not allow student practical activities on measuring or assessing risk and, consequently, developing strategies to manage the risk. In general, students are allowed only to deal with tight schedule, and the strategies employed include transferring the risk to another phase (see Figure 1), reducing the negative effect of the risk (i.e. rework), and accepting some or all of the consequences of a particular risk. Hypothetical situations are explored in theoretical discussion to mitigate such weakness. In addition, budget is out of scope of SPARTA – we have proposed scenarios (*what-is* situations) to managers in order to instigate them to think about budget and take decisions considering financial impact.

Regarding *requirements management*, the process of identifying, eliciting and documenting are underexploited. However, the process of analyzing, tracing, prioritizing and agreeing on requirements and then controlling change and communicating to relevant stakeholders consist in strength points in SPARTA. By allowing students to practice management, they must take decision especially about tracing, prioritizing and agreeing on requirements.

Initially (2006 and 2007), we do not defined any software configuration management – each manager should use as his/her own convenience. Next, for two year we provided an infrastructure to be used: we defined a server to be used to version control, and the teacher had access to all project area. However, the resources available nowadays motivated the use cloud services chosen by each manager.

One might argue about four groups – why four? why manager, software quality assurance, analyst and designer, and programmer roles? In fact, *analyst* and *designer* roles in different groups would be an option to instantiate SPARTA using five groups, but we considered the increased communication among groups as a threat to the work (and schedule) proposed.

VI. RELATED WORK

Usually, teaching software project management uses simulations tools. Simulations have been becoming increasingly

more prevalent in the education system over the past several decades [15]. Many critiques and reviews regarding management and business simulations have been produced [16]–[18]. However, Salas et al. [19] pointed out that the majority of the literature focusing on simulation in management education is descriptive rather than prescriptive – it describes the current state of simulation technology in management education and what types of simulations are used, but does not provide guidance as to how to most effectively utilize simulation based training (SBT) to develop the skills of management students. They also agree that SBT should be used more frequently in management education. However, tools are not enough, the different perspectives of teaching and developing require methodological approaches to organize the usage of mechanisms to support the teaching-learning process [20].

Also, system project dynamics [21] models have been used supporting risks in software project management [22]. However, we have found no hands on approach for teaching and learning software project management.

VII. FINAL REMARKS

Magni et al. [23] pointed out that: a) organizations and educational institutions are moving toward a training approach that emphasizes the active involvement of participants; b) there is growing interest in understanding how individual engagement in the training experience affects practicing managers' individual learning. Instead of work with models and simulations, we proposed a hands on approach to allow immersion in realistic situation.

Fred Brooks pointed out that there was “no silver bullet” that would ensure project success [24]. We are aware that SPARTA approach is not a “silver bullet” on teaching and learning software project management, but it is worthy. Working in group, using different roles, the student is exposed to different views, what might be helpful to emphasize absorption of concepts and good practices. We have observed that group-level behaviors can mitigate negative effects on individual learning. Most of students have pointed out be worthy to use a hands on approach, even after having faced difficulties during the development process, especially regarding communication.

Most students did not know anything about project management, others had no idea of existence of tools that help for good project managing. Therefore, it was very important the application of these project. Besides, some students were encouraged to research about practices of PMI (Project Management Institute) to apply to their projects.

ACKNOWLEDGMENT

We would like to thank all students who participated in the activities, for their dedication, interest and given replies to survey.

Abstract - The Department of Computer Science at the University of Los Andes has proposed a new curriculum model based on the profile defined by ACM/IEEE, and a pedagogical model based on the "learning by doing" paradigm, in order to ensure a process of self-formation of the student. The knowledge management and the learning process are based on the concept of clouds. The new educational model is based on three clouds: a) the self-formation cloud which is composed of everything related to the student's education (curriculum, etc.); b) the learning paradigm cloud which is related to the paradigms, strategies, forms of assessment, and learning tools; and c) the knowledge sources cloud which is composed of all existing knowledge in the world, in all its forms, from all possible sources. To give support to the educational model, a web platform based on Service Oriented Architecture (SOA) is proposed in this work. The system consists of three management layers; each one manages each one of the clouds described above. The implementation of each layer is made as web services. Each layer has its own data structure defined like ontology. This is called Extended Database, which also has the ability to support processes of reasoning over it.

I. INTRODUCTION

The challenge of the Modern learning environments is exploited the strengths of the students, offering flexibility and openness to the access to resources. An open and flexible learning environment allows sharing knowledge and practices, in order to improve the learning process. In general, e-learning describes the utilization of Information and Communication Technologies (ICT), to support educational activities [4, 11]. But ICT can be used to catalyze innovations in teaching and learning processes. There are several domains where the ICT can be used to do new things, to enable transform teaching, learning and the curriculum [4, 11, 12, 17, 18]. One of these domains is to produce computing tools that are pedagogically and functionally relevant to the learning context. For this case have been studied the learning styles, based on the premise that different students learn in different ways. Some papers have proposed computing tool to provide recommendations about educational resources according to necessities of the

students [12]. Other domain more recent is based on Smart Classrooms, where the environment assists professors, with the integration of the ICT in the learning process [2]. Cloud computing is another domain which is been used in the domain of education. For example, Seattle is a free educational research platform that is community-driven, and supports a variety of pedagogical uses based on the cloud computing paradigm, among others [5].

Additionally, the "Age of Knowledge" is delineated by the continuous and dynamic advancement of technology and information [15], in which there is an immense knowledge available. Today, thanks to the Internet, the information and tools necessary for students to acquire knowledge are completely in its scope, in the most varied forms and perspectives. In the age of knowledge new skills are required, such as [1, 15]: Learn to Learn and Unlearn, Collaboration, Creative Thinking, Technological Culture, leadership development, career self-management, etc. Higher education faces the challenge to stop being a model of teacher-centered education to become a learner-centered model whose emphasis is on providing students with the tools and resources to take responsibility their own learning.

Moreover, there is a growing requirement of professionals trained in the areas of computing, telecommunications, information technology and related (statistics, etc.), with social sensibility. International organizations such as the IEEE and ACM define five profiles of professions covering such areas [7, 13]. As described in [1], in Venezuela different universities offer courses that cover some aspects of these areas, become hybrids of the profiles defined by such organizations.

From the above, the need arises to propose the creation of careers in Computer Science, inspired by the profiles defined by the IEEE/ACM and in the "knowledge era", focused on the needs in ICT of each country; based on the paradigm of learning "learning by doing", also with flexible mechanisms to constantly update the corpus of knowledge.

Thus, the Department of Computer Science, at the University of Los Andes has proposed a career in Computer and Informatics Engineering, based on an educational model, called "Mother Project", which considers the previous aspects. This career has defined a curriculum with

the 5 profiles defined by IEEE/ACM for careers in the computer field [7, 13]. The definition of the flexible curriculum consists in that the student can choose its modules to study, such that he autonomously defines his academic path. The curricular model allows several intermediate outputs (Technician, Engineer, etc.). The Mother Project is based on the concept of clouds. The Project has defined three clouds: the self-formation cloud which is composed of everything related to the student's education (curriculum, etc.); the learning paradigm cloud which is related to the paradigms, strategies, forms of assessment, and learning tools; and the knowledge sources cloud which is composed of all existing knowledge in the world, in all its forms, from all possible sources.

Currently, the project has not a technological platform to support it, so it is essential to build a system that, in addition to manage the students educational process (student registration, etc.), could consider services involved in the student training (adequate educational paradigm, learning objects and online courses that complement the educational process, etc.). In this paper is proposed a web platform to manage the different clouds, based on SOA. In particular, the platform is composed of web services, which offers the student the basic services such as registration, access and view curriculum; but also services tailored to the students. I.e., the system is able to examine the characteristics of the student during his training, and analyze his performance during the career, in order to provide educational services to each student, as tools, activities and evaluation forms suitable for him. This adaptive capacity is the main difference with respect to current educational platforms like Moodle.

II. THEORETICAL BASES

A. Learning environments

An educational platform is a tool, physical or virtual, or physical-virtual combination, which provides the ability to interact with one or more users for educational purposes. It is a tool that helps in the process of learning and teaching. This platform is classified according to distinct aspects:

Teaching Mode: it can be of two types [18]: in classroom, where the teaching-learning relationship is in the same place. The virtual does not require the physical presence of the people using the tool on the same place.

Adaptation: may be general tools that provide generic functionality for users; or customize, which are set according to individual needs of small groups [18].

Features of the Contents: these are subdivided in [18]:

- OpenCourseWare: It is a set of contents in education that can be used as a supplement in a particular course, or as a base of knowledge to communities.
- Learning Management Systems (LMS): set of software tools that provide an online space to facilitate learning and teaching.
- Content Management Systems: collection of procedures used to manage the activities and contents in a collaborative environment, in real time.

- Knowledge Management System: it is a system that is responsible for making operations for the management of knowledge database within an organization.

In an educational platform the students can communicate in 2 ways: asynchronously as blogs, wikis, email; and synchronously as chat, video conferencing, etc. Some educational platforms are [1, 3, 4, 5, 6, 11]: Moodle (Modular Object Oriented Learning Environment), Seattle, Aula CESGA (an e-Learning platform for training, teamwork and innovation experiences in education and research) and Chamilo (LMS for b-learning or e-learning).

B. Ontology Driven Architecture (ODA)

Models Driven Architecture (MDA) proposes the use of models to specify the business logic of an organization, regardless of the specific technology platforms where they are implemented. MDA adopts UML [5, 6] as the modeling language. The main idea using MDA is the separation of the system specification of the specific aspects of the implementation. MDA proposes three models, which are the results of the phases with the same name [10, 16, 19]:

- *Computing Independent Model (CIM):* This model is centered on the system domain as well as functional requirements, non-functional properties, business rules, goals, structure, and processing strategies that the system must satisfy.
- *Platform Independent Model (PIM):* This model defines the system specification. This model represents issues that will not change from one platform to another.
- *Platform Specific Model (PSM):* This model combines (PIM) with details and characteristics of the development platform. In this model are established all aspects for the implementation of the application.

Ontology-Driven Architecture (ODA) is a hybrid approach for the development and deployment of information systems, combining the Semantic Web technologies with development languages such as UML, where ontologies can be considered a special class of models with a formal semantics based on logic [16, 19]. This approach combines formal representation techniques designed for the Semantic Web, with commonly accepted software engineering practices. In general, ODA responds to the need to automate the processes of software engineering from a cognitive perspective, reasoning about required software components, inferring the processes of design and development, among other things. Specifically, we have proposed ontologies to describe the information of each phase [10, 11].

III. MOTHER PROJECT

The Department of Computer Science at the University of Los Andes has proposed an educational model, called "Mother Project", which aims to define a Career in Computer Engineering and Informatics, based on a curriculum with the 5 profiles defined by IEEE/ACM for careers in the computer

field, these being Computer Science, Software Engineering, Computer Engineering, Information Systems and Information Technology [1, 7, 14]. To do this, the curriculum is flexible, allows students the option to choose the modules to be studied, and allows intermediate outputs (Technician, Engineer, etc.).

The Mother Project proposes an educational model which exploits the new tools offered for Internet. The proposed educational model focuses on the paradigm of "learning by doing" [1]. This model is based on a metaphor of clouds, which has been explained in detail in [1, 9, 14]. In general, this metaphor introduces the idea of "clouds effect", which makes their internal dynamics to move with the wind (with the global and national events, industry, etc.), in order to allow the emergency of activities, to-do, etc., and also criss-cross, generating a powerful educational synergy.

Learning Paradigm Cloud

This cloud is related to the paradigms, strategies, forms of assessment and learning tools. Its aim is to provide the learning mechanisms necessary for the process of self-formation. It will guide the dynamics of self-training, establish ways of accrediting courses, collaborative work, among other things. The learning process provided to the students is adapted with this cloud permanently based on the characteristics of each student (learning profile of the student). Some qualities of this module are:

- It is inspired on the paradigm of "learning by doing", which seeking active participation of the students in a work, which can be artistic, technological, scientific, etc.
- All forms of learning which promote learning by doing (active learning, agile learning, blended learning, etc.) are possible to use.
- The collaborative work, sharing knowledge, multidisciplinary work, are issues that enrich the teaching process. Those aspects must be promoted by the different strategies, tools, etc.
- It requires many tools and applications from Internet to manage shared spaces and groups, to assign responsibilities, to monitor works/projects.

Knowledge Sources Cloud

This cloud is composed of all existing knowledge in the world, in all its forms, from all possible sources. Its purpose is to enable greater access to knowledge available worldwide. Learning objects, online courses, e-books, etc., become fundamental sources of knowledge, and are linked by the modules in the self-formation cloud. The methodologies, tools and techniques of this cloud must allow an access critical to that knowledge provide by the other clouds [1, 7, 14]. So, we are not talking about a passive, neutral, access to knowledge, but critical, seen from the process of self-formation according to the curriculum dynamics established in the Self-formation cloud and the learning process dictated by the *Learning Paradigm Cloud*.

Self-formation Cloud

This cloud is composed of everything related to the student's education. The student learning consists of building itself the curriculum, which is composed of modules which are self-contained. In the curriculum are given the option to various degrees, these depend on the number of credits reached and profile chosen by the student. The possible profiles for the students are inspired in the curriculum defined by the IEEE/ACM. Paths for these profiles are proposed initially, but as the student is autonomous, guide his own process of self-education so that he chooses his profile. In this way, the student builds his own net curricular.

IV. SYSTEM ARCHITECTURE

The design of the web platform is based on SOA and on the educational model called *Mother Project*. The system functionality is described in Figure 1, which is composed of three layers, each one manages one of the clouds of the Mother project. The *first layer* manages everything regarding the student, teacher and curriculum. This layer has the different services they need, both the student and the teacher, to manage the process of self-education, such as student registration services, queries to the curriculum, etc. The *second layer* manages the search of virtual objects, both learning objects and digital contents, and offering the student the proper learning resources to their needs, according to their educational profile and position in the curriculum. The *last layer* manages the learning paradigms, in order to specify the tools, types of evaluations and educational activities appropriate for the student's learning style. The implementation of each layer is made as web services. Each layer has its own ontologies, whose instances represent the stored information. That is called in Figure 1 Extended Data Base, which also has the ability to support processes of reasoning.

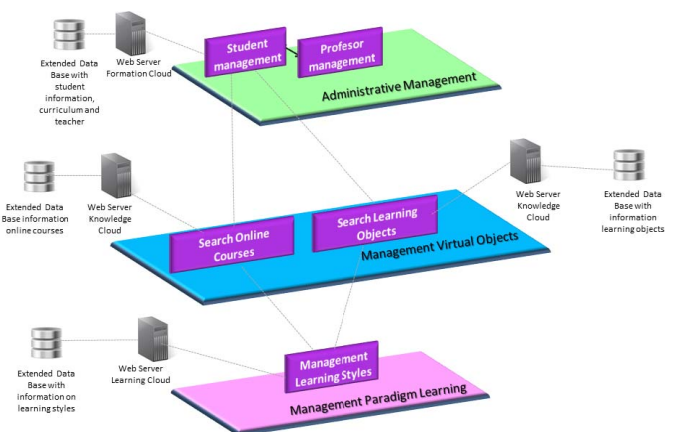

Fig. 1. General Architecture of the Web Platform

An example of utilization of our architecture is defined in the Figure 2, in the case of a student taking a course (module) of the curriculum. He begins with the request by the self-formation cloud (a student already registered) to the cloud of knowledge of a list of learning objects and digital contents for a particular topic for a given module and a student learning profile (step 1). That list should be consistent with the description of the student; for this, the cloud of knowledge makes a request to the learning cloud, to know the tools, activities and evaluation mechanisms to be used by the profile of the student (step 2). That information is sent by the Learning Cloud to the self-formation cloud (step 3). Once with this information, the knowledge cloud searches the appropriate virtual objects, and sends to the self-formation cloud a list ordered by priority, of different learning objects and digital contents associated with that particular student (step 4). Every cloud has a web server with the set of services to be provided. Each server connects to information that has been stored in the extended databases (or ontologies), to respond to requests from the system.

V. SYSTEM DESIGN (PIM AND CIM)

A. Self-formation Subsystem

We begin by defining the non-functional and functional requirements of the platform.

Specification of the CIM.

Functional requirements: The functional requirements required by the system are for two actors: the students and teachers. In the case of students:

- Register in the System: This includes storing the student data, the learning profile, etc. In addition, the student may also enroll modules to study at a given quarter.
- Perform Queries: Queries that can make the student (characteristics of its modules, learning objects and online courses associated with these modules and profile, etc.), characteristic of his learning profile (tools, activities and evaluation techniques appropriate), etc.

Fig. 2. Invocation process between the clouds.

For the Professors:

- Register in the System: This includes data of the teacher and modules that dictates.
- Store Notes: Allows the teacher, after completion of a course, assigning notes to the students.
- Management of Virtual Objects: Allows the teacher, once evaluated a group of virtual objects, certifying. This certification is stored in a database of certified virtual objects, for future use. This database is used by the cloud of knowledge for a faster search of virtual objects.

The diagram of the general activities of this layer is shown in Figure 3. Once a user, either teacher or student, joins the system, the web platform will allow a number of activities. For inquiries is necessary to use the knowledge base (ontology) to reason about the information, for example, module belongs to a subject, subjects belonging to a profile, modules seen by a student, etc.

Non-functional requirements: Among the non-functional requirements that the system must meet, is scalability (the educational platform should be able to allow further development of new functionalities), and quality attributes like security, interoperability, and friendly interface.

In Figure 4 is shown the ontology of the CIM layer. It summarizes the different concepts linked to the web platform and its requirements.

Specification of the PIM.

Each of the functions of the system is developed using web services. Some web services of this layer are:

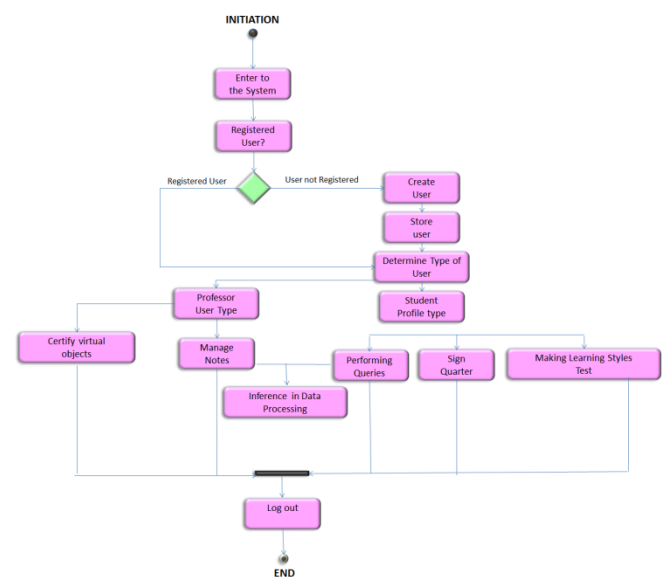

Fig. 3. Activities Diagram of the Self-formation Subsystem

- Query: it is responsible for receiving the name of a module and the ontology queries: code, themes, profile, learning objects, digital contents, among others.
- Store student information: it is responsible for extracting the information provided by the students through forms, and storing it in an ontology. Among the stored information of a student are his data, studied modules, and learning style.
- Store information of a teacher: Records in the ontology data of the teachers, the note to the students, and the virtual objects certified.

The PIM ontology is shown in Figure 5. It describes the web services, and with the class diagram of a web service (see [4, 8]) is obtained a complete description of the system.

B. Knowledge Sources Subsystem

This layer recommends general digital contents (guides, courses, images, videos and others) and learning objects for the self-formation cloud.

Specification of the CIM.

Functional Requirements: Some of them are:

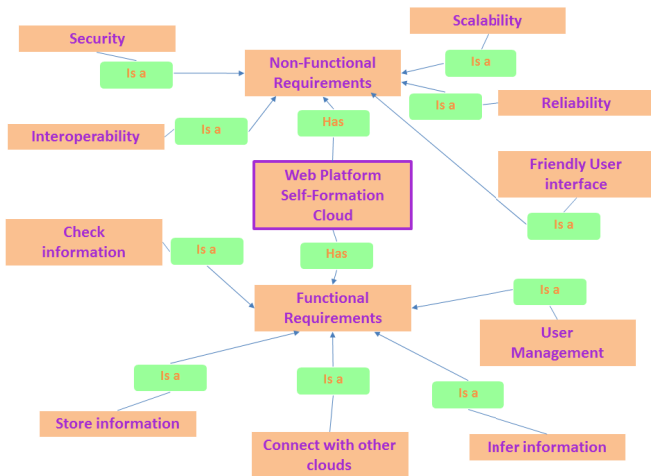

Fig. 4. Ontology of the CIM Layer of the Self-formation Subsystem

Fig. 5. Ontology of the PIM Layer of the Self-formation Subsystem

- Query: It allows at the student and the teacher to consult the information of the digitals contents, depending on the necessity that they have, for example, title, description, tools, activities, and others. Likewise, it too must permit to carry out inferences about the digitals contents that match with a learning style and a specific topic.
- Record: This functionality allows add digital contents.

Non-functional Requirements: the non-functional requirements that the subsystem must fulfill are the same of the previous subsystem. In the Figure 6 we can observe the conceptual ontology of this subsystem.

For other side, the digital contents are described using the standard of the W3C Ontology for media resources 1.0, which is shown in Figure 7.

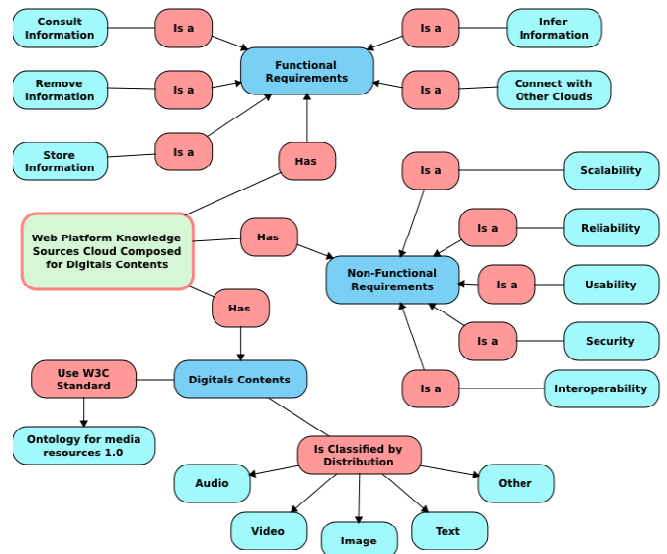

Fig. 6. Ontology of the CIM Layer of the Knowledge Sources Subsystem

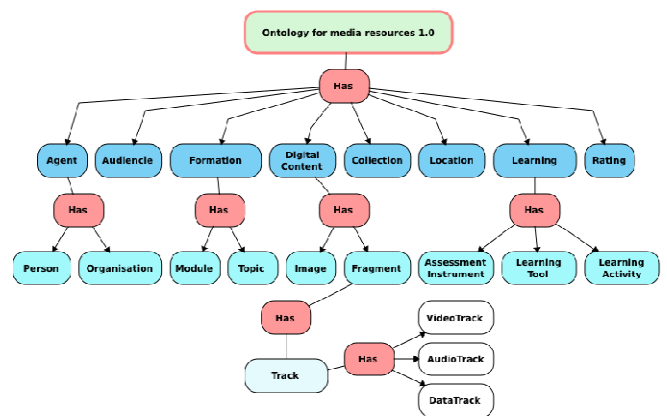

Fig. 7. Ontology for media resources 1.0

Specification of the PIM

The ontology of this layer is shown in Figure 8, where we can observe the functionalities of the subsystem, described how web services. With the general diagram of classes of this subsystem (see [9, 14]) is obtained a complete design of the system.

C. Learning Paradigms Subsystem

Specification of the CIM.

Functional Requirements: This subsystem defines the learning paradigms, learning activities, and learning tools, according to Felder-Silverman learning model (see [8, 9] for more details about that). In specific:

- Check Learning Paradigm, activities and tools. Allows know the paradigm for a student.
- Infer learning activities. It infers the learning activities to be performed for a student, according to his learning style.

In Figure 9 is shown the ontology of the CIM layer.

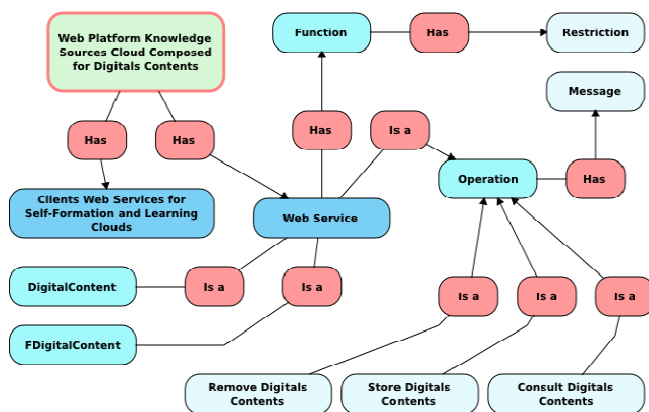

Fig. 8. Ontology of the PIM Layer of the Knowledge Sources Subsystem

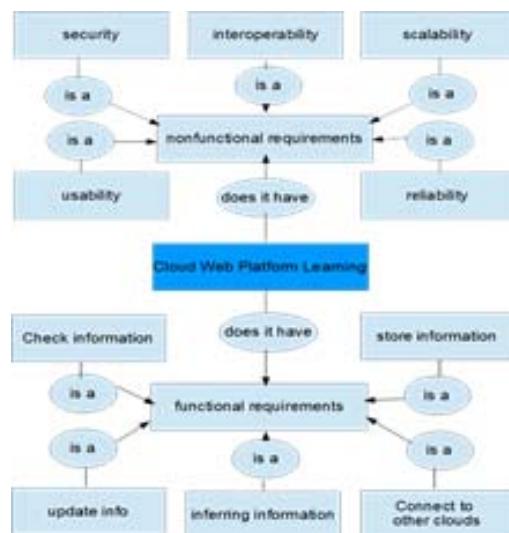

Fig. 9. Ontology of the CIM Layer of the Learning Paradigms Cloud.

Specification of the PIM

Remember, each of the functions of the system is developed based on the Web Services paradigm. With the diagram of classes of this subsystem is obtained a complete design of the system. This subsystem consists of 6 main classes. In the class FelderSilverman is used the FACT ++ reasoner to infer the activities, tools, instruments, paradigms and learning profiles. The BD class allows connecting to the database used by this layer, and performs SQL queries. The rest of classes are defined in [9, 14]. The domain ontology for this layer includes concepts as learning paradigms, learning tools, learning activities, etc.

The ontology of the PIM layer is shown in Figure 10, but now detailing some aspects of that domain ontology of the cloud must solve: determine the profile of student learning, establish parameters for digital/learning objects content search (tools, activities, etc.), among others.

VI. SYSTEM IMPLEMENTATION (PSM)

The system implementation is described in Figure 11, a layer called server contains all web services provide by each cloud, these web services have been developed with JAX-WS. Each service needs to connect to an extended database (ontology) that manages information of each cloud. This connection between web services in Java and ontologies in protégé is through the OWL API, it manages information using the Fact++ reasoner for OWL language.

The client tier hosts all references to Web services of educational platform, allowing use information and knowledge stored, plus it provides the user interface of the system. The communication between client and server layers is through a bus service.

In general, the components of the system are:

- Client browser, this client uses the HTTP protocol to connect to the application server, which contains the complete web application with communication to the knowledge base.

Fig. 10. Ontology of the PIM Layer of the Learning Paradigms Cloud.

VII. EXPERIMENTS

- Web Services (WS), which are classified in web services for the student and the teacher; web services for managing virtual objects or digital contents, and web services for determining the learning paradigm.
- Application server (SWS): contains web applications that define cloud services, communicating via the SOAP protocol.
- Server with the Knowledge Base: groups all the ontologies used by web services hosted on the application server.

The Figure 12 shows the ontology of this layer, where it denotes the different technologies utilized to build the platform: Apache Tomcat, Jax-WS, OWL-API, Protege, FACT ++ and PostgreSQL.

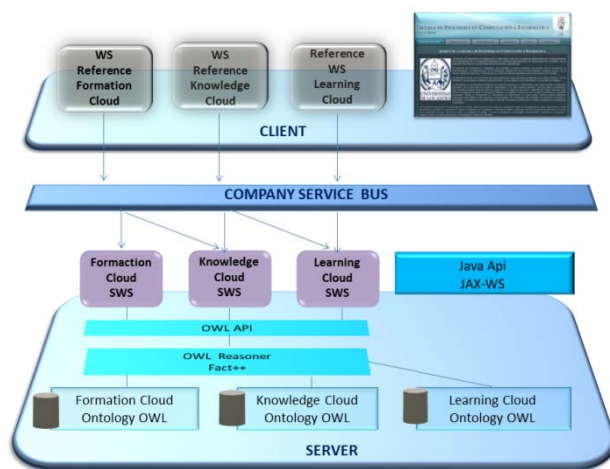

Fig. 11. Implemented Architecture of the Web Platform

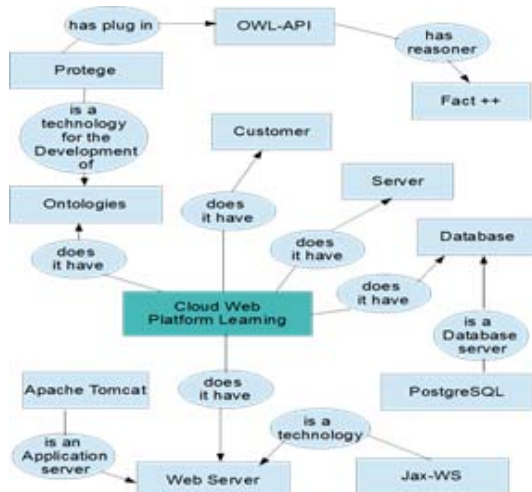

Fig. 12. Ontology of PSM layer of the Web Platform

It is defined for the web platform prototype an experimental protocol that helps verify system behavior. The overall objective is to verify proper operation of the web platform. Various tests are proposed, which are of two types: performance testing and integration.

A. Performance testing

In general, these tests seek to revise the correct for each of the features offered by the system. The first one is to know if the system provides the correct learning style of a student. For that we need to analyze the responses obtained by the student, and calculate a number that will be sent to the cloud of learning paradigms, which represents the style of the student. The form of learning styles is filled out with student data, who completes a test consisting of 44 questions, as shown in Figure 13.

We define an expected result, in this case [4534]. The Figure 14 shows that the test obtained on the platform after the student answers 44 questions, corresponds to that described above. Thus, the proper functioning of the test is checked for the learning styles.

Now we will verify the correct behavior to infer the learning paradigm. To perform the test, we assume the learning style 2121. The learning cloud gives like a learning paradigm for this style: ParadigmB_Learning (see Figure 15).

If we go to Felder Silverman model, theoretically the paradigm B_Learning is ideal for an active, sensory student that learns sequentially and uses visual aids [8, 9]. If we analyze the value 2121, it corresponds to a value that qualifies an active medium, a high sense, a visual medium and high sequential. Thus, the deduction of our ontology that corresponds to the paradigm B_Learning 2121 is correct.

Fig. 13. Interface of Learning Styles

Fig. 14. Test results on the web platform.

B. Integration testing

Now we test how the three clouds work together. The system architecture offers several features, which are distributed in different clouds, which technically represent different web services. We need to verify whether the connection between them work correctly. In particular, the self-formation cloud initially determines the value of the test according to Felder Silverman model. Once the student answer all questions, the result of the questions is shown (the four digits describing the student's learning style, see Figure 15).

After calculating the value of the test, we proceed to determine the appropriate learning resource for that student's learning style (in this case 4534, which corresponds to the paradigm ActiveParadigm). To do this, all four digits are used by the self-formation cloud when invokes the knowledge sources, and those same digits are used by the cloud of knowledge when invoked learning cloud. With that information, knowledge cloud searches learning objects or virtual contents that meets the specifications indicated in the activities (workshops, exhibitions, etc.), tools (video, diagrams, etc.), etc. of that paradigm (see Figure 16).

Figure 16 shows the digital contents proposed by the platform for a student whose educational profile corresponds to 4534, for the theme "Algorithms and Problem Solving" of the course "Fundamentals of Programming 1". According to ActiveParadigm paradigm, these digital contents or learning objects have the following characteristics: based on problems, reading, problem solving; tools can be tutorials, blog, email; and test tools can be based on issues, like questions and answers, individual test. The client Web application of the self-formation cloud references to the web service of the knowledge cloud that performs semantic search of learning objects hosted on a remote server. This service is invoked from the JSP page using scriptlets.

VIII. CONCLUSIONS

This paper proposes a Web platform for "Mother Project" based on the paradigm ODA. A preliminary comment is that there is not methodology for ODA paradigm, so a methodology that combines various methodologies such as MDA and Methontology, was used. CIM, PIM and PSM layers were specified, by merging various UML diagrams with specific ontologies to define each of the layers.

The system architecture is based on the paradigm of SOA. This model shows the features of the 3 cloud systems (self-formation, Knowledge, Learning Paradigms) and how they communicate with each other, achieving an integrated system. The different services were implemented using web services, which ensure great flexibility in system maintenance, enable massive reusability and reduce the level of coupling system, making it easier to update the system functionality in the future. All this facilitates scalability.

Fig. 15. Query of the 2121 style to the Learning cloud

Fig. 16. Answer given by the cloud of knowledge

In turn, the use of ontologies and knowledge bases allow analyzing the information stored by inference processes. This allows in development time the domain understanding, the standardization and the reuse of knowledge; and at runtime, the integration of data sources. That enables the interoperability system.

The learning process is based on "learning by doing", using a learner-centered model. The platform finds learning resources on its registers or Internet, based on the student style and current level of its training. The platform can consider these aspects, in order to provide an excellent learning environment adapted to each student.

As future work we propose to add more security to the web platform, which must consist of a set of preventive and reactive measures that allow safeguard and protect the information handled by the system, seeking to maintain the confidentiality of information, together with the availability and integrity of the same. Other further works need to add the feature of autonomy to the platform, i.e. make the platform has the ability to be reconfigured over time, with features such analyzes the curriculum and update it by learning obtained from the behavior of student (recalculate the learning style of the student based on the academic performance) or learning analytics, among others.

Experience of Experimental Teaching and Management Based on Cloud Computing

Jun Zhang, Sheng Bi, Xueyu Geng, Xianping Fu

School of Information Science and Technology

Dalian Maritime University

Dalian, P. R. China

fxp@dlmu.edu.cn

Abstract—Many laboratories were set up in Chinese higher education institutions in recent years. Some of them in the same university are equipped with similar rigs, which may lead to waste of money and human power in their setup and maintenance, and inconvenience and inefficiency for both faculties and students. An experimental teaching and management system, Open Laboratory Access (OLA), based on cloud computing technology is presented to enable full sharing and deep integration of experimental resources among laboratories and provide improved user experience. OLA provides a comprehensive and multi-angle virtual experimental teaching and management functions, including online experiment schedule and laboratory rig reservation, intelligent experiment guidance, teaching effectiveness evaluation, automatical experiment results statistics, etc. Thin-clients are adopted to reduce cost and ensure consistent user experience. After a one-year trial, the results of a user experience survey indicate that OLA provides good experience of experiment for both faculties and students.

Keywords—cloud computing; thin-client; virtual laboratory

I. INTRODUCTION

Laboratory hands-on experiment is a crucial practical component in many courses for college students to improve their practical ability. Since laboratory rig resource is often scarce, much attention have been paid and a lot of efforts made to have it available online for users (students, faculties, administrators, etc.) to book, collect data from or manage.

Yet we have another problem different from that. In recent years, the importance of experimental teaching is acknowledged by more and more universities and colleges in China. Many laboratories with similar rigs were set up simultaneously and usually managed in a separated way. They are often located in different rooms or buildings and managed without sufficient resource sharing and integration. Although computing power can indeed be shared to some extent among different laboratories by means of file sharing, remote login, etc., performance and user experience, especially those of multimedia, are still poor as a whole due to incomplete data, non-real-time delivery and inconsistent user interfaces. When confronted with virus infection, system or application software upgrading, administrators usually spend a lot of time and energy in recovering the experimental teaching environment.

Moreover, current laboratory management systems for those laboratories are usually intranet-based, thus cannot provide all-time service for users. Support staff of each laboratory have to print blank calendar at beginning of every semester for teaching faculties to fill in to determine experiment schedule, and then teaching faculties need to inform students. That leads to waste of time for both support staff and teaching faculties, and also non-real-time information for students.

A booming trend of making laboratories more open and easier to access has been arising since the beginning of the last decade. A. Gallardo, et al. present the conceptual model and technical design of an online rig booking system for scarce rig resources [1]. Mateos, et al. discuss several access solutions for online virtual laboratory and propose a system design based on SCORM [2] standard [3]. But both of them are not implemented, so the effectiveness is difficult to evaluate. There are some Learning Management System (LMS) frameworks for researchers to work with like [4][5][6], and plenty of systems has been done as modules or plug-ins based on them in the past over one decade. Those frameworks can serve as basic LMSs but difficult to be seamlessly connected to our existing laboratory environment. L. Xu, et al. propose the design and implementation of a virtual laboratory for network security education [7]. Y. Tateiwa, et al. present a virtual system for network administrator education [8]. Those special-purpose systems can be a good fit for particular courses or training objects, but still not suitable for our general-purpose situation.

An experimental teaching and management system, Open Laboratory Access (OLA), based on cloud computing is designed and implemented. Through OLA, faculties can plan experiments and issue the schedule; students are then allowed to book needed experimental rigs online and enter the laboratory afterwards on schedule, powering on the reserved rigs by authentication with their student ID cards to start experiment. After the experiment, faculties can manage the evaluation results and get the statistical data entirely online. Thin-clients are adopted as terminals for software based hands-on experiments instead of PC to reduce the cost of laboratory setup and maintenance, and provide consistent user experience.

II. SYSTEM ARCHITECTURE

The architecture of OLA is shown in Fig. 1. Master Server works as the control and information center of Server Cloud. A

This work is supported by National Natural Science Foundation of China (61370142, 61272368) and Teaching Reform Research Project of Liaoning, China (UPRP20140759).

Xianping Fu is the corresponding author (E-mail: fxp@dlmu.edu.cn).

course management system resides in it to provide course related services, e.g., rig booking, courseware management, etc., and control Slave Servers to fulfill tasks. Video files are also stored in it and sent to Slave Servers for caching when requested. Supervised by Master Server, each Slave Server, providing virtual desk service for thin-clients, serves for one or two physical laboratories. Thin-client is used instead of full-function PC traditionally used in laboratories since it is cheap, virus immune and system update free [9].

For every thin-client or experimental rig, a Wi-Fi module is developed to work as Power Controller, as shown in Fig. 1. When a student swipes his in-university ID card through Card Reader attached to Control Workstation in physical laboratory, a specific signal is sent through Wi-Fi channel to it and a relay switch in it applies power to the reserved thin-client or experimental rig. The circuit board of Power Controller is shown in Fig. 2.

A. Course Management

The course management system in Master Server provides a comprehensive support for virtual experimental teaching functions including experimental teaching schedule, courseware management, portals for students' booking, typical experiment database maintenance, experiment intelligent guidance, teaching effectiveness evaluation, experimental result statistics and other laboratory management related auxiliary functions. Function modules of the course management system are shown in Fig. 3. Workflows of student rig booking and action in laboratory are shown respectively in Fig. 4 and Fig. 5.

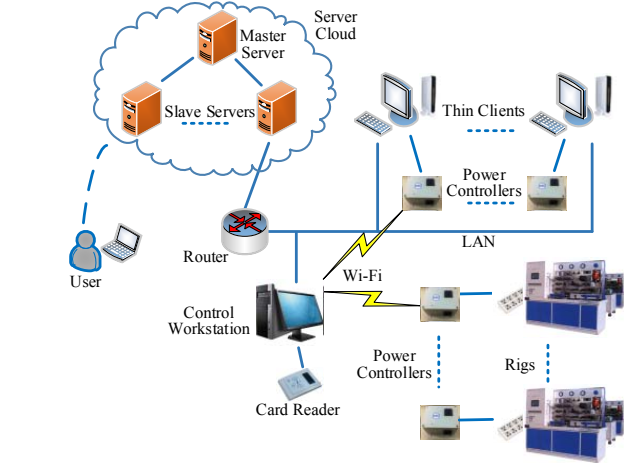

Fig. 1. System Architecture.

Fig. 2. Power Controller.

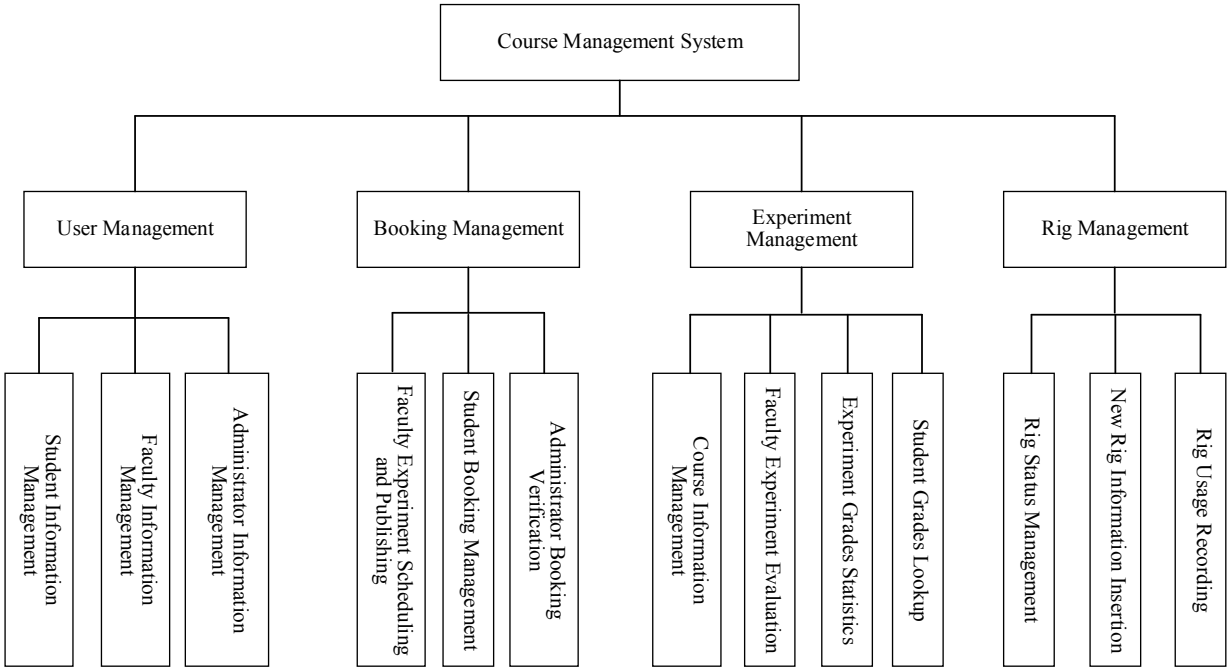

Fig. 3. Course Management System Modules.

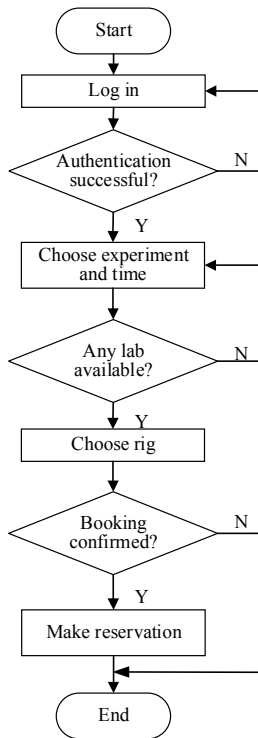

Fig. 4. Student Rig Booking Workflow.

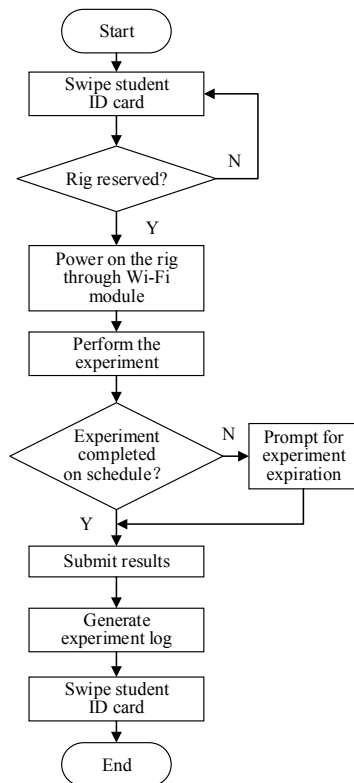

Fig. 5. Student in-lab action workflow.

B. Data Transfer between Slave Server and Thin-clients

The data communication model of *Server/Thin-clients* is adopted for students to perform software-based experiments. Each server (Slave Server in Server Cloud shown in Fig. 1) can generate different pools of virtual desks based on different templates consisting of different amount of computing resources, e.g., CPU, memory, disk, etc., and different kinds of course content [10], as shown in Fig. 6. Each virtual desk pool can be assigned to serve a course like Software Engineering, Java Programming, etc.

A thin-client is a computer that depends heavily on its server to fulfill its computational roles. Almost all data-processing work are done on its server, while thin-client itself is just responsible for displaying graphical user interface to user and pass user's input to its server. When a thin-client is powered on by its user, it directly connect to a Slave Server, and after logging in, a virtual desktop environment will be assigned depending on the user's role to facilitate the hands-on experiments. Using thin-client rather than PC can significantly save the cost of setup and maintenance of the laboratory, e.g., a thin-client of Chinese local brand may cost only 400 RMB (around 65 dollars) or less which is much cheaper than a PC. Traditional thin-client system has some defects, such as over-reliance on computing power of servers, high requirements of network bandwidth and poor performance for multimedia application [11]. To ensure multimedia performance, we chose four thin-client products including NComputing L300 [12] and three products of Chinese local brands, Share FL300 [13], LYBOX C200 [14] and Jieyun J60 [15], to conduct a comparative performance test on data transfer between server and thin-clients. The server is equipped with a CPU of Intel i7 (4770), 8G memory and the OS of Windows Server 2012. Each round of test was conducted in a Local Area Network (LAN) with a Gigabit switch connecting the server and 5 thin-clients of the same brand. After startup, all the 5 thin-clients request in parallel the same video clip with a resolution of 1920*1080. Thin-clients' startup time and the server's consumption increase of CPU and memory are recorded, and client-side video quality are evaluated, as shown in Table I.

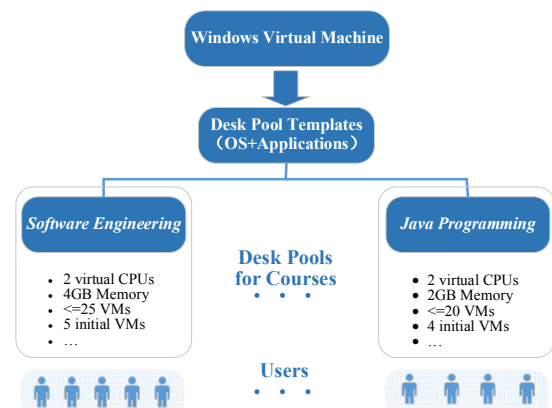

Fig. 6. Pools of Virtual Desks.

TABLE I. PERFORMANCE TEST RESULTS OF THIN-CLIENT PRODUCTS

Features / Performance	NComputing L300	Share FL300	LYBOX C200	Jieyun J60
Virtualization Manager	vSpace	None	LYVM	Jieyun Desktop
Thin-client Startup Time (Seconds)	37.11	28.35	27.52	28.64
Server CPU Consumption Increase	15%	<5%	30%	<5%
Server Memory Consumption Increase	30%	<5%	<5%	<5%
Client-side Video Quality ^a	4	4	5	5

^a Average scores of 10 users in Likert Scale [16]

Results in Table I indicate that Share FL300 and Jieyun J60 are better in multimedia performance. But the former does not have a server-side virtualization managing software, so the latter was adopted.

III. USER EXPERIENCE OF OLA

OLA has been deployed in three laboratories located in two buildings in Dalian Maritime University for more than one year, consisting of 1 master server, 2 slave servers, 50 thin-clients and 24 electronic experiment workbenches. More than 15 faculties and 300 students have taken advantage of it in 5 different courses. To validate the effectiveness and user experience of OLA, a questionnaire survey was conducted among them. There are two versions of questionnaire, one for faculties and the other for students. Both of them consist of three parts: general attitude to virtual laboratory, course management system user experience and in-lab user experience. Altogether, the faculty version contains 18 statements and the student version 17. We recruited 10 faculties and 30 students as participants with gender ratio of 1:1 for each. Average scores (1-5 points in Likert Scale [16]) on some of the overall evaluation statements from faculties and students are shown respectively in Table II and Table III.

TABLE II. AVERAGE SCORES OF FACULTY EXPERIENCE ON OLA

Statements for Faculties	Scores
Virtual laboratory does good to experimental teaching.	4.5
Experiment Scheduling and Publishing is useful for me.	4.4
Experiment Scheduling and Publishing has most features I need.	4.1
Experiment Scheduling and Publishing is easy to use.	4.2
Thin-clients are easy to use.	4.2
Quality of video played by thin-clients is high.	4.0

TABLE III. AVERAGE SCORES OF STUDENTS EXPERIENCE ON OLA

Statements for Students	Scores
Virtual laboratory does good to experimental learning.	4.4
Online booking is useful for me.	4.0
The booking website has most features I need.	4.2
The booking website is easy to use.	3.9
Power control by swiping student ID card is convenient for me.	4.5
Thin-clients are easy to use.	4.1
Quality of video played by thin-clients is high.	4.0

Results in Table II and Table III indicate that both faculties and students show positive attitude to virtual laboratory and have good experience on OLA usage.

IV. CONCLUSIONS AND FUTURE WORK

Focusing on the current status of experimental teaching management of Chinese universities, this paper presents the design and implementation of an experimental teaching and management system based on cloud computing technology. The problems, such as limited time and room for hands-on experiments, shortage of human power for managing and maintaining, application updating and information security threat, have been effectively solved. The course management system provides open, multi-dimensional and interactive teaching environment to improve the utilization of laboratory and experimental rigs, the efficiency of laboratory management and students' ability of practice, innovation and self-learning.

In the future, we plan to do the following work to improve OLA and serve for pedagogical goals.

- Recruit a higher number of students to answer the questionnaire in order to obtain more consistent results.
- Deploy OLA in a wider range and conduct corresponding performance test to technically prove its performance further.
- Introduce multicast and flow label technology for multimedia application to ensure performance of larger-scale deployment.
- Deploy high availability and redundancy to enable a more reliable platform.
- Evaluate the impact of the virtual laboratory in students' performance (grades, knowledge acquisition, etc.).
- Design pedagogical models suitable for different kinds of curricula on a basis of OLA adoption to achieve better teaching and learning results.

Teaching Research and Practice of Blended Learning Model Based on Computational Thinking

Ying Li

School of Computer Science and Engineering
Beihang University
Beijing, China

Yu Liu, Pan Shu

School of Computer Science and Engineering
Beihang University
Beijing, China

Abstract—with the wide use of computers, how to make students understand the special way of thinking of computer science and find the appropriate methods to solve problems in their own fields like computer scientists are the challenges for educators. This paper proposed a computational thinking model based on blended learning *MCTBBL* and a descending dimension method for problem-space transformation. The *MCTBBL* model analyzes and researches the application of computational thinking in computer science by the organic combination of computational thinking and blended learning in a life-cycle perspective. On one hand, the model can summarize the core concepts and important principles in computer science and extract the typical thoughts and general methods of solving problems; on the other hand, the model can implement the teaching and learning of computational thinking by means of blended learning. Based on the model, the teachers can teach the problem-solving process by using computer more intuitively and clearly and the students can understand the application of computer knowledge more easily and simply. The *MCTBBL* prolongs the study life cycle which takes preview as beginning, teacher-student discussion as body and practical application as core to ensure integrity, endurance and consistency of teaching.

Keywords—Computational Thinking; Blended learning; Descending dimension; Abstract; Automation

I. INTRODUCTION TO COMPUTATIONAL THINKING

With the promotion of information technology, computers are everywhere and can be used to solve any problem. Computers not only change the way we live, learn and work, but also affect the way we think and the education patterns we use. Computers have strong ability to process information which greatly expands the scope of science to understand the complex world and improves the ability to solve the real problems. Therefore, the traditional computer education - “teach knowledge, learn tools, master skills” cannot meet the demand for training compound talents in modern society. [1] The great challenges of education are explained as follows: how to make students understand the particular thinking pattern of computer and how to make them apply computer knowledge to solve the problems in their own fields like computer scientists; how to make teachers clearly express human being’s thinking process of solving problems with the aid of computers and how to make them convert the teaching principle from explaining knowledge to teaching thinking.

Computational Thinking (CT) was first put forward by Jeannette M. Wing, a professor of Carnegie Mellon. She thought CT is a series of thinking activities to solve problems, design systems and understand human behaviors by applying

the basic concepts of computer science, which means machine can be used to do some intellectual activities instead of human being. CT is a natural product of the development of computer science and its essences are abstraction and automation. [2] CT contains three core elements: thinking consciousness, computational methods and computing tools. Abstract is a process of transforming the characteristics, states and inherent laws of thing into a symbolic representation through the methods of simplification, transition, recursion, etc. Automation indicates it can take the advantages of computers to solve problems to make up human being’s weakness, e.g. slow calculation speed, low calculation accuracy. [3,4] Therefore, CT is a man-machine thinking mode which emphasizes the formalization, programming and mechanization of human’s thinking and it drives the development of mechanization of thinking. The essences of CT not only directly reflect its two stages to solve problems, but also imply the relationships between the core elements: first, people abstract a practical problem in the real world to a corresponding algorithmic model in the computer world with a special calculation method through conscious thinking; second, people convert the algorithmic model to a symbolic description by a kind of programming language. CT highly summarize the computer’s problem-solving process: using computer to simulate human’s thinking. But this kind of simulation is indirect, constrained and approximate. Because the simplification of the algorithmic model when abstracting the real system, the constraint of the application program when converting the algorithmic model and the error of the result when executing the application program will all affect the quality of solution. The significance of CT is to make people recognize the differences between the practical problem in the real world and the ideal model in the computer world and distinguish what can be solved by computer’s calculation and what must be analyzed through human’s thinking. [5-7] People can obtain a more accurate solution by using computer more efficiently and more easily and can deeply understand the methods and problem-solving process of computer after some specific thinking training. CT can reduce the barriers to human-computer collaboration and make them exert their respective advantages as much as possible. Therefore, the core of CT is to make thinking have the features of computation. But the thinking and computation are limited by computer science, which means the implementation of thinking consciousness is the process of solving problem guided by the laws of computer science and the application of computation methods is the process of writing programs supported by the knowledge of computer science.

But thinking is an innate ability of human and how to clearly express the way of thinking which is understood by students' apperceiving, we need to find an appropriate teaching method. This paper proposed a **computational thinking model based on blended learning** M_{CTBBL} and a **descending dimension method for problem-space transformation** and described the whole teaching and learning process in a modeling way and introduced the application of computational thinking methods in a formal way. This model can make teachers teach *CT* methods more clearly and make students learn *CT* applications more easily.

The rest of the paper is organized as follows. In Section II, we introduced related work of computational thinking and blended learning. Section III analyzed the relationship between computational thinking and blended learning. IV described the M_{CTBBL} model and the descending dimension method. We concluded in section V.

II. REALATED WORK

Computational thinking originated from America. In June 2005, PITAC (President's Information Technology Advisory Committee) submitted a report "*Computational Science: Ensuring America's Competitiveness*" to American President. In this report, they said "The most scientifically important and economically promising research frontiers in the 21st century will be conquered by those most skilled with advanced computing technologies and computational science applications" and "computational science advances all of science and engineering, because all disciplines benefit from high-resolution model predictions, theoretical validations, and experimental data analysis". [8] In March, 2006, Jeannette M. Wing, then the president's department of computer science, Carnegie Mellon University, published a paper in a leading computer journal and first put forward Computational Thinking. Professor Wing. described computer science from the view of thinking and explored the value of computer learning. [1] In the same year, NSF (National Science Foundation) put forward a national plan which contains four projects to develop the students' computational thinking at various age levels. The projects are BPC (Broadening Participation in Computing), CPATH (CISE Pathways to Revitalized undergraduate Computing Educating), CDI (Cyber-Enabled Discovery and Innovation), CE21 (Computing Education for 21st Century).[9]

Since 2007, computational thinking has been widely concerned and developed quickly. In 2007, the CPATH was actually implemented to integrate computational thinking with undergraduate education. [10] In 2008, the Computer Science Teachers Association (CSTA) published a report (Computational Thinking: A problem solving tool for every classroom) supported by Microsoft, which summarized what is computational thinking.[11] In Jan, 2008, professor Wing. made a study of computability and proposed five hierarchical problems: $P=NP$? What can be calculated? What is intelligence? What is information? How to establish a complex system easily? And she discussed them in details. [12] In the same year in July, professor Wing. proposed that computational thinking will affect each filed and each person. And this idea presents a number of new challenges to education. [13] In 2012, with the support of NSF, Carnegie Mellon University constructed an

advanced course which included basic knowledge of computer science and computational thinking. [14]

Computational thinking mainly solves the problems from theory aspect, e.g. the reform of teaching, the integration of computer science and other subjects. And with the rapid development of network multimedia technology, blended learning has emerged. The blended learning provides an effective method for the computational thinking's application in teaching and makes it possible to teach and learn thinking. In 2002, Delaney and Leonard, at the University of British Columbia, said, putting network learning into classroom teaching can not only make students acquire more knowledge, but also have more interaction between teachers and students, which was published in a report. [15] And many educators give different definitions for blended learning according to their own understanding. Curtis J. Bonk described blended learning in a simplest way. He thought it is a combination of face-to-face instruction with online learning. [16] Michael E.W. regarded blending as a combination of E-learning and classroom teaching. [17] Anthony elaborated blended learning in two aspects: in broad sense, blended learning means the combination of the traditional face-to-face teaching and various technologies or media; in narrow sense, it means the combination of traditional teaching method and network teaching mode. [18] Margaret Driscoll thought blended learning can be implemented through combing various elements: the combination of teaching methods and techniques, the combination of teaching tasks and techniques. [19] Kekang He, a Chinese educator, gave a comprehensive definition: blended learning is the combination of the advantages of E-learning and the advantages of traditional learning mode, which makes teachers play a leading role in guiding, inspiring and supervising teaching and makes learners play a principal role in learning. [20]

III. RELATIONSHIP BETWEEN COMPUTATIONAL THINKING AND BLENDED LEARNING

Thinking is a human specific mental activity which indicates human cognitive process of analyzation, synthesization, judgment and reasoning based on appearances and conceptions. *CT* is a series of thinking activities of human being who apply the methods and theories of computer science to simplify, insert, transform and simulate problems. It is a process of internalizing the computer knowledge into the cognitive ability. But thinking is invisible, subjective and independent. We need to find an appropriate carrier to represent it visually and systematically. Through a lot of investigation and analysis, blended learning is supposed to fit the characteristics of *CT* perfectly and it provides an effective method both for the teachers who teach the methods of *CT* and for the students who learn the applications of *CT*. Blended learning is the effective combination of learning styles, learning theories, leaning contents, leaning strategies, leaning medias, leaning resources, leaning activities and leaning environments. The main aspects are explained as follows: (1) the combination of teachers' dominant role in teaching and students' principal role in learning; (2) the combination of classroom teaching and online learning; (3) the combination of the traditional teaching resources (teaching material, courseware, audio-video file) and the digital media resources (virtual classroom, teaching

software, course platform); (4) the combination of studying objective knowledge and constructing subjective cognition; (5) the combination of the planned study based on the teaching schedule and the unplanned study according to the learning situation; (6) the combination of teaching model (situational teaching, online teaching) and the learning model (independent learning, collaborative learning); (7) the combination of learning theories (cognitivism, constructivism, humanism). The purpose of blended learning is to achieve the best result through reasonable combination, proper blending and optimized integration. In a word, it provides appropriate methods to appropriate persons in appropriate ways through appropriate mediums.

A. CT tasks students as the center of learning and teachers as the guiding of teaching:

The teaching objective of *CT* is to teach students how to solve the problems in their own fields by applying computer knowledge more efficiently and to form their good habits of thinking. The evaluation standard for *CT* is the students' cognitive levels and constructive abilities which refer to the degree of comprehension of the natures and laws of thing, but not the capacity of knowledge instilled into the students' mind by teachers or the degree of external stimulation. "Knowledge cannot be taught by the teachers' passive teaching, but obtained by the students' active learning". Students play an irreplaceable and principal role in *CT* and each aspect of teaching, e.g. teaching objective, teaching object, teaching process, teaching evaluation, involves in students. Students are the seeker of seeking knowledge, the performers to construct knowledge, the implementers to apply knowledge and the solvers to solve problem. But *CT* is an innate thing and cannot be acquired by self-study. In order to improve students' abilities of thinking, teachers should play a guiding role. The tasks of teachers are changed from imparting computer knowledge to designing learning materials, guiding learning process and training thinking ability. Teachers are instructors to guide students to learn theoretical knowledge, master the way of thinking, understand research methods and are assistants to help students to explore essences, develop principles, discover relationships and are facilitators to encourage students to find problems, pose problems and solve problems. The relationship between teaching and learning in *CT* is consistent with the purpose of blended learning: students can study effectively under the guidance of teachers and teachers can teach knowledge purposely under the demand of students. On one hand, teachers can play their leading role by guiding, inspiring and monitoring teaching; on the other hand, students can play their principal role by adaptive learning, developmental learning and creative learning.

B. CT takes classroom teaching as core and extracurricular activities as support:

The training of *CT* is a long and complex process, because it not only depends on the subjective endeavors of students and the external stimulation of educations, but also has much to do with the existing knowledge, cognitive structure, non-cognitive factors, etc. Classroom teaching cannot meet the demands students' thinking training in *CT* such as logic analysis, abstract thinking and formal description because of its disadvantages of discontinuity and decentralization and it must

be supplemented with a series of extracurricular activities, e.g. discussion online, coaching after-class, to form a centralized and continuous teaching process. *CT* greatly enriches the classroom contents and organically combines classroom teaching and extracurricular activities. It makes full use of extracurricular activities for the advantages of various forms, temporal flexibility and fewer limitations, which makes teaching not restricted by the time, space, resources or forms. Teachers just pay attention to how to teach methods, how to train thinking and how to analyze problems and the general, basic and conceptual knowledge is learned through students' self-study before class and the practical, comprehensive and innovative problems are explored through teamwork after class. Furthermore, the students' ability to solve the problems in their own fields by applying *CT* methods cannot be obtained through simple learning, like memorizing the knowledge mechanically or copying the methods directly but be trained by deep learning, like understanding, processing and applying knowledge continually, which can only be achieved through extracurricular activities. The combination of classroom teaching and extracurricular activities in *CT* is consistent with the various forms in blended learning which indicates the best teaching effect can be attained by appropriately combining different teaching methods to exert their respective advantages.

C. CT tasks classroom teaching as selected spots and online learning as entire areas:

CT well reflects the combination of classroom teaching and online learning. On one hand, the learning of *CT* cannot be implemented without classroom teaching whose characteristic is Face-to-Face teaching. *CT* needs teachers to play their leading role in teaching in the aspects of taking "paying enough attention to the most students' understanding" as principle, taking "organized, articulated and systematical teaching" as body, taking "centralized teaching, questions and answers, group discussion" as form, which makes students master the key concepts, thinking methods and application skills in a limited time as soon as possible. It can eliminate barriers to learning and improve teaching efficiency; on the other side, the developing of *CT* cannot be achieved without the support of online learning whose character is networked learning. Online learning greatly makes up the disadvantages of classroom teaching which is extremely restricted by time, space and form and results in the simplification, non-repeatability and restrictions of teaching activities. It constructs a new study environment which is composed of networked media resource, virtual learning community and online course platform to extend, expand and improve study in depth, extent and strength. Online learning makes fully use of the advanced information and virtualization technologies to make teaching forms much more flexible and various, e.g. repetitive learning, adaptive learning and personalized learning, to play the students' principal role as much as possible. It pays more attention to develop the students' initiative, positivity and creativity and plays an irreplaceable role in training thinking skills, mastering thinking methods and cultivating thinking habits. In *CT*, the classroom teaching and online learning are combined properly and they can promote each other. Online learning is developed based on the objective of classroom teaching and classroom teaching is modified according to the feedback of online learning. Online learning is a powerful complementarity and

infinite extension to classroom teaching and in turn, classroom teaching plays a guiding and supervising role in online learning. *CT* is the best embodiment and executor of blending learning.

D. CT takes thinking development as objective and knowledge learning as foundation:

The objective of education is to cultivate a creator who can think independently and solve problems effectively. The ability of *CT* cannot be developed directly by students' natural talents or self-awareness or by teachers' teaching, but is gained by knowledge internalization. The abilities of students' finding, proposing, analyzing and solving problems are on the premise that they can build a reasonable knowledge structure, accumulate a lot of knowledge and acquire the newest knowledge. Thinking and knowledge are in a proportionality relationship and the more complicated the problem is, the deeper we will think and the more knowledge may be required. *CT* focuses on the teaching process of how to internalize the computer knowledge into the abilities to understand, analyze and solve problems. Teaching computer knowledge plays a fundamental role in applying *CT*. Only with a certain amount of domain knowledge, students can continually acquire, apply and create new knowledge and then they can have a correct and reasonable *CT* ability, which makes knowledge and thinking develop in a spiral way. But the core of *CT* is not teaching knowledge, but developing the students' ability to understand concepts, internalize knowledge and gather experience in the thinking process of solving problems. The real objective of teaching should be identified as thinking development. The purpose of teaching the declarative knowledge of computer (e.g. theory, principle) is to make students understand the characteristics and rules of the procedural knowledge. Teachers should make students understand how to apply knowledge rather than only teach what the knowledge is. The combination of thinking development and knowledge learning in *CT* is consistent with the combination of learning objective knowledge and constructing subjective cognition in blended learning: the development of subjective cognition is based on leaning objective knowledge and in turn, the teaching of objective knowledge must accord with the students' level of subjective cognition, which fully reflects the viewpoint of the unification of subject and object of epistemology.

IV. COMPUTATIONAL THINKING MODLE BASED ON BLENDED LEARNING

CT is designed based on the theory and practice of blended learning, whose core idea is the integration of teaching resources, learning theories and teaching methods under the guidance of *CT*. Students can construct their own knowledge by consciously applying the methods of *CT* with the assistance of teachers and they can learn knowledge, discover laws, master methods and develop thinking in the process of problem solving like computer scientists. The *CT* model based on blended learning refers to each aspect of teaching which includes the action set of teacher, the action set of student, the learning resource set and the teaching evaluation system set. The *CT* model is a three-dimensional and conceptual teaching-learning model, which includes multiple layers, multiple elements and multiple stages. In the model, its elements are

interacted, restricted and influenced with each other. The mathematical expression of the model is shown as follows:

$$M_{CTBBL} = \sum_{i=1}^n F(AT_i, AS_i, RS_i, EV_i) \quad (1)$$

In formal (1), M_{CTBBL} represents the *CT* model based on blended learning. F represents a function. AT_i represents the teachers' action set of the i th class and it is an ordered set of teaching activities which indicates the process of teachers' teaching *CT* methods; AS_i represents the students' action set of the i th class and it is an ordered set of learning activities which indicates the process of students' learning *CT* methods; RE_i represents the set of learning resource of the i th class and it refers to the learning resources which are selected, utilized and optimized under the guidance of *CT*; EV_i represents the set of teaching evaluation system of the i th class and it refers to the teaching evaluation system which is updated, perfected and improved under the guidance of *CT*;

A. AT_i is a two-dimensional ordered array and plays a leading role in M_{CTBBL} :

According to time, AT_i can be subdivided into the three phases, $AT_i = [AT0_i, AT1_i, AT2_i]$, they are teachers' action set before the i th class, in the i th class and after the i th class, respectively.

$AT0_i$ represents the action set of teachers before the i th class, which contains three elements, $AT0_i = [preCon_i, desQue_i, preLes_i]$. $preCon_i$ indicates designing preview contents before the i th class. The preview aimed for *CT* is not to publish the teaching materials directly or to combine the learning resources simply, but to establish a reasonable preview objective and write some special preview materials according to the course schedule and the students' characteristics. The purpose of preview is to build a foundation for classroom teaching and it not only introduces the basic knowledge, fundamental principles and practical skills for students' self-study, but also represents the methods and process of problem solving, which eliminates the learners' barriers to learning and makes them get into learning in advance. The preview contents are designed based on microteaching and are presented in the form of micro segments with the demands of concise text, specific subject and appropriate difficulty and it must be suitable for students' psychology and make them get pleasure and fulfillment from self-study. Meanwhile, teachers invisibly guide students to do the preview by adding annotations and problems into the materials. When teaching Operating System, learners can master the basic concepts (e.g. thread, process) through self-study. Teachers will pose the practical questions related to the knowledge progressively, e.g. "how to arrange your several exams reasonably?", "what conditions must be satisfied?", "is there an optimal solution?". Based on these questions, teachers guide students to think about CPU scheduler algorithm. Students are not allowed to have all the accurate answers, but they can learn knowledge more purposely in class after careful thought and can be directly involved in the process of finding, analyzing and solving problems. $preCon_i$ plays an irreplaceable role in *CT*, which can extend time, expand contents and improve

efficiency for teaching and it is a necessary supplement and strong support to classroom teaching.

$desQue_i$ indicates designing a baseline questionnaire before the i th class: $desQue_i$ is implemented after $preCon_i$, which is used to know about students' leaning in the $(i-1)$ th class and their preview before the i th class, update the contents and adjust the plan. The contents of baseline questionnaire are designed based on the contents of $teaCon_{i-1}$ and $preCon_i$ with the characteristics of understandability, concision and practicality. The type of questions is mainly objective ones and the number is better set from 10 to 15. $desQue_i$ plays an important role in CT , which is used to connect the $(i-1)$ th class and the i th class seamlessly. It feeds both the learners' i th preview and their $(i-1)$ th learning back to the teachers' i th preparation, as shown in figure 1. With the action of $desQue_i$, $preCon_i$ can provide an important reference value to $preLes_i$.

$preCon_i$ indicates preparing a lesson before the i th class. Under the guidance of CT , teachers design teaching materials and write teaching scripts based on the results of $desQue_i$. $preCon_i$ includes two level: in the first level, teachers design teaching cases with the aim of introducing computer knowledge and understanding CT methods. Teachers should teach computer knowledge along based on CT and make students understand computer scientists' problem-solving process with the CT methods of recursion, separation of concerns, simplification, transition, simulation, heuristic reasoning, etc. When teaching networking protocol and OSI model, the abstraction and separation are introduced; when describing memory structure and the process of instruction, the methods involved with cache and automation are explained. In the second level, teachers design practical cases with the aim of solving real problems and applying CT methods. Teachers should design some practical cases related to the knowledge, e.g. designing a course selection process, implementing a document retrieval algorithm, to make students have the experience in the application of CT . Practical cases should be designed more realistically and more sensibly, which can make the abstract knowledge more understandable. $preCon_i$ is the essential phase of ATO_i , which plays a decisive role in CT , because it is the precondition and foundation for successfully implementing ATI_i and directly influences the effect and quality of teaching.

ATO_i is the beginning of the whole CT teaching and it directly determines the number and the value of all the other elements in M_{CTBBL} model. The more prepared by ATO_i , the better performed by ATI_i .

ATI_i represents the action set of teachers in the i th class, which contains two elements, $ATI_i = [teaCon_i, disCon_i]$. ATI_i is the concrete implementation of $ATO_i.preLes_i$, whose two elements correspond to the two levels of $preLes_i$. $teaCon_i$ indicates teaching knowledge in the i th class, which means teachers play a leading role in teaching computer knowledge. In this phase, teachers should emphatically explain the computer scientists' problem-solving process with CT methods while reducing the introduction of basic concepts. But thinking is the product of brain activities and how to clearly express the internalized thinking process is the key

problem needs to be solved in this paper. It needs to find an effective teaching method. Based on the intensive research and practice, this paper proposed **descending dimension method** based on CT which indicates the sensory perception of real problem existing in brain's multi-dimensional space can be transformed layer by layer and finally be mapped into the model existing in computer's one-dimensional space through CT methods. According to the three levels - sensibility, intellectuality, rationality - in human beings' cognitive theory proposed by Kant, the process of descending dimension is mapped into three stages of problem solving with CT methods: formal description, abstract modeling and automatic solution. Taking TSP as example, in the first stage, teachers describe the real problem. Students intuitively acquire the sensory knowledge which describes the problem's appearance by imaginal thinking and they can understand how to state problem. But this kind of sensory perception is usually in a multidimensional, complicated and confusional state. In the second stage, teachers apply CT methods, e.g. "separation of concerns, simplification, transition", to demonstrate the process of abstract thinking to students: how to convert the real problem into a mathematical description (composed of symbol, figures, steps) through simplification and quantification. The mathematical description has the characteristics of formalization and structuralization which is easy to be implemented by computer. Students further acquire the intellectual knowledge which describes the problem's critical characteristics and internal relations by abstract thinking. In the third stage, teachers convert the mathematical description into a data structure which can be stored in one dimensional space and an algorithm which can be implemented by computer based on mathematical model, algorithm theory and the CT methods of iteration, recursion, deduction, etc. Students continuously acquire the rational knowledge which describes the problem's essential attributes and the solutions by computational thinking. The process of teaching CT is the process of descending dimension which contains a series of conversions from the real world to the information world to the machine world. The conversion process is considered to have a programmed characteristic which indicates it can be summarized into a model.

The methods of CT are applied since the second stage. From the first stage to the second stage, it pays attention to human being's thinking and reflects the students' abilities to use the computer. From the second stage to the third stage, it focuses on the implementation of computer and indicates the students' level of computer use. In $teaCon_i$, teachers teach computer knowledge and CT methods with the teaching methods of transforming knowledge into questions and dividing questions into different levels, which are proposed based on CT . It makes students possibly understand the essential differences between human being's thinking and computer's thinking in a cyclic process of asking questions, learning methods and solving questions. (The characteristics of human being's thinking are multidimensional, qualitative and indeterminate; the characteristics of computer's thinking are one-dimensional, quantitative and determinate). Through CT learning, students

can distinguish what must be done by human being and what can be implemented by computer and then they can use computer to solve problems appropriately.

$disCon_i$ indicates implementing practical cases in the i th class, which means learners play a principal role in learning CT methods through class discussion. “ CT can be taught” implies students can gradually understand the thinking process with the programmed characteristic through internalization, self-study and self-experience, which means the ability of CT cannot be obtained directly by teachers’ teaching, but be grasped better through discussion. Teachers emphasize on developing and training students’ thinking methods, thinking consciousness and thinking abilities. In $disCon_i$, teachers change their role from initiators who teach knowledge to instructors who train thinking. They apply various teaching forms, e.g. group discussion, homework presentation, questions and answers, to stimulate students’ desire and interest to solve problems. On one hand, the practical cases are designed based on the requirements of $teaCon_i$; on the other hand, it should be expanded by some new contents for knowledge consolidation and thinking migration. Corresponding to the explaining of TSP in $teaCon_i$, teachers can design some life examples, e.g. courier route, aircraft route, which are easily understood. Students can find the solution to a deeper problem independently through simulating the teachers’ thinking process and then from their own thinking methods gradually. Under discussion, teachers should establish a loose and exciting environment in class, organize students’ discussion and control the schedule. Some training skills, e.g. “Time Limitation, Quick Responses, Group Competition”, are used to keep students’ brains in a good condition. $AT1_i$ reflects the characteristics of CT : teachers not mainly introduce computer knowledge, but regard computer knowledge as a medium to make students apply the CT methods to solve problems. On the basis of simulating and understanding the existing CT methods, students can solve problems creatively.

$AT2_i$ represents the action set of teachers after the i th class, which contains four elements, $AT2_i = [desHow_i, corHow_i, ansQue_i, febTea_i]$. $desHow_i$ indicates designing homework after the i th class. The homework is designed concerning both $teaCon_i$ and students’ actual abilities, while with relative difficulty for training the students’ thinking. The homework can be divided into different categories to meet the needs of students at different levels. Some difficult or comprehensive homework can be completed by collaboration. $corHow_i$ indicates correcting homework after the i th class. Teachers must correct homework timely and properly adjust the teaching plan. $AT2_i$ is an important method to appraise teaching effect. $ansQue_i$ indicates answering questions after the i th class. Teachers should answer the students’ questions as soon as possible through various means, e.g. online course platform, instant communication tools, face to face coaching, etc and perform a statistical analysis to summarize the common or typical questions to supplement classroom teaching. $febTea_i$ indicates feeding effects back to teaching. According to the students’ learning situation, teachers should

do reflection, amendment and evaluation of the completed teaching activities and do modification, updating and estimation of the teaching activities which are not yet implemented.

$AT2_i$ plays an auxiliary role in CT . It serves as a link between the past teaching activities and the future ones: it tests the teaching effects of AT_{i-1} and guides the activities of AT_i .

B. AS_i is a two-dimensional ordered array and plays a principal role in M_{CTBBL} :

Corresponding to AT_i , AS_i is also a two-dimensional ordered array. Based on time, AT_i can be subdivided into the three phases, $AS_i = [AS0_i, AS1_i, AS2_i]$, they are action sets before the i th class, the action set in the i th class and the action set after the i th class, respectively.

The purpose of M_{CTBBL} based on blending learning is developing students’ ability to solve problems. Therefore, the value of M_{MBLM} is decided by the learning effects of most of the learners, not by the teaching quality of a single teacher.

$AS0_i$ represents the action set of students before the i th class, which contains two elements, $AS0_i = [preCon_i, ansQue_i]$. $preCon_i$ indicates previewing contents assigned by teachers before the i th class. Under the invisible guidance of teachers, students analyze the materials by themselves to improve their abilities of retrieving information, exploring problems and constructing knowledge. Meanwhile, they should do take notes properly and write down the difficult problems in time, which can promote the class activities in the subsequent phase in a problem-driven way. $ansQue_i$ indicates completing the baseline questionnaires designed by teachers before the i th class. Students must carefully complete the questionnaires with the quality and quantity guaranteed in a matter-of-fact way.

$AS1_i$ represents the action set of students in the i th class, which contains two elements, $AS1_i = [lsnTea_i, disCon_i]$. $lsnTea_i$ indicates listening to the teachers as objects in the i th class. In class, students learn knowledge in a problem-driven way which can make thinking highly centralized and continuously active. $disCon_i$ indicates discussing the cases as main body in the i th class. Collision and stimulation can produce thinking. Therefore, students can gradually master CT methods, understand the programmed process of solving problems through a planned, aimed and designed discussion guided by teachers. Finally, students can solve the problems in their own disciplines by applying computer knowledge like computer scientist as much as possible.

$AS2_i$ represents the action set of students after the i th class, which contains four elements, $AS2_i = [rewCon_i, doWork_i, askQes_i, febLea_i]$. $rewCon_i$ indicates reviewing the contents after the i th class. Through further learning the computer knowledge and deeply researching the CT methods Students complete a spiral process of study. The spiral process involves two aspects: enhancing computer knowledge with CT methods and summarizing CT methods based on computer knowledge. $doWork_i$ indicates finishing homework after the i th class. Students should complete the tasks by means of applying CT methods, reading relevant materials, discussing with others. According to the difficulty, the homework can be finished by

individuals or groups. $askQes_i$ indicates asking questions after the i th class. Students consult teachers by online course platform, instant-communication tools, etc. $febLea_i$ indicating feeding effects back to learning. Students continuously regulate their learning process by means of reflection, modification and comparison for developing the right attitude and correcting bad study habits and $febLea_i$ can promote the students' learning abilities.

- C. RS_i is a two-dimensional unordered set, which is used to provide the hardware resource and software resource to AT_i and AS_i :

RS_i can be subdivided into the two parts, $RS_i = [hwRs_i, sfRs_i]$. $hwRs_i$ indicates the hardware conditions required in the i th class, which contains two elements, $hwRs_i = [fieldRs_i, equipRs_i]$. $fieldRs_i$ includes the classroom and laboratory provided for class and the meeting room used for coaching or discussions. $equipRs_i$ refers to the instrument, equipment and network environment needed for ensuring the activity of teaching. $sfRs_i$ indicates the software resource adopted in the i th class, which contains three elements, $sfRs_i = [platRs_i, virRs_i]$. $platRs_i$ is online course platform which is mainly used for online learning. It includes resource sharing, online discussion, homework management, online test, etc. $platRs_i$ can be built by some open source software. The commonly used software is called Learning Content Management System (LCMS) which can allow users to build a teaching web site without writing any code. Currently, the most popular LCMS are Moodle, Sakai, ATutor and Claroline. $virRs_i$ is virtual classroom which is provided for remote learning. It is composed of screen-sharing, audio-video transmission, white boards, remote desktop, etc. $virRs_i$ can be designed with the technologies of virtualization and information and it is better to do the secondary development based on the existing systems, because different courses have different teaching materials, teaching patents and teaching scales. Currently, the common software used for real time communication are WebRTC, Openmeetings, Bigbluebutton,

- D. EV_i is a two-dimensional unordered set, which is used to evaluate the teachers' teaching quality and the students' learning effects after teaching:

EV_i can be subdivided into two parts, $EV_i = [teaEv_i, stuEv_i]$. $teaEv_i$ indicates the teachers' teaching quality for the i th class, which contains student evaluation, peer evaluation, expert evaluation and self-evaluation, $teaEv_i = [lerEv_i, perEv_i, eprEv_i, selEv_i]$. All of the evaluation subjects evaluate the teachers' actions in AT_i , respectively. The evaluation contents can be categorized into several indexes: teaching attitude, teaching knowledge, teaching method, teaching ability and teaching effect and each index can be subdivided into many factors, e.g. the evaluation of teaching materials contains highlighted important points, appropriate difficulty, innovative contents, relating to the practice, etc. In view of the practicability, $teaEv_i$ is better to be implemented in the form of marked and each evaluation subject is not forced to complete each $teaEv_i$. $teaEv_i$ reflects the objectivity and fairness of evaluation based on the diversity of evaluation subjects and implements quantitative analysis and qualitative judgment through

modeling methods of analytic hierarchy process and fuzzy decision. $stuEv_i$ indicates the students' learning effect for the i th class, which contains teacher evaluation and self-evaluation, $stuEv_i = [eduEv_i, selEv_i]$. $stuEv_i$ mainly reflects teachers' evaluation of students' actions in AS_i and its evaluation contents can be categorized into several indexes: learning attitude, knowledge and skill, ability and quality. Each index can be subdivided into different factors, e.g. attendance rate, performance in class, online learning time, online community effect, etc. The student's evaluation which is implemented by teachers can be regarded as a management process of lifecycle. Teachers can capture the dynamic learning state of each learner as much as possible by tracing his daily activities in different stages (before class, in class and after class). $stuEv_i$ uses a series of evaluation methods: the combination of self-evaluation and others' evaluation, qualitative evaluation and quantitative statistics, process tracing and result analysis, static evaluation and dynamic evaluation. It not only can make students know their learning behaviors objectively, but also can provide the timely and adequate feedback information to teachers to ensure the normal development of teaching.

EV_i plays a feedback role in M_{MBLM} and it can regulate and control the teaching activities as a whole. Fundamentally, EV_i belongs to a kind of value judgment and in order to draw a scientific conclusion, it must have at least two conditions: first, having scientific evaluation criteria; second, having evidences and materials supported for the final conclusion

V. CONCLUSION

Learning knowledge is closely connected with developing thinking. The emergency and development of computational thinking has great effect on education. The computational thinking model based on blended learning deeply analyzes and researches the application of computational thinking in computer science by the organic combination of computational thinking and blended learning in a life-cycle perspective. On one hand, the model can summarize the core concepts and important principles in computer science and extract the typical thoughts and general methods of solving problems based on the theories of computational thinking; on the other hand, the model can design scientific teaching methods and practical cases. Based on the model, the teachers can teach the problem-solving process by using computer more intuitively and clearly and the students can understand the application of computer knowledge more easily and simply. The teaching philosophy proposed by the model is consistent with the ultimate aim of teaching, which makes students to be a real problem-solver, not the knowledge-copier.

In a word, the computational thinking model based on blended learning provides effective help and guidance for developing students' computational thinking ability and affords theoretical basis and resources for building three-dimensional and blended learning environment and enriches the researches of computational thinking and blended learning.

ACKNOWLEDGMENT

I especially thank Computer Culture Foundation teaching team for their help with designing cases and doing researches. I also

appreciate my assistants and the anonymous reviewers for their thoughtful feedbacks on the paper.

Abstract—This work presents a methodology based on simulator developers to be applied in several courses as well as research activities. This proposal is also based on “The Cathedral and the Bazaar” lessons. First, good programmers know what to write, however great ones know what to rewrite. Students could learn by developing new components to be added to the current simulator. Second, any tool should be useful in the expected way, but a truly great tool lends itself to uses you never expected. The proposed simulator has been developed to teach digital circuits. However, it can be used in many other computing engineering fields. Third point is motivation, where the lessons are driven by the following principle: To solve an interesting problem, start by finding a problem that is interesting to you. Nowadays, we are surrounded by Internet of things, where the simulator engine could be connected to learn and to motivate the students. Image processing could be taught by connecting your web-cam and/or your mobile device camera to your simulator engine. Moreover, mobile phones and/or Arduino devices have a set of sensors that could be captured inside of the virtual simulator lab.

I. INTRODUCTION

Following web popularization, the use of web has been addressed in several approaches to teach in various fields of computer science and engineering in university courses. New innovative practices in education includes: massive open online courses (MOOCs), learning-by-doing or problem-based learning, hands-on homework assignments, virtual labs, Internet of Things (IoT), social networks, video-based learning, flipping, mobile devices (tablets and smart-phones), games, robots, augmented reality systems, etc. In 2014, a survey done by [1] shows that more than 90% of students uses smart-phones, however only 37% of them have used them to study: the most common use are social networks, while laptops are still very popularly used for studying. One approach is to provide interactive exercises/tools to get student immediate feedback based on their interactions in a non-passive way.

Nowadays, the world has a hardware/software heterogeneity which requires that the developer conducts careful planning and design prior to implementation of an application where simulation has an important role. Moreover, there is a great need for programmers to have the qualifications needed to develop software for embedded, mobile, and cloud computing. Skills as object-oriented languages, event-based and distributed programming are important basic fundamentals for these purposes.

Simulation for many reasons is broadly used for educational and research purposes, through training and decision support. More than working with a simulator, this work propose to teach the student how to contribute and collaborate as a simulator developer. Additionally, a simulated-developer approach could be applied in several courses related to engineering and computing education. Since students should learn the fundamental principles of programming prior to working with deep challenges, the proposed approach is incremental and multilevel. Our approach is based on a simple digital circuit simulator, where the students can familiarize themselves with the platform and quickly and easily solve common problems in many domains. Moreover, our proposal is simple, intuitive, and based on engaging technology to be easily integrated to the web, mobile and IoT world.

II. FREE SOFTWARE LESSONS

The proposed methodology is also based on the free software lessons pointed by Eric S. Raymond in his book “The Cathedral and The Bazaar” [2], where he describes good practices used by the open source software community. Although 19 software developer lessons are described in [2], our current proposal explores a subset of them (however, all lessons could be incorporated). This work aims to provide teaching and learning skills in addition to software developing.

The first lesson is code reuse, where the original lesson is “Good programmers know what to write. Great ones know what to rewrite (and reuse)” [2]. Learning-by-doing and learning-by-example approaches could be used from the beginner to the advanced level. When a student modifies and tests his code derived from previous examples to produce new features, these actions will produce a fast feedback to himself. The second lesson justifies our simulator tool choice since “Any tool should be useful in the expected way, but a truly great tool lends itself to uses you never expected” [2]. The Hades simulator was proposed to teach digital circuit design [3], however this work shows that Hades could be useful in many domains to teach and learn computer science subjects. The third lesson is related to motivation and mentions that a good work will be started by a personal itch. Others free software lessons are: release early and often since other students could evaluated your work, choose smart data structures, and at last not at least, perfection is achieved when there is nothing more to take away, as said by Antoine de Saint-Exupéry. Moreover,

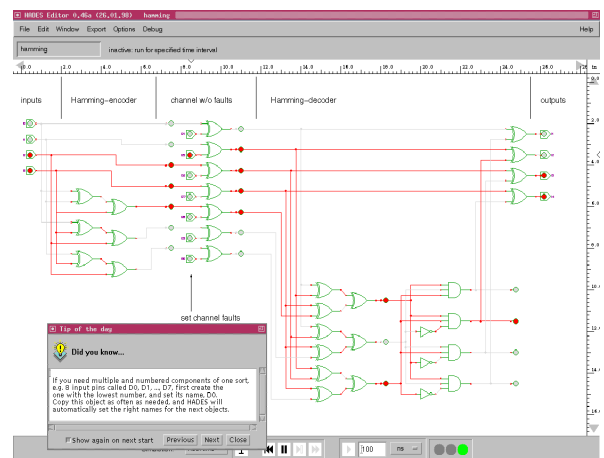

nowadays it is easy to solve a problem by connecting boxes, however the students should go beyond scratching the surface: they need to go deeper to model and to implement inside the black boxes.

III. HADES SIMULATOR

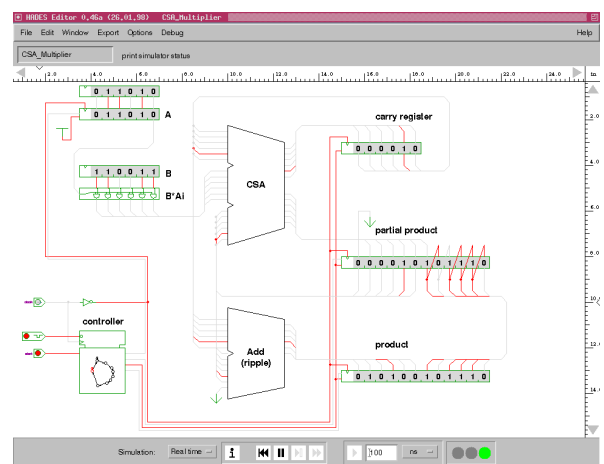

This work proposes to extend the Hades simulator tool [3]. This section describes the main Hades' features and the following sections will illustrate our proposal. Hades (Hamburg DESign) is a Java-based simulator from Hamburg University, Germany, which was presented in [4] to simulate digital circuits. The Hades is available on the web [5], and it could be executed locally or remotely by using a web browser. Therefore, it could easily be integrated in massive open on-line courses (MOOCs). Even when it executes locally as a Java program, the student could directly open an example design from any URL. Fig. 1 depicts three Hades screen-shots: a gate level circuit, a RTL design and a simple processor. Although, Hades was proposed in 1998 for a specific purpose (digital simulation), due to its simplicity and flexibility it is still useful as pointed out by recent e-learning survey papers [6], [7]. First, the implementation is object-oriented based in the Java language and, therefore, it provides all advantages of Java language as a large amount of code reuse and portability. The basic component class has a minimum set of methods that provides a fast learning curve inside a general purpose framework. A wire which connects two or more components is also an object, and it could be used to send/receive from a single bit, a string, a image up to a complex data structure. All designs are stored in a simple structural text format: a component list followed by a wire list. Additionally, all components could have parameters to save and restore the simulation configuration. A new component could be added to the current component library without any modification in the main tool. The simulator engine is an event-list which is simple and generic to model most problems as a distributed system. The graphical user interface (GUI) is simple and parameterizable. The simulator could also be executed in batch mode with or without graphical interface, and it could be controlled by a test/validation script.

A. Component Class

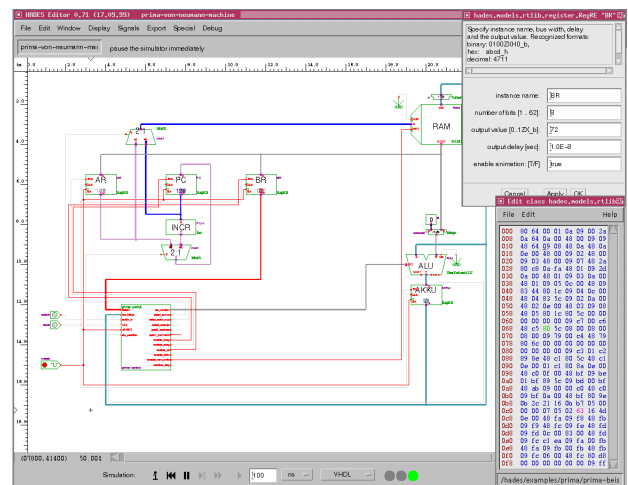

Following the free software lessons, we could say that the component class has a smart structure which simplifies the code and it could reach the perfection since there is nothing more to take away as said Antoine de Saint-Exupéry. The basic Hades class to create a new component has few methods. First, the class *constructor* initialize the port array, which defines the input/output interface. A port could carry any object to communicate to/from an external component wired in this port. When an event occurs in an input port, the *evaluate* method will be called to handle this event. This method implements the component behavior. A component could also generate itself a new event by using the wake-up method. Additionally, the *configure* method is used to open a graphical window to setup the component parameters. Finally, *write* and *initialize* methods are automatically called when a design file is loaded or saved. For more details, readers could refer to Hades tutorial available in [5]. In this work, our examples will complement the Hades documentation to provide new ideas to the future simulator

(a)

(b)

(c)

Fig. 1. Hades Screen-shots: (a) Gate level Hamming Decoder; (b) Multiplier and visualization; (c) Simple processor and memory debug.

developers. Moreover, the component class encapsulates the main features. Inheritance, polymorphism and a graphical user interface (GUI) can be easily integrated using this class. The component class ensures that students remain focused on the

problem modeling, solving approaches and algorithms, without getting distracted by the interface elements. Therefore, the student has a platform with low development cost, which provides a quick expansion, and continuous updating. The GUI is user friendly and it could be used to design from fundamental logic circuits to complex communication applications. Java is familiar to most students and currently one of the most widely used programming language. Finally, learning object oriented programming is included in all computer science curriculum, its use on different context provides opportunities to improve student knowledge.

B. Previous Work and Hades

Since 2004, the Hades tool has been used in teaching and research activities at University of Vicoso (UFV, Brazil). To teach, Hades was used in logic digital design, embedded systems and computer architecture at undergraduate and graduate level, which is the Hades main purpose. Following the free software lessons, "a truly great tool lends itself to uses you never expected" [2], we have taught image processing by using Hades, where the wires carry images instead of bits. Additionally, the students have created new components as well as modified the previous ones, and they also enhance the image component library by encapsulating ImageJ [8] which has a large library of Java source code freely available and in the public domain. ImageJ could manage all formats, and it can filter a 2048x2048 image in 0.1 seconds (40 million pixels per second). As a research tool, Hades has been used to simulate dataflow architectures [9], FPGA compilers [10], coarse-grained reconfigurable architectures (CGRA) [11], and wireless sensor networks [12]. Moreover, as a research and educational tool, Hades versions have been proposed to teach advanced computer architecture concepts in [13], [14], and visualization of the advanced encryption standard (AES) algorithms in [15].

IV. PROPOSAL METHODOLOGY

This work proposes to teach the student to be a simulator developer. The proposed approach is multilevel, and it addresses beginners as well as advanced students in one or more of the computing and/or engineering areas. This section presents examples to illustrate the proposed approach. The first example in Section IV-A shows from the scratch how to model a classical distributed programming problem: philosopher's dinner. As already mentioned, Hades was design as digital circuit simulator, however we will show how to use it to teach a different subject as a high level distributed programming problem, and also to teach graph algorithms in Section IV-B. Section IV-C presents an incremental approach to teach processor design. Section IV-D shows image processing examples. For instance, how to connect the web-cam and import its image inside the Hades simulator. This section also presents a machine learning example. Section IV-E presents two new Hades educational components: a configurable quiz form and a video-player. Finally, Section IV-E shows example how to connect to the real world by using sensors and low-cost Arduino devices.

A. Distributed Programming

We have chosen a distributed programming problem to illustrate our approach. Moreover, students should actually

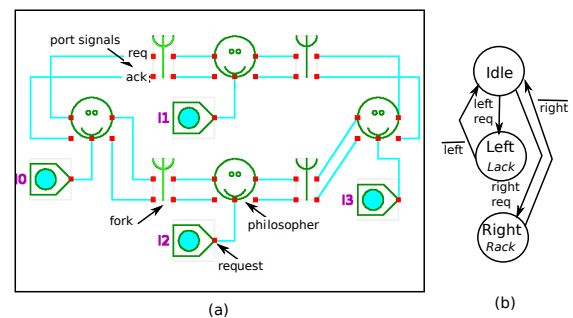

Fig. 2. (a) Hades philosopher dinner screen shot; (b) Fork Behavior as a Finite State Machine.

master the skills of programming of parallel events, and the proposed approach is a easy way to get started. Consider the philosopher' dinner problem, which is a classical problem in literature [16]. Assuming a set of 4 philosophers and 4 forks in a round table as depicted in Fig. 2(a). Each philosopher needs two forks (the ones at his left and right sides) to dinner and, of course, it is impossible that all philosophers have dinner simultaneously.

Assuming two components: the philosopher and the fork. We will show how to produce an initial implementation by thinking locally and by graphically connecting the objects. First, the fork source code is detailed. Assuming that a fork has the left and the right side, a simple interface is a pair of request/acknowledge ports on each side. In addition, we should model the fork behavior. Let us consider the model depicted in Fig. 2(b). For ease of implementation, let us assume that the left side has priority if two requests arrive simultaneously.

As already mentioned, Hades has a large library of components. Let us create our first component by extending a logic gate which is the first example detailed in Hades documentation. The fork Java code is depicted in Fig. 3. The fork class inherits from the *GenericGate* class, and only two methods are overwritten. One is the constructor (lines 6:18), where 2 pairs of request/acknowledge ports are defined, and the fork initial state is set to *idle*. The second method is the *evaluate* where the component behavior is implemented. When any event occurs at any input port, this method is automatically called. Lines 27:46 implements a state machine for the request/acknowledge protocol depicted in Fig. 2(b), where the left request has priority. The *ack* outputs are scheduled by using the *scheduleOutputValueAfter* method, that is inherited from *GenericGate*. Therefore, when an event occurs in any input port, the *evaluate* method handle it and the component reaction is sent back thought the output ports.

In addition to the component code, the student should create a symbol to graphically represent the component. The symbol could be static or dynamic. A static example of symbol definition is shown in Fig. 4, where the I/O port graphic positions are defined in lines 3:7, where the left ports are placed on the left side and the right ports are placed similarly. The fork drawer (a line plus an arc) is described by the lines 1:2.

Once compiled, the component could be evaluated inside the Hades tool. The philosopher component could be implemented by using the same approach. Next, a scenario

```

0 public class fork extends hades.models.gates.GenericGate {
1   static final int IDLE = 0; static final int LEFT = 1;
2   static final int RIGHT = 2; private int state;
3   portStdLogic1164 port_LeftReq, port_Left, port_RightReq, port_RightAck;
4   private StdLogic1164 leftack, rightack;
5
6   public fork() { // Constructor
7     super();
8     port_LeftReq = new PortStdLogic1164( this, "LReq", Port.IN, null );
9     port_LeftAck = new PortStdLogic1164( this, "Lack", Port.OUT, null );
10    port_RightReq = new PortStdLogic1164( this, "RReq", Port.IN, null );
11    port_RightAck = new PortStdLogic1164( this, "RAck", Port.OUT, null );
12    ports = new Port[4];
13    ports[0] = port_LeftReq; ports[1] = port_LeftAck;
14    ports[2] = port_RightReq; ports[3] = port_RightAck;
15    state = IDLE;
16    leftack = new StdLogic1164( StdLogic1164_U );
17    rightack = new StdLogic1164( StdLogic1164_U );
18  }
19  public void evaluate( Object arg ) {
20
21    SignalStdLogic1164 signal_left = (SignalStdLogic1164) port_LeftReq.getSignal();
22    SignalStdLogic1164 signal_right = (SignalStdLogic1164) port_RightReq.getSignal();
23    if (signal_left != null && signal_right != null) {
24      StdLogic1164 value_left = port_LeftReq.getValueOrU();
25      StdLogic1164 value_right = port_RightReq.getValueOrU();
26      System.out.println(state);
27      switch (state) {
28        case IDLE: if (value_left.is_1H()) { // Left request
29                    state = LEFT;
30                    leftack.setToCopy( value_left );
31                    rightack.setToInvert( value_left );
32                  } else if (value_right.is_1H()) { // Right Request
33                    state = RIGHT;
34                    leftack.setToInvert( value_right );
35                    rightack.setToCopy( value_right );
36                  }
37        break;
38        case LEFT: if (value_left.is_0L()) { // Left release
39                    state = IDLE;
40                    leftack.setToCopy( value_left );
41                  }
42        case RIGHT: if (value_right.is_0L()) { // Right release
43                    state = IDLE;
44                    rightack.setToCopy( value_right );
45                  }
46        break;
47      }
48      scheduleOutputValueAfter( port_LeftAck, leftack, t_delay );
49      scheduleOutputValueAfter( port_RightAck, rightack, t_delay );
50    }

```

Fig. 3. Fork Java code Component

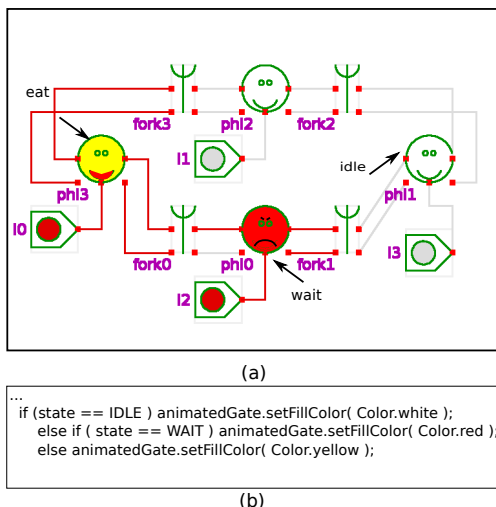

Fig. 5. (a) Color philosopher dinner screen shot; (b) Animation code.

composed of a set of philosophers and forks are created inside the graphical interface and the student can simulate and validate its first implementation. Since Hades has many

```

evaluate()
if ( receiveMsg() and
    not visited )
setcolor(Msg())
for x in Output
x.sendMsg(Msg()+1)

```

Fig. 6. A graph local node algorithm for a breadth-first search and a graph example

resources, for this example one could add an animation to easily debug the code. For instance, the philosopher has three states: idle, wait and eat. Each one could use a different color as shown in Fig. 5(a). Few lines of code should be added as shown in Fig. 5(b). In this example, the philosopher state depends on the request input which is connected to a boolean Hades switch (for testing purposes). However, one could add a clock generator to send request regularly or the student could modify the code by using the mouse click method.

Finally, as depicted in this section, a student could easily create an implementation based on components and events. The graphical interface helps the verification of the code and, also, the better understanding of how to solve a problem. In addition, the student will incrementally learn a simulation tool, Java language, object-oriented programming, graphical interface, etc. It is also important to highlight that the student does not need to understand the simulator engine code to create his first components, since it is encapsulated by an event-list and GUI, and provide a high level simulator framework.

B. Graph Algorithms

Every year, graph algorithms become even more a standard tool not only in computer science but also in several fields in science, humanities and biology. One common strategy on graph algorithm is thinking locally: a node receives a signal and propagates it to its successors. Another example of an unexpected and useful Hades application is to teaching graph algorithms. The student should only code a local node, and then by using the graphical interface build his example and visualize the results. A node could send/receive number or strings as well as change colors.

Fig. 6 displays an example of a graph breadth-first search starting in the red node. Colors and numbers are used to visualize the results. Once modeled the node, the student can instantiate nodes and connect them by using the GUI editor. Then, one node is selected as a starting point, the simulator will automatically propagate the numbers and colors to visualize the breadth-first traversal. One could change few edges (wires), and restarts the algorithm execution. In addition to small examples, the student could write a graph generator and/or import a graph to play with a large number of examples since the Hades design file has a simple form.

C. WYSIWYG Simulator

Most processor simulators have a static interface and the processor behavior is embedded on a specific processor simulator code. For instance, Ravi [13] is a graphical MIPS pipeline simulator with animation and colors. However, the processor

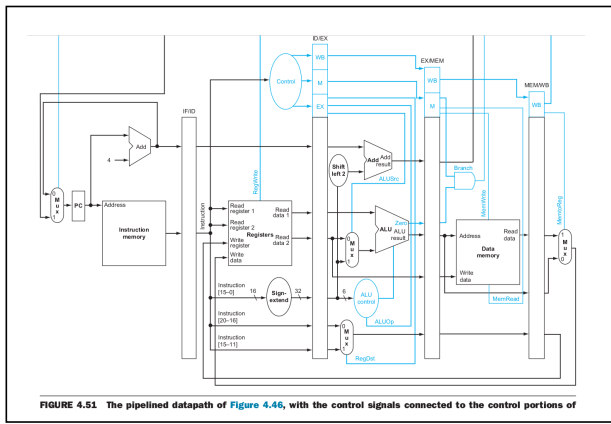

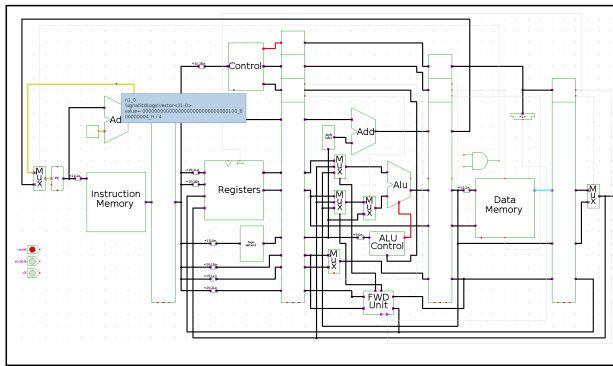

FIGURE 4.51 The pipelined datapath of Figure 4.46, with the control signals connected to the control portions of

(a)

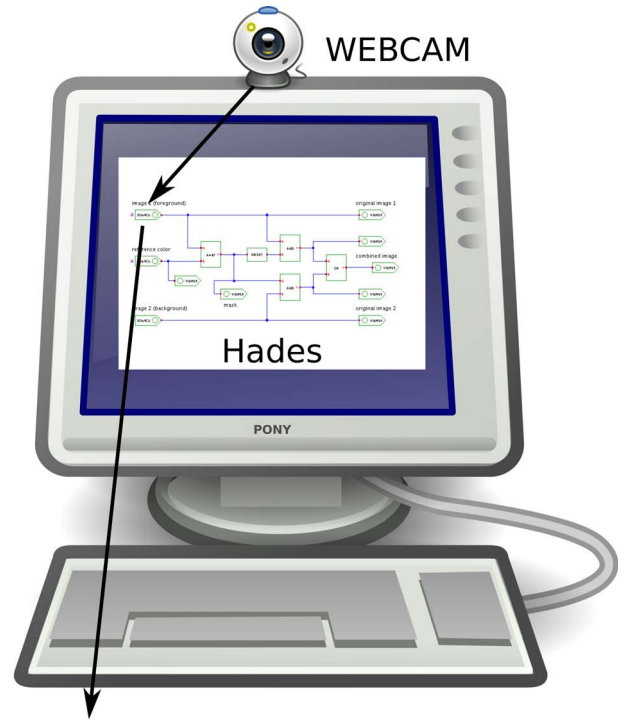

(b)

Fig. 7. (a) MIPS figure extract from the Patterson&Hennessy book [17];(b) Hades Mips screen shot.

design could not be modified without changes in the simulator core code. In [18], the authors propose the DEVJAVA MIPS32 processor simulator, which provides visualization and reusability, and it also based on Java. However, our approach is more general purpose to implement and to visualize. We propose a dynamic and WYSIWYG simulator ("What You See Is What You Get") for the popular MIPS processor, a classical example from the Patterson & Hennessy' computer architecture book [17], which is the first book in Amazon ranking on Microprocessor Design. Fig. 7 shows the book picture and the Hades screen shot. The book methodology presents the processor design by using an incremental approach. Since most of needed components already exist in the Hades library, a student could easily follow the book steps to create his design. In 2014, as a two week student assignment at graduate course of University of Vicosa (UFV), four students have extended few Hades components and redrawn component symbols to make the processor visually similar to the book picture as shown in Fig. 7. Therefore, the students could simulate the processor version and, moreover, they could modify the datapath (by adding multiplexers, wires, adders, control units, ...) to include new instructions or create a new processor implementation. Memory and register bank has a The graphical interface which simplifies the process of design debugging and teaching. Furthermore, since the students could create and model new components, they could deeply understanding inside "the book pictures".

In 2014, four students also implemented a tool that gen-

```
import com.github.sarxos.webcam.Webcam;

.....
public class webcamwindow extends SimObject
{
    public void evaluate( Object arg ) {
        SignalStdLogic1164 signal_s = (SignalStdLogic1164) port_S.getSignal();
        if (signal_s.hasRisingEdge()) {
            getImage();
            if (image != null) scheduleImage();
        } /* evaluate */
        public void getImage() {
            Webcam webcam = Webcam.getDefault();
            webcam.open();
            image = webcam.getImage();
        }
        public void scheduleImage() {
            if (simulator == null) return;
            if (image == null) return;
            Image newimage = image.getScaledInstance(300,300,
                Image.SCALE_SMOOTH);
            Signal signal_Y = port_Y.getSignal();
            if (signal_Y == null) return;
            simulator.scheduleEvent( new SimEvent(
                signal_Y, simulator.getSimTime()+0.5, newimage, port_Y ));
        }
    }
}
```

Fig. 8. A Hades web cam component based on Sarxos web cam Java package

erates Verilog code based on a Hades design as final graduate course assignment in computer architecture. Therefore, a MIPS processor could be simulated on the Hades tool, and the design could be exported to Verilog code, that could be mapped and implemented on a FPGA board. The generator was developed as an external tool, that extends a Hades script tool originally developed to export designs to a subset of the VHDL language.

D. Image Processing

Image processing features have been already implemented in Hades: a small library and a set of example are available in Hades page [5]. Instead of using a local image file or web image, why not to use the student's web cam to capture an image during the lecture to motivate them with real world examples ? A new component to connect Hades to an external web cam can be developed by using Java code available on

```

import com.heatonresearch.book.introneuralnet.neural.feedforward.FeedforwardLayer;
...
public class neural extends hades.models.gates.GenericGate {
...
public neural(){
    super();
}; ... // Neural I/O
port_A = new PortString( this, "A", Port.IN, null);
port_Y = new Port( this, "Y", Port.OUT, null, StringSignal.class );
...// Neural Training Vectors
M_INPUT = new double [MAXIMAL][7];
M_IDEAL = new double [MAXIMAL];
network = new FeedforwardNetwork();
}
public void evaluate( Object arg ) {
...// build training Vector
// set network input value
M_INPUT[train_sample][i] = Double.valueOf(port_phi[i].getValueOrUUU());
// set network output
M_IDEAL[train_sample] = Double.valueOf(port_A.getValueOrUUU());
if (train_sample < MAXIMAL) train_sample++;
...// Training
double INPUT[][] = new double[train_sample][7];
double IDEAL[][] = new double[train_sample][1];
for (int i =0; i< train_sample; i++) {
    for (int j=0; j < 7; j++)
        INPUT[i][j] = M_INPUT[i][j];
        IDEAL[i][0] = M_IDEAL[i];
    }
}
Train train = new Backpropagation(network,INPUT, IDEAL,
0.7, 0.9); int epoch = 1;
do {
    train.iteration();
    epoch++;
} while ((epoch < 5000) && (train.getError() > 0.001));
...// Using.....
double actual[] = network.computeOutputs(IN);

```

Fig. 9. A Neural network component

the web. Fig. 8 shows a web cam component implemented by using few lines of Java code and an open-source web cam package [19]. In addition to capture an image, the web cam package [19] provides motion detection and many others functionalities to elaborate creative and educational projects. The student could also get images by using his mobile device with a mobile application like Droicam [20].

Machine learning is a hot-topic due the Big Data phenomena. Neural networks are one of the widely used machine learning approaches. Fig. 9 depicts a Hades component which includes a neural network from [21]. The full code has around one hundred lines. First, the constructor defines the I/O ports and creates an instance of a neural network. The *evaluate* method performs three tasks. Our implementation is based on a finite state machine model. The first state builds the training vector. The second state creates the neural structure as a function of the training vector. Finally, the neural network computes the output values in the last state as shown in Fig. 9. The neural network component was used to implement a shape recognition application based on moment invariants (translation, scale and rotation) [22] during the image processing undergraduate course at University of Vicosa (UFV) in 2010.

E. Quizzes and Videos

We also includes two educational components: a quiz form and a video player. Since video-based learning is widely used approach for teaching [23], we propose to include a video player inside Hades. Our goal keep all in one window: the student project and the educational support (video, quiz, etc.) as depicted in Fig. 10. We propose two implementations for the video player component. The first one is quite simple, and it only includes a system call to the VLC player. The second one is based on VlcJ [24], which provides a Java framework to allow an instance of a native vlc media player to be embedded in a Java AWT Window or a Swing JFrame. Therefore, the

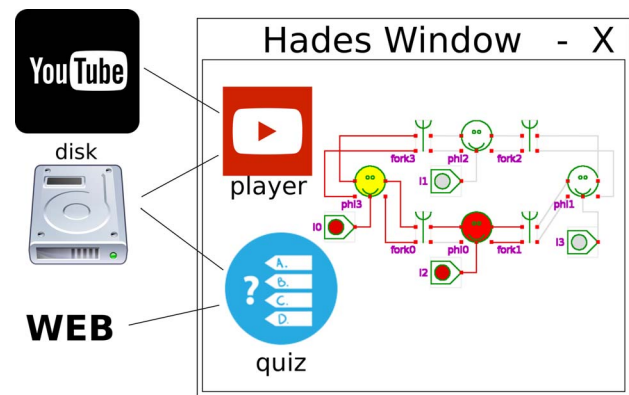

Fig. 10. All in One Window: Video, Quiz and Design

```

....

```

(a)

(b)

Fig. 11. (a) Quiz form file example; (b) Quiz window.

student has a box component inside a Hades design. The video could explain the current task to be developed during the lecture or assignment. The video could be upload from the local disk, web or directly connect to the youtube. Although, videos usually receive a high rating from the students in comparison to other resources offered for learning, professor's lecture notes and exercises receives "very important" ratings according to recent survey presented in [25]. In addition to creating new components and modeling and solving problems, the students also could produce a video to explain their contributions. Unfortunately, textbooks only have been classified as "very important" by 30% of students in [25]. As well as during the problem-modeling and simulation process, significant learning could also be achieved during the video creation process, because in both activities the students should understand better the concepts that they have to learn how to create the video and the simulation.

In addition to video, quizzes are among the most widely used resources in traditional courses as well as in web-based education. We also includes a general purpose component to add quizzes to the design editor. Therefore, teachers and students can produce reusable quizzes and enhance existing materials. The proposed component read a quiz form from a

Fig. 12. Hades connected to an external Arduino board to capture real world sensors.

text file as shown in Fig. 11(a). The quiz form consists on a list of questions. Each question has the question text and a set of answers. Each answer has a text and *True/False* tag. A quiz form could randomly pick up one question from the question list. A quiz form could be also download from the web, or the students could propose questions about the current assignment. Therefore, as a collaborative task, new questions could be produced. The quiz form window is shown in Fig. 11(b).

F. Sensors and Mobile

Nowadays, mobile devices and Arduinos are widely used. Hades could also be easily connected to these kinds of devices to provide new opportunities for teaching and learning programming. In addition to the web cam shown in Section IV-D, a mobile device could export its sensors data through the wireless network by using a sensor application as [26]. Moreover, the Arduino platform and the sensors/actuators are widely used by the student community. In addition to provide a flexible and easy-to-use hardware and software platform, the Arduino IDE has been implemented in Java, and therefore an Arduino component is directly integrated in Hades as depicted in Fig. 12. LabView framework as well as Hades could be easily connected to an Arduino boards, and the student start to play. However to solve more complex problems, it is important to highlight that the software component will require the most attention [27], and once motivated, the student should write code to solve/learn the assignments. Furthermore, the student could perform lab experiments at home.

G. Suggestions

In addition to the examples shown in this work, this section points out some suggestions. First, computer networks is one domain which could be explored by using our approach. Some examples: routing algorithms with a packet viewer as shown in Fig. 13(a), protocol layers as depicted in Fig. 13(b), packing and unpacking, etc. Second, multiprogramming and concurrent programming is also an important skill that can be learned by writing local code and by exploring different connection topologies. Multi-agent systems is also another option to be taught by using our approach.

V. RELATED WORK

Nowadays, motivation strategies include IoT [28], mobile devices and their sensors [29], virtual labs, etc. All these approaches are complementary to our simulator developer

Fig. 13. (a) Routing algorithm and packet viewer; (b) Protocol vertical communication.

proposal and since Hades is Java-based, most of them could be easily integrated. Moreover, we agree with the authors of [30], who mention that there is no silver bullet that would allow to learn in fewer hours. Videos, quizzes, examples and practical assignments as well as lectures are the basic tools. The simulator developer approach is an additional tool to the learning process.

Some approaches includes real-world experiences as the one presented in [31], that was performed by students in six different courses related to software engineering subjects. Our proposal is also to be used in as many courses as possible since it is a general purpose simulator to construct a workplace that offers a self-studying environment to be used in classroom, home and laboratory activities.

Robotics is a complementary approach that, even though it is fun, most of efforts are spent in the hardware and mechanical parts, which could be also very costly, while our proposed software approach is free of cost.

Finally, new methodologies as Flipping, which introduces learning materials (videos and quizzes) prior to the beginning of the classes (first phase) and, then, use class time for more interactive activities (second phase) could also use the simulation approach. As the proposed tool is a simulator and at the same time is a methodology to teach simulator developers, the tool could be used in both flipping phases.

VI. CONCLUSION

MOOCs based on recordings of classes that already exist are not attractive. In addition to record videos, more material as quizzes, practical assignments and virtual labs should be added. Furthermore, we propose to include a simulator developer approach to improve student engagement in learning.

Better than only simulate, the student will enhance the simulation tool, we believe that simulation and visualization will add little educational value unless it engages learners in an active learning activity, as point in [32]. As shown in a long-term study of student performance [30], the students should go deeper to improve their performance. The proposed approach is based on Java and free software lessons: reuse code, find new functionalities, release early and often, and perfection is found when nothing should through away. Even though the Hades simulator was originally proposed for digital logic education, we have shown that this tool could be used in an expected way to teach and learn several computer science subjects and courses. One strategy is to establish closer relationships between programming activities and real-world to motivate the students, which could be done by connecting the virtual and the real worlds. Go beyond by enhancing a simulator tool with designs, models and components could be used by a variety of institutions and organizations worldwide. The Hades tool is simple and powerful enough to perform theses tasks. Our goal is not to replace commercial tools such as LabView, MatLab, and other standard tools, but to offer to the student a flexible tool with a fast learning curve, a large set of educational and research resources and connectivity, and furthermore provide a tool where the students could not only scratch the surface but also he could (and should) go deeper and beyond to improve their skills.

ACKNOWLEDGMENT

The authors would like to thank Norman Hendrich (University of Hamburg), all students from University of Vicosá (UFV), and in special, we would like to thank Geraldo Fontes, Alyson Trindade and Christopher Gull. This work has the financial support of Brazilian agencies CAPES, CNPq, and Fapemig, and Gapso/Accenture Company.

Abstract—STEM education is a wide, advanced and fast-growing educational area. Thus, STEM (Science, Technology, Engineering, Math) courses may become obsolete very quickly (as soon as the next semester). To gather up-to-date information for the core of a course (learning resources) for case studies and seminars, we propose an approach based on the study of recent scientific developments reflected in articles from international research databases.

The process to prepare basic information to design a course in STEM follows the following steps:

1. Students must present one paper to classmates in a seminar (student prepopulates and sent to the teacher specially prepared for this purpose form).

2. Based on several papers, students must present different solutions for one problem in the area defined by the teacher, e.g. urban studies.

We applied our approach experimentally to develop initial learning materials with the first intake of students to a new master program in Urban Supercomputing. During "Urban Systems Analysis" course, students prepared the materials for the next course "Urban Computer's Simulation". The experiment shows, that the proposed approach reduces teacher load in terms of designing learning resources and allows students to adopt and develop additional skills from individual work, project-based training and context-based learning.

Keywords—initial learning materials; learning resources; scientific papers and database; additional skills

I. INTRODUCTION AND RELATED WORKS

Contemporary society and technologies are in constant and reciprocal development. The obvious consequence of this cooperation is diminishing awareness among practicing scholars regarding the latest achievements of science and technologies, especially in interdisciplinary areas. A modern teacher has access to a wide range of information from sources of varying degrees of reliability. In this sea of information, to design, develop and renew a course teachers might find it difficult to find topical materials quickly in relevant advanced

areas of interdisciplinary directions of science and technology. A student might be faced with a similar problem while carrying out a literature study or working on a project.

Approaching scientific education through scientific articles has been conducted at least since the 19th century [1]. Contemporary master's programs of most universities offer a series of courses devoted to the study of scientific materials. For example, master's program in Computational Science of the University of Amsterdam (UA) includes a course in Literature Study¹, and the University of Texas at El Paso offers similar courses in Graduate Research². In 2013, ITMO University³ started a new (for Russian STEM Higher Education) course in Scientific Writing within double-degree master's programs in Computational Science [2], [3]. Many scientific and educational teams joined their efforts to develop and apply original approaches and methods to improve students' skills in literature study and scientific writing and measure the effectiveness of these new tools. In particular, the author of this work [4] offers to change the course or design a new one with the use of the students' reflection upon completion of their work on projects including the study of scientific papers. The paper [5] is devoted to the method of using writing/reading groups to facilitate the efforts of PhD students in acquiring skills in scientific writing. The contribution of [6] is to teach students to write technical reports through peer-writing of non-technical texts. It should be mentioned that many authors confirm that partnerships between teachers of consecutive courses allow the tangible transfer of knowledge. The complex approach to improve teaching methods aimed at developing post-graduate engineering students' skills to prepare scientific publications was offered in [7]. The authors developed a postgraduate course covering a full study of scientific materials and assessment and, for this purpose, they apply various

² <http://ce.utep.edu/mastercourses.htm>

³ Saint-Petersburg National Research University of Informational Technologies, Mechanics and Optics - <http://en.ifmo.ru/en/>

educational methods including a simulated conference sessions.

The mentioned above works show that students are faced with difficulties while working on the tasks in literature study and scientific writing. Analysis of these works and our experience reveal that master's and postgraduate students produce large volumes of materials (texts, software, prototypes) in various areas and quality based on scientific resources. On the other hand, when teachers design a new course in advanced interdisciplinary areas of science and technology, a significant amount of time is spent to find, acquire, actualize and analyze scientific resources to build the required pool of educational materials. In this paper we offer an approach that simplifies and speed up the formation of learning resources for a given course. This approach, based on the above-mentioned works, seeks to answer the following questions:

Q1. How can we prepare up-to-date initial learning materials (ILM) for future courses and involve students in this process through literature study and project work?

Q2. How do we assess the quality of materials prepared by students?

Q3. How do we build a course's content rapidly from ILM derived with the use of mentioned above approach?

Q4. How do we facilitate student's efforts to master future complex interdisciplinary courses?

II. ACADEMIC CONTEXT

In 2012 ITMO University (ITMO) started to apply a double degree master's program (DDMP) in the novel fields of modern science and technologies. At the present time, ITMO has more 30 DDMP, including three programs in computational science [3]. Such a leap in the development of DDMP is directly related to participation of ITMO in the Russian Academic Excellence project called "5-100-2020". The main goal of this program is to maximize the competitive position of a group of leading Russian universities in the global research and education market⁴. In order to meet the requirements of this ambitious project, universities have to provide students not only with courses of high quality but also with skills of literature study, scientific writing and project work. To develop new courses corresponding to the latest advances of related fields in science and technologies [8], we decided to involve not only experts but students who were looking towards developing their project teamwork skills, skills of realization of problem-oriented project, skills to independently solve innovation development tasks and so on. The approach offered in this paper will allow us not only to provide students with above-mentioned skills, but to reduce the time required for gathering ILM for course design and development.

⁴ <http://Stop100.ru/>

III. THE APPROACH DESCRIPTION

In order to accept ILM development of learning resources for the given course (we will call this course a "Next Course" – NC), we engaged students during the "Previous Course" (PrC), which takes place a semester before the NC. This approach involves at least two contact sessions (simulated conferences [7]), where students present results of scientific paper analyses and proposals for IT solutions of problems for the given subjects. To improve the quality of the ILM, we additionally involve the teacher of NC to take part in the contact sessions as an expert.

Fig. 1 shows the sequence of the steps students are engaged in while preparing ILM.

In the first step, the list of papers (2-3 or more pieces per student) is formed and students are asked to fill a so-called "information card". This information card contains the following fields:

- General information of the paper: topic, author(s), organization(s), DOI, journal and abstract;
- Object (process) under consideration;
- Problem statement;
- Brief description of related works (2-3 sentences);
- List of used methods and approaches;
- Description of the offered approach(es) (5-7 sentences);
- List of scientific fields (disciplines) related to the paper;
- Practical (experimental) part of the paper: the real object(s) or process(s), what effect is received, interpretation, discussion and so on (5-7 sentences);
- Conclusion and future works: discussion of solutions to the problem, what are the authors' plans for the future (5-7 sentences);
- Does the article consider methods of system analysis? If "Yes", what is the object of analysis? Could we observe systemic effects?

Having analyzed information seeking patterns [9], this list of fields was formed to facilitate students' efforts of the paper's analysis. In addition, this form allows a teacher (expert) to understand quickly the contents of the paper or determine the *low* quality of student's result. The last field was added in order to provide students with additional opportunity to develop thinking regarding the systems applied. We do not claim that this paper's information card is perfect. Rather, it might (in some cases *should*) be changed depending on the subject area and course level.

The second step is a simulated conference session, where students present the papers they analyzed in a short report with PowerPoint (PP) slides. The teacher of NC is involved in this session and is guided by the following goals:

- selecting first part of the pool of initial learning materials;

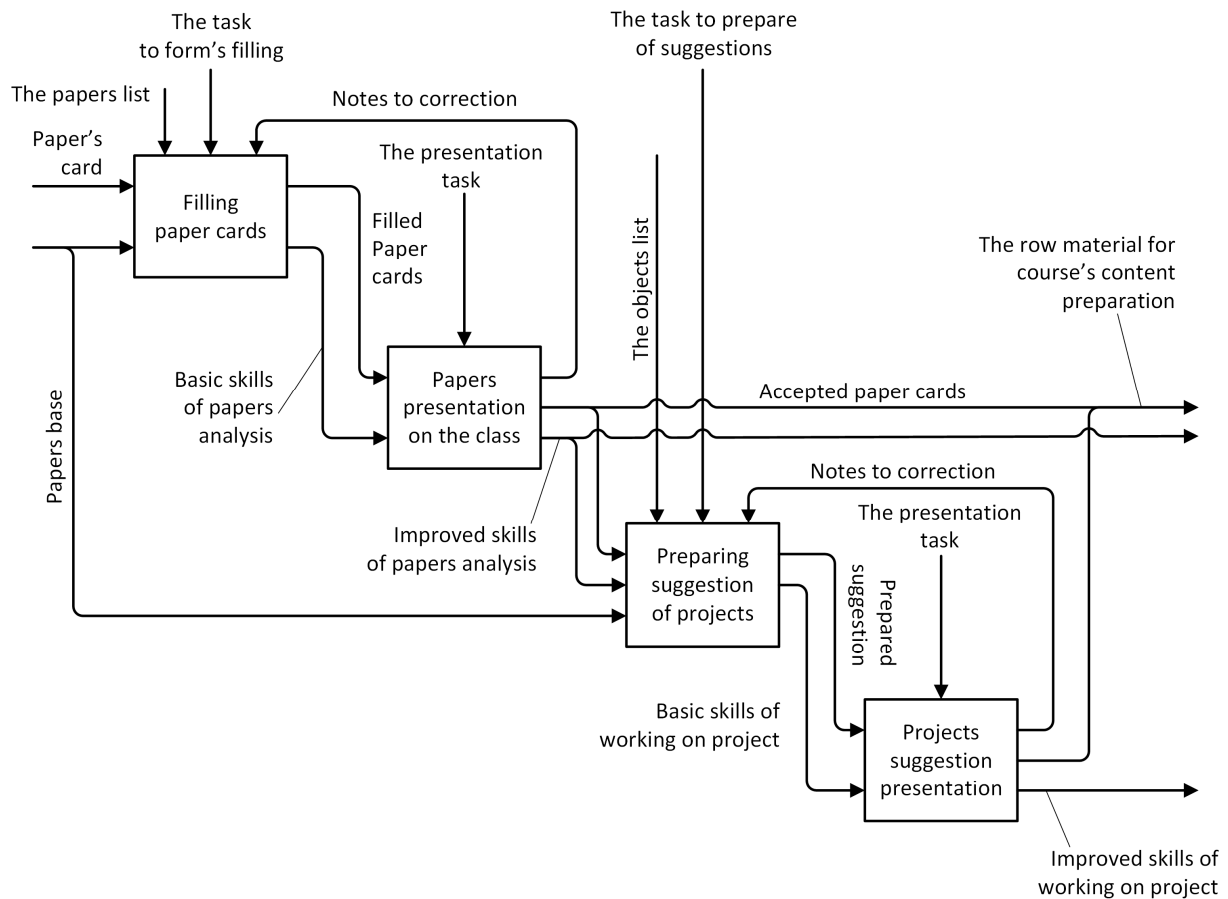

Fig. 1. The scheme of students' involvement into preparation of ILM

- contributing to the assessment of presentations (Q2);
- commenting or introduce corrections if necessary to the students.

If students receive comments from teachers and/or group mates, they should be expecting to analyze them and make any needed corrections. Such students are required to present their updated results again in the next session or, if needed, individually.

When the first and the second steps are completed, students should propose solutions to a chosen problem of the given complex object (step 3). No special requirements are introduced for the text of proposals, except for the following information: problem statement, goals, required data and resources, approaches and methods, application packages (if solution could be implemented in a form of computer program), and description of output results. The text of the proposal should not exceed more than three pages in a Word document. In this way we stimulate students to formulate their joint ideas in a structured manner and in a limited volume.

The fourth step follows second step, but solutions are generated by group work. Students give 15-minute speeches supported by PP slides and followed by Q&A sessions.

Teachers (experts) assess these proposals and make decisions whether to accept proposals or to recommend making modifications. To assess proposals (Q2) teachers use the following criteria (in the scale from 1 to 5 points):

- 1) Completeness of the proposal (what components of the given object are chosen and how they are related each other; what scales were explored);
- 2) Justification of the selected research methods;
- 3) Quality of the selected references, including scientific papers;
- 4) Reasoning for software selection to implement the proposal;
- 5) Interdisciplinary relations (what scientific areas are involved?);
- 6) Suggestions to apply this proposal in education (how the presented suggestion can be used in educational process: at what level, in what area?);
- 7) Quality of presentation, including the speech, slides and answers to questions.

These criteria allow experts not only to render a detailed assessment of the presented group work, but to turn these results into initial learning materials.

These criteria are communicated to the students before they start to prepare for their presentations. In this way, we pursue several goals at once: (i) to clarify the statement of a problem to the students; (ii) to give them exact and clearly evident way of self-assessment; (iii) to prepare the tool for measuring the results of public session by the experts. During the development of the list of criteria we make an attempt to incorporate manifold requirements to high-quality project proposals.

Criteria (1-4) are often used to review scientific papers. For example, criterion 3 corresponds to a “quality of the description of related work”. We intentionally do not determine the quality of a research contribution because at this stage students’ proposals are not fully valid scientific works. They do not implement the prototypes of ICT solutions and do not make experiments with real data. Neither students nor experts should measure the applicability of proposed approaches. However, with the use of criteria 1-4 participants are equipped to develop two important skills: (i) analysis and synthesis of scientific information; (ii) rigorous justification of the proposed solutions (Q4).

The next group of criteria (6-7) focuses on initial versions of learning materials. Interdisciplinary concepts are important because of the essence of computational science. Future professionals in this area should be able to observe complex systems (such as cities) from different perspectives, and to incorporate research methods from several subject fields. Criterion 6 focuses students’ attention to this issue as a way to intensify ‘out-of-the-box’ thinking during the work on proposals. The seventh criteria helps to determine more relevant courses, which can be supplemented with appropriate learning materials. The goal of this last criterion attempts to evaluate speaking and presentation skills.

IV. THE APPROACH IMPLEMENTATION

This unique technique is distinguished by perfecting and shifting the initial learning materials generated at the course in Urban System Analysis of first semester of master program to the course in Methods for Urban Simulation of the second semester of the same program. Moreover, initial learning materials in the format of software solutions are intended to be integrated into CLAVIRE (CLOUD Applications VIRTUAL Environment) platform [10], should these solutions be developed into master graduation projects.

We implemented our scheme to develop initial learning materials (ILM) with the first intake of students to a new master program in Urban Supercomputing. This decision could be viewed as a planned risk, since the average age of teachers at the program is close to 29, and they are inclined to introduce innovations to the course structure. Apparently, it could be explained by the fact that both high performance computing and urban studies are rather novel fields in Russian Higher education, therefore experts in these emerging spheres are willing to move beyond the rigid frames of teachers’ routine.

A. The steps #1 and #2

To launch the first and the second steps, 40 papers devoted to various urban problems were selected. For example, paper [11] analysis the effectiveness of nicotine replacement therapy in New York City with the use of geographic informational systems (GIS).

Eighteen of 20 students successfully mastered this task, e.g. provided good descriptions of papers in a form of information card and managed to deliver their reports during a conference session simulated in class. Therefore we received 18 papers’ description. The remaining two works were not completed since certain students decided to change their majors.

B. The steps #3 and #4

We had chosen a big city as the object for the steps three and four. We asked students to split into small teams of two or three, to choose a large urban area like London and its suburbs they wish to explore (with one exception), determine its problems by studying relevant scientific papers and offer and justify an IT solution. As a result we received nine proposals; six of them were recognized as potential basis for initial learning materials. Large urban areas from around the world were scrutinized, e.g. Guangzhou, Munich, Buenos Aires, Istanbul, Toronto, etc. Special attention was given to the applicability of a solution prototype from one area to the same problem in the other part of the globe. Diversity of cities and its problems as well as unconventional solutions stipulated heated discussions involving students, teacher and experts. Fig. 2 shows the presentation of students’ projects.

Fig. 2. Presentation of the work on the project on identification and extraction of pedestrian trajectories (Step 4).

Below are six proposals of the second part of the experiment that has been proved to be effective as initial learning materials later on in NC:

- 1) Forecast system of trash disposal;
- 2) Database of unstable citizens including personal data ;
- 3) Informational system (IS) for air pollution analysis;
- 4) Model of traffic modeling and air pollution simulation;
- 5) IS for ships traffic in sea port’s area;

- 6) IS for data analysis for police analytics based on graph method.

We are inclined to assume three subject areas:

- 1) Spatial analysis and visualization of industrial city;
- 2) City-logistics model based on SWAT analysis and decision support system with GIS;
- 3) Social network crawling for identification and analysis of people mobility in urban areas;

were left behind due to at least one reason – insufficient background in economics and sociology. This problem may be as an area of the separate research.

V. STUDENT FEEDBACK

Once we have accomplished all four steps, we asked students to comment on their experiences in anonymous survey and some of the feedbacks were:

Student 1. Within the course “Systematic analysis of urbanized areas” an ingenious approach to learning process based on making new ideas and offers using articles on a given topic was used. In a first step we had identified basic goals and motivation in the article. Further, we explored methods and tools, which were applied. Also, one of the main tasks was to make up an information card of the article. This process undoubtedly was helpful as a learning activity and helped me to understand main points of these articles, to perform my individual research project, and to practice my presentation skills.

Student 2. The most interesting part was reading science literature and searching problems in big cities that could be resolved using IT. If we have a problem, and we are sure, that it can be fixed using IT that is not an issue to find an idea of IS. More difficult is to get a picture, how will this IS work. So, I liked this task for two things: you should demonstrate competence in both urban science and IT, and you should do it in group. Unfortunately, there was no *public discussion* about proposed ideas that could be interesting and could give a feedback useful in future.

Student 3. The main advantage of the course in System analysis of urban territories was that it was practice-oriented. We had several tasks of urban problems finding, analyzing and solving. The one, what I appreciate at most was article’s analysis: students were given articles about some urban problem or solution to read it, understand and then present it to group mates. It was valuable experience for me for many reasons: reading scientific work in English, a perfect example of analysis and comparison methods, and understanding modern city transportation system problems, development and policies. Presentations of my group mates, for example, about recreation infrastructure analysis or NY policies on smoking level decrease, showed how many problems exist in cities and could be solved with appropriate application of urban science.

The mentioned above selection of the survey’s results shows that students not only contributed to the preparation of up-to-date ILM (Q1), but formed a good basis to master next complex courses (Q4). This basis includes understanding of

scientific approaches to study and analyze complex systems like urban areas.

VI. PREPARATION OF THE COURSE’S CONTENT BASED ON ILM PARADIGM

Having prepared the learning initial learning materials with the use approach described, we understood that this material could not be used for teaching. Such material needs to be processed. To overcome this problem we might use various approaches to build learning resources with the use of above-mentioned type of materials, for example, Learning Tools Interoperability (LTI) [12] or reusable learning object concept [13]. In the work [14] we proposed a set of methods, cloud tools, based on the CLAVIRE cloud platform [15] and LTI for rapid development of cloud learning resources. In particular, the principles of rapid composition of learning materials for representing the results of scientific research might be applied to build virtual learning labs [16]. Moreover learning models of scientific workflows⁵ in the CLAVIRE cloud platform could be useful [17]. In addition we may complement the learning resources by visualization tools with 3D-Stereo support working on Fusion Engine, as well as design and implement related virtual learning environments [18].

Therefore, we have a set of tools and methods to develop and implement learning resources in course design and to extend existing knowledge base, learning objects including virtual labs with initial learning materials obtained as a result of students’ individual and group work (Q4).

VII. CONCLUSION AND FUTURE PLANS

In this paper, we proposed the approach to form learning initial material for further design and implementation in educational process. The approach of this goal is to involve students into paper’s analysis and to brainstorm solutions to selected problems of the given city. We designed an information card to facilitate analysis of scientific papers and check the quality of the students’ outcome (Q2). Ninety percent of students had mastered this task and proceeded with group tasks searching for computer-aided solutions for diverse urban problems. In the second part of the experiment (steps three and four) students tackled these problems in groups of two or three students. These groups developed prototypes for the problems solutions described in the scientific papers. Two-thirds of teams had presented good results (completed information cards and models of IS for cases from real life). These materials might be used as a starting point to prepare learning resources. Thus, we can form a pool of initial learning materials with the use of students’ resources (Q1). The approach described in this work allows teachers to reduce their efforts in design and development of learning resources and gives student the base for understanding of scientific approaches to study and analyze complex systems (Q4). In addition, we proposed to use the tools and methods for the preparation of the course’s content based on ILM (Q3).

⁵ Scientific workflows is an instruction (sequence of commands) to launch application software in distributed high performance computational environment.

In the future, we are planning to complement the approach with two additional activities: (1) focus on scientific papers' study to boost the command of terminology in the given subject domain of educational program or course and (2) literature review on the given topic (this type of work is often referred to as related works) to stimulate publications in peer review journals and master thesis preparation. This way we could raise English language proficiency level, ability to work in teams and independently and finally focus on in-depth knowledge of the subject matter.

The first activity will be introduced before the first step and will allow students to study papers in the given subject area better and faster. The second activity is planned between the second and third steps to provide students with skills of acquisition, analysis and presentation of information from scientific papers. This experience and skill we hope will allow students to analyze any given case study more effectively and offer adequate and complete decisions to pressing problems of Urban Studies.

Comparing Microcontroller and Analog Methods for Tracking Control Experiments

Chiu Choi

Electrical Engineering Program
University of North Florida
Jacksonville, FL 32224

Abstract— this paper describes the development of undergraduate laboratory experiments for solving tracking control problems by using two different approaches. The first approach is based on microcontrollers and the second approach is an analog approach based on operational amplifiers. The main objective is to compare by hands-on experiments the advantages and disadvantages of these two approaches. Preliminary results of the comparison are presented in this paper. These lab experiments are developed to increase the competency skills of the students rather than just an additional topic to be covered in the course. These experiments will provide guidance to the students in making better choices of tracking controllers in their future robotics or other control system design projects.

Keywords—microcontroller applications; tracking control; position control; linear control

I. INTRODUCTION

This paper describes the laboratory experiments developed for solving tracking control problems by using two different approaches- the microcontroller-based approach and the analog approach with operational amplifiers. These experiments will be incorporated into our sophomore level newly revised microcontroller applications course in the future offerings. Tracking control problems are fundamental control problems arising in electrical, mechanical, and other engineering disciplines. Learning the practical skills of solving these control problems will increase the competency level of our students.

A method for solving tracking control problems is by using proportional, proportional-integral or proportional-integral-derivative controllers. It is our objective to develop laboratory experiments that can deliver to the students the skills for building these controllers from scratch using the two different approaches mentioned above. In the first group of experiments the students will build these controllers using the analog approach and test them on a plant- Feedback Inc.'s Mechanical Unit Model 33-100. A picture of the plant is shown in Fig. 1. The students will document the performances of these controllers by measuring the steady state errors, rise time, peak time and percent overshoot. They will record these parameters for various combinations of proportional gains. In the next group of experiments, they will re-build these controllers as C programs running on the Freescale MC9S12C32 microcontrollers. They will also build the signal conditioning

circuits for interfacing the microcontroller to the same plant. Again, they will document the experimental results of this controller. They will then compare the design, performances, cost, development time and other factors of these two different approaches for solving the same problems.

The Feedback Inc.'s Mechanical Unit Model 33-100 is a servo control plant equipped with an input dial that a user can adjust its angular position. It is also equipped with an output shaft with gear mechanism and electronic circuit that with a correctly designed controller can steer the output shaft to track the angular position of the input dial. The controllers to be described in this paper below were tested on this plant.

Fig. 1: Feedback Inc.'s Mechanical Unit Model 33-100

Theoretical and experimental solutions for solving tracking control problems have been proposed and can be readily found in the literature [1-5]. Advanced methods for tracking controls, e.g., fuzzy logic and other microcontroller-based methods, are also available in the literature, e.g. in [6-9]. Since we are developing the lab experiments at the sophomore level, advanced methods have not been considered.

Tentatively, we intend to incorporate lab experiments of proportional controller and such controller with velocity feedback into our revised microcontroller applications course using both of the approaches. We have successfully completed the development of tracking control experiments using proportional controllers. We are currently developing new tracking control experiments using proportional controllers with velocity feedback. The tracking control experiments using

proportional controllers (without velocity feedback) are described in the next section.

II. EXPERIMENTS DEVELOPED

A. Analog method for tracking control

A block diagram of the tracking control system with the analog controller is shown in Fig. 2. The block diagram except the controller and the comparator is a representation of the plant shown in Fig. 1.

Fig. 2: block diagram of the control system

This tracking control problem is to design a proportional controller using operational amplifiers that will drive the output shaft angle to track the input dial position. Specifically, if the input dial angle is changed, the controller should drive the output shaft to track the changes in the input dial position. The input dial position is read by a potentiometer and is indicated by the signal V_i in Fig. 2. The output shaft position is read by an identical potentiometer which output is indicated by V_o in the same figure. An analog solution of the controller is shown in Fig. 3. The signals V_i , V_o , and V_{out} in Fig. 3 are those indicated in Fig. 2. The operational amplifier circuit in Fig. 3 represents the controller and the comparator combined in Fig. 2. The signal V_{out} is proportional to the error ($V_i - V_o$) and the gain factor is the ratio R_2/R_1 . The selection of R_1 and R_2 are done empirically, not model based because at the sophomore level the students have not taken a model-based control course.

Fig. 3: proportional controller

This analog controller was tested in the plant. Some of the experimental results are shown in Fig. 4. Notice that in Fig. 4 the output shaft signal is tracking the input dial signal but with some undesirable overshoot and ringing. The students will receive guidance on how to resolve this issue by using velocity feedback or derivative control. Such laboratory solutions and the associated lab handouts are being developed.

With this design in Fig. 3 the students can measure the performance parameters for various gain factors. The performance parameters include steady state error, percent overshoot, peak time, etc. These performance parameters can be used as the basis for the comparison of the performance of this controller with the one implemented by using the microcontroller method.

Fig. 4: input dial (yellow) and output shaft (cyan) signals

B. Microcontroller method for tracking control

A block diagram of the microcontroller-based proportional controller is shown in Fig. 5. In that block diagram, the two analog-to-digital (ATD) converters, the comparator and the controller were integrated into the microcontroller. The DC motor of the plant was driven by a pulse-width modulated signal from the microcontroller through an H-bridge housed inside the plant. The pulse-width modulated signal was generated by the microcontroller's on-chip pulse-width modulator (PWM).

Fig. 5: block diagram of the microcontroller-based proportional controller and the plant

As indicated in Fig. 5, signal conditioning circuits were required. It was because the V_i and V_o voltage signals (as indicated in Fig. 2) were in the range of -10 V to +10 V. They were outside the operating voltage range of the on-chip ATD converter, which is in the range of 0 V to +5 V. The signal conditioning circuit should convert linearly the voltage range of -10 V to +10 V to the voltage range of 0 V to +5 V. A solution of the signal conditioning circuit is shown in Fig. 6. Two of such circuit were built and tested. They were used as the interfacing circuits between the potentiometers and the ATD converters.

Fig. 6: signal conditioning circuit

The proportional controller was implemented as a C program running on a Freescale MC9S12C32 microcontroller. The tools for developing the proportional controller in C included CodeWarrior Integrated Development Environment, C compiler running on a Windows machine, and P&E USB BDM Multilink Programmer. Tutorial for using these tools have been written. Pseudo codes for the proportional controller were developed and included into the tutorial. An example follows.

1. Sample the input dial position
2. Sample the output shaft position
3. Calculate error
4. Choose proportional gain
5. Calculate the PWM duty cycle as a function of error and the gain value
6. Load the new duty cycle into the PWM
7. Execute a delay function to give time for the PWM to do the control operation.
8. Go back to step 1.

A code snippet of the main function of the C program proportional controller is shown as follows:

```
// infinite loop for reading Vi and Vo
// and set duty cycle accordingly
while(1) {
    ATDCTL5=0x10; // initiate ATD conversion
    delaysms(10);
    Vi=ATDDR0H; // input dial voltage
    Vo=ATDDR1H; //output shaft voltage

    //proportional controller begins
    n=-(Vi-Vo)/255*0.5*gain+0.5; // duty cycle calculation
    n*=100;
    //proportional controller ends

    //limit n to be between 0 to 100
    if (n>100) n=100;
    else if (n<0) n=0;
        else if ((n>45)&(n<=48)) n=45;
        else if ((n>=52)&(n<55)) n=55;

    //load new duty cycle into PWM
    PWMDTY0=n;
    delaysms(50); // give time for the PWM to do control
} // end while loop
```

The proportional controller equation in the code snippet followed the following specification of the DC motor operation in the plant. The motor rotates in the clockwise direction if the duty cycle is less than 50%. A smaller duty cycle will supply more power to turn the motor in the clockwise direction. The motor will rotate in the counterclockwise direction if the duty cycle is greater than 50%. A greater duty cycle will provide more power to turn the motor in the counterclockwise direction. Further details are provided in [10].

The C program was compiled and flashed into the microcontroller. It was interfaced to the plant through the signal conditioning circuits. The PWM output of the microcontroller was connected to the H-bridge that drove the DC motor. Some of the experimental results are shown in Fig. 7. It is noticed that the steady state error is zero. There was overshoot. Guidance will be provided to the students on reducing such effect.

Fig. 7: input dial (yellow) and output shaft (cyan) signals

III. PRELIMINARY RESULTS

The two approaches described in the last section were compared against each other. The analog approach was easier to prototype and was intuitively simpler for the students to understand than the microcontroller approach. However, it is harder to make changes in the analog approach. For example, to change its proportional gain requires replacement of hardware components (replacing the resistors to different values). On the other hand, the microcontroller approach allows a user to make changes easily. For example, the proportional gain could be changed easily in the software. However, the microcontroller approach required precise signal conditioning circuits for converting the voltage ranges of the input dial and output shaft to the voltage range suitable for the microcontroller. We noticed that imprecise signal conditioning circuits could result in constant steady state tracking error.

These labs also brought the following to the students' attention. In the analog approach, a double rail operational amplifiers was necessary for the proportional controller because the input voltages could swing positively and negatively. Next, higher precision resistors, e.g., 1% resistors, instead of the inexpensive 5% ones were necessary in order to ensure the gains of the controller to be more precisely implemented. In the microcontroller approach, it took longer time to build the controller because of more hardware (both

microcontroller and signal conditioning circuits) to be put together and software programs to be developed and debugged. This approach was not as economical as the analog approach. But extra capability can be programmed into the proportional controller and that can outweigh the extra effort and cost.

IV. CONCLUDING REMARKS

We have completed the development of two working stations for the learning of tracking control. One station is for the analog approach and the other is for the microcontroller-based approach. These two stations allow the students to make comparison of the performance of these two approaches. Further exploration on tracking control by the students also becomes feasible by means of these two stations. It was noticed in the experimental results that the output shaft signal was tracking the input dial signal but with some undesirable overshoot and ringing. This issue can be reduced by using velocity feedback or derivative control. Such solutions will be developed and can be built upon these two current stations. We plan to document all of the experiments in a laboratory manual that can be used in an advanced microcontroller course or a control system lab course.

HELP

If at any time you want to return to this page, select the Help Topics button on the right side of your screen. Left Arrow and Right Arrow buttons on the bottom right provide an easy method to page backward and forward in this section. Text highlighted in orange in this Help section indicates something important to understand. It does not provide a link but is intended to bring something to your attention. Use the navigation buttons on the right to continue.

ACROBAT® SUPPORT

If you have questions about Acrobat® software other than that listed under General Usage Support, please contact:

Customer Service: 800-833-6687
Customer Support: 800-642-3623

(Note: telephone and web case technical support is only available to customers with a support plan contract.)

Monday - Friday 6:00 a.m. to 5:00 p.m. (PST) or visit their website at www.adobe.com

GENERAL USAGE SUPPORT

If you are experiencing difficulty navigating, searching, or using the built-in functionality of this CD/DVD/USB, please call: (352) 872-5544

Monday - Friday 8:00 a.m. to 5:00 p.m. (EST)
You can also send an email to:
info@conferencecatalysts.com

Visit our website at www.conferencecatalysts.com

ACROBAT TOOLBARS

Basic Toolbar: Hand Tool, Select Tool

The Hand tool provides a means of grabbing the page and moving it within the window. This is helpful when higher zoom magnification levels are used. The Select tool allows you to highlight text for copy and pasting information into other documents and applications.

Zoom:

The Zoom tool consists of In, Out, Dynamic, Loupe, Pan & Zoom for adjusting the document. With this tool you can also drag and hold to zoom over a selected area. Additional options: Actual Size, Fit Height, and Fit Width.

Navigation:

Using First Page will take you to the beginning of your document, Previous and Next will move you one page at a time, and Last Page will move to the end of the document. Previous View, and Next View will adjust the zoom settings.

Find:

Within the current document you can use Find to move to text matching the string you entered. You have the option to look for Previous or Next examples within the document.

Help:

Please refer to the Help section for any additional information you may require using Acrobat Toolbars and navigating your document.

Search (Shift+Ctrl+F):

Search for words and phrases across multiple, indexed documents.

BOOKMARKS (F4)

Navigation through the contents of this CD/DVD/USB can be performed by using Bookmarks. If Bookmarks are not visible choose from your menu View, Navigation Tabs, Bookmarks. A panel opens on the left side of the screen displaying Bookmarks in a hierarchy. Each Bookmark corresponds to a location on this CD/DVD/USB. Click on the text in a Bookmark to go to that location.

Entries with lower level Bookmarks show a plus sign (+) when subordinate Bookmarks are hidden and a negative sign (-) when subordinate Bookmarks are visible. Dragging the right margin of the bookmark panel resizes it.

PREFERENCES

To get the most out of this CD/DVD/USB, set the following Acrobat general preferences.

General Preferences:

Edit > Preferences > General

Dialog box similar to the one depicted from Windows.

Open Cross-Documents Links In Same Window:

If you want to keep all viewed documents open, verify that Open Cross-Doc Links in Same Window is NOT checked. Leaving this preference checked closes each document after viewing and is suggested for systems that just meet the minimum memory requirements.

Use Page Cache:

Located under the Startup Category, checking this preference places the next page in a buffer before you view the page in Acrobat. This reduces the amount of time it takes to page through a document.

Page Display:

If display images have ghosting, or outlines, please check to see if Smooth Text, Smooth Line Art, and Smooth Images are checked. These options will affect how images are displayed on this CD/DVD/USB.
